Different people have different demand expectations for the same product. The type of demand item can be determined according to the user's satisfaction degree and the importance degree of product services. Unlike the traditional Kano demand acquisition model, the quantitative Kano model will measure the user's expectation of the product through quantitative indicators, which can more objectively obtain the user's personalized demands.

The initial personalized hierarchical model is constructed. The quantitative Kano model is used to divide the initial demand according to the satisfaction index to determine the personalized demand category. Due to the heterogeneity of users, users are divided into different types. Users' evaluation of the importance of product services is added to improve the quality of personalized demands further and finally obtain the personalized priority demands of heterogeneous users. Getting personalized orders of heterogeneous users can be summarized in Figure 2.

The basic idea of quantifying users' satisfaction degrees and the importance degree of product service is as follows:

Step 1. Identify the initial personalized demand level.

The product specification is checked, and the relevant literature is read to understand the product characteristics that may be customized. At the same time, through face-to-face interviews with the sales staff, technicians, and customers, the requirements are obtained that the customer in the purchase process may mention the product. The original requirements are analyzed, deleted, and modified. The concept scope of the product is broad in the product instructions and interviews. The concept can be hierarchically sorted and summarized according to the affinity graph method, and Figure 3 of the initial personalized demand hierarchy model of the product is constructed ($PR = \{PR_1, PR_2, PR_i, ..., PR_n\}$, $PR_i = \{PR_{i1}, PR_{i2}, PR_{ik}, ..., PR_{is}\}$).

Step 2. Design of a quantitative Kano questionnaire.

Combined with Matzler's research, numerical indicators are set up in the user's product service satisfaction degree and importance degree. The user's demand options are quantified and counted when analyzing the questionnaire. At the same time, the quantitative Kano model is applied to different user groups, and the Kano demand types corresponding to different kinds of user groups are analyzed.

Because the positive answer is stronger than the negative answer, the index scale of satisfaction degree asymmetry can be set in the questionnaire to reduce the influence of negative evaluation and obtain the corresponding quantitative values for different personalized demands [12]. In addition, the importance degree of product services is divided into four degrees, the value is divided according to different levels, and the corresponding quantitative range is formulated. The Kano model requirements for classification evaluation table quantification criteria are shown in Tables 2 and 3.

Step 3. Calculation of customer satisfaction with product services.

Step 3.1. Assume variables.

According to the quantitative Kano model designed by the questionnaire data analysis,

Assume V represents a set of users, and v_j represents the jth user.

$$V = \{v_j | j = 1, 2, \ldots, n\}. \quad (1)$$

Assume F represents a collection with product service attributes, and f_i represents the ith product service attribute.

$$F = \{f_i | i = 1, 2, \ldots, m\}. \quad (2)$$

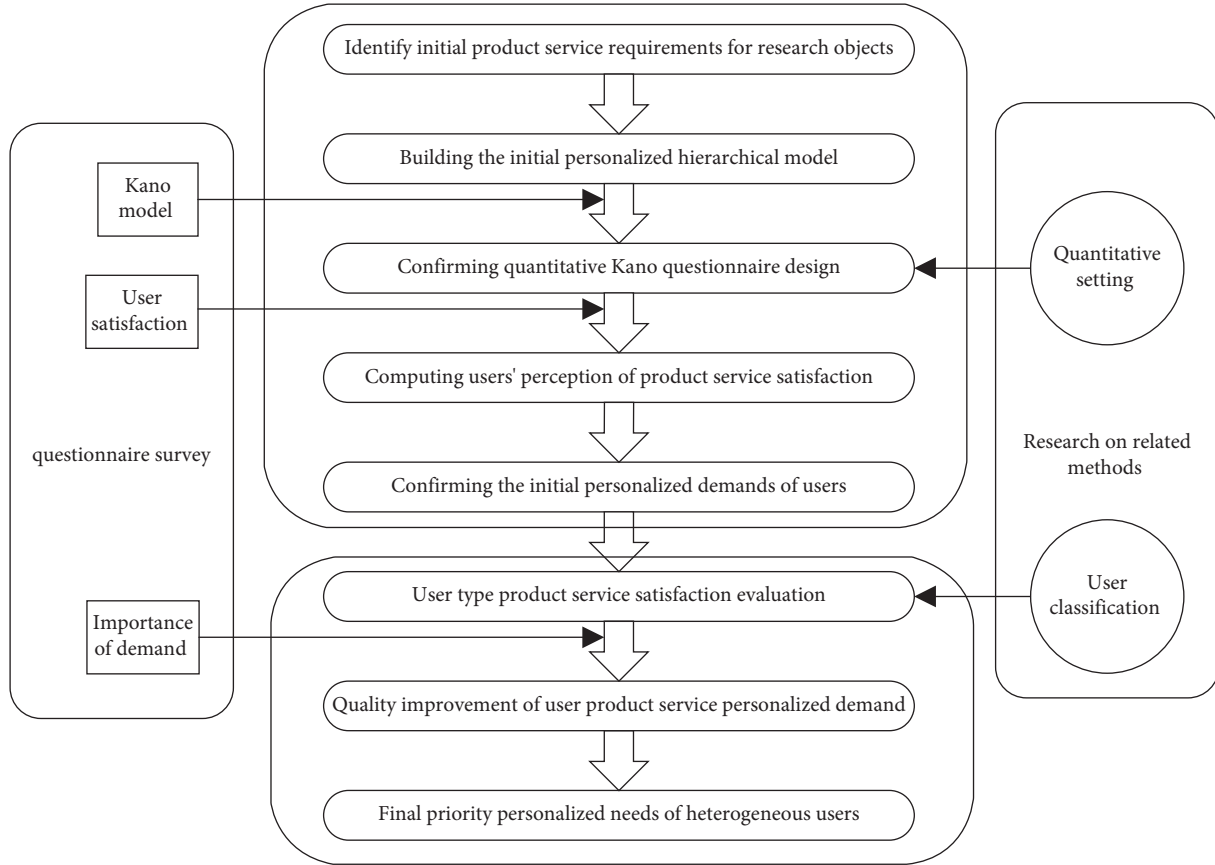
Assume that x_{ij} is the reverse product service satisfaction evaluation of jth users when the product service attribute f_i is not provided. y_{ij} is the positive product service satisfaction evaluation of user j when providing product service f_i. ω_{ij} is the importance evaluation of user j on product service


FIGURE 2: Process of obtaining personalized requirements for heterogeneous users.
FIGURE 3: Initial hierarchy model of personalized requirements.

TABLE 2: Provision/nonprovision of satisfaction values for product and service attributes.

		Like	Naturally	Never mind	Passable	Dislike
Product attributes	Provides this attribute	1	0.5	0	−0.25	−0.5
	This attribute is not provided	−0.5	−0.25	0	0.5	1

TABLE 3: Importance degree of products and services.

Unimportant	Some important	Important	Very important
0–0.25	0.25–0.5	0.5–0.75	0.75–1

attribute f_i. For each user v_j, the evaluation of f_i can be expressed as follows:

$$e_{ij} = (x_{ij}, y_{ij}, \omega_{ij}). \qquad (3)$$

Step 3.2. Calculate the average value of users' positive and negative problems.

By designing a quantitative Kano questionnaire, the values of x_{ij}, y_{ij}, and ω_{ij} can be obtained by questionnaire analysis. $\overline{X}_i$ denotes the average level of user satisfaction with negative problems without providing f_i product service attributes; $\overline{Y}_{ij}$ represents the average level of user satisfaction with a forward problem when providing f_i product service attributes, which are as follows:

$$\overline{X}_i = \frac{1}{n} \sum_{j=1}^{n} \omega_{ij} x_{ij},$$

$$\overline{Y}_i = \frac{1}{m} \sum_{i=1}^{m} \omega_{ij} y_{ij}. \tag{4}$$

The value of $(\overline{X}_i, \overline{Y}_i)$ can be marked in the two-dimensional coordinate diagram. The abscissa is the user's dissatisfaction with the product service attribute f_i, and the ordinate indicates the satisfaction level. Most $(\overline{X}_i, \overline{Y}_i)$ values fall within the range of [0, 1] in the two-dimensional graph, and the negative value is reverse demand or problem demand, which is not included in the average value, as shown in Figure 4.

Step 3.3. Calculate the user product service importance degree and satisfaction degree index.

Product service attributes can be described as $f_i \sim \overrightarrow{r}_i = (r_i, a_i)$ in vector form, where r_i is the moment of vector $\overrightarrow{r}_i$, which represents the importance of the product service attribute f_i to the user and is the Kano importance degree index.

$$r_i = \left| \overrightarrow{r}_i \right| = \sqrt{\overline{x}_i^2 + \overline{y}_i^2}, \quad 0 \le r \le \sqrt{2}, \tag{5}$$

where a_i is the angle between the vector $\overrightarrow{r}_i$ and the horizontal coordinate axis, which determines the relative level of user satisfaction or dissatisfaction with the product service attributes and becomes the Kano satisfaction index.

$$\alpha_i = \text{arctg}\left(\frac{\overline{Y}i}{\overline{X}_i}\right), \quad 0 \le \alpha_i \le \frac{\pi}{2}. \tag{6}$$

Step 4. Decision on quality improvement of product service.

According to the quantitative Kano questionnaire, the user demands are divided into attractive demands, essential demands, expected demands, and nondifference demands, and the user groups filled in the questionnaire are classified. At the same time, the importance of product services filled out by users in the questionnaire is used to further improve the quality of personalized demand for product services. Taking Kano satisfaction degree and Kano importance degree as two dimensions, product service attributes are divided into four quadrants. As shown in Figure 5, $\overline{r}$ is the average value of product service attributes importance degree, and $\overline{\partial}$ is the average value of product service satisfaction degree.

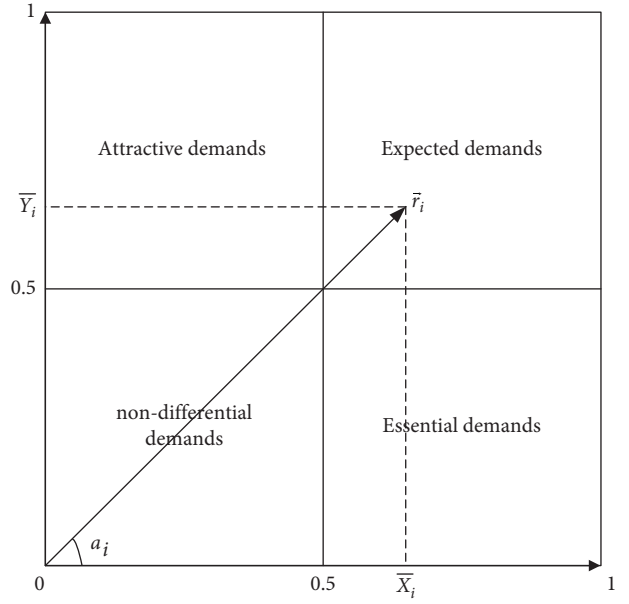
According to the analysis of Figure 5, quadrant I can be summarized as an irrelevant region. The product service attributes of the region have little effect on customer satisfaction and importance degree. Enterprises do not need to spend too many resources to improve these attributes. Quadrant II is the oversatisfaction area. Customers have high satisfaction with the product service in the region, but the importance of this attribute is not high. Investment in the region's attributes can be moderated if companies demand to reduce costs. Quadrant III can be regarded as a performance


FIGURE 4: Quantitative standards for product and service requirements.
FIGURE 5: Decision on quality improvement of product service attributes.

improvement area, which has high satisfaction and an important degree of product and service attributes. Increasing investment in this regional details can improve customer satisfaction. Quadrant IV can be classified as a key promotion area, and it has a low satisfaction degree and a high importance degree. It shows that the product service attributes in the region play a significant role in user demands. If customer satisfaction with these attributes can be improved, the quality requirements of product services can be improved as a whole.

4. Case Study

Taking electric vehicles as an example, this paper establishes the initial demand item model of the electric vehicle, subdivides the customizable part of the electric vehicle, and determines the demand item problem of the quantitative Kano questionnaire. The personalized customization needs of different types of user groups for electric vehicles are obtained through a questionnaire. The quantitative Kano analysis method is used to quantify the satisfaction and importance of users to products and services. Then, the demand items are divided into corresponding types so that enterprises can carry out precision marketing for different demand types of heterogeneous users.

4.1. Construction of Initial Requirements Model for Electric Vehicle. The collected electric vehicle demand items are divided into four categories: internal appearance demand, software and hardware demand, functional demand, and service demand. Among them, the internal and external demand refers to the internal and external decoration, including the vehicle's external characteristics and internal design. The design of this part reflects the user's demand for the overall beauty and comfort of the vehicle. The software and hardware requirements involve the vehicle's software and hardware systems, which can ensure the safety of vehicle performance and the intellectualization of the system. Functional requirements include entertainment, transmission, and additional functions. These functions can satisfy users and meet users' expectations for the vehicle. The service demand can be used as the value-added service of the product. While providing users with product functions, the existence of these functions will make users more satisfied and enhance the value of the product. Therefore, the construction of the initial demand model of electric vehicles is shown in Figure 6.

4.2. Design of the Quantitative Kano Questionnaire. The questionnaire is designed based on the initial personalized demand hierarchy model of electric vehicles. The questionnaire is divided into two parts. The first part is to investigate the characteristics of customers and establish the relevant preferences of customers. The second part is designed in the form of selection (positive and negative problems) and filling (importance degree). The customers' EV demand items are shown in Table 4.

4.3. Analysis of Electric Vehicle Demand Items of Users. Combined with the Kano demand questionnaire of EV and Equations 1–4, the negative and positive satisfaction degree distribution is shown in Figure 7 and Figure 8. There are three customer groups and 25 demand items, and the satisfaction degrees of various preference customers and demand items are different. The results in Figures 7 and 8 demonstrate that the negative satisfaction degree of demand item f_{14} (wheel hub) is the highest, and the positive

satisfaction degree of demand item f_{11} (connection of vehicle networking data) is the highest.

In terms of the statistical results in the previous table, the satisfaction threshold is set to 0.5 for the product service attribute $x_i < 0.5$, $y_i < 0.5$ is divided into no difference. If $x_i \geq 0.5$, $y_i < 0.5$ is classified as an essential requirement. When $x_i \geq 0.5$, $y_i \geq 0.5$, it is considered an expected demand. Similarly, when $x_i \leq 0.5$, $y_i \geq 0.5$ can be divided into charismatic needs. Based on the abovementioned settings, by depicting the data in Figures 7 and 8, we can get the average satisfaction to scatter diagram of all users and different user groups on product service attributes. Different user groups are price advantage users, brand affects users, and service users before and after sales.

According to the scatter diagram in Figure 9, for the samples of all users, the size of trunk space, the setting of the speech recognition system, and the additional products of the vehicle are divided into charm requirements. The four attributes of battery life function, data connection of the Internet of vehicles, exclusive manual customer service, and remote charging are divided into expected requirements. Eight choices, including the choice of seat configuration, car suspension choice, and GPS positioning and navigation system, can be divided into necessary requirements. The other ten attributes, such as the customization of the vehicle color, the selection of sunroof type, and the type of key, can be classified as indifference requirements.

According to the heterogeneity characteristics of users, the perception of the same product service attributes is also different. Users can be subdivided into heterogeneous user groups. According to the description of the scatter diagram, the demand types of users can be classified and summarized according to different groups, and the following product service attributes (Table 5) of heterogeneous user groups about electric vehicles can be obtained.

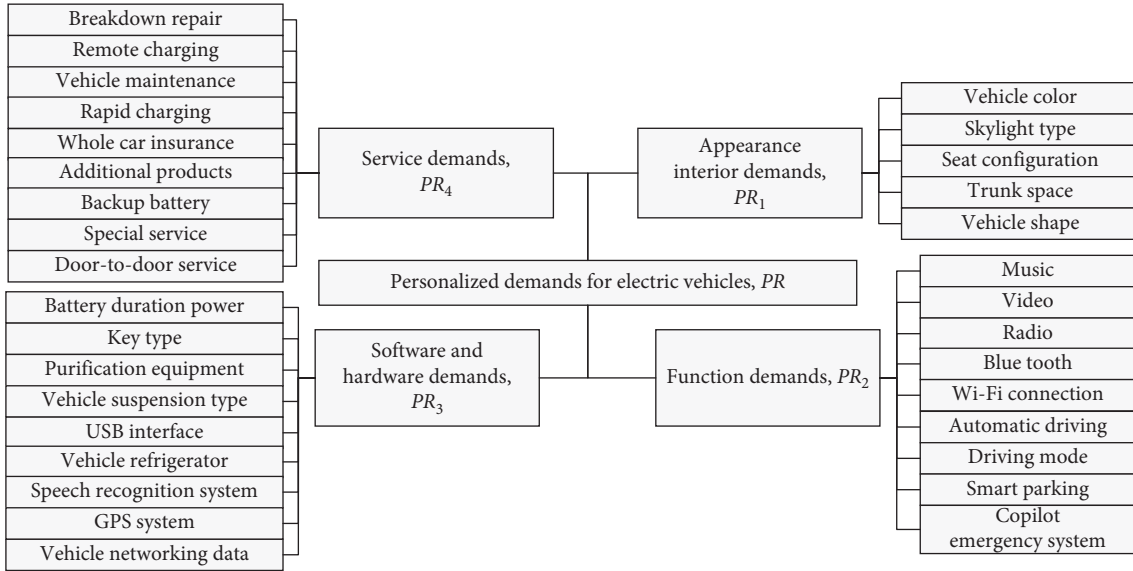
It can be found from Table 5 that different user groups have heterogeneity on product and service attributes, and user stickiness and market influence can be enhanced by providing users with differentiated, personalized product and service attributes. For user groups that prefer price advantage, their user groups pay more attention to the cost performance of products and expect to use the least money to obtain higher quality products and services. They do not have too much expectation for products and services and can meet their basic needs. For the user groups that prefer brand effect, their users pay more attention to the product and service guarantees brought by the product brand and think that the greater the brand influence, the better the effectiveness of their products and services. Such subdivided users have higher standards for the attributes of products and services and expect the attributes of the products and services they use to pass the high-quality screening. This is consistent with the characteristics of the user preference brand effect. User groups who prefer sales services pay attention to the services provided in purchasing products and the sense of the experience of process services. The humanized services of user enterprises often move such users.


Figure 6: Construction of initial demand model of electric vehicle.

Table 4: Description of product/service attributes of electric vehicles.

Product/service attribute number	Product/service attribute number	Benefits for users
f_1	Custom vehicle colors	Personality and pleasure
f_2	The type of sunroof can be selected	Comfortable and safe
f_3	Selection of seat configuration	Comfortable and safe
f_4	Size adjustment of trunk space	Convenient and comfortable
f_5	Battery life function	Value-added and convenient
f_6	Type of key	Personality and convenience
f_7	Selection of onboard purification equipment	Safe and comfortable
f_8	Choice of automobile suspension	Personality and safety
f_9	Customization of entertainment functions	Personality and pleasure
f_{10}	The setting of the speech recognition system	Fast and convenient
f_{11}	Connection of vehicle networking data	Safe and fast
f_{12}	Selection of GPS positioning and navigation system	Personality and convenience
f_{13}	Vehicle additional products	Personality and value-added
f_{14}	Wheel hub	Personality and safety
f_{15}	Exclusive manual customer service	Added value and pleasure
f_{16}	Maintenance service	Fast and safe
f_{17}	Remote charging	Fast and value-added
f_{18}	Copilot emergency system	Safe and convenient
f_{19}	Intelligent parking	Fast and convenient
f_{20}	Automatic driving	Fast and convenient
f_{21}	Rear seat TV	Comfortable and pleasant
f_{22}	Hi-Fi equipment	Comfortable and pleasant
f_{23}	Lamp type	Personality and safety
f_{24}	Vehicle shape	Personality and value-added
f_{25}	Car refrigerator	Comfortable and pleasant

To sum up, users have heterogeneous characteristics for user groups with different purchase preferences. Considering the different needs of heterogeneous users, the classification of the same product and service attributes will also belong to different demand types. Enterprises can pay attention to the expected needs of heterogeneous user groups. Everyday needs are the key for enterprises to improve their competitiveness. Providing personalized, customized services for different users can effectively improve user satisfaction and stickiness to enterprise products and services.

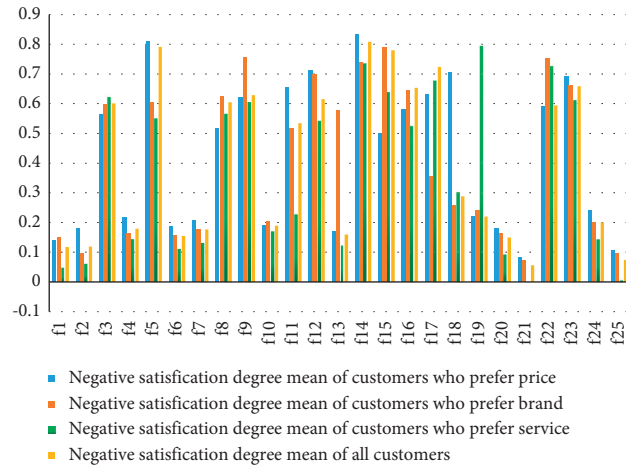
4.4. User Demand Promotion Decision. According to the personalized needs of heterogeneous users, the quality of their product service attributes can be improved accordingly. The $|\overrightarrow{r}_i|$ and α_i values of all users and heterogeneous user groups are calculated. Electric vehicles product and service attributes are classified into four quadrants composed of demand, satisfaction, and importance. The distribution of various demands of overall customers is shown in Figure 10, and the quantitative Kano model decision matrix of customers who prefer price is illustrated in


Figure 7: Negative satisfaction degree $\bar{x}_i$ statistical analysis of electric vehicle individual demand.
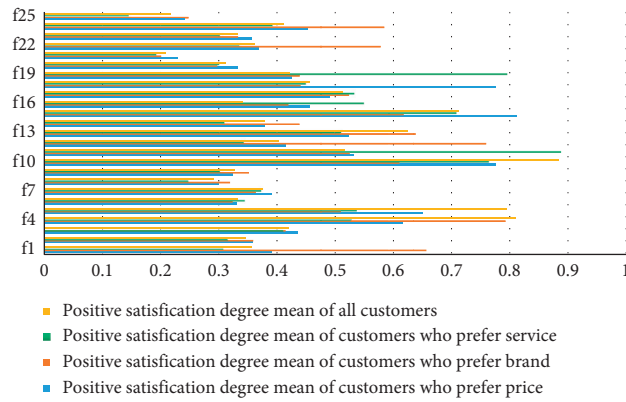

Figure 8: Positive satisfaction degree $\bar{y}_i$ statistical analysis of electric vehicle individual demand.
Figure 9: Scatter chart of mean satisfaction of overall customers with product attributes.

Table 5: Classification and summary of product/service requirements of heterogeneous users.

Product/service attributes	Users who prefer price advantage (73)	Users who prefer brand effect (66)	Users who prefer sales services (53)	All users (192)
f_1	I	A	I	I
f_2	I	I	I	I
f_3	M	M	M	M
f_4	A	A	A	A
f_5	O	O	O	O

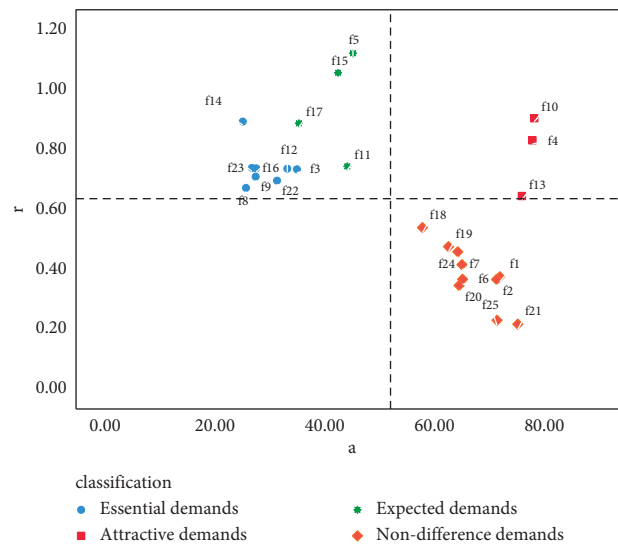
f_{24}	I	A	I	I
f_{25}	I	I	I	I


Figure 10: Quantitative Kano model decision matrix of overall customers.

Figures 11. Figure 12 describes the demand distribution of customers who prefer brand, and the quantitative Kano model decision matrix of customers who prefer service is shown in Figure 13.

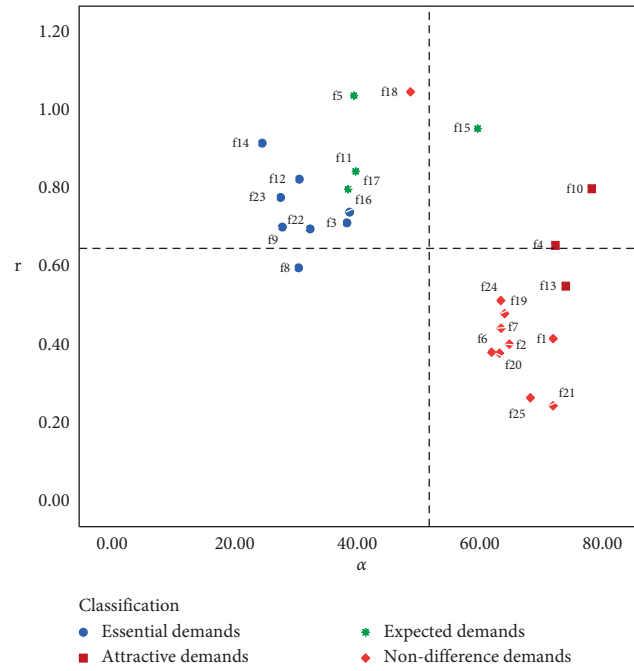
According to the importance of demand attributes, the third quadrant and the fourth quadrant can be divided into performance improvement areas and critical improvement areas. The abovementioned figure shows that whether all users or different types of users, the demand attributes of the third and fourth quadrants are mostly necessary needs and expected needs. On the one hand, it expresses that good products can not only meet the most basic needs of users but also pay attention to the expected needs, that is, pay attention to the core competitiveness of enterprises, which is consistent with the classification of the quantitative Kano model mentioned above, which verifies the necessity of user demand classification. The product service attributes can be improved according to the quality decision matrix obtained


FIGURE 11: Quantitative Kano model decision matrix of customer who prefer price.
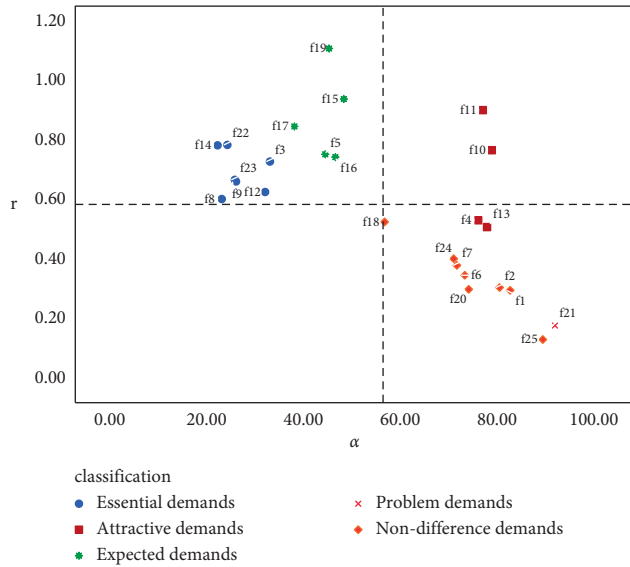
FIGURE 12: Quantitative Kano model decision matrix of customers who prefer brand.


FIGURE 13: Quantitative Kano model decision matrix of customers who prefer service.

from the product service satisfaction and importance, and precise marketing can be carried out according to the user's pain points.

5. Conclusion

In the traditional Kano model, customer demand items are determined according to statistics of positive and negative problems that customers had with product attributes, and it ignores various customer demand classifications. Furthermore, the traditional Kano model leads to subjective demand classification results for its qualitative selection. Satisfaction and importance degree of customers are put forward to judge different demand preferences of different customers for the same product by the quantitative Kano model, and it is helpful to realize precise marketing of the product. The paper takes electric vehicles as an example. An initial demand model of product is first constructed, and then customer demand items are determined. It can get a quantitative perception evaluation of electric vehicle satisfaction and importance degree by the Kano demand questionnaire and Equations 1–5, and the result shows that it can improve demand matching quality. For heterogeneous customers, each product attribute may belong to various demand types. In the process of customer purchase, enterprises should focus on customer's expected demands and essential demands, which will change with different types of customers. The quality of those demands will affect the customer's purchase choice. At the same time, the research results can be applied to the process of customer demand type determination and demand quality decision-making in various industries, which is helpful to the enterprise demand management and upgrading for the corresponding customer. The focus of the further research in the paper is to transmit customer demands into EV product functions based on ontology technology.

In China, driven by the national "3060" double carbon targets (i.e., reaching peak carbon emissions by 2030 and carbon neutrality by 2060), green housing has become one of the major fields to reduce carbon emissions, facilitating the achievement of the double carbon targets. Promoting the growth of green housing is an important way for the real estate industry to achieve low-carbon transformation and improve the quality of housing. Meanwhile, the construction industry also can benefit from green housing to achieve its energy conservation and emission reduction targets. Therefore, it is critical to boost and maintain the sustainable growth of the green housing market in China. However, the literature has not focused attention on the market behavior of the green housing market in China. This study proposes a tripartite evolutionary game model to investigate the subject behavior of the green housing market in China. This model consists of three major subjects in a green housing market: developers, consumers, and governments. Based on this model, this study analyzes the stability of the strategy options for each stakeholder and identifies the stable conditions of strategy portfolios to reach the equilibrium points of the game system. The validity of the proposed tripartite evolutionary game model is tested through the simulation of the impacts from various factors on system evolution. According to the impacts of factors and the stable conditions of strategies, this paper puts forward relevant policy suggestions for the healthy and sustainable growth of China's green housing market.

1. Introduction

Natural resources are being consumed enormously as a result of human uncontrolled exploitation, the resulting series of environmental problems such as greenhouse effect and extreme climate disasters has become increasingly serious [1]. The construction industry is an important area of final energy consumption and carbon dioxide emissions. According to the report released by the United Nations Environment Programme (UNEP), the construction industry accounted for 36% of the global final energy consumption and 37% of the energy-related carbon dioxide emissions in 2020 [2]. Therefore, energy conservation and

emission reduction in the construction industry is crucial to curb global climate change and achieve carbon neutrality goals. The high consumption brought about by traditional buildings has a serious negative impact on the sustainable development of society. In order to reduce the environmental load and achieve the development strategy of buildings adapting to the ecological environment, the green building comes into being. Green buildings have the characteristics of energy conservation, environmental protection, and resource conservation, as well as high economic benefits [3–6], which have a broad market prospect in advocating sustainable development today. Green housing is an important branch of green building. It emphasizes the

harmonious coexistence of residential area and environment. Therefore, the impact on the natural environment is taken into account in all activities such as design, construction, and operation, and the negative impact is controlled to the minimum as far as possible [7]. It can be said that green housing is the key to promote the high-quality development of housing construction and promote the green and sustainable development of cities. However, in the context of the country's vigorous development of green buildings, the market development of green housing still faces many problems. First, the low level of technological innovation and high development cost fundamentally hinder the development process [8, 9]; Second, for consumers, they often do not understand the benefits and health value of green housing but are unwilling to buy it because of its incremental cost [10]. Moreover, for developers, the development of green housing faces the dilemma of mismatch between income and expenditure, which hinders the promotion of green housing to a large extent [11]. Therefore, although green housing has the advantages of environment, society, and economy, they will only be considered for the development and adoption of green housing if the interests of major market players are guaranteed.

At this time, using incentive as a driving tool can encourage the adoption of green building and green housing to a certain extent [12, 13]. In general, incentives can be divided into external incentives and internal incentives. External incentives mainly come from the forced promotion of the government, which requires beneficiaries to meet specific conditions or requirements before benefiting, while internal incentives refer to attracting beneficiaries to be incentivized out of volition due to the value of green buildings [14]. Despite their differences, the vast majority of scholars recognize the positive role of the two. Guo et al. [15] affirmed the importance of government incentives and pointed out that legislation is the most effective way to promote the development of green buildings in Hong Kong, while expedited permits and density bonus can encourage market players to adopt green environmental protection voluntarily. He and Chen [16] found that the government subsidy policy has a positive incentive effect for the development of green buildings. Simultaneously subsidizing both developers and consumers obtain the highest social welfare. Therefore, in order to improve the popularity of green buildings, incentives should be provided to both developers and consumers. Bond [17] argued that the government sees the benefits of sustainable construction more through social and environmental benefits, while the private sector is driven more by economic returns. Moreover, when some investors pay more and more attention to corporate social responsibility and social responsibility investment, they will be more willing to promote the construction of green buildings. Love et al. [18] confirmed the catalytic role of clients in driving the sustainability agenda through a specific green building case, where building performance can be significantly improved when the client have a sustained drive and commitment to innovation.

The abovementioned research supports the effectiveness of green building incentive, but mainly focuses on specific incentive measures and policies. In the green building market, the key stakeholders have complex relationships and different needs; it is thus necessary to study the behavior strategies among them. Meng et al. [19] studied the behavior evolution process of the two main stakeholders of green building (contractors and government departments) under different reward and punishment policy combinations, so as to provide useful suggestions for the government to formulate reasonable incentive policies. Cohen et al. [20] used the prisoner's dilemma model to point out that developers and consumers do not adopt green houses, which belong to a suboptimal equilibrium. The government should provide incentives to developers and consumers, so as to make the green housing market move toward the optimal balance. Feng et al. [21] found the interest equilibrium point among green building stakeholders (government, construction units and consumers) by building a game model, so as to provide reference for the development of green building led by the government. Chen [22] analyzed the economic benefits of green building by building a bilateral game model between green building developers, consumers, and the government. The research found that the incremental profit of developers is the primary factor affecting enterprise decision-making, followed by the government's incentive policy, and the final strategic choice will be stabilized to higher economic benefits. Most literature analyzed the behavior strategies and interest conflicts of various subjects in the green building market, where the game relationship between government and developers; government and consumers; developers and consumers; government, developers, and consumers are key topics [23–25].

Throughout the existing literature, it is either limited to a single perspective, such as the incremental costs or payoffs of a tripartite subject and the equilibrium points of interests of subjects in a market, which fails to comprehensively look into the evolutionary path of the subject behavior of a green housing market or it focuses on how to formulate incentive policies to promote the growth of a green housing market; however, the benefits brought by incentive policies and consequently, the impacts of these benefits on the decision-making of governments are overlooked. For instance, how will a government make decisions and other subjects behave if incentive policies fail to deliver more benefits? Meanwhile, some researchers have built relevant models to analyze the behavioral evolution of green housing market subjects, but there is still little theoretical understanding of these models. Furthermore, the dynamic simulation and validation of these models are lacking.

Therefore, in order to bridge this knowledge gap, this study proposes a tripartite evolutionary game model, which considers developers, consumers, and governments, to investigate the subject behavior of the green housing market in China. This study also simulates the evolutionary path of the green housing market to validate the proposed model. The paper consists of the following parts: Section 1 introduces the background and summarizes the relevant literature. Section 2 puts forward model assumption and establishes the game model. Section 3 analyzes the model formulation. Section 4 carries on the numerical simulation. Section 5 draws the conclusion and implication. This study will

provide some reference value to the healthy and sustainable development of the green housing market in China.

2. Model Assumption and Formulation

2.1. Model Assumption. It is well known that the development of green housing market involves multistage decision-making by multiple stakeholders, among which the developers[①], consumers[②], and government[③] are the core subjects. The evolutionary game with them has the following five assumptions.

Assumption 1. In view of the fact that green housing market subjects are not completely rational and accurate in the process of acquiring knowledge and information, all three subjects are participants of bounded rationality who constantly adjust their strategies in the process of interaction and stabilize to optimal strategies over a period of evolution.

Assumption 2. The developers' strategic space $\alpha = (\alpha_1, \alpha_2) = $ (developing green housing, developing ordinary housing); Developers have a probability of x to choose α_1 and a probability of $(1 - x)$ to choose α_2. The consumers' strategic space $\beta = (\beta_1, \beta_2) = $ (purchasing green housing, purchasing ordinary housing); Consumers have a probability of y to choose β_1 and a probability of $(1 - y)$ to choose β_2. The governments' strategic space $\gamma = (\gamma_1, \gamma_2) = $ (providing incentive policies, providing no incentive policies); Governments have a probability of z to select γ_1 and a probability of $1 - z$ to select γ_2. x, y and z all belong to [0, 1].

Assumption 3. A_P is the sales payoff of developers from ordinary housing, while C_P is the development cost of ordinary housing. Meanwhile, A_P is also the spending of consumers purchasing ordinary housing. In the case of green housing, the incremental sales payoff from green housing is A_Z, the incremental development cost on green housing is C_z, and the potential payoff brought by green housing for developers is A_Q. The potential payoff has several streams, including the increased brand value, social image, and reputation resulted from developing green housing, the preferential treatments of taxation and mortgage, and the savings of land use and building materials in the process of development. In addition, when governments provide subsidies as incentive polices, developers get a subsidy of θD_2 from developing green housing, where θ is the proportion of governments' subsidy D_2.

Assumption 4. The payoffs of consumers is S_P when they purchase ordinary housing, with a spending of A_P. When purchasing green housing, the incremental residential utility payoffs obtained by consumers is φS_{Z1}, which includes the financial benefits from the savings of energy and water in the use of green housing. The incremental perception gains obtained by consumers is ηS_{Z2}, which includes the satisfaction and comfort brought by green housing to consumers. The incremental spending paid by consumers on green housing is A_Z. In addition, when governments provide subsidies as incentive polices, consumers who purchase green housing get subsidies $(1 - \theta) D_2$, where θ is the proportion of governments' subsidy D_2 received by developers.

Assumption 5. Governments have two strategies: either providing incentive polices or not. In the case of providing incentive polices, a management cost D_1 will occur as governments have to spend on the propaganda for environmental protection and the regulation and monitoring on environment to facilitate the social promotion of green housing. Consequently, the utility of the use of D_1 is G_1. Meanwhile, the social and environmental benefits brought by green housing are G_2. When both developers and consumers choose green housing, the total amount of subsidies given by governments as incentive polices is D_2. When developers choose green housing and consumers purchase ordinary housing, governments bear social environmental risk costs, which are D_3.

2.2. Model Formulation. According to the previous literature [21–25], combining with the abovementioned relative assumption, the tripartite evolutionary game model of a green housing market has been constructed. Moreover, the logical relationship between each subject in the evolutionary game is shown in Figure 1. Whether or not government incentives, developers have two choices: to develop green housing or to develop ordinary housing; consumers similarly have two choices: to purchase green housing or to purchase ordinary housing, the strategies are marked with arrows. Meanwhile, the mixed strategy payoff matrix of developers, consumers, and governments is constructed with the assumptions stated in Section 2.1, as shown in Table 1.

3. Derivation and Analysis of the Model Formula

3.1. Replicator Dynamics Equations and Phase Diagrams of Each Game Subject's Decision-Making

3.1.1. Developers. The expected payoff E_{11} of developers developing green housing, E_{12} of developing ordinary housing, and the average expected payoff E_1 are given below:

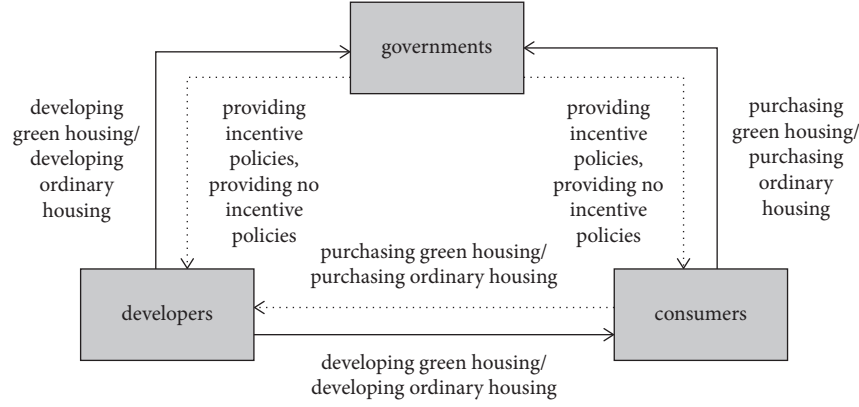
$$\begin{cases} E_{11} = yz\left[(A_p + A_Z) - (C_P + C_Z) + \theta D_2 + A_Q\right] + y(1 - z)\left[(A_p + A_Z) - (C_P + C_Z) + A_Q\right] + (1 - y)z\left[-(C_P + C_Z) + \theta D_2 + A_Q\right] \\ \quad + (1 - y)(1 - z)\left[-(C_P + C_Z) + A_Q\right], \\ E_{12} = yz(-C_P) + y(1 - z)(-C_P) + (1 - y)z(A_P - C_P) + (1 - y)(1 - z)(A_P - C_P), \\ E_1 = xE_{11} + (1 - x)E_{12}, \end{cases} \quad (1)$$


FIGURE 1: Logical relationship between each subject in the evolutionary game of a green housing market.

TABLE 1: Mixed strategy payoff matrix of developers, consumers, and governments.

The game party	Consumers[②]	Governments[③]	
		Providing incentive polices z	Providing no incentive polices$(1-z)$
Developers[①]			
Developing green housing x	Purchasing green housing y	①: $A_P + A_Z - (C_P + C_z) + \theta D_2 + A_Q$ ②: $S_P + \varphi S_{Z1} + \eta S_{Z2} - A_P - A_Z + (1-\theta)D_2$ ③: $G_1 + G_2 - D_1 - D_2$	①: $A_P + A_Z - (C_P + C_z) + A_Q$ ②: $S_P + \varphi S_{Z1} + \eta S_{Z2} - A_P - A_Z$ ③: G_2
	Purchasing ordinary housing $(1-y)$	①: $-(C_P + C_z) + \theta D_2 + A_Q$ ②: $S_P - A_P$ ③: $G_1 + G_2 - D_1 - \theta D_2 - D_3$	①: $-(C_P + C_z) + A_Q$ ②: $S_P - A_P$ ③: $G_2 - D_3$
Developing ordinary housing $(1-x)$	Purchasing green housing y	①: $-C_P$ ②: $S_P + \varphi S_{Z1} + \eta S_{Z2} - A_P - A_Z + (1-\theta)D_2$; ③: $G_1 - D_1 - (1-\theta)D_2$	①: $-C_P$ ②: $S_P + \varphi S_{Z1} + \eta S_{Z2} - A_P - A_Z$ ③: 0
	Purchasing ordinary housing $(1-y)$	①: $A_P - C_P$ ②: $S_P - A_P$ ③: $G_1 - D_1$	①: $A_P - C_P$ ②: $S_P - A_P$ ③: 0

The replicator dynamics equation of residential developers' decisions is as follows:

$$F(x) = \frac{d(x)}{dt} = x(E_{11} - E_1) = x(1-x)\left[y(2A_P + A_Z) + z\theta D_2 + A_Q - A_P - C_Z \right].$$ (2)

The first derivatives with respect to x and the set $G(y)$ are, respectively, as shown below:

$$\frac{d(F(x))}{dx} = (1-2x)\left[y(2A_P + A_Z) + z\theta D_2 + A_Q - A_P - C_Z \right],$$

$$G(y) = \left[y(2A_P + A_Z) + z\theta D_2 + A_Q - A_P - C_Z \right].$$ (3)

Based on the stability principle of differential equations, the probability of developers choosing developing green housing in a stable state must be satisfied by $F(x) = 0$, where $d(F(x))/dx < 0$. Because $\partial G(y)/\partial y > 0$, $G(y)$ is the increasing function of y. Therefore, when $y = [(A_P + C_Z) - A_Q - z\theta D_2]/(2A_P + A_Z) = y^*$, $G(y) = 0$; at this point, $d(F(x))/dx \equiv 0$, $F(x) \equiv 0$, which means that in a group of developers, any proportion of individuals

choosing developing green housing is a stable strategy. When $y < y^*$, $G(y) < 0$, $F'(x)|_{x=0} < 0$, $F'(x)|_{x=1} > 0$; at this point, $x = 0$ is the stable evolution point of developers, which means that when the proportion of consumers choosing purchasing green housing is less than $[(A_P + C_Z) - A_Q - z\theta D_2]/(2A_P + A_Z)$, developers will turn to ordinary housing. On the contrary, $x = 1$ is the stable evolution point of developers; in other words, developers will choose developing green housing. The decision-making

evolution phase diagrams of developers are shown in Figure 2.

3.1.2. Consumers. The expected payoff E_{21} of consumers for purchasing green housing, E_{22} for purchasing ordinary housing, and their average expected payoff E_2 are, respectively, as follows:

$$
\begin{cases}
E_{21} = xz\left[\left(S_p + \phi S_{Z1} + \eta S_{Z2}\right) - \left(A_P + A_Z\right) + (1-\theta)D_2\right] + x(1-z)\left[\left(S_p + \phi S_{Z1} + \eta S_{Z2}\right) - \left(A_P + A_Z\right)\right] \\
+ (1-x)z\left[\left(S_p + \phi S_{Z1} + \eta S_{Z2}\right) - \left(A_P + A_Z\right) + (1-\theta)D_2\right] + (1-x)(1-z)\left[\left(S_p + \phi S_{Z1} + \eta S_{Z2}\right) - \left(A_P + A_Z\right)\right], \\
E_{22} = xz\left(S_p - A_P\right) + x(1-z)\left(S_p - A_P\right) + (1-x)z\left(S_p - A_P\right) + (1-x)(1-z)\left(S_p - A_P\right), \\
E_2 = yE_{21} + (1-y)E_{22}.
\end{cases}
\tag{4}
$$

The replicator dynamics equation of consumers' decisions is as follows:

$$
F(y) = \frac{d(y)}{dt} = y(E_{21} - E_2) = y(1-y)\left[z(1-\theta)D_2 + \phi S_{Z1} + \eta S_{Z2} - A_Z\right].
\tag{5}
$$

The first derivatives with respect to y and the set $G(z)$ are, respectively, as follows:

$$
\frac{d(F(y))}{dy} = (1-2y)\left[z(1-\theta)D_2 + \phi S_{Z1} + \eta S_{Z2} - A_Z\right],
\tag{6}
$$

$$
G(z) = \left[z(1-\theta)D_2 + \phi S_{Z1} + \eta S_{Z2} - A_Z\right].
$$

Based on the stability principle of differential equations, the probability of consumers choosing purchasing green housing in a stable state must be satisfied by $F(y) = 0$, where $d(F(y))/dy < 0$. Because $\partial G(z)/\partial z > 0$, $G(z)$ is the increasing function of z. Therefore, when $z = (A_Z - \phi S_{Z1} - \eta S_{Z2})/(1-\theta)D_2 = z^*$, $G(y) = 0$; at this point, $d(F(y))/dy \equiv 0$, $F(y) \equiv 0$, which means that in a group of consumers, any proportion of individuals choosing purchasing green housing is a stable strategy. When $z < z^*$,

$G(z) < 0$, $F'(y)|_{x=0} < 0$, $F'(y)|_{x=1} > 0$; at this point, $y = 0$ is the stable evolution point of consumers, which means that when the probability of governments chooses providing incentive polices is less than $(A_Z - \phi S_{Z1} - \eta S_{Z2})/(1-\theta)D_2$, consumers will choose purchasing ordinary housing. On the contrary, $y = 1$ is the stable evolution point of consumers; in other words, consumers will choose purchasing green housing. The decision-making evolution phase diagrams of consumers are shown in Figure 3.

3.1.3. Governments. The expected payoff E_{31} of governments choosing incentive polices, E_{32} of governments choosing no incentive polices, and their average expected payoff E_3 are, respectively, as shown below:

$$
\begin{cases}
E_{31} = xy\left(G_1 + G_2 - D_1 - D_2\right) + x(1-y)\left(G_1 + G_2 - D_1 - \theta D_2 - D_3\right) \\
+ (1-x)y\left[G_1 - D_1 - (1-\theta)D_2\right] + (1-x)(1-y)\left(G_1 - D_1\right), \\
E_{32} = xyG_2 + x(1-y)\left(G_2 - D_3\right), \\
E_3 = zE_{31} + (1-z)E_{32}.
\end{cases}
\tag{7}
$$

The replicator dynamics equation of governments' decisions is as follows:
FIGURE 2: Evolution phase diagrams of developers' decisions in the case of develop green housing. (a) $y = y^*$, y is equal to the stable point. (b) $y < y^*$, y is less than the stable point. (c) $y > y^*$, y is greater than the stable point.
FIGURE 3: Evolution phase diagrams of consumers' decisions in the case of purchasing green housing. (a) $z = z^*$, z is equal to the stable point. (b) $z > z^*$, z is greater than the stable point. (c) $z < z^*$, z is less than the stable point.

$$F(z) = \frac{d(z)}{dt} = z(E_{31} - E_3) = z(1 - z)[G_1 - D_1 - x\theta D_2 - y(1 - \theta)D_2]. \tag{8}$$

The first derivatives with respect to z and the set $G(x)$ are, respectively, as shown below:

$$\frac{d(F(z))}{dz} = (1 - 2z)[G_1 - D_1 - x\theta D_2 - y(1 - \theta)D_2],$$

$$G(x) = [G_1 - D_1 - x\theta D_2 - y(1 - \theta)D_2]. \tag{9}$$

Based on the stability principle of differential equations, the probability of governments choosing incentive polices in a stable state must be satisfied by $F(z) = 0$, where $d(F(z))/dz < 0$. Because $\partial G(x)/\partial y < 0$, $G(x)$ is the decreasing function of x. Therefore, when $x = [G_1 - D_1 - y(1 - \theta)D_2]/\theta D_2 = x^*$, $G(x) = 0$; at this point, $d(F(z))/dz \equiv 0$, $F(z) \equiv 0$, which means that in governments, any proportion of individuals choosing incentive polices is a stable strategy. When $x < x^*$, $G(x) > 0$, $F'(z)|_{z=0} > 0$, $F'(z)|_{z=1} < 0$; at this point, $z = 1$ is the stable evolution point of governments, which means that when the proportion of developers choosing developing green housing is less than $[G_1 - D_1 - y(1 - \theta)D_2]/\theta D_2$, governments will provide incentive polices to encourage the development of green housing. On the contrary, $z = 0$ is the stable evolution point of governments; in other words,

governments will not choose incentive polices. The decision-making evolution phase diagram of governments is shown in Figure 4.

3.2. Stability Analysis of Each Game Subject's Decision-Making.
The simultaneous game of the replicator dynamics equations of three game subjects forms up a three-dimensional discrete dynamical system.

$$\begin{cases} F(x) = x(1 - x)[y(2A_P + A_Z) + z\theta D_2 + A_Q - A_P - C_Z] = 0, \\ F(y) = y(1 - y)[z(1 - \theta)D_2 + \phi S_{Z1} + \eta S_{Z2} - A_Z] = 0, \\ F(z) = z(1 - z)[G_1 - D_1 - x\theta_2^D - y(1 - \theta)D_2] = 0. \end{cases} \tag{10}$$

Thirteen strategic equilibrium points are obtained by solving the equilibrium points of the discrete dynamical system: $E_1[0, 0, 0]$, $E_2[0, 0, 1]$, $E_3[1, 0, 0]$, $E_4[0, 1, 0]$, $E_5[1, 1, 0]$, $E_6[0, 1, 1]$, $E_7[1, 0, 1]$, $E_8[1, 1, 1]$, $E_9[0, y_0, z_0]$, $E_{10}[1, y', z']$, $E_{11}[x_1, 0, z_1]$, $E_{12}[x_2, 1, z_2]$, and $E_{13}[x_3, y_1, z_3]$. Among them, E_1–E_8 are the pure strategic equilibrium points for the three subjects of a green housing market; E_9–E_{12} are the pure strategic equilibrium points for a single subject of a green housing market; and E_{13} is the mixed strategic equilibrium
FIGURE 4: Evolution phase diagrams of governments in the case of choosing incentive polices. (a) $x = x^*$, x is equal to the stable point. (b) $x < x^*$, x is less than the stable point. (c) $x > x^*$, x is greater than the stable point.

point. Some scholars have pointed out that the stable solution of the replicator dynamics system in a multigroup evolutionary game is a strict Nash equilibrium solution. Therefore, except for the eight equilibrium points $(E_1–E_8)$, the remaining states are not asymptotically stable.

Based on the Lyapunov stability theory, the stability of a system at an equilibrium point is determined by the eigenvalues of a Jacobian matrix. When all the eigenvalues have negative real parts, an equilibrium point is asymptotically stable. When at least one of the eigenvalues has a positive real part, an equilibrium point is unstable. When all eigenvalues except those with zero real parts have negative real parts, an equilibrium point is in a critical state and the stability cannot be determined by the sign of an eigenvalue. Therefore, the Jacobian matrix of the discrete dynamical system can be obtained by integrating formula (10) as follows:

$$
J = \begin{vmatrix} \dfrac{\partial F(x)}{\partial(x)} & \dfrac{\partial F(x)}{\partial(y)} & \dfrac{\partial F(x)}{\partial(z)} \\[2mm] \dfrac{\partial F(y)}{\partial(x)} & \dfrac{\partial F(y)}{\partial(y)} & \dfrac{\partial F(y)}{\partial(z)} \\[2mm] \dfrac{\partial F(z)}{\partial(x)} & \dfrac{\partial F(z)}{\partial(y)} & \dfrac{\partial F(z)}{\partial(z)} \end{vmatrix} = \begin{vmatrix} J_{11} & x(1-x)(2A_P + A_Z) & x(1-x)\theta D_2 \\[2mm] 0 & J_{22} & y(1-y)(1-\theta)D_2 \\[2mm] z(z-1)\theta D_2 & z(z-1)(1-\theta)D_2 & J_{33} \end{vmatrix}, \tag{11}
$$

where

$$
J_{11} = (1-2x)\big[y(2A_P + A_Z) + z\theta D_2 + A_Q - A_P - C_Z\big],
$$
$$
J_{22} = (1-2y)\big[z(1-\theta)D_2 + \phi S_{Z1} + \eta S_{Z2} - A_Z\big],
$$
$$
J_{33} = (1-2z)\big[G_1 - D_1 - x\theta D_2 - y(1-\theta)D_2\big]. \tag{12}
$$

$E_1–E_8$ were substituted into the Jacobian matrix to obtain their eigenvalues and analyze the stability of equilibrium points. The detailed results are shown in Table 2.

Corollary 1. *When $A_Q - A_P - Cz < 0$ and $G_1 - d_1 < 0$, the replicator dynamical system has a unique stable equilibrium point $E_1[0, 0, 0]$.*

Proof. According to Chart 2, at this point, condition ① is met, $E_1[0, 0, 0]$ is the stable equilibrium point, and $C_Z + A_P - A_Q > 0$, $D_2 + D_1 - G_1 > 0$. Therefore, $E_3[1, 0, 0]$ and

$E_8[1, 1, 1]$ are also instable points. It is concluded that $E_1[0, 0, 0]$ is unique.

Corollary 1 shows that when the potential payoff of developers developing green housing is less than the sum of incremental payoffs and incremental costs, and the payoff of governments promoting green housing is less than the sum of incremental payoffs and incremental costs, both developers and governments will not choose developing and promoting green housing. Consequently, a green housing market will disappear. □

Corollary 2. *When $A_Q - A_P - C_Z > 0$ and $G_1 - D_1 - \theta D_2 < 0$, the replicator dynamical system has a unique stable equilibrium point $E_3[1, 0, 0]$. Corollary 2 can be proved following the same way to proof Corollary 1. Corollary 2 shows that when the potential payoff of developers developing green housing is greater than the sum of incremental payoffs and incremental costs, and the payoff of governments promoting green housing is less than the one without incentive policies,*

TABLE 2: Eigenvalues of the Jacobian matrix and local stability judgment of equilibrium point.

Equant equation	Eigenvalues of the Jacobian matrix $\lambda_1, \lambda_2, \lambda_3$	Real component symbol	Stability conclusion	Condition
$E_1[0, 0, 0]$	$A_Q - A_P - C_Z, \varphi S_{Z1} + \eta S_{Z2} - A_Z, G_1 - D_1$	$(\times, -, \times)$	Stable point	①
$E_2[0, 0, 1]$	$\theta D_2 + A_Q - A_P - C_Z, (1-\theta)D_2 + \varphi S_{Z1} + \eta S_{Z2} - A_Z, D_1 - G_1$	$(\times, +, \times)$	Instable point	—
$E_3[1, 0, 0]$	$C_Z + A_P - A_Q, \varphi S_{Z1} + \eta S_{Z2} - A_Z, G_1 - D_1 - \theta D_2$	$(\times, -, \times)$	Stable point	②
$E_4[0, 1, 0]$	$A_Q + A_P + A_Z - C_Z, A_Z - \varphi S_{Z1} - \eta S_{Z2}, G_1 - D_1 - (1-\theta)D_2$	$(+, +, -)$	Instable point	—
$E_5[1, 1, 0]$	$C_Z - A_P - A_Z - A_Q, A_Z - \varphi S_{Z1} - \eta S_{Z2}, G_1 - D_1 - D_2$	$(-, -, +)$	Instable point	—
$E_6[0, 1, 1]$	$\theta D_2 + A_Q + A_P + A_Z - C_Z, A_Z - \varphi S_{Z1} - \eta S_{Z2} - (1-\theta)D_2, (1-\theta)D_2 + D_1 - G_1$	$(+, -, -)$	Instable point	—
$E_7[1, 0, 1]$	$C_Z + A_P - \theta D_2 - A_Q, (1-\theta)D_1 + \varphi S_{Z1} + \eta S_{Z2} - A_Z, \theta D_2 + D_1 - G_1$	$(+, +, -)$	Instable point	—
$E_8[1, 1, 1]$	$C_Z - A_Z - A_P - \theta D_2 - A_Q, A_Z - \varphi S_{Z1} - \eta S_{Z2} - (1-\theta)D_2, D_2 + D_1 - G_1$	$(-, -, \times)$	Stable point	③

Note. x means the symbol is uncertain, ① $A_Q - A_P - C_Z < 0, G_1 - D_1 < 0$; ② $C_Z + A_P - A_Q < 0, G_1 - D_1 - \theta D_2 < 0$; ③ $D_2 + D_1 - G_1 < 0$.

developers will still be willing to develop green housing. The reason is that developers think highly of huge potential payoffs in the future. However, this strategy is only theoretically stable. When consumers choose purchasing ordinary housing, a green housing market does not grow.

Corollary 3. *When $D_2 + D_1 - G_1 < 0$, the replicator dynamical system has a unique stable equilibrium point $E_8[1, 1, 1]$.* Corollary 3 can be proved following the same way to prove Corollary 1. Corollary 3 shows that when the payoffs of incentive polices adopted by governments greater than their costs, developers will choose developing green housing, consumers will choose purchasing green housing, and governments will actively encourage them. The subjects of a green housing market jointly promote the sustainable and healthy growth of the market.

4. Numerical Simulation

In order to validate the stability of the evolution of green housing market subject behavior, the replicator dynamical system was assigned with numerical values for numerical simulation analysis. The determination method of numerical value is similar to the method of numerical selection in references [20–22], which is to obtain first-hand data by investigating consumers, developers, and leaders of government departments, and comparing the dimensions of the data to obtain the relative value [26]. Due to the limited length, this study selected numerical values, where $A_P = 50$, $A_Z = 40$, $\theta = 0.5$, $D_2 = 40$, $A_Q = 30$, $C_Z = 50$, $\varphi = 0.5$, $S_{Z1} = 30$, $\eta = 0.5$, $S_{Z2} = 30$, $G_1 = 160$, and $D_1 = 90$. The impacts of A_Z, A_Q, θ, η, and D_2 on the process and results of the system evolutionary game were analyzed when the conditions of $C_Z - A_Z - A_P - \theta D_2 - A_Q < 0$, $A_Z - \varphi S_{Z1} - \eta S_{Z2} - (1-\theta)D_2 < 0$, and $D_2 + D_1 - G_1 < 0$ were satisfied.

4.1. Impacts of Incremental and Potential Payoffs of Developers Choosing Developing Green Housing on the System Evolutionary Game. According to Figure 5, when a green housing market is approaching a state of stability, the incremental payoff of developing green housing for developers is
FIGURE 5: Influence of incremental income A_Z on the system evolutionary game.

increasing, and the evolutionary speed of green housing development is accelerating. With the increase of A_Z, the probability of developing green housing for developers is increasing. When A_Z reaches over 80, however, the system enters a state of instability. At this time, the increase of green housing incremental payoffs brings the increase of incremental costs for consumers purchasing green housing. When incremental costs reach a certain extent, consumers turn to ordinary housing, leading to a state of instability for a green housing market. This shows as a profitable enterprise, the developers excessively pass on the cost of green housing to consumers, thereby result in green housing market instability, which is in accord with Jiang and Payne [27].

As can be seen from Figure 6, when a green housing market is approaching a state of stability, the increase of potential income of green housing obtained by developers will accelerate the evolution speed of green housing development by developers. The application of green strategies such as the solar system and water saving technology can help contribute to building up developers' competitive advantages and bring a potential income for developers [28]. In
FIGURE 6: Influence of potential returns A_Q on the system evolutionary game.

FIGURE 7: Influence of incremental return coefficient $1 - \theta$ on the system evolutionary game.

other words, with the increase of A_Q, the probability of developing green housing for developers is increasing. In the case where governments provide incentive polices, the greater potential payoffs are the earlier a green housing market enters a stable state.

4.2. Impacts of Consumers' Green Housing Subsidies and Green Perception on the System Evolutionary Game.

According to Figure 7, when the total subsidy D_2 for green housing remains unchanged and $1 - \theta$ does not exceed 0.1 (i.e., the proportion of subsidies for consumers is low), the proportion of consumers choosing purchasing green housing drops from 0.3 to 0. However, when the proportion of subsidies $1 - \theta$ increases gradually, the proportion of consumers choosing purchasing green housing increases, and the evolutionary speed of consumers choosing green housing increases as well. He et al. [29] support the idea that the government encourages potential buyers of green houses to purchase through financial subsidies.

Green perception refers to consumers' satisfaction and comfort brought by green housing and essentially represents consumers' cognitive level of environmental protection, thereby determines the willingness to purchase, which is consistent with Guo et al. [30]. As shown in Figure 8, when green perception is low (i.e., η is less than 0.1), even if subsidies from governments for purchasing green housing are in place, the proportion of consumers choosing purchasing green housing drops from 0.3 to 0 at the beginning of system evolution. This means consumers only purchase ordinary housing. However, with the increase of green perception η, the proportion of consumers choosing purchasing green housing increases and the evolutionary speed of consumers choosing green housing increases as well.

4.3. Impacts of the Total Amount of Subsidies and Social Promotion for Green Housing on the System Evolutionary Game.

As shown in Figure 9, when the incremental payoff θ
FIGURE 8: Influence of green perception coefficient η on the system evolution game.

is constant, the total amount of subsidies D_2 provided by governments as incentive polices has a significant impact on developers' decisions. When the total amount of subsidies D_2 is less than 10, the proportion of developers choosing developing green housing decreases from 0.3 to 0. When the total amount of subsidies D_2 is gradually increasing, the proportion of developers choosing developing green housing is gradually increasing from the initial value 0.3, and the evolutionary speed of developers choosing developing green housing is increasing as well, which is in line with the studies by He and Chen [16].

According to Figure 10, when governments use propaganda of environmental protection and deploy regulation and monitoring on environment, the social promotion effect of green housing is limited. In other words, when $G_1 = 100$, the proportion of developers choosing green housing gradually decreases from the initial value 0.3. When
FIGURE 9: Influence of total green housing subsidy D_2 on the system evolution game.
FIGURE 10: Influence of social promotion effect G_1 on the systematic evolutionary game.

intensive propaganda of environmental protection and strong environmental monitoring and regulation are in place, the social promotion of green housing becomes effective. With the increase of the proportion of government incentive policies, the proportion of developers choosing green housing increases and the evolutionary speed of the system increases.

5. Conclusion and Implications

The purpose of this research was to examine that how the behavioral decisions of developers, consumers, and governments among green housing market subjects affect the growth of green housing. First, this study builds a tripartite evolutionary game model to investigate a green housing

marketing, which includes developers, consumers, and governments. Second, this study obtains a three-dimensional discrete dynamic system and identifies the stable conditions of strategy portfolios to reach the equilibrium points of the game system based on the Lyapunov stability theory. Finally, this study assigns real-world values to the proposed tripartite evolutionary game model and conducts numerical simulation to test the influence and relationship of each factor on system evolution, validating the proposed model. Moreover, the results of this study reveal that developers should not blindly pursue the incremental payoffs brought by green housing; otherwise, consumers may turn to ordinary housing. Similarly, the potential earnings from green housing will make green housing more favorable to developers. Moreover, regarding consumers, the perception of green housing determines the demand intensity from consumers. Meanwhile, the more subsidies provided by governments, the more enthusiastic consumers will be in purchasing green housing. Furthermore, when governments do not provide or provide mild subsidies, both developers and consumers will embrace ordinary housing. In addition, governments can effectively increase the initiatives of developers and improve the awareness of consumers toward green housing through intensive propaganda of greenness and environmental protection and strong regulation of environment.

In addition, this study generates the following implications to the sustainable and healthy growth of green housing markets in China.

First, developers are the suppliers in a green housing market, who undertake the development task of green housing. In the process of green housing development, it is not feasible for developers to blindly pursue incremental payoffs brought by green housing. The increase of incremental payoffs for developers will result in the increase of incremental costs for consumers, where consumers may turn to ordinary housing as they cannot afford green housing. This is evident in our simulation when A_Z climbs over 80, the system of a green housing market enters a state of instability. Similarly, the increase of potential payoffs for developers will promote the development of green housing. There are various approaches to increase the potential payoffs for developers, such as taxation deductions and mortgage discounts. By applying these approaches, more developers will be encouraged to enter a green housing market.

Second, consumers are the demand side in a green housing market. Their perceptions toward green housing determines their demand intensity. Therefore, strengthening the publicity of green housing, improving consumers' understanding of green housing, and enhancing consumers' awareness of green housing are necessary measures to initiate the motivation of consumers to purchase green housing. At the same time, subsidies provided by governments to purchase green housing have a strong effect on the will of consumers to purchase green housing. This is demonstrated in our simulation where the increase of the subsidy $1 - \theta$ for consumers will lead to the increase of the

proportions of consumers who purchase green housing. Therefore, high subsidies can boost the demand side in a green housing market, facilitating the healthy and sustainable growth of green housing markets in China.

Lastly, governments are the facilitators and regulators in a green housing market. Governments formulate and implement relevant incentive polices to promote the growth of a green housing market. The incentives and subsidies provided by governments play a key role in cultivating and promoting a green housing market. If governments do not provide or provide little subsidies, both developers and consumers will turn to ordinary housing due to the large incremental costs of developing and purchasing green housing. Our simulation generates a similar result. When the total amount of the subsidy for green housing is less than ten units, developers will choose developing ordinary housing. In addition to subsidies, governments have other measures to stimulate the growth of a green housing market, such as intensive propaganda of environmental protection and strong regulations on built environment. By doing this, governments can boost the initiative of developers to develop green housing and the understanding of green housing for consumers. This is supported in our simulation where a higher effect of green housing promotion can result in a higher supply and demand of green housing. Therefore, intense incentives can accelerate the growth of green housing markets in China. While this study has two limitations such as considering merely the mainland Chinese greenhouse market, ignoring the difference of consumers' educational background and capital, which need to be further researched in the future.

Data Availability

The simulation part of this paper involves data, which are relative data and represent the degree of correlation. The data come from two parts: one is based on the research data of previous scholars and the other is obtained through interviews with relevant personnel of developers, consumers, and governments involved in the real estate market.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding the publication of this paper.

With the advancement of urbanisation, the inflow of population in China's large cities has been increasing and the demand for rental housing of "new citizens" with insufficient housing affordability has become increasingly strong. Therefore, the Chinese government proposes to provide government-subsidized rental housing (GSRH) different from public rental housing. At present, the supply mode of public rental housing in China is mainly government construction and operation, which has the problems of low supply efficiency and low service level. It is critical to explore an efficient supply model in the construction of the GSRH system. Therefore, this study, starting from the three supply subjects of government, market, and society, constructs an evolutionary game model and uses agent-based modelling simulation to explore how multisubjects achieve optimal collaboration in the supply process of GSRH. The results are as follows: First, the development of a collaborative supply system includes four stages: noncooperative behaviour, collaborative exploration, collaborative game, and three-subject collaborative supply. Second, the government is the core of realising multisubject coordination. Increasing government supervision will boost market participation, while increasing government subsidies can fully mobilise the enthusiasm of social subjects but cannot continuously improve the market's enthusiasm. Third, increasing the participation ratio of social subjects will help mobilise the enthusiasm of other subjects to participate, while the excessive participation ratio of market subjects may cause an imbalance in the collaborative supply system. This study provides theoretical support for the efficient supply of GSRH.

1. Introduction

China is currently experiencing the largest scale of urbanisation ever known in human history, with its ratio expected to reach 69 percent in 2030 [1]. The seventh census results show that the national floating population was 376 million in 2020, an increase of nearly 70 percent in 10 years [2]. The acceleration of China's urbanisation process has led to strong demand for housing rentals among "new citizens" in the net inflow of population of big cities such as Beijing and Shanghai. The concept of "new citizens" refers to the population that flows from other places and lives stably in cities, including groups of migrant workers, newly employed college students, and other groups. Owing to the lack of

housing affordability, the housing needs of this group are mainly concentrated in rental housing. However, for a long time, China's real estate market and housing security system have emphasised sales over rent, the housing rental market has not been fully developed, the structure of supply and demand is unbalanced, and the large-scale rental market has not been supported by special policies. Therefore, the new citizen group has become a "sandwich layer" group that neither is within the coverage of public rental housing (PRH) nor can afford commercial housing, bearing the housing pressure and crowding-out effect caused by high housing prices [3]; thus, it is a prominent problem that they cannot afford to buy a house or rent a good house at the present stage [4, 5]. To compensate for the obvious shortcomings of

the housing security system and break the housing dilemma of the new citizens, in July 2021, the General Office of the State Council issued the "Opinions on Accelerating the Development of Government-subsidized Rental Housing (GSRH)," which clearly proposed the concept of GSRH in the top-level design of the housing security system [6]. However, the current policy only proposes the basic concept of GSRH, and scholars and policymakers still need in-depth discussions on supply subjects and supply models.

GSRH is an institutional innovation to alleviate the housing difficulties of new citizens [7]. At present, China has established a housing security system with PRH, GSRH, and coownership housing as the main body. Among them, PRH has two standard lines of low income and housing difficulties and is mainly aimed at urban low-income families in difficulty. The supply mode of PRH is directly led by the government and built on the platform of state-owned enterprises, and the government undertakes the responsibility of the bottom guarantee. GSRH is mainly used to solve the housing difficulties of the new citizen group to make up for the institutional innovation of China's previous imperfect housing security system for the same group. In terms of supply mode, GSRH reconstructs a market-oriented and policy-supported security system and guides multisubject investment and multichannel financing of "small-sized, low-rent" rental housing. GSRH is an important measure with Chinese characteristics that promotes the steady development of the real estate market and stabilises the position of "housing not for speculation."

The single supply of the government subject has problems such as the obvious funding gap, the prominent contradiction between supply and demand, and weak construction enthusiasm caused by a one-sided view of political achievements. At present, the group of new citizens is large, and the shortage of rental housing is obvious. It is necessary for the housing security subject to change from government-based participation to the joint participation of the government, enterprises, and social forces to improve the efficiency and quality of supply. According to the policy background of GSRH, the supply subjects can be divided into government and nongovernmental institutions, in which the former refers to the public sector of local housing management institutions, while the latter are further divided into profit-oriented market subjects (including housing rental franchise enterprises, real estate development enterprises, and property service companies) and nonprofit social subjects (including large private enterprises, state-owned enterprises and institutions, industrial parks, research institutes, and rural collectives). The supply subject can be further abstracted as government, market, and society.

Therefore, this study focuses on how to cooperate with the government, market, and social subjects to participate in the rapid and effective supply of GSRH in large cities. Previous studies on PRH supply have mainly focused on four aspects as follows.

First, regarding the sustainability of PRH supply, [8] has enriched the knowledge of sustainable construction by proposing a building information modelling and life cycle assessment integration approach to comprehensively evaluate the life cycle-embodied environmental impacts of buildings at the design stage. Reference [2] constructs a sustainable development system of public housing project from the perspective of a complex eco-system, exploring the internal operation mechanism and the coupling mechanism among the ecological, economic, and social subsystems. Reference [9] assesses the financial viability of PRH projects in China from a private sector perspective. References [10, 11] propose the application of "green leasing" and "integrated design process" in low-cost housing. Reference [12] studies how to make affordable housing more sustainable from the perspective of stakeholders.

Regarding the relationship between central and local governments, some scholars have suggested that the central government delegates the responsibility of PRH supply to local governments, allowing these to obtain a set of administrative power in public engineering planning, maintenance, and commercial management [13]. Reference [14] believes that this decentralisation process shifts the burden of PRH supply from the state to local governments, with a view to creating new incentives at the microlevel to increase efficiency and productivity. Reference [15] studied the contradictions in China's PRH policy and found that the division of power, incentives, responsibilities, and income sources between the central and local governments runs counter to the national goal of affordable housing. Reference [16] researched campaign-style implementation and affordable housing provision in China, and the findings point to the defects of campaign-style implementation and China's need for more institutionalised mechanisms to implement policies prioritised by the national government.

With regard to local government supply problems, specific political and economic incentives for local governments played an important role in realising the scheme [17]. Many scholars have proposed that PRH brings negative effects such as a difficult integration into mainstream urban life, residential segregation, and job-housing balance [18, 19]. Reference [20] proposes that, driven by economic interests, local governments often construct high-capacity PRH communities in remote areas, thus potentially distorting the ambitious aims and principles of China's affordable housing scheme and negatively affecting the social interaction and life opportunities of the security objects. Reference [15] argues that, based on the interests of land, the spatial distribution of PRH development in China is biased towards the urban fringe to provide an institutional explanation. In view of China's intergovernmental relations, they believe that this discriminatory location approach is the result of urban government efforts to balance top-down political pressure and local fiscal interests.

Regarding changes in the supply mode of public housing, it is difficult for the government as a single subject to achieve the supply of PRH. Some scholars hold that the private sector has financial and professional advantages and can share risks with the public sector, reduce operating costs, introduce competition, increase options, and improve service quality [21, 22]. Using nongovernmental resources can create a more flexible structure to quickly adapt to rapidly changing environments [23]. Public-private partnerships (PPP) are

widely seen as a way to involve the private sector with rich capital and management experience in sharing the financial burden of governments and improving the efficiency and sustainability of the public housing supply [24, 25]. In Austria, the UK, and Italy, innovative mixed arrangements for the development, financing, and management of indemnificatory housing jointly developed by the state, the third sector, market, and community participants show that they can benefit from the participation of market participants and communities [26]. Around 2011, the central government launched an initiative to encourage local governments to cooperate with nongovernmental organisations in providing public housing [27]. Reference [28] evaluated the feasibility of PPP in social housing. Reference [23] studied the structure and mechanism of the role played by nongovernmental actors in public housing governance.

Previous research on PRH supply has mainly focused on its sustainability, clarifying the relationship between central and local governments in the supply process as well as the problems existing in the supply of local governments and exploring the feasibility of public-private cooperation. However, a research gap exists with regard to how a collaborative government, market, and society can supply PRH. In the complex, self-adaptive system of multisubject supply of GSRH, the plan chosen by any subject of the government, market, and society affects the interests of other subjects, and the relationship between different subjects may lead to different supply results. Behaviour is also influenced, to some extent, by the surrounding environment [29, 30]; therefore, it is not enough to only observe the participants in the research on the multisubject supply of GSRH and, more importantly, the research on the relationship between the participants and the interaction with the system environment [31].

The supply of GSRH by the government, market, and society is a science about collaboration. German scholar Haken proposed the synergy concept in system theory, which meant a subsystem's collaboration, cooperation, synchronous combined effect, and collective behaviour in the system, that the whole realised the effect via nonlinearity complex interaction among the subsystem which the individual cannot realise to produce the $1 + 1 > 2$ collaborative effect [32]. In the supply process, this synergy system is dynamic; that is, various factors influence each other through a relationship that is not only collaborative but also evolutionary [33]. Therefore, the supply of GSRH by government, market, and society is based on the coevolution theory. The coevolution theory follows the general analytical framework of Darwinism, which specifies the replicators and interactors in detail, and uses the "variation," "replication," and "selection" to describe the process of coevolution [34]. Evolutionary game theory (EGT) provides a useful method for Darwin's competition by defining a framework of competition, strategy, and analysis model [35].

EGT is based on the assumption of bounded rationality, taking the group as the research subjects, analysing its dynamic evolution process, and explaining why and how the group reaches the current evolutionary state [36, 37]. In the field of housing research, [38] built an evolutionary game model of the government and real estate operators in the housing rental market in the context of financial institutions and public participation in supervision and analysed the impact of different levels of supervision by financial institutions and the public on evolution. Reference [39] established an evolutionary game model between social forces and government to solve the problem of excessive participation of the former in housing rental projects leading to rising rents. Reference [40] constructed the interest game model between the central government and local governments in the process of developing rental housing, analysed the logic and dilemma of land reserve strategy and illegal land reserve problem, and determined the replication dynamic mechanism and evolutionary stability strategy of participants under various conditions. Therefore, this study explores the deep mechanism of supply system dynamic collaboration through a multisubject evolutionary game method based on coevolution theory.

In social systems, understanding a political or economic system requires more than an understanding of the individuals that comprise the system [41, 42]. It also requires understanding how the individuals interact with each other and how the results can be more than the sum of parts [43]. For this highly complex, nonlinear, and self-organising multiagent cooperative supply system based on an evolutionary game, agent-based modelling (ABM) can provide insights into dynamic interactions among real-world phenomena by capturing nonlinear interactions and feedback loops, thereby predicting outcomes that emerge out of complex dynamics in the real world [44–46]. ABM tools provide support for researchers and practitioners to study how the macrobehaviour of the system depends on the attributes, constraints, and rules at the microlevel and is increasingly recognised in ecology, economics, biology, sociology, social sciences, and many other STEM disciplines in simulating dynamic large-scale complicated systems and observing emergent behaviours [40, 47–49].

In summary, this study attempts to use EGT to explore the collaborative relationship of the three government-market-society subjects in the supply process, and it links the behaviour of agents with different information and decision rules with the macrobehaviour of the whole collaborative supply system with the help of the NetLogo multiagent simulation platform. Through large-scale policy experiments, it realises a bottom-up policy simulation of the game results and the collaborative supply mechanism of the three subjects; further, it explores the micromechanism of the evolution of the collaborative supply decision of GSRH under the condition of bounded rationality. The remainder of the paper is structured as follows. Section 2 analyses the evolutionary game model and ABM of GSRH. Section 3 establishes an asymmetric evolutionary game model of government, market, and society. Section 4 establishes an agent-based model based on the EGT model through the NetLogo simulation platform and conducts large-scale policy experiments to determine the evolution stage and collaborative supply mechanism of the three subjects. This study provides theoretical support for the formulation of a coordinated supply policy of GSRH in the pilot cities.

2. Materials and Methods

2.1. Evolutionary Game Theory. This study adopts a dynamic replication evolutionary game method to establish a three-group, two-strategy, asymmetric evolutionary game model to study the dynamic process of government-market-society in the collaborative supply of GSRH.

2.1.1. Game Agent Analysis. The supply subjects of GSRH can be abstracted into three categories: government, market, and society.

The government subject refers to the public sector of the local housing management institutions, including local government housing construction departments at all levels, housing security centres, and others. As quasipublic good, the supply of GSRH cannot and does not need to be fully borne by the government; however, as the executive department of state power, the government is fully responsible for guiding the supply of GSRH and has always been one of the main suppliers. Government participants rely on hierarchical guidance, mainly acting as nonprofit entities [23]. For the supply of GSRH, the state is at the top of the hierarchy, with the central government setting national supply policies and tasks and local governments acting as intermediaries responsible for establishing specific methods for local policy, project development and implementation, and negotiating with other actors to achieve housing construction and distribution [17, 50]. The authority and systematic organisation of government subjects can successfully promote the construction of GSRH, strengthen public services, ensure fair supply, and stabilise economic development. Moreover, the government subject is a key intermediary connecting other subjects [51].

The market subject refers to profit-making organisations that raise funds by themselves, including housing rental franchise enterprises, real estate development enterprises, property service companies, and others capable of directly or indirectly participating in the supply of GSRH. Market players use commercial principles to achieve efficiency, effectiveness, and innovation in providing public goods and social services [52]. The participation of market players reduces government costs and improves supply efficiency and supply effect. Moreover, it can avoid the psychological label effect of the centralised construction of GSRH on the security objects and achieve the goal of coordinating the layout of GSRH and ordinary commodity housing. The market subject is a key participant in effective supply; however, it is usually subject to the profit trend [19]. Compared with commercial projects, participation in GSRH projects has fewer returns and is not attractive to the market, and market subjects thus need certain incentives from the government. The incentive policies and measures are many, including reducing loan interest rates and providing tax relief and cheap or free land [2].

The social subject refers to nonprofit organisations that participate in supply on the principle of voluntary and mutual assistance. In China, these are large private enterprises, state-owned enterprises and institutions, industrial parks and rural collectives, and others. They build or reconstruct GSRH through self-construction, joint ventures, and shares or in other ways, using collectively operated construction land, idle land owned by enterprises and institutions, supporting land for industrial parks, and stock of idle houses. The social subject connects governments, collectives, and individuals and plays a complementary and balanced role in the multiagent collaborative supply system. Compared with government departments, social organisations are independent of the government system, which can get rid of the fixed pattern of the bureaucratic structure of government organisations and form their own unique diversity and flexibility, thus bringing low cost and high efficiency of supply. At the same time, it can effectively compensate for the lack of efficiency caused by the government's single supply or privatisation production mode. Compared with the private sector, the nonprofit goal of social organisations to participate in GSRH supply determines its more public welfare, the pursuit of high quality, and the efficiency of affordable rental housing supply.

2.1.2. Model Hypothesis. Many factors affect the collaborative supply of GSRH by the government, market, and society. This study draws upon several relevant studies and empirical research works. To simplify the problem, the model is constructed and analysed based on satisfying the following assumptions.

Assumption 1. The increased delegation of government tasks to other nongovernmental actors has made the GSRH provision a "governance" model [26]. Therefore, the government has two strategic choices in the process of GSRH supply; the strategy space is {intervention, no intervention} ({I, NI}), in which intervention is divided into subsidies and supervision. Subsidy refers to the use of land policy support, fiscal and taxation relief, financial support, and other policy means by the government subject, guiding the market and social subjects through new reconstruction, idle transformation, and other modes to participate in the supply of GSRH [52]. Supervision means that the government should supervise and correct the relevant behaviours of the market subject and social subject in the planning, construction, and operation of GSRH, establish and improve the housing rental management service platform, strengthen the supervision of the whole process of construction, rental, and operation management of GSRH, and enhance the supervision of engineering quality and safety, especially the problems of unqualified construction quality and indoor decoration health. Nonintervention refers to the free development of the supply system of GSRH without formulating or implementing any subsidy and supervision policies.

Assumption 2. If the government adopts the intervention strategy, the cost of policy subsidies is C_M for the market subject and C_S for social players. Compared with the market subject, social players are more willing to participate in supply because the provision of GSRH is conducive to attracting talents and improving productivity. In addition,

they generally maintain idle houses or land, and the construction costs are also small. Therefore, it is believed that $C_M > C_S$. The supervision cost generated in the process of government intervention is S_M as the market subject and S_S as the social subject. Considering that the supply object of the social subject is unit workers, the supply quality directly affects the unit's operation efficiency through residential satisfaction, the self-discipline level of high-quality supply is high, and the difficulty and cost of government regulation are low; thus, it is assumed that $S_M > S_S$.

Assumption 3. If the government takes a nonintervention strategy, local governments may obtain the leisure and governance resources, effective disposition, and so on, which bring extra gains to government subject as R_0. Economic growth used to be and still is the main criterion for the central government to assess the promotion of local officials [53]; in other words, local officials are more willing to allocate land resources to infrastructure and real estate construction projects that generate significant fiscal revenues to improve promotion opportunities [54]. To realise virtuous interactions between the central government and local governments in the field of housing construction and management, it is proposed that the central government should change the single evaluation system for local officials and establish a multiangle and comprehensive performance evaluation system for local officials [55]. This study abstracts the central government's overall control of the supply of GSRH such that when the government subjects choose the nonintervention strategy, they are punished by the higher authorities as P.

Assumption 4. According to the social contract theory, in addition to the need to fulfil the economic contract, the market and social subjects are obliged to fulfil the social contract. Their behaviour must conform to society's expectations; they must do their duty for social and economic improvement and adjust to the changes in social environment to respond to the stakeholders' interests [33]. Therefore, the strategic space of market and social subject is set as {participation, nonparticipation} ({P, NP}). For market subjects, participation refers to the development and operation of affordable rental housing projects, and the supply target refers to the whole society meeting the population's guarantee conditions. "Nonparticipation" refers to not participating in the GSRH supply and instead investing in the construction of commercial housing and other real estate development projects. For social subjects, participation refers to the use of their own land or idle houses to build or rebuild leased houses nearby, and the supply objects are generally employees and families of the unit. "Nonparticipation" refers to not participating in the supply of GSRH and using investment within social organisations.

Assumption 5. For market players, adopting a participation strategy allows obtaining government subsidy C_M and direct rental housing operating income such as rent; value-added service charges are set as R_{M0}, and indirect reputation gains such as corporate social responsibility are set as R_{M1}.

Investing in other projects, instead of participating in the supply of GSRH, yields R_{NM}. For the social subjects, the government subsidy C_S is obtained by taking the participation strategy. The GSRH supplied by the social subjects mainly uses the stock of land and housing to build in the industrial park and around the company to effectively solve the problem of job-housing balance, improve the enthusiasm of employees, generate a positive income R_{S0}, and bring a certain social reputation income R_{S1}. Social reputation is the higher satisfaction of staff and the social influence of suppliers brought by the physical supply of rental housing. Given the nonprofitability of the social subjects supplying GSRH, the operating income of rental housing is not considered here. Not participating in the supply of GSRH and instead using other investments within social organisations enable receiving R_{NS}, but for social subjects who do not participate, restraint measures shall be taken; that is, they need to pay a certain housing subsidy F to the unit's employees.

Assumption 6. GSRH belongs to the housing security system, which is essentially a certain degree of social welfare provided by the government. The main responsibility of it lies with the government, market, and social subjects through a collaborative supply. If market and social subjects participate in supply, government financial pressure is reduced, and the project's operation efficiency and quality, as well as are the government's reputation, are improved so that the contribution of the market subject participating in supply is GB_M and that of the social subject is GB_S.

Assumption 7. Game participants are bounded rational. Without considering other constraints, government, market, and society all have the bounded rationality characteristic; in other words, each subject cannot accurately calculate its own cost and the income, but it usually tries and imitates unceasingly over time and eventually tends to a stable strategy. Suppose that the proportion of the government choosing the intervention strategy is x, the proportion of the market choosing the participation strategy is y, and the proportion of society choosing the participation strategy is z ($0 \leq x$, y, $z \leq 1$). The specific dynamic game flow of collaborative supply among government, market, and society is shown in Figure 1.

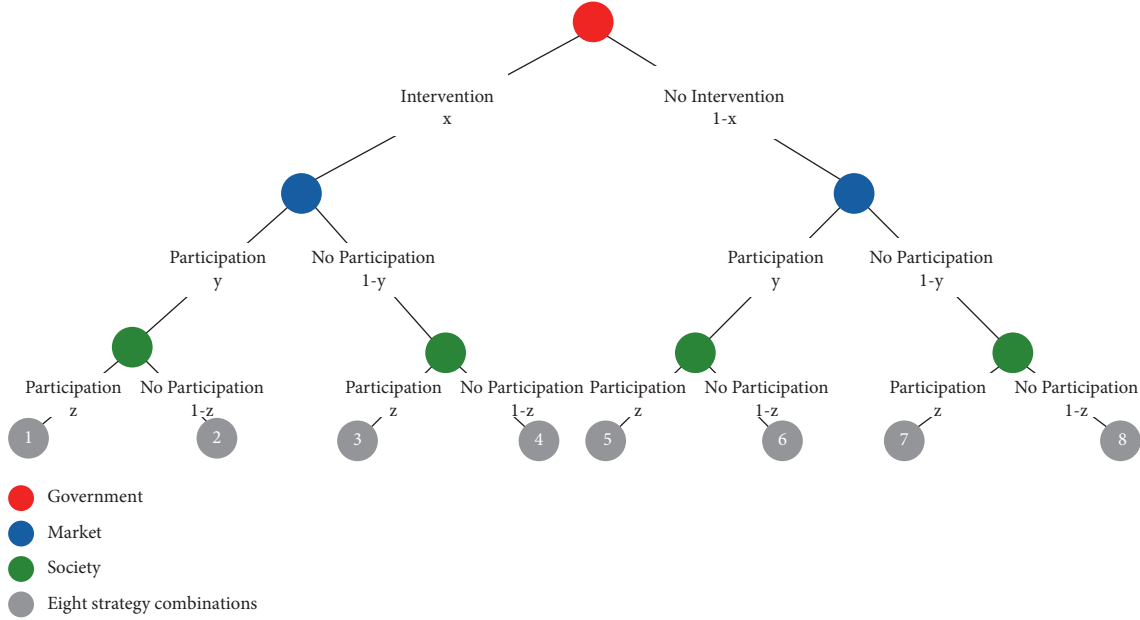
It is worth noting that the impact of the policy environment is complex, and no unified housing policy is applicable to the housing market of each city [56]. The supply of GSRH implements the strategy of "one city, one policy." The key point of this strategy is to let the central government determine the basic principles and then allow local governments to determine the implementation details, which can make the real estate regulation of each city innovative and flexible and can, to a large extent, avoid the systemic risks arising from the unified regulation of the central government [55]. Therefore, this study does not make specific policy and institutional assumptions on the collaborative supply of government, market, and society, but it abstracts this supply as subsidies, benefits, and penalties to


FIGURE 1: Dynamic flow of evolutional game among government, market, and social subject in GSRH supply.

discuss the synergy system. The summary and description of all model parameters are shown in Table 1.

2.1.3. Payoff Model.
In the course of the evolutionary game, according to individual bounded rationality and limited information principle and based on the above model assumptions, the payoff matrix of the government-market-society asymmetric cooperative game is shown in Table 2.

According to the benefits of the strategy combination in Table 2, the expected revenue of the intervention strategy $(G^{(1)})$, nonintervention strategy $(G^{(2)})$, and average benefits $(\overline{U_G})$ adopted by the government subject is, respectively,

$$
\begin{cases}
U_{G^{(1)}} = yz\left(GB_M + GB_S - C_M - S_M - C_S - S_S\right) + y(1-z)\left(GB_M - C_M - S_M\right) \\
\quad + (1-y)z\left(GB_S - C_S - S_S\right), \\
U_{G^{(2)}} = yz\left(GB_M + GB_S + R_0 - P\right) + y(1-z)\left(GB_M + R_0 - P\right) \\
\quad + (1-y)z\left(GB_S + R_0 - P\right) + (1-y)(1-z)\left(R_0 - P\right), \\
\overline{U_G} = xU_{G^{(1)}} + (1-x)U_{G^{(2)}}.
\end{cases}
\tag{1}
$$

The replication dynamics equation of the government subject is therefore

$$
\begin{aligned}
F_{(x)} = \frac{d_x}{d_t} &= x\left(U_{G^{(1)}} - \overline{U_G}\right) \\
&= x(1-x)\left[P - R_0 - y\left(C_M + S_M\right) - z\left(C_S + S_S\right)\right],
\end{aligned}
\tag{2}
$$

where $F(x)$ indicates the rate of change in government intervention strategies, $F(x) > 0$ means that the government tends to adopt an intervention strategy, and $F(x) < 0$ means that the government tends to adopt a nonintervention strategy.

Similarly, the expected revenue of the participation strategy $(M^{(1)})$, nonparticipation strategy $(M^{(v)})$, and average benefits $(\overline{U_M})$ adopted by the market subject is, respectively,

$$
\begin{cases}
U_{M^{(1)}} = xz\left(C_M + R_M\right) + x(1-z)\left(C_M + R_M\right) + (1-x)zR_M + (1-x)(1-z)R_M, \\
U_{M^{(2)}} = xzR_N + x(1-z)R_N + (1-x)zR_N + (1-x)(1-z)R_N, \\
\overline{U_M} = yU_{M^{(1)}} + (1-y)U_{M^{(2)}}.
\end{cases}
\tag{3}
$$

TABLE 1: Evolutionary game model parameters and variable descriptions.

Parameter	Description
GB_M	Benefits of market subject's participation in supply to government subject
GB_S	Benefits of social subject's participation in supply to government subject
C_M	The cost of policy subsidies for market subject by government intervention strategies
C_S	The cost of policy subsidies for social subject by government intervention strategies
S_M	Supervision cost of government intervention strategy for market subjects
S_S	Supervision cost of government intervention strategy for social subjects
R_{M0}	Direct operating income from market participation strategy
R_{M1}	Indirect reputation gains from market participation strategy
R_{NM}	Returns from market nonparticipation strategy to investment in other projects
R_{S0}	Positive benefits of social participation strategy
R_{S1}	Reputation gains of social participation strategy
R_{NS}	Benefits from social nonparticipation strategies to other projects in investment organisations
R_0	Government gains from the additional benefits of leisure and the efficient allocation of government resources when it takes nonintervention strategy
P	Governments that adopt nonintervention strategy will be punished by higher authorities
F	Housing subsidy paid by the society to employees of the unit without participation

TABLE 2: The payoff matrix of the evolutionary game among the government, market, and society.

Strategy combination	(Government, market, society)
(I, P, P)	$(GB_M + GB_S - C_M - S_M - C_S - S_S, C_M + R_{M0} + R_{M1}, C_S + R_{S0} + R_{S1})$
(I, P, NP)	$(GB_M - C_M - S_M, C_M + R_{M0} + R_{M1}, R_{NS} - F)$
(I, NP, P)	$(GB_S - C_S - S_S, R_{NM}, C_S + R_{S0} + R_{S1})$
(I, NP, NP)	$(0, R_{NM}, R_{NS} - F)$
(NI, P, P)	$(GB_M + GB_S + R_0 - P, R_{M0} + R_{M1}, R_{S0} + R_{S1})$
(NI, P, NP)	$(GB_M + R_0 - P, R_{M0} + R_{M1}, R_{NS} - F)$
(NI, NP, P)	$(GB_S + R_0 - P, R_{NM}, R_{S0} + R_{S1})$
(NI, NP, NP)	$(R_0 - P, R_{NM}, R_{NS} - F)$

The replication dynamics equation of the market subject is therefore

$$F_{(y)} = \frac{d_y}{d_t} = y\left(U_{M^{(1)}} - \overline{U_M}\right)$$

$$= y(1 - y)(xC_M + R_{M0} + R_{M1} - R_{NM}).$$

(4)

The replication dynamics equation of the social subject is therefore

$$F_{(z)} = \frac{d_z}{d_t} = z\left(U_{S^{(1)}} - \overline{U_S}\right)$$

$$= z(1 - z)(xC_S + R_{S0} + R_{S1} - R_{NS} + F).$$

(6)

Based on the nature of evolutionary stability strategy, the necessary condition for government subject to achieve evolutionary stability is $dF(x)/dx < 0$.

For the replication dynamic equation (2), when $z = (P - R_0 - y(C_M + S_M))/(C_S + S_S)$, x is a steady state.

The expected revenue of the participation strategy ($S^{(1)}$), nonparticipation strategy ($S^{(2)}$), and average benefits ($\overline{U_S}$) adopted by the social subject is, respectively,

$$\begin{cases} U_{S^{(1)}} = xy(C_S + R_S) + x(1 - y)(C_S + R_S) + (1 - x)yR_S + (1 - x)(1 - y)R_S, \\ U_{S^{(2)}} = R_{NS} - F, \\ \overline{U_S} = zU_{S^{(1)}} + (1 - z)U_{S^{(2)}}. \end{cases}$$

(5)

When $z < (P - R_0 - y(C_M + S_M))/(C_S + S_S)$, $x = 1$ is the evolutionarily stable strategy. When $z > (P - R_0 - y(C_M + S_M))/(C_S + S_S)$, $x = 0$ is the evolutionarily stable strategy. According to $z = (P - R_0 - y(C_M + S_M))/(C_S + S_S)$, a surface M can be drawn, as shown in Figure 2(a). The points on surface M are stable in the x-axis direction, the points above it evolve to $x = 1$, and the points below it evolve to $x = 0$. Similarly, for the point of market subject in surface V to stabilise in the y-axis direction, the point on the left side of surface V evolves towards $y = 0$, and the point on the right side of the surface tends to $y = 1$, as shown in Figure 2(b). For the stability of the social subject in the z-axis direction of
Figure 2: Replicated dynamic diagram of each subject. (a) Government. (b) Market. (c) Society.

the point in plane W, the point on the left side of plane W evolves to $z = 0$, and the point on the right side of it evolves to $z = 1$, as shown in Figure 2(c).

2.2. Agent-Based Modelling. Based on the above evolutionary game model and ABM simulation method, with a bottom-up, this part simulates the evolution process of multiagent supply of GSRH under the collaborative background from the perspective of microinteraction to macroemergence, and it attempts to reveal the micromechanism of collaborative supply of GSRH in the form of policy experiments in view of the advantages of the NetLogo 6.0.3 simulation platform, which can meet the simultaneous operation of multiple agents, set system variables, and parameters easily and quickly and provide a visual evolution interface. With the help of this platform, this study establishes the attributes of each subject, the number of agents in each subject, the selection mechanism of game objects, and the strategy update mechanism, and it compiles the government-market-society, three-agent game simulation programme. Through NetLogo, large-scale numerical experiments are conducted to show the dynamic game process of different subjects under different parameter conditions, verify the evolutionary game model of multiagent synergistic supply of GSRH, realise the simulation and effect evaluation

of relevant parameter and subject strategy selection changes, and provide verification for the effectiveness of policy recommendations.

2.2.1. Basic Variable Settings of the NetLogo Simulation Platform. This study constructs a three-group, asymmetric evolutionary game model composed of agents and game environment and generates a two-dimensional network space with periodic boundary. In a two-dimensional network space, the three-party game subjects are generated as government, market, and social subjects, respectively.

The parameter settings of each subject attribute are shown in Table 3.

The strategy of the government subject is $S_G(t) = \{0, 1\}$, where 0 means adopting a nonintervention strategy, and 1 means adopting an intervention strategy. The strategy of the market subject is $S_M(t) = \{0, 1\}$, where 0 means adopting a nonparticipation strategy, and 1 means adopting a participation strategy. The strategy of the social subject is $S_S(t) = \{0, 1\}$, where 0 means adopting a nonparticipation strategy, and 1 means adopting a participation strategy.

The expected return functions of the three subjects of government, market, and society to adopt their respective strategies are as follows:

$$\begin{cases} IR_G(t) = y_t(GB_M - C_M - S_M) + z_t(GB_S - C_S - S_S), \\ NIR_G(t) = y_t GB_M + z_t GB_S + R_0 - P, \\ PR_M(t) = x_t C_M + R_{M0} + R_{M1}, \\ NPR_M(t) = R_{NM}, \\ PR_S(t) = x_t C_S + R_{S0} + R_{S1}, \\ NPR_S(t) = R_{NS} - F. \end{cases} \tag{7}$$

2.2.2. Simulation Mechanism Design. Agent game and movement mechanism: agents can move randomly in the network space, assuming that the game range of each agent in the interaction process is in a neighbouring position. Initially, each agent selects the corresponding strategy with a random probability. In the simulation period t, according to

the agent's behaviour rules, the agent observes whether there are other agents around its eight neighbour positions. If there are no other agents, the agent moves to any neighbouring position randomly. If there are, it judges whether there are agents of other two types of subjects at the same time, and if this is the case, the game is randomly matched,

TABLE 3: Agent-based model parameters and variable descriptions.

Parameter	Description
$S_G(t)$	The strategic space of government subject
$S_M(t)$	The strategic space of market subject
$S_S(t)$	The strategic space of social subject
N_G	Number of government agents
N_M	Number of market agents
N_S	Number of social agents
$N_{S_G=1}t$	Number of government agents who choose intervention strategy in period t
$N_{S_M=1}t$	Number of market agents who choose participation strategy in period t
$N_{S_S=1}t$	Number of social agents who choose participation strategy in period t
$x(t)$	Probability of government intervention strategy at period t, $x(t) \in [0, 1]$
$y(t)$	Probability of market participation strategy at period t, $y(t) \in [0, 1]$
$z(t)$	Probability of social participation strategy at period t, $z(t) \in [0, 1]$
$FR_{G(i)}(t)$	The $Agent_i$ in the government subject benefits from the actual combination of strategies in the t-period game
$FR_{M(j)}(t)$	The $Agent_j$ in the market subject benefits from the actual combination of strategies in the t-period game
$FR_{S(k)}(t)$	The $Agent_k$ in the social subject benefits from the actual combination of strategies in the t-period game
$IR_G(t)$	Expected benefits of government intervention strategy
$NIR_G(t)$	Expected benefits of government nonintervention strategy
$PR_M(t)$	Expected benefits of market participation strategy
$NPR_M(t)$	Expected benefits of market nonparticipation strategy
$PR_S(t)$	Expected benefits of social participation strategy
$NPR_S(t)$	Expected benefits of social nonparticipation strategy

Note. The total number of agents in each agent remains unchanged.

and the strategy adopted at $t+1$ is determined by learning the algorithm according to the benefits of the game.

Strategy learning mechanisms: since the agent is and asymmetrical information, it is not strictly based on the principle of maximum utility to make decisions in the game. According to the view of biological evolution and replication dynamics, the subject with lower returns continues to learn, imitate, and compare different strategies, then chooses a strategy higher than the expected return of this strategy, always replaces the unsatisfied strategy with a satisfied one, and finally tends to a stable state [38, 57]. The agent takes the result of each game as the actual benefit of its strategic interaction and then compares it with the expected benefit of the two strategies at the same time to judge whether the strategy of the t-period is optimal and whether to update it.

For the government subject, when the strategy of individual i in $Agent_G$ at period t is $Str_{G(i)}(t) = 1$, if $NIR_{G(i)}(t) > IR_{G(i)}(t) > FR_{G(i)}(t)$ or $NIR_{G(i)}(t) > FR_{G(i)}(t) > IR_{G(i)}(t)$, then the strategy of $Agent_{G(i)}$ at period $t+1$ is $Str_{G(i)}(t+1) = 0$. When the strategy of individual i in $Agent_G$ at period t is $Str_{G(i)}(t) = 0$, if $IR_{G(i)}(t) > NIR_{G(i)}(t) > FR_{G(i)}(t)$ or $IR_{G(i)}(t) > FR_{G(i)}(t) > NIR_{G(i)}(t)$, then the strategy of $Agent_{G(i)}$ at period $t+1$ is $Str_{G(i)}(t+1) = 1$, the other cases keep the original strategy unchanged, and the formula is as follows:

$$Str_{G(i)}(t+1) = \begin{cases} 1 - Str_{G(i)}(t), & Str_{G(i)}(t) = 1 \text{ and} NIR_{G(i)}(v) > IR_{G(i)}(t) > FR_{G(i)}(t) \\ & \text{or} NIR_{G(i)}(t) > FR_{G(i)}(t) > IR_{G(i)}(t), \\ & Str_{G(i)}(t) = 0 \text{ and} IR_{G(i)}(t) > NIR_{G(i)}(t) > FR_{G(i)}(t) \\ & \text{or} IR_{G(i)}(t) > FR_{G(i)}(t) > NIR_{G(i)}(t), \\ Str_{G(i)}(t), & \text{other situation.} \end{cases} \tag{8}$$

Similarly, for the market subject, the strategy learning rules are as follows:

$$Str_{M(i)}(t+1) = \begin{cases} 1 - Str_{M(j)}(t), Str_{M(j)}(t) = 1 \text{ and} NPR_{M(j)}(t) > PR_{M(j)}(t) > FR_{M(j)}(t) \\ \text{or } NPR_{M(j)}(t) > FR_{M(j)}(t) > PR_{M(j)}(t), \\ Str_{M(j)}(t) = 0 \text{ and} PR_{M(j)}(t) > NPR_{M(j)}(t) > FR_{M(j)}(t) \\ \text{or } PR_{M(j)}(v) > FR_{M(j)}(t) > NPR_{M(j)}(t), \\ Str_{M(j)}(t), \text{othersituation.} \end{cases} \tag{9}$$

For the market, the strategy learning rules are as follows:

$$Str_{S(i)}(t+1) = \begin{cases} 1 - Str_{S(k)}(t), Str_{S(k)}(t) = 1 \text{ and} NPR_{S(k)}(v) > PR_{S(k)}(t) > FR_{S(k)}(t) \\ \text{or } NPR_{S(k)}(t) > FR_{S(k)}(v) > PR_{S(k)}(t), \\ Str_{S(k)}(t) = 0 \text{ and} PR_{S(k)}(t) > NPR_{S(k)}(t) > FR_{S(k)}(t) \\ \text{or } PR_{S(k)}(t) > FR_{S(k)}(t) > NPR_{S(k)}(t), \\ Str_{S(k)}(t), \text{othersituation.} \end{cases} \tag{10}$$

Evolutionary stable result output mechanism: the three types of agents go through a certain number of games in the simulation period (t) until the evolutionary equilibrium state of collaborative supply is finally reached. The output results of the final evolutionary stability of the government-market-society collaborative supply process are expressed as $x(t), y(t), z(t)$ through the estimation of different strategy proportions of each game party. Based on the complexity of the real world, the NetLogo simulation model established in this study introduces the consideration of uncertainty to deepen the simulation results of the three-subject evolutionary game.

Assuming that the simulation results based on NetLogo have ±10% error compared with the real world, the error terms of the government, market, and social agents are set as α, β, and γ, respectively, where $(\alpha, \beta, \gamma) \in (-0.1, 0.1)$ and $x(t), y(t), z(t)$ are calculated as follows:

$$\begin{cases} x(t) = \dfrac{N_{S_G=1}t}{N_G} \times (0.9 + \alpha), \\ \\ y(t) = \dfrac{N_{S_M=1}t}{N_M} \times (0.9 + \beta), \\ \\ z(t) = \dfrac{N_{S_S=1}t}{N_S} \times (0.9 + \gamma). \end{cases} \tag{11}$$

3. Results

3.1. The Equilibrium Analysis of the Model

3.1.1. Stability Analysis of the Evolutionary Game. By further solving the replicative dynamic equations composed of $dx/dt = dy/dt = dz/dt = 0$, 12 equilibrium points can be found in the cooperative game system of the government, market, and social subjects, which are $E_1 (0, 0, 0)$, $E_2(1, 0, 0)$, $E_3 (0, 1, 0)$, $E_4 (0, 0, 1)$, $E_5 (1, 1, 0)$, $E_6 (1, 0, 1)$, $E_7 (0, 1, 1)$, $E_8 (1, 1, 1)$, $E_9 ((F + R_{NS} - R_{S0} - R_{S1})/(C_S), 1, (C_M + P - R_0 - S_M)/(C_S + S_S))$, $E_{10} ((R_{M0} - R_{M1} + R_{NM})/(C_M), (P - R_0)/(C_M + S_M), 0)$, $E_{11} ((F + R_{NS} - R_{S0} - R_{S1})/(C_S), 0, (P - R_0)/(C_S + S_S))$, $E_{12} ((R_{M0} - R_{M1} + R_{NM})/(C_M), (C_S + P - R_0 - S_S)/(C_M + S_M), 1)$. According to the above assumptions, all initial points and evolution points must satisfy $0 \le x, y, z \le 1$ to have practical significance. The region surrounded by E_1-E_8 is the equilibrium solution of the evolutionary game. When condition $0 < (F + R_{NS} - R_{S0} - R_{S1})/(C_S) < 1$ is satisfied, it leads to $(F + R_{NS} - R_{S0} - R_{S1})/(C_S) > 1$, abandoning E_9 and E_{11}. When condition $P - R_0 < 0$ is satisfied, it leads to $(P - R_0)/(C_M + S_M) < 0$, abandoning E_{10}. When condition $C_M + S_M + C_S + S_S < P - R_0$ is satisfied, it leads to $(C_S + P - R_0 - S_S)/(C_M + S_M) > 1$, abandoning E_{12}. Therefore, the equilibrium point of the dynamic system is E_1-E_8, and these eight equilibrium points constitute the boundary of the evolutionary game domain. The stability of these equilibrium points in the evolutionary system can be

TABLE 4: Eigenvalues of Jacobi matrix corresponding to each equilibrium point.

Equilibrium point	Eigenvalue λ_1	Eigenvalue λ_2	Eigenvalue λ_3
$E_1(0, 0, 0)$	$P - R_0$	$R_{M0} + R_{M1} - R_{NM}$	$R_{S0} + R_{S1} - R_{NS} + F$
$E_2(1, 0, 0)$	$R_0 - P$	$C_M + R_{M0} + R_{M1} - R_{NM}$	$C_S + R_{S0} + R_{S1} - R_{NS} + F$
$E_3(0, 1, 0)$	$P - R_0 - C_M - S_M$	$-R_{M0} - R_{M1} + R_{NM}$	$R_{S0} + R_{S1} - R_{NS} + F$
$E_4(0, 0, 1)$	$P - R_0 - C_S - S_S$	$C_M + R_{M0} + R_{M1} - R_{NM}$	$-(R_{S0} + R_{S1} - R_{NS} + F)$
$E_5(1, 1, 0)$	$-(P - R_0 - C_M - S_M)$	$-(C_M + R_{M0} + R_{M1} - R_{NM})$	$C_S + R_{S0} + R_{S1} - R_{NS} + F$
$E_6(1, 0, 1)$	$-(P - R_0 - C_S - S_S)$	$C_M + R_{M0} + R_{M1} - R_{NM}$	$-(C_S + R_{S0} + R_{S1} - R_{NS} + F)$
$E_7(0, 1, 1)$	$P - R_0 - C_M - S_M - C_S - S_S$	$-(R_{M0} + R_{M1} - R_{NM})$	$-(R_{S0} + R_{S1} - R_{NS} + F)$
$E_8(1, 1, 1)$	$-(P - R_0 - C_M - S_M - C_S - S_S)$	$-(C_M + R_{M0} + R_{M1} - R_{NM})$	$-(C_S + R_{S0} + R_{S1} - R_{NS} + F)$

obtained by the local stability analysis of the Jacobian matrix [58].

$$
J = \begin{bmatrix}
\dfrac{dx/dt}{dx} & \dfrac{dx/dt}{dy} & \dfrac{dx/dt}{dz} \\[2mm]
\dfrac{dy/dt}{dx} & \dfrac{dy/dt}{dy} & \dfrac{dy/dt}{dz} \\[2mm]
\dfrac{dz/dt}{dx} & \dfrac{dz/dt}{dy} & \dfrac{dz/dt}{dz}
\end{bmatrix},
$$

$$
= \begin{bmatrix}

\end{bmatrix}.
$$

(12)

The Jacobian matrix of the evolutionary game system is as follows:

Table 4 shows the eigenvalues of the Jacobi matrix corresponding to each equilibrium point.

3.1.2. Multiscenario Evolutionary Game Analysis. According to Lyapunov's stability theory, the asymptotic stability at the equilibrium point can be judged by the eigenvalues of the Jacobi matrix; that is, when all eigenvalues are negative, the equilibrium point is the stable point of the evolutionary game. It can be clearly judged from the eigenvalue results of the above equilibrium points that the stability of the synergic supply system of GSRH is affected by the value of the parameters; therefore, the evolutionary stable points of the system are discussed in eight cases as follows:

Scenario 1: $P - R_0 < 0$ and $-C_M < R_{M0} + R_{M1} - R_{NM} < 0$ or $R_{M0} + R_{M1} - R_{NM} < -C_M$ and $-C_S < R_{S0} + R_{S1} - R_{NS} + F < 0$ or $R_{S0} + R_{S1} - R_{NS} + F < -C_S$; that is, the additional benefit of the government subject in adopting a nonintervention strategy to transfer resources is greater than that of the higher-level punishment, and the benefit of the market and social subjects in adopting a participation strategy is less than that of the nonparticipation strategy regardless of whether there is an intervention subsidy of government

subjects. Therefore, the government tends to adopt a nonintervention strategy, and the market and social subjects adopt a nonparticipation strategy. The corresponding strategy stability point is $E_1(0, 0, 0)$. In this case, the three subjects cannot form a cooperative relationship.

Scenario 2: $P - R_0 < 0$ and $R_{M0} + R_{M1} - R_{NM} < -C_M$ and $R_{S0} + R_{S1} - R_{NS} + F > 0$; that is, the extra benefits of government subject transferring resources by adopting a nonintervention strategy are greater than the punishment of superior departments. When there is no government subsidy, the market subject's nonparticipation strategy benefits more than the participation strategy, while the social subject's participation in supply benefits more than nonparticipation. Therefore, the government tends to adopt the nonintervention strategy, the market adopts the nonparticipation strategy, and society adopts the participation strategy. The corresponding strategic stability point is $E_4(0, 0, 1)$.

Scenario 3: $P - R_0 < 0$ and $R_{M0} + R_{M1} - R_{NM} > 0$ and $-C_S < R_{S0} + R_{S1} - R_{NS} + F < 0$ or $R_{S0} + R_{S1} - R_{NS} + F < -C_S$; that is, the additional benefits of the transfer of resources by the government subject adopting the nonintervention strategy are

greater than the penalties of the higher authorities, and without government subsidies, the benefits of the market subject adopting the participation strategy are greater than those of the nonparticipation strategy, while the benefits of the social subject participating are less than those of the subject not participating. Therefore, the government tends to adopt the nonintervention strategy, the market adopts the participation strategy, society adopts the nonparticipation strategy, and the corresponding strategy stability point is $E_3 (0, 1, 0)$.

Scenario 4: $C_M + S_M < P - R_0 < C_M + S_M + C_S + S_S$ or $P - R_0 < 0$ and $R_{M0} + R_{M1} - R_{NM} > 0$ and $R_{S0} + R_{S1} - R_{NS} + F > 0$; that is, when the government subject chooses the nonintervention strategy, the punishment of the superior department is greater than the income, and the difference between punishment and income is greater than the cost paid by the intervention social subject and less than the cost paid by the intervention market and social subject. Alternatively, the benefits of nonintervention strategies adopted by government subjects are greater than the penalties imposed by higher authorities, and the benefits of participation in supply by market and social subjects are greater than those of nonparticipation in supply without government subsidies. Therefore, the government tends to adopt the nonintervention strategy, while market and social subjects adopt the participation strategy, and the corresponding strategy stability point is $E_7 (0, 1, 1)$.

Scenario 5: $C_M + S_M < P - R_0 < C_M + S_M + C_S + S_S$ or $C_M + S_M + C_S + S_S < P - R_0$ and $R_{M0} + R_{M1} - R_{NM} < -C_M$ and $R_{S0} + R_{S1} - R_{NS} + F < - C_S$; that is, under the condition of government subsidies, the benefit of market and social subject participating in the supply is less than that of not-participating subjects, and if the government subject adopts the nonintervention strategy, the punishment of the higher authorities is greater than the benefit of resource transfer and utilisation, and the difference between punishment and benefit is greater than the cost of government intervention in the market and social subjects. Therefore, the government subject adopts the intervention strategy, while market and social subjects adopt a nonparticipation strategy, and the corresponding strategic stability point is $E_2 (1, 0, 0)$.

Scenario 6: $C_M + S_M < P - R_0 < C_M + S_M + C_S + S_S$ or $C_M + S_M + C_S + S_S < P - R_0$ and $R_{M0} + R_{M1} - R_{NM} > 0$ or $-C_M < R_{M0} + R_{M1} - R_{NM} < 0$ and $R_{S0} + R_{S1} - R_{NS} + F < - C_S$; that is, the benefits of nonparticipation in supply are greater than participation, and the social subject tends to adopt a nonparticipation strategy. When the government subject adopts a nonintervention strategy, the loss is greater than the cost of intervening in the market subject. Alternatively, the government subject adopts an intervention strategy, and the benefit of a market subject participating in supply is greater than that of

nonparticipation. The government tends to adopt the intervention strategy, and the market tends to adopt the participation strategy. Thus, the corresponding policy stability point in this scenario is $E_5 (1, 1, 0)$.

Scenario 7: $C_M + S_M < P - R_0 < C_M + S_M + C_S + S_S$ or $C_M + S_M + C_S + S_S < P - R_0$ and $R_{M0} + R_{M1} - R_{NM} < -C_M$ and $R_{S0} + R_{S1} - R_{NS} + F > 0$ or $-C_S < R_{S0} + R_{S1} - R_{NS} + F < 0$; that is, the market subject tends to adopt a nonparticipation strategy when it benefits more from nonparticipation in supply than participation, when the loss of government subject without intervention is greater than the cost of interfering with the social subject and when the benefit of social subject participating in supply is greater than that of nonparticipation. When the benefit of social subject participating in supply is greater than that of nonparticipation under the intervention of the government subject, the government tends to adopt the intervention strategy, and society adopts the participation strategy. Thus, the corresponding policy stability point in this scenario is $E_6 (1, 0, 1)$.

Scenario 8: $C_M + S_M + C_S + S_S < P - R_0$ and $R_{M0} + R_{M1} - R_{NM} > 0$ or $-C_M < R_{M0} + R_{M1} - R_{NM} < 0$ and $R_{S0} + R_{S1} - R_{NS} + F > 0$ or $-C_S < R_{S0} + R_{S1} - R_{NS} + F < 0$; that is, when the loss of the government adopting a nonintervention strategy is greater than the cost of adopting an intervention strategy, the government subject must tend to adopt an intervention strategy. Under the intervention of the government subject, the benefit of the market and social subjects participating in supply is greater than that of not participating; thus, these subjects tend to adopt the participation strategy. Therefore, the corresponding strategy stability point in this scenario is $E_8 (1, 1, 1)$.

In conclusion, the collaborative supply of GSRH can be divided into five stages: noncooperative behaviour, invalid exploration stage, collaborative exploration, collaborative game, and three-subject collaborative supply. Among them, Scenario 1 corresponds to the stage of noncooperative behaviour, in which the central government has a low level of control over the supply of GSRH, and local governments are more inclined to transfer investment to other projects that can generate considerable fiscal revenue. In Scenarios 2–4, the central government's control is still insufficient, local governments still choose a nonintervention strategy, and the benefits of participation by the market or social subject are greater than nonparticipation. Based on the quasipublic goods properties of GSRH, the government subject is the core of the GSRH supply, and the market and social subject cannot actively participate in it without the government's guidance; therefore, Scenarios 2–4 represent an invalid exploration stage. As the central government further intensifies its control over the GSRH supply, the government subject begins to choose the intervention strategy; thus, the supply system enters the collaborative exploration stage, corresponding to Scenario 5. In the process of exploring the intervention strategy of the government subject,

intervention strategies are constantly adjusted to attract social or market subject to participate in supply, and the collaborative system enters the collaborative game stage, corresponding to Scenarios 6-7. In the collaborative game among government, market, and society, the three subjects constantly adjust their strategy choices and finally reach the collaborative supply stage of government intervention, market, and social participation, corresponding to Scenario 8. Given that GSRH is a kind of social welfare housing without government policy support and guidance, other subjects do not take the initiative to participate in the driving force. Therefore, the invalid exploration stage without the participation of the government subject is only a theoretical derivation result, which is not in line with the realistic logic of affordable rental housing supply and will not be discussed in subsequent research.

3.2. Simulation Analysis.

This section explores the characteristics of various mechanisms and a more effective mechanism configuration through scenario simulation [59]. Based on the aforementioned setting of government, market, and society, the number of government, market, and social subjects is approximated by county administrative area, real estate enterprises, state-owned enterprises, and institutions, respectively. According to the statistical yearbook, in 2019, there were 2,792 county-level administrative regions, 94,790 real estate enterprises (except state-owned and collective investment enterprises), and 20,486 state-owned enterprises and institutions (in all industries) [60]. It can be concluded that the proportion of government, market, and social agents can be roughly estimated as $1:34:7$. In this proportion, it is assumed that the initial state of the system is $\text{Agent}_G = 10$, $\text{Agent}_M = 340$, $\text{Agent}_S = 70$, and the initial strategy selection proportion of government, market, and social agents is 50%. On the NetLogo simulation platform, with a $t = 500$ simulation period and the probability of positive strategy selection of three game subjects as the main measurement standard, 50 policy simulation numerical experiments are conducted on the simulation parameters of each group. The following simulation results are obtained by analysing and visualising the experimental data.

3.2.1. Experiment 1: Simulation Results and Analysis of the Evolutionary Game of the Three Subjects of Government-Market-Society.

According to the above EGT derivation results, this section verifies the stability of the evolutionary equilibrium state of the GSRH collaborative supply system in each stage. The invalid exploration stage of EGT is only a theoretical derivation result that does not conform to the realistic logic of public housing supply in China. Therefore, this part only conducts a simulation analysis and discussion on the noncooperative behaviour stage, collaborative exploration stage, collaborative game stage, and collaborative supply stage. The parameter settings of each scenario are $P_S = (GB_M, GB_S, C_M, C_S, S_M, S_S, R_{M0}, R_{M1}, R_{NM}, R_{S0}, R_{S1}, R_{NS}, R_0, P, F)$, and the corresponding scenarios in each evolution stage are shown in Table 5.

When the government chooses the intervention strategy with a probability of 0.5 and the market and society choose the participation strategy with a probability of 0.5, the initial state of the evolutionary game system is (0.5, 0.5, 0.5). Throughout these four stages, in the stage of noncooperative behaviour, the punishment of the government subject for nonintervention by the higher authorities is less than the income, and the evolution result is that all the government agents tend to adopt the nonintervention strategy at a fast speed, and the final evolution is stable for the government subject to choose the intervention strategy with a probability of 0. With the decrease in the proportion of government agents taking intervention strategies, the probability of market and social agents taking that strategy tends to 0 at an approximate rate, as shown in Figure 3(a). When the central government pays more attention to the supply of GSRH and takes it as an important indicator for the performance evaluation or urban development of the government subject, the government subject tends to adopt the intervention strategy at a high rate, and the supply system of the city enters the stage of collaborative exploration. As the government subject has bounded rationality and obtains incomplete information in this phase, the enthusiasm of the market and social subjects to participate in the supply is not aroused; therefore, they will tend to adopt the nonparticipation strategy with a probability of 1 at a similar rate, as shown in Figure 3(b). Under the Further increase of subsidies and appropriate intervention by government subject on the market or society subject will attract the participation of the market or social subject and enter the cooperative game of the multisubject supply of GSRH, as shown in Figures 3(c) and 3(d)). In this stage, government agents need to adjust their strategy, actively intervene against nonparticipating agents, and conduct appropriate subsidies and supervision for active participation. In this process, each agent continues to learn and update its strategy; the intervention of the government subject successfully mobilises the enthusiasm of the market and social agents for participating, achieving the dynamic and stable state of the three-subject collaborative supply, as shown in Figure 3(e).

Note: in each evolution stage, the output results of the stability test of each equilibrium point are set as the average values of several parameters in the corresponding scenario.

3.2.2. Experiment 2: The Impact of Government Intervention on Supply Efficiency in the Collaborative Supply Phase.

In the collaborative supply stage of GSRH, different levels of government intervention may have different impacts on the efficiency of collaborative supply, in accordance with the hypothesis that the government's intervention strategy involves subsidies and supervision. To determine the impact of government intervention on supply efficiency, this section designs the following two sets of policy experiments.

The first experiment: for the supervision strategy, the government should increase or relax supervision to give full play to the market advantage to improve supply efficiency. Previous studies have asserted that strengthening

TABLE 5: Parameter values in corresponding scenarios at different evolution stages.

Stage	Scenario		GB_M	GB_S	C_M	C_S	S_M	S_S	R_{M0}	R_{M1}	R_{NM}	R_{S0}	R_{S1}	R_{NS}	R_0	P	F

		8-3	5	5	1.5	1	1.5	1	3	2	6	2	2	5	1	7	2
		8-4	5	5	1.5	1	1.5	1	3	2	6	2	1	5	1	7	1.5

government control can promote greater cooperation among various subjects in public housing supply [18], and the efficiency of public housing supply is a constraint of the government [17]; however, some scholars believe that it is necessary to provide the space for the market to play its advantage.

To clarify this problem, this part controls the subsidy strategy and conducts no supervision, low-supervision, and high-supervision as three groups of parameters, respectively, to conduct the policy experiment on the influence of supervision intensity on the supply system. With $t = 500$ as the cycle, 50 policy simulations are conducted. The parameter settings of the no supervision, low-supervision, and high-supervision strategies are $P_{S1-0} = (5, 5, 1.5, 1, 0, 0, 3, 2, 4, 2, 2, 5, 1, 9, 2)$, $P_{S1-1} = (5, 5, 1.5, 1, 1.5, 1, 3, 2, 4, 2, 2, 5, 1, 9, 2)$, and $P_{S1-2} = (5, 5, 1.5, 1, 3, 2, 3, 2, 4, 2, 2, 5, 1, 9, 2)$. Figure 4 shows the data analysis and visualisation of the output results of large-scale numerical experiments.

From the output results of the above large-scale policy simulation experiments, compared with the low-supervision strategy, when the government agents adopt the no supervision strategy, they do not have to pay the supervision cost, and the cost of participating in the supply is significantly reduced. Therefore, the proportion of government agents choosing the intervention strategy increases significantly during the simulation cycle. Compared with the low-supervision strategy, when the supervision is further increased, the proportion of government entities choosing intervention strategies decreases significantly as the intervention cost increases, and it is lower than the low-supervision strategy. In the early stage of three-subject collaborative supply ($T < 100$), no supervision, low-supervision, and high-supervision strategies have no significant effect on the strategy choice of market agents, and the market participation rate of the low-supervision strategy is higher relatively. With the development of the supply system ($100 < T < 400$), the participation rate of market agents choosing a high-supervision strategy is the highest, while the no supervision and low-supervision

strategies have no significant impact on the market participation rate. Conversely, as the collaborative supply system matures ($T > 400$), "high regulation" restrains the participation rate of market agents.

For the market agents, the simulation results show that, in the early stage of the GSRH collaborative supply, the government's adoption of the low-supervision strategy is relatively efficient and plays a market advantage while regulating the market. In the development stage of the collaborative supply, the government may choose the high-supervision strategy to strengthen its control over the market and promote greater cooperation between the government and market agents [17]. The simulation results also show a significant increase in market participation under the high-supervision strategy. In the mature stage of the collaborative system development, high-supervision restricts the market, while a low-supervision strategy is more efficient. For social agents, the influence of government supervision on their participation rate is not obvious, indicating that the choice of a government supervision strategy is not a key factor for social agents to participate in the supply of GSRH.

The second experiment: how much policy subsidy can realise the efficient synergy of GSRH supply by the government subject with the market and social subjects? To clarify this problem, three strategies of low subsidy, medium subsidy, and high subsidy are set up to conduct policy experiments on the effect of subsidy degree on the supply efficiency of affordable rental housing under the control of supervision. With $t = 500$ as the cycle, 50 policy simulations are conducted. The parameter settings of the "low, medium, and high" strategy are $P_{S2-0} = (5, 5, 1.5, 1, 1.5, 1, 3, 2, 4, 2, 2, 5, 1, 9, 2)$, $P_{S2-1} = (5, 5, 2, 1.5, 1.5, 1, 3, 2, 4, 2, 2, 5, 1, 9, 2)$, and $P_{S2-2} (5, 5, 3, 2, 1.5, 1, 3, 2, 4, 2, 2, 5, 1, 9), 2)$, respectively. Figure 5 shows the data analysis and visualisation of the output results of large-scale numerical experiments.

It can be seen from the output results of the large-scale policy simulation experiment that a medium-subsidy
FIGURE 3: Four-stage simulation results of "government-market-society," three-subject collaborative supply. (a) Stability test of equilibrium point (0, 0, 0). (b) Stability test of equilibrium point (1, 0, 0). (c) Stability test of equilibrium point (1, 1, 0). (d) Stability test of equilibrium point (1, 0, 1). (e) Stability test of equilibrium point (1, 1, 1).
Figure 4: The influence of government supervision on the strategy selection of each agent.
Figure 5: The influence of government subsidy on strategic selection of each agent.

strategy can mobilise the enthusiasm of various agents to participate compared with the low-subsidy strategy for government agents and the participation rate of government agents increases accordingly. While adopting the high-

subsidy strategy, the government's main body is involved in the supply of financial burden overweight, leading to a reduction in the participation rate of government agents. The medium-subsidy strategy has brought a greater guarantee to the income of the supply of affordable rental housing for market players compared with the low-subsidy strategy, and the market participation rate has significantly increased. The market participation rate is lower when the high-subsidy strategy, rather than the medium-subsidy strategy, is adopted, indicating that the government's blind increase of subsidies for the market subject cannot continuously stimulate the enthusiasm of market participation and that this increase should be reasonable. As the social subject participates in the nonprofit supply of GSRH, it is more motivated with a "high subsidy" than with a medium or low subsidy.

3.2.3. Experiment 3: Effects of Market and Social Participation on System Equilibrium. For different development stages of the collaborative GSRH supply system, the different initial strategy choices of the market and social agents may have different degrees of impact on the development of each stage of the collaborative supply system. To clarify this issue, this section designs the following two sets of experiments.

The first experiment: two groups of strategies of $y = 0.5$ and $y = 1$ are set to conduct the policy experiment on the influence of the initial proportion of market agents in the participation strategy on the GSRH supply efficiency. With $t = 500$ as the cycle, 50 policy simulations are conducted. Figure 6 shows the data analysis and visualisation of the output results of large-scale numerical experiments.

At every stage, when the probability of market participation is 1, compared with 0.5, the intervention rate of government agents is significantly reduced as the simulation results indicate that the participation rate of market agents increases in the collaborative supply stage (Stage 4). The participation rate of social agents is also greatly reduced at the same time, while there is no significant influence on the strategy choice of each subject in other stages, as shown in Figure 6(e). The simulation results show that the enthusiasm of market players is excessively aroused in the stage of collaborative supply, and the proportion of market agents occupy an excessively high proportion of the supply system, which leads to the relaxation of government intervention in supply and to social agents being squeezed out of the supply system by the market, resulting in the imbalance of the government-market-society collaborative supply system. The supply of GSRH is vulnerable to "market failure"; therefore, the government should take the initiative to regulate the participation ratio of market agents to avoid market-led supply imbalance in Stage 4.

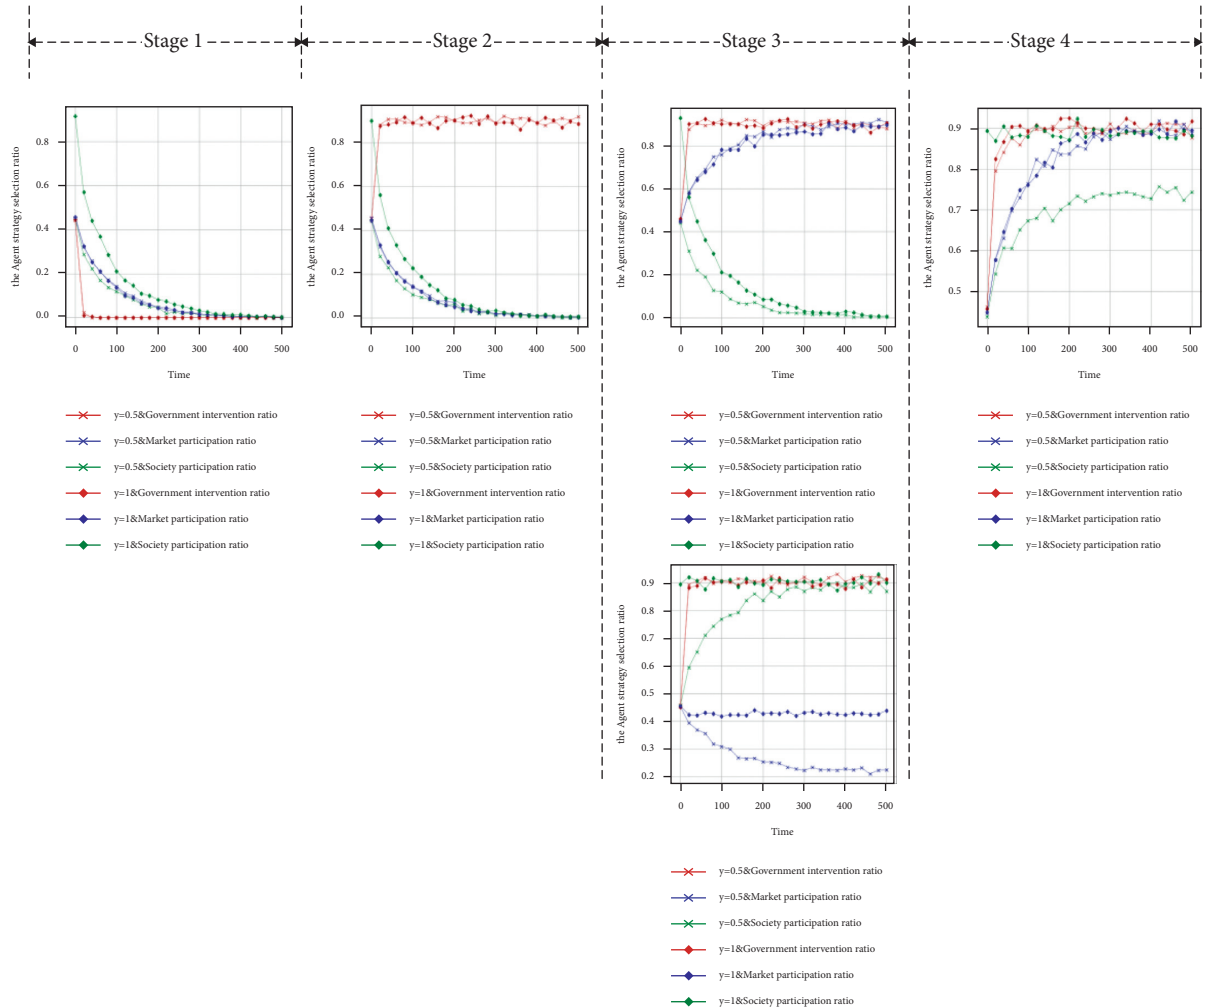
The second experiment: two groups of strategies of $z = 0.5$ and $z = 1$ are set to conduct the policy experiment on the influence of the initial proportion of market agents in the participation strategy on the GSRH supply efficiency. With $t = 500$ as the cycle, 50 policy simulations are conducted. Figure 7 shows the data analysis and visualisation of the output results of large-scale numerical experiments.


FIGURE 6: The influence of initial proportion of market agents' participation strategy on the supply system. (a) $y = 0.5$, $y = 1$, and stability test of equilibrium point $(0, 0, 0)$. (b) $y = 0.5$, $y = 1$, and stability test of equilibrium point $(1, 0, 0)$. (c) $y = 0.5$, $y = 1$, and stability test of equilibrium point $(1, 1, 0)$. (d) $y = 0.5$, $y = 1$, and stability test of equilibrium point $(1, 0, 1)$. (e) $y = 0.5$, $y = 1$, and stability test of equilibrium point $(1, 1, 1)$.

At every stage, the probability of social participation is 1, compared with 0.5 when the evolutionary stability strategy is $(1, 0, 1)$, namely, government intervention, market participation, and social participation, and the participation rate of market agents significantly improves with the increase of the participation rate of social agents in the collaborative game stage (Stage 3) from the simulation results, as shown in Figure 7(d). In the collaborative supply stage (Stage 4), as the participation rate of social agents increases, the market participation rate fluctuates, but the change is not significant, while the government intervention rate clearly increases, as shown in Figure 7(e). The impact on the strategy choice of each agent in other stages is not significant. The simulation results show that the increase of the proportion of social participation helps to mobilise the enthusiasm of market participants in the collaborative game stage and the government agents to intervene in the collaborative supply stage. Therefore, in the process of collaborative supply system development, mobilising the participation enthusiasm of social agents is conducive to the positive development of the collaborative supply system.

4. Discussion

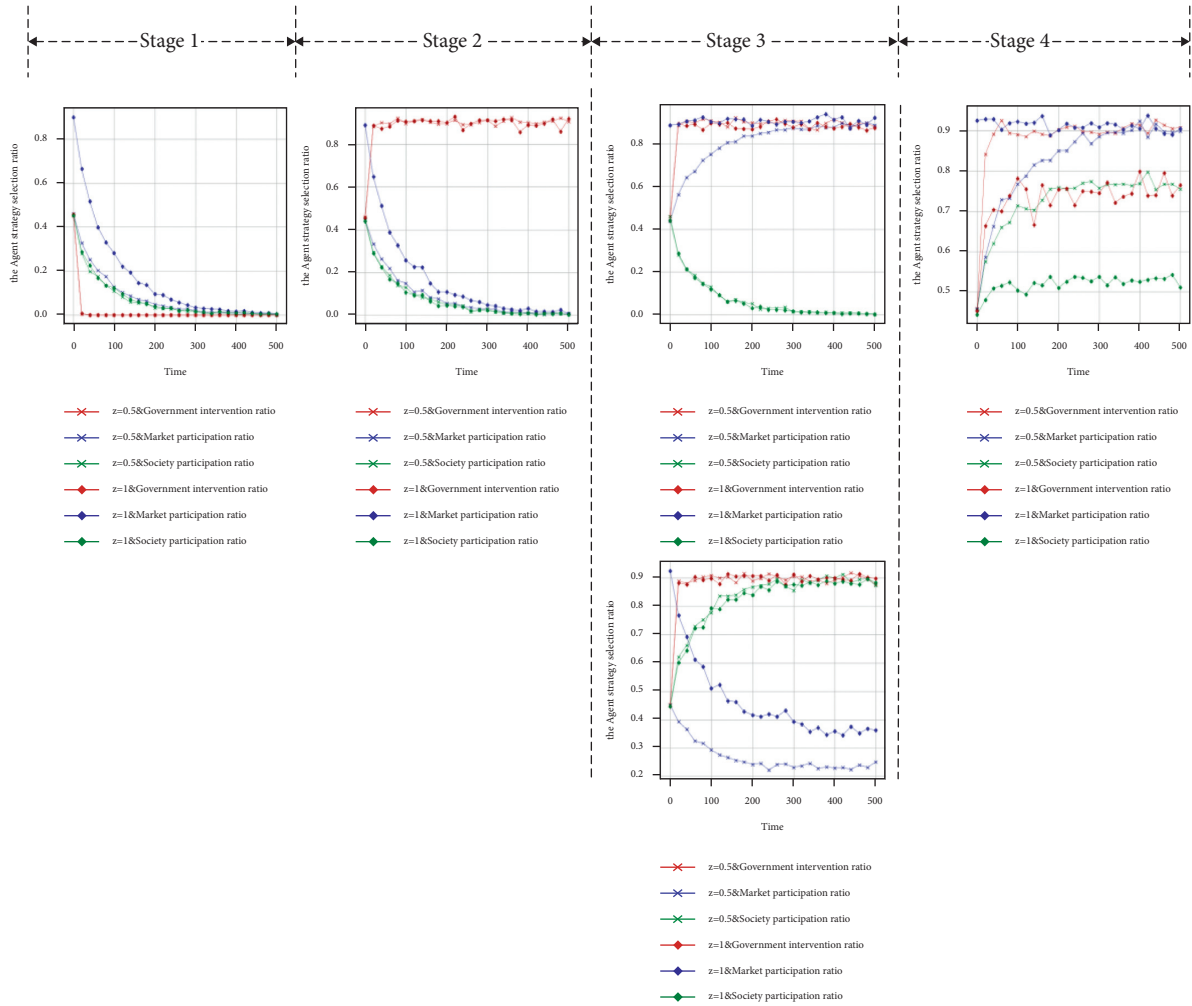
On the basis of confirming previous studies, our results have obtained some new and more specific conclusions. First, the collaborative supply of GSRH can be divided into four stages: (i) noncooperative behaviour, (ii) collaborative exploration, (iii) collaborative game, and (iv) three-subject collaborative supply. Our division of the development stages of the multisubject collaborative supply system fills the gap of systematic research on the multisubject collaborative supply of public housing. The policy simulation of the four stages shows that the government is at the core of realising a multisubject collaborative supply, and the solution to housing affordability cannot rely solely on market forces. This result confirms the previous research conclusion on the important role of government subjects in the supply of affordable housing [26]. In the context of neoliberalism, Australia's study of the housing crises in Sydney and Melbourne also suggests that local governments must play a bigger role [61]. The policy's experimental findings further confirm the important role of specific political and economic


Figure 7: The influence of initial proportion of social agents' participation strategy on supply system. (a) $z = 0.5$, $z = 1$, and stability test of equilibrium point $(0, 0, 0)$. (b) $z = 0.5$, $z = 1$, and stability test of equilibrium point $(1, 0, 0)$. (c) $z = 0.5$, $z = 1$, and stability test of equilibrium point $(1, 1, 0)$. (d) $z = 0.5$, $z = 1$, and stability test of equilibrium point $(1, 0, 1)$. (e) $z = 0.5$, $z = 1$, and stability test of equilibrium point $(1, 1, 1)$.

incentives for local governments in achieving programmes [17]. The government should provide appropriate guidance for the market and social subjects, and it should be cautious in the intervention process. Improper intervention may create an uncontrollable and uncertain environment that affects market efficiency and fairness [62, 63]. And the government should determine the corresponding intervention measures according to the matching of supply and demand of GSRH in each city and the development stage of collaborative supply system so as to maximise the social benefits of these incentive mechanisms and ensure the financial feasibility of the market and social subjects [64].

Second, as the link for realising market and social synergy, how the government can efficiently realise the supply of GSRH is critical to the sustainable development of public housing at the stage of collaborative supply. The government's supervision and guidance strategy on the market and social subjects is equivalent to the "carrot" and "stick" initiative. A previous study discussed the feasibility of introducing housing affordability contributions and

incentives when developers entered the planning process and pointed out that optimum scenarios identified a balance of carrots and sticks [64]. Based on the previous related research, combined with the development stage of the collaborative GSRH supply system, this study determines the government's supervision and guidance of market and social subjects in different development stages of the supply system and obtains more detailed results. The incentive measures applicable to the supply of GSRH in all cities do not exist. Therefore, in the process of realising the multisubject collaborative supply of public housing, the development stage of the collaborative supply system should be determined according to the basic situation of the city, such as the specific population, economic situation, and policy background, combined with the exploration of the multisubject collaborative model of the city, such as public-private partnerships and inclusionary housing. And then, the specific supply policy applicable to the city should be determined according to the development stage of the collaborative supply system and the national support policy.

Finally, affordable housing is increasingly developed, financed, and managed by a mix of state, third sector, market, and community actors. Previous studies on public-private cooperation have focused more on the significance of cooperation among government and private and nonprofit organisations in increasing the supply of indemnificatory housing [26, 65], and private real estate developers have entered into partnerships with the Housing Authority to finance, design, build, and manage the new developments [66, 67]. Based on previous studies, through large-scale policy simulation experiments, this study draws microscopic and more instructive conclusions and discusses the positive and negative effects of different participation ratios of the market and social subjects in the multisubject, collaborative supply. For the different development stages of the collaborative GSRH supply system, the different initial strategy choices of the market and social agents have different degrees of influence on the development of each stage. In different stages, reasonable control of the proportion of the market and social subjects choosing participation strategies is conducive to the balance of the collaborative supply system and to avoid an imbalance caused by the insufficient or excessive participation enthusiasm of market and social subjects.

5. Conclusion

In large cities with a net population inflow, the supply of GSRH is an important measure to alleviate the staged housing difficulties of new citizens and young people, and it plays an important role in promoting new urbanisation and optimising the spatial allocation of human capital in China. The coordination degree of government, market, and society in the supply process directly affects the implementation of the urban GSRH supply plan. Based on the multisubject evolutionary game model, this study establishes an agent-based model with the help of the NetLogo simulation platform, conducts large-scale policy experiments to explore the development status of the collaborative supply system of GSRH and the influence of each agent's strategic choices on the balance of the supply system, and draws the following conclusions.

First, the collaborative supply of GSRH can be divided into four stages: (i) noncooperative behaviour, (ii) collaborative exploration, (iii) collaborative game, and (iv) three-subject collaborative supply. Second, this study determines the government's supervision and guidance of market and social subjects in different development stages of the supply system and obtains more detailed results. (a) Market agents are sensitive to the government's choice of supervision strategy. The government should adopt different levels of supervision strategies at different stages of the development of the collaborative supply system (Stages I–II: supervision; Stage III: increased supervision; Stage IV: supervision), but government supervision is not a key factor affecting the participation of social subjects in supply. Therefore, the government can appropriately increase the supervision of the market and relax the supervision of social subjects in the process of coordination. (b) For the choice of subsidy strategy, the reaction of market agents to the intensity of the government's subsidy strategy has certain limits, beyond which the increase of government subsidies cannot mobilise the market's enthusiasm, while increasing subsidies to social agents can fully mobilise their participation enthusiasm. Therefore, the government should appropriately increase subsidies to market subject and give full subsidies to social subject. Finally, the results of the policy simulation experiment indicate that increasing the participation ratio of social agents helps mobilise the enthusiasm of the government and of market agents to participate in Stage III. However, the excessive participation ratio of market agents leads to the imbalance of the collaborative supply system in Stage IV; thus, the government subject needs to limit the market participation ratio within a reasonable range.

This study has strong theoretical and practical implications for the establishment of collaborative supply system of various public housing. At the theoretical level, in view of the dilemma of the GSRH supply, this study attempts to explore the internal mechanism of the multisubject collaborative supply of GSRH based on the synergy theory and the methods of EGT and ABM. The study enriches the research achievements related to collaborative supply and provides a certain scientific basis for the pilot cities to formulate specific supply policies. In terms of practical implications, this study first clarifies the core status of government subject in the supply of GSRH and provides guidance for the intervention of government subject. Secondly, A "city-specific policies" approach must be followed to avoid distortion of policy results and improper allocation of government resources so as to achieve rapid and efficient GSRH supply [14]. Finally, this study is of great significance to protect the right of residence in human development opportunities.

This study suffers from some limitations that provide directions for future research. First, the supply of GSRH in each pilot city is currently in the planning stage; therefore, the simulation model in this study lacks testing of actual cases. Secondly, the policy simulation experiment lacks quantitative results, and there is no clear quantification of the degree of supervision and guidance strategies that government subjects should give to other supply subjects in different development stages of the collaborative supply system. Moreover, there is no clear quantification of the reasonable participation ratio of market and social subjects in each development stage of this system. Future research will focus on the pilot cities of GSRH, bringing the empirical analysis data into the policy simulation model, quantifying the model, and enriching the existing research conclusions. Further, it will make this research model a policy decision-making tool based on the background research on the pilot city's development, input the research results into the model, and then provide policy suggestions with direct guiding significance for the supply of GSRH in the city.

Quality cost framework (QCF), as a measurement tool and research method, has played a significant role on quality improvement procedure (QIP) and recognition on economics of quality. The four general QCFs are usually conceptually employed assist quality managers to measure the quality cost (QC/COQ) including PAF, intangible loss, process cost, and ABC framework. The question of how to select an appropriate quality cost framework for individual organization is of great significance for implementing quality improvement activities. Considering the *effectiveness* and *feasibility* of the alternative solution, a novel hybrid fuzzy MCDM approach integrating fuzzy DMEATEL, an antientropy weighting technique and FVIKOR method are employed to study the quality cost models and assist managers to select a best QCF for an auto factory. The combined weight from subjectivity and objectivity is embedded into fuzzy VIKOR procedure to obtain alternatives' ranking order. The case study in a Chinese automaker enterprise shows high robustness of the hybrid MCDM approach, and it assists quality mangers to perform quality cost practice. Different from the previous study, the preferred solution is the ABC quality cost framework when feasibility dimension dominates, while the intangible loss framework shows first priority when the organization focuses on effectiveness principle.

1. Introduction

With an increasing fierce marketing situation and multiple products in the auto industry, quality was treated as a crucial element and core competence for industrial organizations [1, 2]. Auto-makers began to focus on quality improvement programs and customer satisfactions' enhancement by quality tools such as total quality management (TQM), lean six sigma (LSS), 8D, and statistical process control (SPC) technique [3–8]. However, with continuous quality improvement practice (QIP), managers in self-brand auto firms show their interests on economics of quality improvement activities. Quality management (QM) practice, for instance,

supplier quality factor, processing technology, and procedure control have proven to be an effective method to promote quality performance [9]. As all industries exist, quality does not come for free as it bears extra inputs and investment. While there are few relative cost measurements during QM practice, especially for expenditures of the quality improvement program (QIP) in self-brand automotive firms. Besides, quality costing becomes an effective trigger and method to control quality improvement activities in the automobile industry [10].

The purpose of QIP is to improve the product performance with lower cost [11] to meet the requirement of customers, which stimulates the cost of quality model

development [12–14]. Freiesleben targeted profit maximization as the objective by taking quality investment, cost of poor quality and revenue effect of better quality into account instead of the cost minimization objective [15]. While the prerequisite work of all these quality innovations is the total quality related cost measurement, to collect quality costs an organization needs to adopt a framework to classify costs. Therefore, it is of great significance and urgency for managers to choose an appropriate quality cost framework (QCF) to recognize the economics of quality [11, 16].

Quality cost (QC) has proven to be an effective way for quality improvement and cost reduction. The concept of quality cost (QC), first proposed by Juran and Feigenbaum, has been studied and applied as an effective tool for cost reduction and quality improvement [11, 17]. Similar to the definition of lifecycle cost (LCC), the COQ focuses on the quality-related cost from product lifecycle perspective [18]. Cost of quality (COQ) represents the cost of not achieving good quality. Any expenditure due to substandard quality contributes to the cost of quality. The term is referred to as "quality related cost," "poor quality cost", or "cost of poor quality," all of which focus on the failure expenditure when the quality cannot meet the customer. Based on the definition of American Society for Quality Control (ASQC, 1971), cost of quality is a methodology that allows an organization to determine the extent to which its resources are used for activities that prevent poor quality that appraise the quality of the organization's products or services, and that result from internal and external failures [19–21].

Quality cost framework and accounting systems are part of every modern organization's quality improvement strategy, and help management plan for quality improvement by identifying opportunities for a greatest return on investment. While there is no general agreement on the definition of COQ, and the specific quality cost differs from author to author, as well as for different industry and organization. As quality scholars and experts advocate that quality cost framework should be tailor-made for particular industrial organization [16]. In order to identify the quality cost items, some organizations are trying to develop its quality cost system based on the quality cost framework (QCF) linking with its own financial accounting system. The cost items can be calculated based its specific activity and cost parameters. The quality cost program is a systematic task whose items need to be developed, modified, deleted, and adjusted according to quality improvement practice and the practical situation of the organization.

Because there are many conceptual quality cost frameworks can guide the organization to develop its COQ program, the appropriate QCF is the crucial step for its success. Moreover, it is important for different individual organizations to choose the most appropriate quality cost framework for better quality management practice. Because the quality cost framework selection is a complicated research problem subjecting to multiple criteria of the individual organization. The quality cost framework selection can be regarded as a multicriteria decision-making problem with respect to multiple conflicting criteria. The MCDM theoretical models have been regarded as truimple for

dealing with the comprehensive evaluation of industrial problems with multiple conflicting criteria [22]. Tsai initially explored a hybrid DEMTELA-ANP model to deal with this issue [16]. However, decision-making techniques are subjectivity-oriented, and it is difficult to collect the decision information with crisp value for the Chinese auto factories [23, 24]. Due to lack of researches in terms of quality innovation on QCF selection, this paper aims at assisting managers to evaluate and select the best quality cost framework to fill the gap by a hybrid fuzzy multi-criteria decision-making (MCDM) method considering the effectiveness and feasibility of alternative model. Meanwhile, the fuzzy-based method has been employed to deal with the uncertainty and vagueness of decision information which facilitates to the data collection for decision makers. This paper aims to enhance the capacity of auto factories to prioritize quality cost framework by a hybrid MCDM approach and address the quality cost innovation. The main contributions of this paper are as follows. First, the hybrid fuzzy multi-criteria decision-making approach integrating fuzzy DEMATEL, anti-entropy weighting technique and VIKOR method is employed for QCF selection, which facilitates data collection and easy implementation. Second, the seven criteria from effectiveness and feasibility of quality cost framework are addressed based on the barriers in COQ model, and the criteria relationship map (CRM) is illustrated in the two-dimension clusters. Third, the combined weighting technique from subjectivity and objectivity has been embedded into fuzzy VIKOR procedure, which makes the approach more flexible according to the decision makers' preference.

The rest of this paper is structured as follows. Section 2 provides the literature review on quality cost related topics. The hybrid MCDM approach integrating fuzzy DEMATEL, anti-entropy weighting technique, and fuzzy VIKOR method is employed to deal with the QCF selection in the next section. In Section 4, a case application is presented in a self-brand auto-factory and this paper is ended with conclusions in Section 5.

2. Literature Review

2.1. Development and Application of QCFs. The quality cost has experienced several decades by researchers and practitioner from all walks of life [21, 25–33], while the concept for different organization or industry has been argued by many researches, due to different considerations and specific procedures. The broad concept of "economics of quality" and "cost of quality" can be traced back to the early 1950s [33]. After the initial researches by Feigenbaum (1956), Juran (1951), and Crosby's (1979) etc., the basic philosophy of quality cost has been widely used and studied with high agreement and appreciation [34]. The prevailing four quality cost frameworks applied in the quality practice are prevention-appraisal-failure (PAF), the intangible loss framework, process cost framework and activity-based cost (ABC) [11, 16, 33, 34] are presented in Table 1.

The quality cost concept, first proposed in Juran's "quality control handbook" and in Feigenbaum's "total

TABLE 1: Four typical quality cost framework details.

	Prevailing QCF	Details and cost items	References
A1	PAF framework	Prevention + appraisal + failure cost	[35–40]
A2	Intangible loss framework	Prevention + appraisal + failure + hidden cost	[29, 41–45]
A3	Process framework	Conformance + non-conformance cost	[19, 28, 46]
A4	ABC framework	Value-added + non-value-added cost	[30, 37, 47]

quality control" [33]. The specific PAF framework is propounded and has been adopted by many researchers and practitioners. There are three categories in this cost framework including prevention cost, appraisal cost, and failure cost. Prevention cost consists of cost items are associated with activities launched to prevent poor quality in products or services. Appraisal costs are related to measurement, evaluation, or auditing products or service to guarantee conformance to quality specification and performance requirements. Failure cost includes cost items leading to products or services not conforming to customer needs from the defective's standpoint, and it can be divided into internal and external failure cost. The PAF cost framework, as a prevailing COQ model, has been applied into many industries for quality costing [31, 32, 48–50], and it is also employed to optimize the quality cost and obtain the optimal quality level [13, 40, 51–53].

With the concentration of customers' satisfaction, loyalty, and brand reputation, the intangible loss cost framework has been recently emphasized by extending the PAF model. Actually, in this group of models' intangible loss or opportunity loss cost is incorporated into a typical P-A-F model, which contained the revenue lost and profit not earned due to the customer complaints. Wang owed customer satisfaction and complaint after-sales to the intangible loss and the traditional COQ models has been illustrated [34]. Snieska et al. divided the hidden costs that are always neglected and usually hardly measured caused by failed quality, into three elements: customers' goodwill, brand value, and image of company [41]. As the quality cost measurement is a systematic work which need multi-department involvement, Yang redefined the "extra resultant cost" and "estimated hidden cost" on the basis of traditional PAF COQ model, which can be measured by quality cost account matrix and responsible weight of each department [45]. Liapis et al. studied intangible quality related cost in fuel supply chain including quality deficits, customer complaint, product mixtures, and negative impacts, etc. [46]. Palikhe studied the detailed quality cost construction considering opportunity cost in electric utility industry based on the PAF framework [54]. This group of models emphasizes the role of intangible cost within the overall quality cost scheme and focuses on the hidden loss, which helps quality managers to recognize the economics of quality and its products' performance better.

In view of a number of drawbacks of the PAF cost framework, the process cost framework developed by Crosby concentrated on the operation process rather than the products or services. The process cost framework has two segments that are cost of conformance (COC) and cost of un-conformance (CONC), and the quality term is treated as "conformance to customers' requirements." The conformance cost is the cost involved in making certain things are performed right at the first time, which is similar to actual prevention and appraisal costs, while the un-conformance cost is the expenditure wasted when the work fails to conform to customer requirements, calculated by recognizing the cost of reworking, correcting, scrapping activities, which is similar to failure cost. Daunorienė has studied the COQ model from the value added chain perspective, which provided an effective way to evaluate the quality cost of the value added chain's procedures [47]. Teli et al. has proven quality cost technique to be a significant tool to reduce total costs in the automobile industry without compromising quality, which presents a case study on failure cost analysis based on Crosby philosophy [50]. The cost items need to be measured based on specific processes and it is influenced by the conformance level. The application of process cost framework is suggested as a preferred method for quality costing under TQM environment due to its quick response on quality issues [34], and it helps quality mangers to identify the importance of process cost measurement and ownership with a more integrated framework [33, 55]. Understanding the related process sufficiently is the first step in quality costing program based on process cost framework; however, the complete concise activity analysis linked with specific process without duplication for an organization may be time-consuming compared with PAF framework.

Even though the above three quality cost frameworks provide management insight on quality costing based on the economics of quality; however, it still cannot provide appropriate methods to include overhead cost items. In other words, the three frameworks are effective enough to cover the cost items and reflect the quality actions in the continuous quality improvement procedure (CQIP), while all of them are category philosophy lacking of feasibility and specific calculation on overhead costs. In addition, due to the lack of quality related data and un-conformance of traditional accounting system, the three frameworks fail to measure the quality improvement benefits, as well as cost elements. Activity-based costing method, first developed by Cooper and Kaplan, filled this gap and was adopted to identify and assign every cost activity to products and services in an organization. It assigns more overhead expenditures into dire costs and is more compatible with cost measurement system. Jorgenson and Enkerlin [56] presented a quality cost program based on ABC framework to identify, quantify, and allocate cost by a manufacturing organization. The ABC method is an alternative way that can recognize the cost items, instead of a COQ model. Based on

the activity-oriented cost (ABC) framework, it is preferred for the auto factory to eliminate the nonvalue-added activities and invest much more effectively during its quality improvement procedure (QIP).

The abovementioned four quality cost frameworks have been widely used by experts and quality practitioners. In addition, some of the above cost frameworks have proven to be adopted by many standard organizations as presented in Table 2.

2.2. Criteria for QCF Selection.

Even though the quality cost framework provides an effective guidance on quality costing, there are many barriers for the quality cost practice due to the lack of quality related data and limited cost information, etc. It is a prevailing phenomenon that many departments usually ignore the importance of the quality cost reporting in Chinese auto factories. The quality manager always focuses quality improvement procedures and quality indexes such as failure frequency (R/1000). Customer complaints and things go wrong (TGW) indicator, ignoring economics of quality [20, 50]. Due to the difficulty on the benefit measurement and invisibility of the immediate improvement, financial manager does not show much interest on quality cost reporting. The less involvement and lack of management support or absence of management interests are the barriers in tracking such costs [20]. In addition, due to the lack of knowledge and cost un-conformance with traditional accounting system, the organization cannot perform quality costing program based on an appropriate quality cost framework (QCF). The well-organized data structure and multi-department involvement based on the appropriate quality cost framework can resolve the dilemma, which helps manager to identify the cost elements and data collection with higher efficiency. Therefore, an appropriate QCF is the crucial step for organizations. Based on previous studies [16, 38, 57, 58], seven criteria from two dimensions are categorized (illustrated in Table 3) to implement this research.

To recognize the most suitable quality cost framework for an organization, a hybrid fuzzy decision-making framework is employed to deal with this problem based on the established criteria hierarchy.

3. Fuzzy Hybrid MCDM Approach for QCF Selection

The purpose of this research is to select the most appropriate quality cost framework for an automotive organization with integrated fuzzy DEMATEL-AEW-FVIKOR approach. The quality cost framework selection is regarded as a *MCDM* problem subject to criteria set $C = \{C_1, C_2, \ldots, C_j, \ldots, C_n\}$, which includes decision makers $DM = \{DM_1, DM_2, \ldots, DM_k, \ldots, DM_K\}$ and alternative set $A = \{A_1, A_2, \ldots, A_i, \ldots, A_m\}$. Suppose $\tilde{x}_{kij}$ is the rating of i-th alternative with respect to j-th criterion provided by the k-th representative, which is represented by the triangular fuzzy number converted from linguistic terms. In addition, the criteria combined weight has been divided into

subjective and objective aspect. Let the relative subjective weight is presented as $\mathbf{w}^s = (w_1^s, w_2^s, \ldots, w_j^s, \ldots w_n^s)$, and the objective weight of criteria is $\mathbf{w}^o = (w_1^o, w_2^o, \ldots, w_j^o, \ldots, w_n^o)$. The φ index is the relative importance of subjective item, and the criteria combined weight is $\mathbf{w}^c = (w_1^c, w_2^c, w_3^c, \ldots, w_n^c)$ integrated with the subjectivity and objectivity. In order to figure out the cause and effect relationship among the criteria, every expert is asked to make a comparison with the direct effect of criterion C_i on criterion C_j with linguistic variables. There are five levels to express the influence degree (Table 4) and let $\tilde{p}_{kij}$ is the influence degree rating of criteria C_i on criteria C_j provided by the k-th expert [59].

3.1. Fuzzy-Based Techniques.

Linguistic variable has been utilized for the multicriteria decision-making problem for the uncertainty and vagueness of the decision information [62, 63]. It helps to collect decision information provided by investigated representatives and can transform the linguistic description into mathematical information. The fuzzy set, introduced by Zadeh in 1965, is an effective tool to deal with the uncertainty and ambiguity of human judgment and evaluation in decision-making science [60]. In practice, it is difficult to recognize the crisp numbered information of the investigated alternatives, which motivates the application of fuzzy-based techniques [64, 65]. It is much better to convert linguistic terms into qualitative fuzzy numbers [66, 67]. The triangular fuzzy number (TFN) has been adopted to quantify the corresponding linguistic term [68].

3.1.1. Triangular Fuzzy Number and Linguistic Variable

Definition 1 (Fuzzy set). Let X be the universe of discourse, and. the fuzzy set A can be regarded as order pairs, which are linked by a membership function that maps each element with the number. The function value is the membership degree for x. The fuzzy number is a particular case of a fuzzy set, which is used to represent the vague scale ratings of the objective.

Definition 2 According to the shape of membership function, the fuzzy numbers can be divided into several forms. Assume triangular fuzzy number $\tilde{A} = (a, b, c)$ and its membership function can be illustrated as Figure 1 shows.

$$\mu_{\tilde{A}}(x) = \begin{cases} \dfrac{(x-a)}{(b-a)}, & a \leq x \leq b, \\\\ \dfrac{(c-x)}{(c-b)}, & b \leq x \leq c. \\\\ 0, & \text{otherwise} \end{cases} \tag{1}$$

There are two kinds of linguistic terms that need to be defined for the measurement of criteria influence description (Table 4) and rating scales of four quality cost frameworks with respect to each criterion (Table 5). Linguistic variables and corresponding rating scales with TFNs are presented in the following two tables.

TABLE 2: General quality cost items by various nations.

Nations	QCF category	QCF items
ASQC (US)	A1-PAF	Prevention + appraisal + failure
BS6143 (UK)	A3-process cost	Conformance and non-conformance
ISO9004-1	A1-PAF	Prevention + appraisal + failure
GB/T13339 (CN)	A2-IL	Prevention + appraisal + internal/external failure

TABLE 3: Specific criteria for the requirement of a beneficial COQ framework.

Dimension	Criteria	Detail description
D1-effectiveness	C1	The selected alternative should support the continuous quality improvement procedures (CQIP)
	C2	The selected alternative should contain as many COQ items as possible
	C3	The selected alternative should be applicable to all the departments of the organizations
D2-feasibility	C4	The selected alternative should have an easy data collection and application
	C5	The selected alternative should have the clear form and type of data needed
	C6	The selected alternative should be based on the concept of production procedures
	C7	The cost item of selected alternative should be easily recognized, calculated and recorded by the organization

3.1.2. Fuzzy Operators and Defuzzification Method. Assume there are two triangular fuzzy numbers $A_1 = (a_1, b_1, c_1)$ and $A_2 = (a_2, b_2, c_2)$, the algebraic operations are implemented according to the fuzzy operators "⊖"

[70]. The common operations between these TFNs can be formulated as follows.

Addition operator: $A_1 \oplus A_2 = (a_1 + a_2, b_1 + b_2, c_1 + c_2)$
Subtraction operator: $A_1 \ominus A_2 = (a_1 - a_2, b_1 - b_2, c_1 - c_2)$
In addition,

$$\lambda A_1 = \begin{cases} (\lambda a_1, \lambda b_1, \lambda c_1), & \lambda \ge 0, \quad \lambda \in R \\ (\lambda c_1, \lambda b_1, \lambda a_1), & \lambda < 0, \quad \lambda \in R. \end{cases} \quad (2)$$

Through the abovementioned fuzzy operators, we can aggregate decision information provided by expert panels. The decision information aggregation can be formed based on the following equation:

$$\tilde{x}_{ij} = \frac{\left(\tilde{x}_{ij}^1 \oplus \tilde{x}_{ij}^2 \oplus \ldots \oplus \tilde{x}_{ij}^k \oplus \ldots \oplus \tilde{x}_{ij}^K \right)}{K}. \quad (3)$$

Fuzzy numbers usually require to be transferred into crisp value for ranking and prioritization purpose, whose process called defuzzification. The GMIR method was employed to transfer the TFNs into crisp values as equation (4) shows [71].

$$x_{ij} = \text{defuzzy}\left(\tilde{x}_{ij} \right) = \frac{x_{ij}^L + 4x_{ij}^M + x_{ij}^U}{6}. \quad (4)$$

3.2. Subjective Weight with the Fuzzy DEMATEL Method. The decision-making and trial evaluation laboratory (DEMATEL) method, first proposed in 1976, has been used to visualize the structure of complicated casual interactions. It helps decision makers to recognize and portray the causes and effects of the criteria with a diagraph map [59]. It has proven to be a big challenge for decision makers to provide crisp values of influence degree of the criteria. In that case, fuzzy logic has been embedded called fuzzy DEMATEL technique has been applied into the subjectivity weight study to address the uncertainty, vagueness, and information leaks. Implementation procedures of the fuzzy DEMATEL method are as follows [72]:

Step 1: Initial direct influence average fuzzy matrix $\tilde{P}$ construction

Based on the linguistic term and corresponding TFNs, the direct influence degree $\tilde{p}_{kij} = (p_{ijk}^L, p_{ijk}^M, p_{ijk}^U)$ can be converted that C_i on C_j by expert k. The diagonal element values of matrix P should be zero based on the definition of influence degree. After the fuzzy aggregation through fuzzy operators, the elements $\tilde{p}_{ij} = (p_{ij}^L, p_{ij}^M, p_{ij}^U)$ in the initial direct influence average fuzzy matrix $\tilde{P}$ can be generated as follows:

$$\tilde{p}_{ij}^L = \frac{1}{K} \sum_{k=1}^{K} p_{kij}^L,$$

$$\tilde{p}_{ij}^M = \frac{1}{K} \sum_{k=1}^{K} p_{kij}^M,$$

$$\tilde{p}_{ij}^U = \frac{1}{K} \sum_{k=1}^{K} p_{kij}^U,$$
$$\tag{5}$$

$$\tilde{P} = \left(\tilde{p}_{ij}\right)_{[n \times n]} = \begin{array}{c} \\ C_1 \\ C_2 \\ \\ \\ C_n \end{array} \begin{array}{c} C_1 \quad C_2 \quad \dots \quad C_n \\ \begin{bmatrix} 0 & \tilde{p}_{12} & \cdots & \tilde{p}_{1n} \\ \tilde{p}_{21} & 0 & \cdots & \tilde{p}_{2n} \\ \cdots & \cdots & \tilde{p}_{ij} & \cdots \\ \tilde{p}_{n1} & \tilde{p}_{n2} & \cdots & 0 \end{bmatrix} \end{array}.$$

Step 2: The normalized direct-influence fuzzy matrix $\tilde{M}$ construction.

The elements $\tilde{m}_{ij} = (m_{ij}^L, m_{ij}^M, m_{ij}^U)$ in the normalized direct-influence fuzzy matrix $\tilde{M}$ can be calculated through the following equation:

$$\tilde{m}_{ij} = \frac{\tilde{p}_{ij}}{s} = \left(\frac{p_{ij}^L}{s}, \frac{p_{ij}^M}{s}, \frac{p_{ij}^U}{s}\right) = \left(m_{ij}^L, m_{ij}^M, m_{ij}^U\right),$$
$$\tag{6}$$

$$s = \max_{1 \le i \le n} \left(\sum_{j=1}^{n} p_{ij}^U\right).$$

Step 3: The development of the total-influence fuzzy matrix $\tilde{T}$.

The total-influence fuzzy matrix $\tilde{T}$ can be obtained from the following equation:

$$\tilde{T} = \lim_{k \to \infty} \left(\tilde{M} \oplus \tilde{M}^2 \oplus \dots \oplus \tilde{M}^k\right) = \tilde{M}(I - \tilde{M})^{-1},$$
$$\tilde{T} = \left(\tilde{t}_{ij}\right)_{n \times n}, \tag{7}$$

where $\tilde{t}_{ij} = (t_{ij}^L, t_{ij}^M, t_{ij}^U)$ and

$$\begin{aligned}
\left[t_{ij}^L\right] &= M_L \times (1 - M_L)^{-1}, \\
\left[t_{ij}^M\right] &= M_M \times (1 - M_M)^{-1}, \\
\left[t_{ij}^U\right] &= M_U \times (1 - M_U)^{-1},
\end{aligned} \tag{8}$$

where I is the $n \times n$ square matrix with ones on its diagonal.

Step 4: Establishment of criteria influential relation map.

The sum of rows and columns are obtained from the total-influence matrix respectively expressed as $\tilde{D}_i$ and $\tilde{R}_i$ equation (9). The criteria in effect group and cause group can be calculated based on the ordered pairs of $(\tilde{D}_i + \tilde{R}_i, \tilde{D}_i - \tilde{R}_i)$.

$$\tilde{D} = (\tilde{D}_i)_{n \times 1} = \left[\sum_{j=1}^{n} \tilde{t}_{ij}\right]_{n \times 1}, \tilde{R} = (\tilde{R}_j)_{1 \times n} = \left[\sum_{i=1}^{n} \tilde{t}_{ij}\right]_{1 \times n}. \tag{9}$$

According to equation (3), the fuzzy ordered pairs $(\tilde{D}_i + \tilde{R}_i, \tilde{D}_i - \tilde{R}_i)$ are defuzzified to the crisp pairs $((\tilde{D}_i + \tilde{R}_i)^{\text{def}}, (\tilde{D}_i - \tilde{R}_i)^{\text{def}})$ through GMIR method, as well as the elements in total-influence fuzzy matrix where $(\tilde{D}_i + \tilde{R}_i)^{\text{def}}$ denotes the degree of the targeted attribute role that the factor plays in the network system and $(\tilde{D}_i - \tilde{R}_i)^{\text{def}}$ means the net effect that the element contributes to the network system. In order to obtain the criteria influential relation map, the threshold value p is established based on total-influence matrix T. Only those influential relationships whose value is greater than the established threshold value should be kept and chosen in the CRM [73]. In this paper, the arithmetic mean of all elements in matrix F is p value [16]. If $(\tilde{D}_i - \tilde{R}_i)^{\text{def}} > 0$, it means the criterion i has an effect on other criteria which will belong to the *cause group*, and if $(\tilde{D}_i - \tilde{R}_i)^{\text{def}} < 0$, the attribute i is being affected by others, which will belong to the *effect group*.

Step 5: Subjective weight calculation.

Based on the following equation (10), the subjective weight of criteria can be obtained through CRM as $\mathbf{w}^s = (w_1^s, w_2^s, \dots, w_j^s, \dots w_n^s)$.

$$w_{i0} = \left(\left[(\tilde{D}_i + \tilde{R}_i)^{\text{def}}\right]^2 + \left[(\tilde{D}_i - \tilde{R}_i)^{\text{def}}\right]^2\right)^{1/2};$$
$$w_i^s = \frac{w_{i0}}{\sum_{i=1}^{n} w_{i0}}. \tag{10}$$

3.3. Objective Weight by Antientropy Weight (AEW) Technique. Shannon Entropy is an effective method for uncertain information measurement formulated in terms of possibility theory. Liu has applied this technique into MCDM problem for the weights acquisition [74]. Objective weights based on entropy value can be realized through the following stages [75].

Step 1: Normalization of the decision-making matrix. The elements of the matrix can be calculated according to the following equation:

$$P_{ij} = \frac{x_{ij}}{\sum_{i=1}^{m} x_{ij}}. \tag{11}$$

Step 2: Calculation for the information entropy of each criterion based on the following equation:

$$e_j = -k \sum_{i=1}^{m} p_{ij} ln p_{ij} = -\frac{1}{lnm} \sum_{i=1}^{m} p_{ij} ln p_{ij}. \tag{12}$$

Step 3: The objective weight of each criterion can be obtained through the following equation:

$$w_j^o = \frac{1 - e_j}{\sum_{j=1}^{n}(1 - e_j)}. \tag{13}$$

3.4. Ranking Method Based on Fuzzy VIKOR Procedure. The VIKOR (VlseKriterijumska Optimizacija I Kompromisno Resenje) method has proven to be an effective method for multi-criteria prioritization problem [76–80]. The fuzzy VIKOR is the extension VIKOR method integrated with fuzzy-based techniques. The philosophy of VIKOR method is based on the particular measure of closeness to the ideal solution started with the following form of L_p-metric.

$$L_{p,i} = \left\{ \sum_{j=1}^{n} \left[\frac{w_i(f_j^* - f_{ij})}{f_j^* - f_j^-} \right]^p \right\}^{1/p}, \ 1 \le p \le +\infty, \tag{14}$$

$$i = 1, 2, \ldots, m.$$

It can be ranked by the index to choose the compromise solution. The implementation steps of FVIKOR method are as follows [75]:

Step 1: The normalized difference d_{ij} calculation.

The normalized difference d_{ij} is calculated based on the best value f_j^* and worst value f_j^- in following equation.

$$d_{ij} = \frac{f_j^* - x_{ij}}{f_j^* - f_j^-}, \tag{15}$$

where

$$f_j^* = \begin{cases} \max_i x_{ij}, \text{the more the better,} \\ \min_i x_{ij}, \text{the less the better,} \end{cases}$$
$$f_j^- = \begin{cases} \min_i x_{ij}, \text{the less the bad,} \\ \max_i x_{ij}, \text{the more the bad.} \end{cases} \tag{16}$$

Step 2: Compute S_i and R_i with criteria combined weight

The relative importance of subjective weight compared with objectivity is φ. According to equations (10) and (13), the combined weight of criteria $\mathbf{w}^c = (w_1^c, w_2^c, w_j^c, \ldots, w_n^c)$ can be calculated. Then the maximum group utility value S_i and minimum individual regret value R_i can be obtained in equation.

$$S_i = \sum_{j=1}^{n} (w_j^c d_{ij}),$$
$$R_i = \max_j (w_j^c d_{ij}), \tag{17}$$
$$w_j^c = \varphi w_j^s + (1 - \varphi) w_j^o.$$

Step 3: Calculation of the comprehensive utility value Q_i, $i = 1, 2, \ldots, m$.

$$Q_i = v \frac{S_i - S^*}{S^- - S^*} + (1 - v) \frac{R_i - R^*}{R^- - R^*}, \tag{18}$$

where
$S^- = \max_i S_i, S^* = \min_i S_i, R^- = \max_i R_i, R^* = \min_i R_i$. In order to reflect the attitude of decision makers, $v \epsilon (0, 1)$ represents the relative importance of maximum group utility, while the 1-v is the relative importance of individual regret.

Step 4: Alternatives ranking based on the three index value: S, R, and Q. The candidate $A^{(1)}$ will be regarded as the compromising solution, who has the minimum comprehensive group utility value Q, if the following two conditions (acceptance advantage and its stability) can be satisfied.

4. Case Study

4.1. Background and Data Collection. A real numerical case for the application of the hybrid MCDM approach integrating the fuzzy DEMATEL, anti-entropy method, and FVIKOR technique is presented in this section, and it has been applied into the quality cost framework selection of an automotive enterprise in China. The enterprise is a famous vehicle-assembly firm providing vehicle products such as cars, sport utility vehicles (SUVs), vans, and multipurpose vehicles (MPVs). With the implementation of quality improvement activities (8D and Six sigma), the quality index (PP100 and R/1000) is improved dramatically [67]. While, there is no appropriate quality cost framework helps managers to recognize the quality related cost and it is not enough to identify the COQ based on the financial report. In that case, it is of great urgency for CA Company to select the best quality cost framework to help its manager identify the COQ during the product whole lifecycle, especially for the continuous quality improvement procedure.

As the previous analyzed, there are four QCF alternatives in this study, which are evaluated from the two dimensions (effectiveness and feasibility). Expert panels include the quality manager, financial manager, and an expert on COQ. In order to obtain the required data, a questionnaire is prepared and distributed among the decision-making team, and each representative provide a judgment with linguistic variables for the direct influence of criteria (Table 6) and A1 alternative's performance subject to each criterion (Table 7), respectively.

In order to reflect the robustness of the proposed hybrid MCDM framework, the sensitivity analysis on the decision parameters φ and v are conducted in eleven experiment scenarios illustrated in Tables 8 and 9. In addition, in order to explore the best solution of the QCF under different consideration, the relative importance of the effectiveness (ρ) is defined with 11 experiment scenarios in Table 10.

4.2. Application of the Proposed Approach. The fuzzy DEMATEL method was used to recognize interdependence

and influence relationships among the criteria. The initial fuzzy direct influence matrix provided by the three representatives was collected by pairwise comparison in terms of influences (Table 5) and the fuzzy average direct influence matrix $\widetilde{P}$ was calculated based on equation (5). According to equations (6)–(9), the total-influence matrix $\widetilde{T}$ was derived and the threshold value p is established. The various indexes calculation results by FDEMATEL method are presented in Table 11 and criteria relationship map (CRM) was drawn based on the order pairs $(\widetilde{D}_i + \widetilde{R}_i)^{\mathrm{def}}$, $(\widetilde{D}_i - \widetilde{R}_i)^{\mathrm{def}}$, as shown

in Figure 2. In addition, the objective weight of criteria based on AEW method based on equations (12)–(14) is illustrated in Table 11. Let $\varphi = 0.5$, the combined weights can be calculated.

According to Table 11, the criteria weight can be obtained by fuzzy DEMATEL and antientropy method, which are embedded into fuzzy VIKOR procedures. The S, R and Q value and alternative ranking result can be obtained based on equations (15)–(18) as presented in Table 12.

As can be seen in the above table, the ranking order has the same sequence by S, R, and Q index. In addition, $Q(A^{(2)})-$

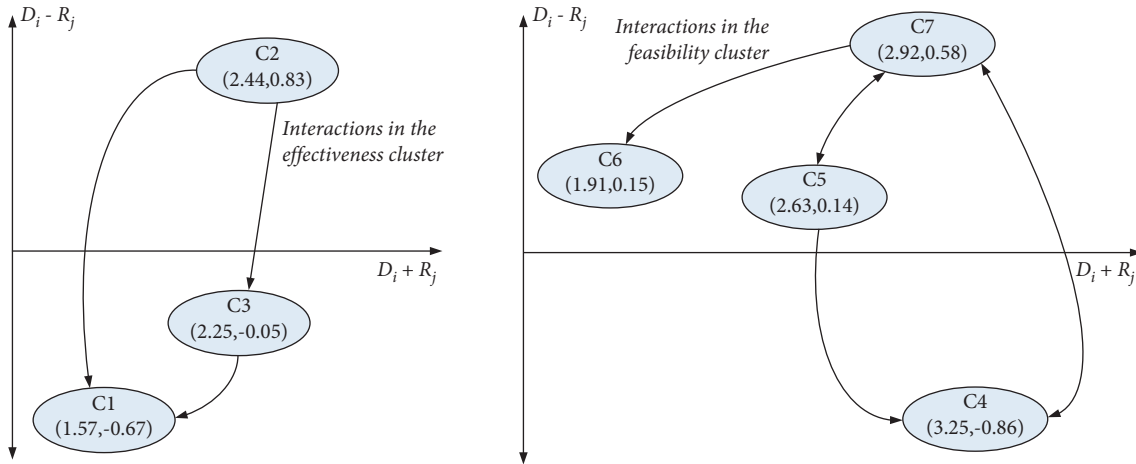

FIGURE 2: Criteria relationship map (CRM) in the two dimension clusters.

TABLE 12: Four QCF alternatives ranking result based on S, R and Q value.

Alternative	The proposed integrated framework				TOPSIS-based method	
	S value	R value	Q value	Ranking by $S/R/Q$	RC value by the TOPSIS steps	Ranking by RC
A1-PAFF	0.892	0.164	1	4	0.492	4
A2-ILF	0.513	0.155	0.563	3	0.523	3
A3-PF	0.370	0.153	0.420	2	0.758	2
A4-ABCF	0.319	0.119	0	1	0.952	1

$Q(A^{(1)}) = Q(A3) - Q(A4) = 0.42 \geq DQ = 0.33$. Therefore, the ABC quality cost framework (A4) is the best selection for its satisfaction on the two conditions. The research result shows high conformity with Tsai's study that the ABC model is the best choice for enterprise to recognize the economics of its quality improvement procedure [16]. Besides, the ranking lists show a high conformity with the TOPSIS-based method.

4.3. Sensitivity Analysis.
The abovementioned analysis shows the application of the proposed hybrid MCDM approach for the quality cost framework selection. In order to analyze the robustness of the proposed method, the sensitivity analysis is performed to understand effect on ranking result of the decision parameters. Established experimental scenarios are set in Tables 8–10.

4.3.1. Sensitivity Analysis on Relative Importance of Group Utility v.
The relative importance of group utility v reflects the optimistic attitude, and the Q value reflects the comprehensive group utility of compromising solution. The

calculated Q index values in different experimental scenarios (Table 8) are presented in the following Figure 3.

As Figure 3 shows, the best QCF selection is always the ABC model and the last one is PAF model (A1), even though there is a little fluctuation for the specific Q values of the middle two alternatives in different scenarios. The ranking order of the four quality cost framework alternatives keeps steady which means the group utility weight does not influence the decision result.

4.3.2. Sensitivity Analysis on Relative Importance of Subjectivity φ.
The defined decision parameter φ shows the relative importance of subjective weight, which reflects the weight of subjectivity in decision making. In this case, the sensitivity analysis on parameter φ (Table 9) is conducted to investigate the influence of subjectivity weight on the QCF alternative ranking results. The obtained Q values in established scenarios are illustrated in Figure 4.

The above figure shows high stability of the best solution (A4) when parameter φ varies. Similar to the sensitivity
FIGURE 3: Sensitivity analysis on group utility weight v.
FIGURE 4: Sensitivity analysis on importance of subjective weight φ.

FIGURE 5: Sensitivity analysis on relative importance of two principles ρ.

analysis result of parameter v, the Q value of the middle two alternatives in established 11 scenarios keep a slight fluctuation which does not influence the ranking order.

4.3.3. Sensitivity Analysis on the Relative Importance of Effectiveness Dimension ρ. The decision parameter ρ reflects the attitude and validity of the representatives when the enterprise wants to select an appropriate quality cost framework. The conflict and paradox of the COQ model and traditional cost framework exist due to their unconformity. It is difficult for an organization to choose a best QCF with the two dimensions into consideration. In this part, the aim of sensitivity analysis is to explore the best solution variation when the firm focused on the different dimension.

As can be seen in the above Figure 5, the PAF quality cost framework is always the last alternative solution compared with other three ones. While the Q index values and ranking orders of other three alternatives fluctuate dramatically. When $\rho \leq 0.5$, the organization focuses on the feasibility of quality cost framework, and the best solution is ABC model catered to Tsai's research. However, when $\rho > 0.5$, the intangible loss quality cost framework shows its priority than other three alternatives due to the dominance of effectiveness dimension of QCF.

4.4. Discussion and Management Insight. The sensitivity analysis on the three decision parameters has been conducted to analyze the robustness of the proposed hybrid MCDM method. The analysis result shows that the best

solution keeps a stable priority in terms of parameter v or φ. However, best selection shifts from A4 to A2 with the increasing of parameter ρ. It is very interesting to find the different research conclusion compared with Tsai's research that the ABC model priors to other alternatives when the organization focuses on the feasibility of quality cost framework, while the intangible cost model shows its priority when it concentrates on effectiveness dimension. When the CA organization focus on the effectiveness dimension of quality cost framework, the intangible cost framework is more appropriate.

The best solution change means Chinese companies tend to focus on the importance of the hidden cost due to product unconformity, customer complaints and reputation loss, since they want to take these intangible cost items into consideration in its quality cost framework and costing report. However, it is really very difficult to quantify the cost item for either PAF model or intangible cost framework for manufacturing firms. Even some published papers have been studied on the quality cost calculation, the specific application was usually based on the organization's particular requirement. The QCF selection is a team task with all related departments involvement, and this paper presented a systematic procedure to establish an appropriate QCF integrating decision information from multigroups. The manager can select the appropriate quality cost framework based on the practical consideration of the organization. Actually, as Schiffauerova and Thomson studied [11], the quality cost framework alternative is only just a basic concept and the concrete costing systems or costing report still differ from company to company.

From the case application of the investigated organization in this paper, there occur two kinds of best solution, one is the ABC model and the other is the intangible loss framework. The intangible loss quality cost framework is the best choice when decision makers pay more attention on effectiveness principle and it can illustrate the quality related cost item from prevention, appraisal and failure term, as well as the hidden cost, which provides and extensive looking. While the best choice is the activity-oriented cost (ABC) measurement method when decision makers focus on feasibility dimension more, and it can help manager to investigate specific cost item. The new quality cost framework

from lifecycle and COQ dimension would be welcomed for both effectiveness and feasibility.

5. Conclusions

This paper employed a hybrid fuzzy multicriteria approach for quality cost framework selection from the typical four alternatives (PAF, intangible cost, process cost, and ABC), which helps the quality manager to develop quality cost practice based on appropriate QCF. The case study by the hybrid fuzzy MCDM approach integrating fuzzy DEMA-TEL, anti-entropy weighting technique, and fuzzy VIKOR method shows high robustness and flexibility on decision parameters. In addition, the fuzzy-based technique has been adopted to facilitate the decision makers to collect decision information. According to the model result, it caters to Tsai's study when the organization concentrates on feasibility principle, while the intangible loss cost framework shows the top priority when decision makers pay more attention to effectiveness for CA organization. This hybrid fuzzy MCDM approach shows its advantage on the flexibility of decision making and easy implementation due to the combined weighting technique and fuzzy method, and the auto-factory can perform quality costing practice based on this selection model. However, this study carries some limitations. First, the influential criteria can be extended based on different organizational industries by considering specific characteristics of individual requirements. Second, the decision-making information mainly comes from the judgements of experienced expert panels, and the big data driven techniques can be developed to make full use of operational information of objective firms. Finally, the AI-based decision-making framework could be explored to achieve smart determination and reduce the subjectivity.

In order to construct a prediction model of sports economic operation indicators, this paper combines deep learning and ensemble learning algorithms to integrate and improve the algorithms and analyzes the principles of the LightGBM ensemble learning model and the hyperparameters of the model. Moreover, this paper obtains appropriate intelligent algorithms according to the data analysis requirements of sports economic operation. The break-even analysis method of sports event operation is to find the critical point of the program's profit and loss by analyzing the relationship between the operating cost and profit of the sports event. In addition, this paper uses deep learning and ensemble learning to comprehensively evaluate sports events, constructs a summary evaluation structure of sports items, and evaluates the model in this paper combined with experimental research. The test results verify the reliability of the model in this paper.

1. Introduction

With the development of economy and the continuous growth of social material wealth, people began to pursue leisure consumption, and leisure consumption demand gave birth to the leisure industry. The leisure industry refers to the general term for the production of leisure goods and leisure service industries in the national economy triggered by leisure consumption demand [1]. It widely exists in the three major industries of the national economy, including the primary leisure industry, the secondary leisure industry, and the secondary leisure industry. The tertiary industry, of which the tertiary leisure industry is the main industry of the leisure industry, is mainly composed of tourism, culture, sports, and other leisure industries [2]. The transformation of the economic growth mode, especially the consumption-driven economic growth mode, has promoted the rapid development of the leisure industry. Leisure consumption has gradually become a new growth point for the national economy in many countries and regions, and some have even become the dominant region or country [3]. Leisure

industries, especially in some tourist cities, have become local pillar industries, and even the economic growth model has shifted from relying on a single leisure subindustry to relying on the overall development of the entire leisure industry. However, the development of China's leisure industry is relatively late, the development of subindustry is unbalanced, tourism and leisure are developing rapidly, out-of-the-box, and the economic effect of the industry is outstanding. The development of cultural leisure and sports leisure is obviously lagging, and the industrial effect is not obvious. This has caused the development of China's leisure industry. The overall level of development and competitiveness is not high; furthermore, tourism and leisure have experienced extensive development for two to three decades, and its development momentum and development space are obviously hindered, which further restricts the growth of China's leisure industry. It is particularly important to explore how to quickly and continuously promote the comprehensive and rapid development of China's leisure industry and make it a new pillar industry of the national economy.

The country's economy has taken off, and people's economic consumption levels have also taken a qualitative leap. More and more people have begun to put forward new requirements on their spiritual level, and they have begun to spend their leisure time by improving their aesthetics. Therefore, various top-notch domestic competitions have increasingly become a spiritual demand of people. In recent years, large-scale sports events have become more and more frequent on the world stage. However, the quality of my country's event services is uneven. As an important basis for running sports events, the organizers urgently need to make a big fuss about the quality of event services, because of the excellent service quality of large-scale sports events. Inferiority directly affects the quality and effect of the event. Good service quality will allow participants to continue to support the sport, and poor service quality will make participants feel disgusted and no longer support the sport.

Based on the previously mentioned analysis, this paper combines deep learning and ensemble learning to construct the sports economic operation index prediction model, evaluate the sports economic operation, and provide a reference for the subsequent development of the sports economy.

2. Related Work

Literature [4] believes that the distinguishing characteristics of large-scale festivals and ordinary events are as follows: first, this event must attract a large number of participants and viewers, forming a kind of global attention; second, large-scale festivals are also a kind of market strategy; for the tourism industry, especially, it can make organizers and regions receive extremely high attention in the international market; finally, large-scale festivals can create long-term heritage, which can still play a role after the event is over.

Literature [5] conducts a systematic literature review of the industry chain efficiency research from the five perspectives of industry chain competitiveness, efficiency (performance), ecological stability, sustainable development capability, and overall effect. Literature [6] adopts the concepts, methods, and means of performance evaluation to realize the process of performance evaluation of the government.

It has become a common phenomenon that sports events drive the development of the tourism industry. Literature [7] believes that hosting sports events can increase the visibility of a city, bring in a large number of visitors, and promote cultural exchanges between cities. Literature [8] explains the specific role of urban characteristics and how sports events shape the unique characteristics of the city and proposes to use the creation of sports events to shape urban characteristics and communicate the distinctive humanistic spirit through tourism. Sports events play an important role in shaping the image of the city and driving the development of the city. Literature [9] believes that the economic effects of sports events lead to the rapid development of urban economy and tourism. Literature [10] proposes that the shaping of sports landscape is also an important means of displaying the culture of the host city, and it has a positive

effect on the transmission of the city's image. Literature [11] mentioned the role of sports events in shaping and transmitting the image and brand of the city. Literature [12] proposes that sports events, as one of the most used cultural activities of the city, have a positive impact on the city's image and puts forward five strategies to convey and shape the image of the city.

Literature [13] takes urban sports as a research perspective and establishes a scientific evaluation system for the current situation of urban sports. Literature [14] established a sports rights evaluation system for college students. Literature [15] analyzes the job role and work process of referees and builds an evaluation index system for referee selection. Literature [16] studies sports tourism, gives an evaluation index system for sports tourism human resources, and develops a corresponding evaluation scale. Literature [17] has conducted research from the perspective of economic benefits. The indicators mainly include facility utilization rate, equipment integrity rate, venue revenue, venue self-sufficiency rate, and profit. Literature [18] assesses the economic benefits of stadiums and uses multifactor comprehensive analysis to construct a grading model of stadiums. The literature [19] mainly studies the two basic attributes of venues: "public welfare" and "business." Literature [20] constructs an evaluation index system for the normal operation of stadium operation and management after sports events are held.

3. Deep Learning and Ensemble Learning Prediction Algorithm

Ensemble learning is a machine learning technique commonly used in business and economic analysis. Machine learning algorithms usually cannot directly obtain models with better performance in all aspects, while ensemble learning can upgrade multiple weak individual learners with preferences to a strong learner to obtain higher accuracy. The essential idea is to first generate a set of learners, then use strategies to integrate them, and continuously optimize towards the objective function in the iterative process.

The GBDT algorithm consists of a gradient boosting algorithm (gradient boosting) and a decision tree algorithm (decision tree). It uses a decision tree as the base learner, uses the boosting algorithm to combine multiple weak learners into a strong learner through residual fitting, and uses the gradient information from the previous round to construct a decision tree in the iterative process.

3.1. Gradient Lifting Algorithm. The idea of the gradient boosting algorithm is an extension of the boosting method. In the iterative process, the loss function is optimized by adding submodels. If the loss function is extended to a differentiable function, and the boosting method and the gradient descent method are combined to obtain the gradient boosting method, the basic idea is as follows.

The formula of the compound model is shown in formula (1), where $f_i(X)$ is the submodel.

$$F_m(X) = \sum_{i=0}^{m} f_i(X). \tag{1}$$

We assume that the loss function is $L(Y, F_m(X))$, use a greedy way to ensure that the loss function is reduced every time a new submodel $f_m(X)$ is added, and use gradient descent to perform residual fitting.

$$F_m(X) = F_{m-1}(X) + f_m(X),$$
$$L(Y, F_m(X)) < L(Y, F_{m-1}(X)). \tag{2}$$

3.2. Decision Tree Algorithm. The decision tree algorithm uses a tree structure, the root node contains all the samples, the internal nodes represent the feature attribute test, and the leaf nodes are the results of the classification. The learning process of decision tree includes three steps: feature selection, decision tree generation, and pruning. The key point is the division of optimal attributes in the splitting process.

There are three criteria for feature selection: information gain, information gain ratio, and Gini coefficient. Among them, it is commonly used to perform top-down division according to the information gain criterion, and calculate the information gain of each feature during each division and select the maximum value.

The information Ent(D) is defined as formula (3), where P_k represents the proportion of the k-th sample in the sample set D.

$$\text{Ent}(D) = -\sum_{k=1}^{|y|} p_k \log_2 p_k. \tag{3}$$

In the information gain formula, D^v represents the value sample contained in the v-th attribute A in the V branch nodes, and the formula is as follows:

$$\text{Gain}(D, A) = \text{Ent}(D) - \sum_{v=1}^{V} \frac{|D_v|}{|D|} \text{Ent}(D^v). \tag{4}$$

The decision tree splitting method in the GBDT algorithm is divided into two, one is the method of leaf-wise growth according to the maximum profit, and the other is the method of direct level-wise growth.

According to the way of leaf growth, the required decision tree can be grown with a smaller computational cost. The advantage of this method is that it has high accuracy and can quickly and effectively complete the growth of the tree, but at the same time, it is easy to overfit and the growth process is sequential and cannot be directly accelerated in parallel. Figure 1 is the process of decision tree growth by leaves.

The way of layer growth means that each node of each layer must be split. Therefore, this method can directly perform parallel acceleration, but it will generate redundant split nodes, which requires a high computational cost. At the same time, each iteration needs to traverse the complete dataset, so higher running memory is required. Figure 2 is the growth process of a decision tree split by layer.

LightGBM is mainly based on the framework of decision tree algorithms such as GBDT to optimize the use of histogram algorithm, histogram difference optimization, tree growth based on restricted optimal leaf nodes, unilateral gradient sampling, and reordering of category feature histograms. Compared with other decision tree models, it has improved speed, memory consumption, and accuracy.

In order to reduce the computational cost and obtain better accuracy, the LightGBM model uses a tree growth method that splits according to the optimal leaf node. Algorithms can only be executed sequentially in principle, so three methods of feature parallelism, data parallelism, and voting parallelism are used, and parallel acceleration is performed from the three perspectives of feature, data, and communication.

3.2.1. Optimization of Histogram Algorithm. The basic idea is to divide continuous feature values into many #bins, use discrete values as indexes, and then search for the best split point on #bin, reducing the computational cost and storage cost. Moreover, the difference optimization of the histogram can be used to further speed up and get better performance. At the same time, due to the discrete nature, LightGBM can naturally handle category features.

The histogram algorithm only needs to store the discretized value #lbin, does not need the original feature value, and does not need to sort. The #bin value can use smaller data types to store training data, such as the uin8_t type, which can reduce memory consumption to 1/8 of the presorting algorithm. The memory optimization process is shown in Figure 3.

3.2.2. Gradient-Based Unilateral Sampling Algorithm (GOSS). The idea of GOSS algorithm was first applied to the AdaBoost model. The essential idea is to sort the gradients first, retain all instances with large gradients (errors) for sampling, and only randomly sample all instances with small gradients, so as to reduce the amount of information calculation for feature selection in the iterative process. At the same time, in order to reduce the accuracy of the loss, a certain weight value will be given to the small gradient of the sample.

O is the training data set on the fixed node of the decision tree, the instance is $\{x_1, x_2, ..., x_n\}$, and the gradient of the loss function is denoted as $\{g_1, g_2, ..., g_n\}$. Then, the traditional calculation of the variance gain of the split feature j of the node at d is defined as

$$V_{j|O}(d) = \frac{1}{n_O} \left[\frac{\left(\sum_{\{x_i \in O; x_{ij} \leq d\}} g_i\right)^2}{n_{l|O}^j(d)} + \frac{\left(\sum_{\{x_i \in O; x_{ij} > d\}} g_i\right)^2}{n_{r|O}^j(d)} \right]. \tag{5}$$
FIGURE 1: Decision tree divided by leaf growth.
FIGURE 2: Decision tree split by layer.

On the left are int_32 store index and float_32 store values

The right is where uint8_8 stores the # bin value
FIGURE 3: Schematic diagram of LightGBM histogram algorithm memory optimization.

Among them,

$$\begin{cases} n_O = \sum I[x_i \in O] \\ n_{l|O}^j(d) = \sum I[x_i \in O: x_{ij} \le d] \\ n_{r|O}^j(d) = \sum I[x_i \in O: x_{ij} > d] \end{cases}. \tag{6}$$

When using the idea of the GOSS algorithm, the algorithm first sorts the training examples in descending order

according to the absolute value of the gradient and composes the instance subset A by the larger gradient $\alpha \times 100\%$. After that, the algorithm samples the remaining set with a smaller gradient composed of $(1 - a) \times 100\%$ instances as a subset B of size $b \times |A^c|$. Finally, the gain $\tilde{V}_j(d)$ calculated according to the subset AUB is

$$\tilde{V}_j(d) = \frac{1}{n}\left[\frac{\left(\sum_{\{x_i \in A_r\}} g_i + 1 - a/b\sum_{\{x_i \in B_r\}} g_i\right)^2}{n_l^j(d)} + \frac{\left(\sum_{\{x_i \in A_r\}} g_i + 1 - a/b\sum_{\{x_i \in B_r\}} g_i\right)^2}{n_r^j(d)} \right]. \tag{7}$$

The definition of each subitem is as follows:

$$\begin{cases} A_l = \{x_i \in A: x_{ij} \le d\}, A_r = \{x_i \in A: x_{ij} > d\} \\ B_l = \{x_i \in B: x_{ij} \le d\}, B_r = \{x_i \in B: x_{ij} > d\} \end{cases}. \quad (8)$$

Using the estimated gain $\widetilde{V}_j(d)$ on a smaller subset of instances instead of the accurate gain $\widetilde{V}_j(d)$ on all instances to determine the split point can greatly reduce the computational cost. It is proved that GOSS will not lose much training accuracy, but the efficiency is better than random sampling.

3.2.3. Mutually Exclusive Sparse Feature Binding.
The optimal feature bundling problem can usually use a greedy algorithm to obtain an approximate solution to select the feature values that need to be combined. For the mutually exclusive feature merging process, since the histogram data is discrete, the original data can be distinguished by the offset to achieve the purpose of merging features.

3.2.4. Comparison of LightGBM and XGBoost Models.
Compared with another popular ensemble learning framework XGBoost model, the LightGBM model released later has made the following improvements, as shown in Table 1.

The most important parameter settings of the LightGBM model include the learning rate of the algorithm, the maximum depth limit of the decision tree, the number of leaves of a single decision tree, and the selection ratio of features in the iterative process.

The following are the main parameters for control and optimization of the LightGBM model.

(1) mum_leaves is the main parameter that controls the complexity of the tree model, representing the number of leaves per tree. Usually, it is considered that mum_leaves is less than 2mar_sdeph; otherwise, it is easy to cause overfitting problems. Among them, the corresponding relationship between the number of leaves of a full binary tree and the depth of the tree is

$$\text{num\_leaves} = 2^{\max\_depth}. \quad (9)$$

(2) learning_rate is the learning rate of the algorithm. If it is too small, the optimization efficiency of the model will be too low. If it is set too large, it may reduce the accuracy.

(3) max_depth refers to the maximum depth of the tree model, which can prevent overfitting when the data is small.

(4) max_bin is the maximum number of features stored in bin.

(5) min_data_in_leaf is the minimum amount of data that can be set on the leaf, and the small amount of data can also prevent overfitting.

(6) feature_fraction and bagging_fraction are the ratio of selected features to the total number of features and the ratio of selected data to the total data volume

respectively. The values of these two parameters are usually between 0 and 1, which can determine the speed of model training and can also deal with overfitting problems.

(7) mm_iterations represents the number of iterations of boosting.

It can be seen that some parameters overlap in improving the accuracy of the algorithm and dealing with the overfitting problem. Therefore, this paper selects the parameters that are relatively important to the model to optimize.

We configure parameters to obtain a better model from the balance of training speed, accuracy, and prevention of overfitting. The following are the hyperparameters that have a greater impact on model prediction:

(1) improving training speed: increasing learning_rate and decreasing max_bin

(2) improving accuracy: increasing max_bin, increasing mum_leaves, and decreasing learning_rate

(3) preventing overfitting: limiting the tree depth max_depth and reducing min_data_in_leaf and using smaller mum_leaves

Tuning machine learning model parameters through optimization algorithms is a common research content. After using the particle swarm algorithm to select the hyperparameters of the support vector machine, the optimized support vector machine is applied to the research of power load forecasting, and the optimization ability of the particle swarm algorithm is proved through experiments. However, the algorithm needs to adjust more parameters. Grid tuning is another common method of tuning machine learning model parameters. Through research, Cheng Chen et al. found that the method is relatively single and the parameter improvement range is limited, making it difficult to search for the best on a global scale. Therefore, a new quantum particle swarm algorithm is proposed to optimize the hyperparameters of the XGBoost model. In the research experiment of forecasting marketing data, compared with the XGBoost forecast based on the grid method tuning, the experiment proved that the new model has obtained higher forecast accuracy.

The Drosophila optimization algorithm is an excellent optimization algorithm suitable for machine learning tuning. Its advantages are simple implementation and fewer configuration parameters. The algorithm simulates the characteristics of the fruit fly colony capturing food in the air through smell and first collects various tastes in the air. The fruit flies in the colony obtain the place with the highest concentration of food taste according to their position information, and then, all the fruit flies fly to the smell point. After that, the algorithm also uses the olfactory characteristics of fruit flies to identify the location of the companions and iterates again, using the olfactory and visual characteristics of fruit flies, to gradually find the point with the largest odor concentration in the current area, and obtain the food location, that is, the global approximate optimal solution.

TABLE 1: Comparison of the details of the XGBoost and LightGBM models.

Model details	XGBoost	LightGBM
Tree growth pattern	Growth in layers	Growing by leaves restricted by depth
Split point search method	Feature presorting (default)	Histogram algorithm
Income calculation method during split	Data characteristics	Tbin container characteristics
Memory overhead	Big	Small
Categorical characteristics	One-hot encoding	Histogram data processing

Figure 4 is a schematic diagram of the optimization model of the standard fruit fly optimization algorithm.

The standard fruit fly algorithm is simple to implement, and its operation steps are as follows.

Step 1. The algorithm first initializes the fruit fly population, that is, initializing the population size Sizepop, setting the maximum number of iterations T, and randomly initializing (X_axis, Y_axis) as the initial position of the fruit fly population [21].

$$\begin{cases} X\_axis = random \times (top - bottom) + bottom \\ Y\_axis = randomx(top - bottom) + bottom \end{cases}. \quad (10)$$

Among them, random is a random number between [0, 1], and top and bottom are the upper and lower bounds of the search interval.

Step 2. The algorithm generates a random number within a certain range for each individual fruit fly and uses it as the direction and distance of the individual fruit fly in the random search process. The algorithm assigns values to the initialized fruit fly individuals to obtain the next position of the fruit fly. Among them, random value is the search distance.

$$\begin{cases} X_i = X\_axis + RandomValue \\ Y_i = Y\_axis + RandomxValue \end{cases}. \quad (11)$$

Step 3. The algorithm obtains the taste concentration determination value S_i by calculating the distance Dist between the current position of the fruit fly and the origin of the coordinate.

$$Dist_i = \sqrt{X_i^2 + Y_i^2},$$
$$S_i = \frac{1}{Dist_i}. \quad (12)$$

Step 4. The algorithm substitutes the obtained S_i into the taste concentration determination function, which is the corresponding fitness function, and calculates the taste concentration Smelli at the individual position of the fruit pupae.

$$Smell_i = Function(S_i). \quad (13)$$

Step 5. The algorithm finds the fruit flies with the best odor concentration (take the maximum value as an example) in the current fruit flies population and sets it as the best taste concentration point.

$$bestSmellIndex = SelectionMax(Smell_i). \quad (14)$$

Step 6. The algorithm judges whether the best taste concentration value is better than the previous best taste concentration. If it is better, the algorithm records the best taste concentration value and the position information bestSmellIndex and makes all fruit flies fly to this position.

$$\begin{cases} X\_axis = X(bestSmellIndex) \\ Y\_axis = Y(bestSmellIndex) \end{cases}. \quad (15)$$

Step 7. The algorithm starts iteratively to find the optimal solution. At the same time, it is judged whether the maximum number of iterations set by the algorithm is reached, and the conditions for satisfying other early termination algorithms are obtained. If the current best taste concentration obtained in the iterative process is better than the previous best taste concentration, Step 6 is executed; otherwise, Step 2 to Step 5 is repeatedly executed until the approximate optimal solution is obtained.

The execution flow of the FOA algorithm is shown in Figure 5.

It can be seen from the algorithm execution flowchart that the time required for each optimization of individual fruit flies in the FOA algorithm is T. At the same time, in the iterative process, each individual fruit fly needs to perform a search until the algorithm reaches the maximum number of iterations, so the time complexity of the standard fruit fly optimization algorithm is O(T' × Sizepop). Therefore, the key to the calculation cost of the control algorithm lies in the setting of the maximum number of iterations T and the size of the fruit fly population size.

Prediction evaluation refers to the evaluation of the accuracy of model prediction results or the measurement of prediction accuracy. In statistics, the magnitude of prediction error is commonly used to measure the quality of the prediction effect. Commonly used regression prediction evaluation methods include mean absolute error, mean square error, root mean square error, mean square log error, mean relative error, mean square log error, median absolute error, and coefficient of determination.

y_i is the actual value of a commodity price series, and $\widehat{y}_i$ is the predicted value.

(1) Mean Absolute Error (MAE). MAE is used to describe the difference between the predicted value and the true value. The smaller the value, the better. The average absolute error of *n* samples is as follows:
FIGURE 4: Schematic diagram of standard fruit fly optimization algorithm optimization.

$$MAE = \frac{1}{n} \sum_{i=1}^{n} |y_i - \widehat{y}_i|. \tag{16}$$

(2) Mean Square Error (MSE). The mean square error is calculated as the square error between the predicted value and the actual value. The MSE of *n* samples is calculated as follows:

$$MAE = \frac{1}{n} \sum_{i=1}^{n} |y_i - \widehat{y}_i|^2. \tag{17}$$

(3) Root Mean Square Error (RMSE). For the extremely large or extremely small error values in a set of prediction result data, using the root mean square error can well represent the deviation of the prediction result. The calculation is as follows:

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (f_i - y_i)^2}. \tag{18}$$

(4) Mean Square Logarithmic Error (MSLE).

$$MSLE = \frac{1}{n} \sum_{i=o}^{n-1} [\log_e (1 + y_i) - \log_e (1 + \widehat{y}_i)]^2. \tag{19}$$

When the target has the characteristics of exponential growth, this indicator is most suitable to use. MSLE is more sensitive to predictions below the true value.

(5) Median Absolute Error (MedianAE). The median absolute error uses the median of all absolute differences between the target and the forecast to calculate the loss, which can reduce the influence of outliers and is defined as

$$MedianAE = \text{median}(|y_1 - \widehat{y}_1|, ..., |y_n - \widehat{y}_n|). \tag{20}$$

(6) Coefficient of Determination (R^2 score). The best fit between the prediction model and the real data is judged to be 1, and it can be a negative value. The R^2 score of *n* samples is as follows:

$$R^2 = 1 - \frac{\sum_{i=1}^{n} (y_i - \widehat{y}_i)^2}{\sum_{i=1}^{n} (y_i - \overline{y}_i)^2}. \tag{21}$$

4. Sports Economic Operation Index Prediction Model Based on Deep Learning and Ensemble Learning

The break-even method is mainly to evaluate the uncertainty of the operating profit of sports events. The break-even analysis method of sports event operation is to find the critical point of the program's profit and loss by analyzing the relationship between the operating cost and profit of the sports event. The procedure for judging the impact of uncertain factors on the economic effects of the sports event operation plan is used to illustrate the degree of risk in the implementation of the sports event operation plan. This critical point is called the break-even point (BEP), as shown in Figure 6.

BEP is the break-even point of sports event operations, *s* is the income from sports event operations, and Q is the numerical value of sports event operation output. Ql is the numerical value of sports event operation output at the point of win-loss balance, *c* is the total cost of sports event operation, and Cr is the cost of sports event operation.

Based on the development standards of China's sports industry, this paper fully considers the general characteristics of the development of the sports industry to construct a first-level indicator system with the guidance of sports industry development theory. The specific content is shown in Figure 7.

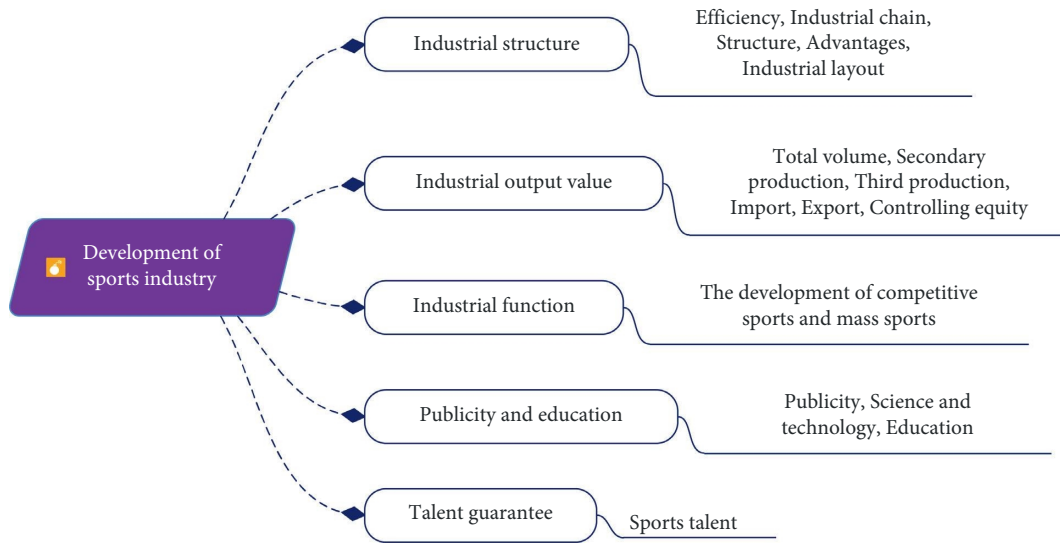
This article uses deep learning and ensemble learning to comprehensively evaluate sports events. In the process of comprehensive evaluation, we often use a combination of
Figure 5: The execution flow chart of the standard fruit fly algorithm.
Figure 6: Break-even analysis.


Figure 7: Schematic diagram of the development index of the sports industry.
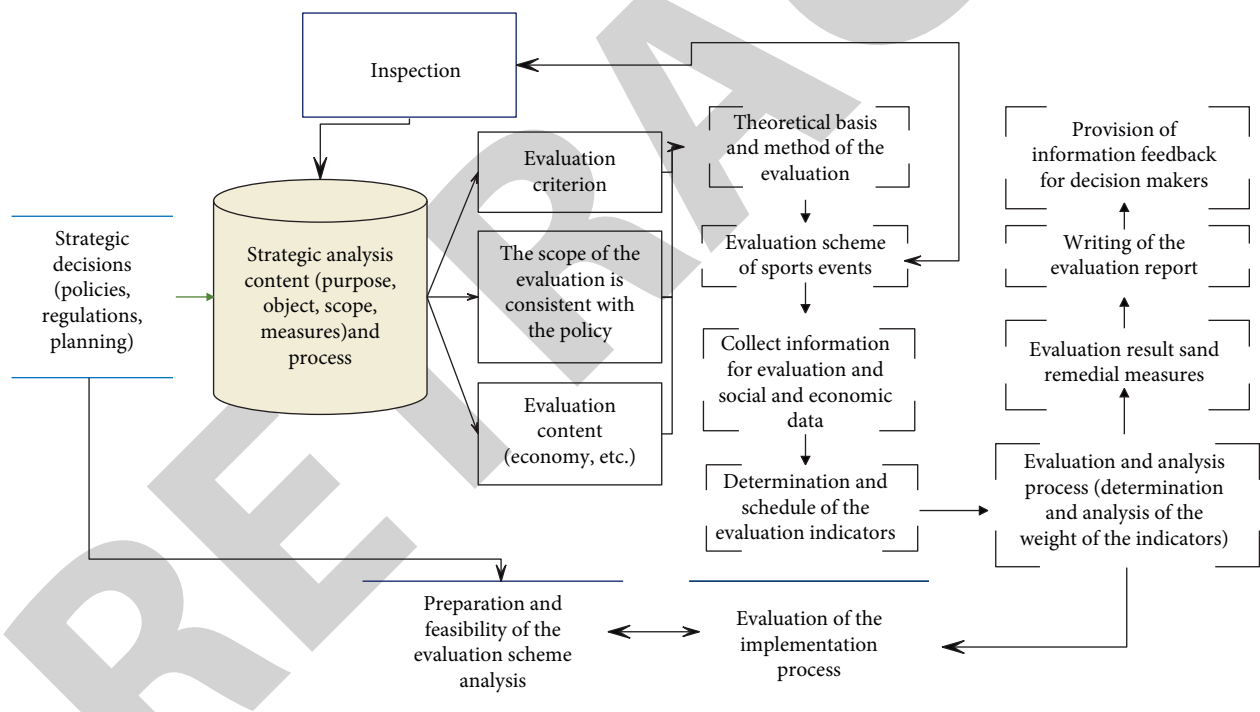

Figure 8: Evaluation program diagram of large-scale sports events.

qualitative and quantitative methods, or the analytic hierarchy process, for comprehensive evaluation. No matter which method or means is adopted, attention must be paid to the validity and reliability of the evaluation. The reason is that the purpose of comprehensive evaluation is ultimately to give an evaluation of whether the decision is feasible or not and the success or failure of sports events. From the previously mentioned main procedure, we can get the procedure of sports event evaluation as shown in Figure 8.

After constructing the above model, we evaluate the effect of the method in this paper. The data of the algorithm in this paper is processed through deep learning and ensemble learning. Therefore, first, the effect of the algorithm in this paper on the processing of sports economic operation indicators data is tested, and the results shown in Table 2 and Figure 9 are obtained.

From the previously mentioned analysis, it can be seen that the method proposed in this paper has a good effect in the data processing of sports economic operation indicators.

Table 2: The processing effect of sports economic operation index data.

Number	Data processing	Number	Data processing
1	96.00	17	92.20
2	92.13	18	96.89

15	70.54	31	89.47
16	73.19	32	72.08
Figure 10: Statistical diagram of predictive evaluation of sports economic operation indicators.

After that, the prediction effect of the sports economic operation indicators of the model in this paper is evaluated, and the results shown in Table 3 and Figure 10 are obtained.

Through the previously mentioned research, we can see that the sports economic operation index prediction model based on deep learning and ensemble learning proposed in this paper has good results.

5. Conclusion

This article attempts to combine China's national conditions and the characteristics of large-scale sports events to construct an index system, which can diagnose and predict various service quality problems existing in the current events, and put forward constructive opinions. The improvement of the service quality of sports events can realize the faster and better development of the urban sports event industry, form a systematic and scientific sports event service quality evaluation system, and provide guidance for the holding of other large-scale sports series events. This article combines deep learning and ensemble learning to construct a sports economic operation index prediction model, evaluate the sports economic operation, and provide a reference for the subsequent development of the sports economy. Through experimental research, it can be known that the sports economic operation index prediction model based on deep learning and ensemble learning proposed in this paper has good results.

Aiming at the problems of the traditional industrial robot fault diagnosis model, such as low accuracy, low efficiency, poor stability, and real-time performance in multi-fault state diagnosis, a fault diagnosis method based on DBN joint information fusion technology is proposed. By studying the information processing method and the deep learning theory, this paper takes the fault of the joint bearing of the industrial robot as the research object. It adopts the technique of combining the deep belief network (DBN) and wavelet energy entropy, and the fault diagnosis of industrial robot is studied. The wavelet transform is used to denoise, decompose, and reconstruct the vibration signal of the joint bearing of the industrial robot. The normalized eigenvector of the reconstructed energy entropy is established, and the normalized eigenvector is used as the input of the DBN. The improved D-S evidence theory is used to solve the problem of fusion of high conflict evidence to improve the fault model's recognition accuracy. Finally, the feasibility of the model is verified by collecting the fault sample data and creating the category sample label. The experiment shows that the fault diagnosis method designed can complete the fault diagnosis of industrial robot well, and the accuracy of the test set is 97.96%. Compared with the traditional fault diagnosis model, the method is improved obviously, and the stability of the model is good; the utility model has the advantages of short time and high diagnosis efficiency and is suitable for the diagnosis work under the condition of coexisting multiple faults. The reliability of this method in the fault diagnosis of the joint bearing of industrial robot is verified.

1. Introduction

Currently, automated production is developing rapidly in the direction of automation and intelligence. More and more companies use industrial robots to replace traditional manual operations, which significantly improves production efficiency while reducing labour costs [1, 2]. In automated production operations, the division of labour among the robots in each segment is relatively straightforward, and the synergistic relationship is close. When a robot malfunction occurs, it will inevitably lead to problems in the whole operation process, which has a significant impact on the progress and safety of the operation [3–5]. Therefore, it is necessary to judge the operation status of industrial robots in advance and deal with the initial failure in time to avoid various safety hazards caused by robot failure.

Based on this, some scholars used different methods to complete the fault diagnosis of industrial robots. Verma and Simmons [6] established a plan of robot fault diagnosis based on discrete-time observers by designing observers. The method achieves the fault diagnosis of robot joints through the co-operation of detection and diagnosis observers, which requires a large amount of joint sensor information. Jaber and Bicker [7] collected the vibration signal of the working state of the robot, used the methods of wavelet transformation time-frequency domain analysis to analyze the fault signal of the robot under various working conditions, and realized the fault diagnosis of the robot. Capisani et al. [8] established a fault diagnosis model for robots using a sliding observer and applied it to the fault diagnosis of Comau robots. This method can accurately diagnose a single fault, but it does not perform well in diagnosing robots with multiple responsibilities. Long et al. [9] used sparse

hybrid autoencoder (SAE) and support vector machine (SVM) to build a basic fault diagnosis model by learning fault information posture dataset, which can better complete the diagnosis of different faults of multi-joint industrial robots. However, it is difficult to implement large-scale sample training, and the accuracy of multi-fault classification is not high. Shan et al. [10] presented a fault diagnosis method for rolling bearings based on variable mode decomposition (VMD) and backpropagation (BP) neural networks. The energy of each component is obtained by decomposing the time-domain signal of bearing vibration into an intrinsic mode function, and the point is input as a feature into the training of the BP network. A diagnostic model for VMD-BP is established. The bearing fault type diagnosis can be completed well, but the accuracy of diagnosis is not ideal due to the boundary effect and the impact of sudden signals.

With the deepening of fault diagnosis research, the fault diagnosis method based on DBN has achieved good results in mechanical fault diagnosis such as bearing, gearbox, and motor [11–13]. Therefore, taking the joint bearing of industrial robot as the research object and the vibration signal as the starting point, this paper constructs the fault diagnosis method of industrial robot based on DBN. At the same time, considering that the accuracy of information fusion conclusion of traditional D-S theory is not ideal, the fusion problem of high conflict evidence is solved by improving D-S evidence theory. Taking the output layer of the model as fault evidence, the conflict between sample evidence is analyzed by using the improved D-S fusion rules and decision rules. Finally, a fault diagnosis model based on DBN joint improved D-S is established to improve the recognition accuracy of the fault model. It is of positive significance to further improve the service life and operation safety of industrial robots.

2. Related Knowledge

2.1. Information Fusion Technology. Information fusion technology is a multi-level and multi-faceted statistical process in its essence by detecting and combining the estimation of multiple sources of data to obtain information that information fusion can use [14]. Unlike simple signal processing techniques, multi-source information fusion techniques are suitable for handling multi-modal and conflicting forms of data and can achieve different levels and conditions of information fusion [15]. Thus, it performs well in improving the real time and reliability of mechanical systems, increasing the detectability of mechanical systems, and reducing the uncertainty of mechanical equipment.

According to the different levels of fusion processing, information fusion is mainly divided into three groups: data layer fusion, feature layer fusion, and decision layer fusion. Among them, the feature layer fusion technology extracts the corresponding features of the sensor data based on the type of the original signal, fuses the resulting feature information in the feature layer, and after normalization, forms a single feature vector to finally complete the classification of information and realize the identification of faults. The fusion process is shown in Figure 1.

2.2. Deep Belief Networks. Deep belief network (DBN) is a kind of neural network that can perform the tasks of feature recognition, data classification, and generation well. The scalability of the network is vital, so it is widely used in machine learning. DBN framework adopts the restricted Boltzmann vector machine (RBM) structure, and the model consists of visible, hidden, and output layers. In the DBN model, any two adjacent layers can be considered one RBM structure. The number of neurons in the visible layer is consistent with the dimension of the input data, which is mainly responsible for receiving the data from the bottom layer and outputting the computation results to the hidden layer. The BP artificial neural network (BPNN) in the top layer of the network classifies the features. It combines some of the labelling information to fine-tune the network parameters backwards to obtain the optimal network model [16, 17]. The DBN structure is shown in Figure 2.

The probabilistic generative model used in DBN differs from the discriminative model of traditional neural networks. DBN uses probability generation models to build the joint distribution of data and labels, train the hidden and visual layers of the network layer by layer, update and optimize the weights between layers and transfer parameters continuously so that the entire network model can generate training data with maximum probability, mine the correlation between higher-order data, and realize the extraction, classification, and identification of fault feature data [18]. The neurons in the same layer of the network are independent of each other and connected with the neurons in the adjacent layer, which makes the network have good conditional independence, which improves the parallel computing ability of the network and dramatically improves the training efficiency. Taking the DBN containing two RBMs as an example, the network training process is shown in Figure 3.

The training process of DBN consists of two main phases: unsupervised pretraining and supervised reverse fine-tuning.

(1) *Unsupervised Pretraining.* Multiple stacked restricted Boltzmann machines form a deep Boltzmann machine, and the output of the previous RBM is the input of the next RBM. Two steps carry out the training process of each RBM: forward computation and reverse reconstruction, and the optimal parameters of each RBM are finally obtained after multiple iterations in different batches.

(2) *Supervised Inverse Fine-Tuning.* After the pretraining, the RBM extracts the original data features, then classifies them using the top-level classifier, and finally fine-tunes all parameters top-down using the BP algorithm in combination with the label information to finally obtain the optimal model parameters.

3. Fault Diagnosis of Industrial Robot Based on DBN

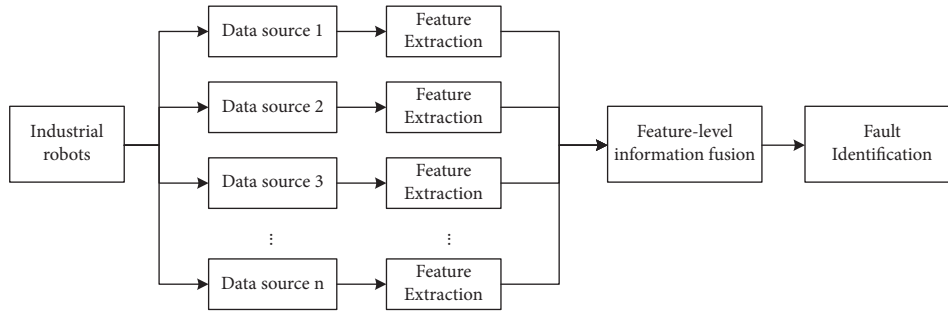
3.1. Vibration Signal Preprocessing. The signal collected by the sensor contains the vibration of the joint itself and internal and external noise and non-smooth interference


FIGURE 1: Feature layer fusion.
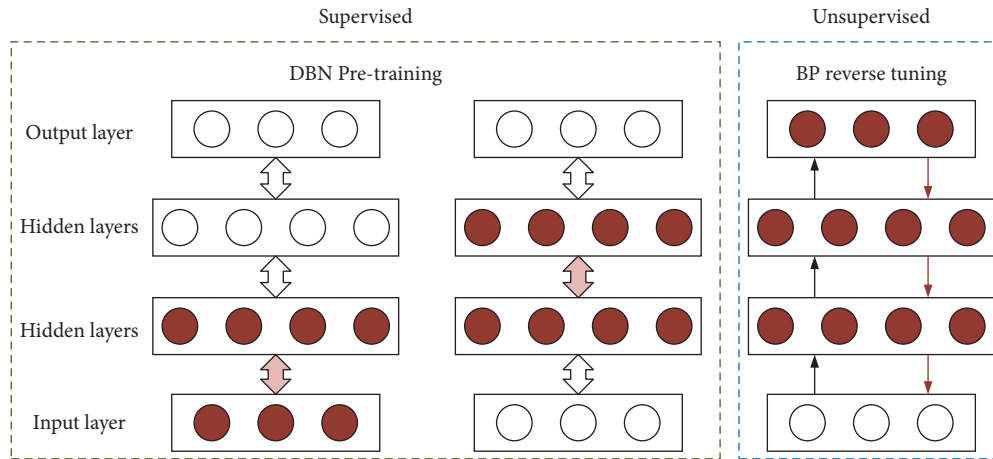
FIGURE 2: DBN structure.


FIGURE 3: DBN training process.

signals such as resonance signals, so the vibration signal needs to be processed for noise reduction for the next operation. Wavelet packet transform (WPT) can divide the signal in a multi-level form and decompose the high-frequency part in depth, adaptively select the frequency band according to the characteristics of the analyzed signal, ensure the frequency band and the signal spectrum match each other, and thus improve the time-frequency resolution [19]. Therefore, in this paper, wavelet packets are used to complete the noise reduction of industrial robot vibration signals. The wavelet transform process and decomposition process are shown in Figure 4.

The steps of noise reduction based on wavelet packet transform signal are as follows.

Step 1. Select the wavelet basis according to the decomposition level of wavelets and decompose the signal.

Step 2. Determine the optimal wavelet packet basis and calculate the optimal tree after the entropy criterion.

Step 3. Select an appropriate threshold value for the high-frequency coefficients at different decomposition scales and perform threshold quantization. The wavelet coefficients larger than the threshold value are
Figure 4: Wavelet transform flow and decomposition process.

considered to have signal generation and are retained; those smaller than the threshold value are deemed to be caused by noise and are set to zero, thus completing the purpose of noise reduction.

Step 4. Reconstruct the signal using the processed coefficients. The signal-to-noise ratio (SNR) and the root mean square error (RMSE) of the estimated signal and the original signal are often used to judge the merit of the denoising performance [20].

3.2. Energy Entropy Normalized Eigenvectors.

After the vibration signal is processed by wavelet transform, it is not suitable as the underlying input to the DBN due to the vast amount of information contained in the signal [21]. The signal's energy entropy normalized feature vector is further calculated, and the energy entropy normalized feature vector is used as the underlying input to the DBN model.

The energy entropy represents the measure of uncertainty [22]. It is defined as follows: if there is a system S containing multiple events $S = \{E_1, E_2, \ldots, E_n\}$ inside, each with a probability distribution $P = \{p_1, p_2, \ldots, p_n\}$, then the information of each event itself is

$$I_e = -\log_2 p_i. \tag{1}$$

The sum of the information entropy of all events in the whole system is the energy entropy, expressed as

$$E_s = \sum_{i=1} p_i I_e. \tag{2}$$

After the wavelet transform of the vibration signal, a total of 2^K nodes are reconstructed, and the energy entropy of each node is calculated to obtain a feature vector composed of 2^K elements. The energy entropy function is expressed as

$$E(u_K) = -\sum_J u_K \log(u_K). \tag{3}$$

The resulting energy entropy is normalized to [0, 1]. The energy entropy normalized eigenvector of the decomposed reconstructed signal is obtained as follows:

$$E(u_J) * = \frac{E(u_J) - E(u_J)_{\min}}{E(u_J)_{\max} - E(u_J)_{\min}}. \tag{4}$$

3.3. Improving Information Fusion with D-S Evidence Theory.

Dempster–Shafer (D-S) evidence theory is a kind of uncertainty inference, which effectively solves the influence of incomplete and uncertain information and other factors on the inference results by describing the uncertainty of the state of each part of the system from different perspectives and generalizing and estimating its probability. However, when the conflict between the evidence is severe, the traditional D-S theory information fusion accuracy is not satisfactory [23, 24]. To solve the fusion problem of high conflicting evidence, this paper uses the improved D-S evidence theory to complete the fusion of information to improve the identification accuracy of the fault model.

The inner vector product is added to the modification of the evidence combination rule. For any set of evidence, represented by a space vector, the average of each evidence vector is obtained by extending the evidence vector w to the n dimension as

$$\overline{w} = \frac{w_1 + w_2 + \cdots w_n}{n}. \tag{5}$$

The distance between each evidence vector and the average evidence vector is

$$DM = [c_1, c_2, \ldots c_n],$$
$$c_i = \frac{\sqrt{2}}{2} c(w_i, \overline{w}). \tag{6}$$

The similarity measure $Sw_i = 1 - c_i$ between two evidence vectors, i.e., the support of each evidence to evidence i, is calculated to represent the support of each evidence to evidence $Sup(w_i)$. Then, the weight $Crd(w_i)$ of evidence w_i is

$$\mathrm{Crd}(w_i) = \frac{\mathrm{Sup}(w_i)}{\sum_{i=1}^{n} \mathrm{Sup}(w_i)}. \tag{7}$$

By assigning a weighted average to the basic probabilities of each piece of evidence and then fusing the data, we can effectively solve the problem of conflicting evidence and further improve the accuracy of the fusion results.

4. Fault Diagnosis Model Based on DBN Joint Improved C-S Information Fusion

The DBN-based industrial robot fault diagnosis model is shown in Figure 5. The diagnosis model mainly contains the feature extraction part, DBN part, information fusion part, etc. Firstly, the vibration signal of the industrial robot joint is collected by the acceleration sensor. The wavelet packet transform is used to filter and reduce the signal's noise to avoid the deviation of the signal caused by the motion frequency and resonance frequency. The energy entropy normalized feature vector of the vibration signal is established using the information energy entropy theory. Secondly, the energy entropy normalized feature vector is divided into the training and test sets. The basic parameters of the DBN model are fine-tuned by unsupervised forward training and reverse supervised fine-tuning. The DBN model is constructed in this way. The output layer of the DBN model is used as the fault evidence for the evidence conflict factor analysis to check whether there is high conflict evidence, and the corresponding combination rules and decision rules are selected accordingly to realize the information fusion and complete the robot fault diagnosis.

5. Experimental Validation

5.1. Fault Dataset. The proposed method is used to construct a DBN classification model, and experiments are conducted to verify the effectiveness of the proposed method by acquiring vibration signals from the joint bearings of industrial robots. The experiments are shown on the Anaconda development platform running on the Windows 10 system as the base environment. The DBN deep learning model is built based on the Google deep learning framework TensorFlow.

Taking the FANUC Robot M-710C industrial robot as an example, set artificial fault on its joint bearing with $f = 12.5$ KHz frequency to collect collaborative vibration data. The data are divided according to the location and degree of the spot. Seven data types are obtained, including normal conditions and 350 sampled data points in each vibration cycle. Therefore, the original data of 7 categories are divided into 840 samples according to the window size, moving step of 1050 data points, and window moving step of 1050 data points to obtain the subseries sample space $R^{840 \times 1050}$, and each sample in the space is decomposed to calculate the time-frequency characteristics of each component to form a feature vector. According to the different fault categories corresponding to each feature vector, the category calibration is performed individually. The training and test sets are divided according to the ratio of 7 : 3. Table 1 shows the industrial robot joint bearings' fault data and category labels.

In the experiment, wavelet transform is used to reduce the noise of all data signals. Then, the energy entropy normalized feature vector and fusion features of the signals are calculated. The features' characteristics are analyzed, and finally, the different feature sets are input to the DBN-CS model for verification. Then, the fault diagnosis of industrial robot joint bearings is completed.

5.2. Experimental Results. Parameter setting of industrial robot fault diagnosis model is as follows: DBN network structure 128-100-36-7, network forward training is set to 100 times, and reverse optimization is set to 1000 times. The learning rate $\varepsilon = 0.05$, the momentum $m = 0.6$, the maximum number of iterations of the network is 50, and the training batch size is 100. Then, 180 rounds of training are carried out on the model using the training set, and the test set is used to verify the model's accuracy. The accuracy change curves of different sample sets are shown in Figure 6.

As shown in Figure 6, the accuracy rate increases with training rounds and stabilizes when the number of training rounds reaches 95. If we continue to train the data, it will not only not improve the accuracy significantly but also increase the computational time cost and even lead to the occurrence of overfitting. Therefore, the DBN model was tested after 95 rounds using the test set data, and the prediction results were compared with the actual category. Figure 7 shows the comparison between the predicted results and the actual categories.

In Figure 7, if the category labels obtained by the classification model overlap with the corresponding actual category labels, the classification result is correct; otherwise, it means that the classification fails. Of the 252 test samples, 5 were misclassified (points offset in Figure 7). Among them, one fault-free state was misclassified as outer ring light fault, two external ring light faults were misclassified as outer ring medium faults, one outer ring serious fault was misclassified as outer ring medium faults, and one inner ring medium fault was misclassified as internal ring light faults. To quantitatively analyze the accuracy of different fault classifications, the confusion matrix is used to represent the classification results of DBN on the test set, and the test statistics are shown in Table 2. The rows and columns in the table indicate the actual fault type and the diagnosed fault type, respectively.

To verify the stability and adaptability of the diagnostic model in the paper, the model is trained ten times with the same parameters, and the data are selected from the dataset without repetition as the training set and the test set in a random way to test the detection accuracy of the fault diagnosis model. The classification results are shown in Figure 8.

As can be seen from Figure 8, the diagnostic accuracy of the training set varies smoothly, with an average accuracy of 99.12%; the accuracy of the test set is lower than that of the training set, but the average accuracy still reaches 97.96%, which shows that the model designed in the paper has a high fault diagnosis rate and good stability. It is suitable for the diagnosis of joint bearings in multi-state coexistence.

5.3. Performance Comparison of Different Diagnostic Models. To make the industrial robot fault diagnosis models designed in this paper comparable, different fault

Figure 8: Accuracy of the experiment.

diagnosis models are constructed for testing with the same standard data, and the accuracy on the final test set is used as the evaluation criterion for model performance to verify the performance of the models in the paper. The fault diagnosis domain models involved are standard DBN, VMD + BPNN, VMD + SVM, EMD + DBN, and EMD + SVM models. The performance comparison results are shown in Table 3.

As can be seen from Table 3, compared with other algorithmic models, the diagnostic accuracy of the model designed in this paper is higher, and the standard deviation of the model is lower. Although the running time increases compared with VMD + SVM and EMD + SVM models, the increase is lower. It can better balance the relationship between diagnostic accuracy and real time to complete the fault diagnosis in complex fault states.

TABLE 3: Performance comparison of different fault diagnosis models.

Diagnostic models	Training set accuracy (%)	Test set accuracy (%)	Running time (s)	Standard deviation
DBN	87.34	81.66	61.63	0.0703
VMD + BP	92.72	86.58	39.17	0.0418
VMD + SVM	—	92.08	20.07	0.0658
EMD + DBN	90.21	86.17	48.55	0.0277
EMD + SVM	—	94.25	17.43	0.0491
The proposed method	99.12	97.96	23.46	0.0074

6. Conclusion

Taking industrial robot joint bearings as the research object, the problems of the current fault diagnosis methods are investigated by combining modern signal processing methods and deep learning theory. The accuracy rate is low when fault diagnosis is performed by the DBN alone, and it cannot meet real-time demand. Therefore, information fusion technology is combined to improve the performance of the fault diagnosis model to ensure the stability of the model and the accuracy of the diagnosis results. The experimental results show that the fault diagnosis accuracy of our method is higher than that of the traditional method and the average accuracy of the test set reaches 97.96%. The information fusion method with improved D-S evidence theory can effectively solve the evidence conflict problem and further improve the accuracy of the fusion results, suitable for handling the diagnosis of robot joint bearings under multiple fault states.

Class-Incremental Learning on Video-Based Action Recognition by Distillation of Various Knowledge

Vali Ollah Maraghi and **Karim Faez**

Department of Electrical Engineering, Amirkabir University of Technology (Tehran Polytechnic), Tehran, Iran

Correspondence should be addressed to Karim Faez; kfaez@aut.ac.ir

Recognition of activities in the video is an important field in computer vision. Many successful works have been done on activity recognition and they achieved acceptable results in recent years. However, their training is completely static, meaning that all classes are taught to the system in one training step. The system is only able to recognize the equivalent classes. The main disadvantage of this type of training is that if new classes need to be taught to the system, the system must be retrained from scratch and all classes retaught to the system. This specification has many challenges, such as storing and retaining data and respending training costs. We propose an approach for training the action recognition system in video data which can teach new classes to the system without the need for previous data. We will provide an incremental learning algorithm for class recognition tasks in video data. Two different approaches are combined to prevent catastrophic forgetting in the proposed algorithm. In the proposed incremental learning algorithm, two approaches are introduced and used to maintain network information in combination. These two approaches are network sharing and network knowledge distillation. We introduce a neural network architecture for action recognition to understand and represent the video data. We propose the distillation of network knowledge at the classification and feature level, which can be divided into spatial and temporal parts at the feature level. We also suggest initializing new classifiers using previous classifiers. The proposed algorithm is evaluated on the USCF101, HMDB51, and Kinetics-400 datasets. We will consider various factors such as the amount of distillation knowledge, the number of new classes and the incremental learnings stages, and their impact on the final recognition system. Finally, we will show that the proposed algorithm can teach new classes to the recognition system without forgetting the previous classes and does not need the previous data or exemplar data.

1. Introduction

Recognition of human activity in the video has many applications, such as human interaction with computers, surveillance systems, and monitoring of human behavior in industrial environments. Approaches based on deep learning have reported excellent results in recognizing activity, especially human activity. But using these methods in real and dynamic environments such as urban space, wildlife, and industrial environments faces challenges. Because it is always possible to see new activities that the existing recognition system has not already seen, in this case, there is a need to update the system constantly.

Deep learning has significant achievements in terms of recognition and classification [1–3], but it also has some constraints. Training a model with a deep learning approach requires many annotated data and computational resources due to its increasing depth and complexity. Most successful methods restrict the batch setting: data are provided before training; hence, optimizing metaparameters and model selection is usually based on a complete dataset. Also, the training can rely on the assumption that the data and its underlying structure are static. But this is contrary to real-world scenarios. In the actual situation, training data is not available for all classes initially, and the number and nature of classes are not necessarily clear. A classification system in real environments should learn new classes incrementally when their training data becomes available and, of course, does not undermine the recognition of previous ones. But the main problem is that training a neural structure using

only new classes' data leads to forgetting previous classes, called catastrophic forgetting.

On the other hand, training a system from scratch to learn new classes faces challenges, including the high cost of training, storing previous class data for future training, and perhaps privacy restrictions for maintaining some data. So, as computer vision moves closer towards artificial intelligence, more flexible approaches are needed to handle the large-scale and dynamic situation more felt. The purpose of this work is to learn new categories to model without the need for previous data and without reducing the model's performance about previous classes, known as class-incremental learning in literature.

This paper provides a class-incremental learning method for recognizing human action in video data. The base model is an RNN-based deep neural structure, given the achievements of deep learning in classification, that should learn human action classes in video data. Class-incremental learning for RNN-based deep structures has rarely been done. The proposed method combines two common approaches in incremental learning (network sharing and network knowledge distillation). Using the proposed algorithm, we will show that new classes can be taught to a human action recognition system without data from previous classes. Of course, the system's overall performance will not be greatly impaired. We propose the distillation of network knowledge in two levels of classification and feature. The feature section can be decomposed into two sections of distillation of temporal and spatial features. We also proposed using Temporal Segment LSTM (TS-LSTM) for the temporal representation of the video instead of the usual use of LSTM. This technique helps to better temporally represent the video and improve the recognition system's performance. The proposed method will give comparable results to exemplar-based methods without the use of exemplar data. Meanwhile, in the Related Works section, we show that the class-incremental learning of action recognition in video is rarely done without the exemplars. We evaluate the proposed algorithm and compare it with other methods based on exemplar data, and we show that the proposed method has performed better. Under similar conditions, the recognition accuracy has improved by almost 8% and 6.5% compared to the existing methods on the UCF101 and HMDB51 datasets.

The innovation of this work is in three cases: first, network distillation at classification and feature levels, where distillation at the feature level is done separately for spatial and temporal features, second, providing class-incremental learning in video data without storing data or exemplars, and third, initializing new classifiers using previous classifiers to learn new classes faster and better. Also, our base model is an RNN-based structure, and other existing methods are not effective for these structures.

In the rest of the paper, we review some related works in Section 2. The proposed algorithm is presented in Section 3. We present the experimental results and evaluations in Section 4, discuss results in Section 5, and conclude the paper in Section 6.

2. Related Works

2.1. Incremental Learning on Video Data. Class-incremental learning means that a classifier architecture can accommodate new classes at any time during the training process without requiring access to all training data seen so far. The minor works in incremental learning in video data are almost related to domain-incremental learning [4]. Class-incremental learning to recognize human action in video data is suggested using a recursive-tree structure [5], which adds one class to the tree as each new class's data is added.

In deep learning, very little work has been done on class-incremental learning in video data, especially on action recognition in video. The adaptive RNN tree is proposed for large-scale action recognition, adapted to new classes by augmenting an existing model [5]. The ODN (Open Deep Network) [6] detects new categories by applying a multiclass triplet thresholding method and dynamically reconstructs the classification layer. It opens the deep network by continually adding predictors for new classes. The weights of the new classifiers are initialized from the average weights of the previous classifiers. The new model is fine-tuned using both new and old samples. The goal is to reduce the training energy from scratch and still require previous data. A temporally attentive knowledge distillation method is presented, which distills the network knowledge over the network and intermediate layers and uses it to prevent catastrophic forgetting [7]. Importance weights are estimated during training, and knowledge is distilled from these importance weights during incremental learning. This method also uses the storage of exemplar data for use in incremental learning. To improve the performance of incremental learning based on network distillation, the spatial-temporal feature decomposition into two parts, spatial and temporal features, is presented [8]. A dual granularity exemplar selection method is proposed to select exemplar data from previous classes for use in incremental learning [8].

As mentioned, little work has been done on incremental learning in video data. The exemplar data storage of previous classes is also usually used. On the other hand, the deep structures used for classification tasks in a single image are similar to video classification's deep systems. Therefore, catastrophic forgetting is a common phenomenon in the image and video domains. So, reviewing incremental learning in single images can give us a better insight into this issue.

2.2. Incremental Learning on Image Data. Mensink et al. [9] showed that the nearest class mean (NCM) classifier could do so. NCM represents each class by the average feature vector of all examples observed for the class so far. NCM has performed well for incremental learning and is more robust than other standard parametric classifiers [9–11]. The prototype-based classification idea of NCM was adapted for incremental classifier and representation learning (iCaRL) [12] where the average vector is computed only over a specifically chosen subset of all examples. The dilemma of

prototype-based methods deals with complex classification problems, where the number of classes increases and their nature becomes more complicated.

The recent success of deep neural networks can be mainly attributed to their suitable data representation [13–16]. The main problem in learning representation in the incremental learning mode is catastrophic forgetting, introduced by McCloskey and Cohen in 1989 [17]. Training a neural network with new data causes the previous data to be forgotten. Inspired by the idea of transfer learning [18], the previous model's knowledge can assist in learning new related classes. It has been shown that the features extracted in the lower layers of CNNs are general, which can be used in various domains, similar to Gabor filters and edge or corner detectors [19]. In contrast, the extracted features from the end layers are more abstract and specific for a class. This feature of CNNs is the basis of the transfer learning and partial sharing approach for incremental learning [20].

Much of what has been done recently for incremental learning in neural networks is based on the freeze/growth scenario [20–22]. Splitting the base network into various subnetworks and creating a tree structure are proposed to incrementally learn the new classes [23, 24]. An adaptive hierarchical network composed of DCNNs is proposed for incremental learning that grows and learns as new data becomes available [25]. In [26], the Bayesian transfer learning algorithm is proposed to avoid retraining the whole model from scratch. Selecting a portion of the initial exemplar data and storing it for training new classes are also provided to prevent catastrophic forgetfulness [12, 27, 28]. This scenario requires additional resources to store exemplar data. Using the generative adversarial networks (GANs) to create fake data is proposed [29, 30]. This approach eliminates the need for additional resources to store data but leads to additional training GANs. A method based on bias correction is proposed to solve the educational data unbalancing issue [31].

Network knowledge distillation has been used to reconstruct previous classes' features and train new classes to solve the catastrophic forgetting problem [32, 33]. In [32], the input is given to the previous model to extract the previous classes' information in the input image. The model responses to inputs are used as the ground truth for old classes during training the new classes to the system [14]. Castro et al. [34] proposed that, to train the new class, use network knowledge distillation to calculate the output of prior categories and generate a set of logits. These logits are then used to calculate the loss in training new classes to force the network to retain information from previous classes. An attentive feature distillation approach was proposed to distill necessary knowledge using both top-down and bottom-up attention for incremental learning object detection [35]. Incremental learning in the semantic segmentation of objects is also proposed with the same approach [36]. This approach is also used for incrementally object detection tasks [37] to train the class of new objects.

A review of related work suggests that if the main goal is to classify with one output class for each input, the appropriate approach is network sharing or storing and reproducing some of the data from previous classes [12, 20–24, 27–30]. For tasks with multiple outputs per input, such as multiple object detection, the use of network knowledge distillation may be a good approach, given the possibility of having information about multiple classes in a single input [35–37].

3. Proposed Approach

The purpose of this work is class-incremental learning for action recognition in video. A review of related work showed that the appropriate approach for class-incremental learning in single-output tasks is network sharing or storing and reproducing some of the data from previous classes [12, 20–24, 27–30]. The network distillation approach is more suitable for tasks where the input includes multiple classes, such as multiple object detection and multiclass segmentation. The new class data may consist of parts of some previous classes in these cases. So, the distillation network distills the information about those classes, which helps preserve previous network information in new training. However, these conclusions are for single-image data and may not be entirely valid for video data.

Our work is to recognize the action in the video, which is a single-class classification task. A specific action may consist of several subactions, some of which may be present in other activities. The way action recognition algorithms work in video is usually that first low- and high-level features are extracted from video frames (usually by a CNN). Recursive structures represent the temporal dependence of these features, and, finally, the classification is based on this representation. The extracted features in the first step are abstract visual features, and, due to a large number of frames in the inputs, the feature extraction module becomes general. In other words, the feature extraction module obtained from the training of the early classes also can extract the appropriate features from the data of the new classes. Therefore, the network sharing technique can be used for incremental learning in this work.

As mentioned, an action consists of its various components, including various subactions and abstract properties. The feature extraction module obtains abstract features in the first step. Subactions and their combinations are calculated to represent the action by recurrent structures in the second step. A new action may contain components that already exist in previous classes. Therefore, if a new action class data is applied to the model, the recurrent section may also represent different components of previous actions. In this case, the previous network information can be distilled using network distillation. Thus, although this is a one-class classification task, the network distillation approach can also be used for class-incremental learning.

3.1. Class-Incremental Learning. Our main goal in this work is to apply class-incremental learning to recognize the action in the video. Our proposed algorithm combines two approaches: network sharing and network distillation. After training the basic model with the data of some classes, it is

assumed that the feature extraction section (CNN) can extract appropriate properties of other classes. Therefore, the feature extraction module is fixed (frozen) for subsequent training efforts. This trick implements the concept of network sharing.

Distillation of network knowledge is the extraction of information learned from the network and applying this information to the network during incremental learning to prevent forgetfulness. In fact, the previously taught model as a teacher controls training the new model (student) not to forget the previous information. The teacher model is not updated during incremental learning. Distillation of network knowledge can be applied at the classification level (probabilities generated by the classification layer) or at the feature level (feature maps obtained in the middle layers). In a simple knowledge distillation algorithm, only the output of the classification layer is used to extract network knowledge and remind it in incremental training. In this case, the student network tries to preserve past information by reproducing the values generated by the teacher model. The last layer classifiers generate a probability for each class for each video input. Before new training, these probabilities are first calculated for the new class input, and, during the new classes training, the previous classifiers are forced to reproduce the previous probabilities. Therefore, when training the student model to train the new classifiers, the previous classifiers retain previous knowledge by being forced to reproduce their corresponding values in the teacher model. The task of preventing the forgetting of past knowledge in these circumstances is the sole responsibility of the classification layer.

But the information recorded in the network is available throughout the network. By extracting this information and reminding it to the network, it is possible to help preserve the network knowledge in new learning [7, 8]. In this situation, the teacher model controls the training of the student model throughout the model, not just in the classification portion. The feature maps obtained from the middle layers in 3D neural structures for video representation form a tensor with $T \times H \times W$ dimensions. This tensor contains spatiotemporal information obtained from video, including spatial information in dimensions H and W and temporal information in dimension T [8]. Separating spatial information and temporal information and distilling them has been shown to help improve incremental learning performance [8]. Pooling in temporal and spatial dimensions must be performed to decompose the tensor containing spatiotemporal information into spatial and temporal parts, respectively.

In our case, the model used to recognize action from the video is an RNN-based deep structure described in Section 3.2. In this type of structure, spatial features are first extracted at the frame level, and then temporal relations are represented by a recurrent part. Figure 1 shows this process. Therefore, spatial information is available separately from temporal information at the end of the first section (convolutional feature extraction module in Figure 1). Temporal representation is also available at the output of the recurrent part (LSTM module in Figure 1). Therefore, no process is required to parse spatial and temporal information.

According to the above, the network knowledge distillation technique is used to apply incremental learning by controlling the training of the student model by the teacher model. This control is applied at three levels: classification layer, spatial features, and temporal features. Figure 2 shows this control. Therefore, the knowledge of the network is distilled at three levels of classification, spatial characteristics, and temporal characteristics.

$$L_{cD} = \sum_{f=1}^{F} \left(-\frac{1}{N} \sum_{i=1}^{N} \sum_{j=1}^{C} \widehat{p}_{ij} \log \widehat{q}_{ij} \right), \tag{4}$$

The technique of distillation network knowledge and applying it during incremental learning is done by calculating the loss function and backpropagating it. The base network is trained using the common cross-entropy classification loss function (L_{cl}). The loss function in the incremental learning phase (L_{inc}) consists of two parts, one part related to classification and the second part associated with knowledge distillation. As for the base model training, the first part is a cross-entropy loss function (L_{cl}) and the second part is a distillation loss function (LD).

$$L_{inc} = L_{cl} + \gamma LD, \tag{1}$$

where γ is hyperparameter. The cross-entropy loss (L_{cl}) is as follows:

$$L_{cl} = -\frac{1}{Ns} \sum_{i=1}^{Ns} \sum_{j=1}^{C} p_{ij} \log q_{ij}, \tag{2}$$

where p_i is the grand truth for sample i and q_i is a softmax score of the logits of a classifier for sample i. Ns and C denote the numbers of samples and classes, respectively. The distillation loss function (LD) used to maintain previous classes consists of two parts, classification and feature:

$$LD = L_{cD} + \propto L_{fD}, \tag{3}$$

where L_{cD} and L_{fD} are the classification distillation loss and the feature distillation loss, respectively. The classification distillation loss is as follows:where $\widehat{p}_i$ and $\widehat{q}_i$ are the modified versions of p_i and q_i, which are obtained by raising p_i and q_i to the exponent $1/T$, as described in [38], where T is the distillation parameter. Distillation loss is calculated for all F previous classes. Choosing $T > 1$ forces the network to learn a more fine-grained separation between classes. This parameter is set to 2 for all experiments. Feature distillation loss can be calculated as fused spatiotemporal or separately in two parts: spatial and temporal. Due to the superiority of separate spatial and temporal distillation and separate access to these two features, we use separate distillation. So the feature distillation loss is formulated as follows:

$$L_{fD} = L_{tfD} + \beta L_{sfD}, \tag{5}$$

where L_{sfD} and L_{tfD} are the spatial and the temporal terms of the feature distillation loss. These losses are calculated as follows: the Euclidean distance between the features taken from the base model and the model under training.

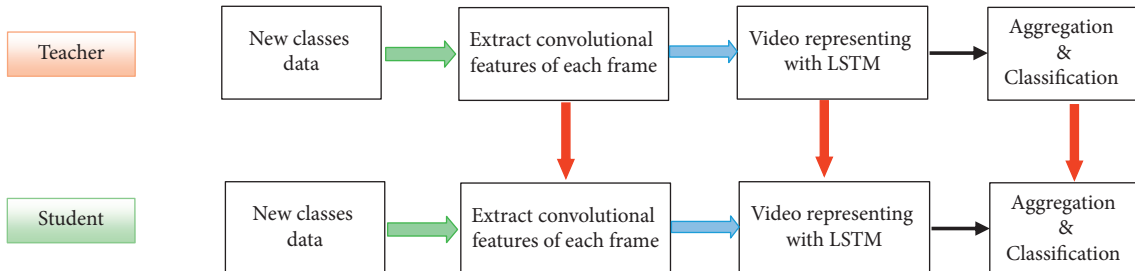
FIGURE 1: Block diagram of the process in each processing stream. At first, the convolutional features of each frame are extracted. Then, the whole input video is represented by the LSTM block. Finally, the elements are aggregated.


FIGURE 2: Control of student model training by teacher model at three levels of classification, temporal features, and spatial features. The teacher model is not updated during training the student model.

$$L_{fD} = \sum_{i=1}^{F} f_{ib} - f_{in}^{2}, \qquad (6)$$

where f_{ib} and f_{in} are the features obtained from the base model and new model, respectively.

So, the overall loss function formed as follows:

$$L_{inc} = L_{cl} + \gamma \left(L_{cD} + \propto \left(L_{tfD} + \beta L_{sfD} \right) \right). \qquad (7)$$

Therefore, the proposed class-incremental learning algorithm is as follows:

(i) A human activity recognition system is taught from scratch to recognize the initial classes. This trained model is used as the teacher model for the next training.

(ii) The new model (student model) is created by sharing the base model and adding classifiers for new classes.

(iii) The feature extraction module of the base model, except two last layers, freezes and is not updated during incremental learning. This work is derived from network sharing approaches.

(iv) The student model is taught using new class data under the supervisor of the teacher model. During this training, knowledge distillation is done by supervising the teacher model by calculating the loss function according to (7).

(v) The new taught model will be used as the teacher model for future training. In other words, the subsequent incremental learnings are done from step (ii) onwards.

We introduce an excellent neural structure for action recognition in video data in the following.

3.2. Action Recognition System.
An important feature of video data is temporal information in the video that can efficiently represent the video and identify the target class.

But what is the best way to exploit time information? Many previous methods, which follow a two-stream ConvNets [39], use optical flow images to take advantage of temporal information in one of the processing streams [40–44]. In these methods, visual appearance in spatial and temporal flows and their relationship are not considered, which is one of the essential components in activity recognition tasks. Therefore, they will not perform well for these tasks.

Therefore, we can consider a three-stream structure that the first and second streams process on RGB images, and the third stream includes the processing of optical flow images. This three-stream structure was previously introduced for action recognition in the video [45] and modified for verb recognition through zero-shot learning on human-object interaction (HOI) recognition [46]. We use this structure as a base model to investigate the proposed class-incremental learning algorithm. The operation of this structure and each of its three streams is described in full detail in [45]. We briefly introduce it below. Each stream has three main processing steps shown in Figure 1. The processing flows of the three streams are almost similar.

Patch-Based Representation. Activity-related areas are first estimated in each RGB frame in this processing path. These action patches are then used to extract the convolutional properties of each frame. The extracted feature map is given to the LSTM block to represent the temporal relationship. The resulting output vectors are aggregated to form the final representation vector for estimating the action class.

Focal Representation. In this path, the activity-related area is first estimated (like as first path), the other regions are blurred, and a new RGB image is obtained. The convolutional properties are extracted from each frame's resulting image, and the process's continuation is the same as the first stream.

Motion Representation. Short-term information in a video clip can be represented by optical flow. The RNN block can obtain long-term information. Therefore, the

third path can represent motion with optical flow. The convolution properties of each frame are extracted from the optical frame by a CNN network. The next steps are exactly like the other two streams.

The long short-term memory (LSTM) module is used as RNN to temporally represent the video. The LSTM module does the representation of the temporal relationship in the video. The extracted per frame CNN features are split into k-frame chunks in each input video and fed to the LSTM module. Each chunk fed to the LSTM module contains feature maps extracted from F/k consecutive frames of input video, where F is the total number of input frames and k is chunks number. Next, the LSTM outputs are fed into a densely connected feedforward neural network with a Softmax output layer, giving each chunk the probability of belonging to each C-action class. These probabilities are added for all chunks of each video to predict the class. The direct use of LSTM to consider temporal information is only similar to simple temporal pooling methods, such as mean or max pooling, due to the limited temporal dynamics of representing ConvNet-derived features [47]. It is shown that the features obtained from the frames of a video have similar representations [47]. Because a large portion of the video has the same feature representations over time, RNNs cannot learn the temporal information well. In the TS-LSTM method [47], the input sequence is divided into several temporal chunks, and their distinctive feature representations are learned. Each video is sampled into N frames and divided into M chunks. The features extracted from F input frames are split into F/k chunks. Temporary pooling is performed on each chunk, and then the pooled features of all chunks are fed to the LSTM module to represent the entire video. The output of this module will be used for recognition in the next dense layer. The TS-LSTM module learns the nonlinear feature combination and its segmental representation over time.

We substitute this TS-LSTM technique for the primary three-stream structure technique. The direct technique uses LSTM to represent each chunk typically, performs a recognition for each, and then sums the recognition results of all the fragments. The TS-LSTM technique, unlike the direct technique, uses all the video space for recognition, which will improve system performance. Due to the temporal pooling in each chunk, the total computations for recognizing a video are also reduced.

The results of the three introduced streams are merged to recognize the input video action class. The integration is as follows: A score is given to each class by a dense network in each stream. The total score of each class is calculated by summation of its scores in three streams. The class with the highest score is the recognized action class.

3.3. Initialization of new Classifiers.
Creating a new model (student model) for incremental learning is done by sharing the teacher model and adding new classifiers related to new classes. The initialization of the weights of these new classifiers is usually done randomly. Thus, in the created student model, the weights of the new classifiers are without any

initial training, while the previous classifiers are fully trained. To solve this imbalance, initializing the weights of the new classifiers with the previous weights can be helpful. The use of previous weighted averages to initialize new classifiers is proposed to reduce the learning time in the continuous training of categories for the open-set problems [6]. This work is not intended for class-incremental learning without the previous data and only makes learning the new model faster with more classes. Due to the nature of human action, which can consist of several subactions, using the information in the previous classifiers to initialize the new classifiers makes it easier to train and converge them.

We use this trick to initialize the weights of the new classifiers. Of course, we do not recommend the average of all the weights of the previous classifiers. It is best to use the average of the most similar classifiers for each new class. By feeding the data of each new class to the teacher model, the classifiers that produce the biggest probability for the input data are likely to be the most similar classifiers to the new class. Therefore, by estimating the most similar classifiers, the new classifier weights are initialized with the average of these weights as follows:

$$W_{N+1} = \frac{1}{M} \sum_{i=1}^{M} W_i, \tag{8}$$

where M denotes the M similar classifiers. The weights of the new classifier are denoted by W_{N+1} and W_i denotes the weights of previous classifiers (from the teacher model).

4. Results and Experiments

We present the results of our method in this section and compare them with those of some other class-incremental learning methods and the static training mode (training all classes to the model in one stage). Our proposed algorithm does not use exemplar data storage. At the time of doing this, there was no other similar method for comparison. Therefore the performance of the proposed method was compared with those of incremental learning methods based on exemplar data storage.

4.1. Datasets.
For human action understanding in videos, several appropriate datasets have been provided and published, such as UCF101 [48], HMDB51 [49], and Kinetics-400 [50]. We evaluated our method using the HMDB51, UCF101, and Kinetics-400 datasets.

HMDB51 includes 51 action classes with 6766 videos collected from various sources. There are three training/test splits, like the setting in [45], and, in each evaluation stage, the mean average accuracy is reported.

UCF101 consists of 101 action classes, 13k clips, and 27 hours of video data. This dataset contains the user's uploaded videos, including camera motion and cluttered background. The videos of each category are grouped into 25 different groups based on some characteristics such as environments and camera movement. The dataset is separated into three training/test splits; in each split, 18 groups are used for training and seven groups for testing.

The third dataset is Kinetics-400, a large-scale video classification dataset containing 400 human action categories. Kinetics-400 is a YouTube-type video dataset that provides 240k and 20k 10-second videos for training and validation, respectively.

4.2. Implementation Details. The recognizer system has three streams: two spatial streams and one temporal stream. The two spatial CNN streams use an AlexNet architecture pretrained on UCF sports. The first stream inputs are the estimated action patches, and the proposed focal representation is fed for the second stream. For the 3rd stream as motion representation, we used the CNN network like the network architecture used by Wu et al. [31]. This motion-CNN is pretrained on the optical flow images of UCF sports. There are many options for generating optical flow images. The two most common methods are Brox [51] and TV-L1 [52], in which TV-L1 performed slightly better based on the evaluation in [47]. So, TV-L1 is used as input for the temporal stream.

The FC7 layer of three CNNs extracts a 4096-dimensional feature vector for each input video frame. After obtaining feature vectors for all F frames of the input video in three CNNs, these feature vectors are used by the RNN module for temporal representation. For the RNN module, an LSTM block with 256 hidden units is used. Two FC layers, respectively, with the number of neurons equal to 256 and the number of action classes, are used as a classifier in each stream.

For training the base model with initial classes, the learning rates are initially set to 5×10^{-6} for two spatial streams and 5×10^{-3} for temporal stream. These learning rates are divided by 10 when the accuracy is saturated. The weight decay and momentum for all ConvNets are set to 1×10^{-4} and 0.9, respectively. The batch sizes for all ConvNets are 8. The LSTM module is trained with an Adam optimizer and learning rate of 5×10^{-5}.

The size of the input images is 224×224 for all streams. The number of sampled frames in each video is $N = 24$, and the number of temporal segments is selected as $M = 6$.

4.3. Experimental Results. In class-incremental learning scenario, To evaluate the proposed method, we follow the strategy used in [7]. First, the base model is trained with initial classes, and then the other classes are incrementally trained to model. For this purpose, all classes are sorted randomly, 50% classes (51 classes for UCF101 and 26 classes for HMDB51) are used to train the base model, and the remaining classes are used for incremental learning. The remaining 50 classes of the UCF dataset are taught to the model in 5 steps of 10 classes, ten steps of 5, and 25 steps of 2 in incremental learning. For the HMDB dataset, the remaining 25 classes are taught to the model in 5 stages of 5 classes and 25 stages of 1 class in incremental learning. Because the nature of the classes affects the result, these experiments are performed three times with randomly ordered classes. The model's classification accuracy is calculated on the seen classes in each step, and its average value is calculated.

The initialization of new classifiers is performed according to (8) with $M = 5$. First, the five most similar classifiers are calculated by calculating the teacher model's output on the new class's data for each new class. Their average weights are calculated and set as the initial values of the new classifier weights.

We test three scenarios for class-incremental learning based on using distillation knowledge and how much network sharing. These three scenarios are summarized in Table 1. The type of used distillation is depicted in the fourth column where cD represents distillation at the classification level and tfD and sfD represent distillation at the temporal and spatial features, respectively.

We train the model with the first available classes in experiments with the first scenario settings (3Stream-D). Then, the feature extraction module and the LSTM block are frozen, the classifiers corresponding to primary classes are discarded, classifiers for new classes are added, and the model is trained for new classes. During the training of new classes, only the new classifiers are taught. This experiment is just a network-sharing technique, and there is no distillation.

For the second scenario, as in the first scenario, the base model (teacher) is first trained for the primary classes. The student model is created by sharing the teacher model and adding the new classifiers. In this scenario, during incremental learning, the trained classifiers of the teacher model are not discarded. ConvNets is frozen in all streams. The distillation type is only a classification distillation. In other words, in (7), the alpha parameter is equal to 0.

The third scenario is similar to the second scenario and uses network knowledge distillation, except that, in this scenario, the distillation loss is calculated by classification and temporal features distillation. This increases the control of the teacher model on the student during incremental learning. In this case, spatial distillation is not used, and $\beta = 0 \propto$ in (7), while $\propto > 0$ is used.

Table 2 shows the class-incremental performance on UCF and HMDB datasets and compares the above scenarios with three other methods. The TCD [7] is proposed for video data, but UCIR [53] and PODNet are proposed for image datasets that are evaluated for video in [7]. All these three methods use exemplar data storage for incremental learning. The proposed algorithm does not use exemplar data. Still, for better comparison with the compared methods, the performance of the proposed method using exemplar data is also tested and is reported in Table 2.

The results of Table 2 show the efficiency of the proposed algorithm. The proposed algorithm has a much higher performance than other methods if it uses exemplar data. If exemplar data are not used, the proposed algorithm still performs better or is similar to the compared methods. Of course, part of this better performance is due to the structure used, which in static learning mode is more accurate than the compared methods. In other words, the accuracy of the used model before applying incremental learning is better than the compared models at the same time. However, Figure 3 shows that the rate of accuracy drop is acceptable by

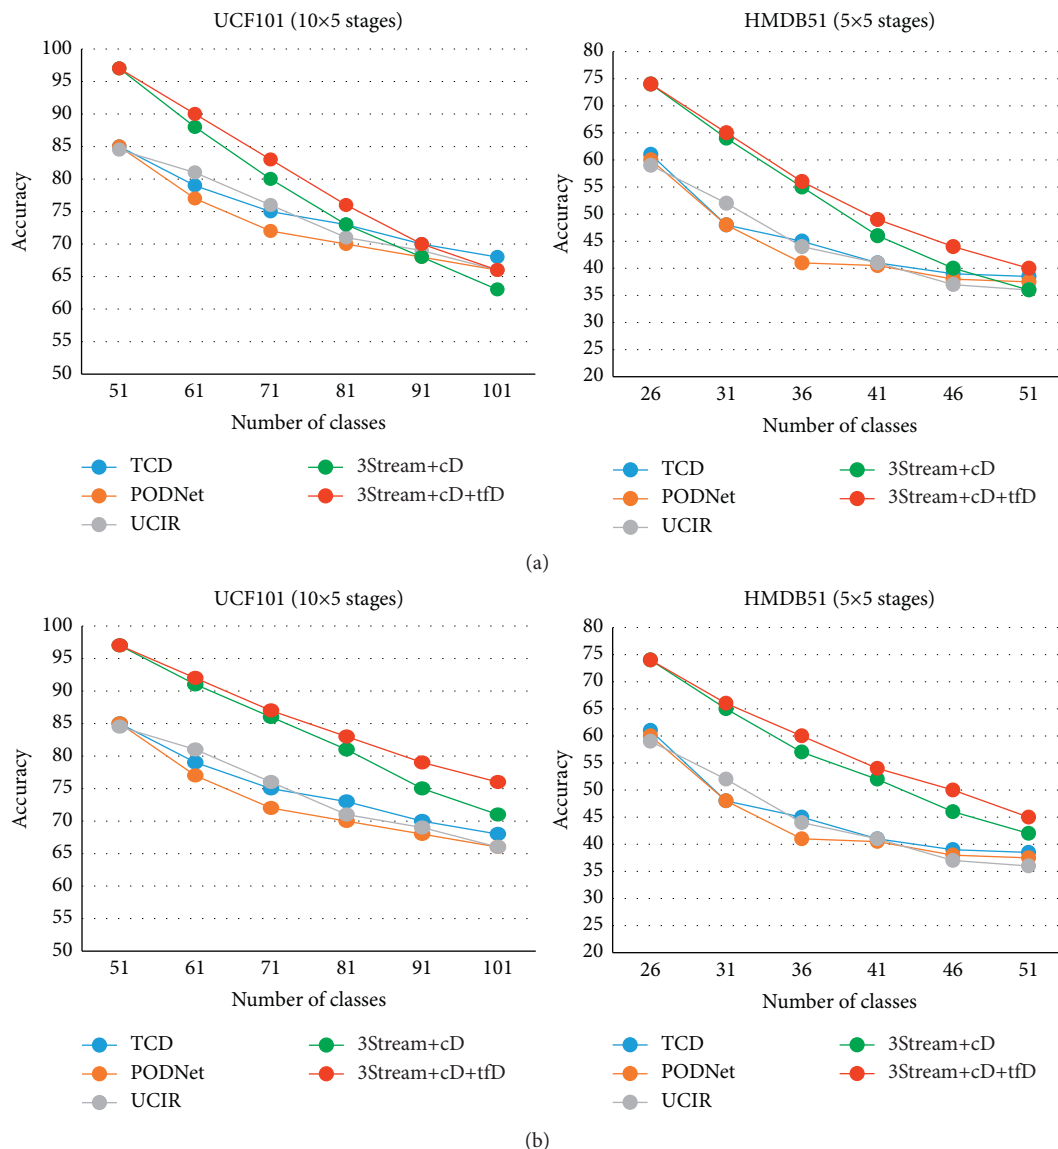

FIGURE 3: Accuracy chart in terms of incremental learning step. The top row does not use exemplar data for the proposed method, but, in the bottom row, the proposed method also uses exemplars. Compared methods use exemplar data in all cases. (a) 3Stream methods without using exemplars and (b) 3Stream methods use exemplars.

applying incremental learning despite not using the previous sample data. The curves in Figure 3 show that the final model obtained by the proposed algorithm performs better than other methods if the exemplar data are used. Also, if exemplar data are not used, the performance of the final model is acceptable compared to exemplar-based methods.

For the first scenario (3Stream-D), a large part of the network (ConvNets and LSTM) is frozen. Just the parameters of classifiers are updated, so the network learning capacity is reduced. Hence, the model's accuracy on the new classes is not very high. In the final model, the extractor modules and the primary classifiers have not changed during incremental learning, and the accuracy on the primary classes has been high. Still, in the final model, the classifiers related to the primary and secondary classes have not been trained relative to each other. If the model with all classifiers is considered, the error rate increases, and therefore the overall accuracy is not very high.

For the second scenario (3Stream + cD), the base model is precisely the same as the first one. The accuracy of the final model on all classes is increased. This improvement is because network knowledge distillation has been used, and primary classifiers have been updated against new classes. Updating the LSTM block probably reduces the model accuracy on the initial classes after incremental learning. Still, due to the distillation of network knowledge, this performance reduction is not expected to be very large. Of course, it should not be forgotten that this performance improvement is in exchange for a slight increase in training energy during incremental learning. However, the energy of the error backpropagation in the recursive structures is much less than that of the convolutional structures, and, due to the freezing of the convolutional parts, the training energy is much less than that of the static training. More control of the teacher model over the training of the student model in the third scenario (3Stream + cD + tfD) causes the previous information to be less affected by the new information, and the accuracy of the model decreases less.

4.3.1. Evaluation for Large Dataset.
The above tests and evaluations were performed on the common UCF101 and HMDB51 datasets. Still, these two datasets do not have a large number of classes, and a larger dataset is needed to conclude situations with a large number of classes. The Kinetics-400 dataset is a large dataset that contains 400 action classes. The evaluation of the presented algorithm on this dataset can be useful for examining conditions with a large number of classes. However, since other methods have not been evaluated on this dataset and their performance has not been reported, we evaluate the results only with the proposed method and the degree of the models' accuracy with incremental learning steps.

In this case, 300 classes have been randomly selected and used to train the base (teacher) model. The remaining 100 classes are taught in incremental learning in various steps to the model. The final models of incremental learning results are also compared with the results of static training in which all classes are taught in one step. The experiments were performed three times, and the average results were reported. Table 3 shows the evaluation results of the proposed method on this dataset.

The important columns in Table 3 are the results of the final models and their comparison with the base model and the static mode training. These results show that the use of knowledge distillation outperforms network sharing methods. Also, the knowledge distillation from different levels of the network reduces the attenuation of the model and increases the final accuracy. Reducing system performance is reasonable if the exemplar data are not used, but, given the knowledge distillation, the accuracy of the final model is not disappointing. Also, the results of Table 3 show that the number of incremental learning stages and the number of classes in each stage affect the performance of the final model. In general, the fewer incremental learning stages and the fewer new classes added to the model in fewer stages, the better the performance of the final model.

4.3.2. Effect of Initialization.
To initialize the new classifiers, we propose using the average weights of the most similar old classifiers. In this experiment, we evaluate the effect of this technique on system performance with equal epochs in training. We used the UCF101 dataset for this evaluation. Table 4 shows the recognition accuracy of the final model.

The results of Table 4 show that using the average weights of the most similar classifiers to initialize the new classifiers makes the final performance of the model better than the random initialization mode in equal training epochs.

4.3.3. Spatial Features Distillation.
In experiments performed so far, we have not used distillation of spatial features, and we have used distillation at the level of classification and distillation of temporal features. Here we also evaluate the impact of using spatial features on incremental learning. The exemplar data are not used in incremental learning. The results of recognition accuracy are reported in Table 5.

As expected, the results of Table 5 show the positive effect of spatial feature distillation on the system's final performance. Distillation of spatial features is applied only to the first part (CNNs), and its training is separate from the rest of the network. On the other hand, the spatial part of the system includes the convolution structure, which is costly to train. Therefore, it is not unjustifiable to put it aside by accepting the slight decline in final accuracy.

5. Discussion

This work's primary goal is to train new classes to a recognizing system, provided that the system's performance is not impaired for the previous classes. We tested three different scenarios and compared them with some other methods. Experiments and comparisons with other methods have shown that adding distillation of network knowledge at the feature level helps increase class-incremental learning accuracy. Distillation of knowledge at the feature level at both temporal and spatial feature levels increases

Table 3: Class-incremental action recognition performance on Kinetics-400 dataset. Mean-named columns show the average recognition accuracy (%) of all incremental learning steps. The other values report the recognition accuracy of one model.

Exemplar	Base model	20 × 5 stages		10 × 10 stages		5 × 20 stages		Static mode	Final
		Methods	Mean	Final	Mean	Final	Mean		
3Stream + cD	15	73.5	64.42	60.26	63.02	58.34	60.74	55.23	69.84
3Stream + cD + tfD	15	73.5	68.25	**65.78**	66.83	63.36	64.86	61.73	69.84

3Stream + cD	0	73.5	60.4	56.86	58.7	54.21	55.38	51.63	69.84
3Stream + cD + tfD	0	73.5	63.9	**61.42**	62.43	60.12	60.9	58.35	69.84

Table 4: Effect of initialization on class-incremental action recognition accuracy on UCF101 dataset.

Exemplar	Methods	Random		Similar classifiers mean	
		10 × 5 stages	5 × 10 stages	10 × 5 stages	5 × 10 stages
3Stream + cD	5	70.14	67.23	71.32	68.86
3Stream + cD + tfD	5	75.31	72.7	76.47	73.76
3Stream-D	0	52.67	49.0	53.24	49.63
3Stream + cD	0	61.45	57.36	62.56	58.5
3Stream + cD + tfD	0	65.27	62.64	66.84	63.74

Table 5: Effect of spatial features distillation on class-incremental action recognition accuracy. Only the accuracy of the final model has been reported.

Methods	UCF101 10 × 5 stages	Kinetics-400 20 × 5 stages	HMDB51 5 × 5 stages
3Stream + cD	62.56	56.86	36.43
3Stream + cD + tfD	66.84	61.42	40.26
3Stream + cD + tfD + sfD	**68.17**	**62.97**	**41.14**

recognition accuracy (see Table 5). In the absence of exemplar data, our evaluations show that the proposed method can still have results comparable to exemplar-based methods (Tables 2–4).

We also investigated the effect of classifier initialization and showed that using the most similar classifiers is helpful for initialization (see Table 4).

Evaluation on large Kinetics-400 dataset showed that the fewer incremental learning stages and the fewer new classes added to the model in fewer stages, the better the performance of the final model. Although more classes in incremental learning lead to a greater decline in system accuracy, several incremental learning also increase system decline.

Experiments have shown that distillation from different model parts can help retain prior information during the training of new classes and reduce the model performance drop. Of course, this may increase the cost of training. Comparing the proposed method with other methods that use exemplar data, it has been observed that the proposed method has a similar or even better performance without using exemplar data.

6. Conclusion

In this research, we proposed an algorithm for class-incremental learning to an action recognition system based on deep learning that does not greatly impair the recognition accuracy of previous classes by training new classes to the system. The importance of this work is reflected in the reduction of system retraining energy for all classes and the lack of need to maintain data from previous classes for future training. In this research, a three-stream structure is used, swhere each stream includes the feature extraction section, a recurrent section, and classifiers. The main idea in this work is to maintain the network knowledge related to the previous classes and also to use this knowledge in training new classes, which helps the network not forget the previously learned information. Extracting network knowledge and reminding it to the model are done in different network parts and levels.

Our focus in this research is the distillation of network knowledge, during which the network knowledge is extracted using the training data of new classes. While learning new classes, this extracted knowledge is used to prevent the network from forgetting previous classes. Distillation of network knowledge is done at the level of classification and feature, which at the feature level can be decomposed into two parts, spatial and temporal. We also suggest that the average weights of the most similarly trained classifiers be used instead of random values to initialize new classifiers. We have shown that this low-cost work improves system performance.

Other basic structures that perform better for incremental learning for future work can be used. In this work, the classes added in the incremental learning phase are from the same dataset of classes used for initial training. Incrementally learning classes from one dataset to a system taught

with another dataset is a challenge that needs to be addressed. Also, we intend to integrate this work with our previous work in the field of zero-shot learning recognition of human-object interaction (HOI) recognition [46].

Data Availability

The datasets used to support the findings of this study are included in the article [48–50].

Quantifying Carbon Emissions Generated by Monorail Transits: A Life Cycle Assessment Approach

The use of rail transits results in the generation of a large amount of carbon emissions. Throughout the life cycle of a rail transit system, huge amounts of carbon are emitted, which contributes to the threat posed by carbon emission on the city ecosystem. Despite the many methods previously proposed to quantify carbon emissions from rail transit systems, a method that can be applied to measure carbon emissions of monorail systems is yet to be developed. We have used the life cycle assessment (LCA) method to propose a method that can be used to quantify carbon emissions from monorail transits. The life cycle of a monorail transit system was divided into four stages (production, construction, use, and end-of-life). A monorail transit line segment in Chongqing, China, was selected for a case study. The results show that the "use" stage of the monorail transit line system significantly increases (93.2%) carbon emissions, while the "end-of-life" stage does not contribute significantly to the total carbon emitted. The processes of generation of steal, concrete, and cement are the three leading processes that contribute to the emission of carbon dioxide. The percentages of carbon emitted during these processes are 32%, 29.6%, and 13.3%, respectively. Prestressed concrete activity accounts for the largest proportion (91.1%) of the total carbon emissions. The results presented herein can potentially help in realizing sustainable development and developing green transportation.

1. Introduction

Global climate changes have aroused great concern worldwide as they have seriously affected social sustainability [1]. One important way to address the problem of climate change is to reduce carbon emissions [2]. The transportation sector facilitates human travel and helps in economic development. However, a large amount of energy is consumed during transportation, resulting in substantial carbon emissions. It has been reported that the transportation sector accounts for 14% of total carbon emissions worldwide [3]. Moreover, carbon emissions from the transportation sector have increased by 29% from 1990 to 2009 [4].

The monorail system uses a single rail instead of two rails as used in traditional rail systems during operation [5]. The monorail systems are low-noise systems that are safe to use. They are characterized by good climbing ability and small turning radii [6, 7]. At present, monorails are in operation in many countries worldwide, such as Japan, Germany, and the United States of America. Egypt, Thailand, Brazil, China, and a few other countries are actively building their monorail systems. This provides a glimpse into the great potential for further advances of monorail transits in the future. Huge quantities of raw materials (such as cement, concrete, and steel) are required for the efficient development of infrastructure required to build the monorail systems. The production of these raw materials is often accompanied by an enormous amount of carbon emissions. As large-scale construction of monorail systems will be realized in the near future, it is necessary to quantify carbon emissions to realize sustainable development.

Life cycle assessment (LCA) is a method of assessing the impacts exerted by products on the environment during their lifetime [8]. In general, process-based LCA consists of four steps: (1) goal and scope definition, (2) inventory

analysis, (3) environmental impact assessment, and (4) interpretation [8]. The LCA method has been widely used to evaluate the environmental performance of rail transits in recent years (Table 1).

Table 1 presents the data and research contexts of 25 selected works in which LCA was applied to research into transport systems. Among these 25 selected studies, 12 articles focused on HSR systems, 9 on metro or subways, and 6 on railways. Results obtained by studying light rail transits (LRTs) were reported in two papers. To the best of our knowledge, there are no reports on the carbon emissions from monorail transit systems. It has also been observed that the life cycle has been described and categorized differently by different research groups. Researchers chose the length of the life cycle based on the characteristics of the system. The results obtained in different cases were different. Researchers analyzed databases from their own country or nearby countries to match their local situation. For example, CLCD is generally used as the database for Chinese research. The object of research considered in this paper is a monorail transit in Chongqing, China. Hence, CLCD was selected as the database.

Table 1 demonstrates that LCA can provide a systematic framework to evaluate the life cycle environmental impacts of various rail transit systems. However, there are some research gaps:

(1) To date, researchers have widely focused on metro and HSR. To the best of our knowledge, carbon emission has not been quantified from the perspective of the whole life cycle for the case of monorail transit.

(2) Researchers have widely studied the four stages of rail transit systems (i.e., production, construction, use, and end-of-life), but a detailed study on the carbon emissions caused by materials production and construction works in the maintenance stage of the rail transit systems has not been conducted.

The aim of the present work is to quantify carbon emissions attributable to monorail transit systems using an LCA approach, with a monorail transit line in Chongqing, China, as a case study. The research work here is organized in four sections. Section 1 provides a brief introduction to the Chongqing monorail line 2 in China. Section 2 briefly introduces the methodologies of the LCA calculation. In Section 3, the case study for calculating the carbon emissions during the four stages of a monorail transit line in Chongqing is presented; the calculation results are interpreted; the observations are discussed; the uncertainty analysis and sensitivity analysis are conducted; recommendations are given. In section 4, the conclusions are derived and a summary of the key findings are presented. The results presented are expected to serve as a source of information and data that can be used to conduct LCAs in the future.

2. Materials and Methods

This study is based on a process-based LCA method. The different steps involved in the execution of the LCA method are defined in ISO 14040 [8]: goal and scope definition, life cycle inventory analysis, environment impact analysis, and interpretation. The results obtained following the LCA method reveal the potential environmental impacts of the monorail system (from cradle to grave). The methodology is shown in Figure 1.

2.1. Goal and Scope: Definition. The goal of this study is to assess the carbon emissions of a monorail transit line segment during the whole life cycle of its operation. The system boundary of the monorail transit was defined based on the guidelines presented in the EN 15978 standard [34]. Specifically, the process is divided into the production (associated with the extraction and upstream production, transport to a factory, and manufacturing processes), construction (associated with the processes of transportation to the working site and installation), use (associated with the use, maintenance, repair, and replacement of the system and the usage of operational energy), and end-of-life (associated with the processes of demolition, material transport, waste processing, and disposal) stages. The basic assumptions made have been presented:

(1) The life cycle length of the system is 50 years. The lifespan is the same as the lifespan assumed in previous works on a Chinese subway [22] and a light rail case [33].

(2) Vehicles were absent from the system, and this could be attributed to the lack of data. Studies have been previously conducted under similar situations, and the results have been reported [17, 19–22, 26–31].

(3) All the wastes are landfilled, and carbon emissions caused by waste transportation during the process of waste processing and waste disposal are primarily considered.

(4) Operational energy consumption remains the same every year (this assumption helps simplify the calculations).

(5) All the materials are locally available, and the transportation distance is 50 km.

The detailed system boundary is illustrated in Figure 2.

2.2. Inventory Analysis. The second step in LCA involves the process of inventory analysis. In this step, information on carbon emission factors associated with different materials and resource (material and energy) consumption at all stages is collected.

2.2.1. Carbon Emission Factors. We chose data presented in the Chinese Core Life Cycle Database (the most authoritative database for LCA in China) [35] to conduct our research to effectively reflect the Chinese conditions. The baseline emission factors of China's regional power grid (from 2011 to 2017) in Chongqing were obtained based on the data from the Ministry of Ecology and Environment of the People's Republic of China [36].

2.2.2. Materials and Energy. Data on material consumption is obtained from construction files, which contain information on the types and quantities of materials used. The

Budgetary Norm of Highway Project (JTGT_3832-2018) [37] is studied to determine the machine-teams involved in the different working activities occurring in the construction
FIGURE 2: System boundary.

stage and during the process of demolition associated with the end-of-life stage. The Budget Norm of Maintenance and Strengthening of Highway Bridges (YNG/T B02-2011) [38] is considered to determine the machine-teams involved in the maintenance works associated with the use stage. The data presented in the Expense Standard of Machine-Team of Highway Project (JTGT_3833-2018) [39] are analyzed to obtain the unit energy consumption of different machine-teams. The China Urban Rail Transit Almanac 2019 [40] is referred to, to determine the amount of electricity consumed by the monorail transit lines and stations. The carbon emissions of the monorail transit line are obtained by multiplying the electricity carbon emission factors with the total quantity of electricity.

2.3. Environmental Impact Assessment.
The third step involves environmental impact assessment or life cycle impact assessment [41]. Results obtained using the various analytical methods reveal that carbon emission (for monorail transits) is realized in four stages. Total carbon emission is calculated using the following equation:

$$C_{tot} = C_{PD} + C_{CS} + C_{US} + C_{EL}, \quad (1)$$

where C_{tot}, C_{PD}, C_{CS}, C_{US}, and C_{EL} correspond to the amounts of carbon emitted during the life cycle, the production stage, the construction stage, the use stage, and the end-of-life stage, respectively.

The amount of carbon emissions produced in the production stage is equal to the carbon emission factors of various materials multiplied by the corresponding material quantities. This can be represented by the following equation:

$$C_{PD} = \sum_i CF_{MF,i} \times Q_{MF,i}, \quad (2)$$

where $CF_{MF,i}$ represents the carbon emission factors of the $i - th$ material and $Q_{MF,i}$ represents the consumed quantities of the $i - th$ material.

Carbon emissions produced during the construction stage are primarily generated during the transportation of the construction materials and consumption of energy (by different construction machines). The amount of carbon emissions generated in the construction stage can be represented by the following equation:

$$C_{MC} = \sum_i CF_{mt,i} \times Q_{mt,i} \times D_i + \sum_i CF_{cf,i} \times Q_{cf,i} + CF_e \times Q_{ce}, \quad (3)$$

where $CF_{mt,i}$ represents the carbon emission factor for the $i - th$ construction material transportation mode, $Q_{mt,i}$ represents the quantity of the $i - th$ transported construction materials, and D_i represents the distance between the production factory and the construction site. Here, it is assumed that road freight is the only transportation mode adopted. $CF_{cf,i}$ represents the carbon emission factor of the $i - th$ consumed fuel mode in the construction stage, $Q_{cf,i}$ represents the quantity of the $i - th$ fuel consumed in the construction stage, CF_e represents the regional carbon emission factor for electricity, and Q_{ce} represents the quantity of electricity utilized by the construction machines during the construction stage.

The carbon emissions during the use stage are primarily generated during maintenance works and the consumption of electricity by the vehicles and stations. The amounts of the carbon emissions produced during the use stage can be determined using the following equation:

$$C_{US} = C_{op} + C_{mt}, \quad (4)$$

where C_{US} represents the amount of carbon emissions generated from the monorail line in the use stage, C_{op} represents the carbon emissions produced during the operational phase, and C_{mtp} represents the carbon emissions produced during the maintenance phase.

$$C_{op} = C_{sy} \times Y, \quad (5)$$

$$C_{sy} = CF_e \times Q_{oe}. \quad (6)$$

In (5) and (6), C_{sy} represents the annual carbon emissions generated from the monorail line in the course of its operation, Y is the service life in the operational stage, and

Q_{oe} represents the amount of electricity consumed during the operational stage.

In the maintenance phase, the origin of carbon emissions can be attributed to the processes of material production and fuel consumption (consumed by construction machines). The amount of carbon emissions produced in the maintenance stage can be calculated using the following equation:

$$C_{mt} = \sum_i CF_{mt,i} \times Q_{mt,i} + \sum_i CF_{mfc,i} \times Q_{mfc,i} + CF_e \times Q_{me},$$

(7)

where $CF_{mt,i}$ represents the carbon emission factors of the $i-th$ material, $Q_{mt,i}$ represents the consumed quantities of the $i-th$ material, $CF_{mfc,i}$ represents the carbon emission factor for the $i-th$ consumed fuel (consumed by machines during the maintenance process), $Q_{mfc,i}$ indicates the quantity of the $i-th$ fuel consumed (realized during the maintenance process), and Q_{me} represents the quantity of electricity utilized by the construction machines during the maintenance process.

The carbon emissions generated during the end-of-life stage are produced during the consumption of energy by the construction machines during the processes of demolition and waste transportation. The amount of carbon emission produced during the end-of-life stage can be calculated using the following equation:

$$C_{EL} = \sum_i CF_{f\,d,i} \times Q_{f\,d,i} + CF_e \times Q_{de} + \sum_i CF_{dm\,t,i} \times Q_{dm\,t,i} \times D_i,$$

(8)

where $CF_{f\,d,i}$ represents the carbon emission factor corresponding to the consumed fuel mode (disposal process), $Q_{fc,i}$ represents the quantity of the $i-th$ fuel consumed during the disposal process, Q_{de} refers to the quantity of electricity utilized by the construction machines during the disposal process, $CF_{dm\,t,i}$ represents the carbon emission factor for the $i-th$ disposal transportation mode, $Q_{dm\,t,i}$ represents the quantity of the $i-th$ transported materials, and D_i indicates the distance between the construction site and the disposal area.

2.4. Interpretation.
In this step, the conclusions are arrived at based on the results obtained during inventory analysis and impact assessment. The key stages, working activities, and materials (used throughout the life cycle) that affect the extent of carbon emission produced during the functioning of a monorail transit were identified. The uncertainty analysis and sensitivity analysis methods were used, and the data were analyzed using Oracle Crystal Ball software to determine the possible range of life cycle carbon emissions of a monorail transit. The parameters that affect the results are also identified.

3. Results and Discussion

3.1. Monorail Transit Line: Background Information.
The monorail transit line 2 in Chongqing, China, is selected for a case study to demonstrate and validate the proposed LCA approach. It was inaugurated in December 2004 as the first straddle monorail line in China. It is one of the two straddle monorail lines that are currently in operation in China. Its operational mileage has reached 31.36 km. We have selected a section (from Niujiaotuo to Daping; length: 2409.09 m) of the entire route for our studies. We have quantified the carbon emissions produced in the selected section. The specific route under consideration is shown in Figure 3.

3.2. Calculating Carbon Emissions: Results

3.2.1. Carbon Emissions in the Production Stage.
According to equation (2), the carbon emissions produced during the production of the materials primarily used for production are shown in Table 2.

The total amount of carbon emissions produced during the production of main materials was 3,365.43 t.

3.2.2. Carbon Emissions Produced during the Construction Stage.
The carbon emissions produced during the construction stage are primarily generated during the processes of material transportation and construction. Equation (3) and the assumptions made were taken into consideration to calculate the amount of carbon emissions produced during the process of transportation of the materials (Table 3).

The total amount of carbon emissions produced during the transportation of materials was 113.49t. The amount of carbon emissions produced during the process of on-site construction was calculated (equation (3), Table 4). The carbon emission factors corresponding to electricity and diesel are 1.294 t CO_2/MWh and 3.664 kg/kg, respectively.

The amount of carbon emissions produced in the area of the chosen line segment was calculated to be 5,653.58 t. When the amount of carbon emissions produced during the transportation of the main material is taken into account, the total amount of carbon emissions generated during the construction stage is calculated to be 5,767.18 t.

3.2.3. Carbon Emissions Produced during the Maintenance Phase of the Use Stage.
The assumptions were taken into account, and the carbon emissions produced during the maintenance phase were calculated (equation (7), Table 5). The guidelines presented in the Budget Norm of Maintenance and Strengthening of Highway Bridges (YNG/T B02-2011) [38] were followed, and it was assumed that each time, one concrete treatment, 100 m-long expansion joint, 10 dm³-volume bearings, 1000 m-long cracked concrete, and 400 m³-area concrete beam section were maintained. According to the Budget Norm of Maintenance and Strengthening of Highway Bridges (YNG/T B02-2011) [38], the maintenance works are carried out once every ten years.

The total amount of carbon emissions produced during material, electricity, and fuel consumption during the construction of the machine was calculated to be 16.87 t/10 years. If the life cycle is considered to be 50 years long, the total carbon emission is calculated to be 60.51 t.

3.2.4. Amount of Carbon Emissions Produced during the Operation Phase of the Use Stage.
The data presented in the
FIGURE 3: Case scenario.

TABLE 2: Carbon emissions generated during the production of materials primarily used for production.

Material	Unit	Quantity	Factor (kg/unit)	Carbon emissions (t)
Cement	t	622.30	719.62	447.82
C20 concrete	m^3	868.71	201.38	174.94

Ministry of Ecology and Environment of the People's Republic of China [36] was analyzed to determine the baseline emission factors corresponding to the regional power grid in China. The data for different years were collected, and the carbon emission factors of different regions (time range: 2006–2017) were determined. Chongqing is situated in central China. The ARMA time series method was used to predict the electricity carbon emission factors of central

TABLE 5: Amount of carbon emissions produced during maintenance works.

Working activities	Items	Unit	Quantity	Carbon emission factors	Carbon emissions (t)
Concrete treatment	Polymer mortar	m^3	2.80	354.75 kg carbon emissions/m^3	0.99

	Total carbon emissions	t	10.91		

China (for the years spanning 2002–2018) based on the existing data, as data for the years before 2006 and after 2017 were unattainable. The forecast results for 2002 and 2018 are 1.294 t CO$_2$/MWh and 0.5907 t CO$_2$/MWh, respectively.

The annual power consumption amounts and the annual passenger turnover were determined by analyzing the statistical data presented in the China Urban Rail Transit Yearbook 2019 [40]. The amount of carbon emission produced was calculated accordingly. The amount of carbon emissions produced by monorail line 2 (during its operation in 2018) was calculated to be 34,029.22 t. The total amount of carbon emissions produced during the 50-year-long life cycle was calculated to be 1,701,461 t. The amount of carbon emissions produced per unit length was 54255.77 t/km. The amount of carbon emissions produced by the chosen part of line 2 (length: 2.4 km) was 130,213.85 t. Equation (4) was used to calculate the total amount of carbon emissions generated during the whole use stage. The amount was calculated to be 130,274.36 t.

3.2.5. Carbon Emissions Produced during the End-of-Life Stage. Equation (8) was used, and the assumptions made were considered to calculate the amount of the carbon emissions produced during the process of structure demolition and waste disposal during the end-of-life stage. The engine-driven air compressor within 9 m^3/min was primarily used during the demolition process. The total amount of energy consumed during the demolition process was calculated to be 11,916.83 kWh. The total amount of carbon emissions generated during the demolition process was calculated to be 356.35 t. The total amount of carbon emissions generated during the process of waste transportation was calculated to be 113.49 t, and the total amount of carbon emissions produced during this stage was 469.84 t.

3.3. Amount of Carbon Emissions Produced during Different Stages. A comparison of the amounts of carbon emissions produced during different stages of the life cycle of the material is presented in Figure 4(a) and Figure 4(b). Analysis of the figures indicates that the maximum amount of the carbon emissions generated during the life cycle of the monorail transit is produced during the use stage (93.2%). The amount produced in this stage is significantly higher than the amount produced during the other stages. This can be primarily attributed to the fact that the amount of carbon emissions produced during the process of energy consumption during the entire 50-year-long operation period is considered during the study of the operational phase. A huge amount of carbon emissions is produced during this phase. Various maintenance works are carried out during the life cycle of the material. Each stage requires a certain amount of manpower and materials for completion. Different types of machinery are also required for the effective execution of the process. Maintenance work is carried out once every 10 years. Thus, a total of five maintenance cycles are carried out during the whole life cycle. This results in the generation of a large amount of carbon emissions in the use stage. A considerable amount of carbon emissions is also produced during the construction stage (4.1%). This can be attributed to the fact that a huge quantity of energy is consumed by different working machines during this process. The amount of carbon emissions generated during the production stage (2.4%) is slightly lower than the amount generated during the construction stage. It has also been observed that the amount of carbon emissions generated from the end-of-life stage is only 0.3% of the total amount generated, an insignificant amount as compared to emissions produced in other stages.

3.4. Carbon Emissions from Different Materials. Figures 5(a) and 5(b) provide a comparison of the amounts of carbon emissions produced during the use of different materials. As the figures show, there are significant differences in the amount of carbon emissions generated by different types of materials. The top 11 construction materials that contribute the most toward the production of carbon emissions are listed in Figure 5(a). The cumulative amount of the carbon emissions generated by these 11 materials is 3365.15 t, accounting for almost all of the total carbon emissions generated during the production stage. Specifically, the use of steel (32%), concrete (29.6%), cement (13.3%), and mortar (13%) results in the production of the maximum amount of carbon emissions during the production stage.

This can be attributed to the fact that a monorail line is a reinforced concrete structure that requires the use of a large amount of steel (1,376.36 t), concrete (3,549.61 m^3), cement (622.3 t), and mortar (1,144.91 m^3). The corresponding carbon emission factors are significantly high. The total amount of carbon emissions produced is large as the consumption and carbon emission factors of these materials are significantly high. Therefore, the key to improving the environmental performance of monorail transit lies in decreasing the amount of carbon emissions generated by these materials. It has been previously reported [42] that an efficient water reducing agent can be used to replace cement during the process of concrete production. This can help in reducing the amount of carbon emissions produced during the material production stage. The concrete strength can be improved simultaneously to reduce the amount of cement and concrete used. Furthermore, designers could consider using more amounts of renewable construction materials (such as renewable concrete) in the design stage [43]. Mortar, bricks, building blocks, gravel, sand, and other materials also contribute to the generation of carbon emissions in the production stage. The use of these materials results in the generation of insignificant amounts of carbon emissions.

3.5. Carbon Emissions: Analysis of Working Activities Occurring in the Construction Stage. A comparison of the amounts of carbon emissions generated at different stages of the construction stage is presented in Figure 6. Fifteen working activities are considered. The results reveal that prestressed concrete activity accounts for the largest proportion (91.1%) of the total carbon emissions produced in this stage. The amount of carbon emission produced during prestressed concrete activity is significantly higher than the amount produced during other construction activities. This can be primarily attributed to the fact that a huge quantity of electricity is consumed during the operation of machines single-cylinder slow-motion winch within 30 KN (2,681,021.27 kWh), single-cylinder slow-motion winch within 50 KN (934,667.96 kWh), Φ100 mm electric multi-stage water pump (≤120 m; 204,479.87 kWh), and concrete delivery pump (60 m^3/h; 98,556.12 kWh). In addition, a considerable amount of carbon emissions is generated during the construction of the beam concrete (3.6%). The amount of carbon emissions generated during the processes of beam reinforcement (1.5%) and rebar processing (1.5%) is slightly lower than the amount produced during the process of beam concrete construction. The amount of carbon emissions attributable to other construction activities accounts for less than 1% of the total carbon emissions originating from all construction activities. This indicates that these activities do not significantly affect the environment.

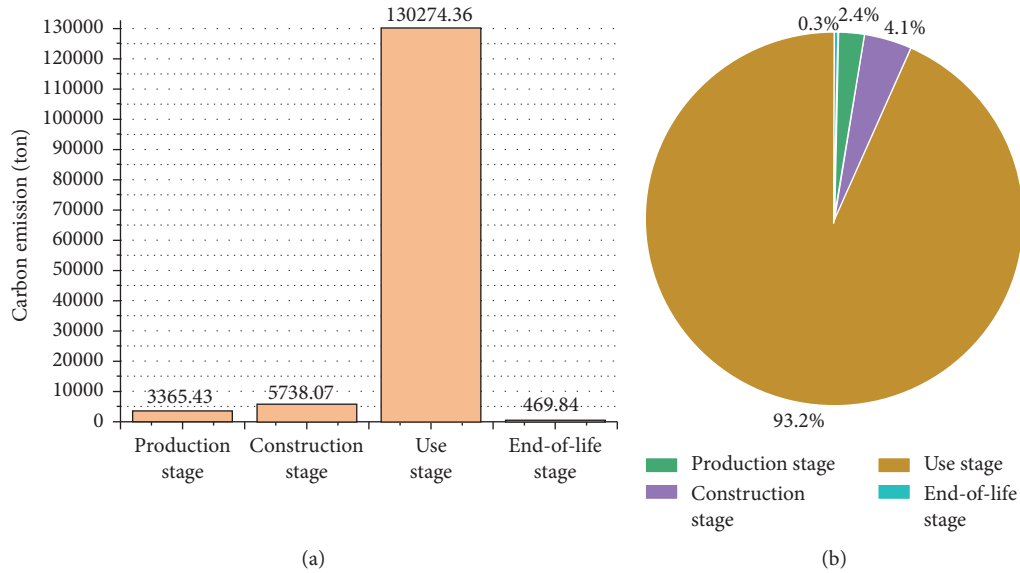
3.6. Uncertainty Analysis: Construction Stage and Production Stage. The uncertainty of carbon emissions corresponding to material and fuel consumption can be attributed to construction errors. Uncertainty analysis was conducted using the Oracle Crystal Ball (Figure 7) to evaluate the possible range of carbon emissions for a monorail segment during its life cycle. Standard normal distributions were assumed for the input parameters, and the number of testing times was set to 100,000. The probability distributions corresponding to the target variables were normal distributions. The variation range calculated for carbon emissions was 100,000–180,000 t.


FIGURE 4: (a) Amounts of carbon emissions generated during different stages of operation throughout the life of the material. (b) Proportion of carbon emissions generated during different life cycle stages.
FIGURE 5: (a) Amounts of carbon emissions generated during the use of different materials. (b) Proportions of carbon emissions generated during the use of different materials.

3.7. Life Cycle: Sensitivity Analysis. The Oracle Crystal Ball was used to determine the sensitivity of carbon emissions during the life cycle of the monorail transit line. The results are shown in Table 6.

Analysis of the data presented in Table 6 reveals that the length of the life cycle, amount of electricity consumed annually, single-cylinder slow-motion winch within 30 KN quantity, single-cylinder slow-motion winch within 50 KN quantity, use of C40 concrete quantity, cement mortar (1 : 3) quantity, and brick 200 × 95 × 53 quantity are the sensitive factors that affect the final carbon emission results. The length of the life cycle and the amount of electricity
Figure 6: Proportions of carbon emissions generated during different construction activities.
Figure 7: Uncertainty analysis conducted for carbon emissions produced during the life cycle of the material.

consumed annually during the operation of the system significantly influence the amount of carbon emission produced by the monorail system during its lifetime. In addition, the quantities of single-cylinder slow-motion winch within

30 KN, single-cylinder slow-motion winch within 50 KN, C40 concrete, cement mortar (1 : 3), and brick 200 × 95 × 53 also exert a certain influence on the results. It was observed that the degrees of influence were almost the same.

TABLE 6: Sensitivity analysis conducted for carbon emissions produced during the production stage.

Order	Parameters	Variance contribution (%)	Rank correlation
1	Life cycle length	47.0	0.69
2	Annual operation electricity consumption	46.9	0.68
2	Single-cylinder slow-motion winch within 30 KN	0.1	0.02
3	Single-cylinder slow-motion winch within 50 KN	0.1	0.01
4	C40 concrete quantity	0.1	0.01
5	Cement mortar (1 : 3) quantity	0.1	0.01
6	Brick 200 × 95 × 53 quantity	0.1	0.01
7	Others	0.1	-

3.8. Discussion of the Approach. This calculation framework can be used to calculate the amount of carbon emission produced by a monorail line during its lifetime, but it can also be used to calculate the amount of carbon emissions produced by ordinary railway, light rail, subway, and other rail transportation systems. The calculation results can help design the monorail transit system, and the results can help reduce the amount of carbon emission produced at the initial stages of the process.

As there are few monorail lines in operation in China, it is difficult to obtain field data. It is challenging to verify the universality of the results calculated from the only data available. More data can be obtained in the future as the construction of monorail traffic has been planned. Our model will be further optimized to make it universal.

3.9. Recommendations for Future Research. More attention should be paid to the following research directions:

(1) Verification and application of the approach used by us should be realized by analyzing fundamental data. Therefore, attention should be paid to obtaining more amounts of data to improve the developed approach.

(2) Some scenarios can be designed to simulate the carbon emission reduction effects based on the calculation results presented. This can potentially help in proposing helpful suggestions that can be exploited by designers and politicians for the sustainable development of the city.

4. Conclusions

We calculated the amount of carbon emissions produced during the operation of a monorail transit line (during its lifetime) using the LCA method. A segment of the Chongqing monorail line 2 was selected for the case study for validating the developed model. The following conclusions were drawn:

(1) The life cycle of the monorail transit line can be theoretically divided into four stages: the production, construction, use, and end-of-life stages. The use stage contributes >90% of the carbon emissions produced during the lifetime of the monorail transit line. A significant amount of carbon emissions is produced during the construction and production stages. The amount of emissions produced during the end-of-life stage is less than the amount produced in the other three stages.

(2) Steel, concrete, and cement are the most important sources of carbon emissions.

(3) Prestressed concrete activity accounts for the maximum proportion (91.1%) of the total carbon emissions. Significant amounts of carbon emissions are generated during the process of beam concrete construction (3.6%). The amounts of carbon emissions generated during the process of beam reinforcement (1.5%) and rebar processing (1.5%) are slightly lower than the amounts generated during the process of beam concrete construction.

In summary, the results presented herein can help gain a better understanding of the effects of the monorail transit industry on the ecosystem. The results can potentially help develop ideas that can be used by designers working in the rail transit industry to meet low carbon emission goals.

With the rapid development of construction projects, more and more engineering corruption problems have emerged. Therefore, this paper proposes a SEIR (susceptible-exposed-infected-recovered) based corruption model to better understand the propagation process of corruption cases in construction projects. In this model, the data samples are collected from the 2018 Engineering Corruption Case Judgment Document, the propagation parameters are obtained through actual case analysis with the help of complex networks, the change process and key influencing factors of actual nodes in engineering corruption cases are simulated by Python. The study results indicate that the personnel conforms to the "4–9 transmission law," in which the early stage is a period of high incidence of corruption cases. The network of corruption cases is somewhat vulnerable, and its spread is about minus 8 times the change in crackdown rate and 10 times the change in infection rate. The variation range of the susceptible population S and the removed person R in the propagation simulation curve can predict the relationship between corruption infection rate and crackdown rate, which can provide theoretical guidance for preventing the occurrence of corruption.

1. Introduction

Corruption is extremely harmful to social stability, may hinder economic development, and affect the development of political parties [1, 2]. Corruption in construction projects has become a key factor affecting the construction market environment and the sustainable development of external construction [3]. How to effectively punish and prevent corruption in the construction projects has become a challenge all over the world [4], especially in developing countries such as China [5–12], Ghana [13–15], Turkey [16], Brazil [17], and Iran [18]. Moreover, the construction industry is one of the "disaster areas" prone to corruption, which has seriously restricted the economic development [10]. Corruption cases in the construction projects may cause greater losses and more serious social impacts than general corruption cases because of some of its characteristics, such as multiple and complex participants, clear division of labour, hidden exchange of interests, serious corruption, long incubation period and difficult to play a supervisory role in the power supervision mechanism [19].

The huge investment in infrastructure during China's rapid urbanization can also lead to corruption in the construction projects [7, 20, 21]. In order to prevent corruption in the construction projects, the government has continuously improved regulations and increased the intensity of filing and reviewing cases of violations of laws and disciplines. Advanced screening through the official website of China Judicial Documents revealed that the number of first instance judgments on corruption cases in the engineering industry dropped from 5062 in 2016 to 1718 in 2020. Although the number of related cases has been controlled to a certain extent, the related problems are still very serious [2]. In conclusion, it is imperative to explore the propagation mechanism of corruption in construction projects for better preventing corruption in the construction projects.

Previous studies have analysed the characteristics of corruption in construction projects from behavioral and sociological perspectives, mainly through the data collection methods such as interviews, case studies, and questionnaires. Yu [22] found that the corruption of Chinese construction industry by using association rules is age-related, with the

increase of corruption as managers approach retirement age. However, Zhang [23] pointed that the key factor affecting corruption in the real estate sector is not age growth, but abuse of power based on data from 135 cases. Emmanuel [19] summarized that the contract phase and the postcontract phase may be the main corruption prone stages of construction projects in many developing countries. It is notable that the professional backgrounds of corrupt elements are becoming more and more profound, the means of crime are diversifying, and the number of collective corruption is increasing [11, 23–26]. On the other hand, some scholars have analysed many cases to explore the criminal motives of corruption in the construction projects and the relationship of criminal personnel structure from the perspective of criminology. It is found that flawed legal systems, higher profits, and group complexity of construction projects are the key causes of corruption in construction projects [17]. Diviák [27] prompted that the criminal aggregation network of corruption presents a clear core-periphery structure in many cases, where all involved officials are located in the core of the network and have strong concealment in the corruption network. Wang [5] believed the corruption networks expand through brokerage activities in the form of spanning institutions and enlisting strategic resource holders. From the brief literature review, it can be found that many studies have explored the problem of corruption in construction projects from different perspectives, and illuminated the characteristics of corrupt behavior in construction projects such as complexity, dynamics, concealment, collective nature, and flexibility. It also verifies that individual characteristics have a strong correlation with the degree of corruption in both construction projects. However, these studies focused on the individual corruption characteristics from a behavioral or micro perspective, lacking group evolution context and macro insights. In addition, the research methods are still somewhat subjective such as questionnaires, expert interviews, literature reviews, which lack objectivity. Considering the dynamic nature of corruption behavior in construction projects, this study believes that it is also very important to explore the evolutionary relationship of corruption behavior propagation in construction projects from a macrogroup perspective.

To bridge the research gap, this study will explore the evolutionary process of the spread of corruption in construction projects by adopting the complex network theory and infectious disease SEIR model. This paper attempts to illuminate new ideas for preventing corruption in the construction industry from a macrogroup perspective. The parameters of the infectious disease model are obtained by actual corruption cases through the analysis of complex networks. The model can well describe the propagation mechanism of corruption behaviors in actual groups and is verified by actual corruption cases. The simulation results reveal the characteristics of corruption nesting in the engineering industry and the key factors of corruption governance, thus put forward governance recommendations for reference. Compared with the existing studies, the contributes of our research are highlighted as follows: (1) adopting a dynamic perspective to study the spread characteristics of corrupt behavior, (2) using a more objective

method to determine the model parameters by extracting the actual case data through network feature parameters, and (3) improving the infectious disease model to prevent the corrupt behavior of engineering construction.

2. Literature Review

2.1. Characteristics of Corruption in Construction Projects. Corruption in the construction sector has spread to other industries and almost all the construction phases [28], especially the land grant stage, the bidding stage, and the construction stage [23]. In addition, the corruption cases in construction projects may cause greater losses and more serious social impact than the general ones. Furthermore, it is found that the types of construction projects corruption are determined by the conditioning variables such as type of leadership, position level, region, and age [22, 23, 29]. Among which, the age of 46–50 and 55–60 are the high incidence of corruption cases [22, 23], and engineering corruption is more likely to breed in second-and third-tier cities than in first-tier cities [22, 23]. These characteristics of corruption in construction projects have become a common focus of attention and seriously affected the healthy development of the engineering industry.

In order to further study the characteristics of corruption and reveal the causes of construction corruption, many scholars often explored the influencing factors of corruption by using questionnaire surveys [6, 7], expert interviews [4, 30], literature reviews [4, 31], and multiple case studies [16, 28, 32]. The causes of construction corruption are mainly psychosocial specific reasons, organization-specific reasons [31], regulations specific reasons, and project-specific reasons [31]. Firstly, a flawed legal system may provide opportunities for corruption in the construction industry [7, 10, 11]. Secondly, higher profits may be the another reason for corruption in the construction industry [30]. Thirdly, the complexity of the construction industry, such as the long construction period of the project and the complexity of the participants, makes corruption prone to occur [24, 31]. Finally, government officials play multiple roles in public construction projects, such as decision-maker, approver, project fund owner, and arranger, is easy to intervene the implementation of normal construction projects such as bidding activities [15]. The factors influencing corruption in construction projects are complex and variable, which also reflects the value of exploring the dynamic evolutionary relationship of the analysis of the law of corrupt behavior in construction projects.

The people who are in the core network will also change over time due to the dynamics, complexity, and concealment of the corruption network of the construction project [29, 33, 34]. Similarly, some scholars found that the network structure adjusts with time in the evolution of drug crime networks, and roles have great flexibility and variability at different mission stages and at different times [34–36]. Nekovee [37] quantitatively analysed the infection of corruption within the organization from a dynamic perspective, and found the lower threshold of corruption infiltration in the organization with a flat structure compared with the higher

structured organization. Wang [5] found that the core of corrupt networks expanded by crossing institutions and securing strategic resource holders through brokering activities. Due to the versatility and flexibility of corrupt groups, corrupt groups spread through specific pathways within a certain spatial and temporal context [5], and such interactions against groups can be considered as the contagion of corrupt behavior [38]. Social contagion is similarly defined by scholars as "transmission among individuals in a group through interactions between individuals" [37, 38]. The current corruption phenomenon has shown a "fissile spread," which spreads from individuals to groups, and even to the whole organization according to management logic. Similarly, the research on corruption behavior in construction projects still focused on the static or micro perspectives such as individual behavioral characteristics, corruption behavior influencing factors, corruption governance measures, and corruption degree assessment. In fact, the corrupt behaviors among corrupt groups in construction projects are contagious, and the interactive, dynamic and complex nature of the spread of these behaviors need to be taken into account. It is also very important to explore the evolutionary relationship of corruption behavior propagation in construction projects from a macrogroup perspective.

2.2. Theory of Complex Networks and Infectious Disease Models. Complex network is a theoretical tool for evaluating the operating status of complex systems that has been widely applied to various fields of construction management industry [27]. Generally, the various elements and their relationships within a complex system are abstracted into a network structure diagram. The traditional construction method is to transform each entity of the complex system into a network node, and transform the connection of entities into the connection of nodes [5, 27]. Graph theory is a useful tool to further study the complex network structure such as complex system evolution mechanism, diffusion mechanism and governance strategy and other scientific problems that has emerged in recent years [39].

Complex network of epidemic spread model on has attracted great attention among researchers of physics, mathematics, and epidemiology due to its success in predicting and controlling epidemic spread in reality [40, 41]. Fundamentally, the traditional spread of public opinion, epidemics and violations are simulated by SIR and SEIR [42]. The outbreak of COVID-19 has initiated a large number of numerical studies by using epidemiology models [43–46]. The propagations of diseases, behaviors and information in real systems are rarely independent of each other, but they are coevolving with strong interactions [40]. Fan [47] proposed a contagion model as a simple and powerful mathematical approach for predicting the spatial-temporal evolution of the onset and recession of floodwaters in urban road networks. Nekovee [37] studied the contagiousness of corrupt behavior within the organization, and its transmission behavior is somewhat similar to rumours or infectious disease. It is feasible to use infectious disease models to study the evolutionary pattern of the spread of corrupt behavior.

A systematic review of the literature reveals that corruption in construction projects is a hot area of research for scholars nowadays. Due to the concealment, complexity and seriousness of corruption in construction projects, the management of corruption in construction projects is also the common goal of all countries nowadays. The dynamic nature of corruption networks is illustrated by the close division of labour and the mutual change of roles among the personnel of corrupt groups. At the same time, the infiltration of internal corrupt practices illustrates the contagious nature of corrupt practices. Intermediaries expanded the core of the corruption network, and transmitted the interactions between groups to jointly constitute the complex network of corrupt practices. In addition, infectious disease dynamics model with complex networks have proven to be a key approach for the study of behavioral transmission and have been widely used in various fields. The systematic discussion also provides a rich theoretical foundation and guiding direction for this study. However, the current research on behavioral communication mainly focused on the field of public opinion governance and infectious disease surveillance, and lacked the behavioral communication of corrupt groups in the construction projects field. Most scholars just concentrated on the individual characteristics and construction project corruption features from a behavioral perspective. Therefore, the spread characteristics analysis of construction corruption in this study is a new exploration of the regulation and governance of the construction management industry. Dynamic research on the changing characteristics of different periods is also the key point of this study. To address the research gap, this paper adopts the complex network theory and the SEIR model of infectious disease to study the propagation process pattern and governance measures of corruption cases in construction projects from a dynamic perspective.

3. Construction of an Infectious Disease Model for Corruption Nesting in Construction Projects

Infectious disease behavior on complex networks has been widely used by scholars in various fields. The method of infectious disease dynamics is a mathematical technique that has been developed into a rich interdisciplinary field. Scholars found that the transmission mechanism of infectious diseases is similar to information or human behavior [42]. Infectious disease models have been widely used in various fields such as the prediction and simulation of the new coronavirus [43, 48–50], the spread and intervention of unsafe behaviors of construction workers, flight operation risk spread analysis, panic spread research, the spatial spread and temporal evolution of the onset and recession of floodwaters in urban road networks [42, 47, 51, 52]. Besides, infectious disease models are used in the study of behavioral communication, which can reflect the propagation and evolution process of behavior at the microscopic level, and predict the trend of behavioral diffusion at the macroscopic level [53].

Corruption in construction projects has the characteristics of dynamic and contagious, and its evolutionary pattern can be analysed by infectious disease models. The emergence, replication, and spread of corruption in the engineering field are very similar to the transmission process of infectious diseases [42]. The spread of infectious diseases in the population requires the source of infection, latent persons, susceptible groups, and good conditions for transmission. Generally, the corruption nest of a construction project can be regarded as a transmission process from single individual corruption infection to group corruption infection. Considering that there are generally many people involved in the corruption case of a construction project, and the exchange of benefits is concealed, there may be an incubation period for individual corruption [19]. In addition, the corruption of construction projects has a certain latent nature because some corrupt groups or individuals would weigh the pros and cons before deciding to participate in corrupt practices. The traditional SIR model of infectious diseases does not consider the incubation period of corruption [54]. The spread study of corruption cases is based on the traditional SEIR model [55], which assumes that the overall propagation process of corruption nesters in construction projects conforms to a single process within a system from a state of vulnerability to corruption to participation in corruption and finally to being cracked down and caught. Therefore, this paper adopts an improved SEIR model and adds the incubation period parameter [47] to more reasonably explore the transmission mechanism of corruption behaviors in construction.

In formal rumor-spreading models, a closed population is subdivided into three groups; those who are ignorant of the rumor, those who have heard and actively spread it, and those who have heard but ceased to spread it [37, 42]. This paper designs a SEIR model for the propagation of corruption nests in construction projects with four populations, including susceptible population (S), exposed population (E), infectious population (I), and recovery population (R) [55]. The propagation state of the model is shown in Figure 1. Moreover, the evolutionary relationship of corruption transmission in this study is revealed by the SEIR model that integrated various external real factors to obtain the change rate of infectious diseases.

In this paper, it is assumed that the total number of nodes in the project corruption network is N and the number does not change throughout the propagation process, and the information propagation time is represented by t [50]. This study hypothesizes that corrupt behavior is generated through intergroup organizational interactions. The information propagation process in the SEIR model is described as follows.

(1) The susceptible population refers to the group who are prone to participate in the illegal and corrupt behavior of the construction projects.

(2) The latent population refers to the group who have been exposed to the corruption behaviors but have not yet decided to participate and has no transmission motivation.

(3) The people infected by corruption refers to the group who participate in the case of corruption or commit corruption and have the motivation to spread corruption.

(4) The dismissed people refer to the group that have been cracked down by external discipline inspection departments, courts, and other channels and are in a state of being dismissed.

(5) When $t = 0$, corruption of the initial project generated in the network. The susceptible nodes in the network first convert to exposed nodes with the probability of λ, and then the exposed nodes convert to the infected node with the Probability of u. Finally, the infected nodes can be converted into the Remove nodes with the probability of r[44].

(6) The overall process of spreading corruption in engineering projects can be expressed as follows: if the susceptible state individual m is considered to have corruption behavior with neighbouring corrupt individual j in the period $[t, t+1]$, then susceptible state individual m will be in latent state E by deciding whether to participate in corruption or not. When individual m in the latent state participates in corruption by choice, individual m will become a member of the corrupt group I in the construction projects. When individuals m in a corrupt state are under the supervision of external government departments and other relevant agencies, they are eventually arrested and become a removal group R [42]. In the whole process of corrupt spreading behavior in construction projects, each node may involve in corruption, which mainly depends on the comprehensive impacts of multiple factors.

(7) During the initial propagation of corruption in construction projects, it is assumed that the people in the group will be in one of the states where corrupt interactions occur with their neighbouring nodes during the beginning of corruption propagation.

The dynamic differential equation expression of the infectious disease model is shown in equation.

$$
\begin{cases}
\dfrac{\mathrm{d}S(t)}{\mathrm{d}t} = -\lambda * S(t) * I(t), \\[2ex]
\dfrac{\mathrm{d}E(t)}{\mathrm{d}t} = \lambda * S(t) * I(t) - \mu * E(t), \\[2ex]
\dfrac{\mathrm{d}I(t)}{\mathrm{d}t} = \mu * E(t) - \gamma * I(t), \\[2ex]
\dfrac{\mathrm{d}R(t)}{\mathrm{d}t} = \gamma * I(t), \\[2ex]
N = S + E + I + R.
\end{cases}
\tag{1}
$$

Among them, $S(t)$ represents the density of vulnerable nodes, $E(t)$ represents the density of latent nodes, $I(t)$
FIGURE 1: State transition diagram of the SEIR model.

represents the density of infected nodes, $R(t)$ represents the density of attack removal nodes, $S(t) + E(t) + I(t) + R(t) = 1$. λ, μ, γ represent the probability of conversion between personnel at each node, $0 \le \lambda$, μ, $\gamma \le 1$, λ is the corruption infection rate, μ is the potential decision rate, and γ is the crackdown rate.

The infection rate λ refers to the probability that an infectious disease will infect from a susceptible population to an individual in a complex network, mainly refers to the probability that a susceptible population becomes a potential individual node in the corrupt network. The incubation state refers to the incubation period of the infectious disease from the individual infection state to the outbreak stage of the group infection. In the corruption case network, the potential decision rate μ is used to express the probability that the potential individual corrupt personnel is willing to participate in the corruption case after the balance of income and expenditure analysis. The crackdown crate γ refers to the probability that the infected node is cured by some measures, which also means the probability that the official organization arrest the corrupt personnel.

4. Model Parameters

The parameter of the infectious disease model generally is a measurable indicator. Previous studies set the relevant parameters mainly through historical data, related literature, genetic algorithms and particle swarm optimization algorithms [42, 45, 46, 48, 56].

4.1. Data Collection. There are many news and network reports on corruption cases of construction projects, but there are two problems: description bias and selection bias [27]. Given the sensitiveness and implications of criminal proceedings, criminal intelligence and investigations strive for achieving the most accurate representation of each case [57]. China Judgments Online is an official platform sponsored by the Supreme Court [20], which provides numerous corruption cases including the construction projects. Moreover, the China Judgment Online records in detail the interaction of corrupt persons and other groups in the construction projects. In order to ensure the validity and authenticity, the data in this paper are derived from the legal judgment documents published in China Judgments Online.

This paper uses the advanced filtering function of the China Judicial Documents to obtain all the data. In the process of data screening, this study sets the case type, the trial procedure, court level, year, and document type as "criminal case," "criminal first instance," "all," "2018," and "judgment" respectively, and then conducts a full-text screening for "bribery," "acceptance of bribes," "construction projects" and "project corruption." After screening, analysing and sorting out specific content, a total of 2158

engineering corruption cases were found, involving people in 12 provinces and 1 municipality.

The cases of corruption in construction projects were filtered according to the following criteria: (1) The information of all judgment documents is complete, and the content of which is related to the field of construction projects. (2) All the judgment documents should be read in detail and adequately hand-screened to find interrelated cases. Based on the defined filtering rules. Then, a total of 109 cases with the most complex case relationship, large amount of corruption and long latency are selected for analysis. The cases selected in this paper are suspected of several charges, including bribery, acceptance of bribes, abuse of authority, collusion in bidding. All actors named in the selected adjudicative instruments as being involved in illegal activities are included in the detailed detail record. The earliest of the arrested core criminal officers began participating in corrupt activities in construction projects in November 2007 and were arrested and prosecuted in late 2017. Analysis of the data shows that nodes 2, 4, 5 and 34 are government department officials. The rest of the nodes are contractors except for the group of people associated with government officials. In addition, nodes 1, 2, 3, 4, and 5 are the key individuals who were eventually apprehended for participating in or committing corrupt acts on the construction projects. The selected cases involved 34 persons and institutions, more than 14 million single-person crime, and an incubation period of up to 10 years. The five adjudication documents of the selected cases are all first instance judgments of criminal cases, numbered (2018) Xiang 1224 No. 17, (2018) Xiang 1224 No. 64, (2018) Xiang 1224 No. 65, (2018) Xiang 1224 No. 196, (2018) Xiang 1281 No. 175 respectively.

In this paper, all names of personnel and company are replaced by numbers for conveniently analysing the relationship between corrupt personnel, then a $34 * 34$ one-dimensional adjacency matrix and a directed engineering corruption nest personnel relationship network are constructed to determine the parameters of the infectious disease model.

4.2. Partial Model Parameter Settings. This study determines the relevant parameters through the analysis of corruption cases in actual construction projects. Corruption contagion in actual construction projects can be initiated by several people or a small group; whereas the corruption spread of the construction projects involved in this case is initiated by one person and then gradually expands based on the detailed analysis of the five legal judgments involved in this study. Therefore, this paper selects one key person as the source group of corruption communication. The total number of people in the network is assumed to be $N = 34$ by analysing the actual case. S, E, I, and R represent the initial number of

personnel at each state node. Therefore, this study assumed the number of each group as $I = 1$, $E = 0$, $R = 0$, and $S = 33$ in the initial state, respectively. Due to the complexity, dynamics, concealment and sensitivity of corruption cases in construction projects, it is difficult to directly quantify the management measures such as supervision, close visits and talks in corruption cases in construction projects. For the setting of the crackdown rate of corruption in construction projects this study is replaced by the number of corrupt group members arrested and imprisoned. Considering that five people have been arrested in the organization's 34-person corruption network, the rate of attack is $r = 5/34 = 0.147$; The potential decision rate μ depends on the cost-benefit risk of corruption involved in the project, with a random possibility each time; The potential corruption decision rate u of corrupt personnel is taken as 0.5, in order to make this group of personnel have the same possibility each time. The analysis found that the incubation years of the five corruption offenders were 10 years, 9 years, 7 years, 5 years, and 4 years, respectively. The propagation time of 10 years in this study is the maximum incubation time for all groups of people and institutions involved in construction corruption projects. Therefore, this paper will use the incubation time as the parameter of the propagation time to describe the interaction of the group's corruption behaviors during the entire propagation period.

4.3. Corruption Infection Rate Parameter Setting.

This study attempts to determine the magnitude of personnel corruption contagion rate in the construction projects through complex network modelling. At the node level, degree centrality is used to represent the structural position of actors in a network [58]. The nodes with greater degree centrality in complex networks can be regarded as important conduction nodes [29, 58, 59]. In this study, the higher the degree of node centrality in the corruption network of the construction project, the more people have corrupt behavior. Therefore, this study reveals the number of corruption contagions in the corruption nesting network of construction projects according to the connection effect of several important nodes with greater centrality [29]. The corruption infection rate is defined as the average contact degree of the core personnel, as shown in equation.

$$\lambda = \frac{1}{n} \sum_{i=1}^{n} C_i. \tag{2}$$

Among them, λ is the corruption infection rate, C_i is the node ratio of the i-th core corrupt personnel to the corruption network, i is the i-th core corrupt personnel in the corruption network, and n represents the number of core personnel in the corrupt network.

4.3.1. Complex Network Model Construction.

Considering the complexity and interaction of corrupt behaviors among corrupt groups in construction projects, it is difficult to visualize the connections between nodes through textual narratives, and the use of complex networks can be a good

way to visualize the relationships among nodes. Based on the five selected adjudication documents, the relationship between groups of people is analysed in detail. If there is corruption between any two individuals in the corrupt group, a link is established. The corrupt personnel and the corruption relationship between personnel are abstracted as the network nodes, the edge of the network respectively, then the corruption relationship network is established [5, 60]. The corruption network can be represented by the adjacency matrix $An * n$, so that if there have been corrupt behaviors between personnel, then $a_{ij} = 1$, otherwise $a_{ij} = 0$. The adjacency matrix can reflect the relationship between groups in the complex network, as shown in Table 1. Ucinet software can build a corruption network for the corruption case group of construction projects based on the relationship of the adjacency matrix. A complex network of the personnel contact in the engineering corruption case is built by using Ucinet software, as shown in Figure 2. A detailed adjacency relationship matrix data is shown in the supplementary materials Annex 1.

4.3.2. Corruption Infection Rate in Complex Networks.

The nodes with larger out-degree and in-degree values can be considered as the important conduction nodes of the network in this study. In addition, it can be considered that the formation of corruption network is due to the corruption of a group or multiple individuals. Betweenness centrality is used to measure the transportation capacity of nodes in a complex network. The higher the betweenness centrality, the more influence the node has. It is believed that the nodes with high intermediary centrality in the corruption network of construction projects have strong corruption transmission capabilities. Closeness centrality is a characteristic value that reflects the distance between a node and the centre of the network [27, 29]. Thus, it is significant to calculate the degree centrality, betweenness centrality, closeness centrality, and core edge analysis of the corruption case network, so as to determine the key personnel in the corruption network [27, 39]. This study assumes that the corruption contagion rate of the corruption case is determined by the average degree centrality of the core personnel. The centrality indicators of each corrupt network node are shown in Table 2. Detailed data can be found in supplementary materials Annex 2.

Table 2 reveals that the top eight nodes with the highest total degree of centrality are: 5, 1, 3, 2, 22, 24, 4, and 11 respectively. The order of nodes with high betweenness centrality is 5, 2, 1, 22, 3, 4, 24, 8; The distribution of nodes with more tightness centrality is 2, 3, 1, 31, 5, 22, 4, 34. According to the degree of close connection between nodes in the complex network of the corruption case, the core and edge personnel in the corruption network are determined by using Ucinet software [35, 57, 59], as shown in Table 3.

According to the three-centrality analysis and core-edge structure of the corruption network personnel in Table 2 and Table 3, 7 people, namely Node 1, 2, 3, 4, 5, 22, and 24, are identified as the core personnel of the corruption network in this case. The corruption contagion rate of the project is $\lambda =$

0.239 according to the above assumption of equation (2). In summary, this paper uses the network characteristics of the case personnel to determine the improved SEIR model parameters, as shown in Table 4.

5. Simulation Verification and Analysis

5.1. Evolutionary Relationship of Corruption Contagion in Construction Projects under Actual Cases. This paper defines the total number of research groups as $N = S + E + I + R$. Where S, E, I and R represent the number of personnel at each status node in the process of corruption propagation. The corruption infection rate λ of initial corruption cases is 0.239. Potential decision rate μ, crackdown rate of the formal organization γ, and corruption propagation time t are 0.5, 0.147 and 10 years respectively. This paper use Python to simulate the infectious disease model in the state of corruption nest, then obtain the evolution results of people in each stage of the spread process of corruption nest, as shown in Figure 3.

Figure 3 shows that the number of corrupt personnel I node will first increase to a certain level and gradually decrease over time, then stabilize, and finally reach a peak in three years. The number of individuals at the latent node E is consistent with the changing trend of corrupt personnel as a whole, and the peak value is less than the number of corrupt personnel. It demonstrates that in a relatively closed network structure, the construction project-related personnel who would like to participate in corruption will eventually become a member of corruption to externally intervene in the construction project. The number of groups S in the perishable stage declines in a power law over time, indicating that the degree of corruption is relatively serious.

The number of R in an immune-strike state shows an increase in the power rate, which shows a good effect in combating corruption by the official organization. Throughout the propagation, the crackdown by official organizations and the spread of corruption coexisted, intersecting in about 4 years. Furthermore, the simulation curve of corruption propagation reveals that the effect of corruption cracking is significantly stronger than the level of corruption after 4 years, and the number of people in each state cluster is basically in a stable state after a latent period of about 9 years, which is consistent with corruption incubation period of around 10 years in the current construction project [23]. On the one hand, it illustrates the significant effect of the crackdown by official institutions in reducing corrupt practices during their dissemination online. On the other hand, it also shows that the complex and closed corruption network structure will eventually collapse by itself after a certain time of spreading due to the sparseness of the network and the multiple complexity of the personnel. This is also evidence of the vulnerability and poor flexibility of corruption case networks in long-term propagation.

The source data of five selected engineering corruption cases reflects that the time of 80% corruption criminal to form a group of corruption is less than 4 years. It also illustrates that the corruption criminal will quickly form a

TABLE 4: Probability of each parameter.

Range	0.239	0.5	0.147	10 years
FIGURE 3: Variation in the nodes number of personnel during corruption with actual parameters.

network of corruption in various ways under the premise of satisfying the profit of all parties. In addition, it can also be found that the parameter settings are based on the actual construction project corruption cases in this study. The peak number of personnel for corruption propagation throughout the construction project is the same as the number of core personnel for corruption apprehension in the actual case. At the same time, by observing the evolution of the corruption propagation pattern, we can find that only five of the most central corrupt people in a corrupt network of 34 people were arrested, which is also consistent with our actual data of corruption cases in the magisterial documents. Other groups of people involved in corruption in construction projects may have been prevented from corruption by a variety of measures such as external supervision, confidential visits and interviews, combat and arrest only the most central key personnel, which is similar to the realistic measures to prevent corruption in construction projects.

The results show that the corruption and infectious disease model constructed in this paper is feasible and consistent with the actual situation. The "4–9 propagation law" of construction project corruption nest cases was discovered through actual case analysis.

5.2. The Impact of the Formal Organization's Crackdown Rate on the Spread of Corruption. This study sets the parameter of crackdown rate and others based on the specific construction projects corruption cases to investigate the effect of the crackdown rate on the contagion behavior in the construction project. Under the condition of constant corruption infection rate of 0.239 and other parameters, the crackdown rate γ of the formal organization is set to be [0, 1].

Variable parameters should be allowed to vary within a certain range to better reflect the real situations of corruption contagion behavior. However, when the parameters of corruption transmission behavior are freely changing, the simulation of corruption transmission behavior for construction projects does not truly reflect the correspondence under the changes of corresponding factors. More importantly, the factors under the infectious disease model are fixed parameter variation studies under transmission behavior analysis [42, 46, 48]. To overcome these shortcomings, this study uses sensitivity analysis to explore corruption contagion behavior under several relatively varying scenarios. Taking into account the actual crackdown rate of 0.147, the parameter values of the crackdown rate of the formal organization were set to 0.05, 0.1, 0.147, and 0.2, respectively, by sensitivity analysis of the crackdown rate [42, 61]. Based on the infectious disease model, Python is used to simulate the crackdown rate of personnel informal organizations. The change in the number of personnel at each node in the state of corruption is shown in Figure 4.

Figure 4 and Table 5 show that when the crackdown rate of formal organizations exceeds 0.2, corruption will hardly occur. With the increase of the crackdown rate, the peak value of corrupt personnel nodes I gradually decreases and the propagation time to reach the peak value gradually increases. When the corruption crackdown rate is increased from 0.05 to 0.1 by 5%, the degree of corruption is relatively reduced by 42.85%, and the peak propagation time of corruption is relatively increased by 8.57%. When the corruption crackdown rate increased by 9.7% from 0.05 to 0.147, the degree of corruption decreased by 78.57%, and the propagation time of corruption at its peak increased by 14.29%. It can be seen that the crackdown rate is negatively correlated with the degree of corruption in construction projects, and positively correlated with the peak propagation time of corruption. The corruption spread, the propagation time of corruption cases reaching the peak is about minus 8 times, 1.6 times of the crackdown rate respectively.

The number of perishable personnel S and the number of immune-strike personnel R also show power-law changes, and the magnitude of the change in the two curves reflects the relationship between corruption and crackdown in the corruption case. It can be seen from Figure 4 that when the crackdown rate is 0.05, 0.1, and 0.147, the susceptible S and the remover R intersect at 2.5 years, 3.2 years, and 4 years, respectively. The size of the intersection reflects the speed of the spread of personnel corruption in the corruption nest case. The whole corruption nest case network is in a stable state. When the crackdown rate increases by 5% and 9.7%, the increase of s of corrupt personnel in the project is 150% and 500%, respectively, which is 9.375% and 31.25% greater than the decrease of R of corrupt personnel in the project. With the increase of the crackdown rate, the increase of perishable personnel S in the construction project is greater than the decreased number of personnel removed from the immunization crackdown of the official organization of the construction project. It shows that the number of people involved in the spread of corruption is far smaller than the effect of the corruption crackdown, and the crackdown rate

of the corruption case of the project is also relatively high, which meets the crackdown requirements.

The analysis shows that the occurrence of corruption prevention cases can be reduced from the source through the dynamic monitoring of the project and strengthening the crackdown on the organization.

5.3. The Impact of the Infection Rate of Corrupt Personnel in the Engineering Corruption Case on the Spread of Corruption. Under the constant condition of crackdown rate (i.e., 0.147) and other parameters, the value of the corruption infection rate λ of the personnel in the engineering corruption network is [0, 1]. Considering the actual corruption transmission rate of 0.139, the values of corruption transmission rate parameters were set to be 0.139, 0.239, 0.339, and 0.439 by sensitivity analysis of the transmission rate [61]. Based on the infectious disease model, the extent of corruption nesting in construction projects under different corruption contagion rates is simulated by Python. The personnel change of each node in the state of corruption is shown in Figure 5.

According to the simulation results in Figure 5 and Table 6, it can be seen that corruption hardly occurs when the corruption infection rate of a construction project is less than the crackdown rate. When the corruption infection rate increases by 10% from 0.239 to 0.339, the transmission time of corruption nest cases reaching the peak decreases by about 25%, and the peak number of people involved in corruption increases by about 100%. When the corruption infection rate increases by 20% from 0.239 to 0.439, the propagation time of corruption cases reaching the peak is relatively reduced by about 50%, and the peak number of people involved in corruption is relatively increased by about 200%. The transmission scale and rate of corruption network increased with the increase of the change range of corruption infection rate. The infection rate is positively correlated (i.e., 0.1 times) with the corruption degree of the construction project, and negatively correlated (minus 0.4 times) with the time of the construction corruption reaching the peak of transmission. The infection rate of engineering project corruption has a great impact on the spread of corruption cases. The control of the infection rate of corruption must start from multiple aspects including real-time dynamic monitoring, reduce the spread of corruption, and ensure the normal implementation of the entire process of the project from the source.

In the whole process of corruption propagation, S curve and R curve show a power-law trend. Figure 5 shows that the simulation curves of the S curve and the R curve intersect at 4 years, 2.5 years, and 2 years, with intersection points of 6 people, 14 people, and 12 people respectively, as the infection rate increases. There will more perishable groups S and removed groups R over time. In a stable state of transmission, the relative reduction of personnel prone to corruption in the project is about 50% when the infection rate of corruption increases by 10%, which is greater than the increase of 27.27% by the formal organization of the project. The rate of decrease of perishable personnel in engineering projects is about 83.33% when the infection rate of

(c)

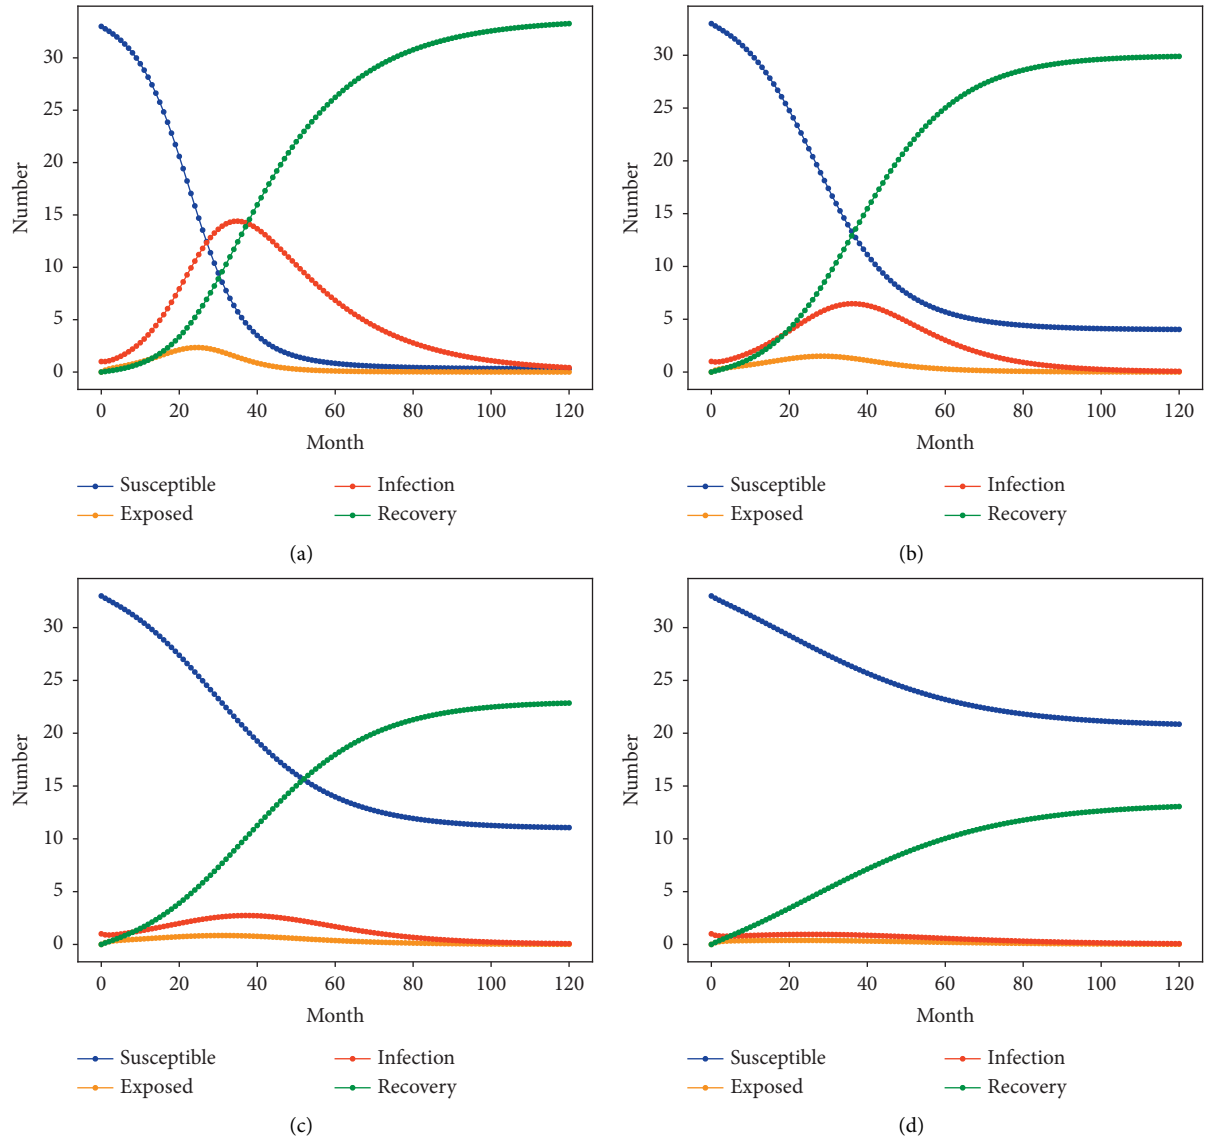
(d)


FIGURE 4: The relationship of changes under different crackdown rates. (a) $\gamma = 0.05$, (b) $\gamma = 0.1$, (c) $\gamma = 0.147$ (d)$\gamma = 0.2$.

TABLE 5: Parameter variation relationship of nodes at different crackdown rates.

γ	t	$S(t)$	t	$E(t)$	t	$I(t)$	t	$R(t)$
0.05	70	2	25	3	35	14	120	32
0.1	90	5	30	2	38	6	100	29
0.147	100	12	30	1	40	3	110	22
0.2	120	21	—	—	0	1	120	13

corruption increases by 20%, which is greater than the rate of 45.45% in the official organization of the project to crack down and remove the increased personnel. It can be seen that the spread of the number of people involved in corruption infection is far greater than the effect of corruption attacks with the increase in the infection rate. In addition, the impact of the intensity of corruption infection rate will be greater when the reduction of corruption prone personnel is greater than the increase personnel in the formal organization of the project.

5.4. The Impact of Changes in Latency Period on the Level of Corruption in Construction Projects. Parameters obtained from actual cases are taken as the corruption contagion rate and combating rate of construction projects. The influence of the evolutionary pattern of corruption nesting behaviors in construction projects under different incubation periods is studied separately. This paper selects the incubation period of 6 years, 8 years, 10 years and 12 years as the characteristic parameters to analyse the evolution relationship between the incubation period and the corruption degree of the project.

(a)

(b)

(c)

(d)
Figure 5: Relationship between changes under different infection rates. (a) $\lambda = 0.139$, (b) $\lambda = 0.239$, (c) $\lambda = 0.339$, and (d) $\lambda = 0.439$.

Table 6: Parameter variation relationship of nodes with different infection rates.

λ	t	$S(t)$	t	$E(t)$	t	$I(t)$	t	$R(t)$
0.139	100	28	—	—	—	—	110	6
0.239	90	12	30	1	40	3	110	22
0.339	60	6	22	3	30	6	80	28
0.439	50	2	18	4	20	9	60	32

Based on the infectious disease model, the extent of corruption nesting in construction projects under different corruption Latency Period are simulated by Python. The change of the personnel number at each node in the state of corruption is shown in Figure 6.

According to the simulation results in Figure 6 and Table 7, a very interesting phenomenon of corruption group evolution can be found when the rate of corruption contagion and the fight against corruption in construction projects are determined. The change of latency time has little effect on the peak value of group I in the construction projects corruption. When the incubation time is less than 10 years, the number of corruption-prone groups S and the number of removal-strike stage groups R are still in the process of propagation evolution. This also verifies the accuracy of the 10-year latency time for the five construction projects corruption adjudication documents selected in this study.

This is contrary to the traditional latency period of engineering projects and significant relationship between the degree of corruption. This is mainly because the number of corrupt groups in construction projects is relatively fixed
Figure 6: Relationship between changes under different latency periods. (a) $t = 6$ years, (b) $t = 8$ years, (c) $t = 10$ years, and (d) $t = 12$ years.

Table 7: Parameter variation relationship of nodes with different infection rates.

t	t	$S(t)$	t	$E(t)$	t	$I(t)$	t	$R(t)$
72	—	—	30	1	40	3	—	—
96	—	—	30	1	40	3	—	—
120	90	12	30	1	40	3	110	22
144	90	12	30	1	40	3	110	22

in this study, except the relatively fixed values of the contagion rate and strike rate parameters that affect the behavior of corruption transmission in construction projects. Similarly, this evolutionary relationship illustrates that the length of latency time cannot influence the peak state of corruption contagion behavior in construction projects when the propagation parameters are in a determined state, unless the latency time is short enough to influence the formation of corruption nesting networks in construction projects. This

also validates the infectious behavior of the corruption nest in construction projects will be rapidly infected to form a complex and hidden corruption network among the group in about 4 years.

This study demonstrates the behavior of corruption transmission in construction projects by changing the incubation time, and the simulation results also verify the rationality and scientific validity of the infectious disease model designed in this study.

6. Discussion

6.1. Findings. The construction and practical validation analysis of the construction projects corruption nesting SEIR model shows that the model constructed in this paper is scientific and reasonable in line with the actual situation. Due to the dynamics, complexity, and concealment of the corruption network of the construction projects, the people who are in the core network will also vary over time [27, 34, 36]. Zhang [42] proposed the MI-SEIR model considering the influence of media and interpersonal relationships on opinion dissemination based on the SEIR model. Nekovee [37] explored the mechanism of penetrating and spreading corrupt behavior within the organizations, and the behavioral interaction between corrupt group. The traditional spread of public opinion, epidemics and torts are generally based on models such as SIR and SEIR [42, 45]. The dynamic time dimension is used to study the propagation law of corruption in engineering projects according to the changing relationship of incubation time.

Because of the time lag between the occurrence of corruption and its apprehension, the length of the incubation period of corruption largely influences the extent of the spread of corruption in construction projects [19, 22, 23]. In the propagation model constructed in this paper, the relevant parameters are obtained from the actual case. The simulation results found that the level of corruption fight in a corruption network after a latency period of more than 4 years will be significantly stronger than the level of corruption propagation, and hardly exist after 9 years. Yu [22] found that the average latency period was significantly longer (i.e., 6.4 years) in construction-related corruption. There are 11 cases over 10 years, with the longest being 15 years. Zhang [23] also analysed the average corruption latency period of 8.02 years through actual data, which is also consistent with the nonexist corruption of about 9 years' latency time in this study. This shows that the corruption nest group in construction projects can quickly form a complex and flexible corruption network within the first 4 years. When the incubation period exceeds nine years, the corruption network of the construction project basically disintegrates and the core group in the corruption network will be hit.

The single factor analysis of corruption communication reveals that the corruption will hardly occur when the crackdown rate of formal organizations exceeds 0.2 or the rate of corruption infection is less than the crackdown rate, which shows that the corruption case network has certain fragility. There is a strong correlation between the crackdown rate, infection rate and the degree of corruption. Corrupt groups spread through specific pathways within a certain spatial and temporal context due to the versatility and flexibility, and such interactions against groups can be considered as the contagion of corrupt behavior [5, 38]. The increase of the crack-down inhibits the maximum scale and rate of corruption risks in the network, and the increase in the rate of infection determines the scale and rate of spread of the corruption case network. The spread scale of corruption cases, the propagation time reaching the peak is

about minus 8 times, 1.6 times of the crackdown rate respectively. The spread scale of corruption cases is about 10 times of the corruption rate, and the spreading time is about minus 2.5 times of the infection rate. The best way to reduce the incidence of corruption cases is to prevent corruption infection and strengthen the crackdown. The serious phenomenon of corruption spreads from individuals to groups and even to the whole organization, and from lower levels to higher levels according to management logic.

6.2. Theoretical Implications. On the one hand, we try to explain and discover the corrupt behavior of construction projects and its laws by using the contagion theory model. It enriches the theory and method of construction project corruption behavior research, while expanding the application scope of contagion model theory. This paper analyzes the evolution relationship of corrupt behavior in engineering projects, and focuses on the evolution law of corrupt behavior groups. This study broadens the research field of corruption behavior in construction projects, enriches the scope and conditions of application of the contagious disease model theory to the contagious behavior of corruption in construction projects, and applies the contagious disease SEIR model to the contagious behavior of corruption in construction projects. By analysing the evolutionary relationship of corruption contagion behavior in engineering projects, the paper focuses on the changing relationship of corruption contagion behavior under the influence of factors such as external corruption contagion behavior and crackdown under the change of latency time. The study breaks the traditional research for the degree of corruption in construction projects, the characteristics of corruption, corruption governance under a single perspective to consider the problem starting. The nature of corruption contagion behavior is analysed and sorted out, which helps to understand the inner evolution law of corruption contagion behavior in construction projects and expand the boundary area of corruption research in construction projects.

On the other hand, the complex network theory used in this paper combined with the contagion model theory explores the characteristics of the spread of corrupt behavior from a dynamic perspective. The method of determining model parameters through complex networks obtains more objective data than the questionnaires and expert interviews used in traditional studies. It also provides a theoretical reference for scholars to adopt new methods for data acquisition and consolidates the exploration of scientific governance in the field of corruption management of construction projects. At the same time, the evolutionary relationship of corruption contagion behavior in construction projects also breaks the tradition of analysing the relationship characteristics of corruption behavior mostly from a static perspective. It also reveals the changing characteristics of group behavior under the whole time of corruption transmission, and also provides a new theoretical exploration for the targeted fight against the occurrence of corruption.

6.3. Practical Implications. The study provides clearer target and compelling rationale for policy makers to select the right strategic tool in their fight. First of all, in view of the prevalence of such corruption in construction projects, the fight against corrupt groups should use a variety of means for full process control. Secondly, considering the simulation analysis of the actual case dissemination process in this study, the early stage is a high-frequency stage prone to corruption in construction projects. Therefore, the government supervision department should attach great importance to the control of small groups in violation of regulations in the early stage of the project such as the bidding process. Thirdly, the corruption hardly occurs when the strike rate of formal organizations exceeds 0.2 or the corruption infection rate is lower than the crackdown rate. Therefore, the government supervision department can choose appropriate crackdown and supervision strategies to improve the efficiency of project management according to the degree of corruption of local construction projects. Finally, government departments should pay more attention to the informal organization groups in the construction process of construction projects, and strengthen the control of the generation and dissemination of inter-group violations.

7. Conclusions and Future Study

7.1. Conclusions. This study proposes an improved SEIR model of corruption contagion behavior in construction projects based on the epidemic model considering the variation of latency time of group personnel. Five adjudication documents collected from the official website of Chinese adjudication documents were used to validate the propagation model test of corruption nesting cases in construction projects. This paper demonstrates that the model is consistent with the process of corruption propagation in construction projects, explores the evolutionary relationship of corruption propagation, and investigates the effects of changes in crackdown rate and contagion rate on the contagion time and the degree of corruption. Based on the simulation results, the following conclusions can be drawn.

(1) The improved SEIR model for infectious diseases proposed in this paper is scientifically and rationally compatible with the actual process. (2) A complex and hidden network of corruption in construction projects can be formed rapidly within four years or even less. When the latent period exceeds 9 years, the corruption network of construction projects will basically disintegrate and the core group in the corruption network will be crackdown. (3) If can target to Enhancement of the crackdown rate or even some regulatory measures by external regulatory agencies can effectively reduce the spread and proliferation of corruption behavior at the early stage of corruption contagion behavior in construction projects. Otherwise, if external regulators allow corruption to occur, corruption in construction projects will rapidly spread throughout the corrupt community. (4) There is a strong correlation between the crackdown rate, infection rate and the degree of corruption,

the increase of the crack-down inhibits the maximum scale and rate of corruption risks in the network, and the increase of the infection rate determines the scale and rate of spread of the corruption case network. The spread scale of corruption cases, the propagation time reaching the peak is about minus 8 times, 1.6 times of the crackdown rate respectively. The spread scale of corruption cases is about 10 times of the corruption rate, and the spreading time is about minus 2.5 times of the infection rate.

7.2. Limitation and Future Research Directions. Due to the limitation of the data source of corruption cases in construction projects, the dissemination process of corrupt behaviors in this study does not consider realistic issues from external factors such as investment in construction projects, local economic conditions, and government transparency. In addition, this study considers the parameter settings under real cases. However, the effect of free variation of factors in the interval is ignored because the parameters under the SEIR model of infectious diseases need to be fixed when analysing the effect of changing states of factors on the behavior of corruption transmission in construction projects.

The modelling analysis and feature disclosure in this article are based on a specific engineering corruption case; however, a complex network can be constructed with the help of big data techniques to determine the parameters of the infectious disease model.

In the context of Industry 4.0, the vigorous development of digital intelligence technology provides an efficient tool for the engineering management industry. In future research, the SEIR model of infectious diseases should be further improved when considering more influencing factors, such as the investment situation of construction projects, regional GDP, legal regulatory system, and local integrity index. The combination of digital intelligence technology and infectious disease models can dynamically predict the possibility of each behavior in real time. On the other hand, future research on corruption nests in engineering projects will consider multicase data to deeply analyse the evolutionary relationship of propagation behavioral.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

Acknowledgments

Supplementary Materials

The adjacency relationship matrix data used to construct the complex network of Figure 2 will be provided in supplementary materials Annex 1. The complete data of the three centralities used to analyse complex networks in Table 1 will be provided in supplementary materials Annex 2. The original judgment documents used by the literature research room will be provided in supplementary materials Annex 3. The supplementary material Annex 4 contains the source code of the manuscript. (*Supplementary Materials*)

In this paper, an intelligent model is constructed to facilitate real-time dynamic analysis of the factors affecting the export of film and television copyrights and to track the process of spatiotemporal context. The algorithm analyzes the factors affecting the export of film and television copyrights according to actual needs. Through the comparative analysis of experimental models, the influence and optimization of gamma correction and Laplace distribution weighting on spatial context information and confidence map update are verified. In addition, this paper uses the gray relational algorithm to construct an analysis system of factors affecting the export of film and television copyright. The research shows that the analysis model of the influencing factors of film and television copyright export based on the gray relational algorithm can play a very good role in the analysis of these factors.

1. Introduction

In the new normal economic environment, there is no doubt that China's export structure also needs supply-side reforms. In terms of film and television cultural works, our country has been in a state of deficit in international trade for a long time. With the development of economy, people began to pursue spiritual and cultural life after satisfying their material life. With the transformation of society and changes in consumption concepts and lifestyles, as well as the promotion of technological factors such as Internet technology and new media technology, film and television cultural works appear more and more frequently in people's lives, and people's expenditure on film and television cultural works is also increasing.

On the one hand, as a kind of copyright, film and television copyright has the characteristics of copyright, which can be summarized into three types: "exclusiveness," "territoriality," and "timeliness." "Exclusivity" means that copyright is as exclusive as ownership. Copyright is exclusively owned by the right holder, and this right of the right holder is strictly protected by law. Moreover, in addition to the exceptions provided by the law, the use of the work by others must obtain the permission of the right holder. "Territoriality" means that the effectiveness of copyright is restricted by space and only extends to the territory of the country, which is strictly territorial. Unless international conventions or bilateral treaties are signed between countries, intellectual property rights do not have extraterritorial effects, and anyone outside of the country can freely use the copyright. However, due to the accelerating process of today's world integration and the increasingly frequent exchanges between countries, transnational copyrights and transnational jurisdictions of copyrights and worldwide intellectual property protection organizations have emerged. Therefore, the characteristic of "territoriality" is gradually diminishing [1]. "Timeliness" means that the protection of copyright is limited by time. If the copyright exceeds the copyright protection period stipulated by law, it will no longer be protected. Generally speaking, the authorship right, the right to modify and, the right to protect the integrity of the work in the personal rights of copyright are not restricted by time and will not disappear due to the death of a person. The right of

publication in property rights and personal rights is restricted by the term of copyright protection [2]. On the other hand, film and television copyright also has its own characteristics. Film and television works are a collection of independent works such as music, songs, scripts, audio, and video. It is based on these independent works as a whole formed through the processing of modern technology and takes the whole as the object of copyright protection. At the same time, these independent works are separately protected by the law, and the protection of the copyright of these works does not prevent the film and television works as a whole from being protected by the law. Therefore, there is a unique problem of multiple copyrights in the protection of film and television copyrights [3].

In order to facilitate the analysis of the factors affecting the export of film and television copyrights, this paper constructs an intelligent model for real-time analysis of the factors affecting the export of film and television copyrights, which provides a theoretical reference for subsequent related research.

2. Related Work

In international trade, cultural trade is extremely special. It is based on cultural industries and involves trade in goods, trade in services, and intellectual property rights. The International Monetary Fund (IMF) describes international cultural trade as exchanges between countries and between residents and nonresidents, and personal, cultural, and entertainment service transactions are all within the category of cultural trade. It is subdivided into the following two categories: one is audiovisual and related services, and the other is other cultural and entertainment services [4].

The rise of cultural trade has attracted the attention and research of many economists, hoping to find a theoretical basis that can explain cultural trade [5]. Literature [6] believes that traditional trade theory can explain the rise of cultural trade. For example, the United Kingdom has a comparative advantage in Shakespeare's plays, and the United States has a comparative advantage in movies, so that the two countries can exchange works with each other. The United Kingdom concentrates on producing and exporting dramas and importing relatively disadvantaged movies, while the United States concentrates on producing and exporting movies and importing dramas. In this way, both countries can gain benefits in international trade. Literature [7] believes that traditional trade theories such as comparative advantage theory and factor endowment theory are more suitable for imitable cultural products. For example, the labor force in developing countries is relatively surplus and has a comparative advantage in the production of imitable cultural products, so that the export of labor-intensive cultural products can be profitable. However, traditional trade theories have no explanatory power for the trade of cultural products that cannot be imitated.

Literature [8] believes that there are external economies of scale in the cultural industry and the agglomeration of producers in the geographic location forms a large-scale operation. Several film and television companies in Hollywood, the United States, have concentrated on all the links of film production, showing a highly vertical integration

situation and forming an efficient external scale economy effect. This vertical integration can achieve large-scale operations; reduce unnecessary market circulation links, thereby reducing production costs; and help companies integrate their own advantages, realize resource sharing, and achieve good economic benefits. Literature [9] believes that there are also internal economies of scale in the cultural industry. Take the production of movies as an example. Copying ready-made templates can greatly reduce the production costs of movies. Large-scale film and television groups integrate small-scale scattered resources to reduce production costs in production, so as to obtain cost advantages in competition, thereby forcing small companies to withdraw from the market and gaining market share.

Literature [10] puts forward the so-called first actor advantage theory while considering the effect of economies of scale on international cultural trade. Literature [11] argues that the reason why the United States can occupy an absolute share of the global TV market and continuously export cultural products to the outside world is that it has economies of scale and first actor advantages. Large-scale production has given American TV production companies a stronger cost advantage, with the ability to share fixed costs; product upgrades; and relatively sufficient funds required for advertising, making it a greater advantage in the competition of similar cultural products. The first actor advantage considers certain technical conditions, and through actions such as first improving management, increasing labor productivity, improving marketing channels, and being familiar with the market conditions of the exporting country, American cultural production companies can obtain a "leading" advantage in the production of cultural products [12].

Literature [13] applies demand preference theory to cultural trade. Literature [14] believes that the consumption of cultural products can be understood as the satisfaction that people get from current consumption and the accumulation of future knowledge and experience. Therefore, the past consumption structure of cultural products largely determines the future consumption structure.

Literature [15] believes that the theory of comparative advantage can be used to analyze cultural trade. Literature [16] believes that factor endowments, production technology, production methods, and innovation capabilities can cultivate the comparative advantages of the cultural industry. With these comparative advantages, cultural trade can be carried out. Literature [17] used the theory of comparative advantage to explain cultural trade, specifically pointing out that the main advantages of cultural industry participating in international trade are the resource endowment on the supply side, the advantages of knowledge and technology, and the scale of demand.

Literature [18] agrees that the theory of economies of scale is applicable to cultural trade. Take American movies as an example; the formation of Hollywood has reduced the production and production costs of American movies to a large extent. This specialized assembly line and industrial chain have enabled American movies to dominate the world and win high profits. Literature [19] points out that cultural trade is intraindustry trade and uses demand preference

theory to analyze it. The vast majority of international trade in cultural products is carried out between a few countries and is highly concentrated in a few countries, which is a typical intraindustry trade. The theory of preference similarity can explain the phenomenon that the import and export of international cultural trade are highly concentrated between European and American countries with a common cultural background and between the United States and Canada in North America [20].

3. Factor Analysis Model Based on Gray Relational Algorithm

This paper mainly analyzes the influencing factors of film and television copyright export through gray relational algorithm and improves it based on the kernel K-means algorithm. By taking the nonlinear constraint of the kernel K-means algorithm as a penalty term, that is, taking the last term of the constraint in the formula as an independent penalty term, it is combined with the kernel K-means clustering algorithm. In order to extract more effective information in the process of clustering, orthogonality constraints and nonnegativity constraints are added to the proposed model at the same time, and the improved penalized K-means clustering model (PKKM) is obtained in this paper. The objective function is as follows:

$$\max_H Tr\left[H^T K H\right] - \alpha \left\|1_n^T - 1_n^T H H^T\right\|_F^2,$$
$$s.t.\, H \geq 0, H^T H = I. \tag{1}$$

Among them, K represents the kernel matrix, and α is a hyperparameter.

When H satisfies the orthogonality constraint, based on the properties of the Frobenius function and the trace function, the penalty term in (1) can be written as follows:

$$\left\|1_n^T - 1_n^T H H^T\right\|_F^2 = Tr\left[1_n 1_n^T\right] - Tr\left[H^T 1_n 1_n^T H\right]. \tag{2}$$

Therefore, (1) can be written in the following form:

$$Tr\left[H^T K H\right] - \alpha\left\|1_n^T - 1_n^T H H^T\right\|_F^2,$$
$$= Tr\left[H^T K H\right] + \alpha Tr\left\|H^T 1_n 1_n^T H\right\|_F^2 - \alpha Tr\left[1_n 1_n^T\right], \tag{3}$$
$$= Tr\left[H^T (K + \alpha E) H\right] - \alpha n.$$

Among them, $E = 1_n 1_n^T$ represents an $n \times n$ matrix, and all elements in the matrix are 1.

Because the proposed PKKM model has orthogonal and nonnegative constraints, in the process of optimizing the above objective function, the nonconvexity of the model itself makes the solution of the model an NP-hard problem. Therefore, this paper proposes a simple but robust numerical algorithm. The algorithm splits the original matrix variable into two variables through the splitting method and satisfies the orthogonality and nonnegativity constraints. The problem of solving the objective function is transformed into a problem of seeking extreme values of two variables. Furthermore, the algorithm uses an alternate iteration method to find solutions that meet

the constraints. The split model is a more relaxed model. The objective function of the model is as follows [21]:

$$\max_{x,H} Tr\left[H^T (K + \alpha E) H\right] - \frac{\mu}{2}\|H - X\|_F^2, \tag{4}$$
$$s.t.\, H \geq 0, H^T H = I.$$

Among them, the second term in formula (2) can be written as follows:

$$\frac{\mu}{2}\|H - X\|_F^2,$$
$$= \frac{\mu}{2}\left(\|X\|_F^2 - 2Tr\left[H^T X\right] + \|H\|_F^2\right), \tag{5}$$
$$= \frac{\mu}{2}\|X\|_F^2 - Tr\left[H^T (\mu I) X\right] + \frac{\mu k}{2}.$$

Therefore, the solution to the subproblem of H in the above problem can be described as follows:

$$\max_H\left[H^T (\mu I) X\right],$$
$$s.t.\, H^T H = I. \tag{6}$$

Among them, $K = K + \alpha E + \mu I$.

The above-mentioned problem is also called the orthogonal Plucker problem, which has a closed-form solution. Below, we solve it by alternating iterative method.

When the variable X is fixed, the original problem is transformed into the following: for any matrix $A \in R^{n \times k}$, the objective function of the related optimization problem for $H \in R^{n \times k}$ is as follows:

$$\max_H Tr\left[H^T A\right],$$
$$s.t.\, H^T H = I. \tag{7}$$

Formula (5) has a corresponding closed-form solution:

$$H^* = U(:, 1: k)V^T. \tag{8}$$

Among them, $A = U \sum V^T$ is the singular value decomposition of A.

The relevant proof is as follows:

First, $A = U \sum V^T$ is the singular value decomposition of A, and the solution of the H subproblem is as follows:

$$H^* = \arg\max_H Tr\left[H^T A\right]$$
$$= \arg\max_H Tr\left[U \sum V^T\right]$$
$$= \arg\max_H Tr\left[\left(U^T H V\right)^T \sum\right]$$
$$= U\left(\arg\max_H Tr\left[H^T \sum\right]\right)V^T \tag{9}$$
$$= U\begin{bmatrix} I_k \\ 0 \end{bmatrix}V^T.$$

The solution to the X subproblem is as follows: when the orthogonal matrix H cannot satisfy the nonnegativity constraint, the update rule for X is as follows:

$$X = \max(0, H). \tag{10}$$

Therefore, the entire process above is to update the variables between the Stiefel manifold and the nonnegative quadrant.

In this part, we will discuss the relationship between the proposed PKKM algorithm and some commonly used classic clustering algorithms, such as classic K-means algorithm, orthogonal nonnegative matrix factorization (ONMF) algorithm, spectral clustering, and projection nonnegative matrix factorization (PNMF) algorithm.

This relationship is shown in Figure 1. As can be seen from the figure, compared to the other three clustering algorithms, the model proposed in this paper is the closest relaxation model to the K-means model, and its scalability can be changed according to its model. The following part will discuss the relationship between PKKM model and K-means model, ONMF model, spectral clustering, and PNMF model.

When $\alpha = +\infty$, the PKKM algorithm is equivalent to the K-means clustering algorithm.

In the PKKM model, when the parameter $\alpha = +\infty$ of the penalty term in (1) is met, and the constraint condition $1_n^T - 1_n^T HH^T = 0$ is satisfied at the same time, (1) can be written in the following form:

$$\max_{H} Tr\left[H^T K H\right], \\ s.t. \, H \geq 0, H^T H = I_k, 1_n^T - 1_n^T HH^T = 0. \tag{11}$$

Formula (9) is equivalent to the objective function formula of the kernel K mean value.

When the parameter of the penalty term in (1) is $\alpha = 0$, the PKKM model can be written in the following form:

$$\max_{H} Tr\left[H^T K H\right], \\ s.t. \, H \geq 0, H^T H = I_k. \tag{12}$$

Equation (12) corresponds to the ONMF model.

Spectral clustering is the orthogonal relaxation of the proposed PKKM model. The objective function of the spectral clustering model is as follows:

$$\max_{X} Tr\left[X^T L X\right], \\ s.t. \, X^T X = I_k. \tag{13}$$

In formula (13) of the PKKM model, the kernel matrix $K + aE$ in the model is replaced by L, and then the non-negativity constraint in the model is removed. Then, the objective function of PKKM is equivalent to the model of spectral clustering.

The PNMF algorithm is a nonnegative relaxation of the proposed PKKM algorithm, and its objective function is as follows:
Figure 1: The relationship between PKKM algorithm and other clustering models.

$$\max_{x \geq 0} \left[M - MXX^T\right]_F^2. \tag{14}$$

In formula (1) of the PKKM model, $\alpha = 0$, and the orthogonality constraint is removed; then, the PKKM model and the PNMF model are equivalent.

4. Analysis of Influencing Factors of Film and Television Copyright Export Based on Gray Relational Algorithm

The export destinations of Chinese movies are mainly concentrated in two types of countries. One type is Southeast Asian and East Asian countries, which are close to our country's cultural distance and can have a better understanding of Chinese movies. Therefore, in the early stage of our country's film export, works were mainly exported to Southeast Asia, North Korea, and other countries. The other type is European and American countries, which have a developed domestic market and a wealth of domestic works, so there is not much demand for Chinese works. However, due to the relatively developed economies of European and American countries and the demand of local Chinese for domestic films, domestic films can also have some overseas income in Europe and the United States.

The film and television copyright management system creates an end-to-end streaming media content protection platform, while providing all the services needed from the content preparation stage to the delivery stage. The function flow chart of the film and television copyright management system is shown in Figure 2.

The film and television copyright management system uses the HLS protocol for video transmission. The HLS protocol is a streaming media transmission protocol based on HTTP, which can be used to realize video playback on terminal devices. It differs from the common RTP/RTCP and RTSP in that the client-side algorithm obtains complete media content. The content transmitted by HLS mainly includes M3U8 description files and continuous, equal-length TS format media files. Then, it uses the index file of M3U8 to play. The HLS work flow chart is shown in Figure 3.

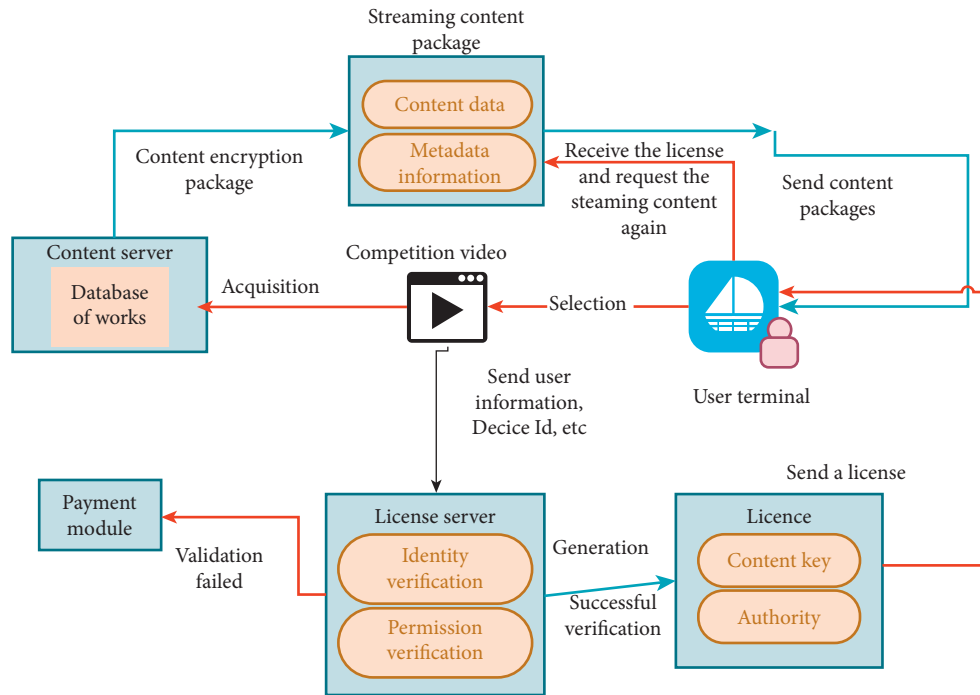
The copyright tracking system of film and television works will extract and track the feature codes of the film and television works in the library to timely understand the relevant infringement status of the works on the Internet, provide a direction for combating copyright infringement of works, and provide technical support for the copyright protection of film and television works.


FIGURE 2: Function flow chart of film and television copyright management system.
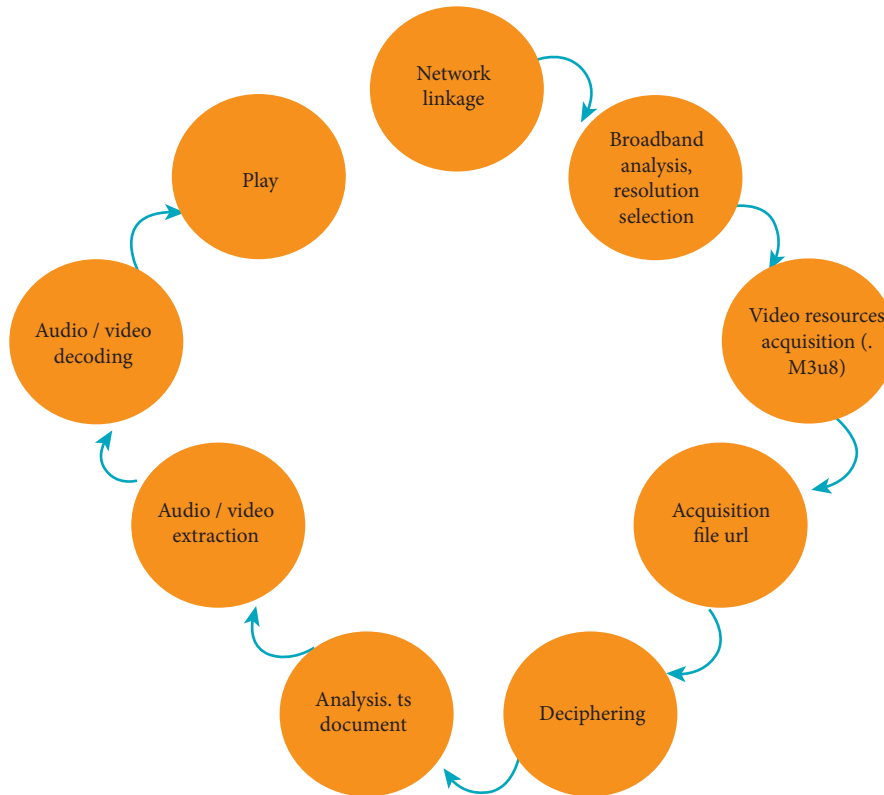

FIGURE 3: HLS flow chart.

After analyzing the needs of the copyright tracking system for text works, it is determined that the system is divided into the following three major modules: infringement information collection, statistical analysis, and auxiliary function modules. Among them, the collection of infringement information is a necessary function, which mainly includes the functions of system importing works, feature code extraction, web crawlers to collect infringement

information, and related process scheduling. The statistical analysis module mainly displays some analyzed data, mainly including functions such as hot infringement list, work infringement information query, and infringement information list. The auxiliary function module mainly configures some data of the system operation module, including authorized website management, key monitoring website management, parameter configuration, and domain name information management. The specific system function module structure diagram is shown in Figure 4.

Aiming at solving the problem of information asymmetry between the seller and the authorized party during the transaction of digital works, a trusted counting mechanism is proposed, as shown in Figure 5. Under this mechanism, trusted counters are introduced into the authorized party (authorization system), seller (sales system), and trusted third party (digital work transaction management platform system). Under the combined effect of the three counters, the supervision of digital works transactions is realized. After the sales system receives the order, it extracts the transaction information (including transaction time, seller ID, content provider ID, price, transaction quantity, and digital copyright identification) in the order and then calls the trusted counter of the sales-oriented system for processing. The sales system trusted counter first checks whether the format of the incoming data is legal and generates a transaction request number and a sales random number. Then, it assembles the data into sales permission request data according to the communication protocol in the counter and then signs the sales permission request data to form uploaded data. Finally, it puts the uploaded data into the data buffer pool, and finally the uploaded data is sent to the trusted counter for the management platform through the network. The authorization system obtains authorization-related information (including order information and authorization time) from the outside and calls a trusted counter for the authorization system to process the data. The trusted counter for the authorization system first checks whether the format of the incoming data is legal and generates an authorized random number. Then, the data is assembled into sales license data according to the communication protocol in the counter, and then the sales license data is signed to form upload data. Finally, the uploaded data is put into the data buffer pool and sent to the trusted counter for the management platform through the network. After the trusted counter in the trusted third party receives the uploaded data from the authorized end and the sales end, it first authenticates the data; the data that fails the authentication will be written into the log, and the data that is successfully authenticated will also be matched with the transaction data. Transaction data matching aims mainly to determine whether two uploaded data items belong to the same transaction. If the matching is successful, the uploaded data will be put into the matching database. If the matching fails, the uploaded data will be placed in the unmatched database. In addition, since there are locally generated random numbers in the two types of uploaded data, a certain degree of uniqueness of the data can be guaranteed, and the

data signature can ensure the nonrepudiation of the data. Therefore, the mechanism in Figure 5 is credible.

Figure 6 is a schematic diagram of the overall business architecture where the trusted counting system is located. The trusted counter for the sales system, the trusted counter for the authorization system, and the trusted counter for the platform constitute the trusted counting system. The trusted counter for the sales system is used by content sellers. The main function is to complete its own configuration, test the connectivity with the platform counter, complete the processing of transaction information, and upload it to the trusted counter for the platform. The trusted counter for the authorization system is used by integrators and content providers. In addition to completing its own configuration, connectivity testing, and uploading authorization data, it also supports querying the sales records of content sellers. The platform-oriented trusted counter is mainly responsible for the receipt, authentication, and final storage of the data uploaded by the sales and authorized ends (calling the relevant database interface). In addition, it is also responsible for managing the configuration information and usage status of the trusted counter for the sales system and the trusted counter for the authorization system and provides data for the sales record query of the authorized end (calling the relevant data query interface). The trusted transaction management platform conducts statistical supervision of transactions and provides external query services based on the data provided by the trusted counting system.

Figure 7 is a schematic diagram of the digital content publishing business process. First, the publishing unit processes the resources to be released and then releases it to the content provider. After the content provider obtains the resource, according to the nature of the resource and its own situation, it will carry out digital content services through direct sales or consignment by channel dealers. In the case of direct selling, the content provider acts as a content seller at the same time and directly deals with users. There is no issue of credible counting involved here. In the case of consignment sales by channel dealers, content providers have no control over content sellers. At this time, the role of a trusted counting mechanism is needed to help regulators supervise the transactions of data works through three types of counters: trusted counters for sales systems, trusted counters for authorization systems, and trusted counters for platforms. Users (including individual readers and institutions) obtain digital content through purchase and payment, and read or use it through a certain method (designated reading software). Throughout the transaction process, the supervisor monitors the information provided by the trusted counting system to ensure the fairness and credibility of the transaction.

On the basis of the above subsystems, this paper combines the gray correlation algorithm to analyze the factors affecting the export of film and television copyright and constructs the intelligent factor analysis model shown in Figure 8.

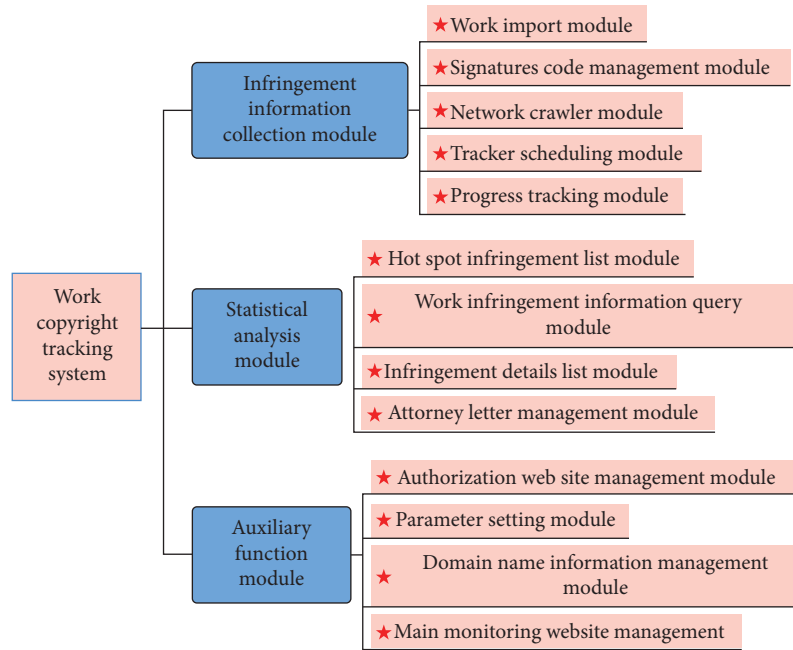
After constructing the above model, this paper evaluates the real-time monitoring effect of the film and television


FIGURE 4: System function module structure diagram.
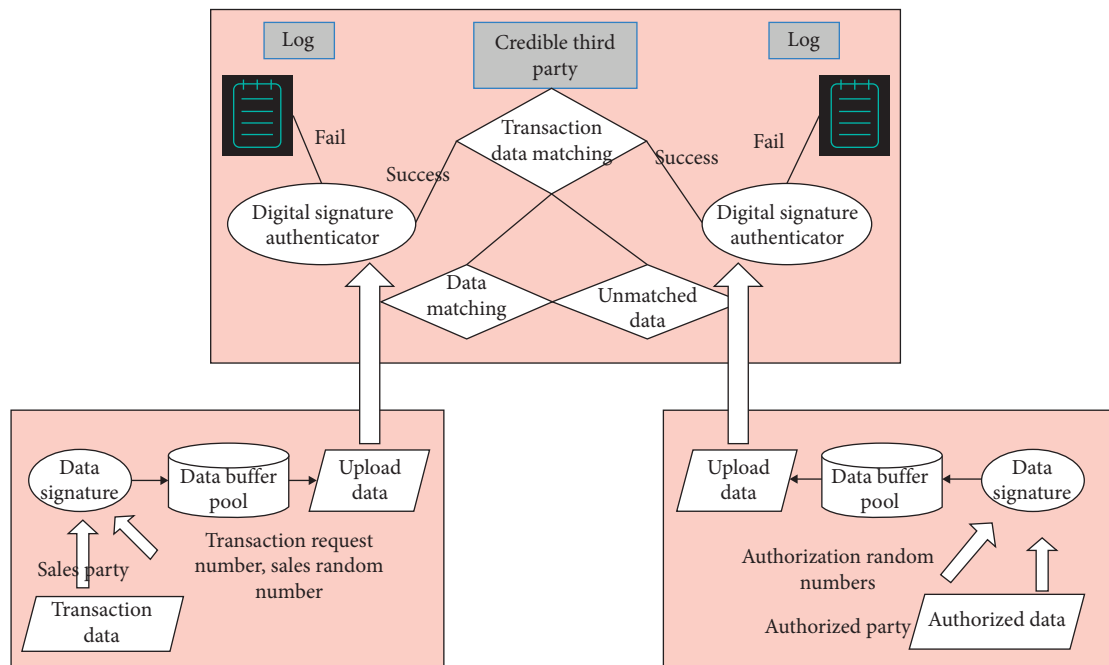

FIGURE 5: Trusted counting mechanism framework.

copyright export of this system and obtains the results shown in Table 1 and Figure 9.

On the basis of the above analysis, this article evaluates the measured effect of the analysis model of the influence factors of film and television copyright export based on the gray correlation algorithm, and the results are shown in Table 2 and Figure 10.

From the above research, it can be seen that the analysis model of influencing factors of film and television copyright

export based on gray correlation algorithm proposed in this paper can play a certain role in the analysis of these factors.

Through the analysis of the above model, we can see that different influencing factors have inconsistent degrees of influence on the import and export of our country's film and television cultural works. The increase in the number of movie screens represents the rapid development of our country's movie market in recent years, which means that the Chinese market's demand for film and television cultural

with higher education who have a stronger ability to consume spiritual and cultural products. Therefore, it will also increase the consumer group and consumption of film and television cultural works. In addition, other economic factors such as GDP, technological factors of Internet penetration rate, national policy factors of cultural undertakings, and growth of internal factors such as the number of movies and TV series will cause an increase in the import of film and television cultural works through their respective influence channels. Among the many influencing factors, the GDP growth rate has the strongest correlation with the export of film and television cultural works. The GDP growth rate reflects China's economic growth rate. Although it is a
Figure 10: Visual diagram of the actual measurement effect of the analysis model of the factors affecting the export of film and television copyright based on the gray correlation algorithm.

macroeconomic indicator, the overall economic development is an economic environment for a small industry, which will also have a corresponding impact on its export volume.

5. Conclusion

Film and television copyright owners will be subject to certain restrictions in the process of exercising film and television copyrights. All countries in the world, including China with its copyright laws, have set certain restrictions on the exercise of copyright. It is mainly reflected in three legal systems: the fair use system, the statutory license system, and the compulsory license system. The fair use system is a basic system of copyright law. It refers to a system where the law allows others to freely use copyrighted works under certain conditions without having to obtain the copyright owner's consent or paying the copyright owner. The factors affecting the export of film and television copyright will continue to change with changes in the general environment, so they need to be studied in light of the actual situation. In order to facilitate the analysis of the export influencing factors of film and television copyright, this paper constructs an intelligent model for real-time analysis of these factors, which provides theoretical reference for subsequent related research. The research results show that the analysis model of film and television copyright export influencing factors proposed in this paper based on the gray correlation algorithm can play a certain role in the analysis of these factors.

The self-balanced loading test is a state-of-art pile testing method, but its suitability to pile bearing capacity determination in transformer substation engineering in mountainous and hilly areas is not yet clear. In this study, a two-dimensional axisymmetric numerical model is established by the PLAXIS software to simulate the behavior and bearing mechanism of shallow rock-socketed short piles based on the self-balanced loading test. The model is first validated by simulating the field tests of two adjacent piles under self-balanced loading. Then the influence factors of the load-displacement curves of piles are analyzed. Thereafter, the mechanical mechanism of the self-balanced loading tests is simulated and compared with the conventional static loading tests. It is observed that the rock modulus, rock-socketed depth of piles, and burial depth of the Osterberg Cell affect the load-displacement significantly, but the cohesion of the rocks affects little. Moreover, compared with the conventional static loading tests, the shear stress of the pile-soil interface distributes less uniformly under self-balanced loading conditions. On this basis, a bearing capacity computation method of shallow rock-socketed short piles based on the self-balanced loading test is proposed.

1. Introduction

With the rapid and continuous urbanization, there are more and more transformer substation engineering, as important urban infrastructures, constructed in mountainous and hilly areas. Rock-socketed piles with small diameter (generally 600–800 mm), short length (generally 10–20 m), and shallow rock-socketed depth (generally 0.5–1.0 times the pile diameter) are usually adopted for transformer substations in these areas in China. The bearing capacity of these piles is usually obtained by the static loading test [1–8]. This method is to apply physical loads to the pile top at specific time intervals and monitor the displacement at the loading point until failure [9]. The static loading test is the most direct, reliable, and widely used testing method to obtain the bearing capacity of piles, but has some disadvantages such as

high cost, heavy workload, and long testing period in particular for high capacity piles [7–10]. For the mountainous and hilly areas with complex geological conditions, it is difficult to transport concrete blocks or sandbags needed for providing adequate reactive capacity for static loading tests. Besides, adverse environmental problems such as vegetation destruction, solid waste generation, energy consumption, and carbon emission may occur in the stacking loading process. Therefore, the application of the conventional static loading test in transformer substation engineering in mountainous and hilly areas is not cost-efficient and environmentally friendly. More economical and sustainable pile testing methods for transformer substation engineering in mountainous and hilly areas are needed.

The self-balanced loading test also referred to as the Osterberg Cell loading test, firstly introduced into

engineering practice by Osterberg in Northwestern University [11], is an advanced pile testing approach. When this method is used for pile testing, a particularly designed loading device called Osterberg Cell is placed at the specified position inside piles. The Osterberg Cell is a hydraulic jack-like device with displacement transducer wires extended to the ground surface. During the testing process, the Osterberg Cell is pressurized internally and expanded in a vertical direction [12–16]. Thus, an upward and a downward force inside the pile are generated, and the displacement of the two parts of the pile (above and below the Osterberg Cell) is measured. The actual applied load is in equilibrium with frictions between the upper segment of the pile and the soil, self-weight of the pile, frictions between the lower segment of the pile and the soil, and pile-end resistance. Therefore, dead weight or reaction frame is not required in the self-balanced loading test. The bearing capacity can be obtained from two load-displacement curves of the upper and the lower segment of the pile [17–31].

Compared with the conventional static loading test, the self-balanced method has many advantages. Firstly, because the multilevel Osterberg cell test is frequently employed and over one hydraulic jack can be installed on the same level, the capability of the self-balanced loading test can meet the requirements of almost all piles [22]. Secondly, for the piles with very high design loads, a conventional static loading test needs a very large weighted platform or very strong frame for reaction, which has been prohibitively costly and also difficult to arrange in the available time and space [13]. However, the self-balanced method is economic since a smaller testing area and less testing period and is particularly suitable for areas where a conventional static loading test is difficult to arrange in space. Thirdly, the self-balanced loading test has advantages even in the places where the conventional static loading test can be performed, such as less solid waste and other environmental impacts. Therefore, the self-balanced method is considered a more sustainable pile testing method [32].

Nowadays, the self-balanced loading test has been used for high-rise buildings, bridges, and offshore engineering projects [22–24]. However, there are still many problems not addressed. Firstly, when using the self-balanced loading test, the equilibrium point of the testing pile must be determined before Osterberg Cell placement. But engineering practice shows that it is difficult to estimate the equilibrium points accurately, which fails in the upper and lower segments of the piles to reach the ultimate bearing capacity simultaneously in the self-balanced loading test. Secondly, the loading point and loading mode of the self-balanced method is different from the actual stress condition, resulting in different frictional resistance distribution at the pile-soil interface [16, 17]. In addition, rock-socketed piles used in transformer substation engineering in mountainous and hilly areas usually have lower bearing capacity compared with other engineering projects because of smaller diameter, shorter length, and shallower rock-socketed depth. Therefore, the uplift bearing capacity of the pile will be obviously reduced if the Osterberg Cell is installed inside the pile body. In this study, a two-dimensional axisymmetric numerical model is established by the PLAXIS software to investigate the behavior and bearing mechanism of shallow rock-socketed short piles based on the self-balanced loading test. The model is first validated by simulating the field tests of two adjacent piles under self-balanced loading located in southern Anhui, China. Then the influence factors of the load-displacement curves of piles are analyzed. Thereafter, the mechanical mechanism of the self-balanced loading tests is simulated and compared with the conventional static loading tests. On this basis, a bearing capacity computation method of shallow rock-socketed short piles based on the self-balanced loading test is proposed. The simulation results and computation method should provide valuable information for managers to improve the efficiency of management of transformer substation engineering in mountainous and hilly areas.

2. Numerical Modeling

2.1. Description of the Field Test. The field tests were carried out to investigate the behavior of two adjacent cast-in-place concrete piles under self-balanced loading in a 500 kv transformer substation engineering located in southern Anhui, China. The length and diameter of the piles were 16.8 m and 0.6 m, respectively. The rock-socketed depth of the piles was 0.7 m.

The subsoil profile of the construction site consists of 4 soil layers. The 4 soil layers from top to bottom are as follows: compacted fill (10.8 m thick), clay (4.6 m thick), gravel (0.7 m thick), and limestone (3.6 m thick). There is no groundwater on the site. The material properties are illustrated in Table 1.

Figure 1 shows the details of the testing pile, ground condition, the Osterberg Cell, and the displacement monitoring system. The Osterberg Cell was located at the pile end and loaded through the loading system above ground. The displacement bars were connected to the upper or lower loading plates of the Osterberg Cell. Multi-stage loading was adopted for the pile testing. The first loading of the test was set to 260 kN, and the loading increment for each stage was set to 130 kN. During the test, each level of loading was maintained until the pile deformation was stable. For the Osterberg Cell selected for the field test, the maximum loading capacity was 2500 kN and the maximum loading stroke was 100 mm.

Figure 2 shows the measured upward displacement of pile bodies (UDPB) and downward displacement of pile ends (DDPE) of the two adjacent piles (A1 and A2) during the self-balanced loading test. It can be seen that their load-displacement curves were generally coincident, indicating that the self-balanced loading tests have good repeatability. During the field tests, when loaded to the 15th grade (2080 kN), the UDPB and DDPE of A1 were 4.10 mm and 77.06 mm; and the UDPB and DDPE of A2 were 4.81 mm and 71.88 mm. The total displacement nearly reached the maximum loading stroke of the Osterberg Cell and therefore the loading was stopped.

TABLE 1: Summary of the subsoil properties.

Material	Layer 1	Layer 2	Layer 3	Layer 4
γ (kN·m^{-3})	17.8	19.5	19.8	22.0
ω (%)	18.0	24.0	19.0	–
e_0	0.80	0.55	0.60	–
E_{50}^{ref} (MPa)	22.0	18.0	23.0	43.5
c (kPa)	16.0	20.0	25.0	23.0
φ (°)	30.0	27.0	30.0	42.0

Note: γ = unit weight; ω = water content; e_0 = initial void ratio; E_{50}^{ref} = secant modulus in standard drained triaxial testing; c = cohesion; φ = friction angle.

FIGURE 3: Axisymmetric numerical model of the self-balanced loading test.

2.2. Finite Element Mesh and Boundary Conditions.

The finite element software PLAXIS is adopted in this study. PLAXIS is developed by the Delft University of Technology and could be used to simulate the nonlinear, time-dependent, and anisotropic behavior of soils and rocks [33]. Figure 3 shows the two-dimensional axisymmetric numerical model of the self-balanced loading test. The axis of symmetry is set at the axis of the pile. The boundary conditions are taken as rollers on the vertical boundary surfaces of the model and as fully fixed at the base of the model [34]. In the numerical model, the upper and lower loading plates of the Osterberg Cell are represented by two uniform distributed loads. In other words, the stress and displacement of the pile are simulated by applying upward and downward uniformly distributed loads to the upper and lower segments of the pile, respectively. The finite element mesh is set to be fine and automatically divided by the PLAXIS software. As

shown in Figure 3, the interface elements of PLAXIS are used to simulate the interaction between the pile body and soils.

2.3. Material Parameters.

The hardening-soil (HS) model is adopted for the soils and rock. The HS model is an advanced Duncan–Chang model. The yield surface of the HS model is not fixed but can expand with plastic straining, and the hardening modes consist of compression hardening and shear hardening [33, 35].

In the HS model, the confining stress dependent stiffness modulus E_{50}, which is corresponding to the 50% ultimate deviatoric stress, is used to account for the hyperbolic stress-strain relation in primary loading and is given by the equation:

$$E_{50} = E_{50}^{ref} \left(\frac{c \cos \varphi - \sigma_3' \sin \varphi}{c \cos \varphi + p^{ref} \sin \varphi} \right)^m, \qquad (1)$$

where p^{ref} is a reference pressure and the default setting of p^{ref} in PLAXIS is 100 kPa; E_{50}^{ref} is a reference stiffness modulus under the reference confining pressure of p^{ref}; σ_3' is the confining pressure in a triaxial test; m is the power for the stress-level dependency of stiffness.

The unloading/reloading stiffness (E_{ur}) can be expressed as

$$E_{ur} = E_{ur}^{ref} \left(\frac{c \cos \varphi - \sigma_3' \sin \varphi}{c \cos \varphi + p^{ref} \sin \varphi} \right)^m, \qquad (2)$$

where E_{ur}^{ref} is the reference unloading/reloading stiffness corresponding to the confining stress p^{ref}.

Table 2 summarizes the values of the constitutive parameters of the soils used in the numerical simulation. The constitutive parameters for the HS model are obtained by using the following empirical relationships: $E_{ur}^{ref} = 3E_{oed}^{ref} = 3E_{50}^{ref}$, in which E_{oed}^{ref} = tangent stiffness for primary oedometer loading [33]. For simplicity, m is assumed to be 0.5.

2.4. Modeling Procedure.

The modeling procedures were the same as the field tests: (1) Define the material properties of the numerical model; (2) Initiate the boundary and initial stress conditions, and the initial equilibrium state; (3) Activate the pile and the interface elements between the pile body and soils, and calculate to the equilibrium state; (4) Activate the upward and downward uniformly distributed loads to the upper and lower segments of the pile. The uniformly distributed load started at 260 kN and gradually increased to 2080 kN in 15 grades, that is, the corresponding stress on the loading surfaces increased from 920 kPa to 7360 kPa. Each grade of the loading was calculated until mechanical equilibrium and displacement stability.

2.5. Numerical Results

2.5.1. Deformation.

Figure 4 shows the computed displacement contour and deformed mesh of the numerical model under the self-balanced loading of 2080 kN, in which

TABLE 2: Model parameters of the subsoil.

Material	Layer 1	Layer 2	Layer 3	Layer 4
Material model	HS	HS	HS	HS
γ (kN·m^{-3})	17.8	19.5	19.8	22.0
E_{50}^{ref} (MPa)	22.0	18.0	23.0	43.5
E_{oed}^{ref} (MPa)	22.0	18.0	23.0	43.5
E_{ur}^{ref} (MPa)	66.0	54.0	69.0	130.5
m	0.5	0.5	0.5	0.5
ν_{ur}	0.2	0.2	0.2	0.2
c (kPa)	16.0	20.0	25.0	23.0
φ (°)	30.0	27.0	30.0	42.0

Note: E_{oed}^{ref} = tangent stiffness for primary oedometer loading; E_{ur}^{ref} = unloading/reloading stiffness; m = power for stress-level dependency of stiffness; ν_{ur} = Poisson's ratio for unloading-reloading.

the deformed mesh is magnified by 10 times. According to Figure 4(a), the largest displacement occurs at the pile end (over 100 mm) while the upward displacement of the pile body is very small (less than 10 mm). As shown in Figure 4(b), although there is relative sliding between the pile body and the surrounding soil along with the pile-soil interface, the sliding momentum is small. The rock at the pile end deforms greatly than the pile body, indicating that the end bearing resistance of the pile is more fully developed than the side friction resistance.

2.5.2. Load-Displacement Curves.

Figure 5 compares the displacement curves obtained from the field testing measurements and numerical simulations. It can be found that the DDPE (80 mm) is obviously larger than UDPB (10 mm) and the two groups of load-displacement curves are both approximately linear. The simulation results are in good agreement with the field testing measurements, indicating that the developed numerical model is reasonable and can be used to simulate the self-balanced loading test.

3. Sensitivity Analysis

The influences of different rock modulus, rock cohesion, rock-socketed depth of pile, and Osterberg Cell burial depth on the load-displacement curves of piles under self-balanced loading were analyzed. To simplify the analysis process, the foundation soil was assumed to contain two layers of soil: the upper layer was the 20 m thick soil and the lower layer was the 20 m thick rock. The length of the pile was 21 m, of which the rock-socketed depth was 1.0 m. The Osterberg Cell was located at the pile end initially. The parameters of the soil and rock are simplified and shown in Table 3.

3.1. Rock Modulus.

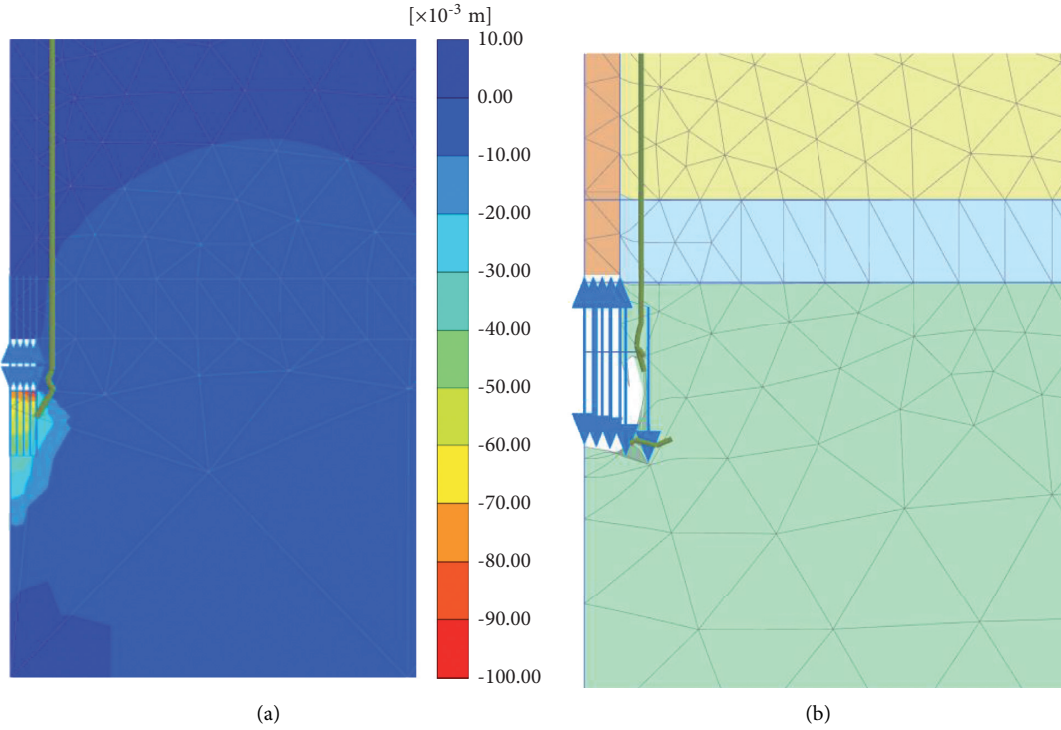
Figure 6 compares the load-displacement curves of the self-balanced loading test piles under different rock modulus. The representative modulus E is set to be 40, 80, 120, and 240 MPa, respectively. The secant and tangent stiffness (E_{50}^{ref} and E_{oed}^{ref}) of the HS model is assumed to be equal to the representative modulus E, and the unloading/reloading stiffness E_{ur}^{ref} is three times the representative modulus (i.e., 120, 240, 360, and 720 MPa). It can


FIGURE 4: Simulated deformation of the testing pile and surrounding soils under self-balanced loading. (a) Displacement contour. (b) Deformed mesh.
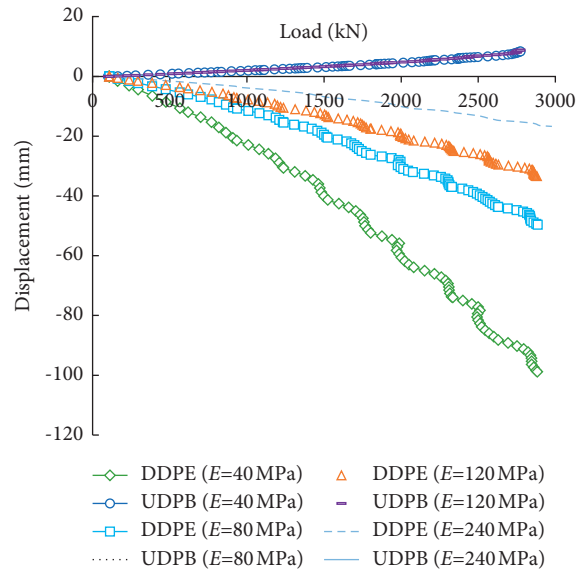
FIGURE 5: Load-displacement curves of the field testing measurements and numerical simulations.


FIGURE 6: Load-displacement curves under different rock modulus.

TABLE 3: Simplified model parameters.

Material	γ (kN·m^{-3})	E_{50}^{ref} (MPa)	E_{oed}^{ref} (MPa)	E_{ur}^{ref} (MPa)	c (kPa)	φ (°)
Soil	17.8	22.0	22.0	66.0	16	30
Rock	22.0	40.0	40.0	120.0	23	42

be found that when the rock modulus increases from 40 MPa to 240 MPa, the DDPE decreases from 96 mm to 16 mm, while the curves of the UDPB approximately coincides. This means that the deformation modulus of rocks has significant impacts on the DDPE but little impact on the UDPB under the self-balanced loading.
FIGURE 7: Load-displacement curves under different rock cohesion.

FIGURE 8: Load-displacement curves under different rock-socketed depths of the pile.

3.2. Rock Cohesion. Figure 7 compares the load-displacement curves of the self-balanced loading test piles under different rock cohesion. The value of the cohesion c is set to 20, 40, and 80 kPa, respectively. It can be seen that the load-displacement curves under different rock cohesion approximately coincide, indicating that only compression deformation is developed in the rocks but shear failure does not occur.

3.3. Rock-Socketed Depth of the Pile. Figure 8 compares the load-displacement curves of the self-balanced loading test piles under different rock-socketed depths. The rock-socketed depth is set to be 1.7D, 3.3D, 5.0D, and 6.7D (D is the diameter of the pile, and $D = 0.6$ m), respectively. It can be seen that the rock-socketed depth has a significant influence on the load-displacement curves of the self-balanced loading test piles. When the load is small, the load-displacement curves of different rock-socketed depths basically coincide. As the rock-socketed depth increases, the side resistance of the pile body and the end bearing capacity of the pile end increase correspondingly.

3.4. Osterberg Cell Burial Depth. Figure 9 compares the load-displacement curves of the self-balanced loading test piles under different burial depths of the Osterberg Cell. The burial depth of the Osterberg Cell (H) is set to be 20, 18, 16, and 14 m, respectively. It can be seen that the burial depth of the Osterberg Cell affects the load-displacement curves obviously. When the Osterberg Cell is located at the pile end, the UDPB is small and the downward displacement of the lower plate of the Osterberg Cell (DDLP) increases approximately linearly with the load. Both the side friction resistance of the upper segment of the pile and the end bearing resistance of the pile end have not reached the
FIGURE 9: Load-displacement curves under different burial depths of the Osterberg Cell.

ultimate state. When the burial depth of the Osterberg Cell decreases, the DDLP is also decreased. The UDPB varies not obviously when the load is small with the burial depth of the Osterberg Cell decreasing. However, there exists a critical load. When exceeding the critical load, the upward displacement of the pile body increases significantly, indicating that the side friction resistance has reached the ultimate state. The shallower the Osterberg Cell set, the lower the critical load is.

4. Comparison with the Conventional Static Loading Test

The load-displacement curves and stress states of self-balanced loading test piles are different from the conventional static loading test piles. Comparative studies were carried out based on the validated numerical model to investigate the displacement and mechanical performance of the piles under self-balanced loading, static uplift loading, and static compressive loading. The geometric size of the numerical model was the same as those in Section 3, and the Osterberg Cell was located at the pile end. The static uplift loading and compressive loading were applied on the top of the pile. The constitutive parameters of the numerical model were shown in Table 3.

4.1. Self-Balanced Loading and Static Uplift Loading.
Figure 10 compares the upward displacement of piles under self-balanced loading and static uplift loading. It can be found that both curves are approximately linear when the load is not large. But when the load exceeds a critical value, the displacements of the piles suddenly increase. These critical loads, which are basically equal under the two loading conditions, can be regarded as the ultimate uplift bearing capacity of the piles. Therefore, the self-balanced loading test can precisely determine the uplift bearing capacity of shallow rock-socketed short piles.

In addition, the upward displacement of the pile under the self-balanced loading is slightly larger than that of the pile under the static uplift loading. Therefore, when the self-balanced loading tests are used to determine the displacement of piles under uplift loading, the results are biased towards safety.

Figure 11 compares the shear stress distribution of the pile-soil interface of the piles under the self-balanced loading and static uplift loading. The interface shear stresses under the two loading conditions are both downward. As shown in Figure 11, when the load is small, the distributions of the shear stress under the two loading conditions are basically coincident. Increasing the applied load will increase the interface shear stress. The minimum shear stress is located at the pile top and the maximum shear stress is at the pile end. This is because the shear stress of the pile-soil interface is related to the shear strength of the surrounding soil. The greater the depth, the greater the horizontal earth pressure, which increases the shear strength of the interface.

It can be also found that the shear stress of the pile-soil interface is distributed more uniformly under the static uplift loading when the load is less than 2080 kN. Specifically, the interface shear stress of the upper half part under the static uplift loading is larger than that under the self-balanced loading, and the lower half part is the opposite. This is because the shear stress of the pile-soil interface is also related to the relative displacement between the pile and soils. The static uplift loading is applied to the pile top, and the relative displacement between the pile and soils is the largest at the pile top and decreased with depth. However, the self-balanced loading is applied to the pile end and the relative displacement is also the largest at the pile end. Therefore, the interface shear stress of
FIGURE 10: Load-displacement curves of piles under the self-balanced loading and uplift loading.
FIGURE 11: Shear stress distributions of the pile-soil interface under the self-balanced loading and uplift loading.

the lower half part under the self-balanced loading is larger than that under the static uplift loading.

When the load reaches 2080 kN, the interface shear stresses under the two loading conditions become a consistent distribution, indicating that the shear strength of the pile-soil interface is fully developed and the testing piles all reach the ultimate state. However, the curve of interface shear stress under static uplift loading is not smooth because a larger slip occurs between the pile and soil.

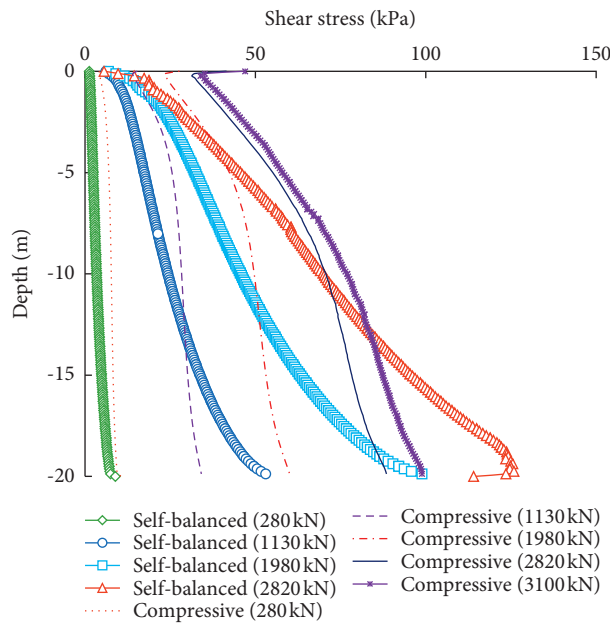
4.2. Self-Balanced Loading and Static Compressive Loading.
Figure 12 compares the load-displacement curves of the piles under the self-balanced loading and static compressive loading. It can be seen that the displacement
Figure 12: Load-displacement curves of piles under the self-balanced loading and compressive loading.


Figure 13: Shear stress distributions of the pile-soil interface under the self-balanced loading and compressive loading.

of the static compressive loading pile is significantly smaller than the DDPE of the self-balanced loading test pile. The UDPB of the self-balanced loading test pile keeps linear when the load is not large. But there exists an ultimate load, beyond which the displacement increases obviously.

Figure 13 compares the shear stress distribution of the pile-soil interface of the piles under the self-balanced loading and static compressive loading. The direction of the interface shear stress under the self-balanced loading is downward, while the direction of the interface shear stress under the compressive loading is upward.

As shown in Figure 13, when the load is small, the distributions of the interface shear stress under the self-

balanced loading and compressive loading are basically coincident. Increasing the applied loads will increase the interface shear stress. The minimum shear stress is located at the pile top and the maximum is located at the pile end. The shear stress of the pile-soil interface is distributed more uniformly under static compressive loading conditions. These are also because the shear stress distribution of the pile-soil interface is related to the shear strength of the surrounding soil and the relative displacement between the pile and soil.

However, when the load is increased from 2820 kN to 3100 kN, the interface shear stress of the piles under the compressive loading changes not significantly. This is due to the effect of the pile-end resistance.
FIGURE 14: Load-displacement curves for different loading conditions. (a) Compressive loading. (b) Self-balanced loading.
FIGURE 15: Comparison of the pile bearing capacity from the self-balanced and compressive loading tests.

5. A Bearing Capacity Computation Method of Piles

Based on the statistics of the numerical simulation results, a bearing capacity computation method of the shallow rock-socketed short piles under the self-balanced loading is established. In this method, the Osterberg Cell is set at the pile end and the ultimate compressive bearing capacity of the pile can be calculated by

$$Q_u = Q_{uu} + Q_{ud}, \tag{3}$$

where Q_u represents the compressive bearing capacity of the pile; Q_{uu} represents the ultimate side resistance of the pile

(the load corresponding to the inflection point of the load-displacement curve of UDPB); and Q_{ud} represents the pile end bearing capacity corresponding to the allowable settlement of 40 mm.

Figure 14 shows the load-displacement curves computed by the numerical modelings under the compressive and self-balanced loading conditions. The pile length varies from 14 m to 20 m. As shown in Figure 14(a), the static compressive test-based ultimate bearing capacities corresponding to the allowable settlement of 40 mm are 2990, 3370, 4050, and 4300 kN for the different pile lengths of 14, 16, 18, and 20 m. According to Figure 14(b), for different pile lengths of 14, 16, 18, and 20 m, the ultimate side resistances Q_{uu} are 1710, 2130, 2610, and 3000 kN, and the pile end bearing capacities Q_{ud} are 1090, 1110, 1150, and 1200 kN. The ultimate compressive bearing capacities of the piles determined by the proposed computation method are 2800, 3240, 3760, and 4200 kN.

Figure 15 shows the ultimate bearing capacity obtained from the numerical simulation results under the two loading conditions. The results based on the field test measurements are also shown in Figure 15. It can be seen that the ultimate bearing capacities of these two methods are approximately consistent. Therefore, the proposed bearing capacity computation method of the shallow rock-socketed short piles under the self-balanced loading is reliable.

6. Conclusions and Recommendations

In this study, a two-dimensional axisymmetric numerical model is established by the PLAXIS software to investigate the behavior and bearing mechanism of shallow rock-socketed short piles based on the self-balanced loading test. The model is first validated by simulating the field tests of two adjacent piles under self-balanced loading located in southern Anhui, China. Then the influence factors of the

load-displacement curves of piles are analyzed. Thereafter, the mechanical mechanism of the self-balanced loading tests is simulated and compared with the conventional static loading tests. On this basis, a bearing capacity computation method of shallow rock-socketed short piles based on the self-balanced loading test is proposed. The simulation results and computation method should provide valuable information for managers to improve the efficiency of management of transformer substation engineering in mountainous and hilly areas. The following conclusions can be drawn:

(1) The side resistance and end bearing of the pile increase with the rock-socketed depth. Downward displacement of pile end will decrease with the decrease of the burial depth of the Osterberg Cell. Increasing the rock modulus will also decrease the downward displacement of the pile end but has little impact on the upward displacement of the pile body. However, the rock cohesion has little effect on the load-displacement curve of the piles.

(2) Compared with self-balanced loading test piles, the shear stress of the pile-soil interface distributes more uniformly under static uplift or compressive loading conditions. The interface shear stress of the upper half part of the pile under the self-balanced loading test is larger than that under static uplift or compressive loading, and the lower half part is the opposite.

(3) For the self-balanced loading test of the shallow rock-socketed short piles, the Osterberg Cell is recommended to be set at the pile end. The ultimate uplift bearing capacity of the piles can be directly determined by the inflection point of the load-displacement curve of the pile body. The ultimate compressive bearing capacity of the piles is the sum of the ultimate side resistance and the end bearing capacity corresponding to the allowable settlement of 40 mm.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Correspondence should be addressed to Zhihui Li; lizhihuityx@llu.edu.cn

With the advent of the information age, Internet technology and computer technology are gradually applied in various fields. Human daily life is inseparable from the help of information technology. The progress and development of the times are also changing our industrial environment. The Internet of things, artificial intelligence, and digital production have been widely used in the industrial field. We need to integrate the new intelligent management concept in the industrial 4.0 era into the modern industrial system and media communication. In the communication of sports culture, how to integrate the intelligent technology under the background of industry 4.0 and realize the spatiotemporal modeling and analysis of human behavior and behavior characteristics is the main content of our research. Firstly, this study briefly analyzes the development and historical process of industry 4.0 era and explores the impact of Internet of things and information technology on sports culture communication. This study analyzes the development process of Chinese sports culture communication and probes into the influence and significance of sports culture communication on human behavior. Under the background of industrial 4.0 management, a model of human temporal and spatial behavior change in sports culture communication is established. Human behavior trajectory is analyzed by data mining, human behavior recognition algorithm, behavior quantitative analysis method, and behavior feature model. The results show that under the background of industry 4.0 management, human behavior modeling can clearly describe the basic characteristics and behavior state in the process of sports culture communication and can predict and analyze the human behavior performance of such social activities and phenomena. Through data mining, data preprocessing, and behavior quantitative analysis, human behavior trajectory is studied. It has a positive impact on the behavior trend in human daily life. The main factor affecting behavior change is whether to receive sports culture news.

1. Introduction

With the continuous renewal of the development of industrialization, we divide the different periods of the industrial age into grades [1]. At present, it is roughly in the "4.0" era. The development mode, scale, and speed of industry are different in different industrial environments [2]. From the 18th century, Jenny textile machine changed the production efficiency and provided effective help for the liberation of human hands. Until Watt improved the steam engine, every industrial revolution was to make human work easier and easier [3, 4]. Traditional manual labor has been gradually replaced, and mechanical development and mechanical production have gradually become the main pillars of the industrial era. In the industrial 1.0 era, mechanical equipment manufacturing has become the main content of production mode in the whole period [5]. This defect is that the equipment covers an excessive area, and the production space can ensure the production demand through the increase of the number of machinery. Until the 20th century, the development of electric power has brought new opportunities to the fields of communication and automobile [6]. Human civilization began to move towards the industrial 2.0 era. The emergence of wired, wireless communication, chemical knowledge, and fuel vehicles has led to a sharp increase in the number of human labor in the industrial field. In the production environment, the division of labor is gradually clear, and the scale is further expanding. The new industrial level and equipment can bring more profits to enterprises [7]. Assembly line production is the

main industrial process in this era. After World War II, the industrial 3.0 era began to enter people's lives. Machinery and equipment replace human labor and handicraft industry and become a substitute for assembly line enterprises [8]. The expansion of production scale no longer depends on the increase of the number of equipment but on the improvement of production methods and technical level. This era has further expanded the mode of mechanical equipment replacing human labor [9].

With the continuous development of human society and the progress of scientific and technological innovation and information technology, new opportunities have been brought to the industrial environment [10]. Scientific and technological innovation has led to great changes in human society. In order to accelerate the speed of scientific research achievements, many countries take the lead in setting up R&D centers such as scientific and technological manufacturing. Internet technology and information technology have also made great contributions to the advent of the industrial 4.0 era [11]. In project management, how to use big data technology to establish an intelligent management system is a key topic in each field. If managers cannot recognize the relationship between work needs and modern technology, they will not be able to adapt to the changes of the times. In the field of communication, the communication of sports culture in China has always been in a relatively weak link [12]. There is no deep-seated research on the impact of sports culture communication on human behavior.

This study is mainly divided into three structures: the first part briefly describes the development status of industry 4.0 model in various countries and analyzes the specific help provided by human behavior modeling research. The second part first explores the essence of sports culture communication in the industrial 4.0 environment and models the impact of sports culture communication on human behavior. Data mining and processing methods are used to analyze human behavior data, and modeling research is carried out from the spatial characteristics of human behavior. Finally, it analyzes the necessity of modeling human behavior characteristics in the communication of sports culture. The intelligent recommendation algorithm is used to actively realize the news prediction service of sports culture in the human behavior analysis model. The third part analyzes the research results of human behavior space modeling of sports culture communication under the environment of industry 4.0 and the research results of human behavior feature modeling.

2. Related Works

The core technology in the industrial 4.0 era is the field of Internet of things and information technology [13]. Communication technology and information development have played an important role in the industrial 4.0 era. Artificial intelligence can use electrified equipment and program calculation in Ronnie simulation to help analyze human behavior in the industry [14]. In the big data environment, processing huge information and complex data sets also

need to use big data for mining and processing. Big data technology can provide effective and accurate data for industrial 4.0 intelligent management, intelligent transportation, intelligent production, and other modes and help industrial development move forward steadily [15]. In Internet computing, cloud computing can provide information and software resources for management devices and analysis devices. When big data collects and analyzes information, heterogeneous distribution, measurement, and other functions can be realized by using cloud computing [16]. The above are the main technologies ahead of the industrial 4.0 era. They provide technical support for the progress of the industrial era. The analysis, detection, and modeling of human behavior are often complex, but the efficient management function can be realized by using various modern technologies in the industrial 4.0 environment. We analyze the development status of countries in the industrial 4.0 era as follows [17]:

With the implementation of the industrial 4.0 era, Germany has made new changes in talent training mode. The dual system can improve the selection of talent training objectives, structural system, and professional ability training [18]. It puts forward new challenges for the types of talent training. With the gradual reduction of the matching between postwork and actual ability, enterprises pay more and more attention to the ability level of recruiters. The optimization of talent training program in vocational education schools is also a major problem to be solved. Facing these challenges, German vocational schools put forward the dual system training management model. The industrial 4.0 environment complies with the development of the times, expands the direction of professional development, and transports professional talents for the country [19].

The development of information technology and modern industry in the United States is relatively advanced, and they have always been in a leading position in the process of industrial reform [20, 21]. With the continuous application of modern equipment, the manufacturing industry is also in urgent need of improving its own technology. Under the environment of industry 4.0, there is a higher demand for equipment manufacturing and equipment manufacturing industry. Intelligent reform has become the main direction of industrial 4.0 mode. The intelligent management of robot equipment in industrial operation has also become the main topic. They applied the sensor technology of Internet of things in the industrial 4.0 era to the transformation of industrial robots and realized the intelligent development to a certain extent [22].

The apprenticeship reform system in Italy has changed with the advent of the industrial 4.0 era [23, 24]. When the apprenticeship reform becomes the focus again in the world, Italy's national and regional management system puts forward new policies for the apprenticeship reform. In terms of system management, innovative measures have been taken in the application of industrial 4.0 intelligent management, curriculum development, and quality inspection. Under the industrial 4.0 environment, different types of apprenticeship systems can be positioned differently, realizing the effect of system optimization.

Taking Hong Kong and Macao as examples, China has transformed the manufacturing industry under the background of industry 4.0 to intelligent development [25]. Enterprises in the manufacturing industry are prone to many internal problems in the process of transformation. In this case, intelligent management in the era of industry 4.0 can help Hong Kong and Macao quickly change to the intelligent manufacturing industry. This study puts forward effective countermeasures and suggestions for its development path and solving problems. Based on industry 4.0 intelligent management environment, this study analyzes the human behavior modeling of sports culture communication.

3. Research on Human Spatiotemporal Behavior Modeling and Behavior Characteristics of Sports Culture Communication Based on Industrial 4.0 Intelligent Management

3.1. Intelligent Management of Sports Culture Based on Mobile Network. The main features of the industrial 4.0 era include interconnection. Connecting all things has always been the theme of the industrial 4.0 era. The universality of the connection scope can closely gather equipment, manufacturers, enterprises, communication institutions, users, and other objects together. In order to comply with the development trend of the Internet of things, the sensor equipment, intelligent management system, embedded equipment, mobile communication equipment, and intelligent communication equipment of the Internet of things constitute an intelligent network model. The production process of the factory can also be highly intelligent. Intelligent factories can be controlled by the Internet of things. That is, the production process is completely integrated by computer. The real-time production monitoring program knows what new materials and processes are needed to ensure the smooth progress of the production process. This is not a simple problem of production automation but the realization of intelligent control. If the system detects a sudden failure in the production process, the machine will automatically suspend operation and repair itself, rather than continue to operate and continuously produce defective products. Through information technology, the most effective utilization of energy can be ensured, which are the characteristics of intelligent chemical plants in the future.

It can integrate digital development with the physical world and connect with each other, so as to ensure that human society can live more conveniently. Every industrial revolution can help human progress. We analyze the process of industrial development in time and space, as shown in Figure 1.

As can be seen from Figure 1, industry 4.0 is a new era and its development time is expected to be long. With the advent of the new era, human behavior has gradually changed in diversity. We focus on sports culture communication.

Sports is a complex object in the development of social culture. It can combine the body and spirit as the basis of daily activities. With the continuous improvement of human growth and development, the mastery of sports and skills can ensure the healthy growth of physical quality. In order to achieve the all-round development of quality education, improve the physical quality of the whole people, and improve the way of life, we need to pay attention to the dissemination of sports culture. Although China's economic development is relatively rapid, it has not brought significant results to China's sports communication. We compare the gap between Chinese and foreign media in sports culture communication, as shown in Figure 2.

As can be seen from Figure 2, with the increase of years, China's attention to sports culture communication has gradually increased. But in 2010, it still cannot be compared with western countries. With the advent of the industrial 4.0 era, intelligent devices and the Internet have brought diversified development to human behavior. From the perspective of media communication mode, sports communication has an indispensable relationship with the development of Internet data. We make statistics on the data of Internet users and show the process of users obtaining sports and cultural news by means of mobile communication, wired Internet access, wireless Internet access, and virtual communication, as shown in Figure 3.

The continuous increase of survey behavior data is shown in Figure 3. From the beginning of mobile communication business, it has been transforming to wired Internet and wireless Internet. With the change of industry 4.0 era, virtual Internet also gradually exists in people's daily life. Therefore, the factors affecting human behavior by the dissemination of sports culture in the industrial 4.0 era are significant. We conduct modeling research on human behavior. Firstly, we analyze the range changes of individuals in time and space:

$$B := \{(s_i, t_i, c_i) | i = 0, 1, 2, \ldots\}. \tag{1}$$

In the formula, B represents the time-space behavior sequence, and (s_i, t_i, c_i) represents the element set. The range of each element in the collection is expressed as follows:

$$b = (s, t, c) \in B, \ s \in D^{|s|}. \tag{2}$$

We analyze that the spatial diffusion of human behavior change trajectory is decreasing. In the sample data, the data of users who are concerned about the dissemination of sports culture actively hiding information are analyzed. It can be found that the spatial change of human behavior is an exponential distribution. The mathematical formula can be expressed as follows:

$$p(\lambda) \sim (\lambda + \lambda_0)^{-b} \cdot e^{(\lambda/k)}. \tag{3}$$

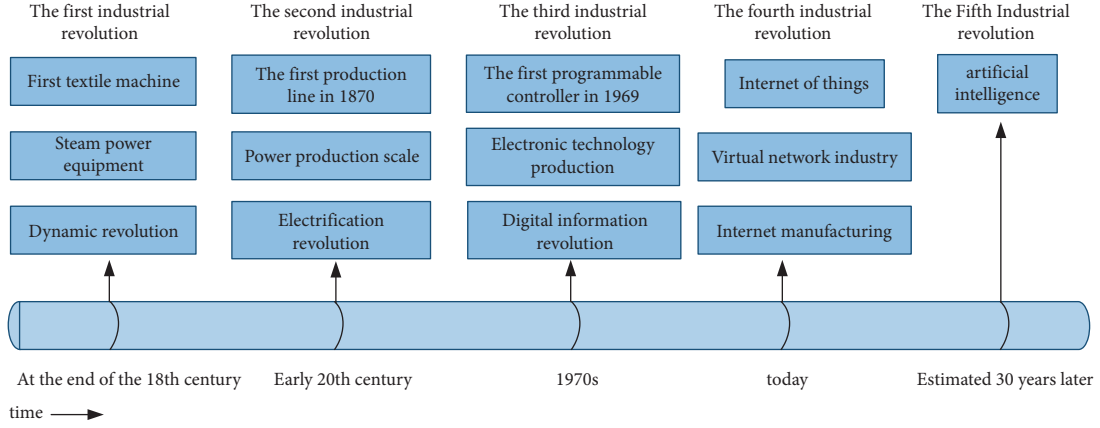
The distribution of exponential function is between 0 and 2. Different cultural news takes different values. In the analysis of human spatiotemporal behavior, we need to


FIGURE 1: Industrial development process.

FIGURE 2: The gap between Chinese and foreign media in sports culture communication.

observe from multiple angles. The spatiotemporal movement variation of each individual can be defined as follows:

$$R_g^2 = \frac{1}{n} \sum_{k=1}^{n} (r_k - r)^2. \qquad (4)$$

In the formula, R_g^2 represents the characteristics of human behavior. We calculate the function law satisfied by the distribution of human behavior by using the transfer structure. The formula is as follows:

$$p(\lambda) = \int_0^\infty P(\lambda \mid R_g) P(R_g) dR_g. \qquad (5)$$

According to the above formula, the spatiotemporal pattern of human behavior can be determined. The law is calculated from the track data of the impact of sports culture communication on human behavior in the industrial 4.0 environment. Behavior pattern modeling can conform to the general process of human cognition. From the observed objects, it is found that many users have common characteristics. At present, more and more countries begin to pay attention to human behavior research. From the early stage of industry to 4.0, there are more and more technical means to study the human behavior model. We consulted relevant literature and analyzed the content release trend of human

behavior modeling research over the years, as shown in Figure 4.

It can be seen from Figure 4 that the development of the industrial age has a great impact on human behavior modeling. Since 2015, the number of human behavior modeling literature published in China has increased significantly. However, compared with the foreign release, it is still in a weak position. In order to further explore the impact of sports culture communication on human behavior, we also need to study from the analysis of behavior characteristics.

3.2. Research on Sports Culture Communication Based on Industry 4.0 Intelligent Management in Human Behavior Feature Modeling. In China's sports, table tennis and volleyball have always been the proud contents of the people. In the process of talking about sports news, the dissemination of cultural knowledge is realized. As China continues to win the Olympic Games, people all over the country begin to discuss sports news. People's attention to sports events is also the main manifestation of their attention to sports culture. Government communication and people's communication are the main channels. However, the way of sports culture communication should focus on itself. This communication effect is not only related to the development of national influence but also has an important impact on the performance of people's daily life and behavior.

Under the background of industry 4.0, the information communication model based on human behavior characteristics can more accurately describe the effect and process of sports communication. The main advantage is that it can choose the response after receiving information according to the set of human behaviors, including evaluation, forwarding, no response, and so on. Modeling human behavior can simulate the effect of data transfer in a variety of states. In sports culture communication, modeling based on human behavior characteristics can monitor the process of culture communication, which is a process from individual to collective modeling. It can take into account the personalized behavior judgment of users, so as to realize accurate information push and other functions. With the
FIGURE 3: The process of obtaining sports culture news in various ways.

FIGURE 4: The content release trend of human behavior modeling research over the years.

gradual application of industry 4.0 management in Internet information dissemination, network data and human behavior data indices increase. In order to facilitate accurate push of everyone's behavior data, we need to conduct personalized behavior feature modeling. Before behavior feature analysis and modeling, we compare the data acquisition speed of intelligent management system in industrial 4.0 environment with that of traditional data mining system, as shown in Figure 5.

As can be seen from Figure 5, with the increase of massive information in big data environment, the acquisition speed of traditional data mining system tends to decrease. The intelligent management data system in industrial 4.0 environment can effectively judge accurate data and useless data and realize the function of rapid acquisition. In the estimation of human behavior characteristics, we use mathematical formula as follows:

$$\text{Interest}(w) = f\big(\text{Interest}_{\text{Activit}}(w), \text{Interest}_{\text{Freq}}(w), \\ \cdot \text{Interest}_{\text{Time}}(w)\big). \tag{6}$$
FIGURE 5: Comparison of data acquisition speed between the system and traditional data mining system.

$\text{Interest}_{\text{Activit}}$ is the actual action of human behavior, and $\text{Interest}_{\text{Freq}}(w)$ represents the number of information access. In order to study the number of human information browsing actions, we define the calculation function as follows:

$$\big(\text{Interest}_{\text{Activit}}(w) = f\,(\text{Sava}(w), \text{Keep}(w), \text{print}(w), \text{Copy}(w)\big). \tag{7}$$

Among them, they respectively represent the times of saving, collecting, and printing sports culture web pages and forwarding of information content. The browsing action can be represented by a binary function. The specific formula is as follows:

$$\text{Interest}_{\text{Activit}}(w) = \{0, \text{Sava}(w), \text{Keep}(w), \text{print}(w), \text{Copy}(w)\}, \tag{8}$$

$$\text{Interest}_{\text{Activit}}(w) = \{1, \text{Sava}(\varpi), \text{Keep}(\varpi), \text{print}(\varpi), \text{Copy}(\varpi)\}. \tag{9}$$

Investigation shows that most users rarely save and collect web pages when browsing sports culture news. Therefore, we cannot fully obtain the overall behavioral characteristics of human beings by using behavioral interest analysis. We need to calculate the number of visits and residence time respectively, so as to realize the feature modeling of human behavior. The number of behavior-based stops can be expressed by the following function:

$$\text{Stop}_{\text{Freq}(w)} = \frac{\text{Freq}(w)}{\max\limits_{E \in W}(\text{Freq}(w))}. \tag{10}$$

Among them, w represents the number of news visits by users in a certain period of time. With the increase of time, the number of behaviors is also accumulating. We update the number of visits in a cycle in the formula in proportion. In mathematical calculation, it can be calculated according to the following equation:

$$p = \frac{\left(\left|\mathrm{Freq}_{\mathrm{new}}\left(w\right) - \mathrm{Freq}_{\mathrm{old}}\left(w\right)\right|\right)}{\mathrm{Freq}_{\mathrm{old}}\left(w\right)}, \tag{11}$$

$$\mathrm{Freq}\left(w\right) = \left(\mathrm{Freq}_{\mathrm{new}}\left(w\right) + \mathrm{Freq}_{\mathrm{old}}\left(w\right)\right). \tag{12}$$

When the coefficient p less than 0, it represents human behavior, and the number of visits of users in the cycle does not change significantly. This study defines the browsing speed of each page of sports culture communication page as follows:

$$\mathrm{Speed}\left(w\right) = \frac{\mathrm{Size}\left(w\right)}{\mathrm{Time}\left(w\right)}, \tag{13}$$

where size (w) represents the storage size of the propagation interface and time (w) represents the time coefficient. Finally, the data delay in the management interface is calculated as follows:

$$\mathrm{Time}\left(w_i\right) = T\left(w_j\right) - T\left(w_i\right). \tag{14}$$

Next, the coefficient of influence on human behavior characteristics in the process of sports culture communication is calculated as follows:

$$R = \frac{\mathrm{Interet}_{(w)}}{\left(\mathrm{Speed}\left(w\right)/\max_{E \in W}\right)}. \tag{15}$$

According to the above formula, we can model the characteristics of human behavior and explore the impact of sports culture communication on human behavior under the management of industry 4.0. In the sports culture communication interface, we use the nonlinear normalization method to process the sample data. Compared with the traditional processing method, we compare the error coefficient, as shown in Figure 6.

As can be seen from Figure 6, the error coefficient of the traditional processing mode begins to increase with the increase of human behavior data. The data processed by nonlinear normalization can maintain basic accuracy.

4. Modeling of Human Spatiotemporal Behavior and Analysis of Behavior Characteristics Based on Sports Culture Communication in Industrial 4.0 Intelligent Management

4.1. Analysis of Research Results of Human Spatiotemporal Behavior Modeling of Sports Culture Communication Using Mobile Network in Industrial 4.0 Intelligent Management. In the industrial 4.0 environment, the intelligent management mode can liberate human labor and realize behavior interaction and industrial production on the basis of human wisdom. This model can optimize the traditional communication mechanism into intelligent communication mechanism in the field of communication and provides the core technology in human behavior analysis and modeling. Dealing with the invisible factors in the Internet era can change the performance and accuracy of human behavior model from uncontrollable to controllable under the
Figure 6: Comparison of error coefficient between traditional processing method and nonlinear normalization processing method.

premise of massive data. Firstly, we analyze the accuracy change of data in the process of human behavior modeling in the industrial 4.0 environment, as shown in Figure 7.

It can be seen from Figure 7 that the traditional human behavior model cannot guarantee the accuracy of data in the modeling process based on the massive data in the Internet age. The human behavior model in the industrial 4.0 environment can ensure the processing speed and control the accuracy above the standard range. In the mobile network environment, sports culture communication can be guaranteed. We build a human behavior model on mobile users. In the above calculation process, it is found that there are strong temporal and spatial characteristics and scene factors in the behavior participation characteristics of mobile networks. These scene factors are easily affected by many aspects. For example, the response of surrounding people to cultural news can indirectly affect individual behavior changes. We use objective quantitative method to map human behavior participation modeling. The response behavior influence coefficient of people in three states to sports cultural news is analyzed, as shown in Figure 8.

As can be seen from Figure 8, the influence coefficient of the crowd who obtains sports news is relatively stable, and the influence coefficient of the crowd who indirectly obtains news information is relatively severe. The influence coefficient of people who do not get sports news is low. The above trends of human behavior can well explain that the impact of sports culture communication on behavior characteristics is significant.

4.2. Analysis of Research Results of Sports Culture Communication of Industry 4.0 Intelligent Management in Human Behavior Feature Modeling. In an intelligent video surveillance system, the accuracy of background model has an important impact on the subsequent judgment of foreground detection, classification, tracking, and behavior understanding analysis. In other words, it largely determines the performance of the whole video surveillance system.
FIGURE 7: Accuracy changes of human behavior modeling data in industrial 4.0 environment and traditional models.
FIGURE 8: Influence coefficient of response behavior of people in three states to sports cultural news.

Complex scenes greatly increase the impact on the accuracy of model monitoring. The human behavior modeling process faces complex scenes in the industrial 4.0 environment, which will be affected and changed by many aspects of the outside world. Human beings may have a variety of behavior characteristics under the specified time and space sequence, or there may be no characteristic changes. Therefore, in the detection process, we need to locate and analyze from the initial cause to the behavior space. The calculation is based on the modeling of human behavior characteristics, including the judgment of the change of user interest. At different times, people staying in the same news can have different effects on the calculation results. With the increase of human behavior data, we need to study feedback efficiency in the model. The feedback speed of human behavior characteristic data before and after industrial 4.0 intelligent management is mainly compared, as shown in Figure 9.

As can be seen from Figure 9, the traditional management mode cannot meet the needs of efficient feedback in the dynamic change characteristics of data. The intelligent management mode in the industrial 4.0 environment can help the analysis model of human behavior characteristics to ensure the feedback efficiency. In the verification process of this study, the main flow of data feature processing is shown in Figure 10.
FIGURE 9: Feedback speed of human behavior characteristic data before and after industrial 4.0 intelligent management.

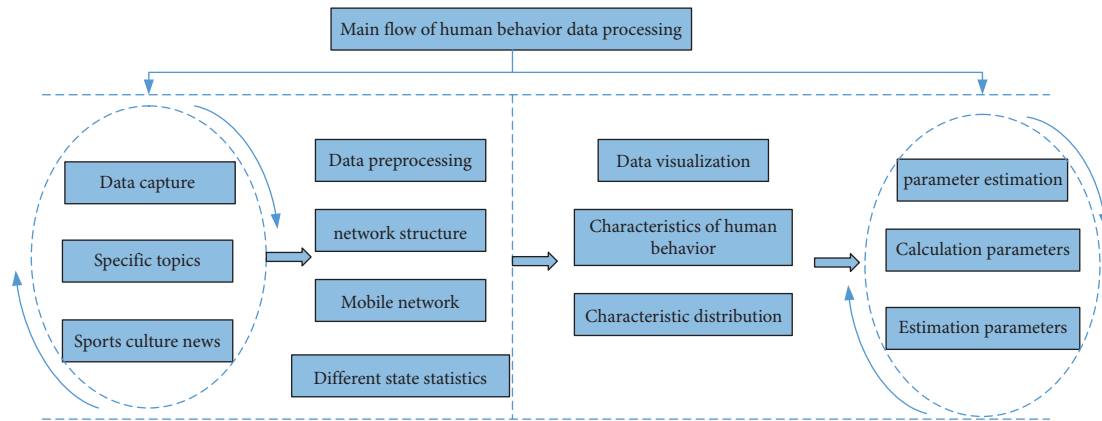
As can be seen from Figure 10, firstly, in data mining, we capture the main content of sports culture on an Internet platform. Secondly, the obtained data are preprocessed to facilitate the analysis of key features. The basic structure of the Internet is extracted, and the form of active behavior is taken as the general category of data statistics. Finally, the data distribution principle is used for visual analysis, and the


Figure 10: Main flow of data feature processing.

characteristic changes of human behavior are verified by hypothesis theory. In the final experimental results, we found that there are positive and negative trends in the impact of sports culture communication on human behavior under the industrial 4.0 Internet mode.

5. Conclusion

This study proposes to model the human behavior of sports culture communication in the industrial 4.0 intelligent management environment. Firstly, it analyzes the development process of industrial 4.0 environment and the current situation and difficulties of sports culture communication in China. Through data mining, data preprocessing, and behavior quantitative analysis, human behavior trajectory is studied. Under the condition of sports culture communication, the temporal and spatial changes of human behavior are modeled. The influencing factors of human behavior are divided into multiple models to calculate the data distribution of the temporal and spatial characteristics of individual behavior. Based on individual data set, it is transformed into the statistical analysis of group behavior. Finally, according to the track of human behavior and historical traces, the specific factors affecting behavior changes are analyzed. Search modeling is used to explore the characteristic changes of human behavior. The results show that in the industrial 4.0 environment, the communication mechanism and industrial process have changed by leaps and bounds. The results of this study have a positive impact on the behavior trend in human daily life. The main factor affecting behavior change is whether to receive sports culture news. It promotes the process of traditional culture communication and especially helps the communication of sports culture form a good cycle. In order to explore the process of the influence of sports culture news on human behavior. However, this study does not carry out simulation verification analysis on the model data, and further elaboration is needed in future research.

Technical decision-makings (TDMs) are a vital part of the decision-makings in construction megaprojects, facing high risks brought by technical complexity, dynamic environment, and subject cognition. Identifying technical decision-making risks (TDMRs) and exploring their interactions are important in megaproject management. Due to the high complexity of TDMs in megaprojects, TDMRs are complex and diverse. However, there is a lack of research on exploring the systematic TDMRs in megaprojects. To address this gap in knowledge, this paper aims to better understand the dynamic complexity of TDMRs in megaprojects by identifying the risks and exploring their interactions from a dynamic and systematic perspective. Grounded theory (GT) and system dynamics (SD) were adopted for this research. First, the GT was used to identify TDMRs in megaprojects and create a conceptual model depicting the relationships among TDMRs. Then, an SD model characterizing the causal structure of the TDMRs system in megaprojects is developed in both qualitative and quantitative manners. The developed model involves interrelationships among environmental risks, decision-making process risks, and decision-making execution process risks. After the validation of the model, a model simulation is conducted to predict the dynamic evolution process of the TDMRs. As a result, a multilayer risk list consisting of 42 index layer risk indicators, 13 field layer risk indicators, and 3 standard layer risk indicators is identified. The SD modeling results show that these multilevel TDMRs interact dynamically and have intricate influences on the total risk level of TDMs in megaprojects. The results of this study could be useful for decision-makers to identify and mitigate TDMRs in megaprojects.

1. Introduction

Construction megaprojects are characterized by significant technical complexity that requires multitechnology integrations [1–3]. Hence, substantial technical decision-makings (TDMs) are required in megaprojects on almost all management hierarchies [4]. The TDMs refer to the process of identifying and analyzing key problems, as well as developing, selecting, and implementing technical schemes to resolve the problems. Hence, the TDMs include both long-term technology development strategies and short-term

technology selections [5, 6]. The outcome of a TDM process is a technical decision-making scheme, consisting of decision objectives, key variables, measures, and criteria [7]. The TDMs must be conducted properly to ensure the successful delivery of megaprojects [2, 7, 8].

Due to the high technical complexity of megaprojects, TDMs in megaprojects also have higher complexity. The complexity of TDMs comprises uncertainties and ambiguities (e.g., dynamic environment, ambiguities of decision-making goals, etc.), as well as the complex interrelationships among influencing factors in TDM issues (e.g., technical

complexity relating to the size and multitechnology integration of the project) [9–12]. Thus, TDMs are generally exposed to various risks. Technical decision-making risk (TDMR) is an extension of project risk and decision-making risk [13, 14]. TDMRs are potential hazards existing in the process and outcome of TDM, which negatively affect the TDM quality and project performance. These risks can cause project cost overruns, delays in delivery, and irreversible accidents [15–17]. For instance, in the Busan-Geoje Fixed Link Project, owing to the defective scheme for towing and mooring, the GINA gasket of standard tunnel element E16 was damaged during construction, resulting in a delay of three months and huge financial loss for repairing the GINA gasket [18]. Therefore, effective management of TDMRs in megaprojects plays an important role in successful decision-makings. Further, the TDM in megaprojects is an open environmental system involving multiple subsystems, which has dynamic and complicated relationships among the factors, rather than a series of normative and procedural activities [7, 19]. The dynamic complexity makes TDMRs in megaprojects highly interrelated, and the risks are transmitted between the internal and external environments of the system [20]. Many risk accidents in construction megaprojects occur due to the interactions of multiple risks rather than a single risk [13]. As such, it is imperative to examine the dynamic interactions among TDMRs.

Thus far, a few research efforts have been made to study decision-making risks of megaprojects using both quantitative and qualitative methods, such as optimism-based decision-making risk model for bridge projects [14], decision-making risk mitigation in megaprojects [21, 22], and identifying and assessing specific types of decision-making risks in megaprojects (i.e., design risks [23, 24], technology selection risks [25], social risks [26], and bidding risks [27, 28]). However, the first two kinds of studies were not focused on TDMR, and the last kind of studies was focused on only one specific risk belonging to TDMR (i.e., design risks and technology selection risks). Risks are interrelated and systematic through causal loops in megaprojects [28–30]. Negligence in considering such risk interrelations results in either underestimation or exaggeration of risk effects [12]. Thus, it is crucial to understand how risks are generated and how they transmit through their interactions. It is argued that research is still lacking to explore TDMRs from a systematic and dynamic perspective considering the whole process of decision-making-execution-feedback.

To address the aforementioned research gaps, this paper aims to identify the TDMRs in construction megaprojects and explore their interactions using the mixed method. The grounded theory (GT) is employed to identify all TDMRs in megaprojects, capturing the managers' perception of TDMRs in the practice of TDM in megaprojects. A conceptual framework depicting the relationships among these risks is provided. Then, a system dynamics (SD) model of TDMRs in megaprojects is constructed to explore the casual loops among TDMRs and simulate the interactions among these risks. The contributions of this study lie in two aspects. First, this study investigates TDMRs and their interactions systemically and dynamically for the first time to reveal the

dynamic nature of TDMRs, which deepens the understanding of TDM in construction megaprojects and enriches theories of construction decision-making and risk management. Second, the identified TDMRs and the simulation model proposed in this study could be adopted as a tool to evaluate and control TDMRs dynamically. The rest of this paper is structured as follows. Section 2 introduces the related work, followed by research methodology in Section 3. The results are presented in Section 4, and discussions and implications are illustrated in Section 5. Lastly, Section 6 summarizes and concludes this study.

2. Literature Review

2.1. Decision-Making Risks in Megaprojects. In recent years, many scholars have indicated the significance of identification and control of the complexity and risks of decision-makings in megaprojects [29, 30]. For example, Shi et al. [7] presented a comprehensive framework of decision-making complexity in megaprojects, which includes six dimensions which are technical, social, financial, legal, organizational, and time. Liu et al. [14] proposed an optimism-based decision-making risk model for bridge projects, where explicit benefits, implicit benefits, construction cost, and operation cost are considered. To mitigate decision-making risks in megaprojects, several researchers proposed risk mitigation strategies via degrading the uncertainty and complexity. Salet et al. [21] put forward three solutions to reduce the complexity and uncertainty of megaprojects to mitigate the decision-making risks, including changing organizational structure, enhancing organizational learning atmosphere, and controlling the number of alternative options for decision-makings.

Furthermore, efforts have been made to identify specific decision-making risks in projects, such as design risks [23, 24], technology selection risks [25, 31, 32], social risks [26], investment risks [33], and bidding risks [27, 28]. Although the aforementioned design risks and technology selection risks belong to TDMRs, each of these existing studies was focused on only one type of TDMRs. Some studies also attempted to assess decision-making risks. For instance, Kurhade and Wankhade [33] proposed a risk assessment framework for decision-making and identified four risk categories for infrastructure investment decision-making, covering political risk, economic risk, social/environmental/cultural risk, and technology risk.

Nevertheless, previous studies on decision-making risks are static without considering the dynamic nature of risks. Attention is lacking to systematically examine TDMRs in construction megaprojects considering the whole process of decision-making. This research gap is addressed in this paper by eliciting the perceptions of managers on what create and drive TDMRs and how they interact with each other by GT.

2.2. Risk Assessment Methods in Megaprojects. Risks can be interrelated, especially in megaproject [34]. Megaprojects are characterized by dynamic interactions of multiple

subsystems, extreme complexity, and technology challenges [35]. Such dynamic complexity makes the risks in megaproject a dynamic system, where the risks are highly interrelated [36]. To capture the dynamic nature of risks and their complex interactions in megaprojects, various risk analysis methods have been applied, such as interpretative structure models (ISM) [37], complex network (CN) [38, 39], social network analysis (SNA) [40], decision-making trial and evaluation laboratory (DEMATEL) [41], the analytic network process (ANP) [42], Bayesian network, and system dynamics (SD) [36, 43–45].

Among these methods, ISM is a qualitative method aiming to develop the hierarchy structure of the factors with direct and indirect correlation paths, and the developed model is influenced by the number of risk factors [37]. Different numbers of risk factors may result in different hierarchy structure of risk factors. Further, CN, SNA, and DEMATEL aim to analyze risk factors from the network perspective, whereas they failed to evaluate risk state in accordance with the interactions of factors. Meanwhile, ANP and Bayesian network (BBN) can be used to explore the interactions among risks and evaluate the risk state quantitatively, while they require large amounts of data. Wu et al. quantify the risk level of a subway station construction using fuzzy ANP via the synthesis of weight matrices, which requires much more computation for pairwise comparison between risk factors [46, 47]. BBN performs excellently to model complex relationships among risks on the bases of the conditional probabilities of the nodes [48]. However, it can only deal with discrete functions. In recent years, various artificial intelligence (AI) methods, such as machine learning and neural networks, have been utilized to identify, evaluate, and predict potential risks in constructions qualitatively and quantitatively [49]. For example, Yaseen et al. [50] developed an AI model integrating Random Forest classifier and Genetic Algorithm optimization to assess the risk of delay in construction, which indicated a robust and accuracy result for project delay risk prediction. Nevertheless, the above-mentioned risk assessment methods analyzed the relationships of risks based on the topology of the network rather than a dynamic and holistic description of the variations of risks. SD developed by Glaser and Strauss [51] is a modeling method dealing with complex causal relationships among components of the system [52]. The foundation of SD is the theory of system thinking, which holds on the view that everything is connected in a dynamic and complex system [53]. SD can not only study the dynamic relationships among risk factors but also simulate risk status during a time period [54]. Hence, SD has been widely used for megaproject risk assessment including modeling of the interrelationships and feedbacks of the risk system. For example, Boateng et al. [55] implemented SD to model the interactions among social, technical, economic, environmental, and political (STEEP) risks considering the complexity and dynamics of megaprojects. Xue et al. [36] proposed a risk coupling model based on SD for risk assessment of High-Speed Rail projects considering the interactions among risks. Wang et al. [56] developed an SD-based safety risk model that covered organizational processes and technical systems and demonstrated the model on an urban metro tunnel project. To identify and control the system risks of automatic metro, Zhao et al. [57] proposed an SD-based model embodying system risks and factors of organizational resource assignment, organizational experience, and avoidance of driver error to reveal the feedback mechanisms of automatic metro. In summary, SD can provide a powerful insight in understanding the complexity and dynamics of construction risk systems [54].

However, there have not been studies exploring the dynamic interactions among TDMRs in construction megaprojects. In this study, SD will be adopted to model the dynamics and interactions among TDMRs.

3. Methodology

A research framework based on a mixed method integrating GT, SD, and Shannon's entropy was proposed in this study to identify TDMRs and explore their dynamic interactions, as shown in Figure 1. Among the three methods, GT is widely used to identify risks from qualitative data [58], SD is an effective approach for modeling the dynamic relations among risks based on mathematical modeling techniques [59], and Shannon's entropy method is one of the various methods for objective weighting measures. GT, along with qualitative data collection techniques (e.g., case study, interviews, focus groups, etc.) and data analysis techniques (e.g., opening coding, axial coding, and selective coding), can be used to develop SD models based on qualitative data [60]. A mixed method is adopted to draw the advantages and minimize the disadvantages of both qualitative and quantitative methods [61–63]. Several studies have successfully implemented similar mixed methods with GT and SD [53, 64, 65]. For example, in [53], safety archetypes of construction workers were identified by GT and the behavior archetypes of safety involving construction workers were explored with SD.

Therefore, the mixed method was conducted in this study as follows. First, GT was employed to identify TDMRs in megaprojects and develop the conceptual model of these risks, as explained in Section Grounded theory. Then, an SD model of TDMRs in megaprojects was built, which involved qualitative modeling, quantitative modeling, model validation, and model simulation, as discussed in Section System dynamics. Further, the parameters involved in SD equations were determined based on the weights of risk indicators calculated by Shannon's entropy, as introduced in Section Shannon's entropy. Lastly, a simulation was conducted to understand the behavior of the system.

3.1. Grounded Theory.
This study uses GT to identify TDMRs and build the conceptual model. GT put forward by Forrester [52] as a qualitative research method linking concepts to generate meaningful theories [66], where concepts and their interdependencies are obtained from analyzing qualitative data (e.g., interview transcripts). GT could be applied by three approaches, namely, the Straussian
Figure 1: Research framework.

approach [67], the Glaswegian approach [68], and the Constructive approach [69].

Compared to other approaches, the Straussian approach is more prescriptive as it provides systematic procedure for data analysis including open coding, axial coding, and selective coding [70, 71]. On the other hand, the Glaswegian approach and the Constructive approach have no clear guidelines for data analysis. Therefore, the Straussian approach is adopted in this study to identify TDMRs from real megaprojects in a systematic way. Following the Straussian approach, the GT process of this study includes (1) data collection and (2) data analysis consisting of open coding, axial coding, and selective coding, as described in the following [67].

3.1.1. Data Collection. Qualitative data were collected based on a case study so that practical insights could be addressed to enable changes in practice to occur [72]. A case study can include either one single case or multiple cases, and there are different opinions on the required number of cases for understanding a phenomenon [72, 73]. The case study in this research was conducted on three megaprojects in China, namely, the Hong Kong-Zhuhai-Macao Bridge Island Tunnel Project (HZMBIT), the Foshan West Railway Station Comprehensive Transportation Hub Project (FWRSCTH), and the Kunming Comprehensive International Transportation Hub Project (KCITH), to enable generalizations on the TDMRs. These cases were selected because (1) the authors had access to the major stakeholders of these

projects, (2) these megaprojects were representative, characterized by multitechnology integrations and high technical complexity, and (3) these projects were under construction or completed less than three years during data collection. The selected cases covered different type of projects (tunnel, railway, and building), and they were all demonstration megaprojects jointly developed by national and local governments. All the cases had multitechnology decision-makings along project lifecycle, which made it possible to collect substantial qualitative data for TDMRs identification.

The case data were collected by semistructured interviews and review of technical documents. Semistructured interviews were conducted with experts from designers, contractors, consultants, and university partners of the three megaprojects. According to Bernard and Bernard [74] and Creswell and Poth [75], interviews with a sample size of 5 to 25 are appropriate for GT studies. In this study, 12 experts were selected for interviews, and the experts had 8 to 27 years of experiences in TDMR management in megaprojects, as shown in Table 1. The selected 12 experts provided meaningful insights that adequately represented the experiences of construction professionals on TDMR management. The interview questions were designed to collect relevant data about TDMRs in megaprojects. The interviewees were asked to elaborate their understandings on TDMRs, provide examples of TDMRs according to their working experience, describe the risk issues, and explain how they deal with risks in the TDM process. For example, the questions asked included (1) what factors drive TDMR events in megaprojects, and what factors contribute to a TDM failure? (2) Do

TABLE 1: The personal particulars of interviewees.

TDMRs interact with each other and how? And (3) what happens if a TDMR event happens in megaprojects? Each of the 12 interviews lasted for 60 to 100 minutes.

In addition to interviews, technical documents of the three megaprojects were also collected to understand the TDMRs in these projects. Due to the large amount of TDMs, the three projects had a large number of technical documents including result-based documents (i.e., construction drawing, technical schemes, and contractual documents) and process-based documents (i.e., safety technical disclosure, environmental checklists and reports, records of technical scheme assessment meeting of the project). A total of 63 technical documents were selected as the raw data including 29 documents from HZMBIT project, 18 documents from FWRSCTH project, and 16 documents from KCITH project.

3.1.2. Three-Level Coding.
After data collection, all the collected data were analyzed based on three-level coding, namely, open coding, axial coding, and selective coding. Open coding is an analytic process that identifies the concepts and discovers their properties and dimensions through line-by-line analysis [67]. Hence, in the open coding step, the original data collected from interviews and technical documents were examined and coded to find major TDMRs in megaprojects (i.e., initial codes). Then, axial coding clusters the identified TDMRs into subcategories (i.e., focalized codes) and categories based on their properties and dimensions. Lastly, selective coding was to detect the relationships among different categories [67]. Selective coding is the last step of GT for theory refining and integrating. A conceptual model linking different categories to reveal their relationships was built during this step via reviewing the memos gathered during the analysis and interviews.

3.2. System Dynamics.
As presented in Section 2.2, SD is used in this study to model the interactions among TDMRs in megaprojects and to reveal how TDMRs interact dynamically and how these interactions contribute to the overall risk. The SD model is developed in the following four steps. In Step 1 (qualitative modeling), based on the identified TDMRs and the conceptual model, system analysis is conducted to draw the system boundary, and the logical structure of the system is defined with a causal loop diagram. Then, Step 2 (quantitative modeling) is performed to formulate the relationships among TDMRs with the stock-flow diagram. Next, Step 3 (model validation) is carried out through structure validation, behavioral validation, and sensitivity validation. Lastly, Step 4 (model simulation) simulates how the system reacts under diverse scenarios.

3.3. Shannon's Entropy.
Shannon's entropy is capable of measuring the uncertainty of a random process. It is widely used to calculate the weight of each risk indicator based on expert scores [76]. First, the expert scores are normalized using equations (1) and (2) for the-larger-the-better.

Criteria and the-smaller-the-better criteria are, respectively:

$$Y_{ij} = \frac{X_{ij} - \min(X_i)}{\max(X_i) - \min(X_i)}, \tag{1}$$

$$Y_{ij} = \frac{\max(X_i) - X_{ij}}{\max(X_i) - \min(X_i)}, \tag{2}$$

where X_{ij} is the score of the ith expert with regard to the jth risk indicator ($i = 1, 2, 3,\ldots,m; j = 1, 2, 3,\ldots,n$) and Y_{ij} is the normalization value of each risk indicator.

It is important to note in this paper that since the experts score based on the importance of each risk indicator, all scores of indicators are processed following the-larger-the-better criteria.

Subsequently, the entropy value E_j of each risk indicator is calculated as follows:

$$E_j = -\frac{1}{\ln m} \sum_{i=1}^{m} p_{ij} \ln p_{ij}, \tag{3}$$

where m is the number of experts; $p_{ij} = (Y_{ij}/\sum_{i=1}^{m} Y_{ij})$. If $p_{ij} = 0$, $\lim_{p_{ij} \to 0} p_{ij} \ln p_{ij} = 0$. Then, the weight W_j of each risk indicator can be calculated as

$$W_j = \frac{1 - E_j}{\sum_{j=1}^{n} (1 - E_j)}, \tag{4}$$

where E_j is the entropy value of each risk indicator, and n is the number of the indicators.

4. Results

4.1. Identification of TDMRs in Megaprojects.
According to the Project Management Institute (2008), a risk is "an uncertain event of condition that, if occurs, has a positive or negative effect on project's objectives." Following this definition, all the collected data were examined and TDMRs were identified through GT-based data analysis. In the open coding step, by identifying and describing overall constructs relevant to TDMRs based on the collected data, 97 key concepts were extracted through line-by-line and sentence-by-sentence analysis. Then, the 97 key concepts were summarized as 42 initial codes (A1-A42). Next, the axial

coding step identified connections between the initial codes and aggregated the initial codes into focalized codes and categories. As a result, the initial codes were grouped into 13 focalized codes (B1–B13) and further into three categories (BB1-BB3). Table 2 gives some examples of how the collected data were coded in open coding and axial coding.

Table 3 shows the coding results of TDMRs including 42 initial codes, 13 focalized codes, and 3 categories. Due to space limitation, the 97 key concepts are not shown in the table but can be obtained from the corresponding author upon request. According to the coding results, TDMRs in megaprojects are divided into three categories: decision-making process risk, decision-making execution process risk, and environmental risk.

Four layers of risk indicators (shown in Table 4) are established from the coding results including (1) target layer risk indicator (i.e., the total TDMR in a project), (2) standard layer risk indicators (i.e., corresponding to three categories), (3) field layer risk indicators (i.e., corresponding to 13 focalized codes), and (4) index layer risk indicators (i.e., corresponding to 42 initial codes). Risk indicators in each layer are determined by indicators in the lower layers. For example, B1 is determined by A1 to A5, and BB1 is determined by B1 to B5.

Decision-making process risk (BB1) represents risks within the process of identifying and analyzing problem and developing and choosing the technical solution. This process involves decision-makers, information, and procedure, and the outcome is a decision-making scheme. Five field layer risk indicators are related to BB1 including decision-making participants risk (B1), decision-making information risk (B2), procedure risk (B3), decision-making mechanism risk (B4), and decision-making scheme risk (B5).

Decision-making execution process risk (BB2) refers to risks associated with the execution process of the final technical decision-making scheme. Corresponding to the elements and characteristics of decision-making execution, executive, premanagement, in-process management, and technology management are key issues for successful execution of decision-making. Three field layer risk indicators are associated with BB2 including management risk (B6), executive risk (B7), and construction technical risk (B8).

Environmental risk (BB3) describes risks related to the external environment of TDM. The environment contains elements related to society, technology development, economy, and natural and political environment. Five field layer risk indicators are correlated to BB3 including technical environmental risk (B9), economic environmental risk (B10), natural environmental risk (B11), social risk (B12), and political environmental risk (B13).

In selective coding, three categories of risk indicators (BB1-BB3) were linked following a single storyline around which everything else was draped [77]. A conceptual model of their relationships was developed with grounded theory, as shown in Figure 2. The risk lies in the interaction between the subject and the environment [78]. The TDMR accidents in megaprojects occur under the joint influence of the environmental risks, the decision-making process risks, and the decision-making execution process risks. When environmental risks occur, there will be an increased tendency for the risk of the decision-making process and the risk of decision-making execution process. At the same time, the decision-making process risks may transmit to the decision-making execution process risks.

4.2. Dynamic Model of TDMRs in Megaprojects

4.2.1. Qualitative Modeling of TDMRs in Megaprojects. To qualitatively model TDMRs and understand the feedback loops among TDMRs, a causal loop diagram containing the three categories and 13 focalized codes of TDMRs is depicted, as shown in Figure 3. A causal loop diagram aids in visualizing how TDMRs and variables affect one another by arrows with positive or negative labels (Bala et al., 2017). The diagram is created based on the abovementioned coding results, especially the conceptual model of relationships among TDMRs in megaprojects, as well as the 12 interviews. Furthermore, a group interview was conducted with the abovementioned experts to validate the structure of the diagram. It is noted that the developed causal loop diagram aims to reveal the main causal loops among TDMR. Thus, the index layer risk indicators are not considered in the causal loop diagram since risk indicators in each layer are determined by indicators in the lower layers and the index layer risk indicators are the lowest layer. As presented in Figure 3, TDMRs interact with each other in 3 ways: (1) by the process of decision-making (i.e., the risks lie in decision-making process transmit to the decision-making execution), (2) by the life cycle of the project (i.e., the TDMRs lie in previous construction stage transmit to the next construction stage), and (3) from the external risk to the internal risk (i.e., environmental risks transmit to decision-making process and decision-making execution process). The decision-making process risks may transmit to the decision-making execution process risks. The diagram includes five balancing loops, which interact with each other.

Loop 1: Decision-making information risk--(+) Decision-making process risk--(+) Decision-making execution process risk--(-) Decision-making information risk. This is a balancing feedback loop meaning that the increase of decision information risk will stimulate the rise of decision-making process risk, with which decision execution process risk will grow, and then much attention will be paid to decreasing the risk of decision-making information risk. According to Pirzadeh and Lingard [79], technical decision-makings arise as the result of information exchanges between projects actors. Information is essential as an input of the decision-making process [23, 80].

Loop 2: Decision-making scheme risk--(+) Decision-making process risk--(+) Decision-making execution process risk--(-) Decision-making scheme risk. This is a balancing feedback loop indicating that the increase of decision-making scheme risk will result in a higher level of decision-making process risk, and then there will be a higher risk during the execution process of decision-making, which will attract more attention and the decision-making scheme will be checked and improved in turn. Decision-making

TABLE 2: Example of coding process in GT.

Collected data	Open coding		Axial coding	
	Key concepts	Initial codes	Focalized codes	Categories
Decision-maker lacks experience; the requirements of owner are beyond our ability; the chief decision-maker makes decisions based on their own knowledge, experience, and rationale, rather than information from other consulting subjects, which sometimes is impulsive, without enough information. Decision-maker cooperated with the consulting agency in the past; decision-maker usually prefers to choose the scheme he is familiar with rather than the more satisfying one; sometimes, it is hard to control the quality of scheme. Decision-making quality may deviate from the expectations; the consulting agency failed to provide proper advice. The lack of good communication and coordination ability among the decision-making participants leads to instability of the decision-making team. It is hard to coordinate the interests of all parties.	a01 decision-maker lacks ability and professional knowledge	A1 poor professional quality of decision-makers	B1 decision-making participants risk	BB1 decision-making process risk
	a02 the style of decision-maker is different a03 the psychological tendency of decision-makers matters a04 the value preference of decision-maker is different	A2 psychological tendency and value preference of decision-makers		
	a05 decision-making behavior changes	A3 risk of alienation of decision-makers' behavior		
	a06 the advice of experts is not adopted as expected a07 the consulting agency fails to support the decision-makers	A4 no prominent role of the decision support layer		
	a08 unreasonable sharing of risks among project participants in decision-making	A5 game risk of interest groups		

scheme is the outcome of a decision-making process, guiding the execution process [7]. Thus, the decision-making risk could transmit to decision-making execution process imperceptibly until the risk events happen. For example, in the HZMBIT project, the rib rubber mound was initially recommended as the structural design of the artificial island. However, it is found that the scheme may result in quality defects, delay, and pollution in execution process. Therefore, the initial design scheme was replaced by the large diameter deep inserted steel cylinder scheme, which sped up the schedule greatly [81].

Loop 3: Decision-making information risk--(+) Decision-making participants risk--(+) Decision-making process risk--(+) Decision-making execution process risk--(−) Decision-making information risk. This is a balancing feedback loop including a part of Loop 1. In addition to the information shown in Loop 1, Loop 3 also illustrates that the decision-making participants are more likely to make wrong decisions with incomplete and inaccurate information, which will result in a higher risk level of the decision-making execution process. Then it will provide feedback to improve the information quality. Research has shown that the knowledge to make a TDM resides in more than one decision-making participant [82]. TDM arises as the result of interactions and information exchanges among decision-making participants [79]. Hence, it is safe to claim that decision-making participants, such as project managers, play a pivotal role in successful TDM [83].

Loop 4: Decision-making information risk--(+) Decision-making scheme risk--(+) Decision-making process risk--(+) Decision-making execution process risk--(−) Decision-making information risk. **Loop 5:** Decision-making information risk--(+) Decision-making participants risk--

(+) Decision-making scheme risk--(+) Decision-making process risk--(+) Decision-making execution process risk--(−) Decision-making information risk. The balancing Loop 4 and Loop 5 include parts of Loop 1 to Loop 3. Loop 4 and Loop 5 further explain how risks transmit among decision-making information, decision-making scheme, and decision-making participants. The poor quality of decision-making information makes it more difficult for decision-making participants to make decision-making schemes [79]. The timely and effective exchange of information among participants is critical for the development of TDM schemes [84].

4.2.2. Quantitative Modeling of TDMRs in Megaprojects. To quantitatively model the interactions among TDMRs, it is essential to draw the system stock-flow diagram and build the dynamic equations. Based on the causal loop diagram of TDMRs in megaprojects as well as the characteristics of TDMRs in megaprojects, the system stock-flow diagram with four stock variables, four rate variables, 22 auxiliary variables, and 33 constant variables is built with three subsystems, namely, the decision-making process risk subsystem, environmental risk subsystem, and decision-making execution process risk subsystem. The meanings of SD variables in system stock-flow diagram are shown in Table 5. Arrows connect the four types of variables, indicating either substance or information flow between the two variables. As shown in Figure 4, a set of variables are involved in each subsystem. (1) Subsystem of decision-making process risk: decision-making process risk is quantified with the equations in Table 6. (2) Subsystem of decision-making execution process risk: decision-making execution process

risk is a stock variable, which is influenced by the growth rate of decision-making execution with equations in Table 6. (3) Subsystem of environmental risk: environmental risk was determined by the growth rate of environmental risk with corresponding equations in Table 6. In terms of system of technical decision-making risk in megaprojects, technical decision-making risk is a stock variable and the growth rate of the technical decision-making risk in megaprojects as input of stock variable. Further, the growth rate of the technical decision-making risk in megaprojects was influenced by the decision-making process risk, decision-making execution process risk, and environmental risk. The relationships are depicted by equations in Table 6.

The mathematical equations of variables involved in each subsystem are established based on the stock-flow diagram. The coefficients of variables in each equation are established based on the weights of indicators. To determine the weights of indicators, questionnaires were distributed to seven experts engaged in megaproject management and risk management research at universities and practice fields. The experts included two professors engaged in megaproject risk management research at universities, two engineering managers engaged in whole process engineering consulting, two engineering managers from general construction contracting company, and one engineering manager from megaproject owner. They provide evaluations of the importance of each risk indicator in the index layer.

The experts were asked to score based on the controllability, possibility, and degree of loss of the risk. Responses are made based on a five-level Likert scale (1–5), where 1 represents lowest importance and 5 represents highest importance. In general, there are two categories of weighting methods, namely, subjective weighting methods and objective weighting methods [63]. Thereinto, subjective weighting approach is conducted on the basis of decision-maker's experiences and judgment, while the objective weights were calculated via mathematical computation [63]. According to Deng et al. [72], the method with objective weighting is more applicable when it is difficult to obtain the reliable subjective weights. In this paper, all the selected

TABLE 4: TDMRs in megaprojects.

| Target layer risk indicator	Standard layer risk indicators	Field layer risk indicators	Index layer risk indicators	Definitions
TDMR in construction megaprojects	BB1 decision-making process risk	B1 decision-making participants risk	A1, A2, A3, A4, A5	Inability of TDM participants to contribute to the decision-making activities and poor collaboration among them
		B2 decision-making information risk	A6, A7, A8	Inappropriate and inaccurate information, lack of documents
		B3 procedure risk	A9, A10	Incompleteness of procedure, lack of standardization, and process records
		B4 decision-making mechanism risk	A11, A12	Lack of rules and regulations
		B5 decision-making scheme risk	A13, A14, A15, A16, A17	Inadequate site investigation, mistakes in the TDM scheme, insufficient comparison, and selection of alternative scheme
	BB2 decision-making execution process risk	B6 management risk	A18, A19, A20, A21, A22	Poor management and supervision in implementation of TDM scheme. Inadequate coordination and collaboration on-site
		B7 executive risk	A23, A24	Inadequate experience and qualification of executive
		B8 construction technical risk	A25, A26, A27, A28	inferior quality and low safety level of the project, due to complex construction
		B9 technical environmental risk	A29, A30, A31	The uncertainty and immature of new technology. Industry technology is backward
		B10 economic environmental risk	A32, A33	Insufficient supply of capital and required resources and unfavorable macroeconomic situation
	BB3 environmental risk	B11 natural environmental risk	A34, A35, A36	Natural disasters, complex geographic and climatic conditions, and high environmental requirements for fragile ecological environment
		B12 social risk	A37, A38	The influence of bad public opinion and the instability of society caused by TDM scheme
		B13 political environmental risk	A39, A40, A41, A42	The uncertainty of the project construction caused by changes in the host country's domestic political situation, legal environment, and political relations with other countries

GB	Constant	Government behavior
LR	Constant	Legal risk
GPC	Constant	Government policy changes
CW	Constant	Coup, war

seven experts have much experience in TDMR management, and it is hard to quantify the subjective weights of experts. Therefore, the weights of indicators were obtained via objective weighting method, namely, Shannon's entropy, as illustrated in Section 3.3, ignoring the subjective weights of each expert. The obtained weights of risk indicators are shown in Table 7, and the mathematical equations of variables are presented in Table 6.

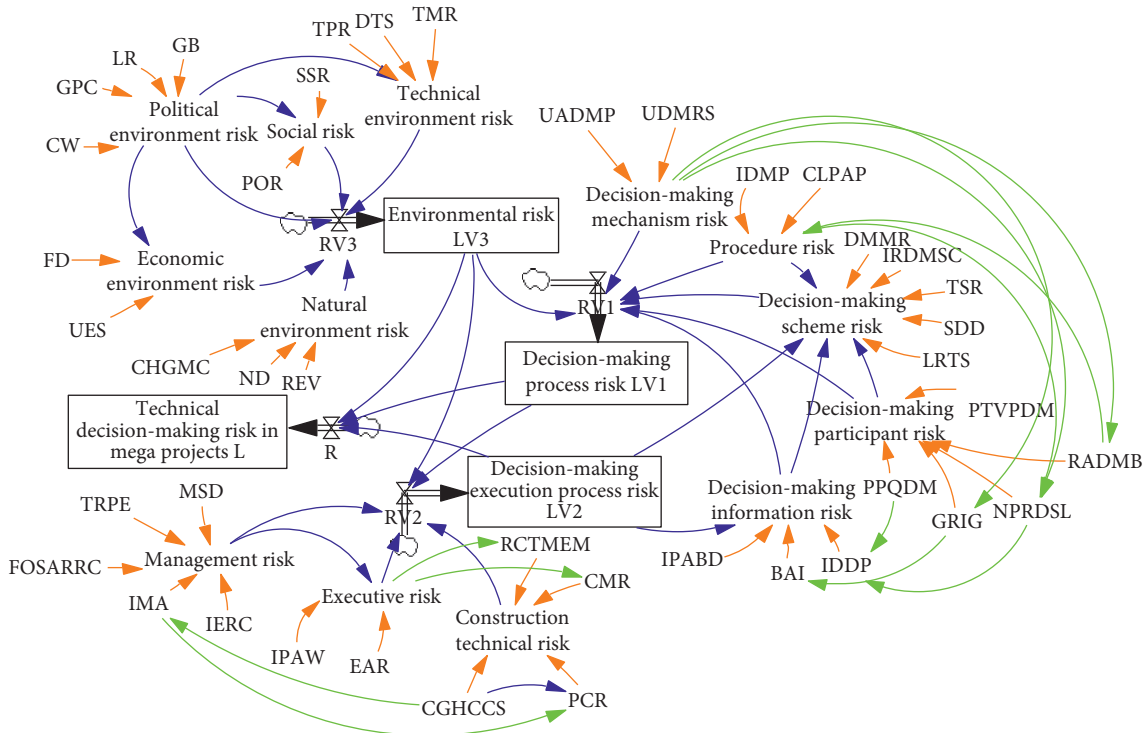
4.3. Model Validation. Structure validation, behavioral validation, and sensitivity validation are performed to test


FIGURE 4: System stock-flow diagram of TDMRs in megaprojects.

the structure of the SD model and observe whether the model is consistent with the actual situation [85]. In this study, the structure validation aiming to assess the structural reliability of the model is conducted via structure verification test and dimension consistency test. The variables in the model are extracted from interviews and technical documents, and their relationships are confirmed with a structure verification through interviews with experts. Then, the behavioral validation test is conducted by running the simulation model for the period of one month and comparing the simulation results with the actual field data. The actual field data were collected from the KCITH project, and the comparison shows that the simulation model could produce similar results with the field data.

Furthermore, sensitivity validation is used to analyze the effects of the alteration of variables on model simulation results and identify critical TDMRs in megaprojects. Taking the decision-making process risk subsystem as an example, it is found that decision-making process risk is the most sensitive to psychological tendency and value preference of decision-makers (PTVPDM), unreasonable allocation of decision-making power (UADMP), and decision-making method risk (DMMR). The influence of PTVPDM on the decision-making process risk can be estimated by changing the initial values of PTVPDM. When the initial value of PTVPDM varies from 0.4 (run 1) to 4 (base run) and 40 (run 2), the decision-making process risk will increase significantly, as shown in Figure 5.

4.4. Model Simulation

4.4.1. Model Parameters. The model simulation of TDMRs was conducted based on case study of the KCITH project, which had an estimated investment of over 900 million USD. The project started in November 2017 and was expected to complete in February 2024. The KCITH project was selected since the TDMs of the project faced a variety of risks such as foundation pit collapse, impact of COVID-19, and policy change, due to the high standard of construction, dynamic external environment, and complex geology and climate conditions. Besides, the construction process involved many high-altitude operations and cross-disciplinary activities. At the time of data collection, the project was under construction and suffered time delays and other various risks in TDMs both internally and externally. Furthermore, the simulation results could help project manager to deal with the TDMRs.

According to the actual construction schedule of the project, the model simulation period was set to 73 months and the step length was one month. To determine the initial values of variables in the model, questionnaire surveys were conducted with seven experts participating in this project, including project managers, chief engineer, university experts, and managers of the project management firm. The questionnaire consisted of an introduction to the research aims and an introduction to the meanings of TDMRs and the scoring rules, which guided the experts to score the risk indicators according to the actual project situation and their experiences. Each risk indicator was scored based on a five-

level Likert scale (1–5), where 1 represented very low impact and 5 represented very high impact. Based on the responses, the initial value v_i of risk indicator i was calculated as the average score of all experts:

$$v_i = \frac{1}{k} \sum_{j=1}^{k} x_{ij}, \tag{5}$$

where x_{ij} was the score given by expert j for risk indicator i and k was the total number of the expert. The obtained initial values of all risk indicators required in the technical decision-making system are shown in Table 8.

4.4.2. Simulation Results. Model simulation was conducted to evaluate the evolution of the main stock variables (L, LV1,

LV2, and LV3) and rate variables (R, RV1, RV2, and RV3) in the TDMRs system, as shown in Figure 6. According to line 2 shown in Figure 6(a), the decision-making process risk LV1 increases faster at the beginning of the simulation period but then increases with a lower rate. The change of LV1 is consistent with the trend of RV1 (line 2 in Figure 6(b)), which increases at first and decreases after the 37th month. Typically, at the early stage of a megaproject, due to the complexity of the megaproject, decision-making participants lack sufficient cognition of the technical decision-making problem as well as the project information, which contributes to higher decision-making process risk. However, with the accumulation of decision-making execution process risk, some risk accidents may happen, which reveal the problems existing in the decision-making process, and measures (e.g., personnel adjustment and technical scheme

TABLE 7: Weights of risk indicators.

Target layer risk indicator	Standard layer risk indicators	Field layer risk indicators	Index layer risk indicators	Weight
Technical decision-making risk of megaproject	Decision-making process risk $W1 = 0.3319$	Decision-making participants risk $W11 = 0.2266$	Poor professional quality of decision-makers	0.0785
			Psychological tendency and value preference of decision-makers	0.5196
			Risk of alienation of decision-makers' behavior	0.0836
			No prominent role of the decision support layer	0.0825
		Decision-making information risk $W12 = 0.2297$	Game risk of interest groups	0.2358
			Blocked access to information	0.2071
			Improper description of the decision problem	0.5858
			Insufficient precision and accuracy of basic data such as survey and design	0.2071
		Procedure risk $W13 = 0.1238$	The incompleteness of decision-making procedures	0.3109
			Compliance and legality of project approval procedures	0.6891
		Decision-making mechanism risk $W14 = 0.1375$	Unreasonable allocation of decision-making power	0.5372
			Unreasonable decision-making regulation and system	0.4628
		Decision-making scheme risk $W15 = 0.2825$	Decision-making method risk	0.1116
			Indicators risk for decision-making scheme comparison	0.1116
			Technology selection risk	0.3353
			Scheme design defects	0.2180

adjustment) will be taken to lower the decision-making process risk.

As shown in line 3 in Figure 6(a), the decision-making execution process risk LV2 is very low in the initial several months and then increases with an increasing rate from the 9th month till the end. The corresponding rate variable (RV2) shows a constant increase throughout the period (line 3 in Figure 6(b)). Typically, at the early stage of a mega-project, many decision-making executions process risks are not obvious and the total effect of these risks on the project is

weak. Once the technical decision-making scheme is implemented, decision-making execution process risk will keep increasing and the increment rate LV2 also undergoes sustained growth unless the risks are controlled in time.

Furthermore, according to line 4 in Figures 6(a) and 6(b), the environmental risk LV3 keeps increasing at a fixed rate during the whole simulation period, which implies that the environmental risks are constant and not affected by other categories of risks.

Lastly, the L (technical decision-making risk in megaprojects) keeps increasing with an increasing rate, as shown in line 1 in Figures 6(a) and 6(b). The result indicates that the total risk will keep extending and lead to risk accidents unless risks are controlled in time. According to Figure 6(a), L remains very low before the 18th month and begins to increase faster afterwards, showing a similar trend with LV2. Hence, it can be inferred that LV2 is one of the most significant risk categories. There is also a strong two-way influence between LV1 and LV2. With the implementation of the decision-making scheme and the continuous effect of environmental risks, the decision-making execution process risks gradually accumulate and emerge, easily triggering risk accidents. Once the decision-making execution process is at a high-risk level, many measures will be taken to improve technical decision-making quality, such as to revise the decision-making scheme or to improve the quality of decision-making information.

4.4.3. Scenario Analysis. To provide policy implications for TDMR management in megaprojects, scenario analysis is conducted. For the purpose of clear illustration, only some major variables were selected to examine and describe their effects. First, two scenarios of PTVPDM and ND were selected as examples to conduct single variable analysis, detecting different effects of two variables on the overall TDMR in megaprojects. Second, a multivariate scenario analysis with three variables including PTVPDM, ND, and IPAW is carried out as an example to approximate to the real system.

For the single variable analysis of PTVPDM, three different values of PTVPDM are considered including 1 (run1), 4 (base run), and 7 (run2), respectively. As shown in Figures 7(a)–7(c), the increase of PTVPDM can increase the values of L, LV1, and LV2, which is in line with the study finding that risk derives from the interaction between people and the environment [86]. The personal characteristics of decision-makers can influence decision-making quality. If the decision-makers have a high tolerance of risk or have insufficient experience, the decision-making process and decision-making execution process may be subject to higher risks. Meanwhile, according to Figure 7(d), the environmental risk (LV3) does not change with different PTVPDM values, which is consistent with the characteristics of environmental risk. The environmental risk subsystem serves as the driver subsystem to the other two subsystems, and itself is hardly influenced by the other two subsystems. Hence, it is suggested that more attention should be paid to the behavioral risk of decision-makers.

For the single variable analysis of ND, three different values of ND, namely, 1 (run 1), 4 (base run), and 7 (run 2), were tested. As shown in Figures 8(a)–8(d), increase of ND will result in increases of all stock variables, which is in line with the influence path of the environment on decision-makings. The increase of ND, which belongs to the environmental risk subsystem, will certainly improve L and LV3, while LV3 will aggravate LV1 and LV2.

There are various complicated scenarios in the actual TDMRs system. It is the effect of risk interactions that inflates risk levels, which is the reason why this study explores the TDMRs in megaprojects systematically and dynamically. The multivariate analysis mainly observes the synthesis of PTVPDM, ND, and IPAW by setting the values of them as 1 (run 1), 4 (base run), and 7 (run 2). The results (Figure 9) show that the values of TDMRs are 42119.4 (run 1), 45348.1 (base run), and 48576.8 (run 2), respectively. Compared with the base run, the value of TDMRs decreases by 7.1% (run 1) and increases by 7.1% (run 2), respectively. However, under the scenario analysis of ND, the value of TDMRs decreases by 4.5% (run 1) and increases by 4.5% (run 2) compared with the base run, while under the scenario analysis of PTVPDM, the value of TDMRs decreases by 2.5% (run 1) and increases by 2.5% (run 2) compared with the base run. This implies that the increase of the TDMRs is not relying on the aggregate effects of individual parameters but the synthesis among them. Thus, it is suggested that decision-makers should fully consider how to mitigate the effect of environmental risks in TDM management of megaprojects. The results demonstrate the complex interactions among multilevel TDMRs. A combination of measures considering the comprehensive effects of risks would better control TDMRs in megaprojects.

5. Discussion and Implications

The main aim of this research is to identify TDMRs and examine their dynamic interactions. To attain the objective, a hybrid methodology consisting of GT and SD was implemented to explore TDMRs in megaprojects, which combines a qualitative content analysis approach and a quantitative simulation method. GT is used to elicit TDMRs in megaprojects from interviews and technical documents at first. Then an SD model of TDMRs is developed to describe how these TDMRs are interacting with each other, and the dynamic interactions among TDMRs are simulated with different scenarios.

As to the implications, this present research advances our understanding of TDMRs in megaprojects from a systematic and dynamic perspective and can serve as a decision-making management tool for the decision-makers in the following aspects. First, the identified list of TDMRs could be used to evaluate the overall risk level of TDM in megaprojects, which have both theoretical and practical contributions. Second, the SD model representing the interactions among multilevel risks of TDM shows that there are homogeneous and heterogeneous interactions within and among the environmental risk, decision-making process risk, and decision-making execution process risk

subsystems. This means that these risk transmissions may aggravate the risk of certain subsystem. Specifically, the results of scenario analysis show that the overall risk level of TDM is inclined to be affected by the synthesis effects of risk interaction rather than the aggregate of individual risks. As such, multilevel measures considering the synthesis effects

are more effective to mitigate TDMRs in megaprojects. For example, it is recommended to establish a risk-management-based TDM process, integrating the iterative risk management and TDM process. For each TDM, firstly, identify the risk factors, then, make a decision-making scheme based on the risk status, and evaluate the risk level of the final

technical decision-making scheme and modify it dynamically until the risk level of the scheme is acceptable. Besides, a flatter organizational structure for decision-making and multiagent (i.e., the government, the owner, designer, contractor, scientific research institutes, the experts, and equipment suppliers) collaborative decision-making could speed up the information exchange efficiency and reduce risk. In addition, the decision-making information risk, decision-making scheme risk, and decision-making participants risk are three key variables indicated from the five casual loops, which is in line with studies of Sutrisna and Goulding [23] and Eweje et al. [80]. Thus, it is necessary to strictly control the quality of decision-making information and develop a reasonable comparison and selection process of alternative schemes. Finally, the simulation model presented in this paper can be adopted to (1) identify changes of TDMRs over time, (2) evaluate the effects of different risk factors on the total TDMR in megaprojects under different scenarios, and (3) take measures to respond to the project changes brought by TDMRs.

6. Conclusions and Limitations

The TDMRs in megaprojects and their interactions are complicated and dynamic, which makes them difficult to control. In the practice of TDMR management in megaprojects, project manager's perceptions of risks may be different from the identified risks in the literature. Therefore, exploring the dynamics of TDMRs fitting the practice of TDM in megaprojects is necessary for both scholars and project managers to gain a better understanding of the complexities of TDMRs in megaprojects. In this study, the TDMRs in megaprojects were identified and a multilayer risk list was determined based on GT. A total of 42 risk factors were identified and classified into 13 subcategories and 3 categories including decision-making process risk, decision-making execution process risk, and environmental risk. An SD model that depicted the dynamic interrelationships among multilevel risks of TDM in megaprojects was built. Rather than exploring single risk's effect, the developed SD model presented the risk-increasing synthesis effects of the interactions among risks.

The results show that the relationships among these TDMRs are complicated. The decision-making process risk and decision-making execution process risk are susceptible to environmental risk, whereas decision-making process risk will transfer to decision-making execution process and decision-making execution process risk may influence the decision-making process in turn. Besides, variables at different levels have varying effects on the total TDMR in megaprojects and the risk level of each subsystem. Among these effects, the synthesis effects of the interactions among risks have a great impact on TDMR in megaprojects. Therefore, it is suggested that a TDM mechanism driven by risk assessment should be established for megaprojects, where only when the risk is in control will the TDM process proceed. Specifically, decision-making execution process risk and decision-making process risk are the two most important risk categories, which need to be paid more attention to.

This study still has several limitations. Firstly, as GT is a qualitative method without quantification and there is a limited amount of original data, the identified TDMRs may be incomplete or inapplicable to other projects. Secondly, the mathematical equations and variable values used in the simulation model are established with from interview data, only considering the objective of each expert, which may not be applicable to other projects. Thirdly, the SD model presented in this paper only depicts the interactions among TDMRs in megaprojects without considering the risk mitigation strategies. Fourth, according to Box et al. [87], at least 50 observations are required to get a useful estimate of the correlation function, while the data used to simulate the model are obtained from the experts rather than practical observation data. Thus, more quantitative indicators and more objective methods (i.e., TOPSIS model for weighting the subjective weights and objective weights) determining the mathematical equations of variables are needed to assess TDMRs in megaprojects. Furthermore, the KCITH project is used for both data collection of GT and model simulation, which may limit the generalizability. Thus, more case studies are necessary to test the applicability and generalization of the presented simulation model [88].

In view of the impact of COVID-19 on the mental health of college students, this paper proposes a study on the relationship between psychological status and epidemic situation of university students based on BP neural network, so as to provide theoretical basis for universities to take targeted mental health education. This paper investigates the effects of COVID-19 on the psychological emotions of college students. According to the behavior and psychological characteristics of college students, the relevant investigation results are obtained through event monitoring, early warning, and usual performance, and a relationship model between college students' psychological status and epidemic situation based on BP neural network is constructed. This paper studies several factors through the relationship model and uses the principal component analysis method to analyze the impact of various factors on college students' psychology. According to the model prediction and result analysis, it concluded that the influence of COVID-19 should focus on improving the professional quality, physical quality, humanistic quality, and moral quality of university students, so as to improve the stability of colleges and universities in the event of public health emergencies. The model constructed in this paper can provide reference for carrying out mental health education and formulating effective intervention programs.

1. Introduction

The COVID-19 epidemic is a global public health emergency, and some people will have a strong stress response and show obvious symptoms of anxiety and depression. Facing the COVID-19 epidemic, the group of college students will have a stress response, which will have a negative impact on their normal life and study, such as a decrease in outing activities, a decrease in communication, and a change in learning methods. Therefore, college students are prone to different levels of emotional problems, and the duration is longer.

In order to win the battle against the epidemic and respond to the call of the country, everyone has been quarantined at home. The development of the epidemic, the restriction of activities, and the changes in the original life state have made everyone anxious and fearful. For college

students who are unable to go to school normally, the continuous expansion of the epidemic has led to uncertain return to school time, home study has led to changes in learning styles, and the employment and graduation issues that graduating students worry about have increased the anxiety and depression of college students, which in turn affects their mental health. Therefore, various universities and the education department have issued guidance manuals on the mental health of college students during COVID-19 to carry out psychological crisis interventions in public health emergencies.

Some scholars have also conducted research on the psychological problems and protection of college students in major epidemics and published relevant results. The results are mainly concentrated in the following three aspects. The first is the investigation of the psychological status of college students under the background of the new crown epidemic

[1]. Many investigations and studies believe that the new crown epidemic has a significant impact on the psychology of college students, causing psychological problems such as panic, anxiety, anger, and stress among college students. Therefore, schools and society should strengthen the cultivation of college students' psychological quality in response to public health emergencies and improve their psychological endurance [2]. The second is the relationship between the awareness of the new crown epidemic and the physical and mental health of college students. The results of data analysis show that the cognitive level of COVID-19 is significantly related to the physical and mental health of college students. The education department should strengthen targeted publicity and education and strive to improve college students' cognitive level of the epidemic and enhance their physical and mental health [3].

Some scholars found in the investigation that the anxiety level of college students was higher than the norm during the epidemic prevention and control period. By summarizing the existing research results, it is found that its characteristics mainly have two scores [4]. One is that some of the results only focus on quantitative analysis of the psychological problems of college students under the background of major epidemics but lack qualitative research on the specific manifestations, characteristics, and effects of psychological problems. Second, some scholars only pay attention to presenting the psychological problems of college students in their research and make suggestions, but there are not many specific measures for the psychological protection of college students under the background of major epidemics.

The report of the 19th National Congress of the Communist Party of China clearly stated that a healthy China strategy should be implemented, and the policy of "prevention first, combined prevention and treatment" was advocated. The epidemic has caused people to experience anxiety, depression, and other emotions, and students' psychological and behavioral problems have also begun to become prominent. How to motivate college students to get rid of the trouble of bad emotions and integrate into college life as soon as possible, and to pose new challenges to college students' physical health education work, has also become an important topic for building a healthy Chinese background. First of all, doing a good job of mental health education for college students in the context of epidemic prevention and control is an important content and internal need for the development of the discipline of mental health education, and it is also an important work to effectively improve the overall level of psychological services. The second is the core task of ideological and political education in colleges and universities in response to the epidemic, which is of great significance to maintaining the stability of the campus and creating a civilized campus [5].

Contemporary college students are in a special period of physical, psychological development and maturity and are in a special stage of life development and have a special social environment and social norms. In this special group, there are many special stressors specifically for them. The stress of foreign college students mainly comes from study [6], social and emotional state or environment [7], personal aspects [8], including examination [9], competition, time, teachers, classroom environment [10], employment, parental relationships, close relationships, economic problems [11], interpersonal relationships, living conditions, appearance, etc. Domestically, it comes from learning troubles, personal worries, and negative life events [12], including study, employment, interpersonal relationships, life, romantic relationships [13], economy, society, family [14], examination, life, learning environment [15], future, ability, personal health [16], competition, etc. The pressure sources of college students at home and abroad are similar. The emergence of these problems has formed the unique characteristics of psychological activities of this group. The results of psychological surveys of college students show that many colleges are living with psychosomatic disorders, and stress is one of the important factors that affect their health [16]. Therefore, understanding the basic conditions and influencing factors of college students' behavior and psychological stress is the basis for further research on college students' behavior and mental health at present and in the future and is the key to formulating plans and implementation steps for college students' physical and mental development. Based on this far-reaching significance, it focuses on systematically elaborating the factors affecting college students' behavior and psychological stress [17].

College students are in an important stage of rapid physical and mental development and change, complex and changeable emotional response, self-consciousness from semi-independence to independence, and social role transition. They lack of understanding of public health emergencies, which is easy to affect their psychological state. It is known from the existing research that the research on the relationship between college students' psychological status and epidemic situation is not deep enough. Therefore, this paper proposes the construction of the relationship model between college students' psychological status and epidemic situation based on BP neural network.

2. BP Neural Network

Artificial neural networks (ANNs) are an algorithmic mathematical model that imitates the behavior characteristics of animal neural networks for distributed parallel information processing. At present, there are dozens of artificial neural network models with more applications, including BP neural network, Hopfield network, art network, and Kohonen network.

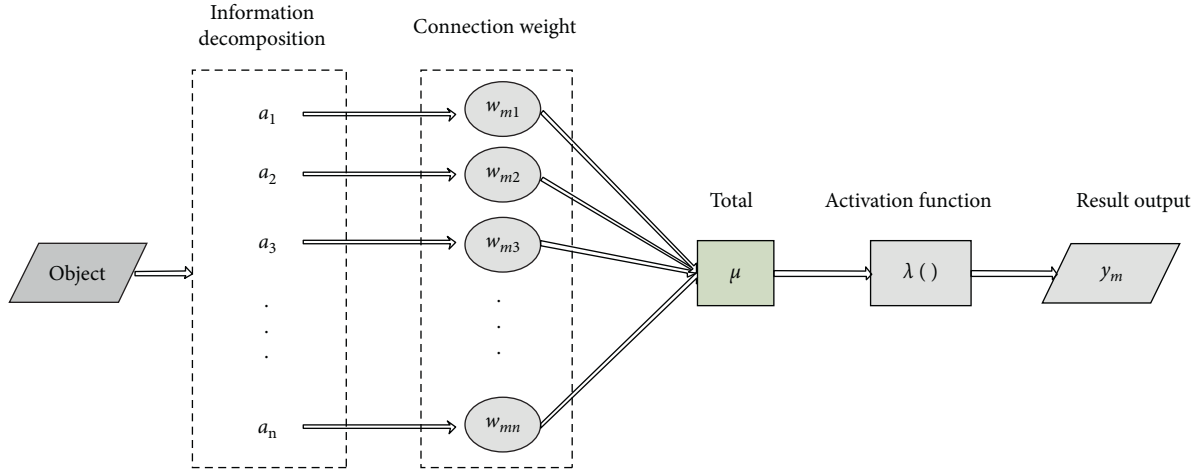
2.1. Neuron Model. BP neural network feeds back the error between the actual output value and the expected output value and then constantly trains and adjusts the model to reduce the error and make the prediction result of the model approach the actual situation. The basic component of BP neural network is neurons, which are connected with each other and transmit information through weighted connection channels. Neurons combine multiple received signals and then calculate the output results through the activation function, as shown in Figure 1.


FIGURE 1: Structure diagram of neuron model.

The calculation formula of neuron output is as follows:

$$y_m = \lambda\left(\sum_{i=1}^{n} w_{mi}a_i - \mu\right), \tag{1}$$

where y_m shows the output value after processing, w_{mi} denotes the connection weight of each transmission signal, a_k represents the input signal of the upper layer, λ represents the activation function of neurons, and μ is the threshold of neurons.

2.2. Construction of Neural Network Model.

BP neural network is a three-layer structure (as shown in Figure 2), which is composed of input layer, output layer, and hidden layer. According to the different problems to be solved, the hidden layer of multilayered structure can be set, but the most classic is only one hidden layer, which makes it easy to understand the relationship between analog input and output. Each layer of BP neural network has multiple neurons, and their number is determined by a specific model, while the two neurons in the hierarchy are not interconnected. All neurons are connected with the nearby hierarchy through one-way connection, and the connected nodes interact through weight. When the signal enters the hidden layer through the input layer, the connection function will process the transmitted data, and then the hidden layer will transmit the processed data to the output layer of the neural network and finally get the output result.

2.3. Implementation Process of BP Neural Network.

The input layer described in this paper includes 3 nodes: basic information of students, epidemic information, and psychological information.

The output layer has only label degree; that is, the output layer is one node. The number of nodes in the hidden layer is l, which is obtained through the analysis of training experiments.

In order to eliminate the influence of different dimensions in the three evaluation indexes of student number,

epidemic severity, and psychological status, the data were standardized. The index variables are mapped to [0, 1] through normalization, and the formula is as follows:

$$q_i^k = \frac{Q_i^k - Q_{i\,\min}}{Q_{i\,\max} - Q_{i\,\min}}, \tag{2}$$

where q_i^k ($k = 300$) is the normalized data, $i = 1, 2, 3$, $k = 1, 2, \ldots, 300$, and $Q_{i\,\max}$ and $Q_{i\,\min}$ are the maximum and minimum values in the k-th original data. 80% of the data are randomly selected from the normalized data set as training data and the remaining 20% as test data.

Input the training data into the neural network, and the output value of the hidden layer can be obtained through equation (3), shown as follows:

$$h_m^k = \sum_{i=1}^{3} w_{im}^{(v)}Q_i^k + l_m^{(v)}, \tag{3}$$

where $m = 1, 2, \ldots, N$, N is the number of nodes in the hidden layer, $w_{im}^{(v)}$ is the connection weight between the input layer and the hidden layer, and $l_m^{(v)}$ is the threshold of the hidden layer.

In order to obtain better convergence effect and improve the accuracy of the model, Sigmoid function is introduced into the hidden layer, shown as follows:

$$p_m^k = \frac{1}{1 + e^{-\sum_{i=1}^{6} w_{im}^{(v)}Q_i^k + l_m^{(v)}}}, \tag{4}$$

where p_m^k is the output value of the hidden layer and k is 900. Take the output value of the hidden layer as the input data of the output layer, and calculate the output value of the output layer by using equation (5), shown as follows:

$$Z^k = \sum_{i=1}^{3} w_i p_i^k + l_i. \tag{5}$$

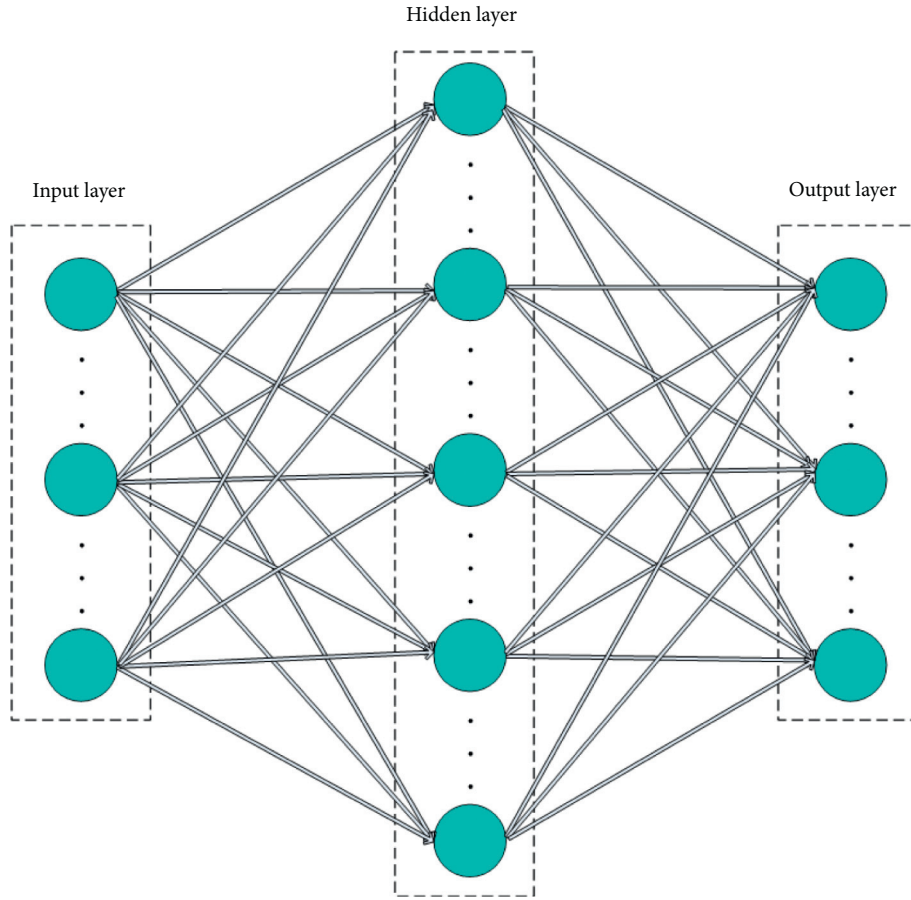
Among them, w_i is the connection weight, l is the output layer threshold, and Z^k is the output data of the output layer. In order to obtain better effect of the model, calculate the


FIGURE 2: Structure diagram of neural network.

mean square error through equation (6), which is expressed as follows:

$$\text{Mean} = \frac{1}{900} \sum_{n=1}^{900} (Z^n - R^n). \qquad (6)$$

Among them, R^n is the actual value and Z^n is the predicted value. The gradient descent method is used to backpropagate the error, correct the connection weight and threshold of each layer, and stop training until the target accuracy or target training times are reached, which is shown as follows:

$$w_{N+1} = w_N - \theta \frac{\partial_{\text{Mean}}}{\partial_w},$$
$$S_{N+1} = S_N - \theta \frac{\partial_{\text{Mean}}}{\partial_S}, \qquad (7)$$

where S_N denotes the threshold of each layer, w_N represents the connection weight of each layer, S_{N+1} is the threshold correction value, w_{N+1} shows the correction value of connection weight, and θ is the learning rate.

3. Method and Modeling

3.1. Variables in Process. In order to discover and further explore the behavioral factors that affect college students

under public health emergencies, this paper proposes corresponding solutions and countermeasures and uses more precise statistical analysis methods to study them. Path analysis is used to study the ways in which earlier variables affect subsequent variables, reveal the hierarchical relationship between factors, and suggest the existence of causal or related relationships. This paper screens out various factors affecting the peak behavior of the new crown epidemic at the 0.05 level. On this basis, this paper establishes the restriction mode of path analysis and obtains the path analysis diagram of the restriction mode to show the hierarchical logical relationship that affects the peak behavior of the new crown epidemic, to provide a basis for improving the behavior of the peak of the COVID-19 epidemic. In path analysis, the path coefficient is a standardized partial regression coefficient, the sign reflects the direction of action, and the absolute value reflects the degree of direct influence between levels. Secondly, the degree of indirect influence can be reflected by the size of the product of the corresponding path coefficients. The standard coefficient of overall influence is the sum of the product of the standard partial regression coefficients of each channel in the path, that is, the sum of direct and indirect influences [18].

In the questionnaire design, this study adds some inverse questions and similar questions. The purpose is to facilitate the screening of invalid questionnaires to prevent misjudgment of the measurement results. A total of 878

complete questionnaires are collected in this survey, and these 878 questionnaires are screened one by one, and invalid questionnaires are eliminated. The principle of eliminating questionnaires are as follows: one is to eliminate questionnaires with inconsistent answers before and after similar questions; the other is to eliminate questionnaires with the same answer for all questions, including inverse questions. This questionnaire is set to submit permissions, so there will be no missing questionnaires.

Based on existing mental health, psychology should actively take the responsibility of maintaining social mental health in response to new problems and new trends in society. The scale was compiled by Derogates and has been modified many times during its use. There are 90 self-assessment items in the SCL-90 scale. The nine factors tested are somatization, obsessive-compulsive symptoms, interpersonal sensitivity, depression, anxiety, hostility, horror, paranoia, and psychosis. In addition, it also includes 1 other factor, which mainly reflects sleep and diet. In general research, it is classified as the tenth factor. At the same time, this paper also designs 13 questions including demographic characteristics. This questionnaire uses a five-level score of 1 (never), 2 (very light), 3 (medium), 4 (heavier), and 5 (very heavy). Moreover, it takes the score of one or more factors in the 10 factors of the SCL-90 scale ≥3 as the standard for testing positive symptoms of mental health. Cronbach's α coefficient of the SCL-90 scale in this study was 0.922 [19].

The contents of the self-made questionnaire are as follows:

(1) Basic information: school, grade, major, gender, age, ethnicity, whether it is an only child, physical condition, whether to serve as a student cadre, learning situation during school, relationship with classmates and teachers, hometown location, hometown new crown epidemic situation, etc.

(2) Coping style: In the standard scale-coping style questionnaire, according to the tendency of individual coping behavior types, it is divided into mature and immature types. The problems reflecting the six coping factors of "withdrawal," "fantasy," "self-blame," "seeking for help," "rationalization," and "solving problems" are selected separately: "Borrowing cigarettes or alcohol to dissipate sorrow"-"Retreat," "I hope that I have solved the problem facing"-"Fantasy," "Always blame oneself"-"self-blame," "Buried unpleasant things in one's heart"-"seeking for help," "calm down the troubles"-"rationalize," "try to see the good side of things"-"solve problems." Each has four options: "Never," "Occasionally," "Sometimes," and "Always." The corresponding scores are 1–4 scores, and the cumulative scores are 6–24 scores. The higher the score, the more mature the college students are in responding to public health emergencies.

(3) Behavioral and psychological investigations during the peak period of the COVID-19 epidemic: (1) Behavior survey: including personal hygiene habits:

hand washing conditions, according to frequency from low to high, it is recorded as 1–3 scores; spitting and throwing garbage anywhere, according to the frequency of occurrence from quotient to low, it is recorded as 1–4 scores; dining in small restaurants outside: according to the frequency of occurrence, it is recorded as 1–5 scores. Improve self-immunity: Whether to pay attention to the diet and nutrition, whether to work and rest on time, whether to exercise: According to the frequency of occurrence from low to high, they are all recorded as 1–5 scores. (2) Psychological investigation (focusing on the investigation of psychological stress): including the frequency of wearing masks, whether you have ever taken healthcare products, whether you have ever taken drugs to prevent the COVID-19 epidemic, whether you are worried about your family members being infected, and whether you feel suffocated in public, etc.

(4) Psychological investigation in the middle and late stages of the COVID-19 epidemic: (1) Anxiety state: In the standard scale—self-rating anxiety scale, we select six aspects of "anxiety," "unfortunate premonition," "fatigue," "can't sit still," and "sleep disorder," respectively. Each item has four options: "No or Rarely," "Sometimes," "Often," and "Always," which are recorded as 1, 2, 3, and 4 scores, and the total score is 5–20 scores. The higher the score, the higher the degree of depression. (2) Depressive state: In the standard scale—self-rated depression scale, three questions of "depressive mood," "irritability," and "emptiness" are selected, respectively. Each item has four options: "No or Rarely," "Sometimes," "Often," and "Always," which are recorded as 1, 2, 3, and 4 scores, and the total score is 5–20 scores. The higher the score, the higher the degree of depression.

(5) Behavioral and psychological investigations in the late stage of the COVID-19 epidemic: (1) Behavioral investigation: including the maintenance of personal hygiene habits: whether to spit and throw trash, whether to gather at a small restaurant, and how often to wash hands every day; improve self-immunity: whether you still pay attention to diet and nutrition, whether you still work on time, whether you still exercise, etc. (2) Psychological survey (focusing on the measurement of subjective feeling): After the COVID-19 epidemic is under control, whether students feel relaxed psychologically is divided into five levels: "not relaxed," "a little relaxed," "some relaxed," "relatively relaxed," and "completely relaxed."

(6) Survey of perceptions and knowledge during the occurrence and development of the new crown epidemic: it mainly involves (1) the communication between the school and the students: whether the students are satisfied with the various prevention and control measures taken by the school during the new

crown epidemic (hereinafter referred to as "Opinions to the School"). (2) Students' social support system: How to resolve the psychological tension caused by the COVID-19 epidemic (hereinafter referred to as the "resolving method"). (3) The impact of the COVID-19 epidemic on students' life and study.

3.2. Establishment of BP Neural Network Model. From the feasibility analysis, it is concluded that when BP neural network is applied to the research on the relationship between college students' psychological status and epidemic situation, it can effectively simplify the evaluation process and improve the evaluation efficiency and accuracy. In the process of creating the network model, it is necessary to maintain the good generalization ability of the model. In short, the network model must be able to widely adapt to different types of samples (i.e., different evaluation objects, indicators, etc.). Therefore, when constructing the BP neural network model, this paper will fully consider and reasonably set the key factors such as the structure, algorithm, number of neurons, and error accuracy of the network model (Figure 3).

In practical research, the number of neurons in the input layer depends on the number of variables contained in the problem. This study involves the evaluation index of the relationship between college students' psychological status and epidemic situation. According to the evaluation index system and the 10 secondary evaluation indexes involved in the questionnaire survey, this paper plans to record the number of neurons in the input layer as 10.

The output layer mainly depends on the actual needs of the studied object. The number of neurons in the output layer is selected after comprehensive analysis and judgment. In this study, the output content is the comprehensive evaluation result of the relationship between college students' psychological status and epidemic situation. Therefore, this paper sets the number of neurons in the output layer as 1.

The BP neural network with only one hidden layer is constructed this time. In order to ensure the effective training of the network model, the network structure needs to be simplified. Because the number of neurons in the hidden layer will directly affect the accuracy of network training, we need to be very careful when selecting the number of neurons. If the number of hidden layer neurons is too small, it will greatly reduce the fault tolerance of the network model and the accuracy of identifying samples. If the number of settings is too large, the network training time will be too long, and the fitting degree of the network model will be greatly increased, resulting in the problem of overfitting. We analyze or calculate the number of neurons contained in the input layer and output layer to determine how many neurons are needed in the hidden layer.

4. Experiment and Result

In this study, the convenience sampling method was used to investigate college students, and all respondents participated voluntarily. With the help of questionnaire star, the survey

list is included in the electronic questionnaire. The questionnaire uses unified guidelines to introduce the purpose and significance of the survey. After checking the collected data, input it into SPSS 20.0 software for data analysis and processing. The count data is expressed in cases and percentages. *T*-test, analysis of variance, correlation analysis, and multiple linear hierarchical regression analysis were used to explore the related factors and their interaction.

The basic status of the undergraduates participating in the survey is shown in Tables 1 and 2. From the questionnaire on the basic information of students and questionnaire on basic information of students affected by epidemic situation, the survey samples in this paper meet the needs of statistical surveys, which shows that the results of the experimental survey conducted in this paper are statistically significant.

Table 3 shows the survey statistics of students' personal behavior during the peak period of the COVID-19 epidemic. It can be seen from the table that, at the peak of the COVID-19 epidemic, although there are quite a few survey subjects who have never attracted attention in terms of hygiene habits and improving autoimmunity, the proportion is lower than that of students who sometimes, often, and always maintain good hygiene habits and pay attention to improving their own immunity.

Shown in Table 4 is the survey statistics of the personal behavior of students after the COVID-19 epidemic. In the later period of the COVID-19 epidemic, 7.21% of the survey respondents occasionally washed their hands, 64% of the survey respondents occasionally, sometimes, or often spit and throw garbage, and 2.35% of the survey respondents often or always dine in small restaurants outside. 8.25% of the survey respondents have never had the habit of regular work and rest. Less than half of the survey respondents sometimes, often, or always exercise their bodies, and 44.87% of the survey respondents never or only occasionally pay attention to the combination of diet and nutrition. Only 14.9% and 1.73% of the survey respondents always work and rest on time and exercise every day, respectively.

At the peak of the COVID-19 epidemic, among 780 students, 273 sometimes or often wear masks, accounting for 35.02%. 237 people have taken medicine to prevent the COVID-19 epidemic, accounting for 30.48%, and 160 people have taken healthcare products to increase their resistance, accounting for 20.50%. 66.75% of the survey respondents once felt suffocated in public, among which 220 people felt suffocated sometimes or often, as shown in Table 5.

The middle and late stages of the COVID-19 epidemic are between the peak of the COVID-19 epidemic and the latter part of the COVID-19 epidemic. As shown in Table 5, the psychological status during this period is measured using five anxiety and three depression items. 47.69%, 65.75%, 60.48%, 92.75%, and 80.76% of students have had obvious feelings of anxiety, premonitions of misfortune, fatigue, akathisia, and sleep disorders, respectively. 61.88%, 42.79%, and 82.48% of the survey respondents had significant depression, irritability, and feeling of emptiness, respectively, as shown in Table 6.

The results of single-factor logistic regression analysis are shown in Table 7. Among them, the eight factors of gender, age, academic performance, peak behavior score, opinions on school measures to prevent the COVID-19 epidemic, resolving ways to confide in others, doing nothing, and coping style scores are significant.

This paper uses reliability to analyze the feasibility and effectiveness of the questionnaire. Reliability refers to the consistency and reliability of the results measured by the test or scale tool. In order to ensure the reliability of the questionnaire, this paper uses the Cronbach coefficient analysis method to analyze the internal consistency of the questionnaire data. For Cronbach coefficient the calculation formula is as follows:

$$\delta = \frac{M}{M-1}\left(1 - \frac{\sum f_i^2}{f^2}\right), \tag{8}$$

where M denotes the total number of items in the scale, f_i is the variance of score in question i, and f is the variance of the total score of all items. According to the formula and based on the data obtained from the questionnaire, the coefficient of this scale is 0.85, which proves that the questionnaire is stable and has high internal consistency and trust level.

Opinions on the school	−0.37905	0.04464	72.79363	0.00002	0.69387
Self-resolving	−0.29139	0.08141	13.00769	0.00030	0.75649

Fit the logistic avoidance model of multinomial ordinal classification to the factors in Table 7. Set the screening standard to 0.15 and reject to 0.05. The results are shown in Table 8. The younger you are, the more satisfied you are with the measures taken by the school, the higher your peak epidemic behavior score, the lower your choice of resolving ways to confide in others, and the lower your coping score, the more psychologically nervous you will be during the peak of the COVID-19 epidemic.

The regression results are shown in Table 9. Students who scored lower in anxiety in the middle and late stages of the COVID-19 epidemic were more satisfied with the measures taken by the school and chose self-resolving methods and felt more relaxed in the later stages of the COVID-19 epidemic.

According to the above experimental results, the following suggestions are put forward. First, multiple coordination is done to jointly protect students' mental health. COVID-19 epidemic should be published through key roles such as various media channels and counselors. On the one hand, it should reduce unnecessary fear and help students master the necessary preventive knowledge.

On the other hand, we can strengthen the health education of college students' lifestyle through a variety of information platforms to promote the generation and maintenance of their healthy behavior. Second, strengthen the construction of teachers and improve the combat effectiveness of epidemic prevention psychological work. In case of public health emergencies, students' cognition of epidemic situation knowledge is easy to deviate and students' psychological emotion is easy to fluctuate. Mental health education is facing new challenges. Therefore, it is essential to improve their psychological competence under the epidemic situation. Through online peer counselors' daily work discussion, supervisors are invited to conduct professional supervision and actively learn relevant knowledge of psychological maintenance under the epidemic, to lay a solid foundation for mental health work under the epidemic. In addition, popularize psychological epidemic prevention knowledge through mental health knowledge publicity, psychological network support, and psychological cloud classroom and improve students' psychological quality and open students' psychological self-help mode [20].

5. Discussion

As an important group in our country, the mental health of college students has always been a hot issue of social concern. The COVID-19 epidemic has affected the learning style, lifestyle, and communication styles of college students and also affected the mental health of college students to varying degrees. China's epidemic prevention and control is still in a tense stage of external defense import and internal defense rebound. The study life and interpersonal communication of college students will still be in a state of restraint and depression in the short term, and such long-term restraint and depression can easily lead to the transformation of some college students' mental health problems from nothing to existence, from small to large. Therefore, under the background of the COVID-19 epidemic, doing a good job in the mental health education of college students, preventing the occurrence of college students' psychological problems, and improving the level of college students' mental health are an urgent task for educators.

This paper combines the COVID-19 epidemic situation to investigate the current psychological emotions of college students through a questionnaire survey. Through investigation and analysis, it can be known that various behaviors of college students under public health emergencies are the result of a combination of multiple factors. This paper studies multiple factors in the research and combines factor analysis to finally get the influence of each factor on the psychology of college students.

6. Conclusion

In order to explore the impact of COVID-19 on college students' mental health, this paper proposes a BP neural network based model for the relationship between college students' psychological status and epidemic situation by evaluating the psychological status of college students and exploring the related factors. The relationship model constructed in this paper is used to analyze the psychological factors affecting college students, and the principal component analysis method is used to explore the factors affecting college students' psychology. From the model prediction and result analysis, it is known that the factors affecting college students' psychological status show multilevel and multifaceted characteristics. During the epidemic period, the psychological status of college students is not only related to demographic characteristics, but also affected by epidemic related factors. At the same time, their own behavior also has a more significant impact on their psychological status. On the premise of ensuring no infection, we should pay full attention to the intervention of college students' health behavior during the epidemic. In addition, the influence of COVID-19 on college students' psychology should focus on improving occupation quality, improving their physical quality, humanistic quality, and moral quality, and improving the stability of colleges and universities in public health emergencies. By evaluating the psychological status of college students and exploring the relevant influencing factors, this paper can provide reference for carrying out mental health education and formulating effective intervention programs.

Existing railway line (ERL) construction safety has received significant attention during the past decades due to the high accident rate and the difficulty of progress development under the limited synthesis construction time schedule (SCTS). However, the previous literature is dominated by the construction safety of new railway lines, while research on construction safety of ERLs is limited. This paper analyzed the interactions and causal relationships between construction safety risk (CSR) and multiple factors and classified feedback loops. Hence, a system dynamics model was developed, and a series of tests were conducted to simulate the evolution of CSR under different group environments. The results indicated that (1) the CSR considering ERLs is significantly relevant to the implementation degree of SCTS. For situations where there are more delays and more schedule pressure, construction safety accidents tend to have a higher level. (2) Work efficiency is negatively related to construction safety accidents probability. The increase of work intensity could reduce schedule pressure in the short term but could increase construction safety risk in a long time. Applying both appropriate work efficiency and work intensity may achieve an acceptable result. This paper adds to the knowledge of construction safety risk management in terms of implementation and offers lessons and references for future construction safety management considering ERLs.

1. Introduction

With the great improvement in train speed and operating conditions, some new railway projects will inevitably be built close to the existing railway lines (ERLs) [1]. Under the background of uninterrupted operation, to ensure the transportation of ERLs, the construction of new railway projects cannot be arranged randomly. It can only operate within a certain time called synthesis construction time schedule (SCTS) [2]. The SCTS is the time reserved in the train operation diagram, specifically used for the construction. No trains will be running during that time. The duration of SCTS should be more than 180 minutes when the construction is near a normal railway and 240 minutes at 0:00–6:00 when the construction is nearby a high-speed railway [3]. When the SCTS is long, the fluency of the transportation organization will be affected, thus affecting

the efficiency of the operation of ERLs. On the contrary, if the SCTS is too short, the normal construction schedule will be restricted, affecting the efficiency of construction operation and increasing the construction cost [4]. Due to the mutual interference between the construction of new railway projects and transportation of ERLs, the effective construction time and space are more and more limited, and the construction safety issues are more prominent [5]. Thus, it is challenging and demanding to ensure construction safety under the background that the transportation organization of ERLs affects the construction organization of the new railway projects.

Each country has different management modes for the construction and maintenance of ERLs. In Japan, for the traffic density of Shinkansen during the daytime, except for necessary patrol inspection, all construction and maintenance work will be arranged within the SCTS of 12:00~6:00 am, and

all trains in the SCTS will be suspended. 12:00~3:00 am is the time for construction or maintenance, and 3:00~6:00 am is the time of inspection and acceptance [6]. Construction and maintenance also adopt the 6 hours of SCTS in France, it is generally during 11:30 pm~5:30 am, and the actual operation time is controlled under 4 hours [7]. High-speed railways and general-speed railways are interlinked alternately into networks in Germany, and the railway lines are mixed passengers and freight trains. For the density and trains that run at night, the SCTS is arranged at 3:30~6:00 am. Only one line is blocked, and the other line is running normally. The express freight trains pass before the SCTS hours, during which only a small number of slow freight trains run. More construction and maintenance work will be carried out on weekends with no train traffic [8]. SCTS of construction and maintenance of ERLs in the above countries takes a long time, and there are no trains or only a few single lines of freight trains running during the SCTS. Transportation has a negligible impact on construction safety, and the construction safety of ERLs is not prominent as that of China. The setting of SCTS has constraints and impacts on the operation and the passing capacity of the railway. If the time of SCTS is too short, it cannot guarantee the completion of the construction task and will affect the quality and efficiency of the construction work, thus affecting the construction schedule.

Safety accidents during construction have been and continue to be a global problem [9], and they can cause casualties and huge economic losses [10]. Generally speaking, accidents are raised by many interacting systemic factors [11]. An accident or an unsafe event may be caused by some elusive causes [12, 13]. Since Heinrich realized that unsafe behavior was the dominant cause of safety accidents [14], there has been a growing amount of research concerning their contribution to accidents in recent years. Bird revised Heinrich's theory and proposed that the essential cause of accidents depends on management. Accidents were more likely to be caused by "unsafe acts of people" and "unsafe mechanical or physical conditions" [15, 16]. The "unsafe acts of people" and "unsafe physical or mechanical conditions" are collectively referred to as on-site errors. Management errors are the deep-seated reason that causes safety accidents [17]. Unsafe behavior can be defined as intentional or unintentional violations of safety compliance expectations [18]. An unsafe condition is when the physical layout, tools, equipment, and/or materials in a workplace or work location violate contemporary safety standards [19]. Avoiding unsafe behaviors and unsafe conditions can be effective in reducing the probability of safety accidents [20]. The majority of existing studies focus on the safety accidents in independent new rail projects [21, 22], and few studies consider CSR in the presence of ERLs. Furthermore, given the huge mediating effect of CSR considering ERLs, the mechanism of how CSR changes under the influence of multiple factors needs more attention. However, the evolution mechanisms of CSR considering ERLs are not yet clear, and it is necessary to be explored further. To fill the aforementioned research gap, this paper aims to investigate the laws and effects of influencing

factors in the safety management system considering ERLs, establishing a scientific causal model, and simulating the evolution of the system under different conditions to provide guidance for management decisions.

System dynamics is a system simulation method for analyzing production management and inventory management created by Jay Forrester and originally named Industrial Dynamics [23]. It has often been used for analyzing and understanding complex safety problems [24]. For example, researchers adopt SD to gain insight into the cause of major accidents [25–27]. SD was applied to gain insight into the complexity and coupling of project elements [28] and was shown as an efficient tool to simulate the dynamics of safety attitudes and behaviors [29] and to organizational learning [27, 30, 31]. As a systematic approach, SD emphasizes the feedback between variables in a system and understanding the behavior and dynamics of complex systems with time [32]. Therefore, it was used as a theory development tool [33]. SD emphasizes the holistic nature of systems and the nonlinear characteristics of complex systems and considers that the behavior patterns and characteristics of a system depend mainly on the internal dynamic structure and feedback mechanisms. The system develops and evolves according to certain laws under the action of internal and external dynamics and constraints. The approach of system dynamics to complex problems is a combination of qualitative and quantitative, and holistic and analytical thinking. It is a method of analysis, synthesis, and reasoning. This paper uses SD to investigate the complexity and coupling of project elements (e.g., construction schedule, safety cost, and safety) from a system thinking perspective considering ERLs.

The paper is organized as follows. Section 2 analyzes the relevant factors that influence the construction safety of new projects near ERLs and sets up the causal model. Section 3 sets up the SD model of construction safety considering ERLs, uses data collected from a construction site, and validates the model. In Section 4, tentative data are used to simulate the relationship between these variables and the occurrence of accidents. The results are analyzed and discussed to understand the dynamics of the management components. Finally, Section 5 provides concluding remarks.

2. Relevant Factors Influence on Construction Safety of ERLs

2.1. Identification of Feedback Loop for Construction Safety. This study is based on unsafe behaviors and unsafe conditions in those two perspectives and only considers the construction progress, cost, and safety factors. Other relevant factors were not considered. This study identifies and refines the factors affecting construction safety and analyzes the relationship between the various factors to establish a causal model. It can visually show the influence of each factor on construction safety and make the relationship among each factor clear. This paper made use of a large amount of literature involving railway construction safety in recent years to summarize while forming a preliminary

understanding of the identification of railway construction safety impact factors considering ERLs. Literature was based on Google Scholar, Elsevier, Web of Science, and Scopus, searched by entering keywords such as railway construction safety. Descriptions of construction safety influence factors considering ERLs in the literature were carefully extracted. According to the literature, the driving factors of construction safety can be categorized as follows:

(1) Construction schedule: if the schedule of the railway construction was out of control, economic and social losses would be inevitable [34]. It is important to note that excellent schedule management does not mean compressed schedules, which can lead to safety incidents [35, 36]. Management measures that are taken to expedite production put workers under pressure to increase productivity, which is negatively impacted[37]. When production pressure (e.g., excessive workload, required work pace, and time pressure) is perceived, workers perceive increased risks and barriers, leading them to be more likely to work with unsafe behaviors [38]. On the contrary, construction safety accidents are likely to cause project delays [39]. Therefore, previous studies have shown that schedule pressure is the critical link between scheduling and safety in construction.

(2) Cost: this paper does not consider the total production cost during the construction. It only analyzes the safety investment within the boundary range of the model. Safety investments generally refer to funds spent on workplace injury prevention measures or activities that aim to protect workers' health and physical integrity [40, 41]. In many previous studies, the components of safety investment have been discussed, such as safety training, safety supervision, and safety protection [42–44]. Since the vast majority of those engaged in the grassroots work of railway construction are migrant workers, they are poorly educated and lack safety awareness [45]. Safety training improves the safety awareness of workers to a certain extent. Safety supervision is a reflection of the management's attitude towards unsafe behaviors [46]. The more strict the supervision of safety managers at the construction worksite, the more the probability of discovering unsafe behaviors [47]. Severe punishment for unsafe behavior can also serve as an effective warning [48]. Not using personal protective is one of the leading phenomena of unsafe behaviors [49]. In view of the high incidence of falling accidents in railroad construction, safety measures can be effectively taken to reduce the rate and severity of accidents [50]. Providing safety protection is a crucial complement to other safety measures (e.g., safety training) and is considered a last resort for hazard control measures for workers [51].

(3) Safety subjects: the research on accident causation theory was pioneered by Heinrich [14], who analyzed 75,000 accident reports and developed a domino theory (model) of accident causation. The analysis led him to conclude that 88% of accidents are caused by unsafe behavior and 10% of accidents are caused by unsafe conditions. Unsafe behaviors and unsafe conditions can directly lead to the occurrence of accidents [52]. According to past statistics in China, more than 80% of accidents were caused by workers' unsafe behaviors [53]. Unsafe conditions on a construction site are events that are not related to people and are a natural part of the initial construction site conditions [19].

2.2. Causality Analysis of Construction Safety. In order to understand the causal relationships of construction safety considering ERLs, the causal loop diagram is proposed, as shown in Figure 1 (the polarities represent a positive or negative impact between variables). Due to the SCTS being fixed and limited, the construction must be executed strictly according to the plan. Owing to the complexity and uncertainty of the construction environment and conditions, schedule delays are inevitable [54–56]. The resulting schedule pressure (e.g., being pressed to work faster) leads to unsafe behaviors [57, 58]. Accidents caused by unsafe behaviors, in turn, lead to delays in production, thus creating production pressure [59]. With increased investment in safety comes increased safety training, supervision, and protection. Safety training and safety supervision are positively correlated with the improvement of safety consciousness and behaviors [60, 61]. Insufficient safety protection leads to the deterioration of cumulative unsafe conditions in the worksite and eventually to accident occurrences, which increases safety investment [62, 63]. In summary, the model reveals these feedback processes, and it is vital to consider schedule, safety cost, and safety on an operational level.

3. Modeling

System dynamics modeling is a typical simulation method, focusing on the interaction between factors of complex systems [64]. It predicts the changing trend of the system and summarizes the dynamic development law of the system by constructing a causal feedback loop to describe the dynamic adjustment process of construction safety considering ERLs, which is an ideal research method. System dynamics modeling requires three steps: determining the system boundaries, constructing the model structure, and quantifying the action paths. The analysis of feedback loops and simulation experiments are typical research methods.

3.1. System Boundary. The SCTS is the most important element in the construction of ERLs; the cost that construction enterprises pay special attention to is taken as the reference elements, while other elements such as quality and environment are not taken as the analysis object. According to the causal model of construction safety, safety accidents
Figure 1: SD modeling for construction safety considering ERLs.

(SA), safety training (ST), safety investment (SI), safety supervision (SS), safety protection (SP), SCTS, schedule pressure, fatigue, unsafe conditions (UC), unsafe behaviors (UB), construction schedule (CS), and safety consciousness (SC) are defined as main systematic variables. This study focuses only on the relationships and interactions among the eleven variables.

3.2. Model Structure. Based on the causal model of construction safety under the context of ERLs, we further defined the stock, flow, and feedback loop in the dynamic system. A stock is the value or level of the core variables accumulated in a dynamic system that reflects the system's changing state. According to the dynamic regulation system of construction safety considering ERLs, the system stocks are the UB level of people and the UC level of physical or mechanical. A flow is an activity that changes the stock. In this study, the flows are the decrease and increase of UB of people as well as the decrease and increase of UC of physical or mechanical. According to the causal model, the reduction and improvement of UB are related to dynamic variables such as ST, SC, SS, fatigue, and schedule pressure. The improvement and reduction of UC are associated with dynamic variables such as SP, working platform restriction, and invasion barriers of equipment and materials. In addition, the auxiliary variables, such as working platform restriction and invasion barriers of equipment and materials which reflect the UC, are closely related to the dynamic regulation of SA and need to be defined separately. In conclusion, the structure of the dynamics model of construction safety considering ERLs is shown in Figure 2.

3.3. Model Hypothesis and Path Quantification. Construction safety considering ERLs may be interfered with by many factors. It is hard to enumerate and quantify all the interactions between variables. The rational assumptions of the system dynamics model allow itself to focus on the vital variables and their influence paths while ignoring the interference of other unimportant and small

probability events, thereby significantly reducing the complexity of the algorithm. In order to standardize the study, five hypotheses are proposed: (1) Only consider the relationship between unsafe behaviors, unsafe conditions, and safety accidents in the construction stage under the background of ERLs. (2) It does not consider the total production cost during the construction and only analyzes the safety investment. (3) The variables, such as total quantity, remaining quantities planned, daily actual quantities completed, daily planned quantities completed, actual quantities completed, planned quantities completed, and construction schedule, should be uniformly treated according to the progress unit. For example, the total quantity is 12,000 m, and the constructions schedule is 50 m/d. (4) Delay is set as a random function, and it is assumed that the delay occurs randomly. (5) Different lines have different actual situations. The values of relevant variables in this paper are derived from the production data of the case. The assigned values of correlation coefficients are the average values obtained after statistical analysis after collecting actual data.

Based on the above model assumptions, some mathematical functions are needed to describe the relationship between the key variables. Planned quantities completed (PQC) is the accumulation of daily planned quantities completed (DPQC); DPQC is related to planned quantities (PQ) and construction period (CP), which is an IF THEN ELSE function, and the specific description is shown in Table 1, so PQC is calculated as follows:

$$PQC = \sum_1^{CP} DPQC. \tag{1}$$

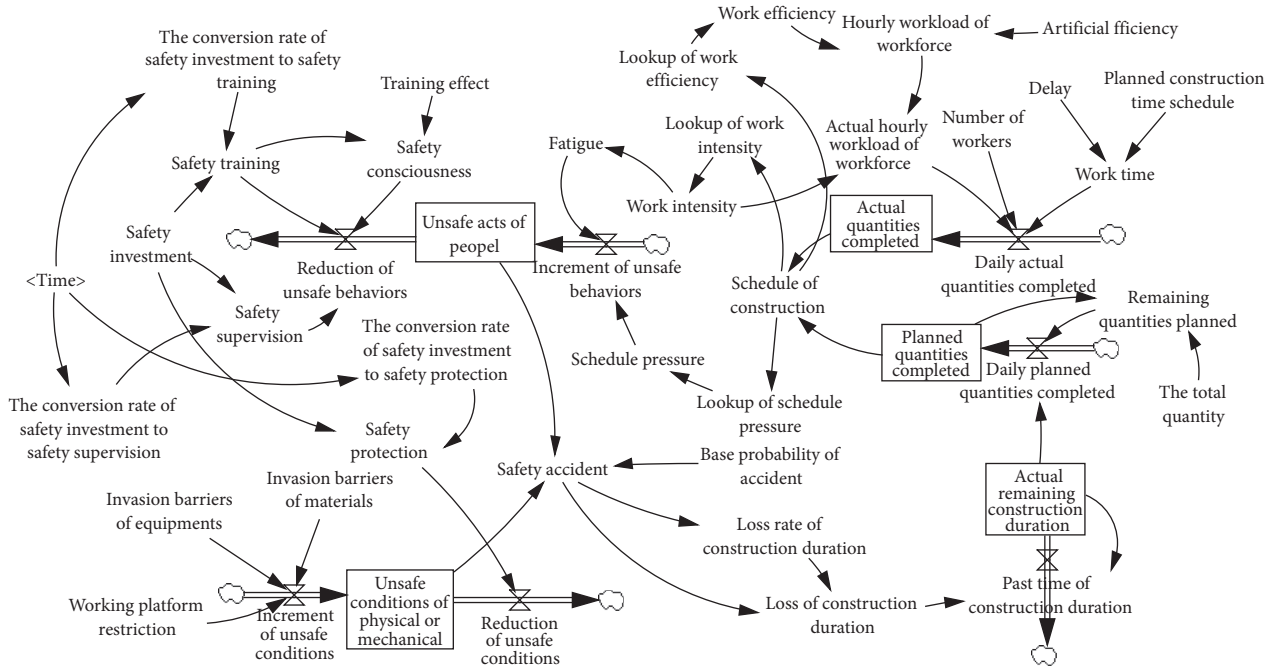
Similarly, the mathematical function of the calculation related to the actual quantities completed (AQC) can be obtained as formula (2), where daily actual quantities completed (DAQC) is related to the following three variables: WN stands for the number of workers per day, AHWW stands for the actual workload of workforce per hour, and WT stands for the work time per day, so the mathematical expression of DAQC is shown in formula (3).


FIGURE 2: dynamics model of construction safety considering ERLs.

TABLE 1: Principal variables and constants description of the SD model.

Variables designation	Unit	Description
Schedule of construction	Dimensionless	IF THEN ELSE (actual quantities completed < planned quantities completed, (1− actual quantities completed)/ planned quantities completed, 0)
Schedule pressure	Dimensionless	1 * WITH LOOKUP (construction schedule ([(0, 0)-(1, 1)], (0, 0), (0.1, 0), (0.2, 0.1), (0.5, 0.7), (0.7, 1), (1, 1))
Work intensity	Dimensionless	1 * WITH LOOKUP (construction schedule ([(0, 0)-(1, 1)], (0, 0), (0.2, 0.3), (0.4, 0.5), (0.6, 0.7), (0.8, 0.9), (1, 1))
Fatigue	Dimensionless	WITH LOOKUP (work intensity ([(0, 0)-(1, 1)], (0, 0.045), (0.1, 0.21), (0.17, 0.3), (0.25, 0.37), (0.3, 0.4), (0.6, 0.4), (0.7, 0.45), (0.8, 0.58), (0.9, 0.76), (1, 1))
Reduction of unsafe behaviors	Dimensionless	0.33 * safety training + 0.33 * safety consciousness + 0.34 * safety supervision
Increment of unsafe behaviors	Dimensionless	0.35 * fatigue + 0.65 * schedule pressure
Increment of unsafe conditions	Dimensionless	0.38 * working platform restriction + 0.31 * invasion barriers of equipment + 0.31 * invasion barriers of material
Safety accidents	Dimensionless	Safety accidents probability (shown as Table 2), base probability of accidents * (unsafe behaviors + unsafe conditions)
Loss of construction period	d	Safety accident * loss rate of construction period
Daily actual quantities completed	m	Work time * actual hourly workload of workforce * number of workers
Daily planned quantities completed	m	IF THEN ELSE (actual remaining construction period ≤ 0, remaining quantities planned, remaining quantities planned/actual remaining construction period)
Hourly workload of workforce	m	Artificial efficiency × (1 + work efficiency)
Actual hourly workload of workforce	m	Hourly workload of workforce × (1 + labor intensity)
Work time	h	Planned construction time schedule−(delay/60)
Delay	min	RANDOM NORMAL (0, 20, 7, 15, 1)

$$AQC = \sum_{1}^{CP} DA\, QC. \tag{2}$$

$$DAQC = WN \times AHWW \times WT. \tag{3}$$

In the above formula, WT is actually determined by planned SCTS and delay per day. The detailed description is shown in Table 1, where the delay is a random function whose output is 0 or the actual delay time. Different delays are set to explore the influence of transportation organization of ERLs on construction safety in this study.

The increment of unsafe behaviors (UBI) is related to the following two variables: fatigue stands for the count of those unsafe behaviors caused by workers' fatigue, SP stands for the count of those unsafe behaviors caused by the schedule pressure of workers. Then, the decrement of unsafe behaviors (UBD) is related to ST, SC, and SS, which stand for the conversion of the safety investment to safety training, safety consciousness, and safety supervision, respectively. So the mathematical expression of the level of unsafe behaviors (UBL) is shown in formula (4), and the mathematical expression of the UBI and UBD is shown in formulas (5) and (6), where α_{1-5} is the influence weight of each variable.

$$UBL = UBI - UBD. \tag{4}$$

$$UBI = \alpha_1 F + \alpha_2 SP. \tag{5}$$

$$UBD = \alpha_3 ST + \alpha_4 SC + \alpha_5 SS. \tag{6}$$

Correspondingly, the increment of unsafe conditions (UCI) is related to the following three variables: MBI stands for the materials beyond the boundaries set for transportation safety, EBI stands for the equipment beyond the boundaries set for transportation safety, and WPR stands for the restrictions on work platforms set to ensure transportation safety. In this study, the decrement of unsafe conditions (UCD) is related to the SP, which refers to the conversion of the safety investment to safety protection. Therefore, the mathematical expression of the level of unsafe conditions (UCL) is shown in formula (7), and the mathematical expression of the UBI and UBD is shown in formulas (8) and (9), where β_{1-3} is the influence weight of each variable.

$$UCL = UCI - UC. \tag{7}$$

$$UCI = \beta_1 MBI + \beta_2 EBI + \beta_3 WPR. \tag{8}$$

$$UCD = SP. \tag{9}$$

The unsafe behaviors and unsafe conditions actually determine safety accidents (SA), but the former two are necessary not sufficient conditions for the latter. γ_s is set as a constant standing for the base probability of an accident. Therefore, SA is calculated as follows:

$$SA = \gamma_S (UCL + UBL). \tag{10}$$

All the previous formulas are the main mathematical functions in this study; more descriptions of variables and constants are shown in Table 1.

3.4. Model Validation. The validity tests of the model include mechanical error tests, dimensional consistency tests, and extreme condition tests. The model was built with Vensim in this study, which has passed the mechanical error tests, dimensional consistency tests, and extreme condition tests. The system model in this study included 35 variables and 10 constants. The main variables and function relationships in the model are described in Table 1.

Workers in the real world are faced with different situations every day and therefore make decisions accordingly. The conditions of the workplace vary day to day. As time goes on, the decision of workers and conditions of the workplace may be changed. To simulate this, the model sets some events (safety training, safety supervision, working platform restriction, etc.), which are triggered every day. According to the functions we set above, unsafe behaviors were performed, and unsafe conditions were accumulated. Consequently, the time step of the model was set to 200 days to ensure that a long enough observation time was available to show all possible trends. The initial value of safety accidents probability was set as 0. Vensim 8.2 was used to simulate the system dynamics in this study. And the input parameters of a railway cutting project close to the ERLs were designed. The main input parameters are shown in Table 3 and were determined by interviewing our industry workers involved in the data collection or based on available research literature and practical survey data. Relevant parameters were input into the model to conduct simulation analysis on the relationship between SCTS, construction schedule, UB, UC, and SA of the project. The simulation results are shown in Figure 3.

The construction risk degree and grade standards of existing lines were set by referring to "Technical Regulations for Risk Management of Railway Construction Engineering and Relevant Regulations," as shown in Table 2. The goal of the system safety management level was set as low risk.

Figure 3 shows that the safety accidents probability of the project reaches the maximum on the 31st day, which was a high-risk degree according to Table 2. It was reduced to medium risk on the 82nd day and low risk on the 187th day. Combined with the actual situation of the case project, it was found that the simulation result of the system dynamics was basically the same as the actual situation. That is, with the increase of construction schedule, unsafe behaviors and unsafe conditions rose to a high level at the end of the first month, which led to the rise of safety accidents. However, the safety investment came into play simultaneously. Various safety measures reduced the unsafe behaviors and unsafe conditions, which led to the reduction of safety accidents, so the safety risk was reduced to a low level on the 187th day. Figure 3 also indicates that the risk level would not decrease indefinitely with the increase of safety investment, which means there is no absolute zero safety risk.

TABLE 2: Degree and countermeasure for construction risk of existing railway lines.

Risk degree	Probability of casualty (0~1)	Countermeasure
Low	< 0.003	No measure
Medium	0.003~0.03	Strengthen daily management and increase investment in safety
High	0.03~0.3	Strengthen daily management and monitoring and increase investment in safety
Extreme high	> 0.3	Measures must be taken to reduce risks and increase investment in rectification

TABLE 3: Main parameters of the model.

| Parameter names	Parameter values	Parameter names	Parameter values
Total quantities	12,000 m	Planned construction time schedule	4 h
Number of works	100	Efficiency	0.075
Training effect	0.85	Safety investment	100 CNY/person·d
Working platform restriction	0.312	Invasion barriers of equipment	0.182
Invasion barriers of materials	0.236	Base probability of accident	0.03
FIGURE 3: Simulation result of safety accidents probability of the case.

In general, it can be seen that the internal relationship among the parameters, the equations, and the parameters established in the system dynamics model established in this study are reasonable and can reflect the actual situation of engineering management.

4. Simulation and Discussion

4.1. Simulation Analysis in Different Delay. The influence of SCTS on safety accidents is essentially reflected in the work time. Although the time of SCTS is planned, which means the work time is fixed, delay on ERLs is inevitable, resulting in frequent changes of work time. To observe the correlation between SCTS and safety incidents, different assignments of delay are shown in Table 4. Different assignments of delay correspond to different implementation degrees of SCTS. The smaller the assignment, the higher the implementation degree. The simulation experiment results are shown in Figures 4–6.

From Figure 4, it can be observed that when the implementation degree of SCTS is high, the safety accidents probability of the project reaches the maximum on the 32nd day, and the valve is 0.066. It is reduced to medium risk on the 79th day and low risk on the 165th day. Eventually, the safety accidents probability is infinitely close to 0.

TABLE 4: Assignment of different implementation rates of synthesis construction time schedule.

Implementation degree of SCTS	Assignment of delay
High	RANDOM NORMAL (0, 20, 8, 15, 1)
Medium	RANDOM NORMAL (0, 30, 10, 8, 1)
Low	RANDOM NORMAL (0, 40, 17, 10, 1)

Correspondingly, when the implementation degrees of SCTS are medium and low, the safety accidents probability of the project reaches the maximum on the 32nd and 33rd days, and the valves are 0.0663 and 0.0772. It is reduced to medium risk on the 87th day and 108th day and kept at the medium risk level until the 200th day. From Figures 5 and 6, it can be seen that, with the increase of implementation degree, schedule pressure and loss of construction period are raised obviously. The reason behind this is that when the implementation degree of SCTS is low, the available working hours are limited. Due to the fact that the daily workload is planned, the schedule pressure increases rapidly. However, the workers will adjust the construction schedule according
FIGURE 4: Comparison of safety accidents probability under different implementation degrees of SCTS.

FIGURE 5: Comparison of schedule pressure under different implementation degrees of SCTS.

FIGURE 6: Comparison of safety accidents probability under different implementation degrees of SCTS.

to the working hours and daily workload. As time goes on, the schedule pressure decreases and begins to level off. Loss of construction period is related to the safety accidents probability. A safety accident could lead to a construction shutdown and then result in loss of construction period.

4.2. Simulation Analysis in Different Safety Investment. Using the three major components categorized by existing researches [40, 65–67] as a point of departure, we chose to study three safety investments: (1) implementation of innovative technological tool proactive protection system, (2) employment of safety supervisor for conducting inspections, and (3) encouragement on being responsible for the safety of themselves and other coworkers with safety training. Three different safety investment assignments of 80, 100, and 120 (unit: CNY/person·d) were set to observe the relevance between safety investment and safety accidents. The simulation experiment result is shown in Figure 7.

The result from the simulation demonstrates the effectiveness of safety investment on construction safety risk. From Figure 7, it can be observed that when the safety investment is 120 CNY/person·d, the safety accidents probability of the project reaches the maximum on the 32nd day, and the valve is 0.0679. Correspondingly, when the implementation degree of SCTS is medium and low, the safety accidents probability of the project reaches the maximum on the 33rd and 35th day, and the valves are 0.0716 and 0.0756. In brief, higher safety investment may result in better safety performance.

4.3. Simulation Analysis of Construction Strategy. Improving work efficiency and increasing work intensity are common means to reduce schedule pressure. To observe the influence of those two factors on the whole model, 5 modes were set, respectively, as shown in Table 5. Different value assignments represented different strategies. Work efficiency and intensity in mode 1 were selected as 1.5 and 0, indicating that the construction was efficient and the work was easy. It would not cause physical and psychological discomfort to the workers. Mode 1 was the ideal mode. Similarly, mode 2 was the crushing mode, modes 3 and 4, respectively, represent some preference mode, and mode 5 was the equilibrium mode. That is, different modes represent different strategies. When other variables remain the same, the dynamics model simulates the evolution by changing the value assignments of the two variables mentioned above. According to the safety accidents probability, change of schedule pressure and loss of construction period after system runs to make rational decisions. The simulation results are shown in Figures 8–10.

According to the comparative analysis of Figures 8–10, mode 1 has the lowest safety accidents probability and loss of construction period but the highest schedule pressure. On the contrary, mode 2 has the most downward schedule pressure and the most increased safety accidents probability and loss of construction period. The result shows that it is unscientific to unilaterally improve work intensity to speed up the progress under the schedule pressure. This practice should be avoided in
FIGURE 7: Comparison of safety accidents probability under different safety investments.

TABLE 5: Value assignments under different strategies.

	Work efficiency	Work intensity
Mode 1	1.5	0
Mode 2	0	1.5
Mode 3	1.5	0.5
Mode 4	0.5	1.5
Mode 5	1	1

the construction of ERLs. Advanced construction equipment and scientific construction methods should be actively promoted to improve construction efficiency. The construction of ERLs should be carried out in a planned and organized way. However, mode 1 can only be used as an ideal mode in management practice. Improving construction efficiency is limited under the current construction technology and method, and other satisfactory solutions can only be sought.

Compared with other modes, the safety accidents probability, schedule pressure, and loss of construction period of modes 3 and 5 all maintain low values, which can be a satisfactory solution. The safety accidents probability of mode 5 is relatively lower, and mode 3 performs better in terms of schedule pressure. However, the progress pressure of mode 4 in the first week is slightly lower than that of mode 3 and mode 5 and then increases significantly; the safety accidents probability and loss of construction period are also at a high level. It indicates that the strategy based on increasing work intensity can only accelerate the progress in the short term. When the fatigue degree of personnel reaches a certain value, the safety accidents probability will be increased, which will interfere with the progress and cause economic losses of accidents and rework.

5. Discussion

The results from the simulations demonstrate that the schedule pressure after stabilization and loss of construction period are proportional to the implementation degree of SCTS. With the decrease of implementation degree of SCTS, the schedule pressure, loss of construction period, and safety

FIGURE 8: Comparison of safety accidents probability under different implementation degrees of SCTS.

FIGURE 9: Comparison of safety accidents probability under different implementation degrees of SCTS.

FIGURE 10: Comparison of safety accidents probability under different implementation degrees of SCTS.

accidents probability all increase to different degrees; especially, the safety accidents probability changes significantly. It can be seen that the evolution of the implementation degree of SCTS has a significant influence on the safety accident probability. To effectively enhance and improve the construction safety management of ERLs, the transportation organization should be optimized, and the implementation degree of SCTS should be improved.

Different safety investments have different effects on the safety accident probability, and safety investments have a positive effect on accident prevention. Good safety training not only raises the level of risk awareness but also persuades individuals to be less tolerant of risks. The findings of this study further showed that the interventions that combine good safety supervision with safety protection are more likely to reduce safety accident probability.

When the schedule pressure is low, it can be preferred to ensure safety. Increasing a certain amount of work efficiency can accelerate the schedule by reasonably arranging the working platform and optimizing equipment and processes. When the schedule pressure is high, increasing work intensity and work efficiency simultaneously is better. Under the condition of ensuring the low safety accidents probability, parallel construction can be organized as far as possible to expand the working platform. At the same time, construction organization and safety protection should be optimized to avoid interference between working platforms and construction procedures. When the construction period is nearing the end, appropriate consideration can be made to increase the work intensity, which can avoid the safety accidents and loss caused by fatigue accumulation in the later period and complete the planned project faster.

6. Conclusions

Based on the causal model of construction safety considering ERLs, a system dynamics model is proposed to simulate the construction safety evolution process, and a series of simulations are performed under different conditions. The results confirmed that the construction safety considering ERLs is significantly relevant to the implementation degree of SCTS. The incidence of construction safety incidents tends to be higher because the greater the possibility of construction delays, the greater the schedule pressure. However, even in each level of construction safety accidents probability, the evolution curve reached the maximum at about one month. As the countermeasure took effect, the evolution curve declined after reaching the maximum value and finally stabilized. Work efficiency has a negative impact on construction safety accidents probability. The increase of work intensity could reduce schedule pressure in the short term. Still, due to psychological and physiological factors, unsafe behaviors increased in a certain range. Interestingly, there is a marginal cost effect on the effect of work intensity on schedule pressure. The improvement in schedule pressure is not significant when work intensity increases to a certain level.

The main contribution of this study is that it is a major step forward in integrating system dynamics and safety in

the examination of construction safety management considering the ERLs. Theoretically, rather than studying construction safety considering ERLs in a static manner, this study examined the evolution as it unfolds over time. This study treats construction safety management considering the ERLs as a dynamic problem caused by "system structure" and a complex phenomenon. In this system, unsafety behaviors and unsafety conditions have significant impacts on construction safety risk considering ERLs. In contrast, almost all existing studies focus on construction safety risks relevant to new railway projects, with little research on construction safety management considering ERLs. Methodologically, a system dynamics approach can provide a rich dynamic perspective to visually explain the causes of construction safety risk changes. In general, this paper complements the body of construction safety management considering the ERLs in terms of theoretical foundations and implementation and offers references and lessons for the design and operation of construction safety management in the railway construction industry in the future.

The limitation of this study is the simplification of the interactions involved in construction safety. In fact, the mutual impacts are very complex, far more than those proposed in the hypothesis of this study. In fact, the vast majority of construction safety accidents are caused by people's unsafe behaviors. Furthermore, workers' hazard perception does play an essential role in the construction safety management considering ERLs. In the future, "how does the worker's hazard perception impact construction safety considering ERLs dynamically" should be studied further.

In multiattribute large-group decision-making (MALGDM), the ideal state indicates a high degree of consensus for decision-makers. However, it is difficult to reach a consensus because the conflict between various decision attributes and decision-makers increases. To deal with the problem, a novel consensus model was developed to manage the decision-making in large groups based on noncooperative behavior. The improved clustering method was used to take account of the similarities among different decision-makers, while similar decision-makers will be grouped into the same group. Moreover, the consensus threshold was determined from an objective and subjective aspect to judge whether the consensus reaching process continues. The noncooperative behavior and adjustment amount of decision-makers' opinions were investigated based on the proposed consensus model, and an emergency decision-making problem in flood disaster is applied to manifest the feasibility and distinctive features of the proposed method. The results show the proposed novel consensus model demonstrated strong applicability and reliability to the noncooperative subgroup problem and can be explored to manage multiattribute interactions in LGDM.

1. Introduction

Decision-making, which aims at identifying an ideal alternative based on the information described by decision-makers, is widely used in all aspects of modern life [1–3]. With the increase in the complexity of decision-making problems, many attributes relevant to decision-making problems have been explored [4]. Decision-makers need to consider all relevant aspects of the problem [5]. The decision-making behavior of decision-makers depends on many factors, including their personal and professional goals, interests, and the experience they pursue to develop themselves professionally [6]. Decision-makers need to know about Business, Management and Accounting, Engineering, Social Sciences, and Computer Science to inform the decision-making process [7]. Group decision-making (GDM) has attracted increasing attention due to its characteristic superiority of gathering knowledge of decision-makers from various fields [8–10]. Problems always involve many interconnected fields, and the decision-making results are related to the benefits of stakeholders. Thus, it becomes

uneasy for small-group decision-making to reach the demands of social development [11, 12]. As the number of people in the decision-making group increases, the problem of multiattribute large group decision-making appears [13].

Clustering processing, the essential part of large group decision-making, is a fundamental but indispensable process in multiattribute large-group decision-making (MALGDM) [14]. The clustering process in MALGDM can improve the efficiency of the decision process [15]. The C-means algorithm [16] and the k-means algorithm [17] are the most available clustering methods in applications. Xue used the Choquet integral (CI) operator to measure each attribute and then aggregated it [18]. Based on Shannon entropy, Li measured the uncertainty of discrete Z-numbers by a new technique [19]. The main features of these algorithms are the early decided clustering numbers and the effect of threshold selection on classification results. Having defined the shape similarity measure, Tapia-Rosero et al. developed a clustering method, in which similar-shaped membership functions are grouped by agglomerative hierarchical clustering technique [20]. However, this method did not

consider the similarity of decision-makers in the same cluster, and there exist errors for the shape similarity measure [21]. Besides, a clustering method based on vector space was proposed by Xu et al. This method considered the similarity of decision-makers' decisions [22, 23]. However, these methods classified the cluster by calculating the similarities between the decision-makers and the cluster. But those methods did not consider the similarities between two decision-makers in the same clusters. The similarities between decision-makers will decrease as the clustering processes develop.

The consensus level is selected to describe decision-makers' differences in opinion and preference. It can also measure the degree of agreement among different clusters in MALGDM [24]. There are many approaches to compute the consensus level [25–27]. In MALGDM, before making a group decision, a consensus reaching process is usually applied to reach the collective agreement [28, 29]. To reach a consensus, some decision-makers must modify their opinions in the dynamic and iterative group discussions [30]. For reaching a consensus process in MALGDM, many scholars do a lot of studies. Pérez et al. introduced a feedback mechanism and built a consensus model based on decision-makers' relevance or importance level [31]. For MALGDM problems, Xu et al. promoted the consensus reaching process in two stages. The novel method could appropriately adjust the preference of decision-makers and the weight of subgroups [32]. Jin et al. adopted a local adjustment strategy to retain preference evaluation of decision-makers as far as possible in group decision-making [33]. To reach consensus, Xu et al. proposed a dynamic consensus method based on an exit authorization mechanism. They thought the subgroup would be suggested to exit the decision-making process once the proximity index could not meet the requirement, and then the delegation mechanism is employed to reserve the cluster's influence by giving trust weights to other clusters [24]. Noncooperative behavior is common in the practical process of decision-making. However, these studies are lacking at considering the influence of noncooperative behavior. To reach a consensus, a suitable method should be adopted to manage the noncooperative behavior. Based on a self-management mechanism of noncooperative behaviors, Dong et al. introduced three kinds of noncooperative behaviors and developed a new consensus framework [34]. They also proposed a novel framework based on a self-management mechanism for noncooperative behaviors in large-scale consensus reaching processes [35]. Palomares provided a consensus model suitable to handle and detect the noncooperative behavior, and the consensus could be reached by decreasing the weight of noncooperative cluster [36]. Wu and Xu proposed a consensus model, in which the clusters can be changed. The clusters can modify if the individuals are able to change their preferences via the consensus reaching process [37]. Quesada et al. introduced a methodology to process noncooperative behaviors, in which a uniform-based weighting scheme was adopted to compute the weight of decision-makers in LGDM [38]. Nazari et al. used dynamic noncooperative games to model these conflicts when stakeholders appear noncooperative behavior

[39]. With the purpose of managing minority opinion and noncooperative behavior in MALGDM, Xu and put forward the concept of comprehensive adjustment coefficient and designed an improved consensus model [40].

To sum up, problems have evolved into many interrelated areas, and the decision-making of large groups needed to meet the requirements of social development. But regarding LGDM, it is not easy to reach the consensus level in decision processes. The goal of large group decision-making is to find a method that can reach consensus effectively in large groups, improve the consensus level in short time, and obtain the accurate decision-making result. In the previous literature, the subgroup obtained in these studies remains unchanged in the consensus reaching process. This is often untrue because decision-makers modify their available opinion. The subgroup opinion must be changed when decision-makers modify their opinion. This will lead to unacceptable results of large group decision making. Meanwhile, the decision-makers in the noncooperative subgroup who are willing to modify their decision opinion should not be penalized. Unlike previous literature, this paper protected individual decision opinion. And previous methods did not consider the similarity of decision-makers in the same cluster. This will reduce the consistency of the group. Mandal et al. acknowledged noncooperative behaviors and divided them with the experts' similar evaluations into a subgroup. But decision-makers were still unable to change subgroup [41]. Therefore, it is necessary to seek a large group decision-making method that can protect the opinions of decision-makers and improve the degree of consensus. The main contribution of the paper is a precise consensus reaching model that we proposed to manage noncooperative behaviors in MALGDM. And an improved clustering method is developed. This method considers the similarities among decision-makers.

The remaining part of the paper is structured as follows: firstly, decision-makers are clustered, and the group consensus level is obtained in Section 2. In Section 3, the noncooperative behavior is detected and managed. A typical example, applied to indicate the utility and applicability of this model, is shown in Section 4. Then, Section 5 discusses the advantages and innovations of the proposed methods in detail. Finally, conclusion and future researches are provided in Section 6.

2. Preliminaries

2.1. Problem Formulation.
MALGDM problems can be defined as a situation where a large number of decision-makers must make a high-quality decision result by choosing the n alternatives. The main parameters of MALGDM are as follows:

(1) A discrete finite set of alternatives $x = \{x_1, x_2, \cdots x_n\}$, where x_i represents alternative solution.

(2) A set of decision-makers can be denoted as $E = \{e_1, e_2 \ldots e_M\} (M \geq 2)$. The weight vector of decision-makers is $\omega = \{\omega_1, \omega_2, \cdots \omega_M\}$, where $\omega_j (j = 1, 2 \ldots M) \in (0, 1)$ and $\sum_{j=1}^{M} \omega_j = 1$. After collecting a

lot of previous literature, we can determine the range of the number of large groups of decision makers. Usually, when the number of experts in a group reaches 20, that is, $M \geq 20$, the group is considered as a large group. And the decision-making process in which they participate can be defined as large group decision-making [42, 43].

(3) A finite set of attributes $F = \{f_1, f_2 \ldots f_P\} (P \geq 2)$, the weight vector of attribute $\eta = \{\eta_1, \eta_2, \cdots \eta_P\}$, where $\eta_k \geq 0 \, (k = 1, 2, \ldots P)$, and $\sum_{k=1}^{P} \eta_k = 1$.

Each decision-maker will give a numerical decision matrix to express the opinion for the alternatives $A^j = (a_{ik}^j)_{n \times P}, j \in M$, where a_{ik}^j represents decision-maker e_j's preference of alternative x_i concerning attribute f_k. The premise of this paper is that there is disagreement among decision-makers in the group. So, it is not possible for all decision-makers to behave the same preference for x_i. This represents that $\max_i \{a_{ik}^j\} \neq \min_i \{a_{ik}^j\}$. Different attributes in MALGDM problems are often measured in different units, so the preference value should decision matrix $V^j = (v_{ik}^j)_{n \times P}$ as follows:

$$v_{ik}^j = \frac{a_{ik}^j - \min_i \{a_{ik}^j\}}{\max_i \{a_{ik}^j\} - \min_i \{a_{ik}^j\}}. \tag{1}$$

2.2. Clustering Method for Large-Group Members.
To simplify the decision-making processes, decision-makers are clustered by individual decision matrix A^j to transform into small-group decision making in LGDM. decision-makers are clustered into l clusters $(1 < Y < n)$ by the improved mean of preference clustering method, which is described in Algorithm 1.

2.3. Determination of Consensus Level.
Decision-makers' respective weights in the decision processes can be determined by the following definitions:

Definition 1. Experts in larger subgroups should be given larger weights based on the majority principle [37]. In line with the number and weight values of experts in the subgroup, the subgroup weight value can be defined as

$$\lambda_l = \frac{\left(\sum_{j=1}^{M} \omega_j \times \theta_{jl}\right)^2}{\sum_{l=1}^{Y} \left(\sum_{j=1}^{M} \omega_j \times \theta_{jl}\right)^2}, \tag{2}$$

where $\theta_{jl} = 1$ represents expert e_j belonging to the subgroup C^l; $\theta_{jl} = 0$ represents expert e_j not belonging to the subgroup C^l, where $l = 1, 2, \ldots, L$, and it is easy to know that $0 \leq \lambda_l \leq 1$ and $\sum_{l=1}^{Y} \lambda_l = 1$.

Definition 2. An individual decision matrix can be obtained by decision-makers' opinions, the subgroup decision matrix is computed by aggregating the individual matrices, considering the weights associated with each decision-maker, and the subgroup decision matrix can be calculated [44].

$$r_{ik}^l = \sum_{j=1}^{M} \omega_j \times v_{ik}^j \times \theta_{jl}. \tag{3}$$

By aggregating single subgroup decision matrixes, the normalized group decision matrix $R^c = (r_{ik}^c)_{n \times P}$ is obtained, where r_{ik}^c is represented as

$$r_{ik}^c = \sum_{l=1}^{Y} \lambda_l \times r_{ik}^l. \tag{4}$$

Definition 3. According to the gap subgroup decision matrix $R^l (l = 1, 2, \cdots, Y)$ and the group decision matrix R^c, the consensus level $CI(R^l)$ between the subgroups' decision matrices $R^l (l = 1, 2, \ldots, Y)$ and the group decision matrix R^c is defined as

$$CI(R^l) = 1 - d(R^l, R^c), \tag{5}$$

where $d(R^l, R^c)$ is the Manhattan distance between R^l and R^c; that is, $d(R^l, R^c)$ represents the similarity between subgroup C^l and C^C, which can be defined as

$$d(R^l, R^c) = \frac{1}{n} \times \sum_{i=1}^{n} \sum_{k=1}^{P} \eta_k \times \left| r_{ik}^l - r_{ik}^c \right|. \tag{6}$$

By calculating the average value of consensus level $CI(R^l)$, the group consensus level LGCI can be obtained:

$$\text{LGCI} = \lambda_l \times \sum_{l=1}^{Y} CI(R^l). \tag{7}$$

If $LGCI = 1$, it indicates that all decision-makers have reached consensus among the large groups. A $\overline{LGCI}$ indicates a higher level of consensus among all decision-makers. $\overline{LGCI}$, as the group consensus threshold, is set to determine whether the consensus reaching process should be carried out. If $LGCI \leq \overline{LGCI}$, the consensus process should be used to change decision-makers' opinions to reach a higher consensus level.

2.4. Determination of Consensus Threshold.
The consensus threshold $\overline{LGCI}$ should be determined to judge whether the consensus reaching process continues or not. The decision-making pressure of large groups often leads to the uncertainty and subjectivity of the opinion adjustment coefficient. In order to improve the accuracy of group decision making, both objective and subjective factors should be considered. And a coefficient should be set to adjust the subjective factors and objective factors.

2.4.1. Subjective Threshold.
For the particular problem, the decision-makers provide the consensus threshold $\overline{LGCI}$ according to the quality of the problem [45]. The consensus threshold $\overline{LGCI}$ reflects its attitude towards the group consensus level and opinion. If the consequence of the decision is important, the consensus threshold should be as high as possible. In this article, let the subjective consensus

---

Input: the individual matrix A^j and the threshold ζ, which is determined according to practical decision situation.

Output: the number of subgroup l and the subgroups $C_1, C_2, \ldots C_Y$.

Step 1. Construct the decision set U comprising all individual decision matrix, that is, $U = \{V^1, V^2, \ldots V^M\}$.

Step 2. Initialize $Y = 1$ as the number of subgroups, and select decision-maker e_1 as the member of this subgroup, this subgroup is defined as C^l, and S stands for a temporary set.

Step 3. Select decision-maker e_q sequentially from the set E and allocate them to the subgroup C^l. Then remove the decision matrix from the set U and let the number of members in subgroup C^l be z_l.

Step 4. Compute the gather degree between decision-maker e_q and each subgroup C^l, which can be denoted as :

$$\mu_{jl} = 1 - \max_{q=1}^{z_l} 1/n \sum_{i=1}^n \sum_{k=1}^P \eta_k \times |v_{ik}^j - r_{ik}^q| \, (j \neq q, e_q \in C^l, l \in Y)$$

where, z_l is the number of decision-maker in the subgroup C^l, μ_{jl} represents the gather degree of decision-makers e_j in the subgroup C^l, if the $\mu_{jl} \geq \zeta$, decision-maker e_j is allocated to the subgroup C^l, and remove it out from the set U, let $z_l = z_l + 1$. Otherwise, decision-maker e_j is allocated to the temporary set S.

Step 5. If S is not null, let $C^{L+1} = S$, $T = $ null and $Y = Y + 1$ respectively, and get back to Step 3; otherwise, go to Step 6.

Step 6. Record the results of clustering. The number of subgroups is recorded as Y, and the number of members is recorded as z_l in the subgroup C^l.

ALGORITHM 1:

---

threshold determined by the decision-makers' experience be $\overline{LGCI}_{sub}$. The subjective consensus threshold is the decision-maker's expected consensus level.

2.4.2. Objective Threshold. The objective consensus threshold $\overline{LGCI}_{ob}$ is determined to improve the feasibility of the consensus reaching process. The objective consensus threshold $\overline{LGCI}_{ob}$ represents that the large group can reach consensus level by the original decision matrices of decision-makers, which is defined as

$$\overline{LGCI}_{ob} = LGCI. \tag{8}$$

Definition 4. The consensus threshold should satisfy two conditions: one is that the consensus threshold meets the requirement of practical decision problem, which is described as subjective consensus threshold; the other is that the consensus threshold can be reached in the opinion adjustment scale, in which the decision-maker is willing to modify, which is defined as the objective consensus threshold. Thus, it is feasible to determine the consensus threshold by the objective consensus threshold and the subjective consensus threshold:

$$\overline{LGCI} = \alpha \overline{LGCI}_{ob} + (1-\alpha)\overline{LGCI}_{sub}, \tag{9}$$

where α is the consensus threshold adjustment coefficient and defined by the number and weight of decision-makers in the subgroup whose consensus level is less than the group consensus level calculated by the initial group decision matrix.

Definition 5. Let the subgroup set where consensus level is more than the group consensus level be G, which is described as

$$G = \{C^l \mid CI(R^l) > LGCI\}. \tag{10}$$

The adjustment coefficient α can be calculated as

$$\alpha = \frac{\sum_{\lambda=1}^Y \lambda_l \times \vartheta_{lg}}{\sum_{l=1}^Y \lambda_l}. \tag{11}$$

where ϑ_{lg} represents the subgroup l belonging to G.

3. Process of Noncooperative Behaviors

In this section, a consensus reaching model suitable for addressing noncooperative behavior in MAGDM problems is proposed. The innovative point of this model features in the abilities to detect and handle individual and subgroup noncooperative behaviors in the consensus reaching process, with the aim of improving the overall consensus reaching process performance.

3.1. Noncooperative Behavior Detection. In the consensus reaching model presented in this study, we define an approach to identify those noncooperative subgroups that exist as decision-makers who are reluctant to change their original preferences to reach a consensus, which is aiming at assisting the subsequent treatment of such decision-makers, so as to improve the performance of the consensus reaching process. The detection approach is first used in the second round of the consensus reaching process, because of its requirement of comparisons among subgroups obtained in the previous and current rounds of discussion. There exist three rules to detect the noncooperative subgroup according to the definition of noncooperative behavior. Let the noncooperative subgroup be C^{l*}. The detection method includes two steps:

Step 1. Determine the detection object

Before the noncooperative subgroup is detected, the detection object should be determined. The noncooperative subgroup includes two common characteristics according to the definition:

(i) The consensus level of the subgroup opinion is smallest, which can be denoted as

$$C^{l^*} = \min_{Y}^{l=1} \left\{ CI\left(R^{l(t-1)}\right) \mid l = 1, 2, \ldots, Y \right\}. \tag{12}$$

(ii) The number of decision-makers in these subgroups is small, in a general way, which is less than [M/n], described by the following formula:

$$\sum_{j=1}^{M} \theta_{jl^*}^{t-1} \leq \frac{M}{Y}. \tag{13}$$

For example, a large group consists of 15 decision makers, and there are three decision options. The number of people supported by the three decision schemes is 7, 5, and 3, respectively. Their CI value size relation is $CI_1 > CI_2 > CI_3$. According to characteristic (i), we can know that the third subgroup may be a noncooperative group. We can know that [M/n] is 5, the third group's number is 3, and 3 is smaller than 5. So, according to characteristic (ii), the third subgroup can be determined by the detection object.

Step 2. Detect the noncooperative subgroup

After the detection object is determined, the subgroup C^{l^*} will adjust their decision opinions by discussion in the $t-1$-th round, and the adjustment decision matrix of decision-maker $A^{j(t)}$ in the subgroup C^{l^*} is obtained, and the temporary subgroup decision matrices $R^{'l(t)}$, in which the form of subgroup is not changed, are calculated. For the noncooperative subgroup, there exists at least one decision-maker in the subgroup reluctant to adjust their own opinions, which is checked to determine whether decision-maker in the subgroup C^{l^*} is willing to adjust their opinions or not. To do this, the temporary subgroup consensus level $CI'\left(R^{l(t)}\right)$ and the temporary consensus level $LGCI'^{(t)}$ can be calculated by the temporary subgroup decision matrices $a^{'l(t)}$. Thus, there are three situations to define the noncooperative subgroup:

(i) Decision-makers in C^{l^*} are willing to adjust their opinions, but the decision opinion adjustment of decision-maker causes negative influence to the consensus level of C^{l^*}:

$$C^{l^*} = \left\{ C^l \mid CI'\left(R^{l(t)}\right) \right. \\ \left. < CI\left(R^{l(t-1)}\right); \ l = 1, 2, \ldots, Y \right\}. \tag{14}$$

(ii) Decision-makers in C^{l^*} do not change their opinions, that is, the consensus level of C^{l^*} in t-th round keeping correspondence with t-1-th round:

$$C^{l^*} = \left\{ C^l \mid CI'\left(R^{l(t)}\right) \right. \\ \left. = CI\left(R^{l(t-1)}\right); \ l = 1, 2, \ldots, Y \right\}. \tag{15}$$

(iii) The decision opinion adjustment of decision-maker causes positive influence to the consensus level of C^{l^*}, but there are only a small part of decision-

makers transforming their opinions, and there exist decision-makers who are not willing to modify their opinions. The noncooperative subgroup detection rule can be expressed as

$$C^{l^*} = \left\{ C^l \mid CI'\left(R^{l(t)}\right) > CI\left(R^{l(t-1)}\right); \sum_{j=1}^{n_l} \sigma_{jl} \neq z_{l,} l = 1, 2, \ldots, Y \right\}. \tag{16}$$

In the example in step (1), there are three decision-makers in the detection subgroup. If the subgroup has noncooperative behavior, then at least one person did not change his preference, or the decision opinion adjustment of decision-maker causes negative influence to the consensus level of C^{l^*}. If all decision-makers adjust their opinions, but $CI'\left(R^{l(t)}\right) < CI\left(R^{l(t-1)}\right)$, this is the first situation of noncooperative subgroup. If all decision-makers do not adjust their opinions, this is second situation. If at least one decision-maker did not adjust his opinion, despite the adjustments made by the rest of the decision-makers, and those adjustments have had a positive impact to the consensus level, subgroups are also considered as noncooperative subgroup. This is the third situation.

where σ_{jl} represents decision-maker e_j willing to change their opinions, and σ_{jl} is detected by change degree. The change degree is introduced to measure the decision-maker who modify his opinion [32]; it can be described as

$$\varphi_{jl}^t = \frac{1}{n} \sum_{i=1}^{n} \sum_{k=1}^{P} \eta_k \times \left| v_{ik}^{j(t)} - r_{ik}^{l(t-1)} \right| \times \theta_{jl}^t. \tag{17}$$

σ_{jl} can be computed by comparing the change degree between t-1-th round and t-th round, which is defined as

$$\sigma_{jl} = \begin{cases} 1, & \text{if } \varphi_{jl}^t - \varphi_{jl}^{t-1} \neq 0, \\ 0, & \text{if } \varphi_{jl}^t - \varphi_{jl}^{t-1} = 0. \end{cases} \tag{18}$$

3.2. Management Strategy of the Noncooperative Behavior. Through Step 3.1, we identified three different types of noncooperative behavior. But the core of this paper is to develop different strategies for different noncooperative behaviors. Thus, unlike the traditional adjustment method for noncooperative behaviors, a new strategy was devised in this study. The management strategy is determined by analyzing the noncooperative degree of noncooperative subgroup. And the noncooperative subgroup is allowed to change. The consensus level needs to be recalculated after the subgroup changed. The concrete process of management strategy is described as follows:

> Step 1: measure the noncooperative degree
>
> For the noncooperative subgroup, the degree of noncooperation is used to describe the decision-maker's willingness to change the decision to improve group consensus level. Thus, the degree of noncooperation is influenced by two factors: one is the number of decision-makers who have changed their views, and the other is whether the changed opinion can increase the level of consensus.

The number of policymakers who changed their minds first needs to be counted. In general, the LGCI can reflect whether the noncooperative subgroup modify their initial opinions or not, and the number of decision-makers who are willing to modify their opinions describe the adjustment degree of noncooperative subgroup, which is expressed as

$$\gamma_{l^*}^t = \sum_{j=1}^{M} \sigma_{jl^*} \times \theta_{jl^*}. \tag{19}$$

And then, Thus, the change of LGCI value can indicate whether a change in decision-makers' opinion has increased the level of group consensus. Thus, the noncooperative degree is measured by the value of *LGCI* and the number of decision-makers who are willing to modify their opinions, which is obtained as follows:

$$\phi_{l^*}^{(t)} = \frac{\left(\text{LGCI}^{'t} - \text{LGDI}^{t-1} \right) \gamma_{l^*}^t}{\left| \text{LGCI}^{'t} - \text{LGDI}^{t-1} \right| z_{l^*}}. \tag{20}$$

$\phi_{l^*}^{(t)}$ can represent the degree of noncooperation, and the number of experts in the MALGDM is odd, so $\phi_{l^*}^{(t)}$ is not equal to 0.5; there are three cases according to the calculation results.

(i) If $\phi_{l^*}^{(t)} \leq 0$, it means that the subgroup C^{l^*} manifests a very high degree of noncooperative behavior. A small number of decision-makers in noncooperative subgroup will change their opinions in the *t-1*-th round, and the changed result is negative for the consensus level.

(ii) If $0 < \phi_{l^*}^{(t)} < 0.5$, the subgroup C^{l^*} is considered as a partly noncooperative subgroup. A small part of the decision-maker in noncooperative subgroup modified their opinions in the *t-1*-th round, and the change result of subgroup is positive for consensus level.

(iii) If $0.5 < \phi_{l^*}^{(t)} \leq 1$, it indicates that the subgroup C^{l^*} is a cooperative subgroup, and more than half of decision-makers in the subgroup C^{l^*} change their opinions, and the change result of subgroup is positive for consensus level.

Step 2: process the noncooperative behavior

When the subgroup's noncooperative degree is got, the novel noncooperative behavior treatment method that considers the change of subgroup is developed. The following strategies are adopted for the three cases with different degrees of noncooperation.

(i) For the noncooperative subgroup, that is, $\phi_{l^*}^{(t)} \leq 0$, the decision-makers in subgroup C^{l^*} not only do not improve the group consensus, but also may cause the group consensus decrease. To speed up the decision-making processes and obtain proper results with a short period of time, the subgroup C^{l^*} will be suggested to withdraw from the decision process.

(ii) For the partly noncooperative subgroup, that is, $0 < \phi_{l^*}^{(t)} < 0.5$, a major part of decision-makers do not change their opinions in the subgroup C^{l^*}. It should be penalized by adjusting the weight of subgroup. But there are minor decision-makers willing to modify their decision opinion, and their opinions should be protected. Therefore, we need to determine whether the decision-maker who changes perspective belongs to the subgroup C^{l^*}. And then the form of subgroup C^{l^*} may be changed. Thus, the treatment method is determined by judging whether the decision-makers belong to the subgroup C^{l^*}.

Let the set of decision-makers who are unwilling to modify his opinion be $C^{'l^*}$ in the subgroup C^{l^*}, and the number is z_{l^*}', the set of decision-makers who are willing to modify his opinion is B^{l^*}. That is, $B^{l^*} = \left\{ e_{j^*} | e_{j^*} \in C^{l^*}, e_{j^*} \notin C^{'l^*} \right\}$. Based on the (17), we proposed a method to judge whether the decision-maker belongs to the subgroup C^{l^*}, which is denoted as

$$\varphi_{j^*l^*}^{'t} = \max_{\substack{q^*=1 \\ z_{l^*}'}} \frac{1}{n} \sum_{i=1}^{n} \sum_{k=1}^{P} \eta_k \times \sigma_{j^*l^*}^t \times \left| v_{ik}^{j^*t} - r_{ik}^{q^*t} \right| \tag{21}$$

$$\cdot \left(j^* \neq q^*, e_{q^*} \in C^{'l^*}, l^* \in Y \right).$$

where $\varphi_{j^*l^*}^{'t}$ represents the conflict degree between e_{j^*} and subgroup C^{l^*} in the *t*-th round.

If $\varphi_{j^*l^*}^{'t} \leq 1 - \varsigma$, it represents that the decision-maker e_{j^*} belongs to the subgroup C^{l^*} after his opinion is changed.

If $\varphi_{j^*l^*}^{'t} > 1 - \varsigma$, it represents that the decision-maker e_{j^*} does not belong to the subgroup C^{l^*} after his opinion is changed, and the decision-maker e_{j^*} can be clustered based on the procedure in Algorithm 1.

Although there are a little of decision-makers to modify their opinions in partly noncooperative subgroup, the subgroup C^{l^*} still expresses the lower cooperative level. Thus, in order to reduce its impact on the group consensus level, the weight of subgroup C^{l^*} also needs appropriate adjustment. The modified function is a decreasing function. To describe the interaction between the weight adjustment and the number of decision-makers, the weight adjustment function is developed based on the number of decision-makers who is willing to modify its own opinion, which is defined as

$$\lambda' l^*_{\ t} = \frac{z_{l^*}^t - z' l^*_{\ t}}{z' l^*_{\ t}} \lambda_{l^*}^t. \tag{22}$$

where $\lambda_{l^*}^{'t}$ is the weight of subgroup C^{l^*} after adjustment in the *t*-th round, and $\lambda_{l^*}^t$ is the weight of subgroup C^{l^*} in the *t*-th round. Generally speaking, subgroup weights reflect their contributions to the group consensus level. When the opinions of decision-makers in the subgroup C^{l^*} are modified, the subgroup' contributions are adjusted too. The greater the contribution of subgroup to consensus level, the more important it is. Individuals who have changed opinion

with negative effect to the group consensus level should reduce some weight [46]. Based on this rule, the contributions of the subgroup are introduced to measure the subgroup weight in the t-th round, which can be defined as

$$D_{l^*}^t = \text{LGCI}^t - \text{LGCI}_{\overline{l^*}}^t. \quad (23)$$

where $D_{l^*}^t$ represents the contributions of subgroup C^{l^*} for the group consensus level. $LGCI_{\overline{l^*}}^t$ denotes the group consensus level without the subgroup C^{l^*} in the t-th round, which is defined as

$$\text{LGCI}_{\overline{l^*}}^t = \sum_{l=1, l\neq l^*}^L \lambda_l^{t-1} \sum_{i=1}^n \frac{1}{n} \sum_{k=1}^P \eta_k \times \left| r_{ik}^{l(t)} - r_{ik}^{c(t)} \right|. \quad (24)$$

To protect the interest of decision-makers who are willing to modify its own opinion, we need to update the weights of the subgroup and recalculate the group-decision consensus level. The following equations show how to update the weights:

$$\lambda_{l^*}^t = \lambda_{l^*}^{t-1} \times \left(1 + D_{l^*}^t\right)^\xi. \quad (25)$$

ξ expresses the impact of the subgroups' contributions on their weights, which are usually given by the decision-makers in advance. If the decision problem is in urgency and has to be dealt with in time, it should be assigned less restrictive values. Otherwise, more restrictive values must be put into use.

(iii) For the cooperative subgroup, that is, $0.5 < \phi_{l^*}^{(t)} < 1$, more than half of decision-makers in this subgroup are willing to modify their initial opinions. This subgroup expresses a very high degree of cooperative behavior. Thus, the motivation mechanism should be adopted to protect the decision opinion of this subgroup. Similar to partly noncooperative subgroup, if the decision-maker e_{j^*} does not belong to the subgroup C^{l^*} after his opinion is changed, Algorithm 1 can be used to cluster the decision-maker e_{j^*} into a suitable subgroup. If the decision-maker e_{j^*} belongs to the subgroup C^{l^*} after his opinion is changed, the motivation mechanism is similar to the treatment process of partly noncooperative subgroup. When the number of decision-makers who modify their own opinions is more than the half of subgroup, the adjustment coefficient of the subgroup in equation (26) is not less than 1. Thus, the weight of subgroup will be enhanced.

3.3. Algorithm of Large Group Consensus.
Adopting consensus reaching model that the basic thought is to adjust decision information matrix, to enable the decision-makers to have a higher consensus level, the noncooperative subgroup is detected and addressed to obtain a higher consensus level. Algorithm 2 of the consensus reaching model is summarized as follows.

Let $t^* = t$. Output the final subgroups' decision matrices $R^{k(t^*)}(k = 1, 2, \ldots, n)$ and the final group decision matrix $R^{c(t^*)}$.

The process of consensus reaching model can be simply described in Figure 1.

4. Case Study

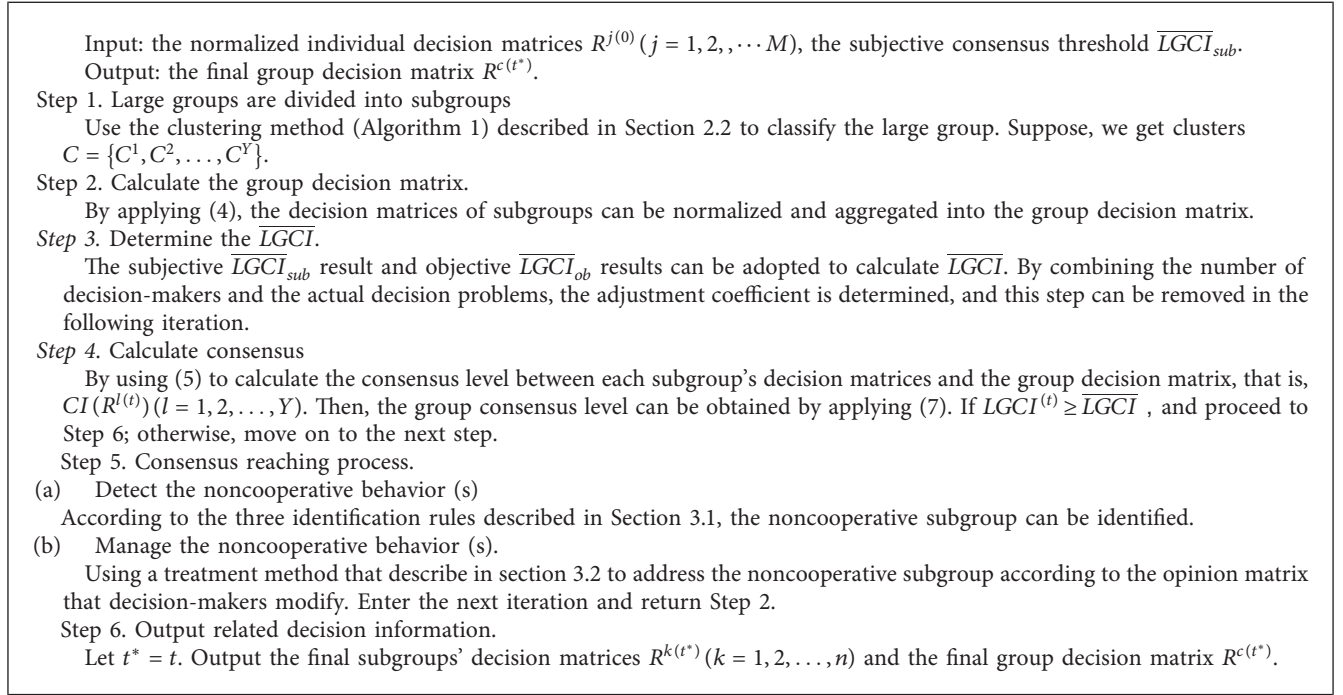
In this section, an example of emergency decision-making problem in flood disaster is applied to indicate the feasibility of the presented method.

4.1. Case Background.
There is a flood disaster hit Hu Nan Province, a south city in China, on July 3, 2018. After the flood disaster, the government carried out an emergency scheme based on instructions. As shown in Table 1, four preliminary plans were rapidly drawn up:

Twenty experts $E = (e_1, e_2, ..., e_{20})$ from different fields were asked to make decisions based on these four alternatives $X = (x_1, x_2, x_3, x_4)$. We consider three criteria for each alternative: (1) personnel security rate (f_1), the scale of evaluation value of personnel security rate is 0 to 1; (2) personnel injured rate (f_2), the scale of the evaluation value of the effectiveness of equipment is the same to personnel security rate; (3) the development of situation of flood disaster (f_3).

4.2. The Process of Group Decision-Making.
We set that the scale of evaluation value of development situation of flood disaster is 1 to 100. Each decision-maker opinion should be seriously taken into account. Suppose that there is no conflict of interest among the decision-makers. In order to obtain the best alternative(s), the following steps need to be performed.

Step 1. Cluster the initial normalized individual decision matrices.

To save space, the normalized individual decision matrices are omitted. Base on the clustering method, which is described in Algorithm 1, the clustering threshold is set as $\zeta = 0.8$, and the group can be divided into several smaller clusters. Table 2 shows the results, indicating that the original decision group can be divided into five clusters.


Step 2. Calculate the group decision matrix.

Aggregate the decision-makers' decision matrices into the subgroups' decision matrices by the (5). The weight of subgroup is calculated by the (2), and the group decision matrix is calculated by the individual decision matrices and the weight of cluster, which is adopted as

$$R^{c(0)} = \begin{bmatrix} 0.5099 & 0.8063 & 0.5721 \\ 0.6400 & 0.4345 & 0.3138 \\ 0.2837 & 0.7329 & 0.2879 \\ 0.4810 & 0.1408 & 0.7346 \end{bmatrix}. \quad (26)$$

Step 3. Consensus measure and calculate the consensus threshold.

Compute the subgroup consensus levels by the (5), that is, $CI(R^{1(0)}) = 0.7949$, $CI(R^{2(0)}) = 0.7388$, $CI(R^{3(0)}) = 0.6488$, $CI(R^{4(0)}) = 0.7263$ and $CI(R^{5(0)}) = 0.6141$. The initial group consensus level can be

Input: the normalized individual decision matrices $R^{j(0)}$ ($j = 1, 2, , \cdots M$), the subjective consensus threshold $\overline{LGCI}_{sub}$.

Output: the final group decision matrix $R^{c(t^*)}$.

Step 1. Large groups are divided into subgroups

Use the clustering method (Algorithm 1) described in Section 2.2 to classify the large group. Suppose, we get clusters $C = \{C^1, C^2, \ldots, C^Y\}$.

Step 2. Calculate the group decision matrix.

By applying (4), the decision matrices of subgroups can be normalized and aggregated into the group decision matrix.

Step 3. Determine the $\overline{LGCI}$.

The subjective $\overline{LGCI}_{sub}$ result and objective $\overline{LGCI}_{ob}$ results can be adopted to calculate $\overline{LGCI}$. By combining the number of decision-makers and the actual decision problems, the adjustment coefficient is determined, and this step can be removed in the following iteration.

Step 4. Calculate consensus

By using (5) to calculate the consensus level between each subgroup's decision matrices and the group decision matrix, that is, $CI(R^{l(t)})$ ($l = 1, 2, \ldots, Y$). Then, the group consensus level can be obtained by applying (7). If $LGCI^{(t)} \geq \overline{LGCI}$, and proceed to Step 6; otherwise, move on to the next step.

Step 5. Consensus reaching process.

(a)   Detect the noncooperative behavior (s)

According to the three identification rules described in Section 3.1, the noncooperative subgroup can be identified.

(b)   Manage the noncooperative behavior (s).

Using a treatment method that describe in section 3.2 to address the noncooperative subgroup according to the opinion matrix that decision-makers modify. Enter the next iteration and return Step 2.

Step 6. Output related decision information.

Let $t^* = t$. Output the final subgroups' decision matrices $R^{k(t^*)}$ ($k = 1, 2, \ldots, n$) and the final group decision matrix $R^{c(t^*)}$.

ALGORITHM 2:

FIGURE 1: The process of consensus reaching model.

TABLE 1: Different selection strategies.

x_i	Concrete measure
x_1	Find out trapped people and evacuate the seriously injured from the disaster areas to avoid further damage caused from flood disaster
x_2	Treat the injured and stop searching for trapped people until the rescue equipment arrived
x_3	Search for trapped people and treat the seriously injured in situ
x_4	Search for trapped people and cease treating the injured until the medical team arrived

TABLE 2: The information of subgroup.

C^k	n_k	e_i	$\lambda_k^{(0)}$
C^1	7	$e_1, e_6, e_7, e_{11}, e_{13}, e_{17}, e_{19}$	0.3500
C^2	5	$e_2, e_3, e_8, e_9, e_{18}$	0.2500
C^3	3	e_4, e_{10}, e_{20}	0.1500
C^4	4	$e_5, e_{12}, e_{15}, e_{16}$	0.2000
C^5	1	e_{14}	0.0500

calculated as $LGCI(R^{c(0)}) = 0.7416$. The consensus threshold can be calculated from the subjective and objective aspect, the subjective threshold is set as 0.8, and the objective threshold is 0.7416. The adjustment coefficient is obtained by the (11), which is expressed as 0.2234. Finally, the consensus threshold is computed as 0.7869. Because of $LGCI(R^{c(0)}) = 0.7416 < 0.7869$, the consensus process should be applied to change some opinions.

Step 4. Consensus reaching process.

(i) First consensus reaching iteration

The detection object of the noncooperative cluster is determined by (12) and (13), and the calculation result shows that the subgroup C^5 is the detection object. The decision-makers in the subgroup C^5 modify their initial decision opinions to reach the consensus, the decision-makers who needed to reconsider their preferences were determined, and the modification criterion of the decision-maker is the group decision matrix. The decision matrix of decision-maker $A^{j(1)}$ can be obtained after modification. The temporary subgroup decision matrix $R'^{5(1)}$ can be computed by the decision matrix of decision-maker $A^{j(1)}$. The consensus level of clusters is calculated by the temporary subgroup decision matrix $R'^{5(1)}$, which is expressed as $CI'(R^{5(1)})$. Comparing the temporary subgroup consensus level $CI'(R^{5(1)})$ with consensus level $CI(R^{5(0)})$, the result shows that the $CI'(R^{5(1)})$ is less than $CI(R^{5(0)})$, and the subgroup C^5 is noncooperative subgroup, which denotes that the subgroup C^5 expressed the high noncooperative behavior.

Based on the noncooperative management method, $\phi_{l^*}^{(t)} \leq 0$, the subgroup C^5 is suggested to quit the consensus process. Thus, the number of subgroups is null, and the decision matrix is 0, and there are four subgroups by clustering the decision-maker after management. Because of the change of subgroup number, the weight of cluster should be recalculated by (2), which is described as $\lambda^{(1)} = (0.350.3500, 0.2500, 0.2000, 0.2000, 0)$. Continuing consensus measure, the new cluster consensus levels are $CI(R^{1(1)}) = 0.7914$, $CI(R^{2(1)}) = 0.7425$, $CI(R^{3(1)}) = 0.7259$ and $CI(R^{4(1)}) = 0.7238$. The group consensus level is $LGCI(R^{c(1)}) = 0.7526 < 0.7869$. Thus, the consensus reaching process continues.

(ii) Second consensus reaching iteration

As $CI(R^{4(1)}) = \min\{CI(R^{i(1)}) | i = 1, 2, 3, 4\}$, the cluster C^4 can be regarded as detection object in the 2-th round iterations, and the decision-makers in the cluster C^4 are required to modify their own opinion. The decision-maker's decision opinion in the 2-th rounds can be obtained after discussion, which is described as $A^{j(2)}$, aggregating the individual decision matrices, obtaining the temporary group decision matrix. The temporary consensus level is determined by the temporary subgroup decision matrix $R'^{4(2)}$ and temporary group decision matrix. Comparing the temporary subgroup consensus level $CI'(R^{4(2)})$ with consensus level $CI(R^{4(1)})$, the result shows that the $CI'(R^{4(2)})$ is more than $CI(R^{4(1)})$, but only part of decision-makers in subgroup C^4 are willing to modify their opinions; thus, the subgroup C^4 is noncooperative subgroup.

The conflict degree of subgroup C^4 is calculated to denote the decision-makers who modify their decision opinion. Based on the result of the calculation, there are four decision-makers in the subgroup C^4 who are willing to modify their decision opinions. The noncooperative degree of subgroup is computed as $0.5 < \phi_{l^*}^{(t)} \leq 1$. According to (20), whether the decision-maker who modifies his opinion belongs to the initial subgroup can be judged. The result shows that the decision-maker e_5 does not belong to the subgroup C^4 after changing their initial decision opinion by the (21), and the decision-makers e_{15}, e_{16} belong to the initial subgroup C^4. The decision-maker e_5 is clustered by the Algorithm 1; the gathered degree between the decision-maker e_5 and the subgroup C^1 is $0.9135 > 0.8$; thus, the decision-maker e_5 belongs to the subgroup C^1. The weights of C^4 and C^1 are updated according to equation (2) and the number of decision-makers. The new subgroup weight can be denoted as $\lambda^{(2)} = (0.4517, 0.2438, 0.1976, 0.1069)$.

The new subgroup consensus levels are $CI(R^{1(2)}) = 0.8014$, $CI(R^{2(2)}) = 0.7956$, $CI(R^{1(2)}) = 0.7643$ and $CI(R^{1(2)}) = 0.7234$. The group consensus level is $LGCI(R^{c(2)}) = 0.7901 > 0.7869$. After two iterations, the decision-makers obtain consistency, and the final group consensus level meets the predefined requirement.

Due to the reaching of consensus threshold by group consensus level, the group decision matrix can be used to determine, which alternative is optimal, and the final calculation result of a group decision is expressed as

$$R^{c(2)} = \begin{bmatrix} 0.5119 & 0.8313 & 0.5596 \\ 0.6358 & 0.4491 & 0.2745 \\ 0.2753 & 0.6829 & 0.3379 \\ 0.4859 & 0.1408 & 0.7529 \end{bmatrix}. \quad (27)$$

According to the weight of the attribute, the decision vector is calculated as $(0.6343, 0.4531, 0.4321, 0.4599)$, and the value of alternative x_1 is 0.6343. Thus, the alternative x_1 is the most optimal.

5. Discussion

In this paper, we proposed a novel method to calculate the consensus threshold from the subjective and objective aspect. It is unlike the traditional determination method consensus threshold. Based on this consensus threshold and the traditional clustering method, the improved clustering method is developed. The improved method depends on the similarities between the decision-makers' decision opinions and subgroups' decision opinion. To better reflect the advantages of the clustering method, the case in Section 3 is adopted to compare the difference between the current clustering method and the traditional clustering method. We take the subgroup that includes the decision-maker e_1 as example, and the gathered degree of decision-makers for different clustering methods can be computed. And comparing the clustering thresholds, the effect of gather degree is shown in Figure 2.

From Figure 2, we can obtain that there are many decision-makers whose gathered degree is less than clustering threshold for the traditional clustering method (see Figure 2(a)); but it can be seen from Figure 2(b) that the gathered degree for any decision-makers is more than 0.8 after using the improved clustering method. The decision-makers using the improved method have higher gather degree than those using the traditional method. The result shows that the traditional clustering method considers the whole gather degree and omits the gather degree among decision-makers. Thus, the improved clustering method is more suitable to divide into the group.

Except for one group comparison, it can also compare the composition of different subgroups and the degree of subgroup clustering. The results of the comparison can be represented in Figure 3.

In Figure 3, groups are more concentrated. And compared to using traditional methods, each group has a higher degree of clustering after using the improved method in this article. The goal of MALGDM is to achieve a high degree of consistency. And the higher degree of clustering represents

that the large group has higher consensus level. Thus, the method used in this article is more effective than the traditional one in dealing with MALGDM problem.

Due to adherence to the principle that noncooperative behavior needs full consideration, the group consensus level increased from 0.7416 to 0.7901, which means that the management of the noncooperative behavior is helpful in reaching the consensus level. Generally, the noncooperative behavior can be addressed by two steps: the detection of the noncooperative behavior and the management of the noncooperative behavior. The current detection method uses the subjective adjustment result of subgroup to detect the noncooperative behavior. Unlike the current detection method, the practical adjustment result of subgroup is adopted to judge the noncooperative behaviors, that is, comparing the change degree of the subgroup decision matrix in the t-th rounds and $t-1$-th rounds.

For the management of the noncooperative behavior, the novel approach is explored to manage the noncooperative behavior. In general, the weight of the subgroup can be adjusted to manage the noncooperative behavior, and the decision matrix is transformed by the adjustment coefficient. In the practical decision problem, the adjustment opinion which the decision-maker is willing to accept should be respected. Thus, the noncooperative behavior is managed by adjusting the weight of subgroup, recalculating the subgroup decision matrix in this paper. In this study, the subgroups are allowed to modify. Generally, the number of subgroups is changed due to an enforced exit rule; nevertheless, the subgroups themselves remained the same. It is assumed that the decision makers can choose to modify their opinions under discussion, which makes it sensible that the subgroups they are classified into may also change. The example in Section 4 validated this point. Meanwhile, the weight of subgroup can be adjusted by the contribution of the cluster in the group consensus level and the number of the decision-makers who are willing to modify their initial opinion in the cluster.
FIGURE 3: Comparisons between different groups under two different methods. (a) The number of each subgroup under two different methods. (b) The gathered degree of each subgroup under two different methods.

Different decision-making models have different emphasis. Therefore, there is no model that can be referred to as the best. Despite offered valuable methods to handle multiattribute large group decision-making problems, there are limitations in the proposed model: it is not easy to determine the subjective consensus threshold in this paper. Similar to other consensus models, the subjective consensus threshold needs to be decided by the moderator or group. Although empirical values for the consensus threshold can be given, the determination of the subjective consensus threshold depends on the actual problems and simulations. The subjective consensus threshold makes it free for the moderator and/or the group to grasp the decision processes.

6. Conclusion

The MALGDM problem becomes more and more significant for participants and stakeholders to make a consensus-based decision. The main contributions of the paper are as follows:

(1) A novel clustering method was adopted to divide the large group into several clusters. The similarity is calculated to express the gather degree of decision-makers, and the decision-maker can be classified by the gathered degree. The value of gathered degree decides the number of subgroups.

(2) A consensus framework for the consensus reaching process in a MALGDM is proposed. The consensus threshold is determined by the consensus level and subjective consensus threshold. Meanwhile, the noncooperative behavior of decision-makers is determined, and the subgroup that includes the decision-maker who expresses the noncooperative behavior is defined as the noncooperative subgroup.

(3) A novel consensus reaching process is designed to address the noncooperative subgroup. The noncooperative subgroup is detected by the number of decision-makers and the consensus level, and by determining three noncooperative behavior situations. The weight of the subgroup is adjusted to reach

the consensus level, and the subgroups in our proposed approach are allowed to change. Thus, there are three approaches to manage the noncooperative behavior: adjustment weight of subgroup, quitting the decision process, and changing the subgroups in each interactive round.

Further, some other clustering methods can be incorporated in the proposal to detect the influences of clustering on model convergence. For the classification of large groups, it may be a good alternative to adopt an automatic feedback strategy such as an optimization-based approach. However, some limitations exist in the research. Due to the difference of risk preference, decision-makers may make decisions that are difficult to coordinate, and this paper does not cover the psychological perception of decision makers, which may be an important research direction in LGDM problem in the future. Meanwhile, there are many factors that can influence the decision-making, and the interactions of factors may influence the results. Thus, the approach considering the interactions of factors will be used to explore multiattribute interactions of LGDM.

As a convenient device for observing neural activity in the natural environment, portable EEG technology (PEEGT) has an extensive prospect in expanding neuroscience research into natural applications. However, unlike in the laboratory environment, PEEGT is usually applied in a semiconstrained environment, including management and engineering, generating much more artifacts caused by the subjects' activities. Due to the limitations of existing artifacts annotation, the problem limits PEEGT to take advantage of portability and low-test cost, which is a crucial obstacle for the potential application of PEEGT in the natural environment. This paper proposes an intelligent method to identify two leading antecedent causes of EEG artifacts, participant's blinks and head movements, and annotate the time segments of artifacts in real time based on computer vision (CV). Furthermore, it changes the original postprocessing mode based on artifact signal recognition to the preprocessing mode based on artifact behavior recognition by the CV method. Through a comparative experiment with three artifacts mark operators and the CV method, we verify the effectiveness of the method, which lays a foundation for accurate artifact removal in real time in the next step. It enlightens us on how to adopt computer technology to conduct large-scale neurotesting in a natural semiconstrained environment outside the laboratory without expensive laboratory equipment or high manual costs.

1. Introduction

Electroencephalography (EEG) has been proved to be a useful methodological tool for understanding brain activities, including the processes of perception, cognition, and decision, which are the basis of daily behaviors, business, and engineering activities.

With the great attention to human decision-making and the recognition of limitations of traditional psychological/ self-reported driven approaches [1–4], the neuromanagement on revealing the mechanism of human's behavior and decision-making based on brain imaging technology is promoted [5–7]. However, due to the high cost of purchasing and maintaining neurometric equipment and the complex operation and data analysis mode, brain technologies are limited to the laboratory environments and hindered from becoming widespread.

Neurophysiological measurements initially rely on high-cost equipment, complex systems, and many professional operations (e.g., measuring the size of the head, marking the position of electrodes on the scalp, placing electrodes on the scalp, and using conductive glue). Benefiting from the development of portable EEG technology (PEEGT), devices become cheaper and smaller, such as single-electrode

NeuroSky MindWave, four-electrode Muse, and fourteen-electrode Emotiv. What is more, with simple preparation, EEG data are collected through the wireless network. The PEEGT devices are suitable for nonclinical studies with better interactive experiences [8]. Nowadays, more and more research and commercial applications use PEEGT as a measurement tool. The utilization of PEEGT significantly expands the application of neurophysiological measurements and dramatically increases the practicability of neurometric equipment, such as in marketing [5], management [9], education [10], and engineering [11].

The PEEGT effectively reduces the threshold of the experimental environment in business and management situations. It is especially suitable for the volatile, uncertain, complex, and ambiguous (VUCA) environment. It makes large-scale and long-time neurophysiological measurements at the lowest cost possible. Moreover, subjects are allowed to have slight movements in position during a long-lasting experiment, for example, adjusting sitting or head posture like in a natural situation; we called this the semiconstrained environment. The semiconstrained environment is different from a constrained environment where subjects in the laboratory are under strict restrictions on autonomous activities. There is also a distinction between a semiconstrained and unconstrained environment where subjects have significant activity freedom. Nevertheless, fewer experimental restrictions in semiconstrained and unconstrained environments bring more artifacts by physical activities, which is difficult for artifacts operation.

Annotation of artifacts is a prerequisite for removing artifacts and EEG analysis. Existing methods of artifact annotation face the tradeoff between testing convenience and annotation accuracy, making it inapplicable in daily business scenarios where there are high requirements for both the convenience of collection and the accuracy of artifact annotation. The methods relying on additional reference signals or biological signal equipment are not applicable for the daily context that needs PEEGT. In contrast, methods relying on multiple algorithms have a long computing delay and are less accurate than methods with additional reference signals. Last but not least, most existing methods can only be used in postacquisition or offline settings, but real time is an essential demand of artifact annotation in business scenarios.

Considering existing methods, effectively annotating artifacts generated from physical activities usually requires manually annotating artifacts in postacquisition offline settings, which is extremely time-consuming and dependent on the data operator's expertise level. What is worse, to ensure the accuracy of the testing results and meet the requirements of business scenarios, tests with PEEGT usually need a larger sample size, a longer test time, and a more uncertain test environment. In a word, it is a great challenge to apply neuroscience in scenarios emphasizing "natural" due to the lack of adequate and suitable artifact processing technology. The artifact problem limits PEEGT to take advantage of portability and low test cost, which is a crucial obstacle for the potential application of PEEGT in the natural environment. It is worth noting that a challenge also exists in the laboratory EEG test, but the traditional experiment has more reference equipment assistance and more processing time. Therefore, in most laboratory cases, the limitation can be arranged by investing more resources.

Intelligent algorithms in computer vision (CV) bring new possibilities to solve the above difficulties. This article proposes one intelligent computing method on real-time portable EEG artifact annotations with computer vision, which changes the original artifact postprocessing mode based on signal recognition to the artifact preprocessing mode based on behavior recognition. It is especially suitable for artifact problems in semiconstrained environments involved in most real scenes in engineering and management. Besides, it provides the foundation for the subsequent artifact intelligent removal by the machine learning algorithm.

Our main contributions can be summarized as follows:

(1) We introduce a thought about changing the original signal recognition-based artifact postprocessing mode to the artifact preprocessing mode based on behavior recognition by the computer algorithm, making it possible to process artifacts in real time using only a camera instead of additional expensive neurological equipment and amounts of manual processing.

(2) We propose an intelligence method based on computer vision to automatically annotate the time segments and categories of artifacts caused by blinks and head movements in real time, which is of great importance for the large-scale application and real-time analysis of PEEGT and traditional EEG.

(3) We suggest a procedure about how to use large-scale neurological measurement in business and management scenarios with fewer restrictions on subjects' physical activities. The method ensures that the artifacts caused by the physical activities in blinks and head movements can be annotated in real time, which greatly expand neuroscience research into real applications environment including engineering and management.

2. Literature

2.1. EEG Artifacts. Electroencephalogram (EEG) is a standard method of measuring human brain activities that change over time in the form of electrograms. EEG data has shown great potential in research and commercial applications. It can be used as a diagnostic and monitoring tool for clinical applications, such as quantifying anesthesia levels before and during surgery [12], and film and advertising evaluation, such as film and television effect research [13]. However, there are many inherent challenges in EEG analysis, specifically the removal of various artifacts.

Generally, the artifacts of the EEG signal are mainly from the physiological activities of the participant and the additional noise artifacts introduced by the EEG acquisition instrument. The latter can be reduced or even eliminated by improving the operating performance of the EEG signal acquisition instrument. However, bioelectrical signals

generated by physiological activities are inevitably hidden in the EEG signals or even submerged in the EEG signals, which seriously affects the authenticity of the EEG signals and complicates the research work of feature extraction and EEG signal analysis. Blinks and head movements are two kinds of major signal artifacts. As a result, the research work of feature extraction and analysis of the EEG signals becomes complicated.

Figure 1 [14, 15] shows typical artifact waveforms with obvious and common interference to EEG signals. The blink artifact is generated by blinking eyes, while the head movement artifact is generated by head rotation or movements.

2.2. EEG Artifacts Annotation Methods.

EEG artifact annotation has always been a challenge in the EEG signals analysis process. Challenges come from the complexity of the method and the nonlinearity of the noise. For example, due to the "nonlinear" nature of the artifact, it is difficult to annotate the artifacts from the original EEG data without affecting the normal signal. In addition, some methods cannot be used for real-time applications. Until now, although researchers have been exploring lots of EEG artifact annotation methods, there is still no consensus on which algorithm is most suitable for a specific application.

In general, there are two categories of EEG artifact annotation methods: direct labeling of artifacts and indirect separation of artifacts [16].

2.2.1. Direct Labeling of Artifacts.

Direct labeling of artifacts refers to annotating artifact signals in real time when EEG signal is collected. However, it requires additional reference signals from reference electrodes channels or additional biological monitoring equipment. Li et al. [17] adopted additional channels of real EMG from neck and head muscles as input and realized the significant separation of EEG and EMG artifacts without losing the underlying EEG features. Mannan et al. [18] realized the simultaneous collection of EEG and EOG signals by adding the channels of EOG electrodes and combined independent component analysis (ICA), regression, and high-order statistics to identify and eliminate artifactual activities from EEG data. In terms of adding monitoring equipment, König et al. [19] used a laboratory-level eye tracker to annotate blink and eye movement artifacts in the constrained environment. Compared with the traditional manual artifact annotation, adding reference equipment has dramatically improved the accuracy and efficiency. Nevertheless, additional channels cause the additional possibility of artifacts. On the other hand, the additional expensive and complicated laboratory equipment will increase the burden of operators and participants and the terms of the test environment.

2.2.2. Indirect Labeling of Artifacts.

Indirect separation of artifacts refers to separating the mixed signals by multiple integrated algorithms without the reference electrodes or monitoring equipment. Jan et al. [20] improved the ICA method to better artifact removal. Chang et al. [21] used artifact subspace reconstruction (ASR) to preprocess EEG data and, combined with the ICA separation method, greatly improved the accuracy of artifact removal. Indirect separation of artifacts avoids extra electrodes, making it convenient in the test environment and reducing the extra noise. However, the method needs to integrate a variety of algorithms, increasing the algorithm's complexity and reducing the artifact annotation's real-time performance. Moreover, due to the lack of reference supervision of the artifact signals, the accuracy of the indirect artifact annotation is generally lower than those of the direct methods.

Although the two above-mentioned methods for artifact annotation have made explorations from different directions and achieved good results, they are based on sacrificing one aspect to improve the other, making it hard to apply in daily business scenarios. More specifically, the direct labeling of artifacts achieves better accuracy of artifact annotation with additional reference electrodes and laboratory equipment at the cost of the convenience in equipment operation and the comfort of participants. In contrast, the method of indirect separation of artifacts achieves more convenient signal acquisition with integrated algorithms at the cost of the accuracy of artifact annotation. Because the scenarios of daily business have high requirements for both the convenience in signal acquisition and the accuracy of artifact annotation, methods used in these scenarios should not only simplify the test environment and ease participant's test burden but also ensure the accuracy of artifact annotation and take the real-time requirements into account.

2.3. Semiconstrained Environment.

In neuroscience, research and experiments are conducted in two kinds of settings, laboratory settings and nonlaboratory settings. A laboratory test environment is carefully designed, in which researchers and participants need to follow strict restrictions and guidelines. Usually, other experimental settings outside laboratories are nonlaboratory settings. However, in most of the research articles, researchers either directly employ the term without further clarification [22] or use nonlaboratory settings to refer to a relatively broad idea [23]. For example, experiments conducted in the unattended home [24] and observational studies conducted in a community [25] are different in settings, but both are referred to as "nonlaboratory."

In the past literature, scientists did not specify how to set up neurological devices in conditions other than a laboratory. It is an unexpected gap in neural experiments. In many cases, it is unrealistic to keep participants motionless in a place with no distraction, especially in the natural environment using PEEGT. Therefore, to provide a more precise scope to clarify the application of our methods and algorithms, we define a term in our paper, a "semiconstrained environment," compared to a fully attended laboratory and an unattended natural setting. A semiconstrained environment describes an experimental setting where participants are required to wear a device; however, the research does not propose a highly restricted demand on participants
Figure 1: Typical artifact waveforms [14, 15]. (a) Clean EEG. (b) Blink artifact. (c) Head movement artifact.

(such as zero movements at all during measurement) since it is not always available to set up a lab-based environment.

3. Methodology

3.1. Method Proposed. In traditional EEG signal artifact processing without additional reference equipment, experienced signal processors must manually mark the abnormal signal period in the test signal after completing signal preprocessing, such as band-pass filtering. Usually, such an operation needs to be repeated 10–20 times for each subject, and more marks lead to a better operation effect. Then, the unique signal processing software will use algorithms such as ICA to automatically remove similar artifact signals according to the manually marked signal form. This method requires a long time and high personnel investment. In principle, such a manual postmarking and removal algorithm cannot ensure accuracy, and there is a certain degree of fuzzy space, even if it is existing in common practice.

In this paper, CV is introduced into neurological experiments. It can detect subjects' behaviors simultaneously during the experiment and mark the events that may produce artifacts from the source shown in Figure 2. Thus, it improves the real-time performance of artifact processing, avoids the later manual investment, and makes artifact marking no longer an ambiguous activity based on experience.

3.2. Process. The key to accurate artifact annotation in a semiconstrained environment is timely identifying the most common participants' physical activities that may cause artifacts, for example, blinks and head movements. In this paper, a method for annotating blink and head movement artifacts with computer vision in daily business scenarios is proposed, which meets requirements under this semiconstrained environment to a great extent. The method is shown in Figure 3. Firstly, it is necessary to collect the participants' initial state and calibrate the algorithm. Specifically, the subjects' eye-closing threshold is collected to measure blinking state during the test, and the subjects' initial sitting orientation is for the measurement of head movement state. Notably, the initialization of PEEGT equipment and standard commercial high-definition cameras, unlike the cumbersome operation of lab eye-

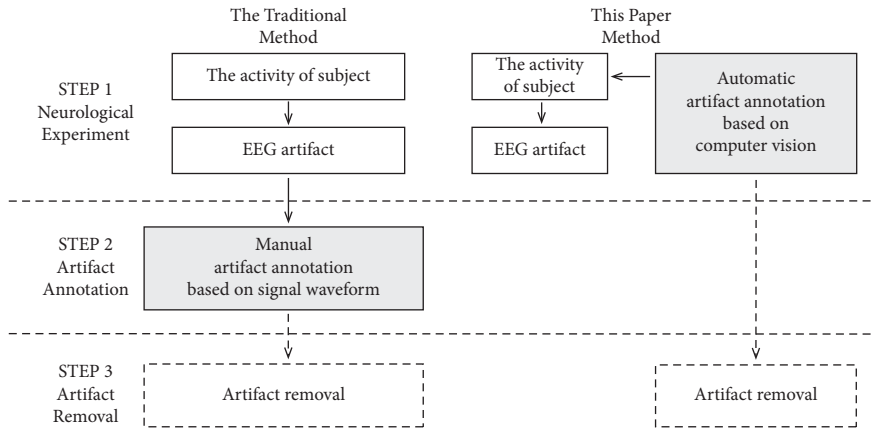
tracking equipment, performs the initial state check and calibration only to ensure the equipment availability and to collect the initial eye and head positions of the subjects.

Next, the PEEGT equipment and camera are used to synchronously collect participants' facial signals and EEG signals in real time. The blinks and head movements are detected with computer vision based on facial feature points. It is critical to note that the original EEG signals are downsampled in sync with the facial signal. Finally, the facial and the EEG signals in the same time series are analyzed and processed with the same analysis frequency. The EEG signals with blink and head movement artifacts are annotated.

The site-setting of the method is shown in Figure 4; the participant is wearing PEEGT devices and looking at the screen. In a semiconstrained environment, the participant can adjust his or her posture during the experiment. The camera ensures that head activity can be entirely recorded. Based on the computer algorithm with supervised real time and synchronization, the method can annotate the time segments of blinks and head movements that cause EEG artifacts.

3.3. Recognition Algorithm

3.3.1. Facial Feature Points Positioning. As mentioned above, the recognition algorithm first needs to collect the participant's facial signals and then monitor facial condition according to the specific facial features. The purpose of facial feature points positioning is to further define facial feature points (facial features and edge). The algorithms collect the baseline values of participants before the test, and the collected data and standards are unified. Therefore, the judgment threshold has corresponding calculations and standards for people of different face types.

The methods of facial feature point positioning can be categorized into the global method, the constrained local model (CLM) method, and the regression method, based on detecting face appearance and face shape information. The global method is to model the global face appearance and global face shape information explicitly [26]. The CLM explicitly models the local face appearance and the global face edge information [27]. The regression method uses global and local appearance information to implicitly embed global shape information for joint feature point detection


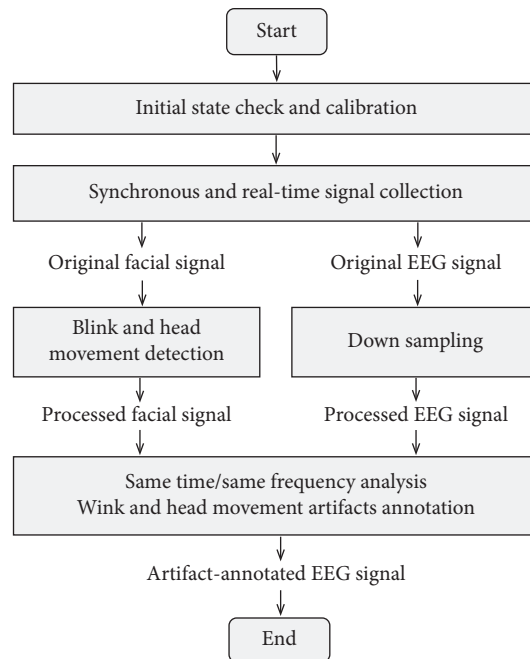


Figure 2: The proposed method.

Figure 3: Method of EEG artifact annotation with supervised computer vision.

Figure 4: The site-setting of blink and head movement artifacts annotation with supervised computer vision.

[28]. Generally, the regression method performs better because it contains more information compared to the other two. One representative algorithm of the regression method is Ensemble of Regression Trees (ERT) [29]. ERT is often used in facial feature point positioning because it is swift (it takes about 1 ms to detect each facial feature point) and can deal with the missing calibration of some key points in the training set.
FIGURE 5: 68 key feature points of each face.

The method in this paper uses the ERT algorithm to position 68 key feature points (as shown in Figure 5) of each face within 1 ms through three steps: shape invariant split tests, choosing the node splits, and feature selection proposed by Kazemi and Sullivan [29], which can estimate the face's landmark positions directly from a sparse subset of pixel intensities, achieving super-real-time performance with high-quality predictions. The pseudocode for this program is as follows (Algorithm 1).

```
def face_landmarks ():
    predictor = dlib       initializes      shape_predictor
("shape_predictor_68_face_landmarks.dat")
    # cv2 is the OpenCv library
    cap = cv2 gets the first camera of the machine
    while (cap is opened):
        flag, im_rd = cap.read () builds 3D matrix
        img_gray = cv2.cvtColor                  (im_rd,
cv2.COLOR_RGB2GRAY)
        faces = detector (img_gray)
        for k, d in enumerate (faces):
            shape = predictor (im_rd, d)
    END face_landmarks
```

The implementation display of the recognition effect in the practical example of this method is shown in Figure 6.

3.3.2. Blink and Head Movement Detection

(1) Blink Detection. In Subsection 3.3.1, basic facial information and 68 key feature points of each face are positioned. In the method proposed, a participant's blink is detected by analyzing the closure degree of the eye region (six feature points forming a closed ellipse), as shown in Figure 7.

$$\mathrm{EAR}_L = \frac{\|p_{37} - p_{41}\| + \|p_{38} - p_{40}\|}{2\|p_{36} - p_{39}\|},$$

$$\mathrm{EAR}_R = \frac{\|p_{43} - p_{47}\| + \|p_{44} - p_{46}\|}{2\|p_{42} - p_{45}\|}. \tag{1}$$

Eye Aspect Ratio (EAR) is equal to the sum of the lengths of two vertical line segments divided by the double length of horizontal line segments. The EAR stands for the state of eyes' opening and closing, and p_i is one of the 68 feature points forming the eye region (as shown in formula (1)). Research shows that EAR can approach zero at the moment of closing eyes and return to the original value when opening eyes [30]. By monitoring whether the value of EAR fluctuates rapidly and approaches zero in real time, this method can identify whether the participant's eyes are closed. However, the threshold for blink detection is undefined in this method, introducing noises in the natural environment. Therefore, considering the sampling rate of CV, this paper monitors the blink state by setting the base value before measurement. That is, the data of eye-closed state for 1 minute before the test are collected, and the blink detection threshold $\mathrm{Blink_{threshold}}$ based on its average value is defined:

$$\mathrm{Blink_{threshold}} = \frac{1}{N} \sum_{i=1}^{N} B_i. \tag{2}$$

In the above equation, N represents the number of samples in 1 minute. Since the sampling rate of CV is 25, $N = 1500$. B_i is the data of eye-closed state collected at the ith time. After collecting and calculating the blink detection threshold $\mathrm{Blink_{threshold}}$, blinks are detected according to the value:

$$\mathrm{EAR_{per\_second}} = \min(\mathrm{EAR}_p),$$

$$\mathrm{Blink_{status}} = \begin{cases} 1, & \text{if} \quad \mathrm{EAR_{per\_second}} \leq \mathrm{Blink_{threshold}}, \\ 0, & \text{if} \quad \mathrm{EAR_{per\_second}} > \mathrm{Blink_{threshold}}, \end{cases} \tag{3}$$

(a)   (b)   (c)

FIGURE 6: The implementation display of recognition effect.

FIGURE 7: Method of blink detection.

where EAR_{per_second} is the minimum value of EAR in each cycle. If EAR_{per_second} is less than or equal to $Blink_{threshold}$, it is determined that there is blinking action within 1 second. If EAR_{per_second} is greater than $Blink_{threshold}$, it is determined that there is no blinking action within 1 second. The pseudocode for this program is as follows (Algorithm 2).

```
def face_ear ():
    if obtain 68 feature points of the face:
        ear_r_list.append (ear_r), ear_l_list.append
(ear_l)
        ear_r_status, ear_l_status = 0
        If N == 25:
            ear_r_persecond = min(ear_r_list),
ear_l_persecond = min(ear_l_list)
            ear_r_list.clear, ear_l_list.clear
            If                    ear_r_persecond ≤
blink_r_threshold:
                ear_r_status = 1
            else:
                ear_r_status = 0
            If        ear_l_        persecond ≤
blink_l_threshold:
                ear_l_status = 1
            else:
                ear_l_status = 0
        return ear_r_status, ear_l_status
    else return null
END face_ ear
```

(2) Head Movement Detection. Head movement (HM) detection is related to face orientation. In facial feature point positioning, 68 key feature points, including eyes and nose, are extracted from each facial image. In this paper, we refer to the center points of the eyes and nose to define the face orientation coordinates [31].

In (2), the eyes and nose have been correctly positioned. The three facial feature points determine an isosceles triangle by connecting lines between the three points. Considering the symmetry of the face, we can calculate the angle between the plane of the isosceles triangle and the image plane to determine the gaze direction. If one side of the triangle is located on the image plane, it is easy to calculate the angle of the gaze direction. The judgment of facial orientation is realized through the calculation of trigonometric function, as shown in Figure 8.

The triangle ABC is the projection of the isosceles triangle *ABE* on the image plane, which means that if the

(a)

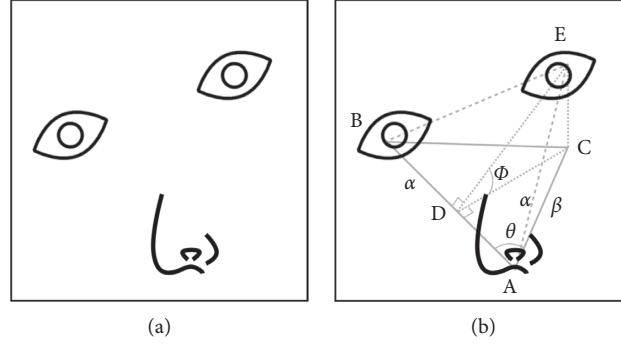
(b)


FIGURE 8: Facial image (a) and projection isosceles triangle model (b).

person in the picture looks straight ahead, the projection triangle will coincide with the isosceles triangle. The triangle CDE is located on the plane perpendicular to the image plane and isosceles triangle plane. If θ is the angle between line α and line β and ϕ is the angle between the image plane and the isosceles triangle plane, then

$$\cos \phi = \frac{|CD|}{|DE|},$$

$$|CD| = |AC|\sin \theta, |AD|$$

$$= |AC|\cos \theta, \tag{4}$$

$\cos \phi$ can be calculated by trigonometric function as follows:

$$\cos \phi = \frac{|AC|\sin \theta}{\sqrt{|AB|^2 - |AC|^2 \cos^2 \theta}}. \tag{5}$$

Therefore, determining the direction of the sight is to see how the isosceles triangle is projected on the image plane: the maximum distance from the eye to the mouth reveals the direction of the human gaze. After obtaining the participant's gaze direction, the attention direction is recorded, while the lateral (HM) of the participant is identified according to point A's coordinates.

Similarly, for head nodding, it is calculated as follows:

$$d = \|p_{27} - p_{30}\|. \tag{6}$$

d_i is obtained for each segment of detection. Thus,

$$D' = \text{Median}\{d_1, d_2, d_3, \ldots, d_N\}. \tag{7}$$

$N = 1500$ represents the number of samples in 1 minute. Then,

$$\phi' = \frac{\|D - D'\|}{D'} * 90. \tag{8}$$

In the above equation, ϕ' is the angle at which the subject's head is nodding, ranging from 0 to $90°$.

In addition, participants sit on the designated spot during the test in a semiconstrained environment and cannot move back and forth smoothly. Therefore, the above two detection conditions can meet the detection marks of

most HM artifacts, and the HM can be estimated by the angle difference between the two moments.

Instead of judging the absolute HM angle of the participant, the proposed method calculates the relative HM angle change in EEG artifact annotation.

Therefore, it is necessary to have

$$\psi = \frac{1}{N} \sum_{i=1}^{N} \varnothing_i,$$

$$\varnothing_{\text{relative}} = \psi_t - \psi_{t-1},$$

$$\text{Head}_{\text{status}} = \begin{cases} 0, \varnothing_{\text{relative}} \leq 10°, \\ 1, 10° < \varnothing_{\text{relative}} \leq 30°, \\ 2, \varnothing_{\text{relative}} > 30°, \end{cases} \tag{9}$$

where ψ is the real-time HM angle of the participant relative to the right ahead direction in a sampling period. $\varnothing_{\text{relative}}$ refers to the change of the HM angle of the participant in the current second relative to the previous second. If $\varnothing_{\text{relative}}$ is less than $10°$, it is judged to be relatively static and counted as 0. If $\varnothing_{\text{relative}}$ is greater than $10°$ and less than $30°$, it is judged as a micro-HM and counted as 1. If $\varnothing_{\text{relative}}$ is greater than $30°$, it is judged as a distinct HM and counted as 2. Head vertical and horizontal movements are calculated separately and $\text{Head}_{\text{status}}$ depends on the bigger one. Therefore, HM artifacts are detected and marked as different levels in the EEG artifact annotation.

The pseudocode for this program is as follows (Algorithm 3).

```
def face_angle ():
    if obtain 68 feature points of the face:
        head_angle_list.append (angle)
        current_angle = angle
        If N == 25:

head_change = current_angle–last_angle
        If head_change ≤ 10:
            head_status = 0
        else if 10 < head_change ≤ 30:
```
FIGURE 9: Process of EEG artifacts annotation with supervised computer vision.

```
                head_status = 1
        else:
                head_status = 2
        head_angle_list.clear
        return head_status
    else:
            last_angle = angle
    else:
        return null
END face_ angle
```

3.4. EEG Artifact Annotation with Supervised Computer Vision.
The process of blink and head movement artifacts annotation with supervised computer vision is shown in Figure 9. Firstly, the participant's facial and EEG signals are collected synchronously and in real time. Then, the blink detection algorithm is used to determine whether the blink action occurs. If there is a blink, the EEG signal in this state is annotated. Then the head movement algorithm, which determines whether a head movement occurs, is activated. If there is no head movement, the blink artifact is identified. If there is a head movement, the EEG signal in this state is annotated, and the head movement and blink artifacts are both identified.

It should be noted that the time window of the above process is 1 second. In a semiconstrained environment where tests generally take a long time, the 1-second time window can significantly reduce the time complexity and space complexity of data processing if enough EEG signals are retained and improve the efficiency of the whole test process. Real-time feedback also plays an important role in meeting the diverse business application needs.

3.5. Method Implementation.
Firstly, in algorithm implementation, we use Python 3.0 as the primary development language, and the development tool is PyCharm. The tool libraries used in the system development are Dlib, OpenCV, math, and NumPy. Specifically, Dlib is mainly used for face recognition and feature point labeling, OpenCV is mainly used for image processing and generation, math is used for mathematical algorithm calculation, and NumPy is used for feature point data processing.

Through the implementation, we verify the feasibility of the above method. In the example, we set the test environment and CV systems as in Figure 4 and performed the EEG acquisition for 24 seconds. In order to ensure the sensitive and accurate acquisition of EEG signals, we used the laboratory EEG equipment (ANT eego^{TM}mylab) instead of PEEGT to measure the example.

The model (by the author team) carried out four activities: blinking twice, towards two directions, and head movements twice, once slight and once severe. The implementation results indicated that all the activities were captured with the methods. All the artifacts were marked simultaneously by the 1-second time window, as demonstrated in Figure 10.

4. Experiment

4.1. Experiment Design and Participant.
We designed the experiment to verify whether the proposed intelligent computing method effectively recognizes and annotates the subject's activities in an authentic test environment.

The experiment recruited one participant that watched TV reality show programs for 15 minutes wearing PEEGT equipment and the test site-setting as in Figure 4. In the semiconstrained environment, the participant was not told
FIGURE 10: The example of the method implementation.

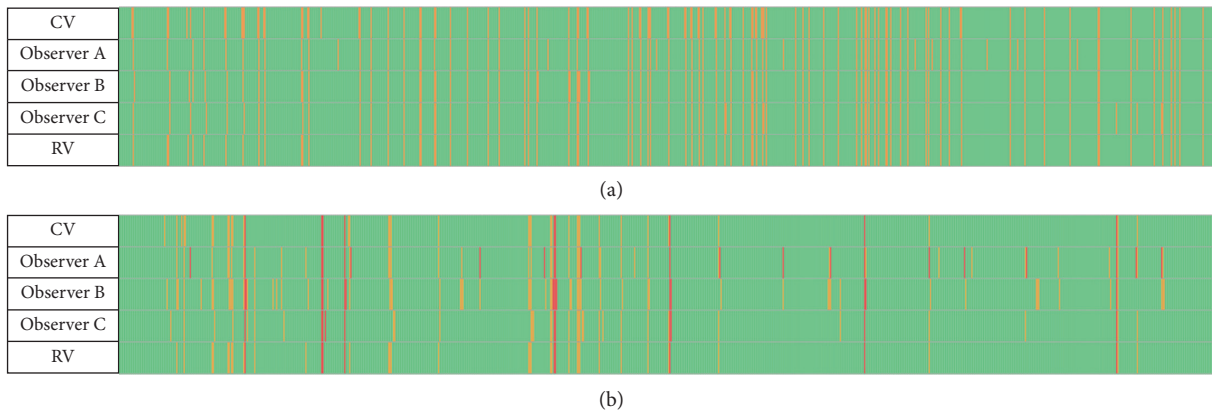

FIGURE 11: The experiment scene.

FIGURE 12: The original results of the experiment.

the requirement of body movement restriction, and no one else was present during the experiment. The camera above the screen recorded the participant's head movements and blinks. The experimenters were observed through one-way

glass and real-time system data. The scene picture is shown in Figure 11.

Three observers with EEG artifact processing experience watched the recorded video. They manually marked the

TABLE 1: Five groups of experimental result.

	Blink left					Blink right					Slight head movement					Severe head movement				
	Detection	Wrong	Miss	TPR (%)	SPC (%)	Detection	Wrong	Miss	TPR (%)	SPC (%)	Detection	Wrong	Miss	TPR (%)	SPC (%)	Detection	Wrong	Miss	TPR (%)	SPC (%)

TPR represents the sensitivity of the data: the rate of real blinks or head movements. SPC represents the specificity of the data: the rate of real nonblinking or non-head-movements. TPR = (detection-wrong)/(detection-wrong + miss) × 100%. SPC = (total-detection-miss)/(total-detection-miss + wrong) × 100%.

participant's activity in the video, including blinks (left eye, right eye, and two eyes) and head movements (slight: rotation or tilt more than 10° and less than 30°; severe: rotation or tilt more than 30°). To simulate a large-scale artifact process task, the three observers perform a 30-minute irrelevant annotating task before the labeling task of this experiment. The participant's video is played at normal speed during the annotating process, and backward progress is not allowed.

The experimental team also manually marked the participant's movements as the reference value to ensure the accuracy of the marking. If necessary, the video can play slowly and repeatedly. For operability, the time granularity of all manual marking is 1 second.

4.2. Experiment Result. The activity markers of the participant were compared among the CV, three observers, and the reference value (RV, by experiment team). The original mark results are shown in Figure 12. The statistical result is shown in Table 1. The time granularity of all manual marking is 1 second, so the total represents 900 seconds, and each row has 900 horizontal grids in Figure 12. Note that the blinks here only refer to the ones detected by naked eyes.

5. Discussion

Overall, the experimental results show that the CV method in this paper got an ideal achievement, including sensitivity, specificity, and detection number. Moreover, the CV method has the advantages of real time and low cost.

For blink annotation, in general, the frequency of blinks correctly identified by the CV method is higher than that by the manual method, and the frequency of missed detections is lower under the close sensitivity and specificity. It is difficult for manual marking to maintain a high concentration and to notice the instant blink event for a long time, even with relevant data processing experience. In addition, the fuzziness of the human brain in judging events in unstructured data such as video will also lead to errors and omissions. The above reasons explain why the traditional artifacts processing cannot be applied to the business large-scale and long-time semiconstrained environment of PEEGT.

On the other hand, as for the CV method used in this experiment, the frequency of errors is slightly higher than that in the manual method in blink detection, which is due to categorizing the subject's eye-drooping activity as a blink event. From the perspective of bioelectrical signal interference, blinks and eye-drooping are the same. However, it is shown that even if the facial feature points can be captured all the time, the CV still has the possibility of recognizing some activity events incorrectly. Nevertheless, by optimizing the model, the false detection rate can be controlled, fully competent for the artifacts annotating long-time continuous EEG signal acquisition. In addition, there may be subtle differences between frequencies of two eyes' blinks in the CV method that independently detects binocular activity, which is distinguished from the

observer's overall observation style. Thus the difference may be more significant for participants with greater eye size differences. However, in large-scale and long-term tests, the influence of the above slight differences is almost negligible, especially in a semiconstrained test environment.

For head movements, the results are similar to the blinks. The CV recognition shows a significant advantage in efficiency, effectiveness, sensitivity, and specificity close to manual marking. Then it shows the great advantage of intelligent computing in a long-term mechanical task, and the method proposed in this paper is effective.

6. Conclusion and Future Work

The method proposed by this paper changed the original artifact postprocessing mode based on signal recognition to the artifact preprocessing mode based on behavior recognition by CV, which combined and optimized three efficient computer recognition algorithms. The paper also proved the method's effectiveness in the experiment. Through real-time monitoring of the participant's facial signals, the intelligent system can identify two main antecedent causes of the EEG artifacts, participant's blinks and head movements, and annotate the artifacts' time segments in real time. In a semiconstrained environment where PEEGT is generally used, the intelligent computing method makes PEEGT break through the current application bottleneck limited by artifacts, which meets the needs of processing large-scale test data with low cost and simple operation demands. The method introduces a new perspective to neurophysiological measurements. It utilizes the algorithm with a readily available commercial camera instead of expensive laboratory equipment or/and high manual costs. In addition, it enlightens us on conducting large-scale testing in a semiconstrained environment outside the laboratory.

The innovation of introducing the CV method into neurophysiological measurements is noteworthy:

(1) We proposed a new idea of detecting behavioral artifacts in EEG signals in real time. Therefore, the paper focuses on introducing the panorama of the method instead of the advantages of specific algorithms.

(2) Most of the machine learning algorithms in neuroscience and behavioral science run offline, but real-time detection is the innovation that the paper emphasized; and scenarios described in the paper are not the same as offline artifact mark recognition and thus are not comparable.

(3) We believe that interpretability is essential for a new method, and the algorithm black box is not conducive to trust and accept the innovation.

However, machine learning can effectively recognize blinking, head movement, and other behaviors in real time. Thus, in the specific recognition algorithms, we chose the method of logical judgment by feature points and achieved

ideal detection results. Nevertheless, with the acceptance of this method and continuous optimization of the algorithm, intelligent methods will be applied on a larger scale. The accuracy of the CV method will be promoted, which is the fundamental advantage of the algorithm compared with the manual annotation.

On the other hand, the efficient and accurate annotation of artifacts caused by the subject's activities is the critical precondition step for intelligent artifacts removal. The algorithm can accurately capture the individual physiological activity differences among participants in the same actions, such as blinks, thanks to the CV method. Thus, the supervised machine learning algorithm can be based on the individual differences for more accurate individual artifact removal and correcting, which will greatly improve the accuracy of EEG artifact signal processing. That is the goal of the next stage of this paper. In the future, it will be critical for PEEGT to start large-scale commercial applications in more complex experimental environments, such as the engineering management, the effects of film and television programs, advertising research, information flow research, aroma cognition test, and game interaction test.

Data Availability

Previously reported face feature selection data were used to support this study and are available at doi: 10.1109/CVPR.2014.241. These prior studies (and datasets) are cited at relevant places within the text as reference [29]. And the experiment data used to support the findings of this study are available from the corresponding author upon request.

How to strengthen physical fitness to improve the effect and efficiency of sports is an important research direction worthy of research. In response to these problems and limitations, Smart Fog Computing technology is introduced in this paper. Taking rats as the research object, the effective quantitative analysis and research of aerobic exercise on myocardial proteome are achieved through combining the business scope of myocardial proteomics, and connecting corresponding continuous aerobic exercises, verified by simulation analysis. The simulation research results show that the smart fog calculation is effective. For moderate-intensity aerobic exercise, the expression and intensity of the corresponding myocardial protein are changed significantly, and the corresponding heart becomes larger; meanwhile, moderate aerobic exercise can improve the metabolism and enhance digestive ability.

1. Introduction

With the continuous development of social economy, sports are increasingly valued and favored by people [1, 2]. However, because people have different physiques and cannot become sports athletes, for ordinary people, it can be achieved through corresponding food or nutritional supplements [3, 4]. It should be noted that some scholars have noticed the influence of related factors and then concentrated on the influence of myocardial mitochondrial protein [5, 6]. The emergence of aerobic exercise can gradually improve the related energy metabolism such as synthase in the corresponding myocardial protein tissue, further save the corresponding heart function, improve the corresponding pumping function, and accordingly meet the corresponding exercise needs. For different cells, the types of proteins are different under different pathological or physiological conditions [7, 8]. Therefore, the proteomics requires to be analyzed in terms of comprehensive and holistic analysis of dynamic changes in cells, so as to analyze protein composition, expression, modification, and other

states, further analyze the relationship between proteins, and reveal the laws of proteomics and cell activity [9, 10].

However, it should be noted that, with the increase of amount of exercise and practice, different exercise loads will be achieved, which will induce corresponding differences in the expression characteristics of the myocardial proteome, and thus discover different physiological and physical loads, which can achieve the differential expression of myocardial proteomics from the various factors such as load density and continuous training period [11, 12]. Therefore, it can be seen that exercise load may guide the recombination of myocardial proteomics to achieve the reshaping of the shape, state, and structure of the heart. In response to these needs and limitations, smart fog calculations is introduced in this paper, and the effective quantitative analysis and research of aerobic exercise on myocardial proteome are realized through combining the effects of aerobic exercise under a certain intensity on myocardial proteomics and taking rats as the research object, connecting corresponding continuous aerobic exercises in series, which is verified by simulation analysis, aiming to quantitatively analyze the influence law of myocardial proteomics.

2. Application Strategy of Motion Feedback System Based on Smart Fog Computing

The principle of network operation situation evaluation is to obtain the evaluation value of the current network operation situation through inference calculation based on the acquisition of operation data of various equipment and network operation and maintenance data, so as to reflect the overall operation of the network. From a mathematical point of view, the network operation situation evaluation is a mapping from the impact factor to the result value, and its mathematical model is

$$SA = f(x_1, x_2, \ldots, x_m). \tag{1}$$

In the formula, SA represents the network situation evaluation value, and the value is taken as $[0, 100]$; x_i is the influencing factor of network operation, that is, the evaluation index, where $i = 1, 2, \ldots, m$; f is the specific evaluation method, which is the realization of quantitative assessment of network operation situation proposed in this article based on the improved BP neural network model of entropy method and LM algorithm.

The entropy method and the Smart Fog Computing improved by the L-M algorithm are used in this paper to conduct the training process of situation assessment as shown in Figure 1.

The steps of determining the BP neural network structure, determining the index system, data preprocessing, and calculation of the index weight through entropy method as the model's initial parameters, BP neural network training model, and LM algorithm modification parameters are carried out successively. If the model error or the number of iterations meets the expected value, then the model training ends.

The square sum of the output resulting errors is taken as the objective function in the network model, and the parameter value is adjusted according to the gradient descent method to reduce the error. The model structure is shown in Figure 2.

Take the network situation assessment as an example.

$$y_j = f\left(\sum_{i=1}^{n} v_{ij} x_i - \theta_j\right). \tag{2}$$

In the formula, the function f is the selected activation function, which is usually expressed with the sigmoid function as

$$f(x) = \frac{1}{1 + e^{-x}}. \tag{3}$$

Similarly, for the kth neuron in the output layer, its output is

$$o_k = f\left(\sum_{j=1}^{m} w_{jk} y_j - r_k\right). \tag{4}$$

The error of the calculation result is expressed by the least square method:

$$E_k = \frac{1}{2} \sum_{k=1}^{l} (o_k - d_k)^2. \tag{5}$$

The above is the forward calculation process.

If the error does not meet the expected value, totaling $(N + L) \times M + M + L$ parameters. This process is a reverse calculation process.

In the reverse calculation process, the partial derivative of each parameter that needs to be adjusted is calculated, the parameter value is changed according to the gradient descent method, and the learning rate η is set to control the range of variation of parameter. w_{jk} is taken as an example, and the weight adjustment value is

$$\Delta w_{jk} = -\eta \frac{\partial E_k}{\partial w_{jk}}. \tag{6}$$

Realization of multiple iterations of forward and reverse directions is needed for Smart Fog Computing, and the number of iterations or allowable error range is set as the iteration termination condition to obtain the final model [13, 14].

The nonlinear mapping ability of Smart Fog Computing is extremely powerful, which can solve many practical application problems, and the network structure is flexible; but there are also some defects, such as slow learning speed, prone to fall into local optimal solutions, etc. These deficiencies may cause the lower accuracy and longer training time of situation assessment model based on the standard BP neural network. In response to these problems, an improved method based on Smart Fog Computing is proposed in this paper.

In the situation assessment method based on Smart Fog Computing, the final training effect of the BP neural network model is affected by the initial value of the model parameters. The index data of the network situation assessment is imported by the BP neural network model, so the index weights optimized by the entropy method are selected as the initialization parameters of the model.

To use the entropy method to calculate the index weight, the index system must first be determined.

For a total of n sample data and m indicators required for situation assessment, the j-th indicator value of the i-th data is denoted as x_{ij}. The normalized definition of data is shown in

$$x_{ij}' = \frac{x_{ij} - \min(x_j)}{\max(x_j) - \min(x_j)}. \tag{7}$$

For convenience, the data x_{ij}' after normalization is still recorded as x_{ij}.

Calculate the proportion of the i-th sample in the j-th index as

$$p_{ij} = \frac{x_{ij}}{\sum_{i=1}^{n} x_{ij}}. \tag{8}$$
The calculation of entropy is

FIGURE 1: Motion feedback evaluation process based on Smart Fog Computing.

FIGURE 2: Three-layer BP neural network model.

$$e_j = -k \sum_{i=1}^{n} p_{ij} \ln\left(p_{ij}\right). \tag{9}$$

In the formula, $k = 1/\ln n$ satisfies $e_j \geq 0$.

Calculate the information entropy redundancy of the j-th index as

$$d_j = 1 - e_j. \tag{10}$$

Calculate the weight of the j-th index as

$$w_j = \frac{d_j}{\sum_{j=1}^{m} d_j}. \tag{11}$$

Smart Fog Computing can deeply reflect the distinguishing ability of indicators, determine the weight of indicators, and have high credibility and accuracy. In the network situation assessment problem, the index weight calculated is used as the initial value of the parameters, which improves the credibility of the initial model and is conducive to the correct and rapid convergence [15].

Here, teachers can create a gamified teaching mode. Taking the 4×100 m relay run as an example, teachers can create different nodes on the sports field and place basketball, table tennis, badminton, boxing gloves, and other props at each node, separately before running. A separate instruction is issued for each club student. The instruction can include the name of a well-known athlete in a certain sport, sports rules, etc., so as to guide students to choose props based on the instruction and put them in the finish basket after finishing the run. The heartbeat, breathing rate, speed, and other data detected in the motion feedback system are scored as well as the correctness and wrong results of the instructions, which not only helps improve the fun of running training, but also realizes the training of students' basic sports knowledge and cultivates students' teamwork awareness and further improve students' enthusiasm for sports and enthusiasm for competition.

For sports, teachers are often accustomed to guiding traditional running and gymnastics to participate in collective exercise. However, due to the different physical fitness of students, the students are not often effectively supervised and guided by this model. Therefore, students' exercise is often conducted just in the classroom, but it cannot achieve the exertion of effect of sports. With the continuous development of technologies such as the Internet of Things, new technologies such as smart fog computing can fully cover and extend the corresponding smart watches and smart bracelets to achieve the full coverage and extension of the monitoring scope of sports. Meanwhile, big data analysis can be used to summarize the overall exercise behavior of students.

Big data intelligent analysis technology can generate instructive exercise information by processing the collected raw exercise data and provide an effective reference for the adjustment of the teacher's teaching plan and the setting of teaching priorities. Taking badminton training as an example, teachers can obtain information about different

students' movement postures, scores, hitting techniques, and sports area routes in the functional modules of the sports feedback system and use big data intelligent analysis technology to obtain the internal information between different indicators. Associate and then realize the quantification processing and calculation of sports information, presenting an intuitive evaluation of sports effects. Teachers need to use the exercise effect evaluation to judge the students' deficiencies in sports skills and technical programs and use this as a benchmark to adjust training content and methods, provide students with more professional and effective teaching guidance, and improve their sports skills and communicate effectively. At the same time, teachers can also use big data technology to comprehensively analyze the students' multiple training results and extract the progress curve around their original exercise level, which can be used as the benchmark for the evaluation of students' sports performance, so as to better improve the scientific nature of the evaluation of physical education and promote students' self-confidence in sports and the development of good exercise habits.

3. Application of Motion Feedback System in Middle School Physical Education Teaching

3.1. Promoting the Construction of Physical Education Informatization. For sports feedback, it is a kind of intelligent supervision that gathers big data analysis and intelligent IoT, which can effectively analyze sports behavior data and realize real-time or quasi-real-time analysis and monitoring of indicators, thus forming corresponding sports feedback forms, to realize dynamic analysis and evaluation during sports training, thereby reducing the cost of students' exercise analysis and promoting the in-depth application of smart fog computing.

3.2. Educational Requirements for Implementing Classified Guidance. The corresponding feedback system can be used to realize the collection, sorting, processing, analysis, and decision support of different individual motion modes, exercise speed, and other motion data, provide the corresponding teachers with personalized motion programs, and provide individual targeted guidance in different categories, thereby improving the overall effectiveness of physical education.

3.3. Promoting the Effective Improvement of Students' Physical Quality. The current sports feedback system is mainly embodied as wearable smart devices, including sports bracelets, smart wrist watch, and VR glasses, with functions such as exercise step counting, heart rate monitoring, and GPS positioning, to achieve effective capture of data on student movement trajectories, exercise time, etc. Physical education teachers can use their management authority to obtain the exercise data of different students, use big data intelligent analysis technology to collect the students' heart rate, speed, breathing frequency, and other parameters during exercise, and, at the same time, can judge whether the

student's exercise is in place and whether the trajectory is in place. Meet the requirements, in order to provide students with personalized guidance, with the help of the normative guidance of sports behavior, to better promote the effective improvement of students' physical fitness.

4. Simulation Experiment

4.1. Heart Weight Changes. In order to verify the effectiveness of smart fog computing, the corresponding fault diagnosis model is needed to be collected and constructed, and training can be conducted according to the corresponding data, and finally the online detection is realized in this paper. The specific fault diagnosis is shown in Figure 3:

Sports feedback is integrated; taking rats as an example, the results of their sports feedback are comprehensively compared, as shown in Figure 4. From the results, it can be seen that the heart weight and heart weight index of big data have corresponding changes, so you can see that, after a certain period of aerobic exercise, the rat's heart has undergone certain changes.

4.2. Mass Spectrum Identification Result. After a certain period of aerobic exercise, changes in the expression of myocardial protein in rats occur. Therefore, it is necessary to connect in series and use corresponding instruments for detection and identification to achieve quantitative analysis. As shown in Figure 5, it can be seen from the results that protein 7 is related to the metabolic energy of the myocardium.

4.3. Analysis of Changes in Heart Weight. Through corresponding experimental comparison, it can be seen that the rat's heart weight and heart weight index have increased. Therefore, the change of heart weight is used to analyze in this paper, and it can be obtained that, after a certain period of moderate aerobic exercise, the increase of myocardial physiology can be achieved, which results in a difference in the energy metabolism of some myocardial proteomics, which leads to an increase change in the level of myocardial metabolism, achieving myocardial contraction.

4.4. Analysis of Mass Spectrum Identification. In the process of heart remodeling during exercise, the pathway of cardiac energy metabolism has undergone corresponding changes. These proteins are mainly related to the tricarboxylic acid cycle and amino acid metabolism process in the aerobic oxidative metabolism of the myocardium.

The effect of moderate-intensity aerobic exercise on atrial myocardial tricarboxylic acid cycle: the expression of ACO2 may have expression difference of myocardium in different positions in different intensities, different continuous training periods, and different positions. The mechanism of its differential expression needs further experimental study. This experiment may increase the expression of
FIGURE 3: Data parallelization process.

FIGURE 4: Changes in heart weight index measurement.

FIGURE 5: Mass spectrometric identification of target protein spots related to myocardial energy metabolism.

aconitate hydratase through 4 weeks of moderate-intensity aerobic exercise, so as to improve the energy supply of the heart and enhance the contractility of atrial muscle.

First, collect the list of abnormal events in gateway measurement, and establish a database of abnormal events in metering equipment. Common abnormal events include electric energy meter error exceeding tolerance, PT secondary voltage drop exceeding tolerance, secondary circuit pressure loss, current loss, phase failure, and secondary load overrun, unbalanced current, overlimit demand, abnormal line loss, and unbalanced bus. Then, test typical measurement equipment, and verify the system's identification through the laboratory failure simulation platform to simulate various measurement abnormal events. According to the test results, the system's functions of distinguishing, recording, and alarming abnormal measurement events are verified, and meanwhile, the judgment rules and thresholds of abnormal measurement events are improved and standardized (Figure 6).

The mitochondrial succinate dehydrogenase coenzyme flavin subunit in atrial muscle declined by 7 times, and the expression of cytoplasmic malate dehydrogenase declined by 7.2 times after exercise. The difference in experimental results may be related to many factors. Therefore, a certain period of aerobic exercise can promote the increased expression of the myocardial protein of pyruvate dehydrogenase Elα1, realize the supply of heart energy, and enhance the contraction and pumping ability of the heart.

In this experiment, the mitochondrial succinate dehydrogenase coenzyme flavin subunit in atrial muscle was downregulated by 6.9 times, and the expression of cytoplasmic malate dehydrogenase was downregulated by 7.3 times after exercise. The difference in experimental results may be related to the intensity of exercise. The duration of exercise is related to the structure and function of myocardial tissue in different parts. The main function of the atrial muscle is not to contract and pump blood. Its ejection process is short, and the contraction work value is smaller than that of the ventricular muscle. In addition, there was a 4-week 60%–70% VO2max moderate-intensity aerobic exercise due to low exercise intensity and short exercise duration. It may be that the body is in the stage of exercise adaptation and may not produce strong oxidative stress on atrial muscle cells. Stimulate the expression of malate dehydrogenase and mitochondrial succinate dehydrogenase coenzyme flavin subunits of atrial muscle, but the reasons for the decrease in expression level need to be further explored and verified:

Point 265 is identified as pyruvate dehydrogenase Elα1, which belongs to the pyruvate dehydrogenase complex system. Pyruvate dehydrogenase complex (PDHc) is the key enzyme system that catalyzes the oxidation and decompression of ketone acid to form acetyl-CoA and plays an important role in the body's aerobic oxidation metabolism process.

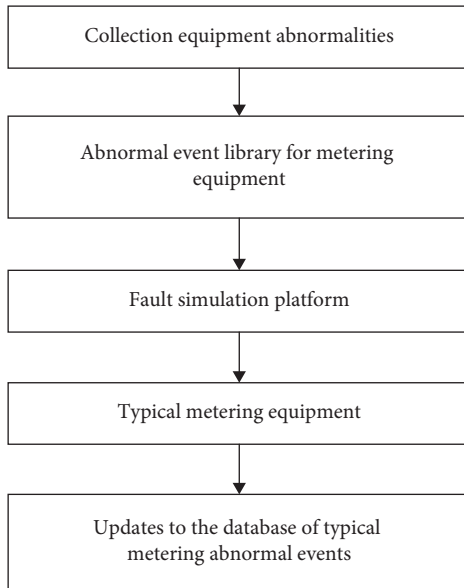
The expression of pyruvate dehydrogenase Elα1 was "absent" in the right ventricular muscle of rats after 4 weeks of moderate-intensity aerobic exercise (70%–80% VO2max). There was no difference in its expression after 8 weeks of exercise, and its expression after 12 weeks of exercise. The expression level was upregulated by 33.3 times. The expression of this protein has a time effect. As the body slowly


Figure 6: Establishment and verification of abnormal event database.

adapts to exercise intensity, it finally shows a high expression of adaptability to improve the myocardial oxidative metabolism capacity. Studies have found that the protein expression in right ventricular muscle is upregulated by 5.3 times after 8 weeks of exercise (60%–70% VO2max aerobic). In the results of this experiment, 4 weeks of moderate-intensity aerobic exercise induced an upregulation of the protein expression in atrial muscle and left ventricular muscle by 6.4 and 5.8 times, respectively. Based on the above research results, long-term moderate-intensity aerobic exercise can promote pyruvate dehydrogenase Elα1 increased expression in various parts of myocardial tissue and, as a result, accelerates the oxidative decompression of pyruvate in the body, provides sufficient acetyl-CoA for the myocardial triacyl acid cycle process, improves the energy supply of the heart, and enhances the contraction and pumping ability of the heart.

The effect of moderate-intensity aerobic exercise on the amino acid metabolism of atrial muscle: point 393 is identified as isovaleryl-CoA dehydrogenase. It is involved in the metabolic decomposition of leucine, an important catalytic enzyme for leucine metabolism. Point 236 is identified as mitochondrial dihydrolipoic acid dehydrogenase, which belongs to the multienzyme complex of glycine dehydrogenase and reductase and participates in the metabolism of glycine. In addition, it also works with pyruvate dehydrogenase and dihydrolipoic acid acetyltransferase. It constitutes the pyruvate dehydrogenase complex and belongs to the FAD-dependent enzyme.

After an acute exhaustive exercise intervention, isovaleryl-CoA dehydrogenase is "absent" expression in the atrial muscle, which may cause the accumulation of isovaleric acid, a metabolite of leucine, in the process of leucine degradation, and make the intracellular pH. When the value increases, the energy metabolism of myocardial cells is impaired, and the myocardial contractility decreases. This

experiment found that 4 weeks of moderate-intensity exercise reduced the expression of isovaleryl-CoA dehydrogenase in atrial muscle by 6.9 times, and the expression of mitochondrial dihydrolipoate dehydrogenase by 5.7 times. The oxygen demand is great, and the energy supply process of mature cardiomyocyte activity is mainly supplied by the aerobic oxidation of sugar, and the energy supply ratio of amino acid is very small. Hafstad's research shows that moderate-intensity treadmill exercise (65%–70% VO2max) improves the utilization of rat myocardial glucose and improves the aerobic capacity of the body. Therefore, the 4 weeks of moderate-intensity aerobic exercise in this study does not require a large amount of amino acid mobilization. It may be so in order to save the body's amino acids and protein. After exercise, the expression of the above two proteins in atrial muscle was inhibited. In this experiment, the downregulation of the expression of mitochondrial dihydrolipoate dehydrogenase may also be related to the upregulation of pyruvate deoxygenase Elα1. In order to optimize the energy supply structure, the upregulation of pyruvate deoxygenase Elα1 competitively inhibited dihydrolipoic acid dehydrogenation. For enzymes, the relationship between them in the metabolism of cardiomyocytes needs to be further explored.

The number point is identified as methylmalonate semialdehyde dehydrogenase [acyl], which plays a role in the metabolism of glycine and HI and belongs to the dehydrogenase family. There is no in-depth study of this protein in the field of sports medicine research: in this experiment, it was found that the expression level of this protein was upregulated by 6.3 times after 4 weeks of moderate-intensity aerobic exercise, which may bring new research content to the study of exercise to improve myocardial material and energy metabolism.

At present, with the continuous development of proteomics research technology, more and more researchers have applied proteomics and related technologies to the research of cardiovascular diseases and have made good progress, involving the expansion type proteomics research on cardiomyopathy, acute coronary syndrome, heart failure, hypertension, coronary heart disease, atrial fibrillation, myocardial infarction, vascular disease, and hyperlipidemia.

The research of sports heart proteomics is still in a preliminary stage of exploration. In recent years, the research on this topic is gradually increasing and deepening. The results of the study found that high-intensity exercise caused significant differences in the expression and quality of the proteome of rat myocardium. The effect of high-intensity exercise on the differential expression of the proteome of atrial and ventricular muscles in rats and exercise is studied. The duration of the load is related. With the extension of the duration of the exercise load, the rat's myocardial proteome changes adaptively, and the expression of more and more types and numbers of protein spots changes adaptively.

In this study, moderate-intensity aerobic exercise during a certain period of cycle does not require a large amount of amino acid to be mobilized for energy. After exercise, the expression of the above two proteins in atrial muscle
Figure 7: Comparison of physical fitness classification of middle school students after the intervention and during the backtest.

Figure 8: Comparison of changes in rats' physical exercise sensation after intervention and during backtesting.

probably was inhibited in order to save amino acids and protein in the body.

The research of sports heart proteomics is still in a preliminary stage of exploration. In recent years, the research on this topic is gradually increasing and deepening. Moderate-intensity aerobic exercise can make good adaptability changes in the heart. The study of the myocardium under this exercise intensity from the molecular level of protein can provide a theoretical basis for explaining the related mechanism as a whole. The changes in the myocardial proteome caused by long-term moderate-intensity exercise mainly occurred in the first 8 weeks, and different myocardial parts showed different differential expression characteristics.

Judging from the physical fitness classification of posttest and backtest, the physical fitness test results of the experimental group rats showed a phenomenon that the concentration of the rats in the test group rose from the "pass" level to the "good" level before the intervention, while, in the control group rats, all three physical fitness test results showed that they were gathered at the "pass" level (Figure 7). This also shows that intervention education has a good effect on improving the physical fitness of rats.

The exercise feeling test after the intervention showed (see Figure 8) that the comparison of the two dimensions of refreshment and active participation in the experimental group of rats was significantly higher than that of the control group ($P < 0.05$), and meanwhile, the quietness decreased, and fatigue sensation increased, but the difference between the groups was not significant (C0.05).

In this study, moderate-intensity aerobic exercise in a certain period of time does not require a large amount of amino acid mobilization for energy. It may be so in order to save amino acids and protein in the body; after exercise, the expression of the above two proteins in atrial muscle was inhibited.

The research of sports heart proteomics is still in a preliminary stage of exploration. In recent years, the research on this topic is gradually increasing and deepening. Moderate-intensity aerobic exercise can make good

adaptability changes in the heart. The study of the myocardium under this exercise intensity from the protein molecular level can provide a theoretical basis for explaining the related mechanism as a whole. The changes in the myocardial proteome caused by long-term moderate-intensity exercise mainly occurred in the first 8 weeks, and different myocardial parts showed different differential expression characteristics.

Long-term aerobic exercise can improve the heart and exercise capacity of the elderly to a certain extent, which in turn promotes the improvement of the cardiovascular skills of the elderly. From the perspective of proteomics, it can be seen that moderate aerobic exercise is beneficial to the heart and can provide a certain practical basis for cardiovascular rehabilitation and treatment of the elderly. Meanwhile, moderate-intensity and continuous practice can physiologically reshape the heart, guide the heart to transform to the direction of contraction and pumping function, and finally complete the continuous expression of differentiation.

5. Conclusions

The continuous development of social economy has promoted people's attention to the body more and more. How to effectively carry out physical exercise and enhance nutrition is extremely important. In response to these problems and limitations, aerobic exercise monitoring is performed for a certain period of time based on smart fog computing technology, through combining the business scope of myocardial proteomics, realizing the effective analysis of aerobic exercise on myocardial proteomics, and a certain verification is performed through simulation analysis. The experimental results show that the method is effective, can promote effective metabolism, and can achieve an effective improvement of digestive ability.

Traditional cold chain logistics has problems such as centralized data storage, low data reliability, easy data tampering, and difficulty in locating responsible persons, which leads to the inability to guarantee consumer rights. To solve these problems, a cold chain logistics traceability system is proposed for fresh agricultural products based on blockchain. Both alliance chain and private chain are used in the paper in order to ensure that the product traceability system not only has certain openness but also must contain enough privacy and security. Alliance chain is mainly used to query and share product traceability information. The private chain will be used to collect and store the product traceability information of each enterprise and then connected to the alliance chain via hash pointers. The proposed system is beneficial for reducing the burden of network transmission of alliance chain and improving the efficiency of consumer product data query. At the same time, the private chain ensures the security and privacy of enterprise product data, which not only has high data storage efficiency but also can meet the requirements of all participants for the traceability system. In the experimental part, the feasibility of this system is verified through simulation experiments, which provides a reference for the combination of blockchain technology and cold chain logistics traceability system.

1. Introduction

Agricultural products and cold chain logistics system from farmland to table involve production, processing, packaging, transportation, storage, sales, and other different links. Each link may have unsafe factors. In recent years, such incidents as "cadmium rice" [1], "aquatic crab," and "smuggled frozen meat" in Guangdong [2] and "malachite green" for bass [3] and "crayfish" in Nanjing have seriously damaged the interests of consumers [4]. At the same time, the production of fresh agricultural products and cold chain logistics enterprises also suffered a heavy blow. These events further triggered a crisis of trust between consumers and fresh agricultural products enterprises [5, 6]. Traceability system has become an effective means of supply chain quality management of fresh agricultural products by reducing

quality and safety risks, improving product recall efficiency, and ensuring public health [7, 8]. The research and establishment of cold chain logistics traceability system for fresh agricultural products, which can achieve effective supervision of the whole process from production to consumption, have become a hot issue of general concern.

The cold chain logistics traceability of fresh agricultural products involves agricultural supplies suppliers, farmers and other producers, processors, middlemen, and end consumers. Among them, middlemen further include logistics service providers, wholesalers, distributors, and retailers. Therefore, the cold chain logistics traceability system of fresh agricultural products is characterized by many points, long lines, wide areas, and intricate intersections [9, 10]. This makes food safety supervision and traceability particularly difficult in operation. The traditional traceability

system relies on the authority to manage the central database in practice, which has the problem of data centralization. Traceability data on each supply chain node is managed by the enterprise itself and is easy to be tampered with. At the same time, the reliability of information transmission among various roles in the supply chain remains to be solved.

Blockchain technology is characterized by tamability, distribution, decentralization, traceability, and high availability. Using these characteristics of blockchain, the combination of blockchain technology and cold chain logistics traceability of fresh agricultural products provides the possibility of solving the problems existing in the current traditional agricultural products traceability system. In recent years, domestic and foreign scholars [11–14] have carried out exploration and research in the field of agricultural product traceability. The existing methods are mostly based on the existing common blockchain systems such as Bitcoin, Ethereum, and Hyperledger Fabric system for application development. They have some bottleneck problems in data storage, such as low query efficiency, high data storage pressure, and poor data security. In practical applications, the following problems may occur when blockchain is used as a data management platform for traceability applications. As the quantity of nodes and data increases, the underlying storage system is frequently accessed by users. This puts forward high requirements on the function and performance of the data storage system.

Therefore, this paper proposed a cold chain logistics traceability system of fresh agricultural products based on blockchain, which is from the perspective of improving the efficient information storage and fast query efficiency of the cold chain logistics traceability system of fresh agricultural products. In order to ensure the high reliability of blockchain operation environment, the traceability system adopts the dual chain structure design of alliance chain and private chain. In the experiment, the feasibility of the system is verified by simulation experiment.

2. Related Work

2.1. Traceability to the Safety of Cold Chain Logistics.
Cold chain logistics generally refers to system engineering to ensure product quality and reduce product loss, keeping refrigerated and frozen products in a specified low temperature environment all the time. Production, storage, transportation, distribution, sales, and consumption before the purchase of each link are included among them. Studies have found that every $6°$ increase in temperature will double the growth rate of bacteria in food and shorten the shelf life by half [15]. When ambient temperatures rise at any point, bacteria multiply more quickly. This is the impact of temperature change on food safety that most people are not aware of.

The essence of traceability is to turn the physical circulation of industrial chain into information flow. The production and circulation information of products can be obtained according to the tracking and query of information flow [16]. Agricultural product safety traceability refers to

the ability to track the flow of products when there are safety problems in agricultural products, then recall the problematic food, cut off the source, and eliminate the harm. Therefore, each link needs to record the corresponding information from the production, circulation, and final consumption of agricultural products. For consumers, traceable agricultural products provide transparent product information. This enables consumers to fully enjoy the right to know when buying and to make the right purchase choice. It has always been regarded as the most complicated and difficult part of food traceability because of the wide circulation range, long chain, and many links of agricultural products.

The accurate and real-time whole process record provided by cold chain logistics provides conditions to trace agricultural product information accurately and effectively. The working principle of cold chain logistics relies on modern information technology with the help of advanced management methods and organization. Typically, a combination of RFID (Radio Frequency Identification), GPS (Global Positioning System), GIS (Geographic Information System), mobile communications, and temperature sensing technology is used [17]. Then, the record of temperature and humidity change is uploaded to the management platform for real-time management of product quality. This intelligent, information-based cold chain logistics process provides technical support for agricultural products traceability. However, in order to complete the traceability management of agricultural products, it is necessary to establish the necessary basic information base for its core information such as planting, storage, processing and distribution, sales, and consumer attention. Through the information management platform, the discovered problems can be queried, and the generated problems can be held accountable.

2.2. Basic Introduction to Blockchain

2.2.1. Blockchain.
Blockchain is a chain structure of blocks of data arranged in chronological order through cryptography algorithms. It can realize decentralized, tamper-proof, traceable, and multiparty jointly maintained distributed database [18]. Each party must agree to update the data according to the pre-agreed rules and implement information sharing and monitoring among the parties. Blockchain integrates P2P network, cryptography [19], smart contract [20], consensus mechanism [21], timestamp [22], blockchain structure, and other technologies. It can realize self-verification and management of data without relying on third parties.

2.2.2. Block Structure.
Blockchain is an ordered chain of data block structure with block as unit, and each block is composed of block head and block body [23]. As shown in Figure 1, each block header contains the hash value of the previous block header. The original block is connected to the current block and forms a chained data storage structure. The properties of the Merkle tree structure and the connection between timestamps and blocks are
FIGURE 1: Structure diagram of block data.

utilized to ensure that each block is connected chronologically and the data is not susceptible to tampering [24]. Even if it is tampered with, it can be quickly located, which ensures the reliability and credibility of the traceability system data [25].

2.2.3. Hash Algorithm. The hash algorithm can map data of any length to a short-fixed length binary value through hash function [26, 27]. It is an irreversible mapping from plaintext to ciphertext; that is, the same input always yields the same output. Using the characteristics of hash function, it can not only verify whether trace data is tampered with, but also ensure the security of data. In practical applications, MD5 [28] algorithm is usually adopted, which generates a 32-bit hexadecimal sequence value for the input of arbitrary length string.

2.2.4. Blockchain Classification. According to the degree of regional decentralization, blockchain is mainly divided into public chain, alliance chain, and private chain [29]. In the traceability system, the responsible subjects of the agricultural supply chain belong to the cooperative relationship, but at the same time, they cannot be completely trusted. There is already association, horizontal interconnection and cooperation, or vertical transaction relationship. Therefore, alliance chain is usually used as

the technical framework for agricultural product traceability system research [30].

3. The Proposed Model in This Paper

3.1. Cold Chain Logistics Process Analysis of Fresh Agricultural Products. In order to design the traceability system of fresh agricultural products, the management mode of its generation to sales will be analyzed first, and then the traceability management method will be designed according to the characteristics of each link. The main body of "base-+ supermarket" agricultural cold chain logistics is clear, and the key points of traceability information flow are easy to define compared with other complex and diverse circulation forms of agricultural products. The specific process is as follows.

3.1.1. Planting and Harvesting. When agricultural products are still in the "field," their growth process will suffer from the soil pesticide residues, heavy metals, and other irreversible harm. Improper fertilization can also cause quality problems in agricultural products. Therefore, all production plots and greenhouses need to be numbered uniformly. The turnover box of picking agricultural products should also be managed by numbering, and strict and accurate records should be made. The harvest time of agricultural products is

short, and the process has little impact on the quality of agricultural products. In this stage, process records and quality testing reports are mainly carried out.

3.1.2. Storage and Processing. Harvested agricultural products that are not immediately listed need to be stored or circulated for processing. This link should strengthen production monitoring. The agricultural products cold storage requirements and the absolute safety of processing are ensured, depending on the temperature sensing technology. In this link, records of storage temperature, humidity, processing, and storage time should be made.

3.1.3. Transportation and Distribution. Transport vehicles for agricultural products shall comply with health requirements and be equipped with a continuous output of temperature records that cannot be artificially altered. The docking of agricultural product information should be carried out before transportation and distribution. In the process of distribution and transportation, GPS and GIS should be relied on to track and monitor the situation of agricultural products and refrigerated vehicles. This is to prevent damage to agricultural products caused by improper handling or microbial damage. In this link, records of transportation temperature, humidity, geographical location, and transportation time should be made. The logistics information recording process is shown in Figure 2.

3.1.4. Supermarket Sales. The sales of agricultural products still need refrigeration preservation technology to ensure the quality of agricultural products, which usually should be displayed and sold in accordance with the storage temperature and humidity of agricultural products. In this link, the refrigeration temperature, humidity, purchase and sale time, and other information should be well recorded.

The record of the above key points provides the prerequisite for the establishment of agricultural products traceability system. First, base operators generate retrospective two-dimensional code for the harvested agricultural products according to the production number and paste it on the packaging of agricultural products. The additional information is mainly the production experience of agricultural products, for example, the planting date; the fertilization date; the fertilization duration; and the use of pesticides, growth promoters, and other related auxiliary products. Record the names; sources; users; and pickers of pesticides, fertilizers, and regulators used. Upload production file information to the platform through information technology. In the subsequent cold chain logistics, the storage file, transportation file, and distribution file of each link should be recorded. Then, the cold chain logistics operator will upload them to the platform in real time. Finally, consumers who buy products at a supermarket scan a QR code on the package. Users can query the detailed information and quality test report of agricultural products from planting, production, transportation, storage, and sales through the platform. At the same time, the upstream subject can also track the information of agricultural products in each link of circulation through the platform. The traceability system of "base + supermarket" agricultural cold chain logistics integrates the records of planting, collection, and key points of cold chain logistics into the database information of the traceability system. Through the operation of the traceability service management platform, the main body of the agricultural supply chain can share information and achieve convenient and accurate traceability of agricultural products.

3.2. Data Structure of Private Chain and Alliance Chain

3.2.1. Participant Setting of the Anticounterfeiting Traceability System. The function and nature of product traceability determine that it has many participants, mainly including various manufacturers, relevant national departments, and consumers. Product traceability system must contain sufficient privacy and security while requiring certain openness. This paper proposes an anticounterfeiting traceability system using both alliance chain and private chain. The alliance chain is mainly used to query and share product traceability information. The private chain will be used to collect and store the product traceability information of each enterprise and then connected to the alliance chain through the hash pointer. This design method is beneficial for reducing the burden of network transmission of alliance chain and improving the efficiency of consumer product data query. The private chain ensures the security and privacy of enterprise product data. It not only has high data storage efficiency, but also can meet the requirements of all participants for the traceability system. The production department, transportation and storage department, sales department, information technology department, and national supervision department of each enterprise jointly maintain the private chain and add product traceability information and audit information of the supervision department to the private chain. Among them, the state supervision department, as the organizer of the private chain, will participate in the audit and authorization of enterprises. The information technology department is responsible for collecting information packaging blocks as the holder of billing rights for the private chain. Other departments in each enterprise and national law enforcement departments jointly maintain the alliance chain and provide external tracing information query function.

3.2.2. Product Traceability Information Structure. Blockchain does not prevent the initial data fraud; that is, it does not prevent companies from falsifying product raw materials, warehousing, and other information. Thus, companies will use IoT (Internet of Things) technology to monitor production, processing, and warehousing in real time and establish a set of intelligent production lines and storage lines to ensure the authenticity of the source data reliability.

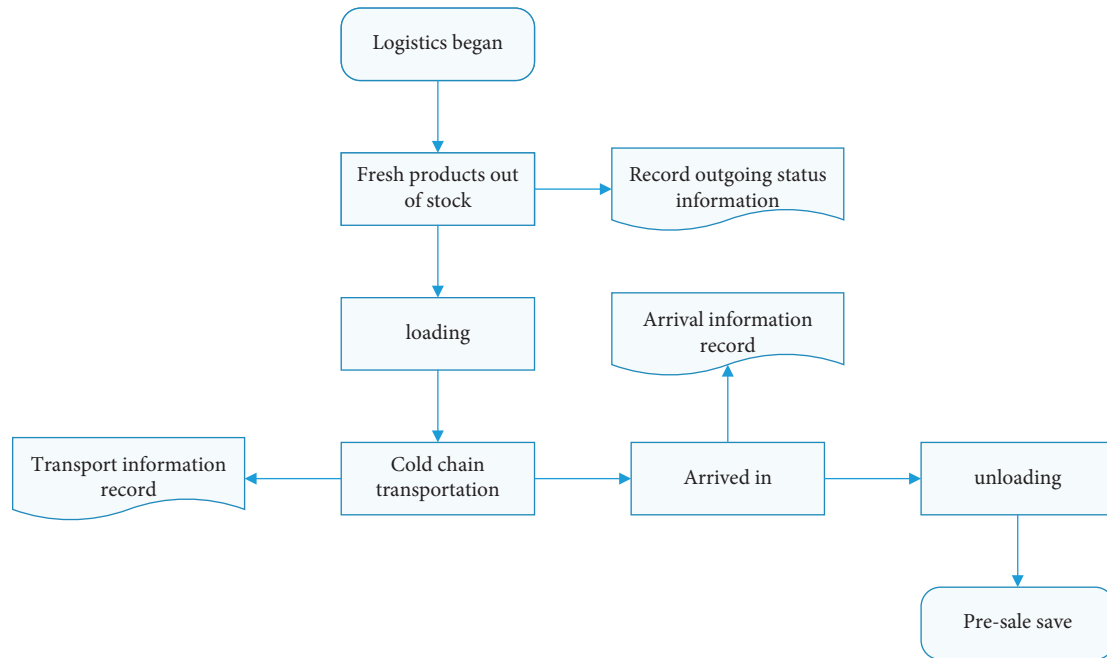
As shown in Table 1, for a certain product, the production information P generated by the production department of the enterprise includes but is not limited to


FIGURE 2: Logistics information recording process.

product ID, product name, raw material information (recorded by sensors and transmitted to the production department), signature S_x of the person in charge, and hash value $H(P)$ of the production information.

As shown in Table 2, for a certain product, the transportation and storage information T generated by the transportation and storage department of the enterprise includes but is not limited to transportation time, transportation mode, storage information (transmitted through temperature sensors, etc.), signature S_y of the person in charge, and hash value $H(T)$ of the transportation and storage information.

As shown in Table 3, for a certain product, sales information S generated by the sales department of the enterprise includes but is not limited to sales time, sales quantity, sales method, signature S_z of the person in charge, and hash value $H(S)$ of sales information S.

In order to prevent enterprises from tampering with their product traceability information, the above three types of traceability information should also be submitted to the national regulatory authorities for audit, and the audit information C can be obtained. Using the input sensitive property of hash function, check whether trace information is tampered with. In case of alteration, responsibility can be quickly confirmed according to the signature of the person in charge in each process to prevent the circulation of illegal products. If there is no alteration, it will be handled by the enterprise information technology department.

After the examination and verification by the national supervision department, the information technology department of the enterprise shall collect production information P, transportation and storage information T, sales information S, and audit information C, and then S_i is signed by the head of the information technology department. A transaction in a private chain block, the structure of which is shown in Table 4 is constituted.

After the above procedure is performed, a secure and reliable private chain of product traceability information will be generated. In order to prevent the leakage of enterprise privacy data, enterprises can only query the information of their own products on the private chain. Due to the large amount of data transmitted in the private chain, it is not suitable for transmission in the alliance chain that provides the query function. Therefore, it is not necessary to store complete product traceability information in the alliance chain block body, but to store the block header hash value of each block in the private chain. This can improve the efficiency of data transmission in the alliance chain. At the same time, according to the characteristics of Merkle tree and hash function, product traceability information items will correspond one by one, and there is no confusion of traceability information. The header of the block in the alliance chain consists of the current block hash, the hash of the previous block header, the timestamp, the Merkle root, and the associated responsible signature. The block body contains the hash value of each block header in the private chain. Figure 3 shows the data structure of the private and alliance chains.

3.3. The Proposed Cold Chain Logistics Traceability System

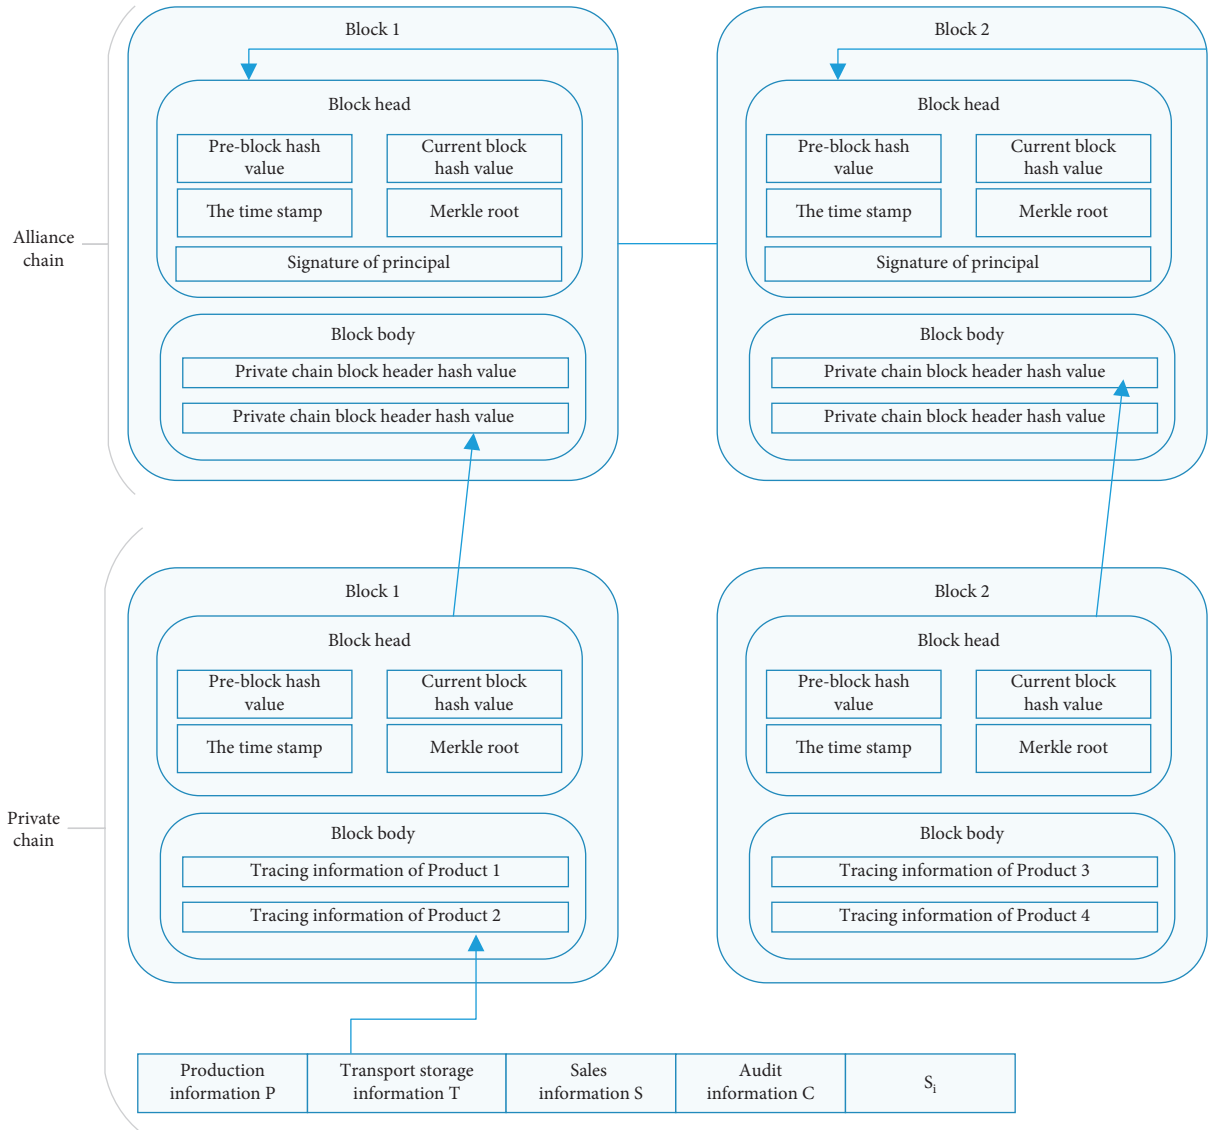
3.3.1. Storage Mechanism Design. There are many participating nodes in the blockchain-based agricultural supply chain, and the data collection volume of nodes in each link is large. If all the nodes are uploaded to the blockchain network at one time, in addition to the slow upload speed, the operation cost will be greatly increased, and the hardware requirements for nodes in each link will be high. Therefore,


FIGURE 3: Data structure of private chain and alliance chain.

TABLE 1: Production information.

Product ID	Product name	Raw material information	S_x	$H(P)$

the dual-storage mechanism will be adopted in this paper; that is, the collected data information of nodes in each link will be stored together in the blockchain network and the relational database. However, the summary of information generated by SHA-3 (Secure Hash Algorithm 3) is stored in the blockchain network, while the complete information is stored in the database. This not only improves the operational efficiency of blockchain, but also solves the scalability problem faced by blockchain.

3.3.2. Design of the Traceability System of Fresh Agricultural Products. After the above process analysis and storage mechanism design of agricultural supply chain, the structure

diagram of agricultural product traceability scheme is designed, as shown in Figure 4.

The data stored in the traceability solution is stored by the blockchain system and the database. Introducing the relational database can solve the scalability problem of the blockchain system. Only a summary of the data is stored in a blockchain system, and the complete data is stored in a database. The database is maintained by the Administration for Industry and Commerce, while the blockchain system is jointly maintained by production enterprises, transportation enterprises, warehouse storage enterprises, sales enterprises, Food and Drug Administration, and Industry and Commerce Administration. The original intention of this system is to provide traceability inquiry services for consumers and provide more convenient and efficient supervision services for the regulatory authorities, so it also includes external users such as the regulatory authorities and consumers.

The information input process of the production enterprise, transportation enterprise, warehouse storage

TABLE 2: Transportation and storage information.

Transportation time	The mode of transportation	Storage information	S_y	$H(T)$

Sales time	The sales amount	Sales way	S_z	$H(S)$

TABLE 4: Private chain transaction structure.

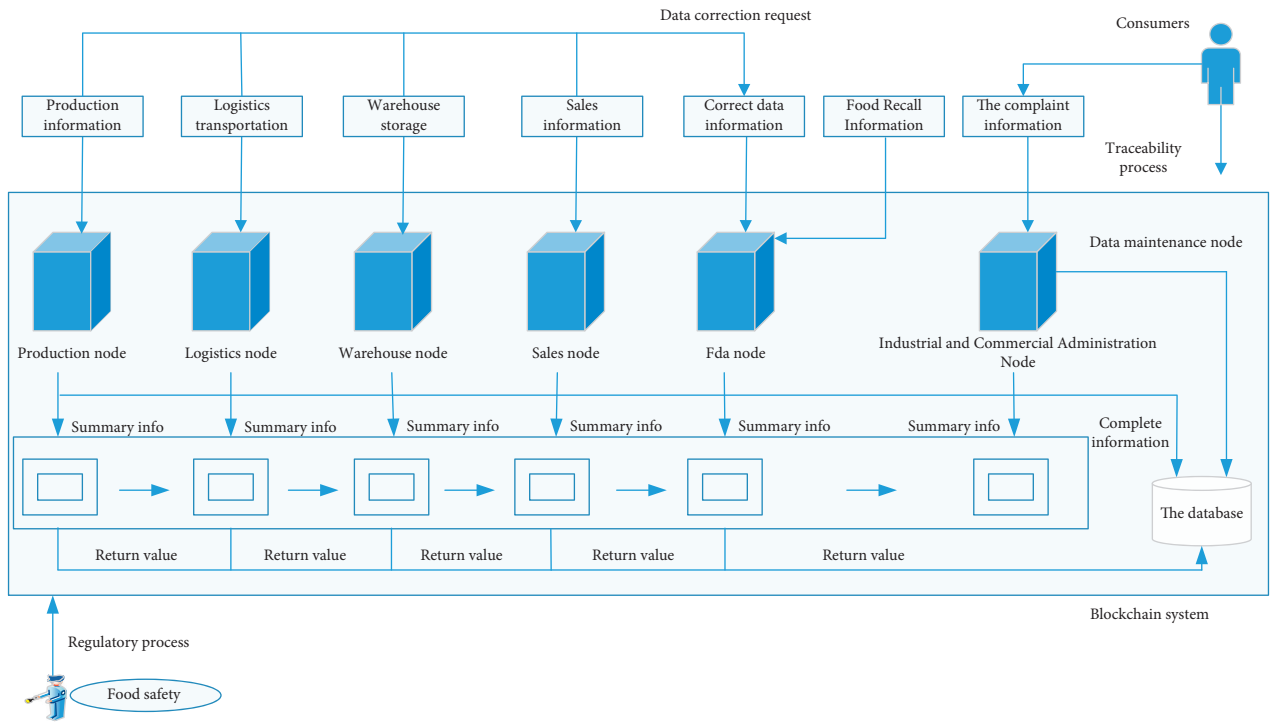
Production information P	Transport warehouse information T	Sales information S	Audit information C	S_i


FIGURE 4: Structure of the proposed traceability system.

enterprise, and sales enterprise is the same. Taking the production enterprise as an example, the production enterprise packages the collected data and inputs it into the node and database at the same time. The production enterprise node generates a summary of the input data using SHA-3 and sends it to the blockchain. After reaching a consensus, the participating nodes write a summary of the information into the block. At this point, the block returns a hash value to be stored in the database, which can be used for data indexing. The Administration for Industry and Commerce and the Food and Drug Administration supervise the behavior of the above nodes.

Consumers purchasing food can use the code on the package in the database for traceability inquiry. If you have doubts about the queried information, you can query and compare the summary of the information in the blockchain to determine whether the data has been changed. If the information summaries are consistent, the data is true and unchanged. When it is found that the query data has been changed, consumers can complain to the Administration for Industry and Commerce. The complaint information will be

stored in the database and blockchain system in the same way as evidence.

Due to the large amount of data collected in each link of the agricultural supply chain, information may be omitted or incorrectly recorded due to manual error or other external interference during information input. In addition, once the information is entered into the blockchain system, the data cannot be changed, so the Food and Drug Administration is introduced into this scheme. If any node in the agricultural supply chain finds any error in the input information, it can send an information correction request to the Food and Drug Administration. After being verified by the Food and Drug Administration, the corrected information can be uploaded to the blockchain system by the FDA node. These methods can eliminate the huge loss of information input errors caused by human operation errors.

The design of agricultural product traceability scheme based on blockchain ensures that data cannot be tampered with and the centralized structure is removed. The traceability of information flow has realized the function of quick search and accurate positioning. According to the actual

needs of targeted introduction of Food and Drug Administration and Industry and Commerce Administration. The Food and Drug Administration can not only deal with information entry errors at all stages of the supply chain, but also provide data correction needs. It can also recall problematic food that may cause damage to human health. The Administration for Industry and Commerce is responsible for the timely acceptance of consumer complaints. Information about complaints that may damage consumers' health will be shared with the Food and Drug Administration in a timely manner, carrying out food recall work in a timely manner.

3.3.3. Traceability Architecture Based on Blockchain.

Figure 5 shows the traceability system hierarchy based on blockchain. The architecture is mainly divided into six layers from bottom to top, namely, operation layer, data acquisition layer, data layer, consensus and network layer, presentation layer, and user layer. The bottom layer is the operation layer, which refers to the production enterprises, transportation enterprises, warehouse storage enterprises, and sales enterprises that need to collect data. It is the source of the entire traceability data. Data acquisition layer refers to the use of radio frequency devices, information acquisition terminals, and application sensors to collect and transmit data at the operation layer and can improve the overall efficiency of agricultural supply chain. The data layer transfers data from the data acquisition layer to the data storage layer. It adopts the dual blockchain mechanism of alliance chain and private chain. Only a summary of the processed information is stored in a blockchain network, while the complete data and the hash values returned after the summarization are stored in a relational database. Consensus and network layer refers to key technologies of blockchain including P2P network, authentication mechanism, propagation mechanism, and PoW and PoS consensus mechanism. Presentation layer refers to the use of B/S architecture and JSP (Java Server Pages) technology to display data according to user needs. The top layer is the user layer, including production enterprises, transportation enterprises, warehouse storage enterprises, sales enterprises, regulatory departments, and consumers. Production enterprises, transportation enterprises, warehouse storage enterprises, and sales enterprises are responsible for information entry. Regulatory authorities and consumers can query product information in the system according to their needs.

4. Experiment

4.1. Experimental Environment.

In this simulation experiment, three PCs are mainly used to achieve traceability by building simulation private chain, alliance chain, and traceability platform. The experimental environment is shown in Table 5. The test is conducted in virtual machine simulation test, and its environment is based on CentOS 8.0. The operating memory is 8 GB, the hard disk is 500 GB, and the bandwidth is 200 Mb/s. The Fabric network contains four Peer nodes and one Orderer node. The default LevelDB database in the Fabric has a single query form. CouchDB meets real world needs and supports rich queries. Composite keys are modeled to support equivalent queries for multiple parameters. Therefore, this paper chooses CouchDB as the test database. Node SDK was used to develop test programs, and REST interface was used to call resources.

4.2. Analysis of Data Generation Efficiency.

In the experiment, a simple private chain system was built on PC1 to store detailed product traceability data, in which raw material information and storage information were roughly represented as product origin and raw material storage place. The traceability data of 20 kinds of products are simulated in the experiment, and the traceability function is realized by connecting them together according to previous_hash. At the same time, any modification of the data will destroy the chain structure and ensure that the data cannot be modified by changing.

Then, a simple alliance chain system is built on PC2 to store the hash value of the block header of the private chain.

Finally, a small product information traceability platform is built on PC3, and its data sources are from private chain and alliance chain. For the query of the traceability data of a product, the system will automatically take its hash value after the user enters the commodity name and then turn it over to the relevant block of the private chain for search after the processing of the alliance chain. The data will be returned to the platform matching request first and then to the user data. If the traceability information is not found, the user can submit feedback.

In terms of system performance, the running time of the anticounterfeiting traceability system proposed in this paper is mainly spent on the collection, transmission, and audit of traceability data. In the process of generating traceability data, the sensor can transmit accurate data in real time and consume less time. In addition, the information generated by each department depends mainly on network factors. As shown in Figure 6, under common network conditions, the system built in this paper was tested 20 times, in which the generation time of private chain transaction data ranged from 524 to 890 ms, with an average of 632 ms. The generation time of alliance chain transaction data ranged from 513 to 73 ms, with an average of 617 ms.

4.3. Query Efficiency Analysis.

Based on realizing the design of the above traceability system, it is necessary to show the information of the growth and circulation of agricultural products to consumers. Therefore, it is necessary to quickly trace the information of agricultural products batch. According to the different ways of storing blockchain traceability data, there are two commonly used query methods as follows:

(1) The first method is the key traversal query, namely, key method. Data information items about the growth, processing, logistics, and sales of agricultural products will be written into the blockchain one by
FIGURE 5: Hierarchy diagram of the proposed traceability system.

TABLE 5: Description of experimental environment.

Name	CPU/memory	Operating system	Main function
PC1	i7-9700/8 GB	CentOS 8.0	Deploying private chains
PC2	i7-9700/8 GB	CentOS 8.0	Deploying alliance chain
PC3	i7-9700/8 GB	CentOS 8.0	Building traceability platform

one. The ID of the traceability information is used as the key value, and the traceability information is stored in the blockchain as the value. The key is used as the index to traverse the previous block from the latest block to obtain the matching value during querying the traceability information. In addition to the fresh agricultural product traceability business, there are multiple traceability information uploading records of agricultural product batches. Batch information is usually obtained during query, requiring multiple traversals of the block by key. The number of iterations is related to the number of agricultural products batch traceability records.

(2) The second method is to query information by the field of batch number, namely, batch method. Specifically, the growth, processing, logistics, and sales of

agricultural products are written into the blockchain. The ID of the traceability information is used as the key value, and the traceability information is stored in the blockchain as the value. The query uses CouchDB's rich query to traverse from the latest block to the previous block by the batch number field in value. To obtain all the traceability information of a batch of agricultural products, you only need to traverse all blocks once to get all the traceability information of a batch of agricultural products.

This paper tests and compares the above two query methods. During the experiment, the same query operation is executed under the same circumstances, and the query time will fluctuate in a certain range. To ensure the objectivity of the data, each set of data is executed 10 times, and its average is calculated as the final value. The above methods were used to test the
Figure 6: Time of data generation.

experiment, and the correlation analysis of the test results was carried out. The correlation coefficient can be calculated by

$$R_{(X,Y)} = \frac{\text{Cov}(X,Y)}{\sqrt{D(X)}\sqrt{D(Y)}}, \qquad (1)$$

where $\text{Cov}(X,Y)$ is the covariance of X and Y. $D(X)$ and $D(Y)$ are the variances of X and Y, respectively.

The comparison diagram of the relationship between the query time and the number of trace records under the specific total amount of trace records for these two query methods is shown in Figure 7. Figures 7(a)-7(c) show the comparison of query time in two different ways when the total number of retrospective records is 1×10^4, 5×10^4, and 9×10^4, respectively. The abscissa is the number of batch traceability records, which is 1, 200, 400, 600, 800, and 1000. The ordinate indicates the time it takes to query information. R represents correlation coefficient. Among them, the query time of key method is positively correlated with the number of batch traceability records. Correlation coefficients R were all >0.89. However, the correlation coefficients of time and trace records by batch method were all <0.5, showing a weak correlation.

Based on the above correlation analysis, the query efficiency improvement rate of the two methods is further analyzed, and its calculation equation is

$$n_{(A,B)} = \frac{t_B - t_A}{t_B} \times 100\%, \qquad (2)$$

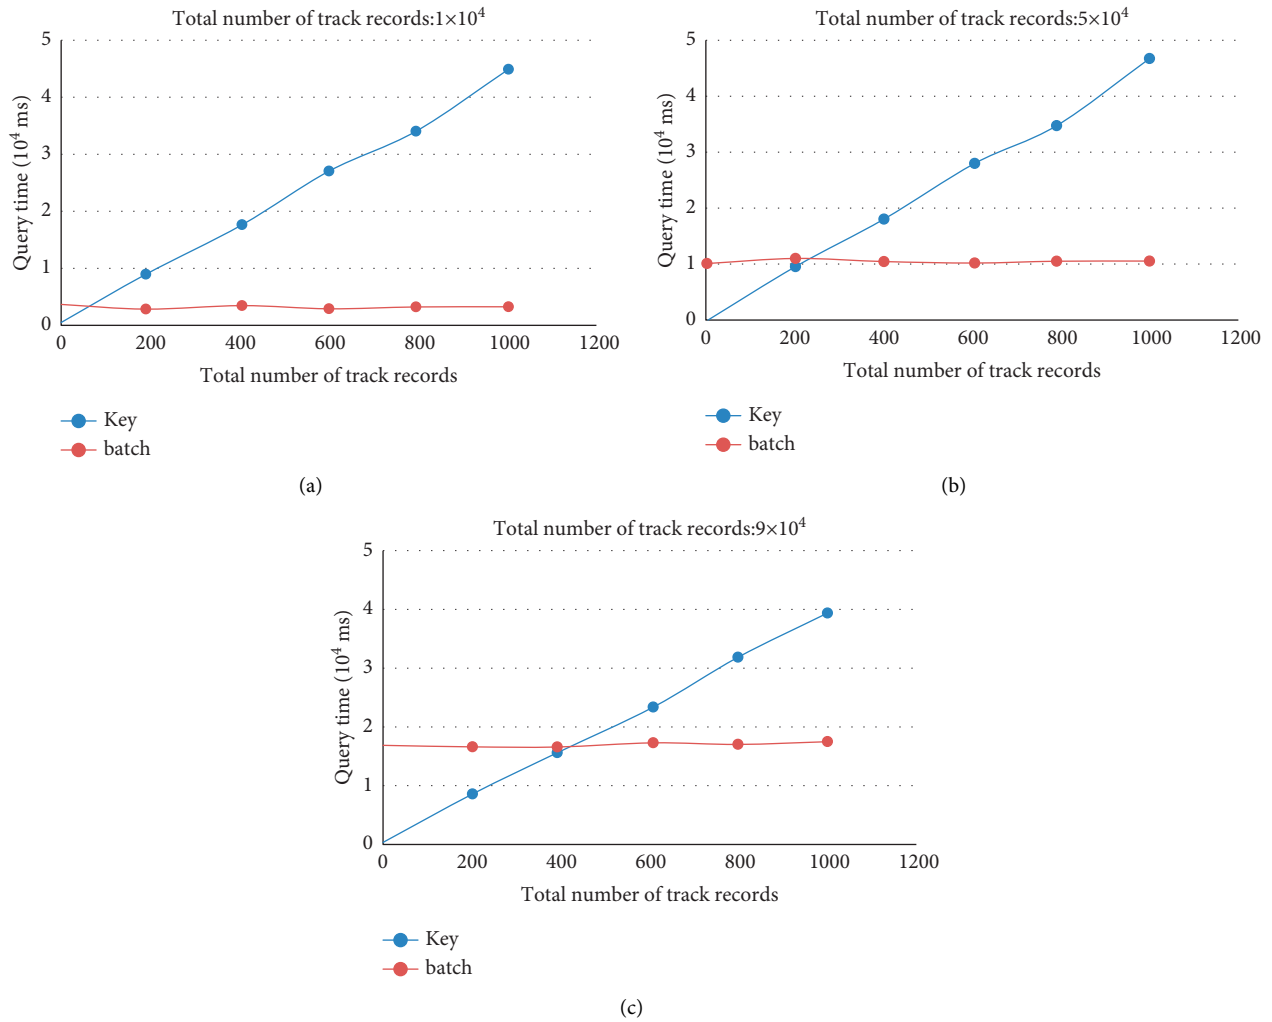
where $n_{(A,B)}$ represents the efficiency improvement rate of A over B. t_B and t_A represent the time required by A and B, respectively.

As can be seen from Table 6, when querying a single traceability record, the query efficiency of batch query method fluctuates compared with that of key method. This is because the time required by a single query is small and the data fluctuation interval is large, resulting in a large difference in query time. When the number of batch traceability records is more than 200, the query efficiency of batch query method is basically stable at 60.77%–

72.42% compared with key method. In practice, agricultural product batches are recorded in the range of 200–400, while the total number of traceability records in the blockchain system increases with each node and time. When the number of batch traceability records is 200, and the total number of traceability records is 1×10^4, 3×10^4, 5×10^4, 7×10^4, 9×10^4, and 11×10^4, the query efficiency of batch method is improved by 70.77%, 71.43%, 69.53%, 69.58%, 69.2%, and 67.73%, respectively, compared with key method. When the number of batch traceability records is 400 and the total number of traceability records is 1×10^4, 3×10^4, 5×10^4, 7×10^4, 9×10^4, and 11×10^4, the query efficiency of batch method is improved by 70.35%, 73.33%, 70.91%, 69.82%, 69.16%, and 71.57%, respectively, compared with key method. From the perspective of the number of batch traceability records, the query efficiency of the content query method increases with the increase of the total number of traceability records.

4.4. System Security Analysis. The anticounterfeiting traceability system based on double blockchain and Internet of Things technology proposed in this paper has strong security, which is mainly reflected in the following aspects:

(1) Any modification of product traceability data will inevitably break the blockchain chain structure based on the security of blockchain itself, such as decentralization, immutability, and high fault tolerance. This increases the cost and difficulty of data modification and ensures the authenticity and reliability of traceability data. At the same time, it can also urge enterprises not to fabricate information in the process of product production to a certain extent.

(2) Use the Internet of Things technology to generate real and objective product data and transfer it to the product data of relevant departments to block the possibility of data source fraud. This measure improves the security and reliability of product traceability data.


(a)

(b)

(c)

Figure 7: Time comparison between the two query methods.

Table 6: Percentage of efficiency improvement.

Total traceability record	Number of batch total traceability records (batch method is compared with key method)					
	1×10^4	3×10^4	5×10^4	7×10^4	9×10^4	11×10^4
1	34.07	7.1	11.96	8.86	21.78	-22.37
200	70.77	71.43	69.53	69.58	69.2	67.73
400	70.35	73.33	70.91	69.82	69.16	71.57
600	69.98	70.43	70.3	64.87	69.85	70.34
800	70.85	71.08	70.78	68.96	72.42	71.38
1000	60.77	68.74	64.21	61.92	60.23	65.85

(3) The double-chain structure of alliance chain and private chain can ensure the high reliability of blockchain operation environment. Alliance chains and private chains are built, deployed, and run based on a trusted partnership. All participants are vetted before joining the blockchain network, which greatly

reduces the possibility of malicious nodes in the system. This can also prevent internal attacks, further improving the security of the system.

5. Conclusion

On the premise that more and more people pay attention to product safety, many problems of traditional product traceability system, such as centralized storage, low reliability of data, easy data tampering, and difficulty in locating the responsible person, are analyzed in this paper. Besides, the related work of other scholars in the field of product traceability is sorted out, and the characteristics of information traceability and non-tampering of blockchain technology are expounded. In order to solve the security and privacy problems in the cold chain logistics traceability system of fresh agricultural products, a traceability system based on blockchain is proposed in the paper. Specific work includes the following: (1) The whole process of cold chain logistics of fresh agricultural products is systematically analyzed. (2) The data structure of private chain and alliance chain is analyzed. (3) Logistics traceability system based on private chain and alliance chain is designed. The alliance chain is mainly used to query and share product traceability information. The private chain will be used to collect and store the product traceability information of each enterprise and then connected to the federation chain via hash pointers. The feasibility of this system is verified by simulation experiments, which provides reference for the combination of blockchain technology and cold chain logistics traceability system. At present, the product anticounterfeiting traceability system using blockchain technology is still in the initial stage of exploration, and its applicable product types need further analysis. There are also some security issues with its integration with the Internet of Things. The next step will continue to refine the details of the combination of the two and improve the product traceability system.

Traditional agricultural product traceability system adopts centralized storage, and the traceability process is solidified, which results in the low reliability of traceability results and the poor flexibility of the system. Aiming to solve this problem, blockchain technology is applied to supply chain traceability, and a supply chain traceability system based on sidechain technology is proposed. Goods management, information sharing, and product traceability in supply chain are realized through Ethereum smart contract. The sidechain technology is adopted to expand Ethereum so that it can meet the needs of practical applications. The experiment results show that the proposed system has a transaction function and information sharing function. Compared with similar trading systems, the proposed system has more advantages in throughput and security.

1. Introduction

ptTraceability of agricultural products refers to the forward tracing and reverse tracing of all links of the industrial chain from production to circulation of agricultural products [1]. After years of development, the traceability system of agricultural products in China is becoming perfect. However, it still has some problems, such as low reliability of traceability results and poor system flexibility. From the very beginning, the agricultural product traceability system has attracted the attention of experts at home and abroad. As early as 2002, the US Congress passed the "Bioterrorism Act" to establish the traceability system of agricultural product quality and safety [2]. So far, the community has reached a consensus on the importance of traceability of agricultural product quality and safety. The construction of relevant systems and systems has also achieved initial results, but there are still many problems in practical work.

In the context of the rapid development of industry 4.0, many new technologies have been applied in the production,

management, and harvesting of agricultural products. The application of these technologies makes the production management of agricultural products more intelligent, efficient, and transparent. Among them, agricultural product traces technology also to ascend a new step. Literature [3] describes the possibility of realizing food quality testing during transportation from manufacturer to consumer. It uses a sensor remote monitoring system combined with the Internet of Things technology to propose a low-cost solution based on Internet of Things real-time food tracking and food transportation process monitoring. Although the Internet of Things technology is mature enough, the production and sales system of agricultural products involves many subjects, complicated uncertainties affecting the system, and large resource consumption for real-time monitoring with the help of sensors [4]. These will lead to difficult and inefficient management of quality and safety traceability system; especially, data storage security is still facing many challenges and problems.

In order to improve the reliability and flexibility of agricultural product traceability system, blockchain can

be used to replace the traditional centralized database. It ensures the safe storage of traceability data and non-repudiation of information source to achieve reliable traceability of agricultural products [5]. In addition, it can decouple the whole industrial chain into multiple independent links and combine them with independent channels in the super ledger into link modules. It can coordinate with the module allocation mechanism, dynamically adjust the traceability process according to the actual production, and finally realize the dynamic traceability of agricultural products. In literature [6], it is proposed to use blockchain distributed storage technology to solve the possibility of tampering or destroying data in the data storage stage by virtue of the irreversibility of blockchain.

Developed from the underlying technology of Bitcoin, blockchain is a distributed storage technology featuring decentralization, traceability, nontampering, openness and transparency, consensus mechanism, and transaction anonymity. However, compared with other industries, blockchain technology for agricultural product quality and safety traceability puts more pressure on the storage of IoT data. In order to achieve the consistency of distributed nodes, the block generation speed and transaction processing capability of blockchain are limited. Therefore, it is not possible to directly apply blockchain technology to process and store large amounts of sensor data. In order to solve the storage problem, cloud computing and cloud storage technologies are used in literature [7] to provide applications. As mentioned in literature [8], the traditional security problems still exist in cloud computing environment, and even traditional security mechanisms are no longer applicable to applications and data in cloud. In literature [9], the dual-chain structure of blockchain is proposed, which uses a chained data structure to store blockchain transaction hashes. It works with the blockchain to form double-chain storage that ensures that agricultural data cannot be tampered with or destroyed. As there are many standards involved in agricultural product traceability, effective policy control is needed for participating nodes. As the amount of data increases, the efficiency of blockchain transactions also increases. A complete public chain can no longer meet these variable needs. Compared with public chain, alliance chain has more advantages in high availability, high performance, programmability, and privacy protection. It is considered as the "partially decentralized" or "polycentric" blockchain. Alliance chain simplifies the number of nodes, which can make the system run more efficiently and cost less. It can confirm that the number of transactions per unit of time is much larger than the public chain, and it is easier to land in the agricultural product quality and safety traceability system.

There are two main problems in big data recording. The first is the issue of record speed caused by the blockchain consensus algorithm. While anyone is free to use Bitcoin's blockchain, only seven writes per second are the limit of its performance. The second is the boundary of the number of participating nodes. Even in participant-limited blockchains targeted at commercial use, the performance deteriorates

dramatically when the number of participating nodes exceeds a few dozen.

In view of the problems existing in the traditional agricultural supply chain system, such as difficulties in trust transmission, opaque transaction information, and difficult information sharing, this paper proposes an agricultural products traceability system of blockchain. In the agricultural product traceability system, the performance of the blockchain is affected as the agricultural product data increases. Sidechain technology can provide some functions such as smart contracts and privacy protection on top of the main chain. These features ensure that users can use them without affecting the performance of the main chain. Therefore, in order to improve the performance of the main chain, this paper uses sidechain technology to expand the capacity of Ethereum to meet the demand of supply chain traceability information on the chain. The innovations and contributions of this paper are listed as follows:

(1) Aiming to solve the problem that the traditional agricultural product traceability system has the low reliability of traceability results and poor flexibility, this paper proposes a supply chain traceability system based on sidechain technology.

(2) Goods management, information sharing, and product traceability in supply chain are realized through Ethereum smart contract. The sidechain technology is adopted to expand Ethereum so that it can meet the needs of practical applications.

The structure of this paper is as follows. The traditional agricultural products traceability system is described in the next section. The current state of blockchain traceability systems is described in Section 2. Section 4 focuses on the design of an agricultural product traceability system. Section 5 presents the experiment and analysis. Section 6 is the conclusion.

2. Traditional Agricultural Products Traceability System

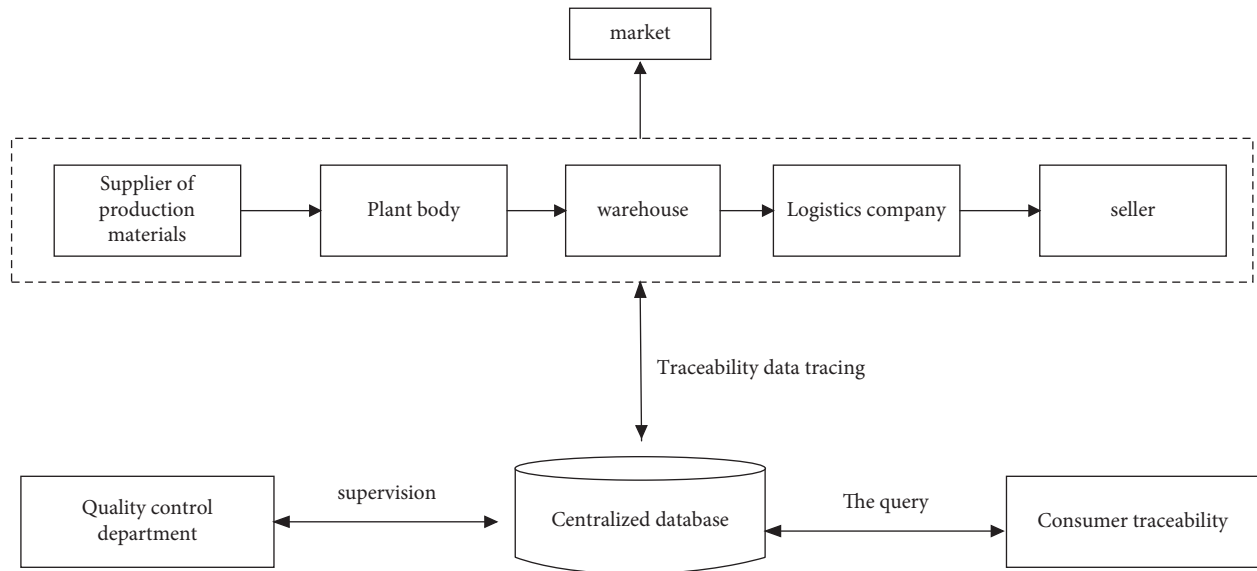
2.1. Traditional Traceability Mode. In 2006, China proposed the establishment of agricultural product quality and safety traceability system [10], which has achieved fruitful results after years of development. Literature [11] proposed a technical system of agricultural product quality safety traceability system of "one core, two axes, and three chains" based on the characteristics of Internet of Things technology. Literature [12] proposed the traceability chain hierarchical model of the traceability system based on the food chain. Literature [13] designed a multilateral traceability system for agricultural product quality safety in view of the decentralized and noncentralized characteristics. Literature [14] constructed a design scheme of agricultural product quality traceability system based on Fabric blockchain implementation strategy. By analyzing the typical traceability system, the traceability model of traditional agricultural products is obtained, and its structure is shown in Figure 1.


FIGURE 1: Structure of traceability model for traditional agricultural products.

Traditional agricultural product traceability system generally centers on a centralized database. In the actual production process, the supply, planting, storage, logistics, and sales of production materials in the industrial chain are arranged in sequence. Then, the traceability data is uploaded to the centralized database. The quality supervision department supervises the quality of agricultural products by collecting information from centralized databases. Consumers send a query request to the centralized database to obtain the traceability information of purchased agricultural products.

2.2. Existing Problems. In the early stage of agricultural product traceability research, researchers usually focus on the full collection of traceability data and complete coverage of the industrial chain. The research on data security storage and system dynamic traceability is relatively few, which leads to the lack of reliability and flexibility of traditional agricultural product traceability system. Some researchers apply blockchain technology to the traceability of agricultural products but seldom optimize the traceability process and system structure by combining the characteristics of both. While the traceability results obtained are reliable, there is still a lot of room for improvement in the flexibility of the system.

Traditional agricultural product traceability system stores data in a centralized database, which brings a series of data security problems. This reduces the credibility of the traceability system for agricultural products. Traditional traceability systems usually trace specific agricultural products in a narrow range. The limitation of traceability objects and production process leads to the solidified transaction processing process of the traceability system. It cannot dynamically adjust the sequence of production link combination according to the actual production scene, which is not conducive to system function expansion and

upgrade. These factors lead to poor flexibility of the traceability system.

3. The Current State of Blockchain Traceability Systems

3.1. Supply Chain Traceability System Based on Blockchain. At present, there are many researches and applications in academia and industry to realize supply chain traceability by using blockchain. Literature [15] applied blockchain to drug supply chain traceability system. It used affiliate link technology and quick response (QR) encrypted codes to establish full-chain traceability for drugs from manufacturer to seller. Literature [16] proposed a new two-step block-out method and designed a joint distributed ledger CoC (supply chain on blockchain) based on this method for supply chain management system. The experimental results show that the two-step block extraction method has good performance, which is faster, more efficient, and safer. Literature [17] used blockchain technology to enhance the elasticity of the supply chain and studied the basic framework of blockchain and its underlying technology. It analyzed the various risks facing the current supply chain and described the specific application scenarios of blockchain technology in the supply chain.

The above literature involves the research of supply chain traceability system but generally does not involve the underlying blockchain platform. In addition, it lacks running and testing on the blockchain. In industry, food industry giants are using blockchain technology to reform the food supply chain. Walmart, IBM, https://www.JD.com, and Tsinghua University set up a safe food blockchain traceability alliance. It uses blockchain technology to track the food supply chain and build safe tables. Among them, Hyperledger developed by IBM, as a kind of underlying blockchain technology, has been widely applied in various fields of supply chain by major companies. In China, Tmall

International products use ant blockchain independently developed by Alibaba for cross-border product traceability, which greatly increases the security of imported goods. The Institute of Intelligent Supply Chain Management of Tsinghua University cooperated with Yonghui Supermarket to use steel gash to trace the numbers of Xingcheng Turbot fish. It achieves one yard per fish to ensure food safety and has been promoted to more than 10 kinds of fresh products. Jingdong Y Business Department launched the Baas platform of "Zhizhen Chain" to realize the traceability of some commodities in Jingdong supermarket by using this platform.

At present, alliance chain technology is basically used in supply chain traceability projects. An affiliate chain is a blockchain network that allows only certain group members and limited third-party access. Because of the access mechanism, the small number of nodes, the use of a high-performance consensus algorithm, and other reasons, the alliance chain usually has higher transaction performance than the public chain. Moreover, the alliance chain can provide queries and other functions to the third party in the form of open API, which is more friendly to supervision. Therefore, it is called "Blockchain 3.0," which flaunts the future development direction of blockchain. The demand and background of the supply chain are consistent with the alliance chain: the members of the supply chain are limited and fixed. The up-chain of supply chain information requires faster transaction speed and lower transaction cost. Supply chain traceability needs the supervision of relevant departments. Therefore, alliance chain technology is suitable for supply chain traceability system. Currently, one of the more active and recognized open-source consortium projects is Hyperledger Fabric developed by IBM. Most blockchain platforms are improved and encapsulated based on Hyperledger.

However, relevant researches show that there are many difficulties in the realization of the alliance chain. Its main bottleneck lies in the weak financial strength of small and micro enterprises, that is, they are unable to maintain the servers required by the alliance chain. Consensus nodes are typically deployed in large enterprises and some third-party organizations. Small and microenterprises in the supply chain generally only have terminal or Internet of Things acquisition devices and do not configure a consensus server. This leads to the imbalance of consensus rights in the alliance chain and the failure of consensus strategies due to too few consensus nodes. In actual deployment, core enterprises gradually deploy consensus nodes in the same consensus domain. Docker container technology is used to generate four nodes on the same server for consensus, and other enterprises in the supply chain use clients to access the alliance chain. This operation saves costs and facilitates small applications and early commissioning. However, it violates the original intention and principle of the alliance chain and cannot play the role of the alliance chain. This system is developed based on Ethereum smart contract to realize supply chain traceability in a decentralized way to save costs for enterprises on the chain.

3.2. Sidechain Technology. To implement supply chain traceability on Ethereum, transaction costs must be considered. Suppliers, processors, and distributors shall chain raw material information, product processing information, and product sales information, respectively. This data can put a lot of pressure on the Ethereum main network and lead to high transaction fees, as well as high confirmation delays. In this paper, sidechain technology is used to expand Ethereum to meet the demand of supply chain traceability information.

The sidechain technology was first used in the expansion of Bitcoin. It is a protocol that allows Bitcoin to be safely transferred to other blockchains and safely returned to the main Bitcoin chain from other blockchains. The protocol moves some frequent, small transactions onto the sidechain. This not only improves the efficiency of Bitcoin's main network but also significantly reduces transaction fees. Therefore, the deployment of the corresponding sidechain technology on Ethereum can reduce the pressure on the main network of Ethereum and improve transaction efficiency. At present, common Ethereum sidechain protocols include Loom Plasma Chain and Snarky. The Loom PlasmaChain is a high-performance DPoS (delegated proof of stake) sidechain that implements the Plasma Cash framework model. It can gain security endorsement from Ethereum's underlying network, allowing users to enjoy the high-performance consensus of DPoS algorithms when using tokens supported by ERC 20 and ERC 721. Snark sidechain solution can expand Ethereum network transaction capacity up to 17000 TPS as a kind of down chain expansion. Snark allows users to transfer tokens and ETH outside Ethereum.

In the existing studies, the sidechain expansion schemes of Bitcoin and Ethereum only include token transfer. Token transactions are transferred to the sidechain for higher throughput and lower handling fees. This paper constructs a sidechain model of user data transfer to provide an expansion scheme for supply chain traceability information so that the supply chain traceability system based on Ethereum can be applied to the actual production.

4. The Design of Agricultural Product Traceability System

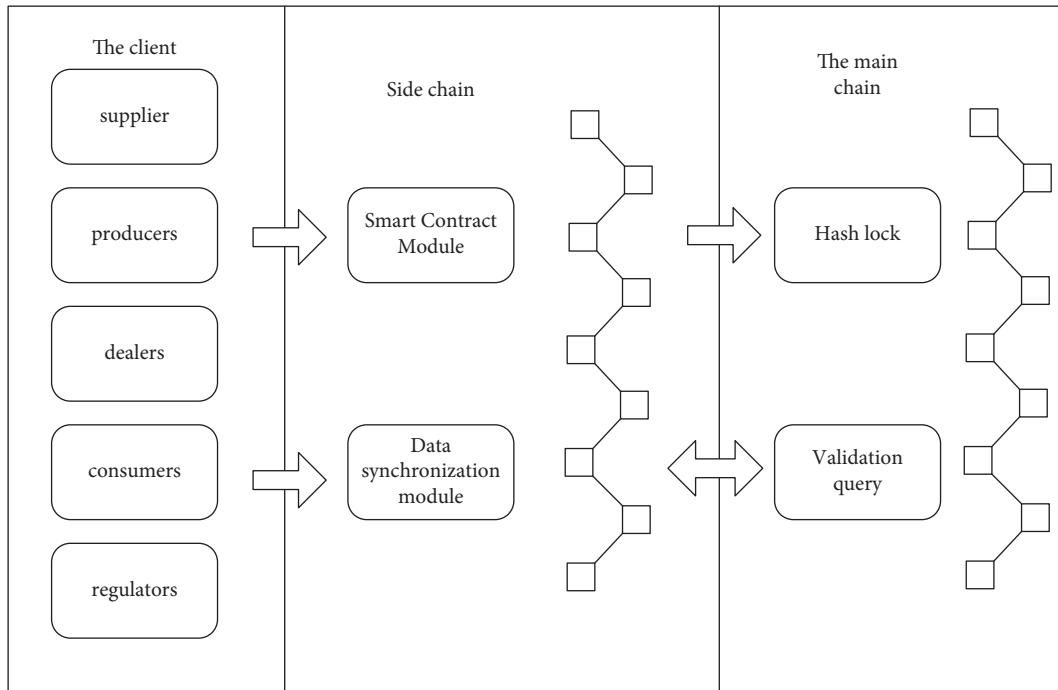
4.1. System Architecture. In this paper, aiming at the shortcomings of the existing agricultural supply chain traceability scheme, Ethereum and smart contract are used to design and implement a supply chain traceability system based on sidechain technology. Its architecture is shown in Figure 2. The smart contract module contains the business logic of the system. It deploys this module on the sidechain, which can greatly increase the efficiency of Ethereum usage, reduce transaction confirmation time, and reduce transaction costs. The data synchronization module is responsible for processing each batch of transaction data and using the Merkle tree algorithm to obtain the transaction hash value. It synchronizes the hash value to Ethereum for locking. When consumers and regulators query, the data synchronization


FIGURE 2: Supply chain traceability system architecture.

module can be used for calculation and verification to prevent data tampering.

In the blockchain supply chain traceability system network, enterprises such as suppliers, manufacturers, and distributors use the Internet of Things collection equipment to collect product information. It generates raw data, uses a terminal for data processing, and sends it to a sidechain server. The sidechain server is maintained by the core enterprise and runs the Ethereum sidechain process. It connects to the Ethereum public chain for data storage. The supervisor and the user use PC and mobile device, respectively, to access the sidechain server and verify the authenticity of the data on the Ethereum public chain.

4.2. Contract Design. There are five types of participants in the supply chain traceability system based on blockchain. As a raw material supplier, the supplier is the source of a batch of product information traceability. It requires the creation of an initial file and traceability number for the raw material. The manufacturer processes and distributes the raw materials and is the source of information for the smallest selling unit of the product. It needs to assign batch numbers and QR codes to traceability products, to achieve one code for one thing. Dealers buy from manufacturers and sell through different channels. It needs to provide information on warehousing, logistics, and so on. The supervisor supervises the production, circulation, and operation of commodities. Consumers can scan the QR code to view the traceability information of the whole life cycle of the product. The relevant operations and processes of participants on smart contracts are shown in Figure 3.

Smart contract includes the following five functions:

(1) User registration. Since the public chain itself has no identity authentication mechanism, it needs to realize user access through smart contract. Companies in the same supply chain need to agree on a number before entering information. The user is registered by executing the userRegister() function. This number groups these companies into a user group, and only the users in the group can add traceability information to the products on the chain. The pseudocode of the userRegister() function algorithm is shown in Algorithm 1.

(2) Input raw materials. As the information source of the supply chain, suppliers need to use the Internet of Things equipment to collect the data of the production environment, production cycle, and the person in charge of operation of raw materials. The rawRegister() function is then used to chain up the data, create an initial file for the raw material, and assign the raw material lot number. For example, a batch of raw material traceability file is modeled as <rawID, rawName, rawFac, produceTime, rawInfo>. The rawRegister() algorithm pseudocode is shown in Algorithm 2.

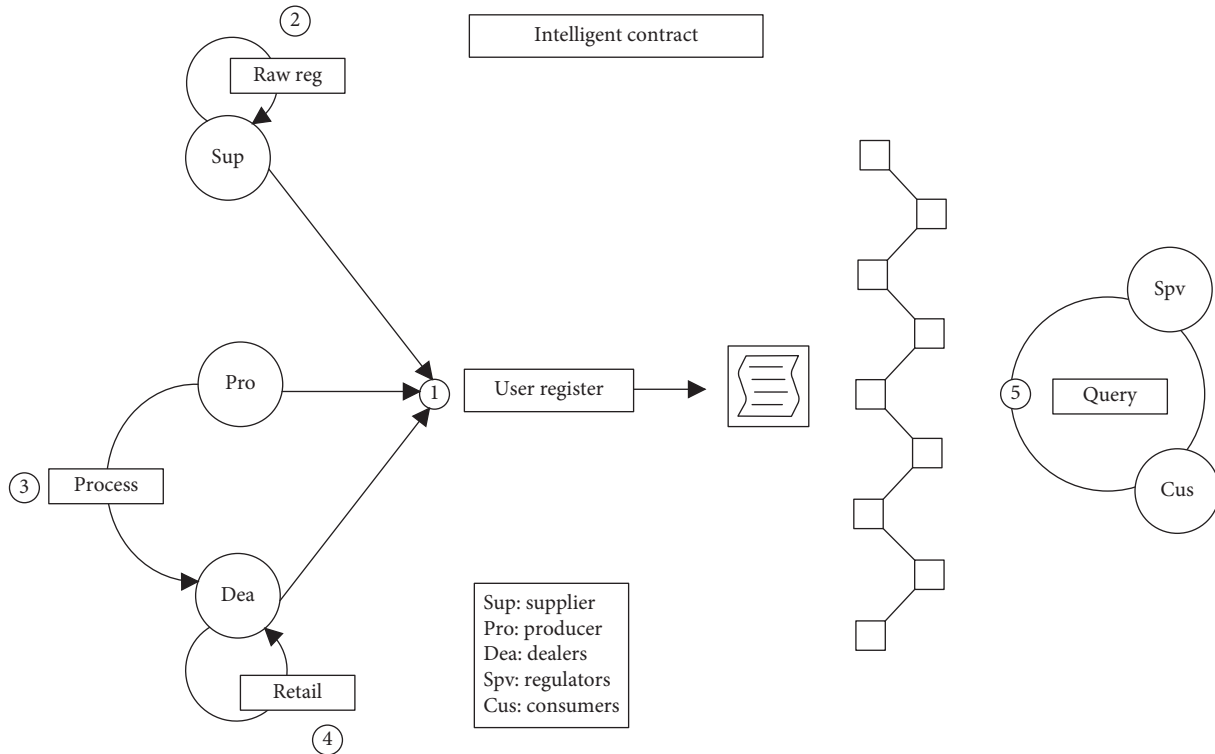
(3) Product production. The manufacturer processes the raw materials provided by the supplier to produce the minimum selling unit of the commodity. In this link, product files based on traceability source code are formally established and provided to consumers in the form of two-dimensional code for inquiry. The manufacturer needs to call the newProduct() function to integrate the raw material information. It can also write URLs to production environment,


Figure 3: Operation flow of smart contract.

production video, and other large files in the product_info field.

(4) Product distribution. This feature records the circulation of products, helps consumers to check the source of goods, and helps manufacturers to prevent the diversion of goods. After handling the goods, the distributor or logistics enterprise uses the product_deal() function to add the distribution information to the goods. Because one or more handling enterprises exist, product information is stored in the structure using the dynamic array Bytes32[] retailerNames. Since the code logic is like raw material entry, the pseudocode of the production and distribution functions will not be described here.

(5) Supervision and inquiry. Consumers can query the traceability information of the batches to which the goods belong, and supervisors have higher authority when querying the goods. In the query function, the

```
The input: supplyChain contract address base_addr, raw material name raw_name, raw material batch id raw_id, manufacturer
raw_factory, production information raw_info, timestamp
The output: raw material entry completed or failed
Require: the input raw_id is not occupied
Require: users are registered
if r.raw_id! = 0 ‖ supplierMap[msg.sender].id = = 0 then
    return FALSE;
end if
r.rawID = raw_id;
r.rawName = raw_name;
r.rawFac = raw_factory;
r.produceTime = timestamp;
r.rawInfo = raw_info; final return: true
```

ALGORITHM 2: rawRegister() function.

identity of the inquirer is first authenticated, and the batch file of the product is returned to the inquirer after passing.

4.3. Data Synchronization and Verification.

After the product traceability information is stored on the sidechain, the Merkle tree algorithm is used for hash locking, and the resulting Merkle Root is synchronized to the Ethereum main chain. Merkle Root changes when traceability information is tampered with.

After a round of trading, the information uploaded by suppliers, manufacturers, distributors, and other nodes in the sidechain is taken as the leaf nodes of the Merkle tree to calculate its hash value. If there are multiple suppliers or resellers, the information from the different nodes is processed as leaf nodes. After obtaining several hashes (H1, H2, ...), perform pairwise hash operation on (H1, H2, ...) to obtain the hash value. The pseudocode of the Merkle tree algorithm is shown in Algorithm 3.

Bind Merkle Root to the product batch number and synchronize it to the Ethereum main chain, which can be used as the traceability verification code of this batch of products. After the user queries the product traceability information, the same method is used to obtain Merkle Root. This can be compared to a reliable value on Ethereum to determine whether the traceability information for the product has been tampered with. Once the data is incorrect, regulators can use the Merkle tree algorithm to locate more quickly which branch the tampered data came from. Then, the accountability can be investigated in the corresponding supply chain links.

4.4. System Business Process.

The business process of supply chain traceability system designed in this paper is shown in Figure 4. Goods are traced back to their original raw materials. The process from rough machining by the supplier to finish machining by the manufacturer can be traced. The process from sales channels to consumers can also be traced back. All information can be tracked in an all-round, multiangle, and wide field. In this way, the origin and destination of products can be traced.

5. Experiment and Analysis

5.1. Fault Tolerance Test of Trading System.

The ability to operate stably when a system is attacked by a malicious node is called system fault tolerance. Therefore, the probability of a certain number of malicious nodes successfully destroying the normal operation of the system is taken as an index to evaluate the fault tolerance performance of the system. Considering the experimental effect and equipment performance, the number of nodes in the supply chain system was set to 50, and the number of malicious nodes gradually increased from 0 to 30. The successful rate of attack of malicious nodes in different states is obtained through several experiments under different number of malicious nodes.

In the supply chain system, the core enterprise will check the qualification of the enterprise applying to join the supply chain. Therefore, the probability that the number of malicious nodes exceeds 1/3 of the total number of nodes is low. At this time, according to Figure 5, the attack success rate is very low. The system has a high fault tolerance performance under the current conditions, but considering malicious attacks outside the system, the system fault tolerance performance needs to be further improved.

5.2. Throughput Analysis of Trading System.

Transaction Per Second (TPS) is used to evaluate system throughput. The transaction system undertakes the transaction function of the supply chain and has certain requirements on the real-time performance of the system. This paper analyzes the throughput of the supply chain transaction system through experiments, which provides a good foundation for system upgrade and deployment. The number of nodes of the trading system was taken as a variable in the experiment, and the number of nodes increased from 0 to 70. The experiment was repeated under different number of nodes. Finally, the TPS value of various nodes is used as the indicator of system throughput in various states.

```
The input: list info = [T1, T2, ..., t1, t2, ...]
The output: root hash merkle_root
Define hashed_info[] to hold the result of the hash operation
Define the array temp_info[] to hold the result of each layer of hash
for true do
    for index = 0; index < len(list_info); index+ = 2 do
        current = list_info[index];
        cur_right = list_info[index+1];
        cur_hash = sha256(current);
        cur_right_hash = sha256(cur_right);
        hashed_info[list_info[index]] = cur_hash;
        hashed_info[list_info[index + 1]] = cur_right_hash;
        Place (cur_hash + cur_right_hash) in temp_info[];
    end for
    if len(list_info) = = 1 then
        break;
    else
        list_info = temp_info;
    end if
end for
The last hash in the hashed_info array is merkle_root
return merkle_root
```

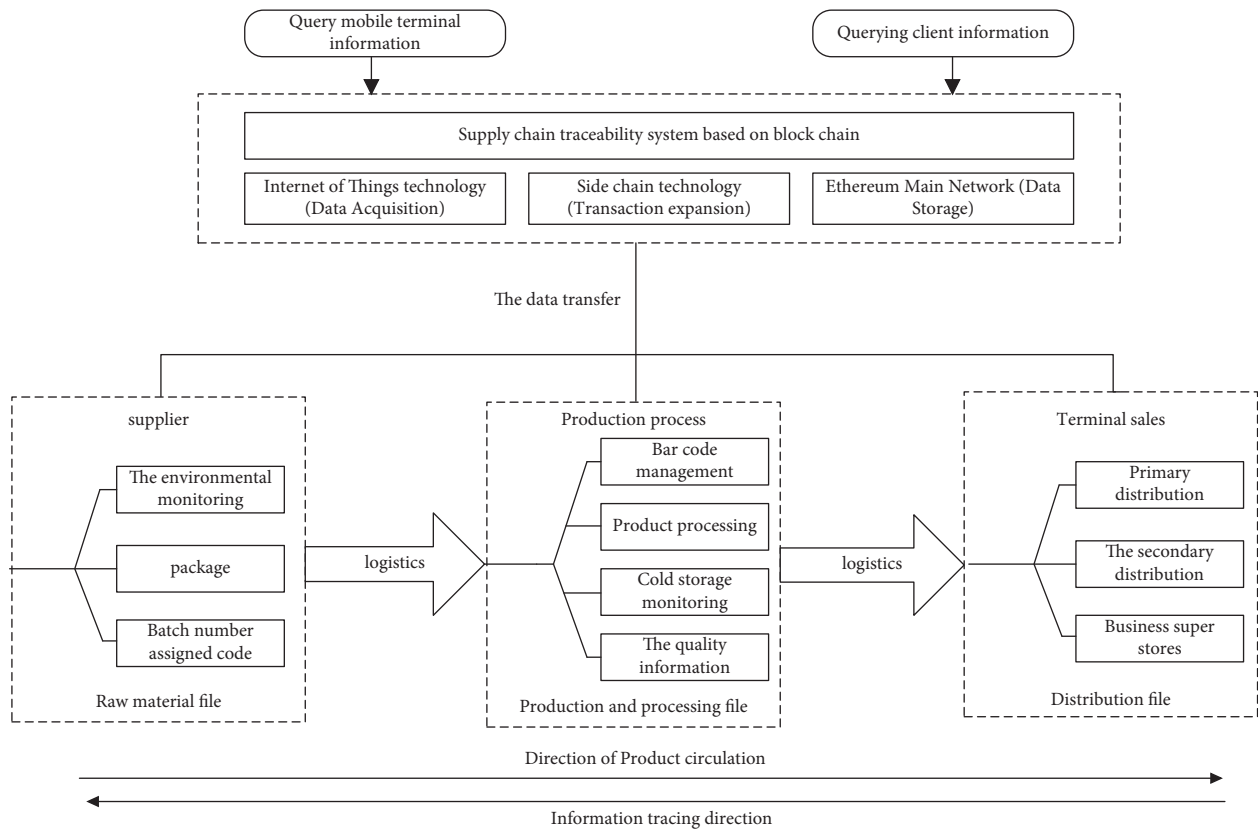
ALGORITHM 3: Merkle tree algorithm.


FIGURE 4: Business process of the traceability system.

It can be seen from Figure 6 that when the number of nodes is 5–45, the throughput of the transaction system rises with the increase of the number of nodes, and the upward trend remains basically unchanged. The throughput of the system in this paper is still small, even in the experimental environment where the operating environment is stable, and
FIGURE 5: Success rate of trading system attack.
FIGURE 6: The throughput of the transaction system under different number of nodes.

the interaction content is simple. There is still a gap between this and the huge data transaction demand of the supply chain. Therefore, according to the actual demand of the supply chain, multichain and layered technologies will be combined to optimize the system architecture in the subsequent research. At the same time, the consensus algorithm is improved by using the advantages of the alliance chain and supply chain system to improve the consensus efficiency and increase the system throughput.

5.3. Comparison of Transaction Throughput. The throughput is an important indicator to evaluate the transaction system and blockchain system. Therefore, the throughput of the transaction system in this paper is compared with that of the transaction system in literature [18–20]. In the experiment, the number of nodes of the trading system was taken as a variable, and the number of nodes increased from 0 to 60. The experiment was repeated under different number of nodes, and the average value of TPS under different states was obtained as shown in Figure 7.

According to the experimental results, when the number of nodes is less than 40, the transaction system in this paper has certain advantages in throughput performance. However, the throughput of the transaction system in literature
FIGURE 7: Throughput comparison of the trading system.

[18, 19] continues to rise and does not decline when the number of nodes reaches 60. Therefore, when the number of nodes in the transaction system is small, the transaction system in this paper has certain advantages in throughput performance. However, the system throughput peak value is small, which has a certain gap with the actual application demand of the supply chain system, and the system throughput performance has a large space to improve.

6. Conclusion

Traditional agricultural product traceability system is generally centered on a centralized database, which leads to the difficulty of traceability and inflexibility of the system. While blockchain technology is in the development stage, how to break through the technical bottleneck of blockchain and better apply it to the production of agricultural products has become the focus of the industry. In order to promote the cooperation between enterprises in the supply chain and improve the efficiency of supply chain cooperation, this paper designs a chain traceability system of agricultural products based on sidechain technology. It provides a trusted platform for data sharing, which is independent of third parties. The experimental results show that the system combines sidechain technology with supply chain traceability, and it provides an expansion scheme for nontransfer transactions. The future work is to compare and analyze different sidechain protocols and select the high-performance sidechain technology that is more suitable for supply chain traceability system to improve the transaction performance of the system.

In order to improve the selection and exploration effect of cultural and creative tourist attractions, this paper applies BP network to the selection and search of cultural and creative tourist attractions. Moreover, this paper improves the algorithm to promote the interrelation of cultural and creative industries and tourism industries to promote each other to form a complex and changeable dynamic system and proposes a personalized recommendation model for tourist attractions based on domain adaptation. Domain adaptation can effectively reduce the distribution difference between different data. In addition, this paper combines experimental research to verify the system model of this paper. The research results show that the cultural and creative tourist attractions selection search system based on the BP network proposed in this paper has a good selection effect of tourist attractions and has an important role in promoting the development of cultural and creative tourism.

1. Introduction

At present, creative products based on regional culture are mostly concentrated in art exhibitions and high-end crafts, which make the audience group smaller. Tourism products on the traditional market have low cultural content and poor product quality, and a large part of the products are direct applications of pictures, so there is no innovation. Domestic and foreign scholars are doing more and more research studies on regional culture, but the design and application of regional cultural elements are in the initial stage. Therefore, it is necessary to start with cultural elements and develop and design tourism cultural and creative products based on regional culture as the research content. Moreover, it is necessary to analyze the cultural elements with the most regional characteristics through the study of regional culture, conduct research and analysis on them, and establish a material library of regional cultural elements, which is conducive to increasing the added value of products and is conducive to product serialization and branding.

At present, many tourism, cultural, and creative products centered on regional culture are seriously homogenized, and many products in scenic spots only replace the parts of the products that can be pasted, resulting in similar products with little difference. Most tourism products have no sense of design, messy types, and no special features. Except for the different pictures, the product modeling functions of the direct map products are almost the same. On the surface, it is because tourism products lack cultural connotation. At a deeper level, it is that the level of cultural excavation is not enough. New technologies and new media are used to rearrange and utilize the regional culture, build a regional cultural material library, and preserve the culture at the same time. More people know the regional culture. Second, the establishment of a regional cultural material library is conducive to the development of the cultural industry, thereby supporting the development and iteration of subsequent cultural creative products. Third, through the study of regional culture, establish a relevant cultural research system, explore relevant research methods and research models, and apply them to the design and research and development of cultural creative products to guide the development of cultural creative products, upgrades, and changes in the current market, so that the products are no longer low quality and low culture. Because of its particularity, regional culture also represents ancient Chinese

culture at a certain level. Using regional cultural elements to develop cultural and creative products will help promote the public to understand regional culture and history and understand Chinese culture. It can not only promote the development of local culture but also enhance tourists' awareness of local culture, thereby driving regional economic development. Development is more conducive to the establishment of national cultural self-confidence.

Regional culture refers to the cultural connotation with regional characteristics within a region containing material and spiritual characteristics, including the development form and social lifestyle of the place from time to time, as well as the unique cultural heritage and material heritage [1]. Natural resources and human resources are integrated into a cultural characteristic that can reflect national characteristics, thoughts, concepts, customs, beliefs, morals, ethics, and so on. Hundred schools of thought, piano, chess, calligraphy and painting, literature, drama, festivals, folk houses, architecture, characters, language, costumes, stories, characters, customs, dialects, singing and dancing, food, traditional Chinese medicine, religion, belief, philosophy, craftsmanship, martial arts, and other diverse regional cultures constitute the broad Chinese culture [2].

Packaging design research based on regional culture is to study the application of regional culture in packaging design. Taking Baminjin series packaging design examples as the starting point, it explores research approaches suitable for Baminjin packaging design, and through the inheritance and development of Bamin regional culture, it reflects the value of cultural innovation and wins a better investment market. It is necessary to apply regional culture in product packaging design and design according to consumers' cultural identity and emotional bonds of the brand, so as to enhance the cultural value of packaging design [3].

This paper applies the BP network to the selection of cultural and creative tourist attractions and builds an intelligent system based on the actual situation to promote the further development of cultural and creative tourism.

2. Related Work

For the study of cultural and creative industries, there have been relatively mature and systematic research results abroad. Literature [4] awakened the definition of the concept of creative industries based on the perspective of cultural economics. Literature [5] analyzed and compared the similarities and differences between the two terms "cultural entrepreneurship industry" and "creative industry" and pointed out that they have essentially the same characteristics. Literature [6] expanded the extension of the creative industry and collectively referred to the cultural industry and the art industry as the creative industry. Literature [7] analyzed the driving factors of innovation and pointed out that market demand plays a key role in guiding innovation, but it also restricts the development of innovation. Compared with technology, market demand has a greater driving role. Literature [8] put forward the "dual-factor theory" for the development of cultural and creative industries and believed that supply and demand are the two main driving

forces that promote the development of entrepreneurial industries. Literature [9] systematically proposed the theory of creative economics, which led to the vigorous development of theories of creative economics. Literature [10] studied the industrial characteristics of traditional handicrafts and pointed out that cultural creativity can give handicrafts more added value. Literature [11] combined creative industries with tourism and pointed out creative tourism, a new idea for the development of tourism. Literature [12] believed that under different economic environments, entrepreneurial industries should apply different development models and advocate different models. The former focuses on market orientation, while the latter believes that government leadership can better promote the development of creative industries. Literature [13] defined industrial agglomeration, took major cities in the world as the research object, and defined the new urban development model of "creative cities." Literature [14] compared several major cultural and creative industry development models. Literature [15] pointed out the evolution trend of Singapore's cultural and creative industries based on the perspective of potential mining. Literature [16] comparatively analyzed the creative industry, cultural industry, and cultural creative industry and sorted out the main similarities and differences of the three. Literature [17] analyzed the main influencing factors driving the development of cultural and creative industries based on the perspective of industrial competitiveness and further analyzed the value of cultural and creative industry chain research. Literature [18] studied the value chain creation mechanism of cultural and creative industries. Literature [19] pointed out that human resources, market demand, institutional environment, and basic environment are the key factors that promote the development of cultural and creative industries. On this basis, a framework of influencing factors of the cultural entrepreneurship industry is constructed. Literature [20] pointed out that the policy environment and cultural environment play a key role in the development of Beijing's cultural and creative industries.

3. Recommendation Algorithm Based on BP Neural Network Model

According to the above conclusions, it is known that the deep convolutional neural network cannot process data in non-Euclidean space and loses its effectiveness when encountering topological structure graph data. However, graph structures are common in real life, so more and more people are beginning to explore how to define convolution operations for graph data.

The main challenges of using convolutional neural networks for graph structures are as follows:

(1) The graph structure data do not satisfy the translation invariance; that is, the structure of each node is different, and the number of connected neighbor nodes is uncertain, so it is impossible to use a convolution kernel of the same size to perform convolution operations.

(2) The graph structure data have directionality. For example, users in social networks are connected.

The graph convolutional neural network for non-Euclidean spatial data is divided into two directions: spectral domain method and vertex domain method.

The vertex domain method of graph convolutional neural network has two ideas. One idea is to design convolution kernel and convolution operation based on graph structure data, and the other idea is to convert graph structure data into Euclidean space data structure.

Like the traditional convolutional neural network, the goal of the BP neural network model is to learn a function to extract features. Each neural network layer can be written as a nonlinear function:

$$H^{(l+1)} = f\left(H^l, A\right), H^{(0)} = X, H^{(L)} = Z. \tag{1}$$

Among them, L represents the number of layers, and $f(\cdot;)$ of each layer differs only in parameters, and Z represents the final output.

$$f\left(H^{(l)}, A\right) = \sigma\left(AH^{(l)}W^{(l)}\right). \tag{2}$$

The feature matrix, adjacency matrix, and weight matrix are subjected to matrix multiplication to reflect the physical meaning of convolution. Obviously the weight matrix is easy to understand. Multiplying the adjacency matrix and the feature matrix is to learn the traditional convolution operation. The traditional convolution operation is to sum the product of the convolution kernel and the corresponding element. The convolution operation of the graph structure also needs to meet the translation invariance; that is, the number of elements in the convolution kernel participating in the convolution operation must change according to the graph structure, and the translation invariance in the graph structure is reflected in the adjacency matrix. Graph structure data are as shown in Figure 1.

$$X = \begin{bmatrix} a_{11}, a_{12}, a_{13}, \ldots, a_{16} \\ a_{21}, a_{22}, a_{23}, \ldots, a_{26} \\ a_{31}, a_{32}, a_{33}, \ldots, a_{36} \\ a_{41}, a_{42}, a_{43}, \ldots, a_{46} \\ a_{51}, a_{52}, a_{53}, \ldots, a_{56} \\ a_{61}, a_{62}, a_{63}, \ldots, a_{66} \end{bmatrix},$$

$$A = \begin{bmatrix} 0, 1, 1, 0, 0, 0 \\ 1, 0, 1, 0, 0, 1 \\ 1, 1, 0, 1, 1, 0 \\ 0, 0, 1, 0, 1, 1 \\ 0, 0, 1, 1, 0, 0 \\ 0, 1, 0, 1, 0, 0 \end{bmatrix}. \tag{3}$$
$Q = AX$, and we only list the first line of Q:

FIGURE 1: Graph structure data.

$$Q_{1\bullet} = \left[a_{21} + a_{31}, a_{22} + a_{32}, a_{23} + a_{33}, a_{24} + a_{34}, a_{25} + a_{35}\right]. \tag{4}$$

Q_1 can be expressed as the sum of the feature vectors of the two neighbor nodes of x_1. If the weight matrix is added, the meaning of weighted average can be expressed, which is the convolution operation in the traditional sense. However, there is one point that needs to be explained here. Since the convolution operation is a weighted average of the central node and the surrounding nodes, the above formula does not involve the central node, the adjacency matrix A is improved, and the original adjacency matrix A is added with its own node.

$$\widehat{A} = A + I. \tag{5}$$

$\widehat{A}$ is normalized to

$$\widehat{A} = \widehat{D}^{-1/2}\widehat{A}\widehat{D}^{-1/2},$$
$$f\left(H^{(l)}, A\right) = \sigma\left(\widehat{D}^{-1/2}\widehat{A}\widehat{D}^{-1/2}H^{(l)}W^{(l)}\right). \tag{6}$$

Although this model is very simple, the model effect is very powerful. Figure 2 shows the use of a simple GCN model on the famous Taekwondo club data set in this paper. After experimentation, it is found that only 3 levels are needed to classify club members. Moreover, the experimental result of using the identity matrix as the characteristic matrix when the characteristic matrix of the node is not known is also very impressive. For many graph networks, there may be no node characteristics, and graph convolutional neural networks can also be used at this time. The identity matrix I replaces the feature matrix X operation.

The second airspace method converts graph structure data into Euclidean space data. First, it selects a representative node sequence from the graph structure and second designs a neighborhood with a fixed convolution kernel size for each node. Then, it converts each graph structure data into Euclidean space data, which can be solved by using traditional convolution operations.

Each image can be regarded as a special graph, and each pixel in the image can be represented as a node. The convolution operation for each image is the weighted average of n central pixels and the surrounding pixels. Therefore, each
FIGURE 2: Diagram structure of Taekwondo club.

graph structure can also be regarded as a weighted average of n central vertices and corresponding neighborhoods, so that the graph structure can be converted into Euclidean space data. Traditional convolution operation is as shown in Figure 3, and graph structure transformation is as shown in Figure 4.

This paper selects n representative nodes, and the node selection is based on the Weisfeiler–Lehman algorithm. It can be understood as calculating the centrality of each node, sorting according to the size of the value, and then taking the first n representative nodes.

The neighborhood of the node is constructed by normalizing the neighborhood in the previous step. Normalization makes the nodes of the neighborhood graph have an order so that the unordered graph space is mapped to the vector space in a linear order. Moreover, this paper defines the optimal graph normalization problem and finds the optimal order by optimizing the function. The operation steps are shown in Figure 5.

$$\mathrm{argmin}_l \mathrm{E}_G \left[\left| d_A\left(A^l(G), A^l(G')\right) - d_G\left(G, G'\right) \right| \right]. \quad (7)$$

Each graph structure data can map the disordered neighborhood to the vector space through node selection and node neighborhood construction. Therefore, the method proposed in this paper is to build a bridge between graph structure data and convolutional neural network and solve the transformed Euclidean space data through traditional convolutional neural network.

In the traditional Fourier transform $\widehat{f}(\omega) = \int f(t)e^{-i\omega t}dt$, the integral operation here can be understood as a linear combination of $f(t)$ and basis function e^{-icx}. We only need to compare the basis function h used here to find the basis function on the graph.

The eigen decomposition of Laplacian matrix L is

$$L = U \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_n \end{bmatrix} U^{-1}. \quad (8)$$

Because L is an orthogonal matrix,

$$L = U \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_n \end{bmatrix} U^{\mathrm{T}}. \quad (9)$$

The characteristic matrix U of the Laplacian matrix L is the base matrix of the graph convolution, so the graph Fourier transform operation $\widehat{f}(\omega) = \sum_{i=1} f(i)u_l^*(i)$ is converted into a matrix form:

$$f^*g = \begin{bmatrix} u_1(1) & u_1(2) & \cdots & u_1(N) \\ u_2(1) & u_2(2) & \cdots & u_2(N) \\ \vdots & \vdots & \ddots & \vdots \\ u_N(1) & u_N(2) & \cdots & u_N(N) \end{bmatrix} \begin{bmatrix} f(1) \\ f(2) \\ \vdots \\ f(N) \end{bmatrix}. \quad (10)$$

Among them, f and g are the original signals, $F(f)$ is the Fourier transform of f, $\cdot$ represents the product, and * represents the convolution operation.

$$f^*h = F^{-1}\left(\widehat{f}(w)\widehat{h}(w)\right) = \frac{1}{2\pi} \int \widehat{f}(w)\widehat{h}(w)e^{iex}d\omega \, . \quad (11)$$

Analogy to $f^*h = U(\widehat{f}\widehat{h})$ in the graph, the Fourier transform $\widehat{h}(\lambda_l) = \sum_{i=1}^N h(i)u_l^*(i)$ of the convolution kernel h is written as a diagonal matrix as follows:

$$\widehat{h} = \begin{bmatrix} \widehat{h}(\lambda_1) & & \\ & \ddots & \\ & & \widehat{h}(\lambda_n) \end{bmatrix}. \quad (12)$$

Therefore, the generalized convolution on the graph is as follows:

FIGURE 3: Traditional convolution operation.

$$f^* g = U \begin{bmatrix} \widehat{h}(\lambda_1) & & \\ & \ddots & \\ & & \widehat{h}(\lambda_n) \end{bmatrix} U^T f, U = (\overrightarrow{u_1}, \overrightarrow{u_2}, \cdots, \overrightarrow{u_n}). \quad (13)$$

U is the unit eigenvector matrix of the Laplacian matrix. Later, in many spectral domain graph convolution papers, it is often represented by $(f^*h)_G = U((U^T h)\Theta U^T f))$, where Θ is the Hadamard product.

The setting of the first-generation convolution kernel directly selects the parameter diagonal matrix to represent.

$$g_\theta(\Lambda) = \begin{bmatrix} \theta_1 & & \\ & \ddots & \\ & & \theta_n \end{bmatrix}. \quad (14)$$

Among them, $\Theta(\theta_1, \theta_2 \cdots \theta_n)$ is n arbitrary parameters. It can be seen that the Laplacian matrix needs to be eigen-decomposed when seeking graph convolution.

Due to the large dimension of the Laplacian matrix of the graph data, calculating the eigenvalues will consume a lot of time. Moreover, because the first-generation convolution kernel does not have local features, many scholars have begun to modify the convolution kernel and proposed the second-generation convolution kernel.

$$g_\theta(\Lambda) = \begin{bmatrix} \sum_{j=0}^{K} \alpha_j \lambda_1^j & & \\ & \ddots & \\ & & \sum_{j=0}^{K} \alpha_j \lambda_n^j \end{bmatrix}. \quad (15)$$

The ingenious thing is

$$\Lambda^j = \begin{bmatrix} \lambda_1^j & & \\ & \ddots & \\ & & \lambda_n^j \end{bmatrix}. \quad (16)$$

When substituting it into the above formula, we can get

(a)

(b)
FIGURE 4: Graph structure transformation.

FIGURE 5: Operation steps.

$$g_\theta(\Lambda) = \begin{bmatrix} \sum_{j=0}^{K} \alpha_j \lambda_1^j & & \\ & \ddots & \\ & & \sum_{j=0}^{K} \alpha_j \lambda_n^j \end{bmatrix} = \sum_{j=0}^{K} \alpha_j \Lambda^j,$$

$$U \sum_{j=0}^{K} \alpha_j \Lambda^j U^T = \sum_{j=0}^{K} \alpha_j U \Lambda^j U^T = \sum_{j=0}^{K} \alpha_j L^j. \quad (17)$$

Therefore, the convolution operation is transformed into

$$y_{\text{output}} = \sigma\left(\sum_{j=0}^{K} \alpha_j L^j x\right). \quad (18)$$

Compared with the first-generation convolution kernel, the second-generation convolution kernel reduces the number of parameters, reduces the complexity of the parameters, and speeds up the calculation. The convolution operation avoids the eigen decomposition of the Laplacian matrix, and the convolution kernel adds the local features of each node.

In addition to cleverly designing the convolution kernel to avoid the eigendecomposition of the Laplacian matrix, Chebyshev polynomials can also be used to fit the convolution kernel, which is a widely used method in GCN papers. The third-generation graph convolutional network (GCN) is proposed.

The first-generation convolution kernel is

$$y_{\text{output}} = \sigma\left(U g_\theta(\Lambda) U^T x\right). \quad (19)$$

Among them, U is the matrix formed by the eigenvectors of the Laplacian matrix.

Using the Chebyshev polynomial instead of the original convolution kernel, we can get $g_\theta(\Lambda) = \sum_{k=0}^{K-1} \beta_k T_k(\widetilde{\Lambda})$, where $T_k(\cdot)$ is the k-order Chebyshev polynomial, β_k is the corresponding parameter, and Λ is the diagonal matrix of eigenvalues.

$$\widetilde{\Lambda} = \frac{2\Lambda}{\lambda_{\max}} - I. \quad (20)$$

It can be seen that the elements of the characteristic diagonal matrix are limited to [0, 1] at this time. The reason for this operation is that the Chebyshev polynomial has a domain of [−1, 1].

$$y_{\text{output}} = \sigma\left(U \sum_{k=0}^{K-1} \beta_k T_k(\widetilde{\Lambda}) U^T x\right),$$

$$y_{\text{owput}} = \sigma \sum_{k=0}^{K-1} \beta_k T_k\left(\widetilde{U\Lambda U^T})x\right), y_{\text{oupput}} = \sigma \sum_{k=0}^{K-1} \beta_k T_k(\widetilde{L})x\right). \quad (21)$$

Among them,

$$\widetilde{L} = \frac{2L}{\lambda_{\max}} - I, T_k(\widetilde{L}) = 2\widetilde{L}T_{K-1}(\widetilde{L}) - T_{k-2}(\widetilde{L}), T_0(\widetilde{L}) = I, T_1(\widetilde{L}) = \widetilde{L}, L = I - D^{-\frac{1}{2}} A D^{-\frac{1}{2}}. \quad (22)$$

We can see that

(1) Chebyshev polynomial as a convolution kernel avoids the eigen decomposition of the Laplacian matrix.

(2) By introducing the adjacency relationship of the graph, the convolution kernel has local features. Therefore, the graph convolution model based on the spectral domain method is a further promotion of the basis function of the Fourier transform and the convolution kernel of the convolution operation.

The data in the social recommendation system can be naturally expressed as a user-user social graph and a user-item graph, and the BP neural network can integrate the node information in the above two graph structures.

Therefore, BP neural network is widely used in product recommendation, movie recommendation, and other fields. User Modeling integrates the user information extracted from the user's social network (which can be understood as the characteristics of friends in the user's social relationship and reflects some of the characteristics of the user) with the user information extracted from the user-item graph structure (can be understood as the user's rating of the item and reflects the user's characteristics).

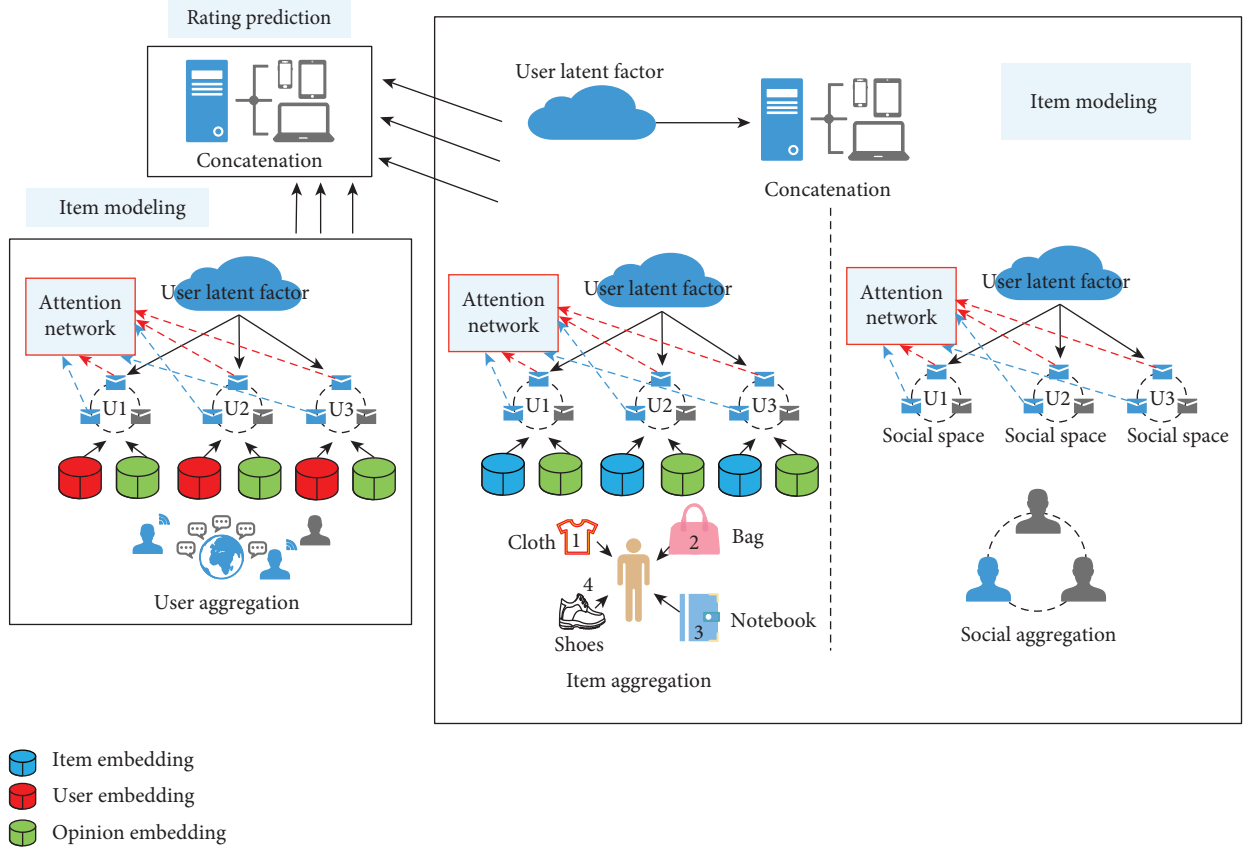
The Graphrec model includes User Modeling, Item Modeling, and Rating Prediction (Figure 6). Item Modeling integrates the characteristics of the item with the characteristics of the users participating in the evaluation of the item to reflect the characteristics of the item. Rating Prediction combines the user potential features extracted from


FIGURE 6: Graphrec model.

the User Modeling and Item Modeling described above with the potential features of the item to predict the rating of each item.

The following is a detailed introduction to the content of the paper.

3.1. User Modeling.
In order to understand the potential characteristics of users, the user model is divided into two parts, user-item graph and social network, and the two parts are described separately.

3.1.1. User-Item Graph Model

$$h_i^I = \sigma \left(W \cdot \text{aggre}_{\text{item}} \left(\{ x_{ia}, \forall a \in C(i) \} \right) + b \right). \tag{23}$$

Among them, $C(i)$ is the item evaluated by user $u(i)$, W, b is the weight and bias of the neural network, and σ is a nonlinear function.

Users will express their opinions when scoring items, so items and item scoring can help users model.

$$x_{ia} = g_v([q_a \oplus e_r]). \tag{24}$$

Among them, x_{ia} is the integration of users and items, x_{ia} is the interactive representation of each item and the score, q_a is the feature vector of the item, e_r is the feature of the five evaluation levels, and $\oplus$ is the connection of two vectors.

Generally, the abovementioned aggretions fusion function directly integrates multiple items evaluated by each user on an average basis, which as follows:

$$h_i^l = \sigma \left(W \cdot \left\{ \sum_{acc(t)} \alpha_i x_{ia} \right\} + b \right),$$

$$\alpha_i = \frac{1}{|C(i)|}. \tag{25}$$

Because the proportion of each item is different for users, it is not possible to directly calculate the average integration. In order to make up for the lack of average integration, the attention mechanism is introduced.

$$h_i^l = \sigma \left(W \cdot \left\{ \sum_{acC(i)} \alpha_{ia} x_{ia} \right\} + b \right), \tag{26}$$

where α_{ia} is the weight of the attention mechanism.

$$\alpha_{ia}^* = \left(w_2^T \cdot \sigma \left(W_1 \cdot [x_{ia} \oplus p_i] \right) + b_1 \right) + b_2,$$

$$\alpha_{ia} = \frac{\exp(\alpha_{ia}^*)}{\sum_{a \in C(i)} \exp(\alpha_{ia}^*)}. \tag{27}$$

Among them, p^i is the feature vector of user u_i, the interaction of items and ratings is connected with the feature
FIGURE 7: Integration mechanism of tourism industry and cultural creative industry.

vector of the user, and W_1 and w_2^T, b_1, and b_2 are weights and biases. The Softmax function is used to normalize the above attention weights to obtain the final attention weights, which can be understood as the contribution of the interaction to the user-item space user latent factor.

In the interaction between users and friends, it can be found that users' evaluations of products are similar to their own friends' evaluations. Therefore, this paper proposes to obtain the potential characteristics of the user by fusing the evaluation of the user's friends on the project and the characteristics of the project itself and design the following fusion function:

$$h_i^S = \sigma\left(W \cdot \text{Aggre}_{\text{neighhors}}\left(\left\{h_o^I, \forall o \in N(i)\right\}\right) + b\right),$$

$$h_i^S = \sigma\left(W \cdot \left\{\sum_{o \in N(i)} \beta_{io} h_o^I\right\} + b\right). \tag{28}$$

Since different friends have different influences on users, this paper introduces an attention mechanism to users' friends.

$$\beta_{io}^* = w_2^T \cdot \sigma\left(W_1 \cdot \left[h_o^I \oplus p_i\right] + b_1\right) + b_2,$$

$$\beta_{io} = \frac{\exp\left(\beta_{io}^*\right)}{\sum_{o \in N(i)} \exp\left(\beta_{io}^*\right)}. \tag{29}$$

The potential user characteristics obtained by the user-item graph model and the user potential characteristics obtained by the user social network model are merged, and the two parts of user characteristics are extracted through the full convolutional neural network to obtain the final user potential characteristics.

$$c_1 = \left[h_i^l \oplus h_i^s\right],$$

$$c_2 = \sigma\left(W_2 \cdot c_1 + b_2\right),$$

$$\cdots$$

$$h_i = \sigma\left(W_l \cdot c_{l-1} + b_l\right). \tag{30}$$

3.2. Item Modeling. The project model is to extract the potential features of the project and extract the potential features of the project by fusing the characteristics of the users participating in the project evaluation and the user's score.

$$f_{jt} = g_{ut}\left(\left[p_t \oplus e_r\right]\right). \tag{31}$$

Each user feature is fused, and the fusion function is designed as follows:

$$z_j = \sigma\left(W \cdot \text{Aggre}_{\text{users}}\left(\left\{f_{jt}, \forall t \in B(j)\right\} + b\right)\right),$$

$$z_j = \sigma\left(W \cdot \left\{\sum_{t \in B(j)} \mu_{jt} f_{jt}\right\} + b\right). \tag{32}$$

Since each user has a different proportion of item feature extraction, this paper adds an attention mechanism.

$$\mu_{jt}^* = w_2^T \cdot \sigma\left(W_1 \cdot \left[f_{jt} \oplus q_j\right] + b_1\right) + b_2,$$

$$\mu_{jt} = \frac{\exp\left(\mu_{jt}^*\right)}{\sum_{t \in B(j)} \exp\left(\beta_{jt}^*\right)}. \tag{33}$$

18	93.70	38	94.74
19	89.54	39	94.22
20	91.77	40	94.23

3.3. Rating Prediction.

Recommendation can be simplified as a matching problem between users and items, which matches suitable items for suitable users and derives users' predictions for items. Proved that the full convolutional layer (MLP) can approximate any measurable function with arbitrary accuracy, so similarity can also be learned using the full convolutional layer (MLP).

$$
\begin{aligned}
g_1 &= \left[h_i \oplus z_j \right], \\
g_2 &= \sigma \left(W_2 \cdot g_1 + b_2 \right), \\
&\cdots \\
g_{l-1} &= \sigma \left(W_l \cdot g_{l-1} + b_l \right), \\
r'_{ij} &= w^T \cdot g_{l-1}.
\end{aligned}
\tag{34}
$$

3.4. Loss Function

$$
L\text{oss} = \frac{1}{2|O|} \sum_{i,j \in O} \left(r'_{ij} - r_{ij} \right)^2.
\tag{35}
$$

Among them, O is the set of tuples (i, j), where the tuples represent the user u_i and the rated item v_j, so this loss function calculates the loss for all rated items and does not consider the loss for the unrated items.

4. Selection Model of Cultural and Creative Tourist Attractions Based on BP Network

From the above introduction to system theory, we can find that the essence of a system is a process. This process has always been in dynamic change and development, and the system structure is the manifestation of this dynamic change. Under the guidance of this theory, this paper combines the economic "supply-demand" structure theory to construct a dynamic process of the integration of cultural and creative

industries and tourism industries. Based on the perspective of system theory, the concept of industry is defined as a systematic combination of related elements such as technology, products, enterprises, markets, and systems. Different industrial factors interact with each other, continuously differentiate and restructure, and promote the development of the industrial system. It can be said that the integration mechanism of industries is the result of the evolution of different divisions of labor between industries or within industries. This evolution process is shown in Figure 7.

The interrelationship and mutual promotion of cultural and creative industries and tourism industries constitute a complex and changeable dynamic system. The main driving force of this dynamic system comes from the continuous expansion of the demand for tourism creativity and the continuous increase of the supply of tourism creativity products. This interactive dynamic system can better promote industrial integration with the support of regional cultural creativity and mature tourism market. The driving force generated by the interaction between the demand thrust and the supply pull and the interaction of various factors in the external market environment constitutes the main driving force for the industrial integration of the cultural and creative industries and the tourism industry.

The recommendation performance of the cultural and creative personalized tourist attraction recommendation system will be greatly reduced, and manual labeling of training data is time-consuming and laborious. Therefore, it is considered to introduce a labeled auxiliary data set related to the target data set to solve the problem of the lack of labeled data in the target data. However, there is a distribution difference between the auxiliary data set and the target data set, so the data distribution difference between the two must be eliminated before it can be used to train a personalized travel recommendation system. Therefore, a
FIGURE 10: Statistics diagram of search results of the cultural and creative tourist attractions selection model based on BP network.

TABLE 2: User satisfaction of the model.

No.	Satisfaction	No.	Satisfaction
1	88.41	21	92.64
2	83.13	22	87.99
3	91.48	23	82.11
4	92.59	24	86.38
5	89.73	25	88.98
6	86.58	26	85.43
7	91.90	27	90.18
8	82.18	28	88.10

19	86.85	39	83.13
20	92.41	40	93.31

personalized recommendation model for tourist attractions based on domain adaptation is proposed. Domain adaptation can effectively reduce the distribution difference between different data. The block diagram of the personalized recommendation model for cultural and creative tourist attractions based on domain adaptation is shown in Figure 8.

Figure 9 is a schematic diagram of setting the time boundary threshold t and the popular/not popular boundary threshold b. It can be seen that the comment values of a large number of scenic spots are concentrated in the lower area of the figure. This distribution of the number of reviews is consistent with the "long-tail effect" in the distribution of scenic spots mentioned in Section 4 and is consistent with the setting of using the number of reviews to reflect the popularity of scenic spots. It is reasonable to set the b value in

the interval shown in the figure. In order to avoid the excessive subjective influence caused by the need to manually set the b value, this paper considers setting the experiment to select multiple thresholds b and analyzes the influence of the scenic spot popularity prediction under different b values.

Based on the above analysis, the effect of this model is verified. The system model in this paper is mainly applied to the selection and search of cultural and creative tourist attractions. Therefore, this paper conducts a simulation experiment on the search effect of the cultural and creative tourist attractions selection model based on the BP network and obtains the results shown in Table 1 and Figure 10.

The above research verifies the search effect of the cultural and creative tourist attractions selection system based on BP network. On this basis, a user satisfaction
Figure 11: Statistical diagram of user satisfaction of the model.

survey is conducted on the model in this paper, and the results are shown in Table 2 and Figure 11.

From the above and the research results, we can see that the cultural and creative tourist attractions selection search system based on BP network has good user satisfaction. On the whole, the cultural and creative tourist attraction selection search system proposed in this paper based on the BP network has a good selection effect of tourist attractions and has an important role in promoting the development of cultural and creative tourism.

5. Conclusion

The development of China's cultural industry has entered a "new stage," and the innovative design of regional tourism cultural and creative products in the cultural industry has risen from corporate behavior to an important position in the national economy. For this reason, the focus of designers has shifted from traditional products to innovative products that highlight the five thousand years of Chinese culture and characteristic regional culture, which makes the cultural and creative industry hot. Chinese history and culture have a long history and a history of 5,000 years. The harmonious development of society and nature is based on the basic condition that the diversity of culture and nature is equally important. This paper applies the BP network to the selection and exploration of cultural and creative tourist attractions and builds an intelligent system based on the actual situation. Through experimental research, it can be seen that the cultural and creative tourist attraction selection search system proposed in this paper based on the BP network has a good selection effect of tourist attractions and has an important role in promoting the development of cultural and creative tourism.

Hydropower offers significant value for global carbon peak and carbon neutrality. However, the construction of hydropower stations leads to significant changes in land use and cover structure in reservoir areas, which affect ecosystem services including carbon balance. Furthermore, the development and operation of hydropower project require vast investment. However, the reservoir ecosystem's carbon storage and carbon emission reduction caused by hydropower could offer economic benefits when the official carbon market trading in China was launched in 2021. Therefore, it is necessary to assess comprehensively the changes in carbon storage and its value to the ecosystem in reservoir areas. The evaluation is of great importance for carbon loss reduction, land management, and hydropower development. This study provides a comprehensive and effective framework for evaluating changes in carbon storage and has its value to the reservoir ecosystem. It combines land utilization classification data obtained from remote sensing image interpretation and the Integrated Valuation of Ecosystem Services and Tradeoffs (InVEST) carbon storage model. Based on the case study of the Xiluodu reservoir area, they were evaluated from two aspects: physical quantity and value quantity. The results show that the carbon storage in the Xiluodu reservoir area increased by 8,504.42 Mg from 2000 to 2018. The spatial distribution of the carbon storage shows a trend of high in the north and west, but low in the south and east. The construction of hydropower stations and the rise of reservoir water level covered a large amount of land, which led to the loss of carbon storage in reservoir areas. By implementing soil and water conservation and vegetation protection policies, parts of the cultivated land and grassland were converted into forestland, which was the main source for increasing the ecosystem's carbon storage. Moreover, carbon emission reduction was achieved by hydropower. In terms of the monetary value, the carbon storage value of the reservoir ecosystem increased to 19 million RMB during the construction period (2005–2015). The carbon storage value of the reservoir ecosystem increased to 611 million RMB during the operation period (2015–2018). The latter was greater than the maintenance cost of the hydropower station and exceeded the amortized cost of hydropower development, indicating the feasibility and economic benefits of hydropower development. These findings provide guidance for future hydropower development decisions in Jinsha River Basin and also others.

1. Introduction

Global warming is one of the biggest challenges to sustainable development of human society and natural ecosystem. It has gradually become a hot issue worldwide [1–3]. Previous studies show that carbon emissions caused by human activities are the main reason of climate change, mainly from burning of fossil fuels [2]. China is working on local and global environmental challenges [4]. These include a commitment to peak CO_2 emissions around 2030 according to the Paris Agreement signed in 2015 and a commitment to achieve carbon neutrality by 2060 at the 75th UN General Assembly in 2020 based on the Paris Agreement [5–7]. Considering the global carbon peak and carbon

neutrality deadlines, it is necessary to reduce dependence on fossil fuels, attach importance to clean energy development, and optimize energy structure.

As the largest share of clean energy (85%) and the most mature and sustainable power resource, hydropower continues to be the focus of future development [7, 8]. However, extensive hydropower development profoundly impacts the ecosystem, changing the local land use status, ecological diversity, and vegetation coverage [9, 10]. Previous studies showed that land use and cover change (LUCC) is the main cause of global carbon cycle imbalance and an important source of carbon emissions that ranks secondary after fossil fuels [11]. The impact of LUCC on the carbon cycle has become an important aspect of ecological benefit literature, mainly focusing on impacts of soil carbon storage and biomass carbon storage in specific ecosystems. However, the impact of LUCC on multiple carbon pools in composite ecosystems remains unclear [12].

Previous studies have confirmed the influence of hydropower station construction on changes of land use and cover type in the reservoir area. Zhang et al. found that the cultivated land, forestland, and grassland in the reservoir area kept decreasing, while the built-up area and the water area kept increasing during 1978–2005 due to the construction of the Three Gorges Dam and environmental protection policies after the completion of the dam [13]. Guan et al. believed that the construction of the Three Gorges Dam changed the land use structure. They used Logistic-CA-Markov and WLC-CA-Markov models to simulate Chongqing's future land use pattern in the Three Gorges Reservoir area. It was found that the grassland and cultivated land in the reservoir area would continue to decrease while the water area would remain stable, and the forestland and construction land would continue to increase [14]. Rufin et al. collected 178 cases of land use structure change caused by hydropower station construction and concluded that land cover change is mainly related to hydropower stations. Moreover, scholars have discussed the influence of hydropower station construction on soil carbon storage and forest carbon cycle in the reservoir area [15]. Kumar and Sharma and Pereira et al. studied the influence of water flooding of hydropower station on the soil carbon content in nearby forests [16, 17]. Dullah et al. discussed the influence of hydropower station construction on forest plant carbon. They believed that the carbon sequestration rate of the remaining forest in studied areas was still considerable, and the carbon sequestration potential was acceptable [18].

However, previous studies on influence of hydropower station construction on carbon storage were mainly concentrated on one or two carbon pools (plant carbon and soil carbon) of particular ecosystem. Therefore, it is necessary to comprehensively evaluate changes in various carbon pools in the reservoir area. Such an assessment is very important for carbon reduction, land management of future reservoir areas, and hydropower station management. The Integrated Valuation of Ecosystem Services and Tradeoffs (InVEST)

model can be linked to Geographic Information Systems (GIS) mapping to evaluate various service functions of ecosystem services [19–21]. The carbon storage and capture models in the InVEST model include four carbon pools: aboveground biomass, underground biomass, dead organic carbon, and soil carbon. They can accurately reflect changes in carbon storage caused by LUCC in terrestrial ecosystem.

The InVEST model has been widely used to evaluate and simulate carbon cycles of terrestrial ecosystems at different scales due to its visualization on evaluation results, data accessibility, and ease of operation [22–24]. However, previous studies with the InVEST model mainly focused on impacts of urban expansion, shelterbelt construction, and returning farmland to grassland on carbon storage. Few scholars used the InVEST model to study impacts of land use change caused by hydropower station construction on carbon storage in terrestrial ecosystems. Moreover, the development and operation of hydropower require vast investment. Taking the hydropower base in the Jinsha River Basin as an example, over 500 billion RMB has been invested in hydropower during past 20 years. With the official launch of carbon market trading in 2021, changes on carbon storage in the reservoir ecosystem and carbon emission reduction caused by hydropower during operation also have specific economic values. Therefore, this paper estimates the value of changes in ecosystems' carbon storage in the reservoir area from the perspective of carbon market value, considering carbon emission reduction caused by hydropower. Then, the value is compared with the hydropower investment and operating costs to evaluate the economic contribution to the reservoir area in different periods. The study provides guidance for decision-making of hydropower development and reservoir ecosystem management. Moreover, the study provides a comprehensive and effective framework for evaluating changes in carbon storage to reservoir ecosystems and their economic value which is based on integrating land use classification data obtained from remote sensing image interpretation and the InVEST carbon storage model.

The Jinsha River Basin has the largest hydropower resources in China. At present, three of the world's top ten hydropower stations are located here in terms of installed capacity and adequate resources for subsequent development. The Xiluodu hydropower station is the fourth largest station in the world and is located in the Jinsha River Basin. In the past 20 years, a large amount of land resources has been occupied by the construction, infrastructure, and immigrant resettlement along with the station development. The stored water has flooded the adjacent land causing the land use and cover of the reservoir area to change significantly. Functions of ecosystem service in the reservoir area have been affected, including carbon balance. Therefore, the Xiluodu reservoir area was selected for this study as a typical case. Particularly, four stages were selected: the period before hydropower station was built (2000); the beginning of construction (2005); the completion of construction (2015); the operation period (2018). Changes in carbon storage in the reservoir area from 2000 to 2018 were studied with an in-depth discussion on impacts of the station. Detailed topics show as follows:

(1) Distribution of land use and cover types in Xiluodu reservoir area in 2000, 2005, 2015, and 2018 due to hydropower station construction, combined with satellite data and environmental changes.

(2) Current changes of carbon storage in reservoir ecosystem and its main reasons, combined with land use, cover types, and carbon density data.

(3) Calculating economic value associated with carbon storage changes in the reservoir area with the market value method. The method accounts for carbon emission reduction caused by hydropower and compares the hydropower investment and operation costs to evaluate the economics of hydropower development.

2. Materials and Methods

2.1. Research Area. The reservoir area is located at $102°49'36''E$-$103°48'9''E$, $27°15'20''N$-$28°17'31''N$ (Figure 1). The reservoir area ($3,613,657\,hm^2$) is situated in a small watershed within the first ridgeline between the Baihetan hydropower station and the Xiluodu dam site. This location is within the first level watershed of Xiluodu hydropower station which is at the junction of Yunnan and Sichuan Province. There are nine counties (districts) in these two provinces. This area belongs to subtropical monsoon climate which is dry and hot. The annual precipitation ranges from 600 mm to 1100 mm. The annual average temperature varies from $10.1°C$ to $19.7°C$. The altitude ranges from 265 to 3,656 m (data source: Environmental Impact Assessment Report of Xiluodu Hydroproject, Edited by Chengdu Engineering Corporation Limited, April 2005). The reservoir is an ecologically sensitive area in China with steep slopes, high and middle gorge landforms.

The Xiluodu hydropower station is located in the Xiluodu Valley because of abundant water in this area which borders Yongshan County of Yunnan Province and Leibo County of Sichuan Province at the lower Jinsha River. The main program of the hydropower station was started in June 2004 and put into operation in October 2015. After Xiluodu hydropower station started operation, the water area in the reservoir area increased by approximately 10,000 hectares, and the cultivated land decreased by approximately 8,000 hectares.

2.2. Research Framework. The purpose of this study is to provide a framework for assessing impacts of hydropower programs on carbon storage of reservoir ecosystem and provide guidance for future hydropower construction and reservoir ecosystem management. Since the carbon trading market was officially launched in the Shanghai Environment and Energy Exchange (SEEE) in 2021, rights of carbon emission have been endowed with an economic value. Therefore, the evaluation of impacts of hydropower programs on carbon storage can be measured from two aspects: physical quantity and value quantity (Figure 2).

During the studied period from 2000 to 2018, the data obtained from remote sensing image interpretation were used to generate maps of the land use and cover type changes and the land use transfer matrix of the Xiluodu reservoir area from 2000 to 2018. Complementing in-situ monitoring of carbon storage changes, the InVEST model has advantages of data accessibility and visibility to results [25, 26]. It can simulate changes in the value of ecological services of various terrestrial, freshwater, and marine ecosystems. Therefore, the InVEST carbon storage model was used to evaluate physical changes in carbon storage in the reservoir ecosystem caused by hydropower programs.

A change in physical amount of carbon storage in the reservoir area reflects the situation of carbon sequestration and carbon emission. Therefore, a positive net change indicates that the ecosystem absorbs carbon from atmosphere, stores it in the ecosystem, and reduces the content of greenhouse gases in atmosphere. On the other hand, a negative net change indicates that the land use change leads to greenhouse gas emissions. Therefore, considering the carbon emission reduction caused by hydropower programs, the value of the reservoir ecosystem's carbon storage in this study refers to monetizing the carbon sequestration (or carbon emission) and emission reduction by hydropower in the reservoir area. The market value method has been widely used to measure the economic value of the forest carbon sink. Price per unit of the carbon sink is an important factor. This paper uses the market value method to calculate changes in the value of the reservoir ecosystem's carbon storage considering carbon emission trading price of the SEEE. In addition, the calculated value was compared with the carbon sink cost (hydropower investment and operation costs) to discuss the economics of hydropower development.

2.3. Calculation Method

2.3.1. Data Source and Processing. We employed the digital elevation model (resolution 30 m × 30 m) to process land use and cover data used obtained from the Data Center for Resources and Environmental Sciences, Chinese Academy of Sciences. The land use and cover data was sourced from Xiluodu reservoir area in 2000, 2005, and 2015, and data in 2018 were from the Landsat TM/ETM+/OLI satellite remote sensing images of the United States Geological Survey (USGS). The remote sensing images were preprocessed by radiometric correction, geometric correction, color enhancement, splicing, cutting, and then artificial visual interpretation. The accuracy of land use and the cover was greater than 85% which meets research requirements.

According to the classification standards issued by the Ministry of Natural Resources of China and the research needs of ecological environment of the Xiluodu reservoir area, the land use and cover types were divided into five types: (1) cultivated land (dry land, paddy land); (2) woodland (woodland, shrubbery, open woodland, and other woodland); (3) grassland (high coverage, medium coverage, and low coverage); (4) water area; and (5) construction land.

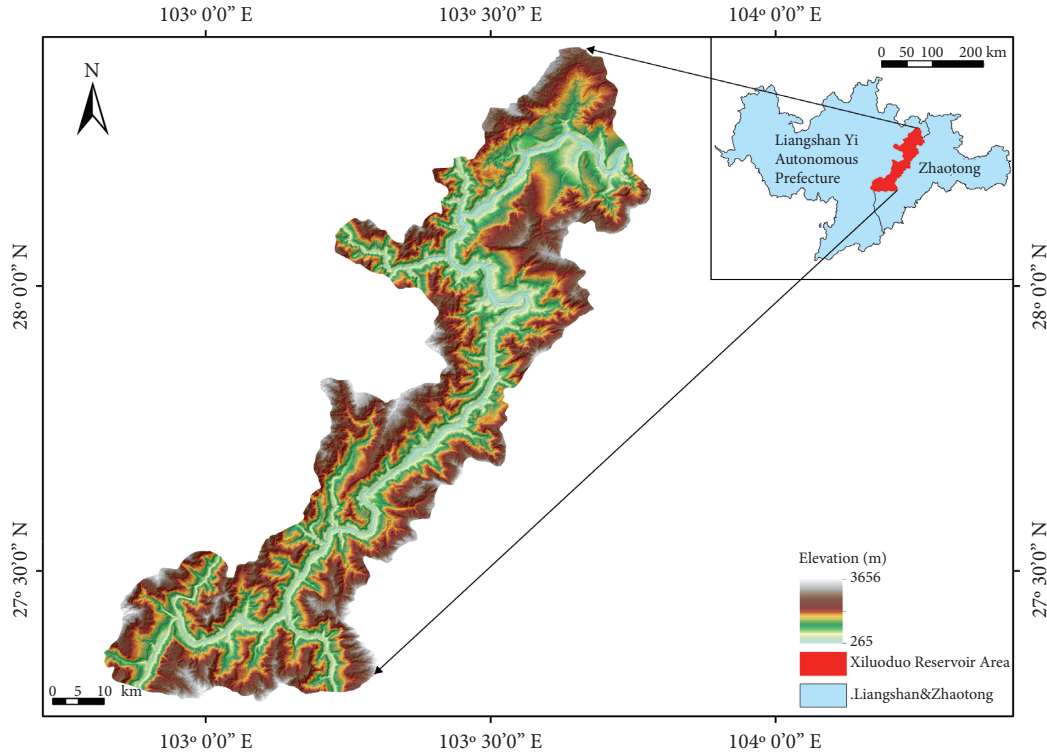
2.3.2. Carbon Storage Model: Application of the InVEST Model. In this paper, the carbon storage and capture model in the InVEST model (version 3.5.0) was used to estimate the


FIGURE 1: Geographic location of Xiluodu reservoir area.

carbon storage of the reservoir area over time, based on the spatial distribution map of land use at different times and carbon density of each land type. The InVEST model simulated the carbon storage of four carbon pools, including aboveground and underground biomass, dead organic carbon, and soil carbon. The top 20 cm layer of soil was studied in this paper. The calculation formula of carbon storage of reservoir ecosystem is as follows:

$$, , C_{total} = C_{above} + C_{under} + C_{dead} + C_{soil}. \tag{1}$$

2.3.3. Carbon Density. The carbon density data of the Xiluodu reservoir area mainly came from areas with a similar natural environment and same classification system as Xiluodu. Data about vegetation type, plant species composition, and vegetation coverage were collected by other scholars via field measurements in the reservoir and nearby areas. Previous studies showed that the conversion coefficient of the biomass to carbon of forest was 0.45–0.50, and that of grassland was 0.40–0.45. The carbon density of the underground root system was determined by ratios of the aboveground biomass to the underground biomass of different land types. The carbon density of the dead organic matter was determined by the ratio of aboveground dead matter to underground dead matter [27, 28]. The final organized data of carbon density of Xiluodu reservoir area are shown in Table 1.

2.3.4. Market Value. Carbon market trading was officially launched on SEEE on July 16, 2021. The closing price on that day was 51.23 CNY/Mg. The carbon in this paper refers to

elemental carbon, while the carbon trading in China uses CO_2eg per ton as trading object. According to the mass conversion coefficient of carbon per ton converted into CO_2eg, which is 3.67, the carbon trading price per ton in this study is converted to 188 CNY/Mg [40].

A previous study showed that the hydropower carbon footprint of the Xiluodu hydropower station is 7.6 gCO_2eg/(kW·h), while the coal-power carbon footprint is 822 gCO_2eg/(kW·h) [41]. The clean energy provided by hydropower station can effectively reduce carbon emissions. By the end of 2018, the cumulative power generation of the station exceeded 300 billion kW·h (date source: China's National Energy Administration, available online), with an emission reduction of 1856.83 million tons of CO_2eg, equivalent to 50.13 million tons of elemental carbon (C). Therefore, the value of carbon storage in the reservoir area can be calculated as follows:

$$V_c = (C_a + C_h) \cdot P_c. \tag{2}$$

V_c is value quantity, C_a is physical quantity change of carbon storage in the reservoir area, C_h is carbon emission reduction by hydropower, and P_c is carbon price (CNY/Mg).

3. Results and Analysis

3.1. LUCC of the Xiluodu Reservoir Area in 2000–2018

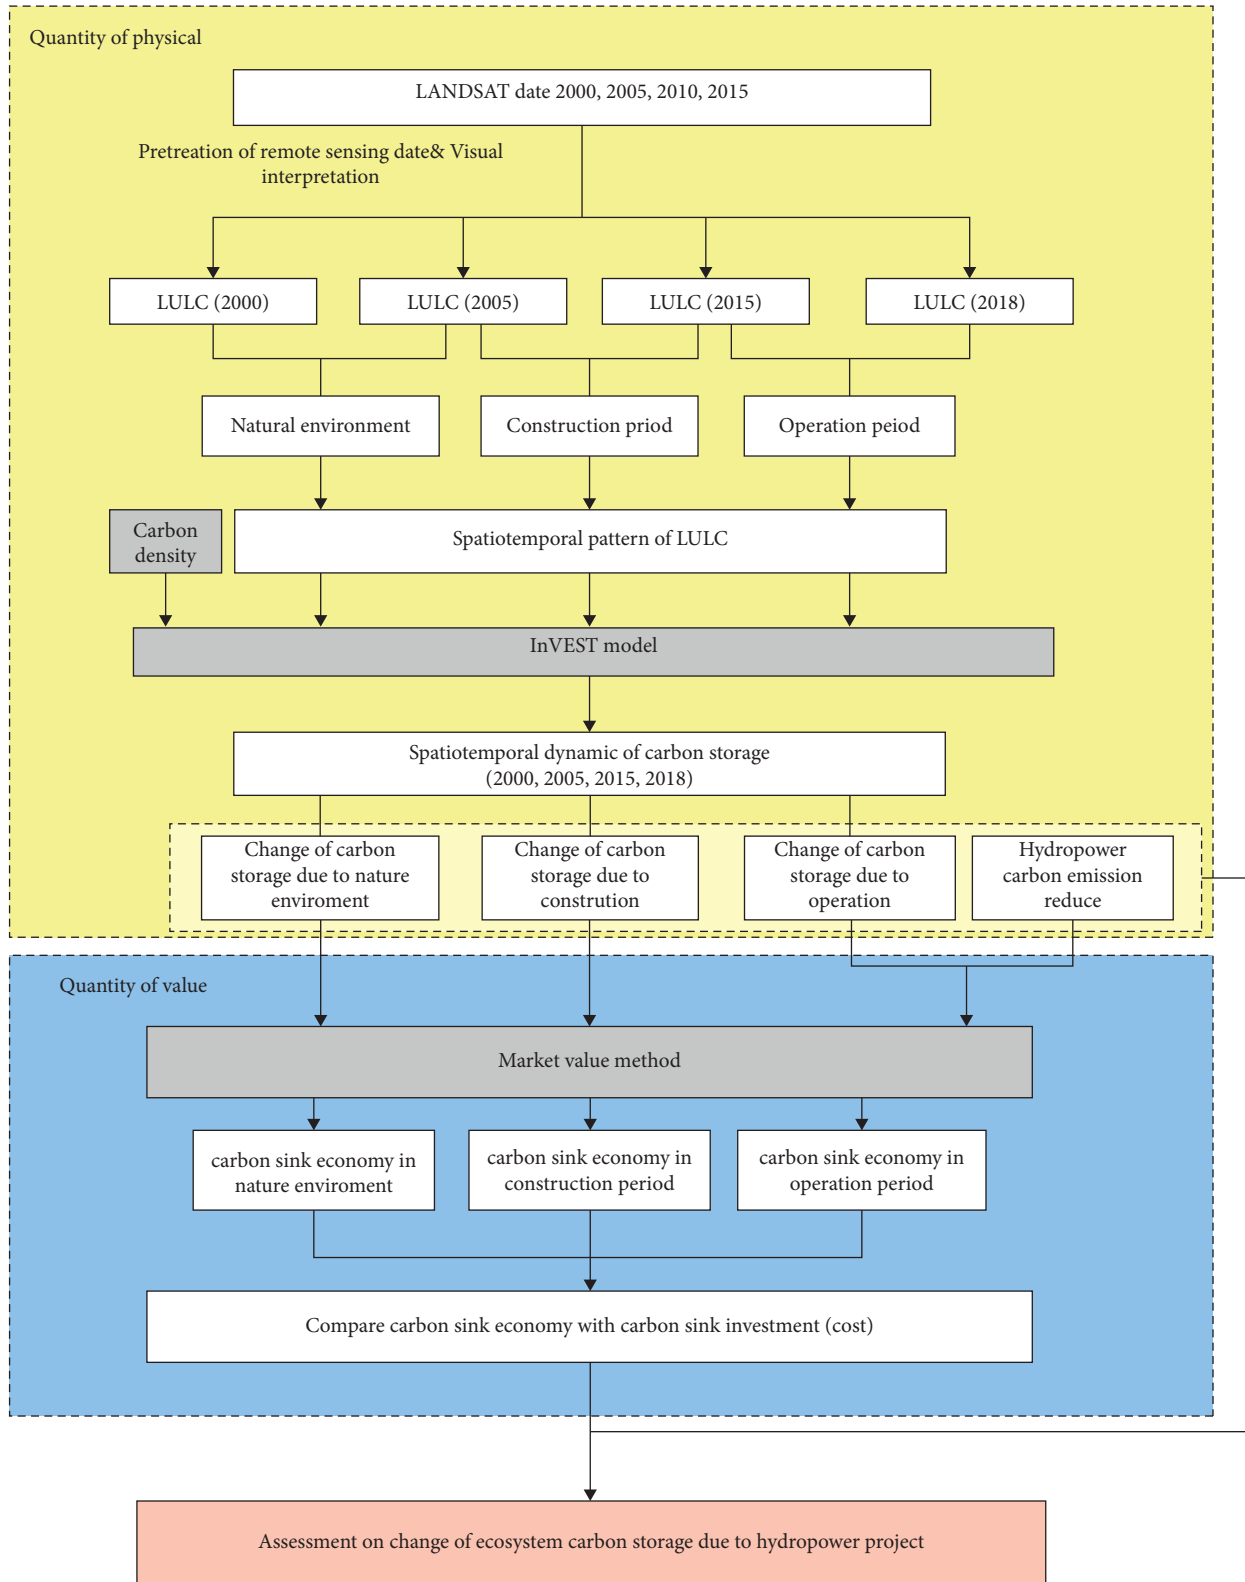
3.1.1. Spatiotemporal Pattern of LULC. The land use and land cover map (LULC) and area changes in the Xiluodu reservoir area from 2000 to 2018 are shown in Figure 3 and Table 2. Before the start of the construction in 2000, the


Figure 2: Methodological framework of the study.

forestland was the main land use and cover type, accounting for 38.91% of the total area of the reservoir area. It was mainly distributed in the mountainous area with a high elevation and a large slope. The grassland accounted for 32.75% of the total area and was distributed in the middle and low altitude areas along the lower Jinsha River. The water area and the construction land accounted for only 0.9% and 0.19% of the reservoir area, respectively. The water

TABLE 1: Carbon densities of different land use types in Xiluodu reservoir area.

Land use and cover types (Mg/hm^2)		$C_{i,\text{above}}$	$C_{i,\text{under}}$	$C_{i,\text{soil}}$	$C_{i,\text{dead}}$	Reference
Category	Type					
Woodland	Woodland	31.95	6.38	146.82	2.96	[29–31]
	Shrubwood	8.1	1.62	91.7	2.48	[31, 32]
	Open woodland	8.1	1.62	91.7	2.48	[29, 30, 33]
	Other woodland	35.03	7.01	142.58	3.75	[29, 30, 33]
Cultivated land	Paddy field	5.42	1.96	92.9	0	[34, 35]
	Dry land	3.64	0	33.46	13	[35, 36]
Grassland	High coverage	2.75	7.37	64.03	4.07	[37, 38]
	Medium coverage	2.205	5.365	48.41	3.035	[37, 38]
	Low coverage	1.66	3.36	25.79	2	[37, 38]
Water area	Water area	0.3	0	0	0	[39]
Construction land	Construction land	0	0	22.25	0	[39]

area was distributed in the river valley area with a low altitude level and a gentle slope, while the construction land was scattered in the upstream river.

During the initial stage of the station construction in 2005, no large-scale engineering construction was carried out since it is at the preparation stage of Xiluodu hydropower station. Therefore, the area was kept under the natural environment, and there were no significant changes in the various land use and cover types. After the station's construction in 2015, the area and distribution of the various land use and cover types changed significantly, with an area reduction of the cultivated land and the grassland. The cultivated land area decreased most, reaching 4732.92 hectares. The forestland area, water area, and the construction land area increased to 39.95%, 1.2%, and 0.2%, respectively. The forestland area increased most, reaching 3736.98 hectares. The increase of forestland was mainly on the west bank of Jinsha River in the hinterland, while the increase of construction land was mainly in the low altitude areas at the front and tail of the reservoir. The increase of the water area occurred mainly on both sides of the Jinsha River.

After the station was completed and put into operation in 2018, the cultivated land and grassland areas in the reservoir further decreased. The biggest reduction in the grassland area decreased to 30.77% and was mainly distributed in the middle and low altitude areas of the central region. The forestland and construction land areas decreased by 788.38 hectares and 293.85 hectares, respectively, compared to 2015, and the reduction was mainly distributed on both sides of the Jinsha River. Only the water area increased greatly, and its proportion increased to 3.7%, mainly distributed in the valley area with a low altitude and a gentle slope.

3.1.2. Land Use and Cover Type Change Directly Caused by Hydropower Station Construction. The land use and cover areas of the Xiluodu hydropower station during preparation (2000–2005), construction (2005–2015), and operation

(2015–2018) periods are shown in Figure 4. Due to construction, the cultivated land and grassland areas in the reservoir decreased considerably, while the water area increased the most, followed by the forestland and construction land area (Table 3). The following observations are noted:

(1) During the construction period, the woodland and construction land were mainly added to the reservoir area, while the cultivated land was mainly removed from the reservoir area. The increased area of both forestland and construction land came from cultivated land and grassland.

(2) Change in the construction land was the greatest, which was four times that in 2005. The increased area was mainly the engineering site of station at the head of reservoir and the immigrant resettlement area at the tail of reservoir.

(3) The forestland area increased by 3726.98 hm^2 downstream of the Jinsha River due to the vegetation restoration measures such as afforestation and natural forest closure during events such as "returning farmland to forest," engineering construction, and immigrant resettlement that began in 1998. Although some forestland was submerged due to water level rise during the station operation, the forestland area still increased compared to 2000. The construction of Xiluodu hydropower station did not cause severe damage to inland plants in the reservoir area.

(4) During the operation period, the water level was raised to inundate other lands in the reservoir area, resulting in a significant increase in water area. The cultivated land and grassland were main sources of the increased water area.

3.2. Carbon Storage in the Xiluodu Reservoir Area from 2000 to 2018

*3.2.1. Spatial and Temporal Distributions of Carbon Storage.*

Figure 3: LULC of Xiluodu reservoir area for 2000, 2005, and 2015.

The total carbon storage of the Xiluodu reservoir area in 2000, 2005, 2015, and 2018 was 31,057,361 Mg, 31,955,862 Mg, 31,510,555 Mg, and 31,067,232 Mg, respectively (Figure 5). The corresponding average carbon densities were 85.94 Mg/hm^2, 85.93 Mg/hm^2, 87.19 Mg/hm^2, and 85.97 Mg/hm^2. SOC was the main carbon pool, followed by AGC, DOC, and BGC. The carbon storage of the reservoir ecosystem decreased by 1,499 Mg from 2000 to 2005. The

	Construction land	32.67	152.73	170.64	264.33	2239.56
Figure 5: Carbon storage changes of different carbon pools.

carbon storage increased by 453,193 Mg during the construction period of 2000–2015. The carbon storage decreased by 443,322 Mg during the operation period of 2015–2018. The carbon storage increased by 8504.42 Mg in 2018 compared to 2000 when the hydropower station was not built.

From changes in proportions of land use carbon storage in the reservoir area (Table 4), the forestland was the largest carbon pool in Xiluodu reservoir area. The forestland had a high distribution density and high carbon density, accounting for 54.55%–57.2% of the total carbon storage of the reservoir area ecosystem, and its proportion continued to rise. The carbon storage of the grassland ranked next to the forestland. The grassland and the cultivated land accounted for 25.34%–26.66% and 17.15%–18.73% of the total carbon storage, respectively. The carbon storages of the grassland and the cultivated land continuously decreased each year. The carbon storage of the construction land and the water area ranked the lowest, which accounted for only 0.05%–0.22%. Although the water area increased significantly from 2000 to 2018, its carbon storage was still the lowest which is only 0.02% due to low carbon density.

In terms of spatial distributions, the carbon storage in the reservoir area was higher in the north and west, but lower in the south and east. The high carbon storage areas were mainly distributed in the high-altitude mountainous forest areas at the upstream and the western boundary of the reservoir. These areas had high vegetation coverage and good vegetation growth which is seldom affected by human activities. Therefore, their natural plants were well maintained. The second high carbon storage area was the grassland area in the south of the reservoir area. The water area was mainly distributed in the mainstream of the Jinsha River and its tributaries with the lowest carbon storage (Figure 6).

The carbon storage and spatial distribution did not change significantly from 2000 to 2005. However, with the construction of Xiluodu hydropower station, the carbon storage and spatial distribution changed significantly from 2005 to 2015 during the construction period. The carbon emission was mainly from the hydropower station construction area in the north and the immigrant resettlement area in the south. The carbon sequestration area was mainly the forestland on the western bank of Jinsha River in the middle of the reservoir area. As the station entered its operation period, the carbon storage along the mainstream and tributaries of Jinsha River decreased significantly from 2015 to 2018. Compared with the construction period in 2005–2015, the carbon emission area increased significantly, mainly due to the water level rise in the operation, which flooded vast grassland and cultivated land (Figure 7).

3.2.2. Carbon Storage Change Directly Caused by the Xiluodu Hydropower Station Construction. Due to the construction of Xiluodu hydropower station, the vegetation density, land use, and cover types in the reservoir area changed, which affect the carbon storage of ecosystem (Table 5). From 2000 to 2005, changes in vegetation densities of forestland, cultivated land, and grassland caused carbon densities to change from $120.499 \, \text{Mg/hm}^2$, $59.058 \, \text{Mg/hm}^2$, and $69.982 \, \text{Mg/hm}^2$ to $120.514 \, \text{Mg/hm}^2$, $59.070 \, \text{Mg/hm}^2$, and $70.123 \, \text{Mg/hm}^2$, respectively. The total carbon storage of the unchanged land use and cover types in the reservoir area increased by 5042.82 Mg. With the area conversion to different land use and cover types, the total increase of the carbon storage was 49,746.58 Mg, and the total decrease was 51,244.96 Mg, while the net decrease was 1,498.48 Mg. The annual carbon emissions of the ecosystem were 299.696 Mg/year.

During the construction period from 2005 to 2015, changes in the carbon densities of forestland, cultivated land, and grassland were $123.122 \, \text{Mg/hm}^2$, $58.913 \, \text{Mg/hm}^2$, and $70.123 \, \text{Mg/hm}^2$, respectively. The carbon storage of unchanged land use and cover types increased by 106,863.66 Mg. Due to the area conversion, the total increase of carbon storage was 827,971.28 Mg, and the total decrease was 373,278.88 Mg, while the net increase was

land use and cover types was 700,667.40 Mg, and the total decrease was 1,143,990.22 Mg, while the net decrease was 443,322.82 Mg. The annual carbon emissions of ecosystem were 147,774.27 Mg/year.

During the entire study period from 2000 to 2018, the carbon storage of ecosystem caused by land use and cover type change was mainly due to the increase in forest area. The policies of "returning farmland to the forest" downstream of Jinsha River since 1998, the Changsha Shelterbelt Program, and the large-scale artificial planting and natural forest closure management since the hydropower program construction influenced the increase in forest areas. The forest areas converted from other types of land during period of 2000–2005, 2005–2015, and 2015–2018 were 38,644.31 Mg, 607,448.39 Mg, and 309,142.4 Mg, respectively, with ratios of 77.68%, 73.36%, and 44.12%. The carbon increase from 2000 to 2005 mainly came from converting cultivated land to forestland. The carbon increase from 2005 to 2015 mainly came from conversion of cultivated land and grasslands to forestland. The carbon increase from 2015 to

2018 mainly came from the conversion of grassland to forestland.

In these three periods, main sources of carbon loss were different. Before the construction (2000–2005), the carbon loss was mainly due to converting forestland and grassland to other land uses and cover types with a lower carbon density. During the construction (2005–2015) and operation (2015–2018) periods, the carbon losses were mainly due to the conversion of cultivated land and grassland to other land uses and cover types with a lower carbon density.

From 2000 to 2005, the main reason for carbon loss of reservoir ecosystem was the conversion of forestland to cultivated land and grassland. The carbon loss was 38,077.15 Mg, accounting for 74.30% of the carbon loss for that period. This was related to China's strict implementation of cultivated land protection policies, such as "Dynamic Balance of the Total Amount of Cultivated Land in the Region" and "Land Use Control," and some forestland has been reclaimed for cultivated land. Meanwhile, the regional ecological environment became fragile due to

TABLE 6: Carbon storage value and carbon sink cost evaluated at the 2000 price level.

Economic benefit and cost	2000–2005	2005–2015	2015–2018
Value (100 million RMB)	−0.001	0.19	19.87
Hydropower program cost (100 million RMB)	0	306.21	9.14
Amortized cost of hydropower program (100 million RMB)	0	0	18.28

cultivation of steep slopes and reclamation, and some forest vegetation was seriously destroyed and changed into grassland. The construction of Xiluodu hydropower station, immigrant resettlement, construction of supporting facilities, and water storage of the Xiluodu reservoir were important reasons for loss of cultivated land and grassland from 2005 to 2015.

During the construction period (2000–2015), the carbon losses caused by conversion of nonconstruction land and nonwater land into construction land and water area were 99,689.03 Mg and 93,397.37 Mg (corresponding to 26.70% and 25.02%), respectively. During the operation period (2015–2018), the carbon loss caused by conversion from nonwater area to water area was 652,691.21 Mg, accounting for 57.053% of the carbon loss in the same period. On the other hand, the carbon loss caused by conversion of nonconstruction to construction land accounted for 1.25%. It can be observed that, during the construction period, the carbon emission area of the reservoir was distributed in the converted area of nonconstruction to construction land and the submerged area with the rising water level. In contrast, during the operation period, the carbon emission area was only distributed in the submerged area with the rising water level.

3.3. Market Value. In order to make the carbon storage value in reservoir area comparable to the cost of the hydropower program from 2005 to 2018, CPI (consumer price index) was used to modify value and cost from 2000 to 2018. The monetary values in this study were prices in 2000. The discount rate of the capital market was assumed to be 8% [28, 42].

In this study, the economic value was evaluated based on the value of carbon storage of reservoir ecosystem during construction (2005–2015) and operation (2015–2018) periods of Xiluodu hydropower station by considering emission reduction. The carbon sink cost refers to the total investment of hydropower station in three periods. From 2005 to 2015, the total static investment of Xiluodu hydropower station was 44.993 billion Yuan in RMB evaluated at the price level of 2005. According to the estimated annual maintenance cost in the environmental assessment impact report of Xiluodu hydropower station, the annual maintenance cost was 1% of the total static investment, i.e., 449 million RMB (2005 price level) [41] (Table 6).

Before the station's construction (2000–2005), there were carbon emissions in the reservoir ecosystem under natural conditions, and the carbon storage value was −0.1 million Yuan in RMB. During the construction period (2005–2015), the carbon storage increased, and the value of carbon storage change was 19 million Yuan. During the

operation period (2015–2018), the carbon storage value increased significantly to 611 million Yuan considering the carbon emission reduction caused by hydropower. Moreover, during the construction period (2005–2015), the total investment of the station was 30.621 billion Yuan. We assumed the life of the station was 100 years [41], so the investment was evenly divided to 306 million Yuan per year from the first year of operation. During the operation period (2015–2018), the maintenance cost of the station was 914 million Yuan. With consideration of construction investment, the program cost was 1.828 billion Yuan.

It can be seen that the ecological protection measures during the construction period improved the carbon capture capacity and made a significant contribution to economy of the reservoir area. In addition, the rapid growth of carbon storage value of the reservoir ecosystem was mainly due to hydropower generation. From 2015 to 2018, the value brought by carbon storage was greater than cost on hydropower station's maintenance and slightly exceeded the amortized cost of the hydropower program. Even if the grid electricity price was not considered, the above analysis still demonstrates hydropower development's excellent feasibility and economic value. Furthermore, Xiluodu hydropower station has also played a substantial role in soil erosion prevention, flood control, sand control, and shipping transportation.

4. Discussion

Based on the InVEST model and the LULC data obtained from remote sensing images, this paper discusses in detail the physical and economic value changes of carbon storage in Xiluodu reservoir area from 2000 to 2018. The results show that the construction and operation of station generated significant changes in land use, cover types, and fluctuations in ecosystem carbon storage in the reservoir area. The hydropower program made positive contributions to economy of the reservoir area:

(1) The construction of hydropower station disturbed the reservoir ecosystem. However, after the construction completion, the ecological restoration measures brought the carbon storage level of the reservoir ecosystem higher than the preconstruction level even though a large amount of land was submerged in the water area. With the comparison of status of before and after station construction, it was found that the forestland, water area, and construction land in the reservoir area increased, while the areas of cultivated land and grassland decreased. The water area reached 10,118.07 hectares which increased most because of water storage in the

reservoir from 2015 to 2018. The water has inundated cultivated land and grassland along the Jinsha River and its tributaries. The cultivated land had the largest reduction in area, reaching 7,835.13 hectares, mainly due to water flooding, immigrant resettlement, land occupation for the station construction, and ecological conversion of farmland.

(2) In terms of physical quantity, the carbon storage in Xiluodu reservoir area increased by 8,504.42 Mg from 2000 to 2018. The spatial distribution of carbon storage exhibited a trend of higher in the north and west while lower in the south and west. During the construction period (2005–2015), the station occupied a large amount of nonconstruction land, and the water level rose to flood nonwater area resulting in the loss of carbon storage. Still, the forest area increased compared to 2005 due to implementation of water and soil conservation and vegetation restoration policies which increased the carbon storage of ecosystem. Considering all land use and cover area, the carbon storage of reservoir ecosystem increased during the construction period. During the operation period (2015–2018), the reservoir water level rose and flooded large cultivated land and grassland. This was the main reason for the loss of carbon storage of ecosystem. However, compared to 2000 when the construction was not started yet, the carbon storage in 2018 was more significant. The change of carbon storage mainly comes from the losses of carbon storage in the construction area in the north of the reservoir area, the resettlement area in the south, the main stream and tributaries of the lower Jinsha River, and the increase of carbon storage in the central and western bank of the Jinsha River. This change may be due to increased vegetation coverage, reduced soil erosion, and a stable terrestrial ecological environment after the construction of station.

(3) During the operation period (2015–2018), the value change of carbon storage of the reservoir ecosystem was greater than operation and maintenance cost on hydropower station and exceeded the station's amortized cost. Even if the income from grid electricity price was not taken into account, the analysis still showed that hydropower development is feasible and economical.

(4) Coal power (49.07%, from the year 2020 data) has been the largest energy source in China. It has become the main option of electrical power development due to low construction cost and fast production. However, the operation cost has increased and the profits have decreased with emergence of carbon emission. Although the initial investment cost of hydropower is higher and the construction period is longer, its sales income of carbon emission rights in the operation period is greater than the maintenance cost and even the investment cost. Therefore, the economic value of hydropower is significantly higher than that of coal power.

5. Conclusions

(1) This study proposes a framework for assessing impacts of hydropower programs on the reservoir ecosystem's carbon storage. It provides recommendations for future land management in the reservoir area and hydropower development management in Jinsha River Basin and other areas. The case study of Xiluodu reservoir area found that afforestation and forest restoration are main factors leading to the increase of carbon storage in reservoir area. Other effective measures to increase carbon storage of the reservoir system include a reasonable plan of the proportion of green and construction land in future land management; conversion from cultivated land to forest land; and increase of vegetation coverage and quality. Moreover, vegetation restoration measures such as natural forest closure management and afforestation in future hydropower development can effectively mitigate the disturbance to the reservoir ecosystem. The land use and cover type with a low carbon density should be selected as much as possible when determining the inundated area to reduce carbon loss caused by the rising water level in the reservoir. In addition, evaluating the carbon storage value of the reservoir ecosystem can help in decision-making of hydropower development.

(2) This paper has several limitations that are subject to future study. First, most carbon density data came from previous literature and were fixed values with which their time variations were disregarded. The constant assumption is different from real situation since the carbon densities are more complex in different land uses and cover types in different periods. Therefore, dynamic carbon densities need to be obtained in future through detailed field monitoring in the reservoir area to improve the accuracy of results. Secondly, the InVEST model can also be used to quantify the ecosystem services in the reservoir area in addition to carbon storage assessment, such as habitat quality and soil erosion. The impacts of hydropower programs on various ecological services in the reservoir area can be assessed in future studies.

In order to reduce the excessive use of multisource traffic information collection system, a multisource traffic information collection combination optimization mode is proposed based on genetic algorithm in this paper. This model is mainly used to analyze the traffic management data in the city. According to the collected data information, the characteristics of the traffic equipment can be effectively analyzed. Basing on the market demand and supply relationship, the multisource traffic information collection combination optimization model is used to complete the reorganization and optimization of the traffic information in this paper, to acquire the main convolution feature variables of the model. The data information combination processing is performed according to the acquired feature variables, and the genetic algorithm is used to adjust the multisource traffic information. During the process of information fusion data analysis, the multisource traffic information clustering and fuzzy constraint control can be performed effectively to realize the optimization of the team's traffic information collection combination. Finally, the simulation results show that the method proposed in this paper is more accurate in realizing the optimization process of multisource traffic information collection and combination and has a better degree of information fusion.

1. Introduction

At present, many large-scale cities in China have gradually increased their investment in urban transportation systems, especially in the collection of multisource traffic information [1, 2], wasting a lot of manpower and financial resources. as the foundation of urban traffic infrastructure, multisource traffic information can be used to effectively improve the During accuracy and efficiency of traffic information collection, laying the foundation for improving the urban intelligent traffic system [3, 4]. However, currently, due to the single structure of the existing acquisition system hardware in the use process, the collected data information is inaccurate, and the cost of investment is huge. The limitation of the single-structured traffic data acquisition equipment lies in the small acquisition range. Fixed information collection period and fixed types of acquired data information, resulting in large-scale investment and serious waste of resources. Meanwhile, all kinds of information collection equipment are damaged seriously leading to huge maintenance costs. The use of different types of information collection equipment will cause repeated collection of traffic information and increase the workload.

Based on genetic algorithm, a combined model of multisource traffic information collection is proposed in this paper. The model can be used to effectively analyze the results of the obtained multisource traffic information, genetic algorithms are combined to collect and combine the initial traffic information, complete the reconstruction of the multisource traffic information spatial structure, and obtain the convolutional characteristics of the traffic information. According to the characteristic variables, the fusion processing and combination of data information can be carried out. Complete distributed clustering of multisource information in the fusion space. Finally, the analysis of experimental simulation results shows that the method in this paper has superior performance and information collection ability in the process of extracting multisource traffic information collection combination.

2. Information Collection and Feature Preprocessing

2.1. Collection Combination Optimization System. The flow of mobile positioning and real-time monitoring system of road vehicle is shown in Figure 1, which mainly includes three parts: extraction and tracking of vehicle targets, road condition detection and real-time monitoring of traffic flow [5, 6]. The extraction and location of vehicle targets are mainly realized by the construction of the detection background to extract the characteristics of the moving vehicle, while monitoring the vehicle parameters in the implementation. The road background is based on for modeling the road condition monitoring, and the road surface can be divided by the acquired data information, and the vehicle detection area is extracted to obtain the conversion between the road plane coordinates and the left side of the multimedia spectrum plane. The data of the road and traffic flow obtained in previous times is integrated by the road traffic to complete the data analysis and statistics of the traffic flow on different lanes [7–11]. This system uses the traffic flow pictures collected by the cameras placed on the platform.

The main control software design is mainly composed of two main programs, which are the main control programs that can complete different business logics and the programs that can realize the user-side GUI process control. The main control program is mainly to receive external commands, and meanwhile send the obtained traffic flow information to the corresponding business module for processing, effectively realizing the business logic between systems.

The main process uses a message transfer mode including a communication module, a message transfer module, and a business module. The communication module mainly establishes a network link [12–14], and sends the received data information from the control information obtained to an arbitration level information commands are sent to the control center through the service interface. The control command center module executes in accordance with the message queue mechanism acquired by the GUI process system and the method of sending and receiving information between the corresponding processes. When the service module mainly processes specific services and all service modules are initialized, the service function module sends the command information that needs to be processed to the message control module. At the same time, when data information is received, the data control center will send the command information to the business module for sorting. The GUI process is developed based on the embedded graphics library mimugui, which is mainly a graphical user interface that realizes the needs of business logic. The GUI process communicates with the main process in the same way as the message queue [15].

The vehicle positioning detection module mainly communicates with the weight measurement platform and adopts the modbus protocol. This module is the master, and the vehicle volume measurement platform is mainly used as a slave device. The input of the vehicle positioning detection module is received using the RS485 interface, and the vehicle

volume detection module is used to extract vehicle volume-related data information, and at the same time, it is sent to the message arbitration module to obtain the quantity statistics operation command from the outside. The output of the detection module includes the transmission of the detection result data to the center via the network. The results of the quantity statistics are stored in the database. The detection of instructions are sent to the detection platform through the RS485 interface. the RS485 interface and the quantity statistics platform are used for the processing of the quantity statistics module to construct information and data associations. Meanwhile, the automatic fixed time is set at the RS485 interface to automatically and regularly read the vehicle information from the quantity statistics platform, and the analysis results are sent to the module for processing through data analysis. The interface to network is used by vehicle positioning detection module to send statistical results to the control center and stores them in the database. The processing steps of the detection module are shown in Figure 2.

The GPS module is used to obtain the geographic information parameters of the vehicle in this paper. When the vehicle image is acquired, and it is used in the system *l*, the processing of the above data can be displayed digitally, and the obtained results will be stored. The input GPS device of the GPS module is GPS information data sent via the network in this paper. The output of the GPS module's data information is encrypted and protected in the network center, and then the message arbitration module is used to store the vehicle-related data information in the GUI module. The warning information about GPS is stored in the database, and the data sent is mainly the warning information of GPS. The paper. GPS module is usually processed with a dedicated network to obtain the GPS device data information and use the GPS data analysis function module to realize the transmission of relevant information data and relevant alarm information by the network center GPS. As shown in Figure 3.

The data transmission task mainly includes the vehicle-mounted terminal transmitting data to the monitoring platform. In addition to the real-time data of the vehicle, it also includes sending the identification information and data mentioned in the link management task to the mainly includes branch of monitoring platform as supplement. The vehicle-mounted terminal can transmit information to multiple monitoring centers, so multiple data transmission tasks coexist. The data management is performed for coordinating multiple data transmission tasks to prevent conflicts and resource competition.

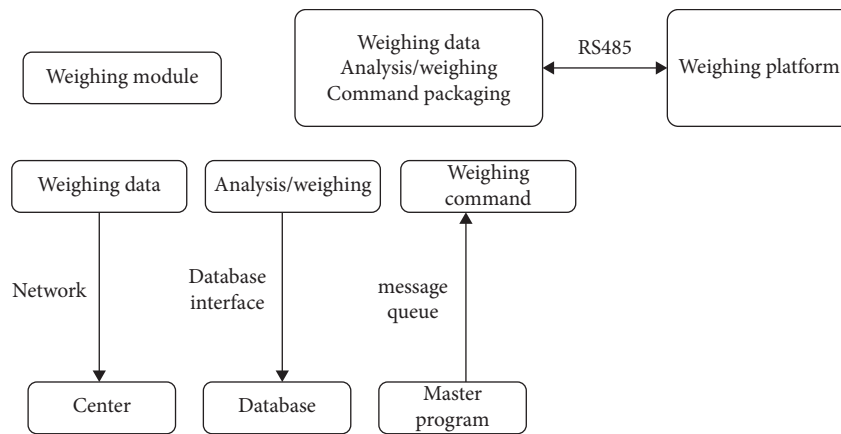
2.2. Collection of Multisource Traffic Information. In order to realize the optimal collection and fusion dispatching of traffic in a complex traffic network environment, first the design of a distributed data structure of multisource and multisource traffic information shall be carried out in the complex traffic network environment, and a multisource traffic information database structure is built in a complex


FIGURE 1: System flow chart.

FIGURE 2: Block diagram of quantity statistics module.

FIGURE 3: GPS module block diagram.

network environment,..0 + the fuzzy decentralized preservation center of multisource traffic information needs to be represented by 4 groups G. Suppose i is the feature space of the interaction of multiple sources of traffic information in a complex traffic network environment. The multisource traffic information is reconstructed in a high-dimensional feature space in a complex traffic network environment using the coupled statistical method of multiple non-linear components, combined with pattern recognition and adaptive clustering methods, to carry out the information fusion and feature extraction of source traffic information in multiple traffic network environments. Based on the above analysis, Figure 4 shows the overall structure model of building a combination of multisource traffic information collection and fusion collection in a complex traffic network environment.

According to Figure 4, the multisource traffic information collection process contains a large amount of
FIGURE 4: The overall structure model combined by multisource traffic information collection and fusion collection.

interference information and road condition information. This multisource traffic information indicates the data by spectral characteristics. The multisource and multisource traffic information contains n variables. $\{y_1, y_2, \ldots, y_n\}$ can be used to represent the variable threshold corresponding to a_j. The simplified mathematical model of multisource traffic information can be explained by the following formula.

$$
\begin{cases}
G_1 = b_{11}a_1 + b_{12}a_2 +, \ldots, b_{1n}a_n \\
G_2 = b_{21}a_1 + b_{22}a_2 +, \ldots, b_{2n}a_n \\
\ldots \\
G_n = b_{n1}a_1 + b_{n2}a_2 +, \ldots, +b_{nn}a_n
\end{cases}
\tag{1}
$$

Among them, a_j and G_k both have a strong correlation, which represents a distributed array of sensors that collect multisource traffic information in a complex traffic network environment, and use multisensor fusion recognition methods for effective information mining in multisource traffic in the Internet of Vehicles. The fuzzy adaptive clustering method is used to construct multisource in multi traffic information statistical feature quantity, combined with normalized feature extraction method, the multisource traffic information autoregressive analysis result is $u(x_j)\xi_j$, and the detection problem of multisource traffic information is transformed into a linear problem of measuring the dynamic distribution of multisources in a complex traffic network environment. According to the above design, the statistical result model of multisource traffic information is analyzed, and the statistical feature sampling method is used to carry out the acquisition of the information of the original multisource traffic [8].

2.3. Big Data Fusion of Traffic Information.
Based on the time-frequency coupling distribution of the multisource traffic bit sequence, the genetic algorithm method is used to remove the interference component and the feature set of the multisource traffic information [9] and realize the fuzzy clustering processing of the multisource traffic information of the automobile network: $k(x_i, x_j)$

$$
\left.
\begin{array}{l}
\min_{w,b,\xi} \dfrac{1}{2}\|w\|^2 + C \displaystyle\sum_{j=1}^{l} u(x_j)\xi_j \\[3mm]
\text{s.t. } y_j\big((w \cdot x_j) + b\big) + \xi_j \geq 1 \\[3mm]
\xi_j \geq 0, \; j = 1, 2, \ldots, l
\end{array}
\right\}.
\tag{2}
$$

Regarding the nonlinear collection and combination problem, based on the temporal variability and random change characteristics of traffic information, the fuzzy dynamic change kernel function $k(x_i, x_j)$ is introduced for dynamic feature separation. The following quadratic planning shows the information fusion of multisource and multisource traffic information problem.

$$
\left.
\begin{array}{l}
\min_{\alpha} \dfrac{1}{2} \displaystyle\sum_{i=1}^{l}\sum_{j=1}^{l} y_i y_j \alpha_i \alpha_j K(x_i, x_j) - \sum_{j=1}^{l} \alpha_j \\[4mm]
\text{s.t. } \displaystyle\sum_{j=1}^{l} y_j \alpha_j = 0 \\[4mm]
0 \leq \alpha_j \leq u(x_j)C, \; j = 1, 2, \ldots, l
\end{array}
\right\}.
\tag{3}
$$

Based on the results of feature extraction, statistical regression analysis is used to analyze the nonlinear structure group of multisource traffic information in a complex traffic network environment [10], and a linear coupling model is derived:

$$
x_k = \sum_{n=0}^{N/2-1} 2\left(a_n \cos \frac{2\pi kn}{N} - b_n \sin \frac{2\pi kn}{N}\right), \quad k = 0, 1, \ldots, N-1.
\tag{4}
$$

Among them, a_n represents the feature distribution of multisource traffic information linear programming in a complex transportation network environment. There are m multisource traffic information nodes $A_1, A_2, \ldots, A_m$ in a

complex transportation network environment to construct multisource traffic information fusion scheduling in a complex transportation network environment. Its mathematical expression is as follows:

$$\min(f) = \sum_{i=1}^{m} \sum_{j=1}^{n} C_{ij} X_{ij},$$

$$\text{s.t.} \begin{cases} \sum_{j=1}^{m} X_{ij} = a_i, \ i = 1, 2, \ldots, m \\ \sum_{i=1}^{m} X_{ij} = b_i, \ j = 1, 2, \ldots, n \\ X_{ij} \geq 0, \ i = 1, 2, \ldots, m; \ j = 1, 2, \ldots, n \end{cases} \quad (5)$$

Assuming that the number of multisource and multisource traffic information distribution nodes in the current complex traffic network environment is n, $N_1, \ldots, N_n$ the learning method of fuzzy convolutional neural network is adopted to realize the big data fusion of traffic information.

3. Collection Combination Configuration Model

When analyzing traffic conditions, a sufficient amount of multisource traffic information must be used as a database, but excessive traffic data will cause data duplication and redundancy [5]. Meanwhile, too many information collection devices have limited improvement in real-time monitoring of traffic conditions, which also causes a waste of social resources. Therefore, the basic idea of modeling in this paper is to comprehensively utilize the advantages of multiple multisource traffic information collection devices, make up for the shortcomings of different types of equipment, and form a multi-source traffic information collection system that constitutes an efficient and low-cost combination structure for correct collection and analysis of the data of the communication status.

A single multisource traffic information collection device is the basis of a composite configuration system. In order to make full use of the applicability of a single device, the principle of single configuration is first discussed.

3.1. Layout Based on a Single Multisource Traffic Information Collection Device.
General information collection devices are considered mainly in this article, which divides the types of devices into fixed and mobile types, and discusses their configuration methods.

3.1.1. Layout Method of Fixed Collection Equipment.
Set the road network as G (T, A), where T is the node in the road network and A is the road section in the road network. α_{ji} is defined as whether i multisource traffic information collection equipment is installed on the j section. If it is set, then $\alpha_{ji} = 1$, if not set, then $\alpha_{ji} = 0$. Based on the maximization of utility, the utility maximization model of collection equipment is established [6]:

$$\max U = \sum_{\alpha_i \in A} \alpha_{ji} f_i r_j,$$

$$\alpha_{ji} = 0 \text{ or } 1, \quad (6)$$

where U is the utility of the collection equipment; f_j is the traffic fluctuation coefficient of road section j; and r_j is the objectively important coefficient of road section j.

(1) Determination of Traffic Fluctuation Coefficient f_j. The traffic variation coefficients in different sections are different. The traffic variation coefficient is mainly affected by the traffic flow [7].

The traffic fluctuation coefficient is determined by the traffic volume. Take the observation sample h_k, $k = 1, 2, \ldots, l$, calculate the sample mean $\mu(h_k)$ variance $\mu(h_k)$, let

$$f_k = \frac{\delta(h_k)}{\mu(h_k)}. \quad (7)$$

The maximum is taken through computation, then

$$f_{\max} = \max(h_k), \ k = 1, 2, 3, \ldots, m,$$
$$f_{\min} = \min(h_k), \ k = 1, 2, 3, \ldots, m. \quad (8)$$

Based on equation (3) (9)

$$\sum_{k=1}^{l} \mu^2(h_k) = \sum_{k=1}^{l} \delta^2(h_k)/f_k^2. \quad (9)$$

Then,

$$\sum_{k=1}^{l} \delta^2(h_k)/f_{\min}^2 \geq \sum_{k=1}^{l} \mu^2(h_k) \geq \sum_{k=1}^{l} \delta^2(h_k)/f_{\max}^2. \quad (10)$$

Due to change in equal change, the following is obtained

$$f_{\max} \geq \left[\sum_{k=1}^{l} \delta^2(h_k)/ \sum_{k=1}^{l} \mu^2(h_k) \right]^{1/2} \geq f_{\min}. \quad (11)$$

Then the fluctuation coefficient of the road section is

$$f_j = \left[\sum_{k=1}^{l} \delta^2(h_k)/ \sum_{k=1}^{l} \mu^2(h_k) \right]^{1/2}. \quad (12)$$

(2) Determination of the Objective Importance r_j of Road Sections. The importance of different roads is almost inconsistent. The location of the bottleneck in the road network has a great impact on the road network. For example, sections with heavy traffic during peak hours and sections in busy streets are compared with the section with small traffic volume has relatively little impact on the road network. For example, unimportant sections near the suburbs.

The importance of the road network can be calculated according to the traffic volume [8]. The total traffic flow $Q = \sum_{j=1}^{r} q_j$ is defined, where r is the total number of intervals, q_j is the flow of interval j, $Q \leq L$ L is the network capacity, and Q is the historical data. Therefore, the objective importance T_j of segment j is

$$r_j = \frac{q_j}{Q}. \tag{13}$$

3.1.2. How to Determine the Sample Size of GPS Floating Car.
Different from fixed information collection equipment, mobile equipment mainly adjusts the input amount to ensure sufficient data collection [9]. This article chooses the floating lane network coverage. γ as an index to evaluate the adequacy of the input amount, there are

$$\gamma = \left(\frac{r}{R}\right) \times 100\%. \tag{14}$$

In the formula: r is the number of road sections that can be covered by the floating car and R is the total road section number in the road network.

The condition for judging whether a road is covered is that GPS floating car information can be obtained during the research cycle. With reference to previous research experience, there is the following relationship between the number of GPS floating vehicles in the road network and the capture rate.

$$\gamma = \exp\left\{-\left(a_0 + a_1 x_2 + a_2 x_2 + a_3 x_3 + a_4 x_4 + a_5 x_5 + a_6 x_6 + a_7 \ln(x_7)\right)^2\right\},$$

$$\begin{cases} \gamma \geq C_1 \\ x_7 \leq C_2 \\ \dfrac{d_r}{d_{x_7}} \geq C_3 \end{cases}, \tag{15}$$

where γ is the coverage of the road network; $x1$ is the area of road network, $100\,\text{km}^2$; $x2$ is the ratio of the expressway in the road network to the total road length; $x3$ is the ratio of the main arterial road to the total road length; $x4$ is the secondary arterial road to the total road length. $X5$ is the proportion of the length of secondary access road to the total road; $x6$ is the density of road network, km/km^2; $x7$ is the number of floating vehicles, (in hundreds); C1 is the minimum threshold of road network coverage, (in hundreds); C2 is maximum number threshold of GPS floating vehicles, (in hundreds); C3 is the minimum threshold of the marginal contribution of the number of floating cars to the coverage of the road network. In the model, a0, a1, a2, a3, a4, a5, a6, and a7 can be obtained by regression analysis.

3.2. Combination Configuration Principle for Multisource Traffic Information Collection.
The combination configuration of multisource traffic information collection shall satisfy the following principles:

(1) Ability to collect more effective multi-source traffic information;

(2) While minimizing the cost of the arrangement of the collection equipment, more effective multisource traffic information can be collected, and multi-function can be used to limit the overlap of data.

(3) The reduction of equipment input discussed in this paper is mainly based on the viewpoint of reducing the redundancy of data collection and subject to the optimization goals of other functions of the equipment.

3.3. Establishment of Model.
The set N is defined as the number of different types of multisource traffic information collection devices, and different collection devices can be put on the same road.

The defined variable a_{ji} indicates whether the ith multisource traffic information collection device is installed on the jth road. If is set, then $a_{ji} = 1$; if it is not set, then $a_{ji} = 0$, a_{ji} form matrix A.

3.3.1. Construction of Objective Function considering Economic Benefits.
Targeting at the lowest total configuration cost of collection equipment, with collecting the best multisource traffic information as the premise, there are various configuration methods for collection equipment. The cost of different equipment is different. In order to minimize the total cost of configuration, the most suitable layout plan can be obtained by optimizing the combination configuration.

In this article, we only considered general fixed and mobile collection equipment. In the construction of the function for the purpose of economic effect, the key variable of the device needs to be considered for the fixed information collection device, and only the number of equipment needs to be considered for the mobile type.

The definition φ_{ji} represents the factor variable of i kinds of multisource traffic information collection equipment on the j section, and the decisive factor is the characteristics of the collection equipment and the characteristics of the road section.

Assuming that there are r sections in the road network, the numbers of fixed and mobile equipment are l and e, respectively. In order to minimize the overall cost of the equipment, the objective function is

$$\min = \sum_{i=1}^{l}\sum_{j=1}^{r} a_{ji} \times \varphi_{ji} \times c_i + \sum_{i=1}^{e} n_i c_i. \tag{16}$$

In the formula: the value of a_{ji} is taken as 1; c_i is the cost of the ith type of equipment; and n_i is the number of the ith type of equipment.

3.3.2. Construction of Objective Function considering Comprehensive Benefits.
In order to meet the basic requirements for collecting data, a multifunctional comprehensive income function is also established to reduce the overall cost of the equipment.

The variables x_{ik} is defined as (x_{ik} 0–1 variables), x_{ik} indicating whether the kth data can be obtained by the ith multisource traffic information collection device, if it can be obtained, then $x_{ik} = 1\nabla(f, f')$, if it cannot be obtained, then $x_{ik} = 0$.

From the above analysis, the following matrix can be obtained:

$$P_{ijk} = [A] \begin{pmatrix} x_{11} & x_{12} & \cdots & x_{1g} \\ \vdots & \vdots & & \vdots \\ x_{(e+l)1} & x_{(e+l)2} & \cdots & x_{(e+l)g} \end{pmatrix} = \begin{pmatrix} b_{11} & b_{12} & \cdots & b_{1g} \\ \vdots & \vdots & & \vdots \\ b_{r1} & b_{r2} & \cdots & b_{rg} \end{pmatrix}, \tag{17}$$

where P_{ijk} is a collection of the kth multisource traffic information obtained by various collection devices on the j section; A is the matrix formed by a_{ji}; b_{jk} is the kth multisource traffic information obtained on the j section; g for multisource traffic information collection = the number of equipment categories, then

$$P_{ijk} = \begin{pmatrix} b'_{11} & b'_{12} & \cdots & b'_{1g} \\ \vdots & \vdots & & \vdots \\ b'_{r1} & b'_{r2} & \cdots & b'_{rg} \end{pmatrix}. \tag{18}$$

The effect maximization function of multisource traffic information collection equipment is

$$\max U = \sum_{j=1}^{r}\sum_{k=1}^{g} b'_{jk} f_j r_j, \tag{19}$$

where b'_{jk} is the k multisource traffic information jointly acquired by all collection equipment on the j section, when $b'_{jk} \geq 1$, $b'_{jk} = 1$, otherwise $b'_{jk} = 0$,. The coverage rate of mobile multisource traffic information collection equipment y is

$$\gamma_y = \frac{\sum_{j=1}^{r} a_{yj}}{r}, \tag{20}$$

where a_{yj} as the coverage rate of the Y multisource traffic information collection equipment in section j.

Finally, the sample supply of y is clarified. In addition, on the basis of benefit maximization and economic benefit optimization, the planning function of multiple objectives is

$$\begin{cases} \min Z = \sum_{i=1}^{l}\sum_{j=1}^{r} a_{ji} \times \varphi_{ji} \times c_i + \sum_{i=1}^{e} n_i c_i \\[2mm] \max U = \sum_{i=1}^{l}\sum_{j=1}^{r} b_{jk} f_j r_j \\[2mm] \text{s.t.} \begin{cases} a_{ji} \geq 0, \ a_{ji} = 0 \text{ or } 1 \\[2mm] b_{jk} = \sum_{i=1}^{l+e} a_{ji} \times x_{ik} \\[2mm] b'_{jk}, \text{ if } b_{jk} \geq 1, \ b'_{jk} = 1, \text{ otherwise, } b'_{jk} = 0 \\[2mm] n_y = \phi\left(\sum_{j=1}^{r} a_{yj}\right) \end{cases} \end{cases} \tag{21}$$

3.3.3. Solving Algorithm.
In order to solve the multiobjective planning function problem, the first step is to maximize the function

$$\begin{cases} \min Z = -\sum_{i=1}^{l}\sum_{j=1}^{r} a_{ji} \times \varphi_{ji} \times c_i - \sum_{i=1}^{e} n_i c_i \\[2mm] \max U = \sum_{i=1}^{l}\sum_{j=1}^{r} b'_{jk} f_j r_j \\[2mm] \text{s.t.} \begin{cases} a_{ji} \geq 0, \ a_{ji} = 0 \text{ or } 1 \\[2mm] b_{jk} = \sum_{i=1}^{l+e} a_{ji} \times x_{ij} \\[2mm] b'_{jk}, \text{ if } b_{jk} \geq 1, \ b'_{jk} = 1, \text{ otherwise, } b'_{jk} = 0 \\[2mm] n_y = \phi\left(\sum_{j=1}^{r} a_{yj}\right) \end{cases} \end{cases} \tag{22}$$

During the process of solving, due to existence of certain conflicts between multiple targets, it is difficult to obtain the ideal optimal solution, so intelligent algorithms can be used to obtain the optimal solution.

In this paper, we use a multisfunctional planning solution based on genetic algorithm to calculate [11]. First, the priority solution $f(x^*)$ is determined, and the solution is 337519; 39 can be found around the solution. (X^*) is the satisfaction solution of the model.

By checking the correlation between the two, two gray correlations can be expressed, that is, a single objective function converted into a solution

$$\begin{cases} \max \nabla(f, f') \\[2mm] \text{s.t.} \begin{cases} a_{ji} \geq 0, a_{ji} = 0 \text{ or } 1 \\[2mm] b_{jk} = \sum_{i=1}^{l+e} a_{ji} \times x_{ik} \\[2mm] b'_{jk}, \text{ if } b_{jk} \geq 1, \ b'_{jk} = 1, \text{ otherwise, } b'_{jk} = 0 \\[2mm] n_y = \phi\left(\sum_{j=1}^{r} a_{yj}\right) \end{cases} \end{cases}, \tag{23}$$

where the gray correlation $\nabla(f, f')$ is

$$\nabla(f, f') = \frac{\min|f'(x^*) - f(x^*)| + \xi \max|f'(x^*) - f(x^*)|}{|f'(x^*) - f(x^*)| + \xi \max|f'(x^*) - f(x^*)|}. \tag{24}$$

Assuming there are p objective functions in total, the solution model based on the gray relational degree algorithm is

$$\begin{cases} \max \sum_{p=1}^{k} \omega_p \dfrac{\min|f'(x^*) - f(x^*)| + \xi \max|f'(x^*) - f(x^*)|}{|f'(x^*) - f(x^*)| + \xi \max|f'(x^*) - f(x^*)|} \\ \\ \text{s.t.} \begin{cases} a_{ji} \geq 0, \ a_{ji} = 0 \text{ or } 1 \\ \\ n_y = \phi\left(\sum_{j=1}^{r} a_{yj} \right) \end{cases} \end{cases}. \tag{25}$$

The approximate optimal solution is obtained through genetic algorithm, and the final optimal solution is obtained through repetition.

3.4. Parking Lot Location Guidance Algorithm Based on Dijkstra Algorithm.

Generally speaking, Dijkstra's algorithm uses an adjacency matrix for storage. The adjacency matrix stores the relationship between each node. However, considering the actual situation of urban roads, although there are many nodes in the road graph, there are few directly connected points. Therefore, the actual road graph is a sparse graph, and the corresponding adjacency matrix is also a sparse matrix. Therefore, if the adjacency matrix is used to store the nodes, a lot of space will be wasted.

In this paper, the adjacency list is used to replace the adjacency matrix, which can reduce the space complexity of the algorithm. The comparison of the two storage methods is as follows:

If it is assumed that there are b nodes in the graph $G = (V, E)$, then its adjacency matrix A is a symmetric matrix.

If G is an unweighted graph, its adjacency matrix can be expressed as

$$A[i, j] = \begin{cases} 1, & (V_i, V_j) \in E(G), \\ 0, & (V_i, V_j) \notin E(G). \end{cases} \tag{26}$$

We believe that the actual city road map is an undirected weighted map. In the adjacency matrix of $G = (V, E)$, the elements are

$$A[i, j] = \begin{cases} \omega_{ij}, & (V_i, V_j) \in E(G), \\ 0, & (V_i, V_j) \notin E(G) \ \& \ i = j, \\ \infty, & (V_i, V_j) \notin E(G) \ \& \ i \neq j. \end{cases} \tag{27}$$

That is, the element on the symmetry line of the adjacency matrix is 0, where ω_{ij} is the weight between two points,
FIGURE 5: A typical undirected weighted graph.

and ∞ represents that i and j are not connected. A typical undirected weighted graph is shown in Figure 5:

The adjacency matrix is

$$A = \begin{bmatrix} 0 & 1 & 2 & 3 \\ 1 & 0 & \infty & 4 \\ 2 & \infty & 0 & 5 \\ 3 & 4 & 5 & 0 \end{bmatrix}. \tag{28}$$

On the one hand, the storage space of the adjacency matrix is only related to the number of nodes and contains n^2 elements in total. However, since the adjacency matrix is mostly a sparse graph, a lot of space is wasted. On the other hand, the time complexity of the Dijkstra algorithm using the adjacency matrix storage method is $O(n^2)$, and the time cost is too large.

The adjacency list is a very useful storage structure for sparse graphs. All the nodes in the graph are stored in a one-dimensional array, and then the edge with it as the end point is linked after each node to form a linked list. The linked list node is composed of three parts: the start point, the end point, and the weight of the edge. As shown in Figure 6, v_0 is a three-way intersection, and there are 3 sides with it as the endpoint. Then, we can build a singly linked list connecting these 3 edges and then connect it to v_0.

Figure 7 is stored as an adjacency list as follows:

The adjacency table storage requires only $n + m$ storage units, far less than n^2.

From the perspective of space complexity, the adjacency table only needs $n + 2m$ storage units, while the adjacency matrix requires n^2, and the storage efficiency advantage of the adjacency table is significant. In terms of time complexity, the complexity of the adjacency list $O(m + n)$ is also much lower than the complexity of the adjacency matrix $O(n^2)$.

In the research process, the graph is regarded as a plane graph, and the shortest path value from the temporarily marked node to the starting node and the Euclidean distance to the target node are added, and this value is regarded as the characteristic value of the marked node. In the selection process of permanent marked nodes, it is necessary to use this value as a theoretical basis to select among the set of temporary marked nodes, and permanent marked nodes can
FIGURE 6: v_o example diagram.

FIGURE 7: Adjacency list of undirected weighted graph.

FIGURE 8: Classic Dijkstra algorithm.

FIGURE 9: The optimized Dijkstra algorithm.

FIGURE 10: Schematic diagram of optimized Dijkstra algorithm.

select the smallest temporary node of this value. This method can ensure that the target node can be found more accurately and quickly through the Dijkstra algorithm, and the search efficiency can be improved.

Through the above algorithm, the premise of determining the permanent mark point is that the above two values add to the minimum value. The concept of an ellipse here is a trajectory corresponding to a point in the surface where the distance between s and t is added to a constant $2c$. Among them, the point p is located on the trajectory, and the distances to the two points s and v are d_{sp} and d_{tp}, respectively, then $d_{sp} + d_{tp} = 2c$ can be obtained. Through this traversal method to find the shortest path method, the end point and the meta point can be regarded as two focal points, which can be regarded as a concentric ellipse. Before Dijkstra algorithm is optimized, the corresponding search process is shown in Figure 8:

After Dijkstra algorithm is optimized, the corresponding search process is shown in Figure 9:

If nodes v_1 and v_k are both temporarily marked nodes, s is the starting node, and t is the target node. It can be seen from Figure 10 that d_1 and d_k are the shortest path lengths between v_1 and v_k and s, respectively, and D_1 and D_k are the Euclidean distances between v_1 and v_k and t, respectively. The Euclidean distance between v_1 and v_k is C.

In the Dijkstra algorithm before optimization, in terms of selecting marked nodes, if $d_1 > d_k$, the marked node selects v_k, otherwise it is v_1. After the algorithm is optimized, if $d_1 + D_1 > d_k + D_k$, then mark the node selects v_k, otherwise it is v_1.

In summary, the search range of the latest algorithm is an ellipse. After optimization, the search efficiency is improved and the number of traversed nodes is reduced.

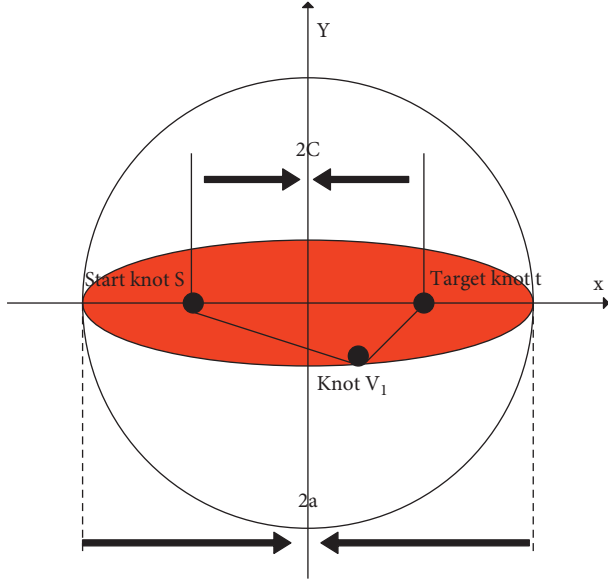
The ellipse limits the range of the search area, see Figure 11 for details. s is the starting node, v_1 is the boundary node, t is the target node, and $2a$ is the maximum limit distance. The Euclidean distance between s and v_1 is denoted by $|sv_1|$, and the Euclidean distance between v_1 and t is denoted by $|v_1t|$, and the specific search range is $|sv_1| + |v_1t| < 2a$. If $|sv_1| + |v_1t| > 2a$, then these nodes can be ignored in the algorithm. The reason is that the distance traveled by s from v_1 to t is greater than $2a$. In this way, an ellipse is formed, the ellipse is composed of all nodes that meet the condition of $|sv_1| + |v_1t| = 2a$, the focus is s and t, and the major axis is $2a$.
In summary, the parameters are set as follows: s and t are selected for the ellipse focus, and $\lambda|st|$ is selected for the length of the major axis. The Euclidean distance between s and t is represented by $|st|$, and the confidence coefficient is λ.


FIGURE 11: Search range restricted by ellipse.

In the process of setting parameters, the main purpose is to find a more reasonable long axis, that is, to calculate the most reasonable λ, and get the desired ellipse search interval.

The principle of finding λ: among the passing road network nodes, a group of nodes with strong representativeness is selected, and the starting node set and the target node are formed by multiplying A and B, which is the C composed of A and B of the required shortest path. C is also a set, that is,

$$C = A \times B$$
$$= \{(a,b) \mid aEA\alpha beB\}. \tag{29}$$

Among them, the starting node is represented by a_l, the target node is represented by b_l, the Euclidean distance between the two is represented by $E_{a_l b_l}$, and $P_{a_l b_l}$ is the specific value of the shortest path. Through $\lambda_i = P_{a_l b_l}/E_{a_l b_l}$, λ_i can be obtained. Regarding what kind of data is selected, the coefficient size of the specific ratio is obtained, and it is expressed in the form of a set, which is Γ. By studying the elements in it, λ_0 is obtained. Then, at $\lambda_i \le \lambda_0$, the confidence level is 95%. Then, λ_0 is the specific coefficient size, so the size of the major axis can be obtained: $2a = \lambda_0 |st|$.

It can be seen from Figure 12 that s belongs to any element in A, t belongs to any element in B, $\lambda = P_{st}/E_{st}$, and the shortest path between s and t is represented by P_{st}, which is $s \longrightarrow v_1 \longrightarrow v_2 \longrightarrow v_3 \longrightarrow \cdots \longrightarrow t$. The Euclidean distance between s and t is denoted by E_{st}. In the process of calculating λ, E_{st} is divided into segments, the number is n, and any segment is denoted as $E_{st1} = E_{st2} = \cdots = E_{st} = E_{stn} (i = 1, 2, 3, \ldots, n)$. According to the situation of segmentation, P_{st} is also segmented, the number is also n, and any segment is $P_{st1} = P_{st2} = \cdots = P_{sti} = P_{stn} (i = 1, 2, 3, \ldots, n)$, and there is $P_{sti} = E_{sti}/\cos \theta_i$.

The calculation process of λ is
FIGURE 12: Schematic diagram of the research on the rule of λ value.

$$\begin{aligned}
\lambda &= \frac{P_{st}}{E_{st}} \\
&= \frac{P_{st1} + P_{st2} + \cdots + P_{sti} + \cdots + P_{stn}}{E_{st}} \\
&= \frac{1}{n}\left(\frac{1}{\cos \theta_1} + \frac{1}{\cos \theta_2} + \cdots + \frac{1}{\cos \theta_n}\right) \\
&= \frac{1}{n}\sum_{i=1}^{n}\frac{1}{\cos \theta_i}.
\end{aligned} \tag{30}$$

In urban roads, θ_i generally takes a value on $[0, \pi/4]$. The following three cases discuss the value of λ:

(1) If s and t have a relatively close distance, n has a smaller value. In order to prevent the shortest path from being found in the search range and to ensure that all valid nodes are included in the ellipse range, the maximum value of λ can be selected at this time.

$$\begin{aligned}
\lambda_{\max} &= \frac{1}{n}\sum_{i=1}^{n}\frac{1}{\cos \theta_i} \\
&= \frac{1}{n} \cdot n\sqrt{2} \\
&= \sqrt{2}.
\end{aligned} \tag{31}$$

(2) If s and t have a very long distance, n is infinite. On $[0, \pi/4]$, θ_i conforms to a uniform distribution, then λ is

$$\begin{aligned}
\lambda_{\infty} &= \int_0^{\frac{\pi}{4}} \frac{1}{\cos \theta}\frac{4}{\pi}d\theta \\
&= \frac{4}{\pi}\ln|\sec \theta + \tan \theta|\Big|_0^{\frac{\pi}{4}} \\
&= \frac{4}{\pi}\ln(\sqrt{2} + 1) \\
&\approx 1.122.
\end{aligned} \tag{32}$$

(3) If s and t have a longer distance, n has a larger value, and λ basically conforms to the normal distribution, then $N(\mu, \sigma^2/n)$, and the specific formula is

$$
\begin{aligned}
\mu &= E\left(\frac{1}{\cos \theta}\right) \\
&= \int_0^{\frac{\pi}{4}} \frac{1}{\cos \theta} \frac{4}{\pi} d\theta \\
&\approx 1.122,
\end{aligned}
$$

$$
\begin{aligned}
\sigma^2 &= D\left(\frac{1}{\cos \theta}\right) \\
&= E\left(\frac{1}{\cos^2 \theta}\right) - \left[E\left(\frac{1}{\cos \theta}\right)\right]^2 \\
&= \int_0^{\frac{\pi}{4}} \sec^2\theta \frac{4}{\pi} d\theta - \left[\int_0^{\frac{\pi}{4}} \frac{1}{\cos \theta} \frac{4}{\pi} d\theta\right]^2 \\
&= \frac{4}{\pi} - \left[\frac{4}{\pi}\ln(\sqrt{2}+1)\right]^2 \\
&\approx 0.01412.
\end{aligned}
\tag{33}
$$

It can be seen that the larger the value of n, the more normal distribution is obeyed. Therefore, in order to obtain more accurate data results, this paper chooses the ellipse with the largest area, then $\lambda = 1.414$. Moreover, when there is a long distance between s and t, when the study is conducted from the perspective of normal distribution, according to the confidence level query, the confidence level reaches 95%.

The performance analysis of the ellipse search algorithm is as follows:

(1) Algorithm validity analysis

In this regard: the main focus of attention is running time. The search range of the Dijkstra algorithm before optimization is

$$
\begin{aligned}
S_{\text{Diksrva}} &= \pi r^2 \\
&= \pi\left(\frac{\lambda+1}{2}|st|\right)^2.
\end{aligned}
\tag{34}
$$

The search range of the ellipse restricted area algorithm is

$$
\begin{aligned}
S_{\text{llipse}} &= \pi ab \\
&= \pi \frac{|st|}{2} \frac{\sqrt{(x^2-1)|st|}}{2}.
\end{aligned}
\tag{35}
$$

(2) Reliability analysis of the algorithm

The so-called reliability is to ensure that the path found belongs to the shortest path.

In a specific road network, nodes do not exist alone and have strong connectivity. There are basically paths connected between two points. If there is a small straight-line distance between the starting node and the target node, it will have a relatively small distance. The traversal range is small, and the path to China Unicom may not be found. In order to avoid this problem, in the research process of this paper, the eccentricity selected by the ellipse algorithm is the largest, that is, the ellipse area is the largest.

In summary, in the case of $\lambda = 1.414$, the confidence level is 95%, that is, only 5% may not be able to find the required shortest path.

(3) Algorithm applicability analysis

In the application process of the ellipse search algorithm, the search range is limited, the work efficiency is improved, and the traversal time is reduced. However, in order to make it clear that all newly appearing nodes are within this range through this method, it is necessary to perform many operations of product and square root extraction, so it takes a lot of time.

The algorithm flow is

The first step is to initialize the data. The algorithm clarifies s and t and calculates the straight-line distance $|st|$ between them based on their latitude and longitude calculations.

The second step is to define the ellipse area. The focus is s and t, $\lambda = 1.414$, from which the eccentricity can be known, and the elliptical area can be obtained.

The third step is to select the breadth-first search method to find the node and compare the value of the sum of the Euclidean distance between the node to b and t with the length of the long axis of the ellipse. If $|sv_1| + |v_1t| < 2a$, then this node is included in the area.

The fourth step is to find the shortest path st in the ellipse interval using Dijkstra's algorithm and then terminate the algorithm.

Through the understanding of the algorithm of the ellipse restricted search area, it is found that the calculation process has a slower speed, takes more time, and has lower work efficiency. Therefore, the algorithm is analyzed and researched. In the calculation process of the rectangular restricted search area algorithm, the required result can be obtained without a lot of calculation, and it has a good effect. The algorithm mainly calculates the circumscribed rectangle of the ellipse area and treats it as a restricted search area, so it achieves the effect of reducing the calculation amount of the algorithm.

The specific content is shown in Figure 13. s is the starting node, t is the target node, and the ellipse equation can be described by s, t, λ. In this process, in order to make the calculation easier, the center of the ellipse is assumed to be the origin of the coordinates, and the two focal points of
FIGURE 13: Schematic diagram of ellipse algorithm coordinates.

FIGURE 14: Comparison of ellipse and rectangular restricted areas.

the ellipse are above the g axis, then the coordinates $(-x_s, 0)$ of s and the coordinates $(x_t, 0)$ of m are obtained, and $x_e = x_t = c$.

The elliptic equation is

$$\frac{x^2}{a} + \frac{y^2}{b} = 1. \tag{36}$$

The parametric equation is

$$\begin{cases} x = a \cos \theta \\ y = b \sin \theta \end{cases} (\theta \in [0, 2\pi]) \tag{37}$$

In the above formula, $c^2 + b^2 = a^2, a = \lambda c$.
The elliptic equation is used to derive the derivative of x:

$$y' = -\frac{b^2}{a^2} \frac{x}{y}. \tag{38}$$

As shown in Figure 13, when a point (x_0, y_0) is taken, the tangent equation is

$$y = -\frac{b^2}{a^2} \frac{x}{y} (x - x_0) + y_0. \tag{39}$$

When $m = -b^2/a^2 x_0/y_0$, the tangent equation is

$$y = mx \pm \sqrt{a^2 m^2 + b^2}. \tag{40}$$

Then the distance between the two tangents is

$$d_1 = \frac{2\sqrt{a^2 m^2 + b^2}}{\sqrt{m^2 + 1}}. \tag{41}$$

As shown in Figure 14, we take a point (x_1, y_1) and its tangent is

$$y = -\frac{1}{m} x \pm \sqrt{\frac{a^2}{m^2} + b^2}. \tag{42}$$

Then the distance between the two tangents is

$$d_2 = \frac{2\sqrt{a^2 + b^2 m^2}}{\sqrt{m^2 + 1}}. \tag{43}$$

If the ellipse has a circumscribed rectangle with the smallest area, then the formulas (38) and (40) can be used to obtain $S_{rectangle}$:

$$S_{rectangle} = d_1 \cdot d_2 = \frac{4\sqrt{a^2 m^2 + b^2} \cdot \sqrt{a^2 + b^2 m^2}}{m^2 + 1}. \tag{44}$$

It can be seen from the above formula that if m^2 is equal to 0, that is, in the case of $m = 0$, the ellipse has a circumscribed rectangle with the smallest area. If the tangent line passes through (x_0, y_0), it is parallel to the axis, and if the tangent line passes through (x_1, y_1), it is parallel to the axis.

If $m = 0$, that is, in the case of $\theta = k\pi/2 \, (k = 0, 1, 2, 3, \ldots)$, the area of the rectangle is the minimum:

$$S_{rectargle} = 4ab = 4\lambda\sqrt{\lambda^2 - 1}|st|^2. \tag{45}$$

If $m = 1$, that is, in the case of $\theta = \pi + 2k\pi/2 \, (k = 0, 1, 2, 3, \ldots)$, the area of the rectangle is the maximum:

$$S_{rectargle} = 2(a^2 + b^2) = 2(2\lambda^2 - 1)|st|^2. \tag{46}$$

It can be seen from Figure 14 that the figure can be obtained as a standard ellipse rotation. The rotation angle is θ, and it translates x_c and y_c in the x and y directions, respectively. The elliptic equation can be obtained by the coordinate values of s and t:

$$\frac{[(x - x_c)\cos \theta + (y - y_c)\sin \theta]^2}{a^2}$$
$$+ \frac{[-(x - x_c)\sin \theta + (y - y_c)\cos \theta]^2}{b^2} = 1. \tag{47}$$

In the above formula, $c^2 + b^2 = a^2$, $x_c = x_s + x_t/2$, $y_c = y_s + y_t/2$, $\theta = \arctan y_t - y_s/x_t - x_s$. x and y:

$$x_m = x_c \pm \sqrt{a^2 \cos^2 \theta + b^2 \sin^2 \theta}, \qquad (48)$$
$$y_m = y_c \pm \sqrt{b^2 \cos^2 \theta + a^2 \sin^2 \theta}.$$

By reduction, the boundary of the rectangular area is obtained:

$$x_m = x_c \pm |st| \sqrt{\lambda^2 - \sin^2 \theta}, \qquad (49)$$
$$y_m = y_c \pm |st| \sqrt{\lambda^2 - \cos^2 \theta}.$$

Then, the area of the rectangular area is $S_{\text{rectargle}} \in [4ab, 2(a^2 + b^2)]$

Performance analysis of rectangle search algorithm:

3.4.1. Algorithm Validity Analysis. If the area of the rectangle is the smallest, the ratio of the search area of the rectangle and the ellipse is

$$\frac{S_{\text{rectargle}}}{S_{\text{ellipse}}} = \frac{4ab}{\pi ab} \approx 1.27. \qquad (50)$$

If the area of the rectangle is the largest, the ratio of the search area of the rectangle and the ellipse is

$$\frac{S_{\text{rectangle}}}{S_{\text{ellipse}}} = \frac{2(a^2 + b^2)}{\pi ab}$$
$$= \frac{4\lambda^2 - 2}{\pi \lambda \sqrt{\lambda^2 - 1}}. \qquad (51)$$

3.5. Parking Space Reservation Module. After the user finds the target parking lot, he may need to make a parking space reservation. Generally speaking, there are two ways to make a reservation: reserve a parking lot or reserve a parking space. The following is an analysis of possible reservation methods: (1) reserve a parking lot with precise reservation: if the reservation method provided to the parking lot of the parking lot means that it cannot fully guarantee that the user will leave a space for reserved vehicles after driving to the parking lot. Therefore, scientific traffic forecasting is required to ensure that a certain number of reserved vehicles arrive at the time of arrival. It can also guarantee a certain parking space. The calculation process of this method is too complicated, and for the peak parking period, the supply is often in short supply. Therefore, it is difficult to realize the reservation behavior of reserved parking. Fuzzy reservation: the parker makes a reservation for a fixed parking time. The parking lot guarantees that the parking space is free at the scheduled time and will not be illegally occupied. In order to ensure the above effects, it is necessary to ensure that there is a certain amount of vacant parking spaces that can be turned over. The berth cannot be used at the highest efficiency. (2) Precise reservation of the reserved parking space: the parking space and the start and end time are accurately reserved by the parker. The system needs to have parking space status detection equipment and parking space occupancy equipment. But for CBD commercial buildings, hospitals, and other areas, parking behavior is of high frequency and changeable. A parking person may delay parking and affect the next scheduled parking person to park the vehicle. Therefore, this kind of contradiction is difficult to solve, so stop. Accurate prediction of the position is not feasible. Fuzzy reservation + precise reservation: fuzzy means that you do not book an accurate parking start time, and precision means that the object of pleasure is the parking space. When a parker chooses a predetermined behavior, the general understanding is that the parker is worried that it is difficult to find a parking space within the arrival time or that the parking space best meets the user's expectations and wants to book in advance. Therefore, the system adopts this method. Specifically, the user has reserved a parking space in a parking lot, and since the reservation, the user's billing starts. In order to balance the user's affordability and the parking revenue, the reservation fee is set as 50% parking fee, the strategy can be optimized in the future, such as different charging standards in different time periods. In summary, only the fuzzy reservation + precise reservation mode for parking spaces is suitable for this system. Parkers can decide whether to reserve a parking space based on the predicted number of empty parking spaces mentioned in the previous chapter and their own needs. If there is a reservation in this mode, the reservation function can be designed with reference to the reservation business process, as shown in Figure 15:

When the user clicks on a parking lot in the reservation module, he enters the parking space reservation details page. The module has a parking space map of the parking lot, and the parking space map indicates the best parking space recommended by the system. The most important factor in the problem of the best parking space in the parking lot is the parking distance, which can be regarded as the shortest path problem (other factors have a weak influence and are not considered for the time being). That is to find the minimum value of stopping distance + driving distance away, so the shortest path algorithm is used to calculate the parking space and guidance path of the shortest path. This module can greatly improve the decision-making efficiency of parking seekers.

Suppose the entrance of the parking lot is E and the exit is S. If a certain free parking space is Pi ($i = 1, 2, \ldots, n$), the shortest path corresponding to the entrance process is $\text{path}(E, P)$, and the shortest path corresponding to the exit process is $\text{path}(p_i, s)$.

Then the entire shortest path length corresponding to the parking space is $d_{\text{path}}(E, p_i) + \text{path}(p_i, s)$

The shortest path length corresponding to the best parking space can be described as $\min\{d_{\text{path}}(E, p_1) + \text{path}(p_i, s), d_{\text{path}}(E, p_2) + \text{path}(p_2, s), \ldots, d_{\text{path}}(E, p_n) + \text{path}(p_n, s)\}$.

In other words, the core of this algorithm is to find the point and path of the minimum value of $d_{\text{path}}(E, p_i) + \text{path}(p_i, s)$.
FIGURE 15: Business process of parking space reservation.

4. Development and Design of System Software

Based on the design of the above-mentioned multisource traffic information collection and combination algorithm, the intelligent multisource traffic information collection combination optimization model is designed for the network design and software design of the multisource traffic information collection combination optimization model, to carry out the network design of multisource traffic information collection combination optimization mode. ZigBee network technology is used to build a three-layer structure model of multisource traffic information collection and optimization model, and ITU-TH.323 and IETFSIP network signaling is used for multisource traffic information collection combination optimization model network control, to design human-computer interaction module, to realize multisource traffic information collection combination optimization mode human-computer interaction response design, an to build in a single network environment multisource traffic information fusion and information dispatch center (Figure 16).

In the MVB bus control protocol and embedded environment, the software development and design of the multisource traffic information collection combination optimization model is realized, and the ZigBee, GPRS, and other network technologies are used to carry out the network design of the multisource traffic information platform. Under the B/S structure system, the network design of the multisource traffic information collection combination optimization model is carried out, the process management and bus scheduling are carried out under the MVB bus control protocol, the Sip protocol stack is used to establish the session protocol of the multisource traffic information platform, and SIP is called. The call interface is used to create an INVITE message, and the data source is wrote to the multisource traffic information collection and combination optimization model DataSet. during Web programming, ADO. NET is used to query, update, and database management of the large-scale multisource traffic information collection and optimization model. Through the above analysis, the software development and design of the system can be realized.

The intelligent parking lot management system designed in this paper is mainly composed of parking lot server and mobile phone client. Communication methods include network communication based on TCP/IP protocol, Bluetooth communication, and Wi-Fi communication. The server uses a PC with Window 10 operating system as the socket communication and data storage device, responsible for socket communication with the mobile phone, and manages user information and parking lot information; adopts the ARM 6410-based development board as the core control of Bluetooth communication module, expand the Bluetooth module outwards, responsible for Bluetooth communication with mobile phones; use Wi-Fi routers to establish a local area network to simulate network communication between users and servers; and simulate the scene of opening the door when
Figure 16: System network networking design.

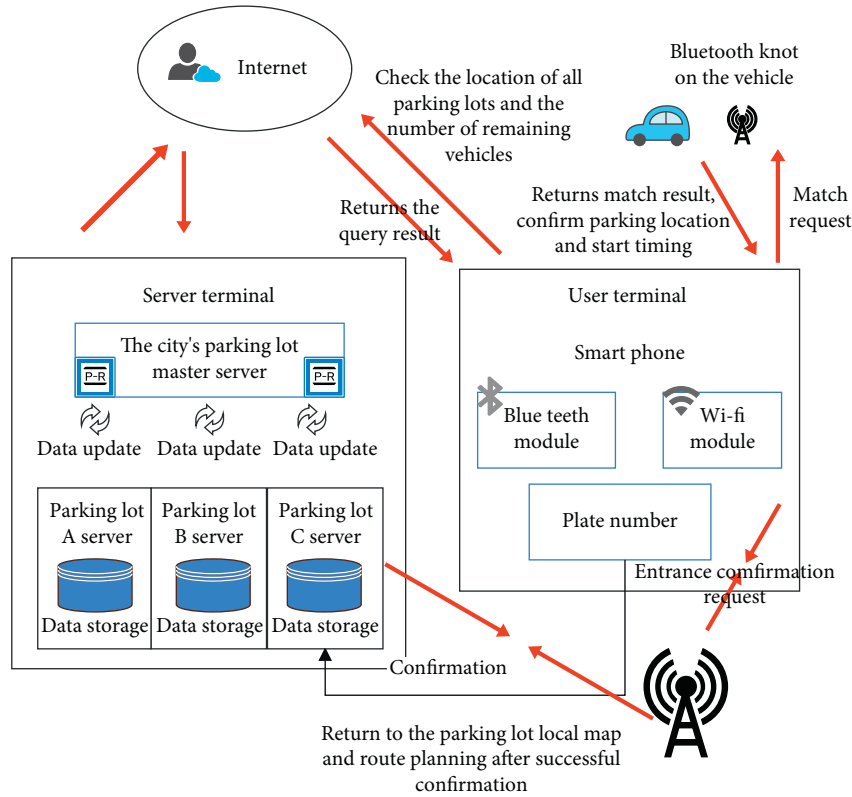
users arrive at the entrance of the parking lot. The mobile client uses a smartphone with Android operating system, equipped with Wi-Fi function, Bluetooth function, and GPS positioning function, etc. The Wi-Fi function is used to detect Wi-Fi signals and communication within the local area network. The Bluetooth function is used to communicate with Bluetooth nodes in the parking space. GPS positioning is used to query the current position. The SDK provided by Baidu Maps gives the distance from the current position to the parking lot. The SDK provided by Baidu Maps gives the driving route from the current location to the entrance of the parking lot. The overall architecture of the intelligent parking lot guidance system designed in this paper is shown in Figure 17.

In order to prevent data loss during the communication process between the user and the server, this design adopts a connection-oriented and reliable TCP/IP protocol, and the communication process is implemented through the socket interface. The function of socket is mainly to provide an interface for data transmission between two different programs. Users only need to know the IP address and port of the server to establish a connection with the server and perform network communication. The workflow is shown in Figure 18.

In this design, the user's mobile phone first accesses the LAN Wi-Fi and automatically obtains an IP address. Establish a connection with the server through the server's IP address and port. The establishment of each connection requires the server to open a new socket thread to receive the registration, login, query, appointment, and other requests sent by the client to the server after the server receives the request, Through the operation of inserting and modifying the database, realize the functions of user registration and appointment; through the query operation to verify the correctness of the user information. The server returns the request result to the user through the user's IP address, as shown in Figure 19.

In this design, an independent Bluetooth node is installed in each parking space, and the Bluetooth node and the parking number are bound one-to-one and stored in the database. When the user receives the parking space address from the server, the Bluetooth on the mobile phone is automatically turned on and starts to detect the Bluetooth address on the parking space. Since the distance of Bluetooth communication is only within 10 m, when the user's car reaches the parking space, the pressure sensor detects the pressure signal. After turning on the Bluetooth module, the mobile phone Bluetooth can search for the address of the Bluetooth module, which can ensure that the user will park the car in the correct parking space and will not match the Bluetooth in other parking spaces. The Bluetooth matching process adopts an automatic matching method. Automatic matching requires program control on the mobile phone. This can reduce the user's operation on the mobile phone and improve the safety of the user's driving. The Bluetooth composition block diagram of this system is shown as in Figure 20.

Figure 21 is a schematic diagram of the entrance to the parking lot. According to the data, there is a negative correlation between Wi-Fi signal strength and distance. As shown in the figure, the distance between the user's mobile phone and Wi-Fi is equal to the distance between the cars plus the length of the car, and the distance between the first car and the second car from the Wi-Fi is one car length plus the distance between the cars. Generally, the length of a family car on the market is about 4 meters to 5.5 meters. The signal strength difference caused by this distance difference is huge. Therefore, it is not possible for two users to detect the same Wi-Fi signal strength.

The entire urban parking process can be represented as a circular ecosystem, as shown in Figure 22, which consists of three parts and two processes. Among them, the three parts are parking users, parking lots, and parking space recommendation systems. Contains the following entities,


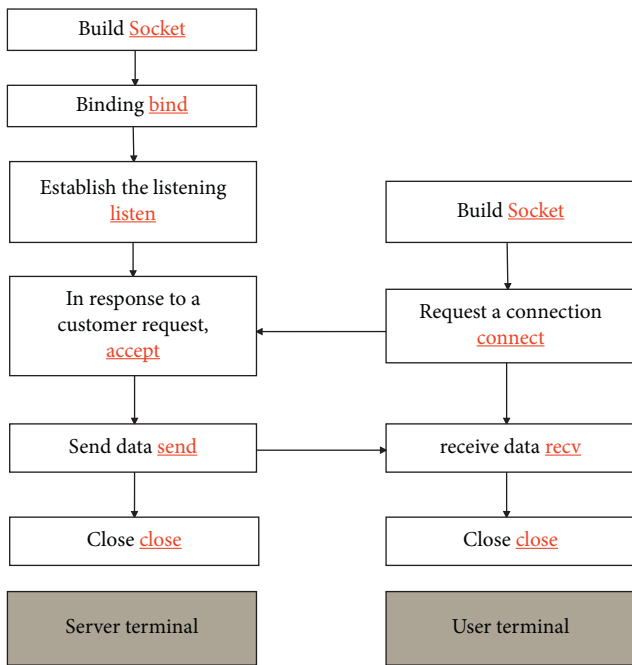


Figure 17: Overall system architecture.

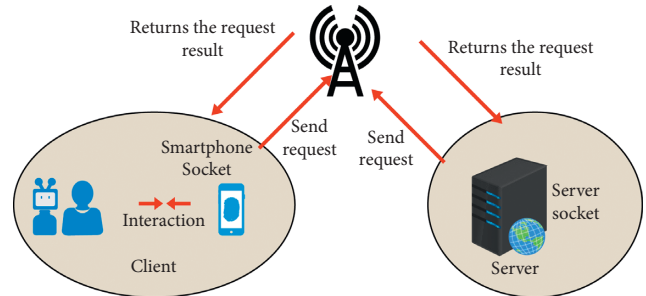

Figure 18: TCP/IP protocol workflow.

Figure 19: Schematic diagram of client accessing server.

parking drivers, vehicles, and various sensors on them, parking lot management systems and parking space detection equipment, and parking space recommendation

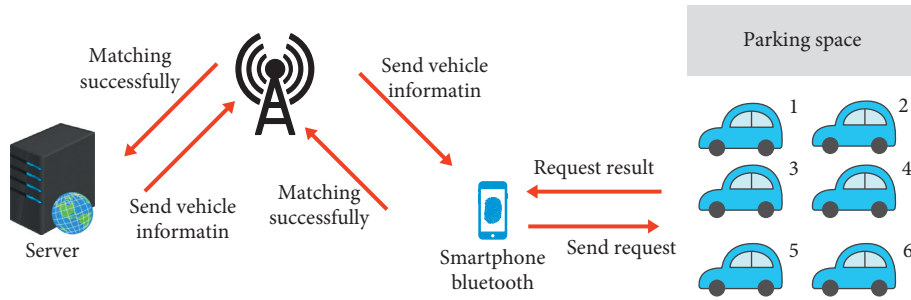
systems. The two processes are data flow and traffic flow. The traffic flow occurs on the road where the driver is looking for a parking space and when the vehicle arrives or leaves the parking lot, which is represented by the yellow double-headed arrow in Figure 22; the data flow occurs during parking. The process of interaction between the user and the parking lot and the parking space recommendation system is represented by a black arrow in Figure 22. The parking space sensor or parking lot management system installed on the roadside uploads the collected real-time parking space data to the parking space recommendation system. The driving vehicle uploads its real-time position, speed, and other status data, and the parking space recommendation system processes the data into effective information, release information on the availability of parking spaces in each parking lot, drivers can obtain the


FIGURE 20: System Bluetooth composition block diagram.

FIGURE 21: Wi-Fi signal diagram at the entrance of the parking lot.

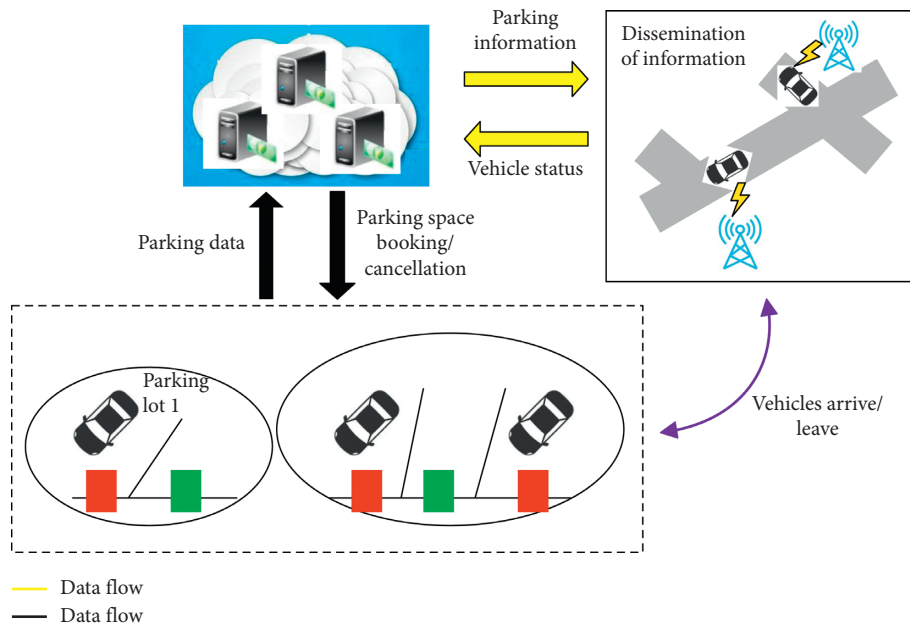

FIGURE 22: Urban parking process.

latest parking information from smart terminals that exchange information with base stations and other transceiver platforms, and turn to the parking area they want, and then park. When the vehicle arrives or leaves the parking space, the parking space sensor updates the parking space available information and uploads the information to the driver looking for the parking space through the intelligent terminal. Considering that when there are many drivers looking for parking spaces in a certain area, they can all receive parking space availability information. It is very likely that competition for a certain free parking space resource will result in parking conflicts. Therefore, the system should have a reservation mechanism. The reservation mechanism includes the reservation of free parking spaces, the cancellation or recycling of reservation orders, etc. The reservation operation causes data flow between the driver, the parking lot, and the parking space recommendation system.
FIGURE 23: System data function structure.

FIGURE 24: is the access delay rate of the traffic information collection combination in various cache percentages.

FIGURE 25: Access delay rate of traffic information collection combinations under various data sizes.

Recommending suitable parking lots and parking spaces for drivers with parking needs so that they can quickly find their own satisfactory parking spaces is the original intention of this research. From the above analysis and combined with the driver user use case diagram, it can be seen that the parking space recommendation system must have parking lot recommendation, parking space reservation, and order management after reservation. However, the realization of a parking application software for driver users requires some other functions, such as system login/registration, user information addition, etc. to be more complete. In addition, the analysis of the circular ecosystem formed by the above-mentioned urban parking process shows that the realization of the parking space recommendation system requires two key steps, namely, real-time data collection and management and parking-related services. Real-time data collection and management includes the collection and management of parking space data and vehicle data. Among them, data collection is the basis for the system to provide parking-related services. However, due to the different parking detection technologies used in the current parking lot, the parking lot application has not been unified. There is no unified standard for the data interface and exchange mechanism. The heterogeneity of parking space data makes the current parking application have a strong closedness, which has great limitations in data collection and use, and it is impossible to obtain more information. Comprehensive parking information provides users with good parking recommendations. At the same time, there are many types of user vehicles, and there are many types of sensors on them. Even sensors of the same type may have different data formats and transmission methods among vehicles, making it difficult to use vehicle data. The system needs to provide a processing method for raw data so that various heterogeneous data can be represented in the same way to support parking-related services. Therefore, the system should also have real-time data collection and management functions. In summary, the functions of the parking space recommendation system based on resource agents in this subject are proposed. The system function structure is shown in Figure 23.

5. Simulation Experiment and Result Analysis

In order to test the application performance of the combined optimization model for multisource traffic information collection designed in this paper, software debugging and simulation experiments are carried out. The multisource traffic information collection combination optimization model provides users with a simple and unified system call interface. The packet size is set to 24 kB/s, the weighting factor $w = 2.19$, the traffic information collection time is 1025, and the size of combined sequence training group is 2100 parameters.

According to the analysis results in Table 1, multisource traffic information collection is combined, as shown in Figure 24, to test the access delay rate of traffic information collection combinations in various cache percentages.

According to Figure 24, the access delay rate of the traffic information collection combination using this method is low. The delay rate of the traffic information collection combination of various data scales is tested, and the test results are obtained as shown in Figure 25.

After analyzing the above simulation results, it is found that using this method, the combined accuracy of multisource traffic information collection is high, the degree of information fusion is improved, and the delay is low.

6. Conclusions

In this paper, the combination ability of dynamic traffic information is improved. According to the improved information data, on the basis of collecting multisource traffic information, an information data processing system is developed combined with genetic algorithm. The multidimensional nonlinear joint statistical methods can be used to multiperform multidimensional feature space combination in the complex traffic network environment. In order to construct a multisource traffic information combination model, the genetic algorithm can be used to effectively collect the original traffic data information. According to the high-dimensional feature quantity, the obtained multisource traffic information is fused and combined to carry out the distributed clustering of traffic information and the effective control of fuzzy directivity constraints. Finally, the combined optimization model of traffic information collection has a high degree of intelligence, accurate information collection, and low delay in this paper.

With the continuous development of social economy, film and television animation, as the spiritual needs of ordinary people, is more and more popular. Especially for the development of emerging technologies, the corresponding voice can be used to change AI expression. But at the same time, how to ensure the synchronization of language sound and facial expression is one of the difficulties in animation transformation. Relying on the compromised node detection of wireless sensor networks, this paper combs the synchronous traffic flow between the speech signals and facial expressions, finds the pattern distribution of facial motion based on unsupervised classification, realizes training and learning through neural networks, and realizes one-to-one mapping to facial expressions by using the rhyme distribution of speech features. It avoids the defect of robustness of speech recognition, improves the learning ability of speech recognition, and realizes the driving analysis of facial expression film and television animation. The simulation results show that the compromised node detection in wireless sensor networks is effective and can support the analysis and research of speech-driven facial expression film and television animation.

1. Introduction

With the continuous development of social economy, film and television animation is more and more sought after and favored by many people, especially rural people. It is not only the consumption of spiritual culture but also an embodiment of national culture [1, 2]. The development of artificial intelligence and other technologies has promoted the development of language pronunciation and facial expression, especially to meet different language pronunciation and interaction with different people; that is, language pronunciation is one person, and facial expression is another person [3, 4]. There is a close synchronous relationship between the two, but how to realize the seamless connection between the two and realize that language pronunciation directly drives facial expression is the research focus and difficulty of human-computer interaction under various

modes, and many industry experts have conducted corresponding research [5, 6]. Generally speaking, the driving of facial expression by speech can be mainly through speech pronunciation recognition and other types of recognition. For speech pronunciation recognition, the corresponding eigenvalues are mainly used for analysis, especially for the basic feature units of speech recognition based on factors and syllables. Mature empirical rules drive a whole set and use corresponding eigenvalues to compare corresponding lip shapes. This method is relatively simple and effective, but it is limited by rules. This rule requires manual definition by various experts and is limited to experts' experience and knowledge. Therefore, qualitative analysis is not accurate enough [7, 8]. At the same time, it is very difficult to realize accurate nonqualitative human speech recognition. This requires directly extracting the corresponding speech features and directly mapping them to the specific parameters

of the face. Therefore, this method can not only avoid the problems encountered in speech pronunciation to a certain extent but also effectively realize synchronization and realism [9, 10].

Some scholars proposed to use artificial intelligence and corresponding prediction to realize the training and learning from speech to facial expression and realize the tracking and relative position of facial expression by inputting relevant parameters [11, 12]. In addition, some scholars have proposed to use the relevant methods of neural networks to synthesize vision and speech, realize the recognition and analysis of speech and face motion parameters, and obtain a better feedback effect [13, 14]. Other scholars used the Markov chain for control analysis and introduced speech recognition for driving analysis of facial animation, that is, getting facial expression motion according to corresponding computer vision analysis technology and realizing learning and control facial expression model. This method can effectively solve visual synchronization on the one hand and human motion behavior on the other hand and realize the expression animation of face driven by voice pronunciation, but in the actual application process, there are still many limitations and specificities [15, 16].

In view of these limitations and requirements, this paper introduces wireless sensor network compromised node detection, combs the synchronous service analysis of voice pronunciation and facial expression, uses unsupervised classification technology to accurately analyze the corresponding facial expression, and realizes manual lip shape adjustment through voice level clustering analysis. At the same time, the video motion data can be used to train the voice to drive the face animation model, improve the authenticity and fidelity of the system, reduce the defects of artificial rules, and use the corresponding rhythm to directly add and map to the face pattern to realize the final driving analysis of face expression film and television animation.

2. Compromised Node Detection Method for Wireless Sensor Networks

By comparing the disadvantages and advantages of speech recognition and nonspeech recognition, this paper selects the latter so that neither the discreteness of speech samples nor the parameter mode of speech directly mapped to face motion needs to be considered [17, 18].

Detection using corresponding wireless sensor nodes can be mainly divided into the following steps:

(1) In the whole network, it is necessary to focus on deploying corresponding sensor nodes to ensure that sensor nodes have overlapping coverage. Therefore, it can be predicted that the occurrence or generation of an element may be detected by multiple nodes, and the node of one sensor can also detect multiple behaviors of other adjacent nodes [19, 20].

(2) For ordinary and distributed sensor nodes, they can only have limited ability and communication ability.

(3) For the transmission channel between the node and the base station, it is necessary to abide by the corresponding transmission routing protocol.

(4) For the base station, it is a computing device capable of representing location information.

(5) For the sensor node, it needs to have enough identifiers to represent it. In the whole deployed network, it needs to compromise according to the corresponding nodes.

(6) All messages are time stamped.

(7) The attacker needs to capture the physical address to obtain the corresponding site location and information.

For the base station site, if there are more resources, it is more secure and difficult to overcome. However, it should be noted that the network may transmit false data.

The whole system can be composed of two parts: one is a distributed network site system, and the other is a centralized system running in the so-called related base stations (Figure 1).

The so-called distributed component is relative to the deployment environment of the network. Each copy of its component runs on different network sensor nodes and is synchronized with the relevant transmission protocol and transmission app on the sensor. When each node detects the possible compromised behavior in adjacent nodes, it needs to report to the nearest base station for transmission in time. This detection method needs to rely on adjacent nodes for detection, and each node needs to detect and analyze adjacent nodes. However, due to the characteristics of wireless sensor networks, such deployment saves a certain cost.

For centralized components, they are higher-level computing devices, so it may be necessary to perform more complex behavior analysis to summarize whether there are corresponding compromised behaviors to the center and whether these compromised behaviors are legal. For the corresponding data collected by the whole network, these are collected and analyzed through their own network resources.

2.1. Distributed Component. Each sensor node has a distributed component running on it, which will record the data from adjacent nodes and establish a baseline based on these records. If a neighbor node continues to perform abnormal behavior, it will be identified as a compromised node and reported to the base station.

As shown in Figure 2, if the corresponding node A is attacked and considered by the attacker to imitate another node and if the neighbor node D does not detect A, then node A cannot directly imitate B or C. In this way, the node has enough neighbors to be solid with each other so that any attack and impersonation can be detected in time.

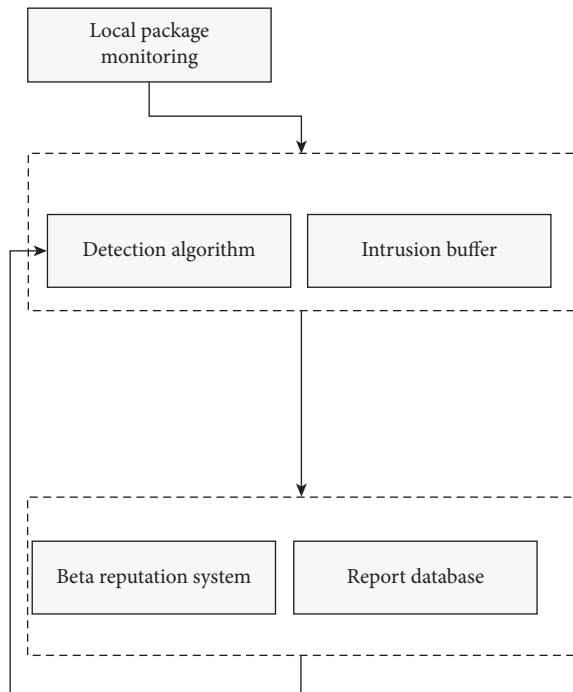
Considering instantaneous errors, such as collisions or other nonmalicious behaviors, ComDet has certain flexibility when determining a node as a compromised node and can tolerate certain abnormal behaviors. When judging whether a neighbor node behaves abnormally, there is no


FIGURE 1: Frame structure.

FIGURE 2: If node *a* wants to impersonate any node, it must pass the detection of neighbor nodes.

cooperation between nodes. This independent decision-making process means that the compromised node cannot affect the perspective of the legitimate neighbor node.

2.1.1. Monitoring Indicators. The first step in designing any detection-based security system is to select the characteristics of the system that will be monitored. In order to support most wireless sensor networks, ComDet only monitors some common features of wireless sensor networks.

① Sensor readings: by monitoring sensor readings, attacks that attempt to distort the collected information can be detected.

② Received power: in a static network, the received power should remain unchanged. Fluctuations may be caused by changes in communication hardware or the location of corresponding nodes.

③ Sending rate: most applications read sensor readings and send them periodically. Any routing data packets will also be sent periodically. Therefore, the rate of data packets sent by a node should follow a consistent pattern. Most attacks, such as selective forwarding, Sybil attacks, and replay attacks, will cause measurement bias. In addition, the sudden idle period may be caused by the opponent's reprogramming of the node.

④ Receive rate: the ratio of incoming and outgoing data packets should be constant because the outgoing data packets can only be data packets routed by the node or generated by the node. A neighbor node that changes its receiving rate but does not change its sending rate may be a compromised node. It should be noted that regardless of whether the data is encrypted or not, the header of the data packet can usually be seen by all nodes.

Because most wireless sensor networks have these characteristics, ComDet has a wide range of applicability. However, these features may not be appropriate in two situations: (1) data packets can only be decrypted by the base station; (2) applications rarely exchange information with the base station.

When the confidentiality of information transmitted on the network is very important, the first scenario will appear. Since the compromised node cannot be detected and blocked immediately, some of the information sent may be eavesdropped on by the compromised node. Therefore, the data packet can be encrypted, and only the base station can decrypt it. Under such conditions, the defect of not being able to monitor sensor readings can be compensated by increasing the number of monitored neighbors so that ComDet can achieve corresponding performance by occupying more memory.

The second scenario is caused by the application of nonperiodic communication. For example, wireless sensor networks located in the quarantine zone only send information when an attack is detected, and they will not communicate in a secure environment. Because the monitored information is not sufficient, it is impossible to establish a baseline for most features. ComDet compensates by making the node send its unique identification code at a certain speed. In order to avoid prolonged silence and fail to discover that the node has been conquered by the attacker, a certain amount of communication overhead is necessary. This mode of behavior is only used when the application has very little communication volume.

2.1.2. Detection Algorithm. There are two types of algorithms for detecting abnormal behavior: anomaly detection and rule-based detection. They all use records of monitoring system characteristics. In anomaly detection algorithms, the existing records are first used to establish a baseline, and any

new records that deviate from the baseline to a certain extent are considered abnormal behaviors. On the contrary, rule-based detection requires the establishment of a specific standard. For example, if any two packets have the same header, it means that a replay attack has occurred. In the ComDet system, the main focus is on anomaly detection algorithms to meet ComDet's requirements for flexibility, rule-based algorithms target specific situations, and the rules they use must be updated continuously for each new situation.

ComDet's distributed components can be divided into five algorithms for attack detection: the first four are anomaly detection algorithms, which use network characteristics such as sensor readings, receiving power, sending rate, and receiving rate; the fifth is a rule-based detection algorithm.

For rule-based algorithms, if a node detects that a new neighbor meets the characteristics in the preset rule base based on the received message, it will consider the node to be a compromised node.

For anomaly detection, we need to identify the abnormal behavior. Based on the abnormal behavior of each node, we need to set different buffers, one is the buffer for normal packets, and the other is the buffer for abnormal behavior. When all detected abnormal phenomena are shared in the exception storage, the window is used for sliding analysis and compared with the corresponding limit. If it exceeds a certain security threshold, the data packet is considered abnormal. Abnormal behavior may have certain intrusion behavior, which will also cause the behavior report of the node.

The specific overview of the received power is shown in Figure 3, and the specific calculation equation is shown in the following formula:

$$\text{Power}_{\text{new}} - \text{power}_{\text{max}} > T, \text{if power}_{\text{max}} > \text{power}_{\text{max}},$$
$$\text{power}_{\text{min}} - \text{Power}_{\text{new}} > T, \text{if power}_{\text{new}} > \text{power}_{\text{min}}. \tag{1}$$

Compromised node detection in wireless sensor networks is used to analyze the maximum and minimum interval values of the received power of the packet buffer. When the received power of a new packet exceeds this interval, it is considered that the behavior is abnormal. Therefore, the abnormal data needs to be divided into abnormal packet buffer. After processing, the corresponding abnormal situation processing caused by environmental change is realized.

As shown in Figure 4, it is a conceptual diagram of using transmission power, which is mainly used to calculate the transmission rate of data packets and the transmission rate of data packets. When the ratio of the two rates exceeds the set threshold range, the adjacent neighbor nodes can be considered as compromised nodes.

The algorithm using the reception rate is different only in two aspects.

All the illegal behaviors of a node detected by the anomaly detection algorithm are stored in a shared illegal behavior buffer.

Once the abnormal behavior of a neighbor is detected, the weight of its abnormal behavior is calculated as shown in the following formula:

Figure 3: Overview of detection algorithms using received power and sensor readings.

Figure 4: Overview of detection algorithm using transmission rate and reception rate.

$$\sum_M \left(t_{\text{current}} - t_{\text{stamp}} \right) + 0.3 \sum_m \left(t_{\text{current}} - t_{\text{stamp}} \right). \tag{2}$$

Once a node determines that a neighbor node a is compromised, it will send three reports about the compromised node to the base pair.

2.2. Centralized Component.
The centralized component runs on the base station and judges whether a reported node is really compromised based on the data from other nodes.

$f(\rho \mid \alpha, \beta)$ can be calculated with Γ function, and its calculation formula is shown in the following formula:

$$f(\rho \mid \alpha, \beta) = \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha) + \Gamma(\beta)} \rho^{\alpha-1} (1 - \rho)^{\beta-1}, \quad 0 \le \rho \le 1, \ \alpha > 0, \beta > 0. \tag{3}$$

The facial motion parameter FAP (facial animation parameter) defined by MPEG-4 is a set of parameters for realizing facial animation. FAP is based on the subtle movements of the face, and through detailed description and quantification of the actions of various parts of the face model, it can reproduce most natural facial expressions and lip movements. The MPEG-4 standard defines a total of 68 FAPs, including lip shape (viseme) FAP and expression (expression) FAP. For these two FAPs, some basic and different phantoms or expression data are stored in advance, and other phantoms or expressions can be formed by a linear combination of these basic phantoms or expressions. The function of lip shape and expression FAP is to accurately and conveniently express simple lip movements and expressions, but for complex and irregular lip movements and expressions, lip shape and expression FAP are difficult to describe

well. Therefore, in the MPEG-4 standard, in addition to lip shape and expression FAP, it is more convenient for users to describe. For subtle facial movements, general FAP definitions are also given. Generally, FAP is mainly used for movements in a specific area of the face, such as raising eyebrows and moving the upper lip up. The general FAP includes details of each part of the face motion description, which can generate more complete and complex animations than the 14 lip shapes and expression FAP defined by the standard. Therefore, the FAP mode in this paper is based on the general FAP. At the same time, it is different from the basic lip shapes and expressions defined by MPEG4. The FAP model described in this paper does not refer to hypothetical speech perception classification, such as cluster analysis of phonemes or words, but is directly obtained by cluster analysis from a large amount of real image data, so that the results obtained can be used more effectively. In face animation, we assume that all possible face poses belong to a certain state in a high-dimensional space plane, and complex face motion can be regarded as a transition between thousands of states.

Aiming at this diverse and complex face motion trajectory, our learning strategy is to use some FA patterns that can effectively characterize the face motion characteristics or represent a certain set of states to approximate this diversification in segments and then use linear interpolation to glue this segmentation to achieve high-fidelity facial animation. Of course, to achieve voice-driven facial animation, the acquisition of these FAP mode sequences must be obtained through a certain prediction method. At the same time, due to the complexity of face motion, only through the results learned from the large-scale audio and video library can we realize more natural face animation. Manual rules cannot meet the requirements. Because neural networks have better characteristics in processing input and output mapping relations and meet the characteristics of the human brain structure, we use neural networks to learn this mapping relationship.

2.3. System Framework. As shown in Figure 5, it is a specific step of synchronous processing of voice-driven facial animation. Using the corresponding technologies such as computer vision tracking, image processing, and wireless sensor network compromised node detection, the features of corresponding facial parameters and facial animation parameters are extracted from the video and calculated according to the corresponding eigenvalues, and the corresponding patterns are obtained by clustering method. By analyzing the learning context, the mapping relationship of learning is obtained, and the effective analysis and synchronization of speech and face animation are realized.

3. Data Preprocessing

3.1. Speech Signal Analysis. There are many kinds of speech signal processing. How to extract the feature elements in speech recognition is not completely effective for the prediction of facial expression, especially how to achieve synchronization, which is worth thinking and analyzing. Speech pronunciation and face behavior recognition may be related to speech and corresponding feature elements, which can ensure complexity and looseness. In the data preprocessing of this paper, different speech features are used for analysis and processing, and the association of prosody and facial expression in speech is used to obtain the pitch stream and ability analysis in speech segments, which are finally synthesized to form a unique feature vector.

3.2. Video Signal Analysis. In order to uniformly obtain the feature data of facial expression, this paper synchronously tracks many facial expression features, such as corners of the mouth, lips, and nose tip, but it is impossible to track the low texture area. Therefore, for a specific system, to effectively track the key low texture and obtain the coordinates of facial feature points and feature positions of each image, it is very important to form visual feature vectors.

4. Clustering and Learning

4.1. Clustering Algorithm. Different clustering results can be obtained by adjusting the clustering algorithm parameters, such as the desired number of clusters, maximum training times, minimum number of samples per class, separation parameter P, and merging parameter C. These specific parameter values can be changed and calculated by formula (4). The specific results are shown in Figure 6.

$$\text{Error Square}\,(X, Y) = \frac{\sqrt{(X - Y) * (X - Y)^T}}{\|X\|}, \tag{4}$$

where the real data matrix is represented by X, the matrix mapped from real data to category is represented by Y, and the matrix size is represented by $\|X\|$.

4.2. Artificial Neural Network. For artificial neural network, it is mainly learning-oriented input and output, which is used to reflect strong computational efficiency and corresponding robustness. The specific structure diagram is shown in Figure 7.

For each frame of speech, the 16-dimensional LPC and RASTA-PLP mixed vector and the 2-dimensional prosody parameters are calculated to form an 18-dimensional speech feature vector, and the front and back 8 frames are combined into an input vector. In this way, the input of each neural network is a vector.

5. Simulation Experiment

In order to cover the pronunciation of a single person as much as possible, this paper selects the sentence synchronous audio and video library in the Chinese speech synthesis library. By marking feature points, the motion data of lips, cheeks, and eyelids can be obtained. The camera converts the collected video into an image at 10 frames/S and uses the tracking program to process the image feature sequence.
FIGURE 5: Speech-driven facial animation synchronization processing framework.

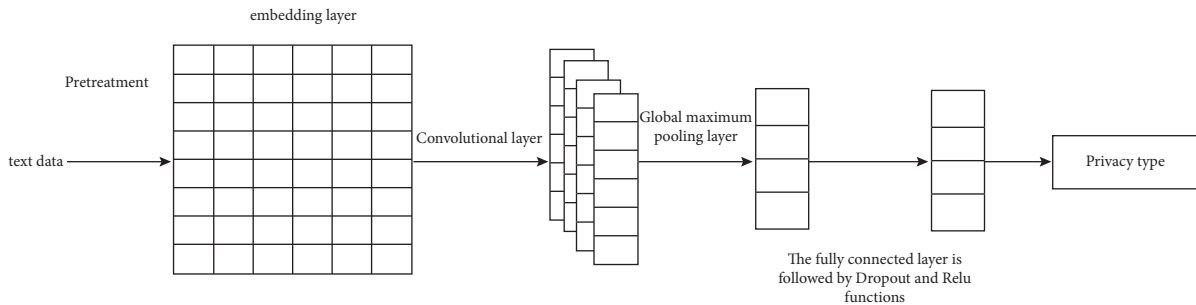

FIGURE 6: Comparison of clustering results.

FIGURE 7: Structure diagram of neural network.

Both qualitative and quantitative evaluation methods are used for the system. Quantitative testing is based on calculation to measure the error between predicted data and real data. Most machine learning systems should use quantitative methods. Qualitative testing is to judge whether the synthesized face motion is true through perception. For synthesis, qualitative testing is very important. In quantitative testing, the specific calculated variance is shown in Figure 8.

The simulation results show that the compromised node detection in wireless sensor networks can not only solve the dynamic change of the upper part of the face but also use the
FIGURE 8: Variance comparison.

recorded original voice and can effectively solve the synchronization problem. Therefore, it has been highly evaluated and proved to be effective in practice.

6. Conclusions

The continuous development of artificial intelligence promotes the improvement and enrichment of film and television animation. People are increasingly pursuing the aesthetic and technical characteristics of film and television animation. Therefore, more technologies are introduced into the field of film and television animation. In view of these needs and limitations, based on the compromised node detection of wireless sensor networks, this paper combs the synchronous business relationship flow of voice signals and facial expressions, analyzes the process of voice processing signals, first detects abnormal behavior and voice using compromise, finds the basic pattern of facial expressions through cluster analysis, and seems to complete the one-to-one mapping from voice to facial expressions. At the same time, quantitative and qualitative evaluation methods are used for analysis and evaluation. The prosodic distribution of speech features is used to realize the one-to-one mapping to facial expression, which avoids the defect of the robustness of speech recognition, improves the learning ability of speech recognition, and realizes the driving analysis of human facial expression film and television animation. The simulation results show that the compromised node detection in wireless sensor networks is effective and can support the analysis and research of speech-driven facial expression film and television animation.

The digital age of artificial intelligence marks the rapid development of tourism engineering and the gradual improvement of intelligent management theory. This study aims to solve the problems of low efficiency of dynamic relationship analysis and low data utilization in traditional intelligent management methods of tourism engineering. This work studies the dynamic optimization model of tourism engineering management theory based on the artificial intelligence data analysis model and designs the dynamic analysis model of tourism engineering management data based on the convolution neural network. The model can collect dynamic data information of tourism management from many aspects and can also be used to study and analyze human behavior patterns based on the convolutional neural network algorithm. According to the human behavior data analysis model and convolution neural network algorithm, this study formulates the real-time management data scheme of tourism engineering and better extracts the characteristic information of the dynamic data of tourism engineering management. The results show that the topology optimization model of tourism intelligent management based on the convolutional neural network achieves high feasibility, high data accuracy, and high response speed. It can improve the collaborative coupling relationship between management efficiency and dynamic data in tourism engineering management based on big data analysis technology. It realizes the effective combination of tourism management, digital management, and artificial intelligence algorithm.

1. Introduction

At present, the traditional "many to many" cluster point information collection is the main data information of tourism project management in China [1]. Since the beginning of the 21st century, the rapid development of artificial intelligence technology in China has also led to the transformation of data analysis methods in tourism engineering management in China. The emergence of modern tourism engineering management analysis methods such as intelligent tourism management theory planning, efficient management data analysis, and coordinated utilization of software and hardware has contributed to the large-scale promotion of "intelligent management of industrial 4.0 tourism engineering" and provides opportunities [2]. Therefore, diversification and high efficiency have become important features of the intelligent degree of tourism

project management in China [3]. At present, although the existing intelligent management system of tourism engineering provides a large number of data information extraction schemes, it is difficult to select a targeted topological representation scheme according to its management dynamic theoretical system and the law of human behavior in the process of dynamic management, so as to achieve the optimal effect of topological analysis [4]. Based on this, this study proposes a theoretical topology analysis model of intelligent management of tourism engineering in the digital age based on big data and the convolutional neural network algorithm.

Aiming at the problems of low data analysis efficiency, low data storage efficiency, and low data classification efficiency existing in the current theoretical analysis model of intelligent management of tourism engineering, this work studies the data mining model scheme of discrete dynamic

analysis based on the convolution neural network algorithm and collaborative processing of big data in the cloud, which is mainly divided into four parts. Section 1 introduces the research background and the overall framework of this study. Section 2 introduces the research status of intelligent management theory and application methods of tourism engineering. Section 3 constructs the theoretical topology model of intelligent management of tourism engineering in the digital age based on big data and convolution neural network algorithm, adopts the multilayer convolution perception neural network factor method, and constructs the evaluation index system of tourism management data analysis and intelligent classification objectives of artificial intelligence analysis. In Section 4, the quantitative effect of data analysis of the industrial 4.0 tourism project intelligent management efficiency dynamic analysis model constructed in this study is experimentally analyzed and verified, and a conclusion is drawn in Section 5.

Compared with the data mining model established by the traditional intelligent management analysis model in tourism engineering, which takes the continuity of static management data as the main research object, the innovation of this study is that the discrete dynamic modeling technology and big data topology analysis strategy based on the convolution neural network algorithm are applied to the dynamic analysis model of industry 4.0 tourism engineering management. It can make full use of a large number of dynamic management data, extract appropriate management data feature information, realize the integrity approach at the simulation level, and quantitatively describe the quantitative representative eigenvalues, similarity of multidimensional management analysis modes, and expected evaluation indicators of different tourism projects in the process of employee management scheme allocation with multitransformed neural network factors. It can efficiently carry out customized analysis on the factors affecting management efficiency and accuracy.

2. Related Work

Although the domestic management theory analysis model has been developed for several years, there are still some deficiencies in the establishment, operation, and upgrading of the sports data mining model compared with some more developed countries [5]. Wei et al. optimized the data analysis process according to the management principle of three-dimensional space. His team proposed that attention should be paid to the development of the three-dimensional basic structure or dynamic theoretical decomposition method of tourism management based on Gaussian mixture [6]. Masterson et al. proved through experiments that the classified data analysis method can play a good role in differential learning, effectively improve the mining efficiency of big data, and use a number of indicators to evaluate the data analysis ability of the tourism management dynamic analysis model [7]. Greatbatch et al. have verified through repeated practice. The final results show that the establishment method based on human behavior discrete modeling technology can improve the data analysis efficiency of

the data mining model and the effectiveness of modifying data. It is suitable for the outside world to carry out continuous R&D planning for tourism engineering management data and find the optimal data structure scheme [8]. Mayro et al. put forward a new group tourism project management data model and database establishment method based on industry 4.0. The multidimensional spatial framework sequence is used to redistribute the data packets of each layer of the original management database, so as to realize the optimal determination of various mining methods in the process of management data capture [9]. According to the traditional establishment mode and practical experience of the data collection system in a general sense, Lang et al. found that the current data mining model has the problems of difficult dimension calculation and poor physical quantity in the process of managing tourism dynamic data analysis. Therefore, they developed a new intelligent data analysis technology based on deep learning [10]. Through logical analysis, adjustment, and summary of different data mining models, Egevad et al. finally established a new data mining system, which can realize delayed capture and real-time feedback of tourism engineering management data [11]. Scholars from Safarnejad L and other universities put forward a new data mining model establishment method based on the multirelationship recommendation algorithm according to the multifactor relationship theory in philology, analyzed the correlation of different modules in the traditional data mining model, and established a double factor analysis model [12]. Verganti et al. comprehensively evaluated the employee management data mining model of a tourism project from the aspects of the selection of the structure form of the tourism management storage database, the classification of the content, and the storage capacity of the database and realized the simulation of the working process of the model database by capturing different types of data [13]. The research results of Kai et al. show that the "data outside" interaction model based on discrete dynamic modeling technology is better than the traditional interaction model in terms of motion data information acquisition ability [14]. In order to improve the acquisition efficiency of tourism engineering management data and the maximum utilization of storage space, Liu et al. conducted various research studies and analyses on different tourism engineering management data and finally classified different data types into various types of data models to avoid storing duplicate data and increase the collection efficiency of tourism data [15]. Goodarzian et al. proved through experiments that the discrete data mining model established can realize the static segmentation of dynamic data and solve the problem that it is difficult to obtain dynamic data in management, but there is a problem of small application range [16].

To sum up, it can be seen that the current tourism engineering focuses on the data mining management analysis model with the continuity of static management data as the main research object in the establishment of the intelligent management analysis model, but there are some problems in this kind of model research, such as low intelligence and low data utilization [17–19]. On the other

hand, although China has done more theoretical analyses and research on the establishment method of the intelligent management and intelligent analysis system of tourism engineering, there is room for progress in the achievement transformation at the actual control level, and there is no establishment of the intelligent multimedia control system model [20, 21].

3. Methodology

The development of big data and artificial intelligence in the digital age has brought great opportunities for the digital development of intelligent management of tourism engineering [22]. The most typical algorithm in artificial intelligence technology based on big data idea is the convolution neural network algorithm [23]. The typical convolutional neural network structure is a feed forward network with three or more layers without feedback and no interconnection structure in the layer. The convolutional neural network is also a basic method for self-learning and updating at the data level. The first and last layers are called the input layer and output layer, respectively, and the middle layers are the hidden layer (also known as the middle layer) [24]. In the convolution neural network, the neurons in each layer are fully connected, and there is no connection between the neurons in each layer. The neural network algorithm used in the topological representation of management is an intelligent algorithm with "human biological characteristics" based on the overall structure of human neurons and the direct two-way regulation and automatic processing of neurons by the brain [25]. The data processing process of the convolution neural network algorithm is shown in Figure 1.

When the industrial 4.0 tourism engineering intelligent management data information is processed randomly, the mutual coupling analysis of two-way management information classification and the vector processing analysis of multiple coupling combinations are carried out through a single neuron structure with multiple neuron structure (synapse) characteristics, the management type with high modular demand is found from the total object to be processed, and the probability of being selected for secondary or multiple analysis is high. On the contrary, the probability of objects with low significance of management features being selected for secondary or multiple reusable framework processing is very low. The new generation of tourism project objectives has dynamic characteristics, which need to be compared and analyzed for many times to produce unified management. In this way, after several two-way information interaction cycles, mixed characteristic individuals conforming to the characteristics of artificial intelligence are finally generated, that is, modular unified processing for a certain type of tourism management data local optimization and feature extraction.

3.1. Establishment Process of the Multiple Grey Convolution Neural Network Model Based on Data Mining. By checking many factors of multimanagement data, we can judge whether there are closely related factors in various data of

intelligent management type of tourism engineering. Tourism information management is a process in which information personnel plan, organize, command, coordinate, and control the tourism information source utilizing information technology. From a microperspective, it includes the management of tourism information content. Macroscopically speaking, it includes the management of tourism information institutions and tourism information systems. In this way, we can not only use the comprehensive average index of these closely related factors or one of them to represent a variety of such factors. In addition, the information carried by these multidata to be processed cannot be seriously distorted. The data analysis process of the convolution neural network topology analysis model based on big data and artificial intelligence strategy is shown in Figure 2.

First, assume that there are n data objects to be processed (tourism engineering management information), which are called implementation objects, and each observation object has m characteristic data (management characteristic information); the sequence can be obtained as follows:

$$
\begin{aligned}
X_1 &= (x_1(1), x_1(2), \ldots, x_1(n)), \\
X_2 &= (x_2(1), x_2(2), \ldots, x_2(n)), \\
X_3 &= (x_3(1), x_3(2), \ldots, x_3(n)), \\
X_m &= (x_m(1), x_m(2), \ldots, x_m(n)).
\end{aligned}
\tag{1}
$$

Then, calculate the absolute correlation ε_{ij} between X_i and X_j for all $i \le j, i, j = 1, 2, \cdots, m$, and the calculation formula is

$$
\varepsilon = 1 - \sqrt{\frac{X_m + X_{m+1}}{X_m - X_{m-1}}}.
\tag{2}
$$

The corresponding coding function is obtained according to the correlation degree

$$
W(x) = \frac{7x^2 + x^4 + 1}{7x^2 + 8x^3 + 5x^4 + 2} \varepsilon_{ii},
\tag{3}
$$

where $\varepsilon_{ii} = 1; i = 1, 2, \cdots, m$ AA. In this process, the following results can be obtained from the simulation analysis of data types in different dimensions. The simulation results without big data coupling factors for different tourism projects are shown in Figure 3.

The simulation results of dynamic coupling quantity under level 1 big data coupling factor for intelligent management types of different tourism projects are shown in Figure 4.

The simulation results of the two-level big data coupling factor in dynamic characterization of intelligent management types of different tourism projects are shown in Figure 5.

For the intelligent management types of different industrial 4.0 tourism projects, the simulation results of three-level big data coupling factors in dynamic characterization are shown in Figure 5.

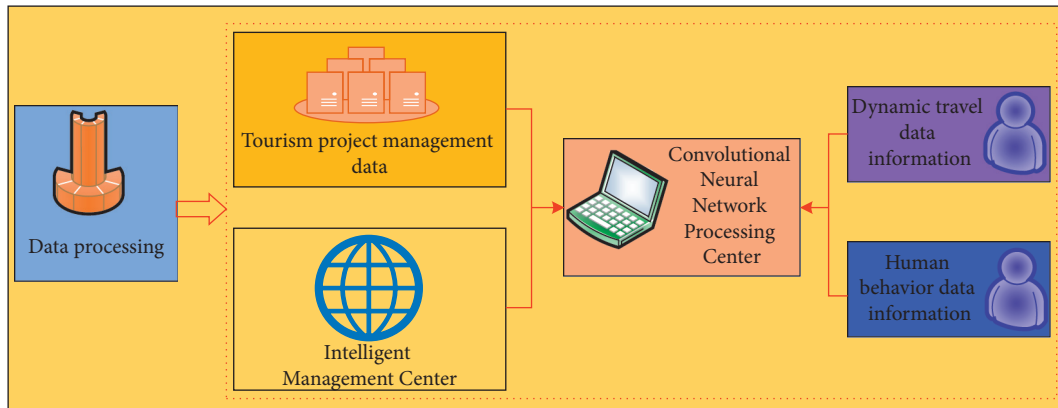
It can be seen from Figures 3–6 that the comprehensive utilization rate of the information of the corresponding


FIGURE 1: Data processing process of the convolutional neural network algorithm.

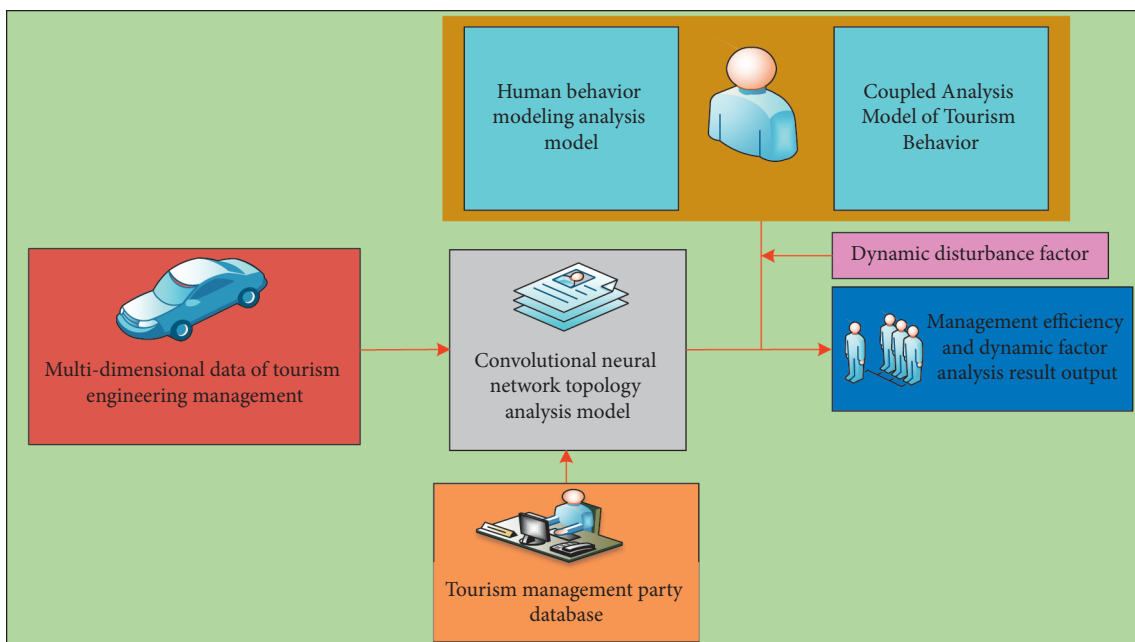

FIGURE 2: Data analysis process of the convolutional neural network topology analysis model based on big data and artificial intelligence strategies.

FIGURE 3: Simulation results of different tourism projects without big data coupling factors.
FIGURE 4: The simulation results of the dynamic coupling quantity value under the first-level big data coupling factor for the intelligent management types of different tourism projects.

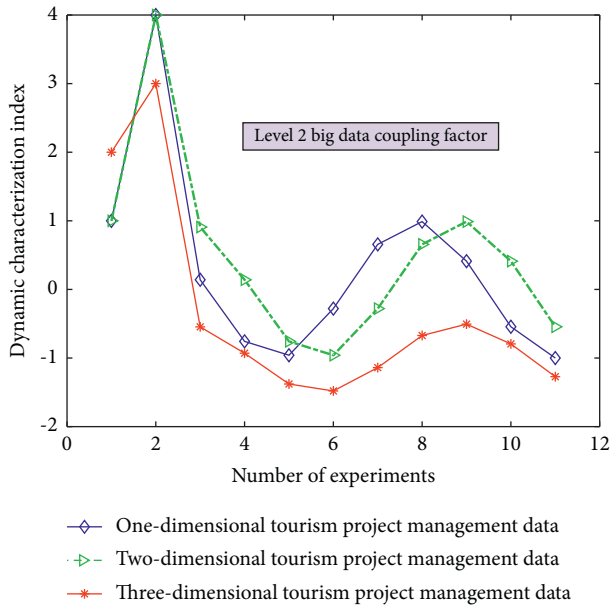

FIGURE 5: The simulation results of the dynamic characterization of the two-level big data coupling factor for the intelligent management types of different tourism projects.

FIGURE 6: The simulation results of the dynamic characterization of the three-level big data coupling factor for the intelligent management types of different tourism projects.

management database changes with the change of the number of topology analyses when performing different degrees of association calculation and processing (level 0/1/2/3 big data coupling factor) for different data under the dynamic relationship topology model of the convolution neural network algorithm and when the level 3 big data coupling factor is added. There are more and more stable branches of its corresponding topological dynamic structure, and its stability utilization rate is also better and

better. This is because in the calculation process, through the computer database information and the preset linear judgment program, some data information can be deeply mined and analyzed, so as to realize the quadratic linear processing of the data after the initial linear analysis. After quadratic linear processing, its stability and data utilization are improved. In this study, the values of the analysis indexes of n data objects to be processed are divided into the class grey group, which is called j index subclass. The convolution network function of j index k subclass is recorded as $H_j^k(x)$.

$$H_j^k(x) = \frac{x + x_j^k(1)}{x_j^k(2) - x_j^k(1)}, \quad x \in \left[x_j^k(1), x_j^k(2)\right]. \quad (4)$$

Among them, $x_j^k(1)$ and $x_j^k(2)$ are the network nodes, and x is the data type.

If the function $H_j^k(x)$ does not have the first and second turning points $x_j^k(1)$ and $x_j^k(2)$, $H_j^k(x)$ is called the lower bound measure convolution network function, which is recorded as $H_j^k[-,-,x_j^k(3),x_j^k(4)]$. In this system, the corresponding lower bound measure function $f_j^k(x)$ is

$$f_j^k(x) = \frac{x_j^k(4) - x}{x_j^k(4) - x_j^k(3)}, \quad x \in \left[x_j^k(3), x_j^k(4)\right]. \quad (5)$$

The moderate measure function corresponding to this model is shown in formula (6), and the expression of the whitening weight function of the upper bound measure is formula (7).

$$Q_j^k(x) = f_j^k(x) = \frac{x_j^k(4) - x}{x_j^k(4) - x_j^k(2)}, \quad x \in \left[x_j^k(2), x_j^k(4)\right]. \quad (6)$$

$$W_j^k(x) = f_j^k(x) = \frac{x - x_j^k(1)}{x_j^k(2) - x_j^k(1)}, \quad x \in \left[x_j^k(1), x_j^k(2)\right]. \quad (7)$$

Among them, $x_j^k(1)$, $x_j^k(2)$, and $x_j^k(4)$ are the network nodes, and x is the data type.

3.2. Tourism Management Efficiency Based on the Convolutional Neural Network Gaussian Mixture Sparse Representation Data Processing Process of the Dynamic Optimization Model.

In this model, in order to better determine the specific significance of management data judgment index in the process of grey linear analysis, carry out factor analysis and provide basis for system decision-making. It is necessary to solve the problem of how to find correlation and measure from random time series. By determining the convolution variable weight linear coefficient, the accuracy of management data mining can be better improved. Therefore, the weighted linear coefficient σ_i^k can be expressed as

FIGURE 7: Stability changes of management efficiency under different topological structures.

$$\sigma_i^k = \sum_{j=1}^{m} f_j^k(x_{ij}) \cdot \eta_j^k,$$

$$\sigma_i = \left(\sigma_i^1, \sigma_i^2, \ldots, \sigma_i^s\right) = \left(\sum_{j=1}^{m} f_j^1(x_{ij}) \cdot \eta_j^1, \sum_{j=1}^{m} f_j^2(x_{ij}) \cdot \eta_j^2, \ldots, \sum_{j=1}^{m} f_j^s(x_{ij}) \cdot \eta_j^s\right). \quad (8)$$

The above formula is called the linear coefficient of the multilayer convolution neural network, and its corresponding linear coefficient matrix is

$$\Sigma = \left(\sigma_i^k\right) = \begin{bmatrix} \sigma_1^1 & \sigma_1^2 & \cdots & \sigma_1^s \\ \sigma_2^1 & \sigma_2^2 & \cdots & \sigma_2^s \\ \cdots & \cdots & \cdots & \cdots \\ \sigma_n^1 & \sigma_n^2 & \cdots & \sigma_n^s \end{bmatrix}. \quad (9)$$

In order to realize data mining of the convolutional neural network linear analysis process, the information of target data needs to be translated into language information that can be recognized by computer through a certain pattern. Therefore, after the feature sparse representation process of the Gaussian mixture industrial 4.0 tourism engineering intelligent management data of the management data, the simulation analysis results of the calculation efficiency of three different types of tourism engineering management data combined with human behavior are shown in Figure 7.

As shown in Figure 7, with the increase of the number of topologies, the stability and computational efficiency of the corresponding tourism engineering intelligent management database are also changing. Because some low-frequency or

meaningless management data information is intentionally deleted or deleted, the process is stored through a specific mode. To facilitate the data recovery required by posterror processing operations, form a special data information record and realize the conversion from data information to computer storage information, and its storage function can be expressed as $T(x)$.

$$T(x) = \frac{\sum_{j=1}^{m} f_j^1(x_j)}{\eta_j^1}. \quad (10)$$

Among them, η_j^1 is the storage coefficient, and its sparse representation can be expressed as $T'(x)$, which can be expressed as

$$T'(x) = \frac{\sum_{j=1}^{m} f_j^1(x_j)}{\eta_j^1 H(x)}. \quad (11)$$

where η_j^1 is the storage coefficient and $H(x)$ is the discriminant function.

Choosing different grey linear methods will make the data in the cluster have different correlation degrees. The topology analysis model based on the convolutional neural network is to fuzzy search and screen the unknown data targets (newly collected industry 4.0 tourism project

management information and known human behavior data) through data mining of multitarget data. The screening function is $P(x)$, and the expression is

$$P(x) = \frac{\sum_{j=1}^{m} (x_j - \overline{x})}{\eta_j^1 \overline{x}}, \tag{12}$$

where η_j^1 is the storage coefficient.

When it is necessary to classify different types of data indicators (such as relevant assessment data indicators of a tourism project), the evaluation model $Z(x)$ can be expressed as

$$Z(x) = \frac{1}{\eta_j^1 \sum_{j=1}^{m} (x_j - \overline{x})}, \tag{13}$$

where η_j^1 is the storage coefficient and $\overline{x}$ is the average number of management decomposition information.

$$Z(x) = \frac{1}{\eta_j^1 \sum_{j=1}^{m} (x_j - \overline{x})}. \tag{14}$$

In the optimal case, the convolution neural network analysis model can realize the recognition of multiple data under a certain similarity. However, there are still some problems in the data mining process and management dynamic algorithm. In order to improve the recognition degree of the association degree between management data information (feature information) and multiple data (management color channel and salient feature) by the multiple grey linear analysis model as much as possible, the expression of the association degree $R(x)$ is

$$R(x) = \frac{\eta_j^1}{\sum_{j=1}^{m} x_j - \overline{x}/x_{j+1} + \overline{x}}. \tag{15}$$

At present, the most commonly used method is to achieve accurate topological linear analysis through big data database statistics and data comparison between the same management types. The above dynamic flapping analysis method is also used to compare and determine the well-known feature recognition information and management sparse representation pattern information.

4. Result Analysis and Discussion

4.1. Experimental Design Process and Data Results. The input layer data used in this experiment are the known industry 4.0 tourism engineering management information data, the hidden layer is the artificial intelligence topology analysis strategy based on big data and the convolution neural network algorithm, the output layer is the dynamic optimal selection combination of tourism engineering management, and its convolution learning strategy is the tourism engineering intelligent management rules and regulations and employee level treatment. When evaluating the topological rate and change type of tourism engineering management data, it needs to be evaluated from many aspects. According to the needs of tourism engineering development, this study proposes 25 indicators to evaluate the quality of

management topology analysis. Through the observation results of 25 relevant data managing topological-mixed features, the above indicators are properly classified and sparse representation analysis, and the characterization standard is simplified by deleting some unnecessary (i.e., less influential) indicators, so as to realize the quantitative representation of the above data indicators, which is more convincing. During the experiment, the management data of three types (6 groups in total, 2 groups in each type) of different tourism projects are verified by topological analysis. The experimental results are shown in Figure 8.

4.2. Analysis of Experimental Results of Management Data Accuracy Based on the Convolutional Neural Network. The analysis results of data accuracy in the experimental results are shown in Figure 9.

From the experimental results shown in Figure 8 and the accuracy analysis results shown in Figure 9, it can be seen that after the analysis of three types of data (two groups each), the corresponding change of topology classification performance index is obvious. Among them, the topology performance of the third group of data is the highest, but the corresponding big data analysis data deviation is also the highest because with the increase of topology structure, the dimension of data analysis is also increasing, so its deviation will also change. On the other hand, among the above data indicators for evaluating the quality of topology analysis, some or several indicators do have correlation or mixed relationships.

In addition, it can be seen from the data shown in Figures 8 and 9 and the experiment that in the process of processing the experimental data, this study adopts an efficient and intelligent topological data analysis method. The model can realize the unified management of sparse representation demand data of different tourism management and different types of management representation method data. According to the local differences between data and the actual needs of sparse representation, the algorithm is used for intelligent optimization, analysis, and processing to realize the high-precision utilization and remote dynamic maintenance of data. Then, through the eigenvalues of the signals collected by the wireless nano data processing equipment and the structural characteristics of different management in the sparse representation process, according to the different eigenvalues such as vector difference and matrix difference, the intelligent optimization processing and deep information mining process based on the machine learning model and neural network algorithm are applied. Realize the classification level division of different management Gaussian mixture feature sparse representation methods in data analysis. Finally, through a series of data analysis processes represented by the neural network algorithm in the sparse representation of tourism management, classify according to the differences of information, realize the high classification of the similarity of different data, and realize the fitting analysis and simulation of approximate or the same data according to the different requirements for the sparse representation of different tourism
FIGURE 8: The results of topological analysis and verification on the management data of 3 types of different tourism projects.

FIGURE 9: Analysis of the accuracy of the data in the experimental results.

management. Then, it completes the efficient and high-precision classification of the sparse representation optimization link of managing Gaussian mixture features.

5. Conclusion

This work studies the discrete dynamic analysis data mining model scheme based on the convolutional neural network algorithm and big data cloud collaborative processing. Compared with the traditional intelligent management analysis model of tourism engineering, which takes the continuity of static management data as the main research object, the innovation of this study is to apply discrete

dynamic modeling technology and big data topology analysis strategy based on the convolution neural network algorithm to the dynamic analysis model of industry 4.0 tourism engineering management. It can make full use of a large number of dynamic management data, extract appropriate management data feature information, realize the simulation level integrity method, quantitatively describe representative quantitative eigenvalues, the similarity of multidimensional management analysis modes and expected evaluation indicators of different tourism projects in the process of employee management scheme allocation, and adopt multiconversion neural network factors. It can efficiently customize and analyze the factors affecting management efficiency and accuracy. However, the algorithm only analyses the impact and correlation degree from the local analysis of management and does not consider other potential factors of sparse representation of management features. Therefore, the comprehensive analysis of the index evaluation system and the influence degree of other factors need to be further studied.

Research Article

Industry 4.0 Engineering Product Life Cycle Management Based on Multigranularity Access Control Model

Longfei Yu [ID] and Shifan Zhu

College of Mechanical and Electrical Engineering, Harbin Engineering University, Harbin 150001, China

Correspondence should be addressed to Longfei Yu; yulongfei@hrbeu.edu.cn

In order to improve the management efficiency of the safety status of Industry 4.0 engineering products, the multigranularity access control model (MGACM) Industry 4.0 engineering product life cycle management (PLM) is adopted to optimize the safety management mode of Industry 4.0 engineering products in this paper. The multigranularity access control model is constructed in this paper, which has strong nonlinearity and better fault tolerance. In addition, the parameters of PLM are optimized through the multiparticle access control model, and PLM search is enabled. Taking into account the slow and easy convergence of the multigranular access control model, a niche technology with full life cycle heterogeneity and elimination mechanism is proposed to solve the premature convergence problem of the multigranular access control model. The final simulation results of this paper show that, compared with traditional algorithms, the proposed multigranularity access control model is more reliable and effective and has faster convergence speed and higher management efficiency.

1. Introduction

With the continuous advancement of society and unceasing enhancement of people's needs, data information has gradually become the basic technology for people's daily life, and the role of Industry 4.0 engineering product life cycle in people's lives has become more prominent. There are Industry 4.0 engineering products [1, 2], wireless communication Industry 4.0 engineering products, etc. Therefore, the Internet is usually used to transmit and receive data and information, and the quality of Industry 4.0 engineering products is more important. According to research at home and abroad, it is shown that the quality problems of industrial products are not simply solved by the use of preventive methods [3]. Under this circumstance, the security status perception of the integrated technology Industry 4.0 engineering products that need to obtain and process security information has attracted attention. However, Industry 4.0 engineering product safety situation management

is an emerging technology, and many research contents have not been resolved so far. In order to provide more effective and accurate management, an improved multigranularity access control model is introduced to optimize the life cycle management of Industry 4.0 engineering products in this paper. First of all, PLM with better nonlinear ability and approximation speed is adopted instead of BP or RBF neural Industry 4.0 engineering products for management. Secondly, the multigranularity access control model is used to optimize the parameters of the neural Industry 4.0 engineering product, which has strong global search capabilities.

By constructing a multigranularity access control model, the access host granularity and access level granularity are optimized and processed. Meanwhile, the life cycle granularity and authorization distribution control granularity of industrial products are used, to complete the optimization process of the model and complete the realization of multigranularity access control. Finally, the analysis of the experimental results shows that the constructed model can

effectively reduce the fault tolerance rate of the industrial product life cycle management system. Meanwhile, it can also strengthen the accuracy and completeness of model access control, which can better meet the special needs of PLM for access control.

2. Granularity Analysis of Access Control for Industry 4.0 Engineering Product Life Cycle Management

2.1. Granularity of Access Subject Composition. The subject that can be accessed by the multigranularity access control model only allows two dimensions: role and user. This article implements its subject by increasing the granularity diameter. Granular composition, as a collection of multiple users, can achieve the completion of its architecture through a combination of different forms. The full range of permissions for function groups and users is open. As the authorizer of the granularity of the access subject, ASD can assign its authority to the restricted relationship with the same structure. If a user is assigned to group A, then the role permissions of group B can be obtained. For example, technicians in the assembly process group can assign permissions to them in accordance with the engineering product management standards of Industry 4.0, and the same user can be assigned different users/assigned roles. Figure 1 shows the granularity of the access control subject and its relationship model.

The authorization of the access subject group can simplify the public permission distribution method for the unused functions in the same unit and can simplify the access control of the temporary project group. Because the user authorization can effectively improve the problems of personnel management, it is effective to reduce the confusion of the role. ASC and ASD are in a static relationship. At the same time, before assigning users to corresponding roles, their roles can be set according to the business rules of industrial products or possible problems can be solved in advance. ASC can make corrections when there is an error in the user's role assignment. The main function of ASD is to simplify the problem of repeated assignment of permissions for different roles. Therefore, the granularity of the access subject and its corresponding relationship can not only simplify its authorization procedure, but also avoid the probability of false authorization [4].

2.2. Access Object Level Granularity. The life cycle management analysis system uses the engineering product sequence information to analyze the life cycle management parameters of the camera based on a specific model. Most of the calculated amount of the engineering product stability algorithm is here, and the accuracy of life cycle management parameters affects the accuracy of the stable engineering product, so it is an important part of the engineering product stability system [5]. The multigranularity access control model MAC is shown in Figure 2 on the visitor layer. Operations (OpeRation, OPAR) can be used in different types of granularity groups. For any optimal granularity, the

achievable results can be used in special scenarios. During Industry 4.0 engineering product life cycle management process, due to the camera shaking during use, the engineering product sequence obtained by shooting will be jittered. The engineering product processing interference caused by this jitter will promote the engineering product life cycle management analysis technology emerging as the times require. Engineering product life cycle management analysis technology has been widely used in many fields of military and civilian use. From the perspective of military applications, large-scale guidance, fire control systems, and small self-seeking missile leading engineering products all involve engineering product life cycle management analysis technology. This technology can be used to improve the attack performance of weapon systems and for improvement of relevant indicators of other operations. In the photography of aviation field and terrain surveying and mapping instruments, in order to ensure that the corresponding measurement benchmarks for life cycle management analysis are obtained in the image plane of the instrument, the accuracy and processing speed of the measurement results are improved. As a new engineering product life cycle management analysis model that has gradually emerged in recent years, the multigranularity access control model can be used for the processing and analysis of Industry 4.0 engineering product life cycle management. The basic principle of this model is to use a different model for any Industry 4.0 engineering product data or perform multiple clustering operations on engineering products under different conditions and select the appropriate method for the calculation results obtained by the clustering operation, clustering and optimizing the data to obtain the best results.

2.3. License Allocation Control Granularity. As a bridge between the operation/object and the accessible subject, the license can realize comprehensive and neat distribution control. The particle progress control can ensure the consistency of the target to be visited. The distribution control particle size of the license can be distinguished according to the four aspects of the controllable control direction within the allowed range, the allowed access restriction, and the license priority. An Industry 4.0 engineering product life cycle management method is proposed. While transforming the two-dimensional engineering product life cycle management to one-dimensional engineering product data, it also evaluates and analyzes the deviation of the engineering product sequence in the life cycle management data, to eliminate the impact of engineering product quality due to lower sequence.

Allowable range, control direction, and access restrictions are static attributes, and allocation permissions need to be set (Table 1). Priority is a dynamic attribute, and the value before system execution is empty. If the system runs and loads all the permissions of the current user, the permissions are sorted according to the allowed source code and the priority of the above permissions. For example, the priority of direct permission from all users is 0, and the priority of permission from the user's group is 1.

3. Multigranular Access Control Analysis

3.1. Control Subject and Object and Related Analysis.

TABLE 1: Access control direction combination relationship.

Control direction A	Control direction B	Combination result
Positive license	Negative license	Refusal
Positive license	Positive license	Allow
Positive license	Zero license	Allow
Negative license	Negative license	Refusal
Negative license	Zero license	Refusal
Zero license	Zero license	Refusal

First, the gradient descent training of error backpropagation is used to select and extract cluster members for the life cycle management of Industry 4.0 engineering products to provide an accurate data basis for subsequent cluster fusion. There is the actual sequence $\{x(t_0 + i\Delta t)\}$ of the information flow of the life cycle management Industry 4.0 engineering product data and $i = 0, 1, \ldots, N - 1$. After setting X and Y as the Industry 4.0 engineering product life cycle management attribute set, the cluster space state vector calculation formula of the Industry 4.0 engineering product life cycle management is

$$X = [x(t_0), x(t_0 + \Delta t), \ldots, x(t_0 + (K-1)\Delta t)] =$$

$$\begin{bmatrix} x(t_0) & x(t_0 + \Delta t) & \cdots & x(t_0 + (K-1)\Delta t) \\ x(t_0 + J\Delta t) & x(t_0 + (J+1)\Delta t) & \cdots & x(t_0 + (K-1)J\Delta t) \\ \vdots & \vdots & \vdots & \vdots \\ x(t_0 + (m-1)J\Delta t) & x(t_0 + (1 + (m-1)J\Delta t)) & \cdots & x(t_0 + (N-1)\Delta t) \end{bmatrix}. \quad (1)$$

In the formula, $x(t)$ represents the time series of the life cycle management information flow of Industry 4.0 engineering products. J represents the phase space time window function of the life cycle management reconstruction of the Industry 4.0 engineering product data and m represents the life cycle management cluster adjustment factor of the target engineering product data. Δt represents the sampling time interval of Industry 4.0 engineering product data.

Then the calculation expression of the discrete sample spectrum feature quantity for the life cycle management of Industry 4.0 engineering products is as follows:

$$X_p(u) = s_c(t)e^{j2\pi f_0 t} = \frac{1}{T}\text{rect}\left(\frac{t}{T}\right)^{j2\pi(f_0 t + Kt^2)/2}. \tag{2}$$

The formula $s_c(t)$ represents the characteristic scalar time series of the life cycle management of Industry 4.0 engineering products. $e^{j2\pi f_0 t}$ represents the discrete sample center of the Industry 4.0 engineering product life cycle management cluster.

$$u_{(i,d)}^{(k+1)} = \begin{cases} x_{(i,d)}^{(t+1)} & f_{\text{titness}}^t < f_{\text{fitness}}^*, \\ z_{(i,d)}^{(k+1)} & f_{\text{titness}}^t \geq f_{\text{fitness}}^*, \end{cases} \tag{3}$$

f_{fitness}^t is the expression representing the reliability coefficient of the life cycle management of Industry 4.0 engineering products. f_{fitness}^* represents the reliability interval coefficient for the life cycle management of Industry 4.0 engineering products.

According to the calculation of formulas (2) and (3), the best solution vector matrix formula for the life cycle management of Industry 4.0 engineering products centered on data clusters is

$$\Sigma_r = \text{diag}(\sigma_1, \sigma_2, \ldots, \sigma_r) \in R^{r \times r}. \tag{4}$$

The formula σ_r represents the position of Industry 4.0 engineering product life cycle management to $k+1$. $R^{r \times r}$ represents the actual matrix of Industry 4.0 engineering product life cycle management.

The diagonal vector indicator of the life cycle management of Industry 4.0 engineering products is close to the target solution, and the following conditions can be met:

$$\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_r > 0. \tag{5}$$

According to the granularity fusion, the IEPLCM system can be divided into related extensions of the control main control, as shown in Figures 3 and 4.

3.2. Analysis of Relevant Elements of Multigranular Access Control.
Industry 4.0 engineering product life cycle management selection results, diversity and accuracy are used to define, comprehensive evaluate, and complete the selectivity of Industry 4.0 engineering product life cycle management. By searching the particle swarm in the Industry 4.0 engineering product life cycle management cluster to form the Industry 4.0 engineering product life cycle, the corresponding Industry 4.0 engineering product life cycle management data information feature vector χ_i is expressed as

$$l_\varepsilon(g) = (1 - \rho)l_\varepsilon(g-1) + \gamma f(\chi_i(g)). \tag{6}$$

In the above expression, f represents the corresponding adaptive function of the feature data feature vector χ_i of the life cycle management of Industry 4.0 engineering products. $\gamma \chi_i(g)$ represents the ε-th life cycle management corresponding media engineering product data optimization in the actual application process.

The expression of clustering π_p in Industry 4.0 engineering product life cycle management II is

$$\text{Acu}(\pi_p) = \text{NMI}(\pi_p, \pi^*). \tag{7}$$

In the formula, π_p and π_q represent the clustering integration of the life cycle management of Industry 4.0 engineering products. If there is less information shared with the Industry 4.0 engineering product life cycle management basic cluster, the accuracy of the basic cluster is low, and vice versa.

Based on the accuracy and diversity characteristics of the clusters based on the life cycle management of Industry 4.0 engineering products, the comprehensive evaluation criteria that define the clusters based on the life cycle management of Industry 4.0 engineering products include

$$\text{Eval}(\pi_p) = \lambda \text{Acu}(\pi_p) + (1 - \lambda)\text{Div}(\pi_p). \tag{8}$$

In the formula $\lambda \in [0, 1]$, the accuracy and diversity of the life cycle management of Industry 4.0 engineering products are an important degree in the comprehensive evaluation standard.

Based on the diversity $\text{Div}(\pi_p)$ of the basic clustering of Industry 4.0 engineering product life cycle management, formula (8) calculates the probability $\text{pro}(\pi_p)$ of selecting the basic clustering algorithm of each Industry 4.0 engineering product life cycle management as the optimized basic clustering. The calculation formula is as follows:

$$\text{pro}(\pi_p) = \frac{\text{Div}(\pi_p)}{\sum_{p=1}^{B} \text{Div}(\pi_p)}. \tag{9}$$

The $\text{pro}(\pi_p)$ calculation result of the benchmark formula (9) is used to use roulette to randomly select the cluster based on the life cycle management of the Industry 4.0 engineering product and obtain the integration cluster of the Industry 4.0 engineering product life cycle management.

If there are N data in the life cycle management of Industry 4.0 engineering products, the attribute dimension of the data can be represented by w, and the position and velocity matrix of Industry 4.0 engineering product data can be represented by N:

$$\delta_1^1 \delta_1^2 \cdots \delta_1^w \delta_1^1 \delta_1^2 \cdots \delta_2^w \cdots \delta_\tau^1 \delta_\tau^2 \cdots \delta_\tau^w \delta_1^1 \cdots \delta_1^w f. \tag{10}$$

Industry 4.0 engineering product life cycle management particle group overall fitness decentralized

$$\psi^2 = -\sum_{\eta=1}^{v} \left(\frac{f_i - f_{\text{avg}}}{f}\right). \tag{11}$$
Figure 3: Correlative spread of common subjects.
Figure 4: Correlative spread of common objects.

In the formula, v represents the number of particles of Industry 4.0 engineering product life cycle management. f_i represents the matching degree value of the ηth Industry 4.0 engineering product life cycle management particle. f_{avgA} represents the average fitness value of current particles in the life cycle management of Industry 4.0 engineering products.

$\psi^2 < \varphi$ represents the determination threshold of the Industry 4.0 engineering product life cycle management φ and can perform optimization of updating the position and velocity of Industry 4.0 engineering product data particles according to the following expressions:

$$v_t = \omega v_{t-1} + \kappa_1 \times \text{rand}_1 \left(\text{pbest} - x_{t-1}\right) + \kappa_2 \times \text{rand}_2 \left(\text{gbest} - x_{t-1}\right), \tag{12}$$

$$x_t = x_{t-1} + v_t. \tag{13}$$

3.3. Key Algorithms for Multigranular Access Control. As
mentioned above, to judge authority through access objects and related analysis, we must fully consider the spreading mechanism between access objects. This solves the set of equivalent access subjects associated with the detection target user and the set of equivalent control clients corresponding to the control target instance. It also provides a basis for authentication based on access control permissions.

Because the solver process that controls the set of equivalent access subjects and the set of objects is similar, the following only introduces the solver process of the set of equivalent access subjects. The pseudo-algorithm for solving the set of equivalent access subjects is described below.

The purpose of IEPLCM's multigranular access control is to temporarily allow or deny the request based on predefined permissions when a specific user requests access to

Input: user u and its context
Output: the equivalent access subject of user U $S_{eqv}(u)$
Begin
Initialize the equivalent access subject set;
Suppose the current detection visitor $s = u$;
According to the subject spread rule, obtain the subject spread set $P(s)$ of s;
Foreach ($p \in p(s)$)
Judge whether p is already in $S_{eqv}(u)$, if not, add p in it, and repeat the previous step with $s = p$;
After the recursive solution of the above process, the final complete result is obtained.
End

ALGORITHM 1: Equivalent access subject set solution.

specific product components or text data. When the access is determined to be a function, the entry parameter of the function is user u. In addition, the operation op performed by the requested access control client object functions as a function that returns b according to a predefined access rule. If the return value of the function is true, it can be executed [6, 7]. On the contrary, the access request is denied, and the corresponding access control is shown in Algorithm 2 based on the analysis of the abovementioned access control model components and masters, guests, and their related relationships pseudo-algorithm of the project process.

It can be seen from Algorithm 2 that the solver process for verifying access control authority is a process of multiple nested loops to ensure the efficiency of the algorithm. The number of permitted rule items sets common access control items for control guests (such as certain types of text, components) that have the meaning of data sets and sets special and individual access control items for specific control guests to achieve access control of data.

4. Product Life Cycle Management Process under the Multigranularity Access Control Model

4.1. Multigranularity Access Control Model.
It describes the composition granularity of the access subject, the level granularity of the access object, the granularity of the life cycle, and the license allocation control granularity from different aspects and levels to control the access to PLM. Based on the above analysis, as shown in Figure 5, a PLM access control model based on RBAC is constructed.

4.2. Formal Description of Multigranularity Access Control Model.
MGACM usually adopts a closed type with three layers of feedforward neural Industry 4.0 engineering products. In the model in this paper, it is assumed that the Industry 4.0 engineering product topology is shown in Figure 6, and there are m nodes in the input layer, h nodes in the hidden layer, and n nodes in the output layer. The input samples are represented by $X_1 \sim X_m$ and the output samples are represented by $Y_1 \sim Y_n$. The stretching and translation parameters are expressed by $a_1 \sim a_h$ $b_1 \sim b_h$, respectively. The link weights in Industry 4.0 engineering products between the input layer to the hidden layer and the hidden layer to the output layer are represented by $w_{11} \sim w_{mh}$ $w_{11}' \sim w_{hn}'$, respectively.

For the hidden layer, Morlet is selected as the main wavelet function and its equation is as follows:

$$\psi(x) = \cos(1.75x)\exp\left(-\frac{x^2}{2}\right). \tag{14}$$

The number h of hidden layer nodes is determined by the number m of input layer nodes. Calculation formula is

$$h = 2m + 1. \tag{15}$$

It follows that

$$g(x) = \frac{1}{[1 + \exp(-x)]}. \tag{16}$$

The x in (1) and (3) represents the data of the previous layer.

The output result of MGACM based on wavelet function is

$$Y_t = \sum_{s=1}^{h} w_{st}'\psi\left(\frac{\sum_{r=1}^{m} w_{rs} - b_s}{a_s}\right). \tag{17}$$

Generally, the gradient descent method is used to calculate the connection weight of Industry 4.0 engineering products, and the parameters in MGACM are more accurate than before. The extreme points of this method are only approximate values. Meanwhile, it is easily troubled by the problem of the best local Industry 4.0 engineering products. Therefore, this article intends to use an improved multigranularity access control model to optimize the parameters of local Industry 4.0 engineering products.

The increase of the fitness value determines the development direction of the multigranular access control model. The error E of MGACM is defined as an individual fitness function:

$$E = \frac{1}{2}\sum_{t=1}^{n}(Y_t - Y_t')^2, \tag{18}$$

$$f = \frac{1}{1 + E}, \tag{19}$$

Input: request user u, request access control object o and its current state os, request operation op
Output: the calculation result of F (u, op, o, os)
Begin
Solve the set of equivalent access F (subject set of u $S_{eqv}(u)$ and the set of equivalent access control object of o $O_{eqv}(o)$, refer to Algorithm 1 for the solution process;
foreach (o_i in $O_{eqv}(o)$))
{
Query the data access rule set R that satisfies the input condition constraints from the authorization rules associated with o_i
foreach (u_i in $S_{eqv}(u)$)
{
foreach (cs in R), where cs is the complex access subject corresponding to the access rule set
{
if ($u_i \in cs$)
{
return true
}
}
}
}
return false;
End

ALGORITHM 2: Access control authority verification solution.

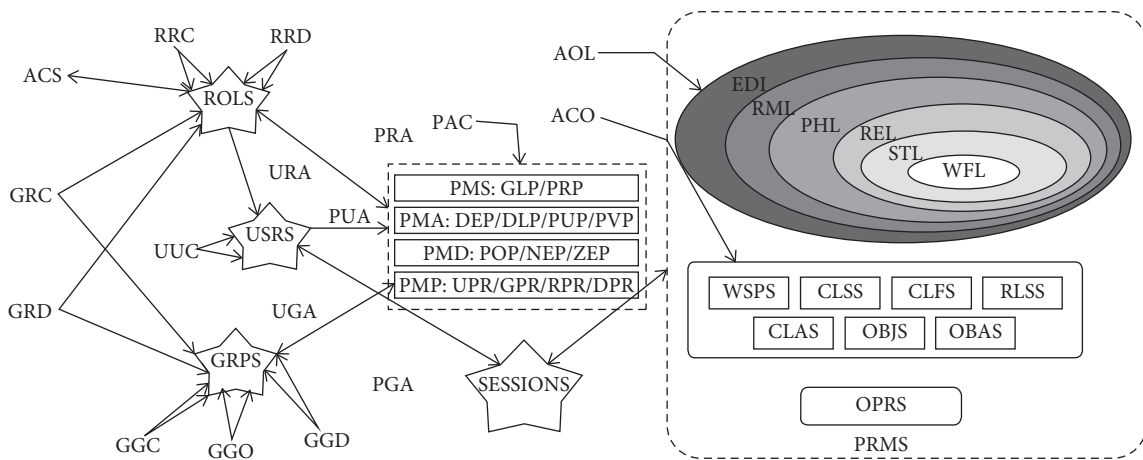

FIGURE 5: Multigranularity access control model and its elements.

FIGURE 6: MGACM's Industry 4.0 engineering product topology.

where Y_t represents the real value of the t-th output node, and Y_t' represents the predicted output.

The most common selection operation is to choose roulette. However, the predictive model is selected with the expected value so as not to harm the best individual at the smaller number of samples [8, 9]. Expected value is calculated by (20). Therefore, the problem of probability is transformed into a problem of frequency. In the meantime, excellent personal retention institutions directly allow individuals to maintain the highest fitness value of the next generation of modern times.

$$q_i = \frac{f_i}{f_{\text{sum}}/N}, \quad i \leq N. \tag{20}$$

This represents the sum of the overall individual fitness values. f_{sum} represents the sum of all individual fitness values. f_i represents the ith personal health value. N represents the total number of people. In addition, rounding is required by q_i.

The choice of parameters is very important in the simulation process of the multigranularity access control model. For fixed values, the classic access control model always relies on crossover and mutation probabilities. However, it cannot dynamically adjust the probability of multigranularity in the evolution process, and the convergence speed is unstable. In addition, in order to deal with crossover operators and mutation operators, a multigranularity access control method is adopted in this paper. The multigranularity access control model probabilities p_c and p_m are defined in the following equations:

$$p_c = \begin{cases} \alpha_1 - \dfrac{(\alpha_1 - \alpha_2)(f_{\max} - f')}{f_{\max} - f_{\text{avg}}}, & f' \geq f_{\text{avg}}, \\[3mm] \alpha_2, & \text{else}, \end{cases} \tag{21}$$

$$p_m = \begin{cases} \beta_1 - \dfrac{(\beta_1 - \beta_2)(f_{\max} - f)}{f_{\max} - f_{\text{avg}}}, & f \geq f_{\text{avg}}, \\[3mm] \beta_2, & \text{else}. \end{cases} \tag{22}$$

Among them, α_1, α_2, β_1, β_2, respectively, represent random values between [0, 1]. In this paper, $\alpha_1 = 0.8$, $\alpha_2 = 0.5$, $\beta_1 = 0.05$, $\beta_2 = 0.001$ are assumed. $f_{\max}$ represents the largest individual fitness value in the population. The average personal fitness value is represented by f_{avg}. The parent fitness value before the crossover operation is expressed as f'. *f represents the fitness value suitable for the mutated individual.* Assuming that the initial multigranularity randomly generates $N \times m \times n$ data, the complexity of the algorithm is $O(m^2 \times n^2)$.

Suppose there are N individuals with multiple granular dimensions. Depending on the size of the genetic factor, problems sometimes arise in real numbers. Therefore, the real number multigranularity should be normalized by the following function:

$$\hat{x}_{pj} = \frac{(x_{pj} - x_{pj\min})}{x(x_{pj\max} - x_{pj\min})}, \tag{23}$$

where x_{pj} represents the multigranularity of the p-th individual at the j-th point in the genetic sequence.

After normalization by (23), the fuzzy similarity matrix R between individuals is created by

$$R_{pq} = \frac{\sum_{k=1}^{Chromlen} \min(\hat{x}_{pk}, \hat{x}_{qk})}{\sum_{k=1}^{Chromlen} \max(\hat{x}_{pk}, \hat{x}_{qk})} \tag{24}$$

The fuzzy similarity matrix satisfies reflexivity and symmetry. According to [10, 11], the ambiguous equivalent matrix solves the problem of ecology degree more effectively. Therefore, by searching the fuzzy minimum transmission limit of the similar matrix R, the corresponding ambiguity equivalent matrix T is obtained in this paper, and the matrix is clustered as a whole.

If the similarity coefficient λ is less than the coefficient T_{pq} of each pair of individuals, that is, $\lambda \leq T_{pq}$, the individuals x_p and x_q are divided into the same niche, until all individuals are divided into appropriate positions.

$$\text{Niche}(k) \Leftarrow \{x_p \cdots x_q\} (1 \leq k \leq \text{Chromlen}). \tag{25}$$

Based on the fuzzy equivalent matrix and the total number, the similarity coefficients λ are dynamically updated as follows:

$$\lambda_t = \frac{\sum_{j=1}^{N} T_{\max j}}{N}. \tag{26}$$

Among them, $T_{\max j}$ represents the equivalent coefficient between the individual with the maximum fitness value $x_{\max}$ and the individual x_j.

In order to use the improved multigranularity access control model to quantitatively analyze the diversity, equation (27) is defined to calculate the multigranularity diversity.

$$d_t = -\sum_{n=1}^{Q} p_n \log(p_n), \tag{27}$$

$$p_n = \frac{L_{mn}}{N}, \tag{28}$$

where Q represents the number of submultigranularities in the t-th generation, $T_{\max j}$ represents the number of n-th submultigranularities, and N represents the total number of individuals of the species. *The higher the d, the greater the diversity.*

If the fitness value for a certain ecological location is much smaller than other values

$$|f_i - f_{\max}| < f_{\text{default}}, \tag{29}$$

then

$$f_i = f_{niche}(i), \quad 1 \leq i \leq n, \tag{30}$$

$$f_{niche} = (f_1', f_2', f_3', \ldots, f_n'), \tag{31}$$

where f_{max} is the highest applicability value in the same generation. The default threshold of the adaptability value is $f_{default}$. $f_{niche}(i)$ represents the fitness of the i-th individual.

4.3. The Permission Consistency Control Operation of the Multigranularity Access Control Model. The session of the multigranularity access control model refers to the process in which a specific user registers and applies the permissions he owns. Through different login methods, the session includes the current user global authentication registration, proxy user global authentication registration, current user project registration, and proxy user project authorization registration. If the login user is set to u, then for any registration method, user u's permission distribution comes from the following 7 methods, allowing direct assignment to users.

$$PA_u(u) = u\_a\_ps(u). \tag{32}$$

The licenses owned by the user's group:

$$PA_{ug}(u) = \bigcup_{g \in u\_a\_gs(u)} g\_a\_ps(g). \tag{33}$$

The permissions owned by the user's role:

$$PA_{ur}(u) = \bigcup_{r \in u\_a\_rs(u)} r\_a\_ps(r),$$
$$PA_{gg}(u) = \bigcup_{g \in \left(\bigcup_{g_y \in u\_a\_gs(u)} g\_d\_gs(g_y) \right)} g\_a\_ps(g). \tag{34}$$

The permission of the user's group on which the user relies:

$$PA_{gr}(u) = \{(p, PAC)|PAC.PMA = DE \ P \lor PAC.PMA = PUP\},$$
$$PA_{rr}(u) \subseteq \bigcup_{r \in \left(\bigcup_{r_y \in u\_a\_r(u)} r\_d\_rs(r_y) \right)} r\_a\_ps(r). \tag{35}$$

The permission of the role that the user's group relies on, and

$$PA_{rr}(u) = \{(p, PAC)|PAC.PMA = DE \ P \lor PAC.PMA = PUP\},$$
$$PA_{rr}(u) \subseteq \bigcup_{r \in \left(\bigcup_{r_y \in u\_a\_r(u)} r\_d\_rs(r_y) \right)} r\_a\_ps(r). \tag{36}$$

The permission of the group on which the user's role depends:

$$PA_{rr}(u) = \{(p, PAC)|PAC.PMA = DE \ P \lor PAC.PMA = PUP\}. \tag{37}$$

Therefore, all the licenses of user u are allocated as

$$PA(u) = PA_u(u) \cup PA_{ug}(u) \cup PA_{ur}(u) \cup PA_{gg}(u) \cup PA_{gr}(u)$$
$$\cup PA_{rg}(u) \cup PA_{rr}(u). \tag{38}$$

License consistency control refers to the combined operation of all the licenses that have the same life cycle state, the same object, and the same operation, but the license distribution control combination operation of all permissions, to finally determine whether this operation is allowed to be executed [12, 13]. Let PA denote a single license distribution, and the license distributions in the four sessions are denoted as $PA_g(u)$, $PA_{dg}(u)$, $PA_p(u)$, and $PA_{dp}(u)$, respectively. The main flow of the permission consistency control algorithm is shown in Figure 7.

The main steps are described as follows:

(1) u log in and load all the license distribution $P(u)$ according to the seven aspects of license distribution. If the proxy is u', all the licenses loaded into u' are allocated to $P(u')$, and all the licenses that can be delegated to $P(u')$ need to be filtered out, that is, all the licenses owned by u as a proxy.

(2) According to whether it is a global authorization, filter with the condition pa.PAC.PMS = GLP to form the current user global permission $PA_g(u)$, current user project permission $PA_p(u)$, proxy user global permission $PA_{dg}(u)$, and proxy user project permission $PA_{dp}(u)$.

(3) If it is a global license, you only need to filter the license set according to the current ACO, AOL, and OPR and obtain all the license sets $P_{cur}(u)$ for the operation of the object in the current life state. If it is a project license, it must not only filter according to ACO, AOL, and OPR, but also filter according to pa.PAC.PMS = PRP, but if the obtained license set is null, the global license of the current object needs to be borrowed; that is, it will be filtered once based on ACO, AOL, and OPR filter again, to get $P_{cur}(u)$.

(4) In view of $P_{cur}(u)$, according to the priority of license allocation, select all the license allocations $P_{pri}(u)$ with the highest priority. Then let the positive license be 1, the negative license is −] (can be replaced by a larger negative number), the zero license is 0, and the pa.PAC.PMD is solved in the sum $P_{pri}(u)$. If the result is greater than zero, the execution is allowed; otherwise the execution is refused [14, 15].

5. Examples and Results Analysis

5.1. Data Preprocessing. In order to verify the validity of the predictive model, the real security provided by the laboratory Industry 4.0 engineering product life cycle management platform is adopted in this paper. The data, based on the evaluation of the safety status of Industry 4.0 engineering products, effectively realized the prediction of the value of the safety status of Industry 4.0 engineering products.

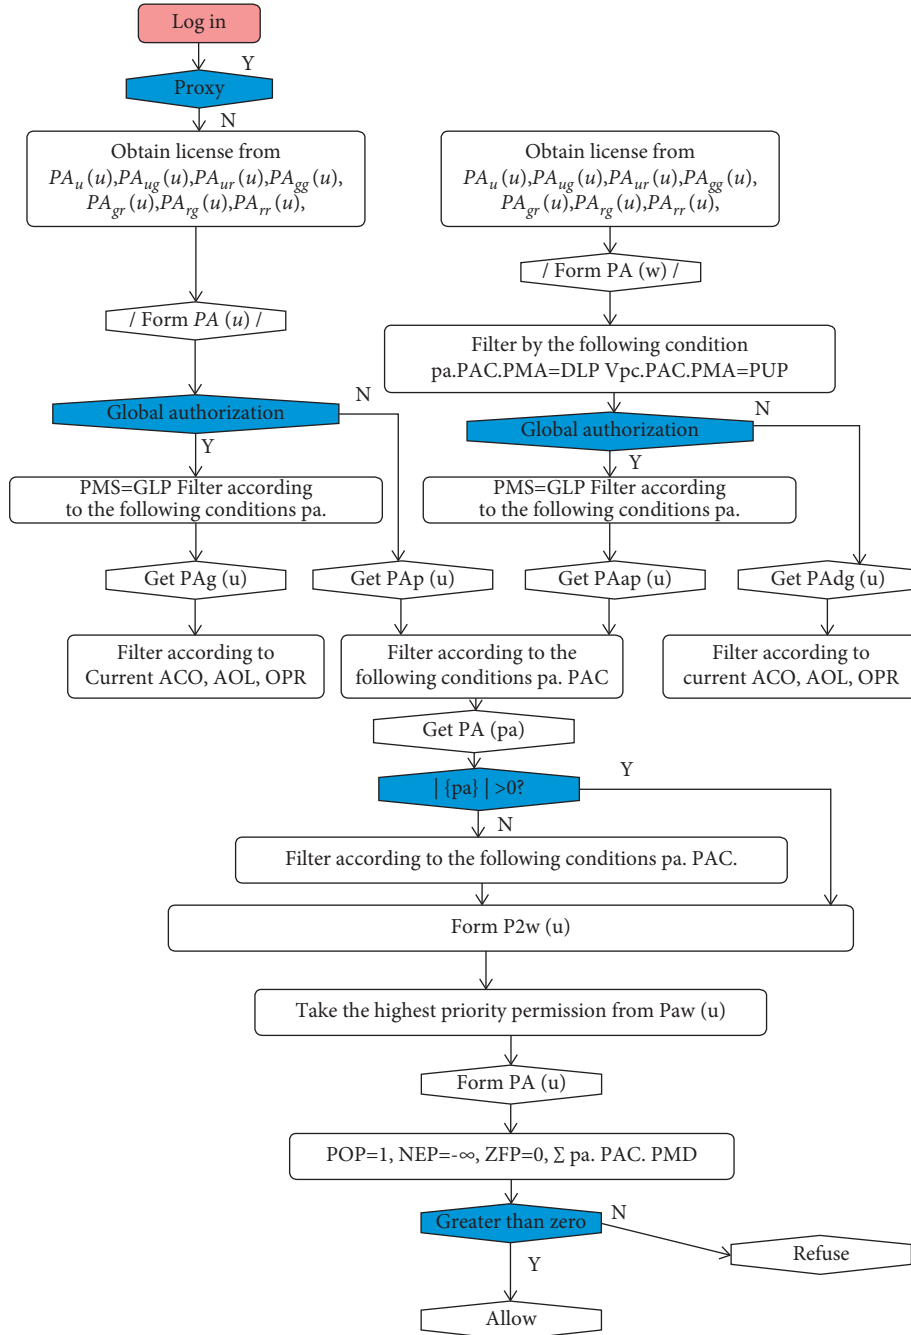
The 90-day continuous data is selected from the product lifecycle management platform for experiment. This data can


FIGURE 7: Multigranularity access control model MAC permission consistency control process.

be divided into two parts. As a training sample 76 days ago, the remaining 14 days were used as a test sample. According to the analysis of security data, deep attacks will be carried out regularly within 5 days. Therefore, this paper uses 5 days as the vector dimension input and 1 day as the vector dimension output. The selection of the dimension of the security situation is shown in Table 2. Confirm that the prediction model of MGACM Industry 4.0 engineering product structure is 5-11-1.

The magnitude difference in the value of the safety situation of Industry 4.0 engineering products will affect the education of Industry 4.0 engineering products. In order to

TABLE 2: Selection of security status dimensions.

Input sample	Output sample
X_1, X_2, X_3, X_4, X_5	X_6
X_2, X_3, X_4, X_5, X_6	X_7
...	...
$X_{71}, X_{72}, X_{73}, X_{74}, X_{75}$	X_{76}

avoid this phenomenon, the safety status values of Industry 4.0 engineering products within 90 days are standardized as follows:

$$\widehat{X} = \frac{(X - X_{\min})}{(X_{\max} - X_{\min})}. \tag{39}$$

This includes the minimum value of the sample and the maximum safety status value of the Industry 4.0 engineering product. X is the safety status value of the standardized Industry 4.0 engineering products successively.

Select the absolute error (AE), and define the mean relative error (MR) and mean square error (RMMSE) as the criterion for predicting accuracy.

$$AE = |Y_k - Y_k'|, \tag{40}$$

$$MRE = \frac{1}{N} \sum_{k=1}^{N} \left| \frac{Y_k - Y_k'}{Y_k} \right|, \tag{41}$$

$$RMSE = \sqrt{\frac{1}{N} \sum_{k=1}^{N} (Y_k - Y_k')^2}, \tag{42}$$

where N is the number of samples of the safety value of Industry 4.0 engineering products. It indicates the actual safety value of Industry 4.0 engineering products and displays the predicted value.

6. Results Analysis and Comparison

In order to prove the superiority of the proposed model, the MGACM, the performance of the multigranular access control model BP and that of the multigranular access control model MGACM are compared. Through the comprehensive training of these algorithms, we have selected convergence speed, diversity, and prediction accuracy to determine the advantages of these algorithms and verified the effectiveness of the proposed model.

In Figures 8 and 9, the horizontal axis represents the generation, and the vertical axis represents the squared error. It can be seen from this paper that different algorithms have different convergence speeds. The multigranularity access control model has the fastest convergence speed, converging to the 68th generation. The second high-speed algorithm is the multigranularity access control model PLM, which ended in the 118th generation. Multigranularity access control models BP and PLM stopped operating in the 139th and 359th generations, respectively, achieving convergence accuracy. Therefore, in this paper, we conclude that the combination of the modified small environment technology and the PLM model effectively reduces the convergence time and improves the prediction efficiency.

Therefore, this article attempts to increase product diversity to improve the premature problem of the multigranularity access control model. Equation (42) is the quantitative analysis of product diversity. It can be seen from Figure 9 that the diversity value of MGACM is stable in the early stage around 0.69. Comparing the classic and access control model, MGACM has great advantages in maintaining product diversity.
FIGURE 8: The convergence rate of the prediction model.
FIGURE 9: Convergence speed of PLM.

7. Conclusions

This paper proposes an MGACM security situation management model for Industry 4.0 engineering products, which uses an improved multigranularity access control model to optimize parameters. This management model combines an improved security situation analysis method with a multigranular access control model. Therefore, the new security situation analysis method has improved optimization capability and convergence speed of the multigranular access control model. In addition, the improvement of product diversity effectively solves the problems of premature and low convergence. The experiment proves the reliability and

validity of the multigranular access control model, which can also manage the security status of Industry 4.0 engineering products more accurately. Therefore, the multigranularity access control model MAC is suitable for large- and medium-sized enterprises, such as aviation and automobile enterprises, that have a wide variety of Industry 4.0 engineering products, complex structures, and strict access control.

Controlling collusion in government bidding is a prerequisite for ensuring social justice and the smooth operation of projects. Based on the prospect theory, this article establishes a four-party evolutionary game model for tenderers, enterprises with higher willingness to collude, enterprises with lower willingness to collude, and supervising enterprises. The study uses replication dynamics to analyze the stability of strategy selection after the evolutionary game. The results show that higher project base returns increase the probability of collusion, while lower market competition, higher risk aversion, and stronger collusive regulation all reduce the probability of collusion. When regulators adopt a strong regulatory strategy, the remaining project participants tend to choose a noncollusive strategy.

1. Introduction

Tendering is an effective way of acquiring and allocating resources developed over time in social and economic activities [1]. China's government investment projects primarily use bidding to determine the project builder. However, due to the asymmetry of information between the bidding parties, the trend of interests, and the imperfection of the restraint mechanism, the parties involved in the bidding process will produce collusion and other illegal and irregular behaviors to maximize their interests [2]. These behaviors will seriously affect the orderly development of China's construction market; therefore, it is of great theoretical and practical significance to control collusion in government investment projects' bidding processes.

The principal-agent theory and game theory are the main methods used by domestic scholars to analyze the engineering collusion phenomenon. Xie points out that although excessive competitive pressure in the construction market can induce collusion, its root cause is excessive returns and insufficient punishment [3]. According to Yu, information asymmetry caused by multiple entrustment relationships in

government-invested construction projects and the low cost of collusion are the main reasons for its emergence [4]. Cheng et al. argue that high profits in engineering projects' bidding processes are the leading cause of vertical collusion [5]. Miklos-Thal argues that collusion is possible without additional costs, but the presence of additional costs can facilitate its occurrence in cases of asymmetric collusion costs [6]. Through their investigation, Yun Chen et al. found that technical and environmental causes are more critical to creating vertical collusion [1].

Current research provides diverse solutions on control measures for collusion in bidding in government investment projects. For example, Wu et al. combined prospect theory and game theory to establish a collusion regulation deterrence model to regulate collusion in government investment projects [7]. Wang Xianjia et al. constructed a control model to prevent collusion between bidding agents and tenderers in the bidding process based on the "prisoner's dilemma" game [8]. Chen et al. used the cooperative game model to analyze the conditions of collusion and provide a reference for the policy formulation of collusion control [9]. Zhang and Wang constructed a two-sided game

model between owners and bid evaluation experts and established a control model to prevent collusion with bid evaluation experts [10].

The above literature review shows that although more scholars have researched vertical collusion in government investment project bidding, the research results have certain limitations due to the methods adopted, mainly focusing on game theory and principal-agent theory. The existing studies focus less on each participant's risk attitude and propensity on a behavioral decision. For simplification, the existing game models on the game behavior research process of vertical collusion process usually consider only two-party or three-party games, which cannot entirely reflect the actual situation [11–21]. In the bidding process of government investment projects, each participant shows different degrees of risk awareness and risk appetite due to different risk management behaviors in the face of complex and variable risk factors. The dynamic formation process of owners' and contractors' risk management behaviors can be seen as the process of both parties adjusting their strategies to form a final stable strategy through trial and error, summarization, and imitation. These methods are consistent with the characteristics of evolutionary games and can be analyzed by evolutionary game theory. This study helps each participant in the bidding process of government investment projects make reasonable risk management decisions by examining each participant's evolutionary behavior in the bidding process of government investment projects. The value function of prospect theory is introduced into the evolutionary game theory, based on the consideration of different collusion tendencies. The risk-benefit perception matrix is constructed to analyze the evolutionary process and inner law of the decision-making behaviors of bidding parties, subjects with high collusion tendencies, subjects with low collusion tendencies, and regulators. Based on MATLAB simulation, the influence of relevant factors on the evolutionary results is analyzed. Therefore, this article introduces prospect theory based on the original evolutionary game approach to analyze collusion in the bidding process. This article divides the bidders into high collusion willingness bidders and low collusion willingness bidders for analysis so that the model is more suitable to the actual situation.

The innovations of this paper are mainly in two ways:

(1) Most of the existing studies related to evolutionary games use two-party or three-party games, regardless of the topic and context of the paper's research. This study considers the game behaviour of four parties in the process of vertical collusive control of government investment project bidding. It has certain contribution in the model approach and broadens the existing research ideas and research perspectives.

(2) In the current research on vertical collusion in bidding for government investment projects in China, most of the parameters for the benefits and costs of each entity are set only considering the impact of penalties such as fines and penalties. Less consideration has been given to social recognition and the possible impact on future development

gains. The study introduces indicators such as the degree of market competition and loss of social recognition to provide an in-depth analysis of the benefits and costs of each subject. By diversifying the parameter model and introducing more detailed considerations, the results of the study are more relevant and reliable.

2. Simulation Model Construction

2.1. Simulation Analysis Model for the Evolution of Collusive Bidding Behavior. Vertical collusion is repeatedly prohibited in the bidding process of government investment projects. Existing studies usually view bidders as a whole, and they are considered to have a high degree of similarity in their behavior. However, in practice, different bid groups have different perceptions of factors such as potential benefits, penalties, and the probability of detection of vertical collusion, as well as large differences in the business philosophies of different companies. Even under the same external conditions, there are significant gaps in decision making between different bid groups. Therefore, this article divides bidders into two groups, high and low, according to their willingness to participate in collusion to improve the study's credibility. Bidders with high collusion willingness will actively seek collusion opportunities and promote collusive behavior. Firms with low collusion willingness are less likely to collude when faced with opportunities, and at the same time, may report collusive behavior.

In this study's evolutionary game-theoretical model, there are four game subjects: bidders, enterprises with a high willingness to collude, enterprises with a low willingness to collude, and regulators. The four parties influence each other in the bidding process. Some enterprises may choose to collude with the government to obtain a project, adopting forms such as bid-rigging and bid-rigging to obtain excessive profits; the regulator (including the regulator and the people) accepts the government's commission or spontaneously carries out supervision of the project. The government entrusts the regulators (including the regulator and the people), or they spontaneously supervise the project; the regulators' management also has a certain influence on the behavior of the government and enterprises. This article focuses on the vertical collusion in the bidding process of government investment projects. In government investment projects, the government side is the bidding side. In the bidding process, there is a bidding side to release the project; enterprises obtain the project by bidding. However, the bidding process involves inconsistency of different enterprises' business philosophies and decision-making tendencies. As such, enterprises with higher willingness to collude and those with lower willingness to collude will have a higher possibility of providing benefits to the bidders and seeking the opportunity to collude to obtain the project. Companies with a lower willingness to collude will not actively seek opportunities for collusion and will monitor and report any collusion found. Bidders, companies with a high willingness to collude, and companies with a low willingness to collude are all subject to the regulator's supervision. Due to the

incomplete symmetry of information and the imperfect rationality of the government and the parties involved in the game, all parties involved may act opportunistically in the project's construction process, making it impossible for all parties to obtain maximum utility. Figure 1 shows the relationship between the various interest subjects in the bidding process.

2.2. Model Assumptions

Assumption 1. The four main players in the game are the bidders, enterprises with higher willingness to collude, enterprises with lower willingness to collude, and the regulator. In the bidding process, the bidders prefer enterprises involved in collusion as the winning bidders. The colluding enterprises must pay a certain extra cost while fulfilling the contract conditions. The regulators monitor the enterprises involved in bidding to reduce corruption and collusion in the project. The enterprises not involved in collusion have a certain probability of reporting parties involved in collusion to ensure their rights and interests.

Assumption 2. In the project bidding process, all stakeholders are finite rational "economic agents," i.e., the parties involved in the project are not fully rational. In the game process, all four parties play a limited number of repeated games.

Assumption 3. Traditional evolutionary games are based on expected utility theory. They do not consider the influence of the various project participants in the decision-making process on the game's outcome due to psychological perception factors. This article addresses the problem by using the prospect theory proposed by Kahneman et al. to modify decision-makers' inconsistent risk preference behavior. The theory states that one cannot have an absolute perception of losses and gains but rather a relative value of perceived losses, expressed using $\Delta\omega 1$, the difference between the actual loss or gain $\omega 1$ and a reference point $\omega 0$. This reference point is subject to the influence of the decision-maker and is chosen differently across research areas. This paper chooses 0 as the reference point. In prospect theory, the expected total utility of a decision is measured using the value function $v(\Delta\omega 1)$ and the weighting function p. The prospect value is

$$V = \sum_{\iota} \pi(p\iota)v(\Delta\omega\iota). \tag{1}$$

Each participating subject makes a judgment on its next move based on its perceived value of the lost gain, and the value function is

$$V(\Delta\omega_i) = \begin{cases} (\Delta\omega_i)^\theta, & \Delta\omega_i \geq 0, \\ -\lambda(-\Delta\omega_i)^\theta & \Delta\omega_i < 0, \end{cases} \tag{2}$$

where θ is the risk attitude coefficient, indicating the game subject's marginal degree of diminishing perceived value of profit and loss. λ is the loss avoidance coefficient, indicating

Figure 1: Four-way diagram of the game.

the game subject's sensitivity to loss; the larger the value, the greater the game subject's sensitivity to loss. At the same time, the game subject judges the weights according to the actual situation of the event, using the formula:

$$\pi(p_i) = \frac{p^\gamma}{(p^\gamma + (1-p)^\gamma)^{1/\gamma}}. \tag{3}$$

Except for minimal probability events, $\pi(p_i) < p_i$, $\pi(p_i) + \pi(1-p_i) \leq 1$ and $\pi(1) = 1$, $\pi(0) = 0$. In prospect theory, the probability of a low-probability event occurring is usually overestimated, and the probability of a high-probability event occurring is usually underestimated.

Assumption 4. The government has two strategies based on its interests and overall interests: participating in government-enterprise collusion or not participating in government-enterprise collusion. Similarly, enterprises with a high willingness to collude have two strategies: to participate in collusion actively or not actively participating in collusion. Enterprises with a low willingness to collude can either report collusion or not. Regulators also have two strategies: to strongly or weakly regulate collusion. A tenderer's probability of adopting a government-enterprise collusion strategy is x. The probability of a firm with a high collusion willingness implementing an active collusion strategy is y, the probability of a company with a low willingness to collude adopting a reporting collusion strategy is z, and the probability of a regulator adopting a strong regulatory model is m ($0 \leq x \leq 1$, $0 \leq y \leq 1$, $0 \leq z \leq 1$, $0 \leq m \leq 1$). Thus, the tenderer's probability of not participating in government-business collusion is $1 - x$. The probability of companies with high willingness to collude of not actively participating in collusion is $1 - y$, the probability of companies with low willingness to collude of not reporting collusion is $1 - z$, and the probability of regulators adopting the weak regulatory model is $1 - m$.

Assumption 5. The government's choice to engage in collusion means that, in the bidding process, it will give preference to a company willing to collude as the winning

bidder; if it chooses not to collude, the government will choose the best company as the winning bidder. Selecting a company with a high willingness to collude means that the company will actively seek collusion plans from the authorities, including bribes, etc., to obtain the project. Choosing not to participate in collusion actively means that, although the enterprise is willing to collude, it does not want to pay extra for collusion. Enterprises with a low willingness to collude that choose to report collusion indicate that this type of enterprise will inevitably report any discovered act for higher authorities to handle. The regulator's choice of a strong regulatory model for collusion can be costly, but collusion will be detected in all regulated projects. The choice of a weak regulatory model means that collusion in regulated projects will potentially go unnoticed.

2.3. Parameter Setting and Model Construction.

Suppose the government chooses to participate in the collusion with an enterprise. In that case, it will receive the social benefits of completing the project. However, it still has to bear the loss R_1 for the nonconformity of the capacity of the vertically colluding enterprise, with a probability of α. The probability of society discovering the collusion is β, and the loss of S_1 (including market distortion and the collusion will cause loss of trust, etc.). The government will receive the basic benefits of the completed project F regardless of whether it is involved in collusion. Still, because no corrupt practices occur during the project bidding process, the sociopolitical climate will increase along with people's trust in the government, with a gain of F_2.

The probability that a firm with a higher willingness to collude will choose to participate in the collusion strategy is β. The project's supply affects the probability that a firm with a higher willingness to collude will choose the collusion strategy. The degree of market competition affects SS, the more intense the competition, the higher the probability of choosing collusion and the higher SS. Suppose firms with a higher willingness to collude decide not to participate in collusion. In that case, the probability of their bid actively is reduced to R_3 while simultaneously reducing the possibility of firm expansion, bringing a loss of S_5.

A firm with a low willingness to collude chooses the strategy of reporting on collusion, in which case the gain is 0; there is a risk of resistance from the government and colluding firms, bringing a loss of S_6, but increased social recognition represented by F_4. The probability of the report being discovered by the government and colluding firms is D; choosing not to report on collusion yields an additional gain of F_5.

The supervising enterprise gains F_6 regardless of which model it chooses. Choosing to select a strong supervision model brings an increase in recognition, represented by F_7, but may be subject to hostility from the regulators involved in the collusion, bringing losses of S_6. Suppose the supervising enterprise does not collude with the enterprise and the bidder in the strong supervision model, choosing the weak supervision model gives a fixed gain of F_6, while there is a probability of G that the enterprise will choose to collude with the contractor. The firm has a G probability colluding with the offerer, which provides an additional F_7 gain (including the potential gain from more opportunities for cooperation between the offerer and the firm) and a D probability of being discovered, resulting in an S_7 loss.

The parameters and their explanations are shown in Table 1.

According to prospect theory, the decision-making group develops perceived utility when facing uncertain costs and benefits. This article assumes that the cost of expenditure and the legitimate monetized benefit obtained are deterministic. The remaining parameters are related to subjective perceptions, calculated using foreground values. Table 2 shows the payoff matrix of the bidding collusion evolution game.

2.4. Model Solution.

The steps for solving the model are shown in Figure 2.

According to Table 1, the prospective expectations and mean expectations for the bidders' sector to adopt the "engage in collusion" and "do not engage in collusion" strategies are

$$
\begin{aligned}
E_{11} = {} & y * z * m * \left(V(F) + \alpha * R_1 - \beta * V(S_1)\right) + (1 - y) * z * m * \left(V(F) + \alpha * R_1 - \beta * V(S_1)\right) + \\
& y * (1 - z) * m * \left(V(F) + \alpha * R_1 - \beta * V(S_1)\right) + y * z * (1 - m) * \left(V(F) + \alpha * R_1 - \beta * V(S_1)\right) + \\
& (1 - y) * (1 - z) * m * \left(V(F) + \alpha * R_1 - \beta * V(S_1)\right) + y * (1 - z) * (1 - m) * \left(V(F) + \alpha * R_1 - \beta * V(S_1)\right) \\
& + (1 - y) * (1 - z) * (1 - m) * \left(V(F) + \alpha * R_1 - \beta * V(S_1)\right), \\
E_{12} = {} & y * z * m * \left(V(F) + V(F_2)\right) + (1 - y) * z * m * \left(V(F) + V(F_2)\right) + \\

Figure 2: Calculation logic table.

The prospective expectations and mean expectations of firms with a high willingness to collude for "active collusion" and "inactive collusion" strategies are

$$
\begin{aligned}
E_{21} = {} & x * z * m * \left(E * \mathrm{SS} * V\left(F_3\right) - S_3 - \beta * S_4 + S_2\right) + (1 - x) * z * m * \left(E * \mathrm{SS} * \left(V\left(F_3\right) - S_3 - \beta * S_4\right) + \right. \\
& x * (1 - z) * m * \left(E * \mathrm{SS} * \left(V\left(F_3\right) - S_3 - \beta * S_4 + S_2\right) + x * z * (1 - m) * \left(E * \mathrm{SS} * V\left(F_3\right) - S_3 - \beta * S_4 + S_2\right) \right. \\
& + (1 - x) * (1 - z) * m * \left(E * \mathrm{SS} * V\left(F_3\right) - S_3 - \beta * S_4 + S_2\right) + \\
& (1 - x) * z * (1 - m) * \left(E * \mathrm{SS} * V\left(F_3\right) - S_3 - \beta * S_4 + S_2\right) + \\
& (1 - x) * (1 - z) * (1 - m) * \left(E * \mathrm{SS} * V\left(F_3\right) - S_3 - \beta * S_4 + S_2\right), \\
E_{22} = {} & x * z * m * \left(R_3 * S_2 + S_5\right) + (1 - x) * z * m * \left(R_3 * S_2 + S_5\right) + x * (1 - z) * m * \left(R_3 * S_2 + S_5\right) \\
& + x * z * (1 - m) * \left(R_3 * S_2 + S_5\right) + (1 - x) * (1 - z) * m * \left(R_3 * S_2 + S_5\right) \\
& + (1 - x) * z * (1 - m) * \left(R_3 * S_2 + S_5\right) + x * (1 - z) * (1 - m) * \left(R_3 * S_2 + S_5\right), \\
\overline{E}_{23} = {} & y * E_{21} - (1 - y) * E_{22}.
\end{aligned}
\tag{5}
$$

The prospective expectations and mean expectations of firms with low collusion intentions adopting the "report collusion" and "do not report collusion" strategies are

$$
\begin{aligned}
E_{31} = {} & x * y * m * \left(V\left(F_4\right) - D * S_6\right) + (1 - x) * y * m * \left(V\left(F_4\right) - D * S_6\right) + \\
& x * (1 - y) * m * \left(V\left(F_4\right) - D * S_6\right) + x * y * (1 - m) * \left(V\left(F_4\right) - D * S_6\right) + (1 - x) * (1 - y) * m * F_5 \\
& + (1 - x) * y * (1 - m) * \left(V\left(F_4\right) - D * S_6\right) + (1 - y) * (1 - m) * \left(V\left(F_4\right) - D * S_6\right)
\end{aligned}
$$

$$+ (1 - x) * (1 - y) * (1 - m) * (V(F_4) - D * S_6),$$

$$E_{32} = x * y * m * F_5 + (1 - x) * y * m * F_5 + x * (1 - y) * m * F_5 + x * z * (1 - m) * F_5$$
$$+ (1 - x) * (1 - y) * m * F_5 + x * (1 - y) * (1 - m) * F_5 + (1 - x) * (1 - y) * z * F_5 +$$
$$(1 - x) * (1 - y) * (1 - m) * F_5,$$

$$\overline{E}_{33} = z * E_{31} - (1 - z) * E_{32}.$$

(6)

The regulators' prospective expectations and mean expectations for a "strong regulatory model" and a "weak regulatory model" strategy are

$$E_{41} = x * y * z * (F_6 + V(F_7) - V(S_6)) + (1 - x) * y * z * (F6 + V(F_7) - V(S_6)) +$$
$$x * (1 - y) * z * (F_6 + V(F_7) - V(S_6)) + x * y * (1 - z) * (F_6 + V(F_7) - V(S_6))$$
$$+ (1 - x) * (1 - y) * z * (F_6 + V(F_7) - V(S_6)) +$$
$$(1 - x) * y * (1 - z) * (F_6 + V(F_7) - V(S_6))$$
$$+ x * (1 - y) * (1 - z) * (F_6 + V(F_7) - V(S_6)) +$$
$$(1 - x) * (1 - y) * (1 - z) * (F_6 + V(F_7) - V(S_6)),$$

$$E_{42} = x * y * z * (F_6 + V(F_7) - V(S_6) + G * V(F_7) - D * V(S_7) +$$
$$(1 - x) * y * z * (F_6 + V(F_7) - V(S_6) + G * V(F_7) - D * V(S_7)$$
$$+ x * (1 - y) * z * F_6 + x * y * (1 - z) * (F_6 + V(F_7) - V(S_6) + G * V(F_7) - D * V(S_7)$$
$$+ (1 - x) * (1 - y) * z * (F_6 + V(F_7) - V(S_6) + G * V(F_7) - D * V(S_7)$$
$$+ (1 - x) * y * (1 - z) * (F6 + V(F_7) - V(S_6) + G * V(F_7) - D * V(S_7) +$$
$$x * (1 - y) * (1 - z) * (F_6 + V(F_7) - V(S_6) + G * V(F_7) - D * V(S_7)$$
$$+ (1 - x) * (1 - y) * (1 - z) * (F_6 + V(F_7) - V(S_6) + G * V(F_7) - D * V(S_7),$$

$$\overline{E}_{43} = m * E_{41} - (1 - m) * E_{42}.$$

(7)

The replicated dynamic differential equation for the choice of an active strategy by bidders, high collusion willing firms, low collusion willing firms, and regulators can be expressed as

$$F(X) = \frac{dx}{dt} = x * (E_{11} - \overline{E}_{13}) = x * (1 - x) * (E_{11} + E_{12}) =$$

$$x * (1 - x) * (y * z * m (2V(F) + \alpha R_1 + V(F_2) - \beta V(S_1)) + (1 - z) * (2V(F) + \alpha R_1 + V(F_2) - \beta V(S_1))$$

$$+ z * m * (2V(F) + \alpha R_1 + V(F_2) - \beta V(S_1)) + y * z * (2V(F) + \alpha R_1 + V(F_2) - \beta V(S_1)),$$

$$F(Y) = \frac{dy}{dt} = y * (E_{21} - \overline{E}_{23}) = y * (1 - y) * (E_{21} + E_{22}) =$$

$$= y * (1 - y) * (z * x * m * (E * SS * V(F_3) - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5 - S_2)$$

$$+ (1 - z) * (E * SS * V(F_3) - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5 - S_2)$$

$$+ z * m * (SS * V(F_3) - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5)$$

$$+ x * z * (SS * V(F_3) - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5),$$

$$F(Z) = \frac{dz}{dt} = z * \left(E_{31} - \bar{E}_{33}\right) = z * (1 - z) * (E_{31} + E_{32}) =$$

$$= z * (1 - z) * (x * y * m * (V(F_4) - D * V(S_6) + F_5) + (1 - y) * (V(F_4) - D * V(S_6) + F_5)$$

$$+ (1 - y) * m * (V(F_4) - D * V(S_6) + F_5) + x * y * (V(F_4) - D * V(S_6) + F_5)),$$

$$F(M) = \frac{dm}{dt} = m * \left(E_{41} - \bar{E}_{43}\right) = m * (1 - m) * (E_{41} + E_{42}) = \tag{8}$$

$$= m * (1 - m) * (x * y * z * (2F_6 + 2V(F_7) - V(S_6) + G * V(F_7) - D * S_7)$$

$$+ (1 - y) * (2F_6 + 2V(F_7) - V(S_6) + G * V(F_7) - D * S_7)$$

$$+ y * z * (2F_6 + 2V(F_7) - V(S_6) + G * V(F_7) - D * S_7)$$

$$+ x * y * (2F_6 + 2V(F_7) - V(S_6) + G * V(F_7) - D * S_7)).$$

When the government party's probability of engaging in collusion is 1, the government party receives a base benefit of F. The prospective value of F is

$$V(F) = \pi(1) * V(F) = F^\theta. \tag{9}$$

When collusion is discovered, a loss of S_1 is obtained, and the prospective value of S_1 is

$$V(S_1) = \pi(1) * V(-S_1) = -\lambda S_1^\theta. \tag{10}$$

Similarly, the foreground values of F2, F3, F4, S6, and F7 can be obtained.

The positive strategy dynamic game equation of quadrilateral game can be obtained by substituting the prospect value:

$$F(X) = \frac{dx}{dt} = x * \left(E_{11} - \bar{E}_{13}\right) = x * (1 - x) * (E_{11} + E_{12})$$

$$= x * (1 - x) * \left(y * z * m\left(2F^\theta + \alpha R_1 + F_2^\theta + \lambda \beta S_1^\theta\right) + (1 - z) * \left(2F^\theta + \alpha R_1 + F_2^\theta + \lambda \beta S_1^\theta\right) +$$

$$z * m * \left(2F^\theta + \alpha R_1 + F_2^\theta + \lambda \beta S_1^\theta\right) + y * z * \left(2F^\theta + \alpha R_1 + F_2^\theta + \lambda \beta S_1^\theta\right)),$$

$$F(Y) = \frac{dy}{dt} = y * \left(E_{21} - \bar{E}_{23}\right) = y * (1 - y) * (E_{21} + E_{22}) =$$

$$= y * (1 - y) * \left(z * x * m * \left(E * SS * F_3^\theta - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5 - S_2\right) +$$

$$+ (1 - z) * \left(E * SS * F_3^\theta - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5 - S_2\right)$$

$$+ z * m * \left(SS * F_3^\theta - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5\right) + x * z * \left(SS * F_3^\theta - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5\right),$$

$$F(Z) = \frac{dz}{dt} = z * \left(E_{31} - \bar{E}_{33}\right) = z * (1 - z) * (E_{31} + E_{32}) = \tag{11}$$

$$= z * (1 - z) * \left(x * y * m * \left(F_4^\theta + \lambda\, D * S_6^\theta + F5\right) + (1 - y) * \left(F_4^\theta + \lambda\, D * S_6^\theta + F_5\right)$$

$$+ (1 - y) * m * \left(F_4^\theta + \lambda\, D * S_6^\theta + F_5\right) + x * y * \left(F_4^\theta + \lambda\, D * S_6^\theta + F_5\right),$$

$$F(M) = \frac{dm}{dt} = m * \left(E_{41} - \bar{E}^-_{43}\right) = m * (1 - m) * (E_{41} + E_{42}) =$$

$$= m * (1 - m) * \left(x * y * z * \left(2F_6 + 2F_7^\theta + \lambda S_6^\theta + G * F_7^\theta - D * S_7\right)\right.$$

$$+ (1 - y) * \left(2F_6 + 2F_7^\theta + \lambda S_6^\theta - D * S_7\right)$$

$$+ y * z * \left(2F_6 + 2F_7^\theta + \lambda S_6^\theta + G * F_7^\theta - D * S_7\right) + x * y * \left(2F_6 + 2F_7^\theta + \lambda S_6^\theta + G * F_7^\theta - D * S_7\right).$$

3. Equilibrium Analysis of the Four-Party Game in Transportation Infrastructure Project Operation

3.1. Game Player Unilateral Stability Strategy

3.1.1. Analysis of the Tenderer's Strategic Stability.
Let $F(X) = 0$ and solve for $x = 0$, $x = 1$, $y = (z - 1) - z * m/z * (m + 1) = Y^*$. It follows from the stability theorem for replicating dynamic differential equations that $F(y) = 0$, $\partial F(x)/\partial x < 0$, x is an evolutionary stabilization strategy. Since the range of values of z, m is [0, 1], in this article $Y* \leq 0$. Thus, there are only two cases, $y = Y*$ and $y > Y*$.

When $y = Y*$, $F(X) = 0$ is constantly established, and the stability point is $x = 0$, $x = 1$. Any value of x is a steady-state,

i.e., the strategy of the construction unit does not change over time.

When $y > Y*$, $F(X) = 0$ is constantly established, and $\begin{cases} \partial F(x)/\partial x > 0, x = 0 \\ \partial F(x)/\partial x < 0, x = 1 \end{cases}$ is established. The stability point is $y = 0$, and any value of x is steady-state, indicating that the perceived costs of the positive pole strategy outweigh the benefits for the bidders, who prefer to bear the penalty of uncertainty rather than investing more.

The bidders' replicated dynamic phase diagram is shown in Figure 3.

3.1.2. Analysis of the Progressive Stability of Firms with a High Willingness to Collude.
Let $F(Y) = 0$ and solve for $y = 0$, $y = 1$,

$$z = -\frac{E * SS * F_3^\theta - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5 - S_2}{x * m * \left(E * SS * F_3^\theta - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5 - S_2\right) - \left(E * SS * F_3^\theta - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5 - S_2\right) +} = Z^*. \tag{12}$$
$$m * \left(SS * V\left(F_3\right) - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5\right) + x * \left(SS * F_3^\theta - S_3 - \beta * S_4 + S_2 + R_3 * S_2 + S_5\right)$$

It follows from the stability theorem for replicating dynamic differential equations that $F(y) = 0$, $\partial F(y)/\partial y < 0$, x is an evolutionary stabilization strategy.

When $z = Z*$, $F(y) = 0$ is constantly established. The stability point is $y = 0$, $y = 1$, and any value of y is steady-state. The high collusion unit's strategy does not change over time.

When $z < Z*$, $F(y) = 0$ is constantly established, and $\begin{cases} \partial F(y)/\partial y > 0, y = 0 \\ \partial F(y)/\partial y < 0, y = 1 \end{cases}$ is established. The stability point is $y = 1$, and any value of x is steady-state. This suggests that parties with a high willingness to collude perceive the benefits of an aggressive strategy outweigh the costs. The benefits include a variety of gains. As shown by prospect theory, game subjects are usually reluctant to take losses when faced with gains, and parties with a high willingness to collude tend to adopt collusive strategies.

When $z > Z*$, $F(y) = 0$ is constantly established, and $\begin{cases} \partial F(y)/\partial y > 0, y = 0 \\ \partial F(y)/\partial y < 0, y = 1 \end{cases}$ is established. The stability point is $y = 0$, and any value of x is steady-state, indicating that the penalties and losses received by the building operator in providing low-quality services are less than the gains under this strategy. In this case, the building operator tends to choose a speculative strategy to obtain higher returns. The party willing to collude replicates the dynamic phase diagram, as shown in Figure 4.

3.1.3. Analysis of the Progressive Stability of Firms with a Low Willingness to Collude.
Let $F(Z) = 0$ and solve for $z = 0$, $z = 1$, $m = \lambda Y_1^\theta - \lambda Y_2^\theta + y/y - 1 = M^*$. It follows from the stability theorem for replicating dynamic differential equations that

$F(z) = 0$, $\partial F(z)/\partial z < 0$, z is an evolutionary stabilization strategy.

When $m = M*$, $F(Z) = 0$ is constantly established. The stability point is $z = 0$, $z = 1$, and any value of z is steady-state. The strategy of the low collusion unit does not change over time.

When $m < M*$, $F(Z) = 0$ is constantly established, and $\begin{cases} \partial F(z)/\partial z > 0, z = 0 \\ \partial F(z)/\partial z < 0, z = 1 \end{cases}$ is established. The stability point is $z = 1$, and any value of z is steady-state, suggesting that, for the low colluder, the perceived benefits of adopting an aggressive strategy outweigh the costs. In this case, the low colluding party tends to adopt a strategy of reporting the collusion.

When $z > Z*$, $F(Z) = 0$ is constantly established, and $\begin{cases} \partial F(z)/\partial z > 0, z = 0 \\ \partial F(z)/\partial z < 0, z = 1 \end{cases}$ is established. The stability point is $z = 0$, and any value of z is steady-state, suggesting that users have greater benefits from adopting nonreporting collusion. The low collusion willingness side tends to be associated with a nonreporting strategy. The low collusion willingness side replicates the dynamic phase diagram, as shown in Figure 5.

3.1.4. Progressive Stability Analysis of Regulators.
Let $F(M) = 0$ and solve for $m = 0$, $m = 1$, $x = (y - 1 + yz - ((1 - y)G * F_7^\theta)/(2F_6 + 2F_7 + \lambda S_6 + G * F_7 - D * S_7)/(yz + y)) = X^*$. It follows from the stability theorem for replicating dynamic differential equations that $F(m) = 0$, $\partial F(m)/\partial m < 0$, m is an evolutionary stabilization strategy.

When $x = X*$, $F(M) = 0$ is constantly established. The stability point is $m = 0$, $m = 1$, and any value of m is
Figure 3: Tenderer replicates dynamic phase diagram.

Figure 4: High collusion replicates dynamic phase diagram.

Figure 5: Low collusion replicates dynamic phase diagram.

steady-state. The strategy of the low collusion unit does not change over time.

When $x < X*$, $F(M) = 0$ is constantly established, and $\begin{cases} \partial F(m)/\partial m > 0, m = 0 \\ \partial F(m)/\partial m < 0, m = 1 \end{cases}$ is established. The stability point is $m = 1$, and any value of m is steady-state, suggesting that the supervisory authority's perceived benefits outweigh the costs of an active strategy. In such cases, regulators tend to adopt strong regulatory measures against collusive behavior.

When $x > X*$, $F(M) = 0$ is constantly established, and $\begin{cases} \partial F(m)/\partial m > 0, m = 0 \\ \partial F(m)/\partial m < 0, m = 1 \end{cases}$ is established. The stability point is $m = 0$, and any value of m is a steady-state, suggesting a greater gain for the regulators in adopting a weak regulatory

strategy. In this case, there is a greater probability that the regulators will forgo regulation and choose not to regulate collusion. See Figure 6 for a phase diagram of regulator replication dynamics.

3.2. Strategy Portfolio Stability Analysis. Let $F(x) = F(y) = F(z) = F(m) = 0$. The equilibrium points can be obtained as follows: $E_1 (0, 0, 0, 0)$, $E_2 (1, 0, 0, 0)$, $E_3 (0, 1, 0, 0)$, $E_4 (0, 0, 1, 0)$, $E_5 (0, 0, 0, 1)$, $E_6 (1, 1, 0, 0)$, $E_7 (1, 0, 1, 0)$, $E_8 (1, 0, 0, 1)$, $E_9 (0, 1, 1, 0)$, $E_{10} (0, 1, 0, 1)$, $E_{11} (0, 0, 1, 1)$, $E_{12} (1, 1, 1, 0)$, $E_{13} (1, 1, 0, 1)$, $E_{14} (1, 0, 1, 1)$, $E_{15} (0, 1, 1, 1)$, $E_{16} (1, 1, 1, 1)$, $E_{17} (x^*, y^*, z^*, m^*)$; E_{17} is the mixed strategy equilibrium point. Suppose the equilibrium point in the three-way evolutionary game is ESS. In that case, it must be
FIGURE 6: Regulators collusion replicates dynamic phase diagram.

satisfied that the equilibrium point is a pure strategy equilibrium, and therefore only the asymptotic stability of E_1 to E_{16} needs to be discussed. The asymptotic stability of the system can be obtained from the analysis of the Jacobian matrix, as proposed by Friedman:

$$ J = \begin{bmatrix} \dfrac{\partial F(x)}{\partial x} & \dfrac{\partial F(x)}{\partial y} & \dfrac{\partial F(x)}{\partial z} & \dfrac{\partial F(x)}{\partial m} \\[2ex] \dfrac{\partial F(y)}{\partial x} & \dfrac{\partial F(y)}{\partial y} & \dfrac{\partial F(y)}{\partial z} & \dfrac{\partial F(y)}{\partial m} \\[2ex] \dfrac{\partial F(z)}{\partial x} & \dfrac{\partial F(z)}{\partial y} & \dfrac{\partial F(z)}{\partial z} & \dfrac{\partial F(z)}{\partial m} \\[2ex] \dfrac{\partial F(m)}{\partial x} & \dfrac{\partial F(m)}{\partial y} & \dfrac{\partial F(m)}{\partial z} & \dfrac{\partial F(m)}{\partial m} \end{bmatrix}. \tag{13} $$

Each of the 16 equilibrium points is substituted into the Jacobian matrix. If the eigenvalues of the corresponding matrix are all negative, the equilibrium point is the system's ESS. The stability of each point is shown in Table 3.

The calculations reveal that this article should analyze the game's stabilization strategy in two scenarios.

Scenario 1: for all parties, the benefits of collusion are greater than the potential costs. In this case, M_2, M_3, $M_{5,}$ and M_6 are all greater than 0. In the game process, the benefits of the collusion process are greater than the costs incurred by the bidding parties, including direct costs, reputational losses, and potential expansion. In this case, the table shows that $E_{16}(1, 1, 1, 1)$ is the equilibrium point, and that the evolving equilibrium strategies are: engage in collusion, active participation in the collusion, report the collusion, weak regulatory model.

Scenario 2: the benefits of collusion are less than the potential costs for all parties. In this scenario, M_2, M_3, $M_{5,}$ and M_6 are all less than 0. In the game, the benefits of collusion to the bidding parties are greater than their costs, including direct costs, reputational damage, and potential expansion. Table 4 shows that there is no stable equilibrium in this case.

4. Analysis of Simulations

4.1. Initial Parameters Setting.
The model is assigned according to the real situation, and numerical simulation is carried out using Matlab 2020b. These choices intuitively demonstrate the influence of key factors on the evolutionary process and results of the multiparty game in the government project bidding process and verify the validity of the evolutionary stability analysis. The studied behavior is vertical collusion in the bidding process of government investment projects. As such, all parties are bound by relevant laws and regulations and hidden costs, and they tend to choose negative strategies at the beginning of the period. The probability of choosing positive strategies is less than 0.5. The probability of choosing the positive strategy is even lower due to the fear of loss and retaliation for reporting vertical collusion. According to the actual situation and this paper's assumptions, x, y, z, and m are set as 0.4, 0.3, 0.2, and 0.3, respectively, see Table 5.

4.2. Single-Factor Sensitivity Analysis

4.2.1. Impact of Changes in the Social Benefits of Project Completion Base.
When $F = \{12, 18, 24, 30\}$, the process and results of the evolution of the thematic strategy of the quadratic game are shown in Figure 7.

As seen in Figure 6, the increase in project completion benefits as the bidders collude impacts each of the four-party's evolutionary strategies. The more obvious change is for the bidders. With the increase of the social base gain, the probability of the bidders to adopt the collusion strategy shows an increase in the magnitude of the change, and the speed of evolution to a stable strategy becomes faster. However, the reduction of social base revenue can only reduce the occurrence of collusion in the short term and delay the evolution to a stable point. Still, it cannot control the occurrence of collusion.

4.2.2. Impact of Changes in Risk Attitude Factor.
When $\theta = \{0.8, 0.5, 0.3, 0.2\}$, the process and results of the evolution of the thematic strategy of the quadratic game are shown in Figure 8.

As shown in Figure 8, as the risk attitude increases, the probability of choosing collusion-related strategies decreases for each project participant. In the four-party game, with the change of risk attitude, the strategy change is more evident in the evolution trend of the bidding party and the party with high collusion willingness. As the risk attitude decreases, we find that the remaining conditions are unchanged. The initial degree of influence regarding the change in risk attitude on the parties' choice is greater than the social base gain. However, the change in risk attitude does not change each group's final choice. Only at the initial stage can the probability of collusive behavior be reduced between the bidding party and the party with high collusion willingness.

4.2.3. Impact of Changes in the Level of Competition in the Market. When $\mathrm{SS} = \{0.5, 0.75, 1, 1.25\}$, the process and results of the evolution of the thematic strategy of the quadratic game are shown in Figure 9.

As shown in Figure 9, the initial probability of bidders and parties with a high willingness to collude to choose collusion strategies also decreases as the degree of market competition continues to decline. However, the tenderers' willingness to collude decreases less in the initial period when the degree of market competition decreases. It decreases more sharply only after maintaining a smaller degree of market competition. However, a decrease in the degree of market competition does not affect each participant's final evolutionary outcome.

4.2.4. Impact of Changes in the Probability of Collusion Being Detected. When $\beta = D = \{0.8, 0.5, 0.3, 0.2\}$, the process and results of the evolution of the thematic strategy of the quadratic game are shown in Figure 10.

As shown in Figure 10, as the probability of detecting collusion rises, the probability that the high collusion willing

party and the tenderer will choose the collusion strategy decreases to some extent. Still, the high collusion willing party is more sensitive to the probability of collusion being detected. At the same time, as the probability of collusion detection being reported decreases, the probability of low collusion willing parties choosing to collude also decreases. Therefore, in controlling vertical collusion, it is essential to establish smooth reporting channels, protect the privacy of those who report violations, and avoid retaliation against whistleblowers. At the same time, it is important to increase supervision and establish a regular inspection and monitoring mechanism. The establishment of an effective monitoring system will improve the effectiveness of controls on collusion.

4.3. Impact of Internal Oversight Measures on Vertical Collusion.
To further investigate the influence of the internal supervision mechanism in government projects' bidding process, the simulation analysis was conducted by setting $z = 0$ and $z = 0.9$ to indicate the two states of the low collusion tendency group to report or not to report collusion. The

evolution process of different initial strategies was simulated for three parties, tenderers, high collusion willing parties, and supervisory agencies, and the results are shown in Figure 11.

From Figure 11, when $z = 0$, i.e., when low collusion-prone firms choose to engage in collusion without reporting, the stabilization strategy of the remaining participants in the bidding process is not unique due to the influence of many external factors. When $z = 0.9$, it has a unique stabilization evolution strategy (participation in collusion, active collusion, and strong regulatory model). Therefore, low collusion-prone firms are encouraged to report collusion; strengthening internal supervision has a better effect on the control of collusion.

4.4. The Impact of External Punishment Mechanisms.
The evolutionary strategy's impact was analyzed by setting the change in the punishment and supervision cost level when collusion was detected to investigate the effectiveness and feasibility of the external punishment mechanism in controlling collusion. Simulations were conducted to analyze the evolutionary process of different initial strategies of the

three parties: the tenderer, the party with high willingness to collude, and the party with low willingness to collude. The results are shown in Figure 12.

As shown in Figure 12, as external penalties increase, the benefits gained by choosing to collude shift from higher than losses (low penalties) to medium penalties (the benefits of choosing to collude are equal to the losses when punished) and high penalties (the benefits of choosing to collude are lower than the losses when discovered). The probability of firms with higher willingness to collude engaging in collusion gradually decreases; however, as the cost of supervision increases, the probability of regulators adopting weak supervision also increases. Therefore, while increasing the intensity of control, attention should be paid to the equilibrium conditions. Such attention can avoid a decrease in

the supervisory body's willingness to supervise due to an excessive increase in external penalties.

5. Conclusions

This study focuses on the generation and control of collusion in the bidding process of government projects in China. It examines how to improve the quality of control of bidding collusion by considering different groups of enterprises and society's external supervision mechanism. The findings revealed the following.

(1) Establishing an effective external supervision mechanism and social supervision system can effectively reduce the probability of collusion among all

participants and achieve the quality of control over speculative behavior in the bidding process. The quality of the supervision system is closely related to the interests of the supervisory body, the benefits of reporting illegal behavior by social groups, and whether the report will bring retaliation from the tenderer and the colluding enterprises. In the control process, it is first necessary to reduce the cost of supervision and increase the incentives for supervisory bodies. Additionally, the application of deep learning, artificial intelligence, and other technologies should be vigorously promoted in the bidding process. Furthermore, a control mechanism should be established, combining artificial intelligence technology and manual auditing to reduce control costs.

(2) While establishing an effective regulatory mechanism, the reward and punishment mechanism should be improved to increase the punishment for law violations. Punishments can be imposed in the form of restrictions on bidding, social publicity, fines, and reduction of qualifications to increase the risk awareness of all participants in bidding and discourage those with a higher willingness to collude from participating in collusive behavior. At the same time, regular "look-back" inspections of phased government bidding projects should be carried out, with each region cross-checking the project's compliance to avoid concealment in the monitoring process.

(3) The bidding threshold and profitability of government bidding projects should be gradually raised under reasonable conditions. The level of competition in the market for government bidding projects should be reduced to control the willingness of project collusion participants. The simulation results show that the willingness of all parties to collude is low when the market is less competitive. Therefore, reasonably controlling the threshold and profitability of government projects can better control collusion. This will facilitate compliance and healthy operation of government bidding projects and the overall bidding market.

(4) Through research, we found that simply increasing the fines for illegal acts or improving the supervision cannot completely solve the vertical collusion in the bidding process of government investment projects. In the actual control process, we need to focus on the combination of internal supervision and external supervision system to enhance the law-abiding consciousness of each interest body, so as to realize that each interest body is unwilling to collude in thought and dare not collude in action, and to promote the effective operation of the bidding market of government investment projects.

The limitations of this study are the following two points.

(1) This study is based on the assumptions of non-fully rational economists and prospect theory. Still, in the government project bidding process, the decision of each game subject is influenced by random factors. Future research can examine the influence of random factors in the decision-making process and consider the influence of subjective emotions. Such an approach will make the results more in line with reality.

(2) This study examines vertical collusion in government investment projects, and the scope is not broad enough; widespread horizontal collusion is not considered. Future research may consider adding horizontal collusion to enhance the scalability of the research results.

In order to improve the effect of tourism demand forecast, the commercial development of the tourism industry, and the actual experience of users, this paper uses adaptive neural network technology to conduct tourism demand forecast analysis. Moreover, this paper improves the adaptive neural network algorithm so that it can handle multiple data for tourism demand forecast. After improving the algorithm, this paper employs the actual process of tourism demand forecast to construct a tourism demand forecast model based on adaptive neural network technology. After that, this paper combines travel time and space data analysis to determine the system's functional structure and network topology. Through experimental research, it can be seen that the tourism demand forecast model based on adaptive neural network technology proposed in this paper performs well in tourism demand forecast and meets the actual demand of modern tourism forecast.

1. Introduction

Since the beginning of the 21st century, the world's tourism industry has developed rapidly. Currently, many cities regard tourism as the pillar industry of their economic development, hoping to use the development of tourism to drive the development of the entire social economy. An obvious difference between tourism and industry, agriculture, and other production industries is the volatility of tourism, which is a huge challenge for enterprises and government planning departments in the tourism market. Therefore, in order to make a successful decision, we need to make an accurate forecast of the future demand of the tourism market. Modern tourism researchers have tried to use many mathematical methods and models to solve this problem. The main models commonly used at present are time series forecast models; regression models, including linear and nonlinear regression models; adaptive models; artificial neural networks; etc.

As a "green" driving force, tourism is not only related to the balance and coordination of resources and the environment, but also one of the important ways to achieve sustainable economic development [1]. Since the reform and

opening up, the development of China's tourism industry has experienced a historical leap from "shortage type" to "large country type." However, with the rapid growth of the tourism industry, the number of complaints about tourism experience is increasing, and the negative information exposed by the media and tourists through the Internet has a serious impact on the image of regional tourism [2]. In the Internet age, the dissemination of these negative information spans traditional geographic distance and time constraints [3] and has attracted more and more attention. Among them, the media and tourists' online attention to negative information such as travel complaints has become an important factor influencing tourists' decision-making and the development of regional tourism. At the same time, the massive amount of network information has made tourism routes more diverse, and the spatial associations between tourism demand-oriented regional tourism industries have become increasingly close and complex. Therefore, the spatial spillover effect of negative information network attention on regional tourism development cannot be ignored.

Some scholars divide the influencing factors into three types: thrust, pull, and resistance. Among them, push refers

to the factors that encourage people to travel, including population size, income trends, income distribution, and education level. Rally refers to the factors that attract people's subjective wishes to travel to a certain area, including climate, business, culture, marketing strategies, relatives, and friends. Resistance refers to the factors that hinder people from traveling to a certain area, including price, competitors, and supply capacity. When foreign countries use quantitative models to analyze influencing factors, they often take economic factors as the main research object. In the process of research, some scholars have discovered that the most critical factor affecting tourism demand and related decision-making is economy. Domestic scholars have also conducted research on the tourism demand of the source country of Hong Kong, showing that the tourism products, the economic level of the region, and the tourism costs are the most important factors. Special events include economic and noneconomic factors, such as social conflicts, sports events, and financial crises. In these three categories, it is generally believed that the influence of noneconomic factors is relatively small and that economic factors are more conducive to the establishment of tourism demand forecasting models; in-depth research was conducted on this basis. However, in terms of the actual situation in my country, my country's tourism demand is also greatly affected by family consumption habits, political and social factors, consumption concepts, and other factors. Therefore, the tourism demand forecasting method that only considers economic factors is not in line with my country's reality.

This paper uses adaptive neural network technology to carry out tourism demand forecast and analysis and build a business intelligence model to improve the forecast effect of subsequent tourism demand.

2. Related Work

Many scholars try to use different models to improve the accuracy and timeliness of demand forecasting, which can usually be divided into three categories: causality model, time series model, and artificial intelligence model. Literature [4] uses search keywords to establish a multiple linear regression function to predict the number of daily tourists and uses a single variable autoregressive moving average (ARMA) model to predict the tourism demand of 9 countries in the Asia-Pacific region. Sigalat Signes et al. [5] constructed a combined prediction model of autoregressive moving average model and BP neural network. Literature [6] applies support vector regression (SVR) model to tourism demand forecasting and combines it with autoregressive integrated moving average (ARIMA) model. Literature [7] uses an artificial neural network model to predict tourism demand in the Balearic Islands. Literature [8] uses a neural network-based fuzzy time series model as a prediction model to predict tourism demand during SARS. Literature [9] proposes a tourism flow forecasting SSVR-PSO (seasonal support vector regression particle swarm optimization) model that combines the seasonal support vector regression model and particle swarm optimization algorithm. Compared with the first two types of models, artificial intelligence

models show great advantages in terms of nonlinear fitting and adaptive learning, but traditional artificial neural networks have problems such as complex training process and long-time consumption. Therefore, finding efficient and accurate new neural network methods has become a hot research direction. Paper [9] proposed ESN (echo state network). Compared with traditional algorithms, the training process of echo state network is simple and efficient. It can approximate dynamic systems infinitely under general conditions and is widely used in various prediction problems. Literature [10] uses ESN to predict mobile communication traffic, and literature [11] uses it to deal with time series problems related to the prediction of certain eigenvalues of sunspots. However, ESN also has its own shortcomings and limitations. For example, ESN parameters and connection weights are randomly set, and only the output layer weights are adjusted during the training process, which is easy to fall into the local optimal solution. The common method currently used is to construct the ESN model when the network selects the optimal output multiple times, or select the parameters based on experience to construct the model. In this regard, many scholars have optimized the structure of the ESN. Literature [12] developed several new storage pool topologies for ESN and predicted the energy consumption of office buildings. Literature [13] proposed an echo state network prediction model with bifurcation structure to improve the prediction accuracy of ESN. Some scholars also use heuristic algorithms to optimize the parameters of ESN and obtain good experimental results. Literature [14] uses genetic algorithms to optimize the initial weights and thresholds of the forward feedback neural network, but there are relatively few studies of this kind at present. The fruit fly optimization algorithm (FOA) proposed by literature [15] has the advantages of low complexity, fast calculation speed, and strong solution ability. It has been applied in many combinatorial optimization and continuous optimization fields. Literature [16] uses FOA optimization for the structural parameters of the artificial neural network (ANN) model, and literature [14] uses FOA to optimize the penalty parameters and conversion coefficients of SVR and has achieved good experimental results. FOA itself has disadvantages such as low convergence accuracy and being easy to fall into local extreme values. Literature [17] proposed an adaptive mutation fruit fly optimization algorithm, according to the population fitness variance and the current optimal value; under the probability P, the mutation operator interferes with the replication to continue the optimization. Literature [18] increases the inertia to change the nonlinear decreasing characteristics and the relationship between individuals and groups, and an improved fruit fly optimization algorithm (IFOA) is constructed.

3. Tourism Demand Forecast Algorithm Based on Adaptive Neural Network

In order to achieve the control goal, the dynamic error system is defined as follows:

$$\tilde{x}_1 = x_1 - y\,d,$$

$$\tilde{x}_2 = \dot{\tilde{x}}_1,$$ (1)

$$\tilde{x}_3 = \dot{\tilde{x}}_2.$$

The design method of linear filter reduction is adopted, and filter variables are introduced to reduce the order of the system. The linear filter is defined as follows. The filter has the properties of exponential convergence, asymptotic convergence, and bounded transfer.

$$e1 = \tilde{x}_1,$$

$$e2 = \dot{e}_1 + 2e_1,$$ (2)

$$e3 = \dot{e}_2 + 2e_2.$$

We define $e = [e1^T, e2^T, e3^T]^T$, $\tilde{x} = [\tilde{x}1^T, \tilde{x}2^T, \tilde{x}3^T]^T$, and then there is the following relationship between e and $\tilde{x}$:

$$e = \left[\begin{pmatrix} I_2 & 0 & 0 \\ 2I_2 & I_2 & 0 \\ 4I_3 & I_3 & I_3 \end{pmatrix}\right] \tilde{x}.$$ (3)

In order to obtain the closed-loop dynamic equations of the three channels, the following equations are obtained by finding the first-order time derivative of $e3(t)$:

$$\dot{e}_3 = \frac{d}{dt}\left(\tilde{x}_3 + 4\tilde{x}_2 + 4\tilde{x}_1\right)$$

$$= \dot{\tilde{x}}3 + 4\dot{\tilde{x}}_2 + 4\dot{\tilde{x}}_1$$

$$= \overset{\text{\tiny t}}{\tilde{x}}1 - \overset{\text{\tiny t}}{\tilde{y}}\,d + 4\tilde{x}_3 + 4\tilde{x}_2$$ (4)

$$= F(x_1, x_2, x_3) + G(x_1, x_2)u - \overset{\text{\tiny t}}{\tilde{y}}d + 4\tilde{x}_3 + 4\tilde{x}_2.$$

By decomposing formula (4), $G(x_1, x_2)$, the following expression is obtained:

$$\dot{e}_3(t) = F(x_1, x_2, x_3) + S(x_1, x_2)DU(x_1, x_2)u - \overset{\text{\tiny t}}{\tilde{y}}d + 4\tilde{x}_3 + 4\tilde{x}_2.$$ (5)

By multiplying both sides of the above equation by $S^{-1}(x_1, x_2)$, we get

$$S^{-1}(x_1, x_2)\dot{e}_3(t) = S^{-1}(x_1, x_2)F(x_1, x_2, x_3)$$

$$+ DU(x_1, x_2)u + S^{-1}(x_1, x_2)\left(-\overset{\text{\tiny t}}{\tilde{y}}d + 4\tilde{x}_3 + 4\tilde{x}_2\right).$$ (6)

By adding and subtracting $(1/2)S^{-1}(x_1, x_2)e3$ at the same time in the right half of (6), we can get

$$S^{-1}(x_1, x_2)\dot{e}_3(t) = S^{-1}(x_1, x_2)F(x_1, x_2, x_3) + S^{-1}(x_1, x_2)\left(-\overset{\text{\tiny t}}{\tilde{y}}d + 4\tilde{x}_3 + 4\tilde{x}_2\right)$$

$$+ DU(x_1, x_2)u + \frac{1}{2}S^{-1}(x_1, x_2)e3 - \frac{1}{2}S^{-1}(x_1, x_2)e3.$$ (7)

Matrix D is a diagonal matrix, and the value of each item in the matrix is +1 or −1. The matrix form is

$$D = \begin{pmatrix} d_1 & 0 & 0 \\ 0 & d_2 & 0 \\ 0 & 0 & d_3 \end{pmatrix}.$$ (8)

The matrix U is an upper triangular matrix, in which each function above the main diagonal is an unknown function item. The matrix form is

$$U(x_1, x_2) = \begin{pmatrix} 1 & U_{12}(x_1, x_2) & U_{13}(x_1, x_2) \\ 0 & 1 & U_{23}(x_1, x_2) \\ 0 & 0 & 1 \end{pmatrix}.$$ (9)

In order to facilitate subsequent control design, a new auxiliary function variable is designed, and the auxiliary function is defined as

$$N\left(x_1, x_2, x_3, y\,d, \dot{y}d, \ddot{y}d, \overset{\text{\tiny t}}{y}d\right) = S^{-1}(x_1, x_2)F(x_1, x_2, x_3)$$

$$+ S^{-1}(x_1, x_2)\left(-\overset{\text{\tiny t}}{\tilde{y}}d + 4\tilde{x}_3 + 4\tilde{x}_2\right) + \frac{1}{2}S^{-1}(x_1, x_2)e3.$$ (10)

By substituting (10) into (7), the open-loop error dynamic system of $e3(t)$ is obtained as follows:

$$S^{-1}(x_1, x_2)\dot{e}_3(t) = N(\cdot) + DU(x_1, x_2)u - \frac{1}{2}S^{-1}(x_1, x_2)e3. \tag{11}$$

The hypersonic vehicle dynamics control signal is defined as $\Phi = u1, \delta e = u2, \delta c = u3$. According to the closed-loop dynamics equation in (10), in order to facilitate the subsequent stability analysis process, the control signal $u(t)$ is designed as follows:

$$u = [\Phi(t), \delta e(t), \delta c(t)]^T = [u1, u2, u3]^T. \tag{12}$$

Here, $u(t)$ is decomposed into

$$ui = uri + u\,di\,, i = 1, 2, 3. \tag{13}$$

uri is defined as follows:

$$uri = di(-ki)e3i. \tag{14}$$

By substituting matrix U, matrix D, and the resulting equation into (14), the closed-loop error dynamic equation is obtained:

$$S^{-1}(x_1, x_2)\dot{e}_3(t) = \begin{bmatrix} N1(\cdot) \\ N2(\cdot) \\ N3(\cdot) \end{bmatrix} - \frac{1}{2}\dot{S}^{-1}(x_1, x_2)e3$$

$$+ \begin{pmatrix} d_1 & 0 & 0 \\ 0 & d_2 & 0 \\ 0 & 0 & d_3 \end{pmatrix} \begin{pmatrix} 1 & U_{12} & U_{13} \\ 0 & 1 & U_{23} \\ 0 & 0 & 1 \end{pmatrix} \begin{bmatrix} ur_1 + ud_1 \\ ur_2 + ud_2 \\ ur_3 + ud_3 \end{bmatrix}. \tag{15}$$

By expanding (15), we can get

$$S^{-1}(x_1, x_2)\dot{e}_3(t) = \begin{pmatrix} N1(\cdot) + d1\left(u12\left(ur_2 + ud_2\right) + u13\left(ur_3 + ud_3\right)\right) \\ N2(\cdot) + d2\left[u23\left(ur_3 + ud_3\right)\right] \\ N3(\cdot) \end{pmatrix}$$

$$- \frac{1}{2}\dot{S}^{-1}(x_1, x_2)e3 + \begin{pmatrix} d1\left(ur_1 + ud_1\right) \\ d2\left(ur_2 + ud_2\right) \\ d3\left(ur_3 + ud_3\right) \end{pmatrix}. \tag{16}$$

The auxiliary function $M1, M2, M3$ is defined as the following form:

$$M1\left(x_1, x_2, x_3, y\,d, yd^{(1)}, yd^{(2)}, yd^{(3)}, ud_2, ud_3\right)$$

$$= N1(\cdot) + d1\left(u12\left(ur_2 + ud_2\right) + u13\left(ur_3 + ud_3\right)\right),$$

$$M2\left(x_1, x_2, x_3, y\,d, yd^{(1)}, yd^{(2)}, yd^{(3)}, ud_3\right)$$

$$= N2(\cdot) + d2\left[u23\left(ur_3 + ud_3\right)\right], \tag{17}$$

$$M3\left(x_1, x_2, x_3, y\,d, yd^{(1)}, yd^{(2)}, yd^{(3)}\right) = N3(\cdot).$$

By substituting (17) into (16), we can get

$$S^{-1}(x_1, x_2)\dot{e}_3(t) = \begin{pmatrix} M1 \\ M2 \\ M3 \end{pmatrix} - \frac{1}{2}\dot{S}^{-1}(x_1, x_2)e3 + \begin{pmatrix} d1(ur_1 + ud_1) \\ d2(ur_2 + ud_2) \\ d3(ur_3 + ud_3) \end{pmatrix}. \tag{18}$$

By using neural network approximation, $M1, M2, M3$ can be written as

$$M1 = \theta 1\phi 1^T(t) + \varepsilon 1,$$
$$M2 = \theta 2\phi 2^T(t) + \varepsilon 2, \tag{19}$$
$$M3 = \theta 3\phi 3^T(t) + \varepsilon 3.$$

Among them, $\theta 1^T\theta 1 \le \theta M$, $\theta 2^T\theta 2 \le \theta M$, $\theta 3^T\theta 3 \le \theta M$, $|\varepsilon 1| \le \varepsilon$, $|\varepsilon 2| \le \varepsilon$, $|\varepsilon 3| \le \varepsilon$, and θM is unknown constant.

ud_i is designed as follows:

$$ud_1 = -d1\hat{\theta}1\phi 1^T(t),$$
$$ud_2 = -d2\hat{\theta}2\phi 2^T(t), \tag{20}$$
$$ud_3 = -d3\hat{\theta}3\phi 3^T(t).$$

By substituting (14), (19), and (20) into (18), the closed-loop error dynamics equation can be obtained:

$$S^{-1}(x_1, x_2)\dot{e}_3(t)$$
$$= \begin{pmatrix} \theta 1\phi 1^T(t) + \varepsilon 1 \\ \theta 2\phi 2^T(t) + \varepsilon 2 \\ \theta 3\phi 3^T(t) + \varepsilon 3 \end{pmatrix} - \frac{1}{2}\dot{S}^{-1}(x_1, x_2)e3 - \begin{pmatrix} k_1 & 0 & 0 \\ 0 & k_2 & 0 \\ 0 & 0 & k_3 \end{pmatrix}e3 - \begin{pmatrix} \hat{\theta}1\phi 1^T(t) \\ \hat{\theta}2\phi 2^T(t) \\ \hat{\theta}3\phi 3^T(t) \end{pmatrix}$$
$$= \begin{pmatrix} \tilde{\theta}1\phi 1^T(t) \\ \tilde{\theta}2\phi 2^T(t) \\ \tilde{\theta}3\phi 3^T(t) \end{pmatrix} + \begin{pmatrix} \varepsilon 1 \\ \varepsilon 2 \\ \varepsilon 3 \end{pmatrix} - \frac{1}{2}\dot{S}^{-1}(x_1, x_2)e3 - \begin{pmatrix} k_1 & 0 & 0 \\ 0 & k_2 & 0 \\ 0 & 0 & k_3 \end{pmatrix}e3. \tag{21}$$

The proposed Lyapunov candidate function is defined as follows:

$$V = \frac{1}{2}e1^Te1 + \frac{1}{2}e2^Te2 + \frac{1}{2}e3^TS^{-1}(x_1, x_2)e3$$
$$+ \frac{1}{2}\tilde{\theta}1^T\Gamma 1^{-1}\tilde{\theta}1 + \frac{1}{2}\tilde{\theta}2^T\Gamma 2^{-1}\tilde{\theta}2 + \frac{1}{2}\tilde{\theta}3^T\Gamma 3^{-1}\tilde{\theta}3. \tag{22}$$

By deriving the Lyapunov function, the following equation can be obtained:

$$\dot{V} = -2e^2_{1,i} + e^T_{1,i}e_{2,i} - 2e^2_{2,i} + e^T_{2,i}e_{3,i} + e3S^{-1}(x_1, x_2)\dot{e}_3(t)$$
$$- \tilde{\theta}1^T\Gamma 1^{-1}\dot{\hat{\theta}}1 - \tilde{\theta}2^T\Gamma 2^{-1}\dot{\hat{\theta}}2 - \tilde{\theta}3^T\Gamma 3^{-1}\dot{\hat{\theta}}3 + \frac{1}{2}e3^T\dot{S}^{-1}(x_1, x_2)e3. \tag{23}$$

By substituting (21) into (23), according to the triangle inequality theorem, (23) can be transformed into the following form:

$$\dot{V} \le -2\|e1\|^2 - 2\|e2\|^2 + \frac{1}{2}\|e1\|^2 + \|e2\|^2 + 1/2\|e3\|^2$$
$$+ e3\left(\begin{pmatrix} \phi 1^T(t)\tilde{\theta}1 + \varepsilon 1 \\ \phi 2^T(t)\tilde{\theta}2 + \varepsilon 2 \\ \phi 3^T(t)\tilde{\theta}3 + \varepsilon 3 \end{pmatrix} - \frac{1}{2}\dot{S}^{-1}(x_1 x_2)e3 - \begin{pmatrix} k_1 & 0 & 0 \\ 0 & k_2 & 0 \\ 0 & 0 & k_3 \end{pmatrix}e3\right) \tag{24}$$
$$- \tilde{\theta}1^T\Gamma 1^{-1}\dot{\hat{\theta}}1 - \tilde{\theta}2^T\Gamma 2^{-1}\dot{\hat{\theta}}2 - \tilde{\theta}3^T\Gamma 3^{-1}\dot{\hat{\theta}}3 + \frac{1}{2}e3^T\dot{S}^{-1}(x_1, x_2)e3.$$

Next, the adaptive update rate $\dot{\hat{\theta}}1, \dot{\hat{\theta}}2, \dot{\hat{\theta}}3$ of neural network weights is designed as

$$
\dot{\hat{\theta}}1 = \Gamma 1 \phi 1\,(t)e3,1 - \Gamma 1\eta 1\hat{\theta}1,
$$

$$
\dot{\hat{\theta}}2 = \Gamma 2 \phi 3\,(t)e3,2 - \Gamma 2\eta 2\hat{\theta}2, \tag{25}
$$

$$
\dot{\hat{\theta}}3 = \Gamma 3 \phi 3\,(t)e3,3 - \Gamma 3\eta 3\hat{\theta}3.
$$

By substituting the adaptive update rate into the original inequality (25), after expansion, we can get

$$
\begin{aligned}
\dot{V} \le\ & -\frac{3}{2}\|e1\|^2 - \|e2\|^2 + \frac{1}{2}\|e3\|^2 \\
& + e3\left(\left(\begin{pmatrix} \phi 1^T(t)\tilde{\theta}1 + \varepsilon 1 \\ \phi 2^T(t)\tilde{\theta}2 + \varepsilon 2 \\ \phi 3^T(t)\tilde{\theta}3 + \varepsilon 3 \end{pmatrix} - \frac{1}{2}\dot{S}^{-1}(x_1,x_2)e3 - \begin{pmatrix} -(k1)e3,1 \\ -(k2)e3,2 \\ -(k3)e3,3 \end{pmatrix}\right)\right) \\
& - \tilde{\theta}1^T\Gamma 1^{-1}(\Gamma 1\phi 1(t)e3,1 - \Gamma 1\eta 1\hat{\theta}1) - \tilde{\theta}2^T\Gamma 2^{-1}(\Gamma 1\phi 1(t)e3,1 - \Gamma 1\eta 1\hat{\theta}1) \\
& - \tilde{\theta}3^T\Gamma 3^{-1}(\Gamma 1\phi 1(t)e3,1 - \Gamma 1\eta 1\hat{\theta}1) + \frac{1}{2}e3^T\dot{S}^{-1}(x_1,x_2)e3.
\end{aligned} \tag{26}
$$

After merging similar items, it is further transformed into the following form:

$$
\begin{aligned}
\dot{V} \le\ & -\frac{3}{2}\|e1\|^2 - \|e2\|^2 + \frac{1}{2}\|e3\|^2 + e3,1\phi 1^T(t)\tilde{\theta}1 + e3,2\phi 2^T(t)\tilde{\theta}2 \\
& + e3,3\phi 3^T(t)\tilde{\theta}3 + e3,1\varepsilon 1 + e3,2\varepsilon 2 + e3,3\varepsilon 3 - (k1)e3,1^2 \\
& - (k2)e3,2^2 - (k3)e3,3^2 - \tilde{\theta}1^T\phi 1(t)e3,1 + \tilde{\theta}1^T\eta 1\hat{\theta}1 \\
& - \tilde{\theta}2^T\phi 2(t)e3,2 + \tilde{\theta}2^T\eta 2\hat{\theta}2 - \tilde{\theta}3^T\phi 3(t)e3,3 + \tilde{\theta}3^T\eta 3\hat{\theta}3.
\end{aligned} \tag{27}
$$

Inequality (27) is reduced to the following form:

$$
\begin{aligned}
\dot{V} \le\ & -\frac{3}{2}\|e1\|^2 - \|e2\|^2 + \frac{1}{2}\|e3\|^2 + e3,1\varepsilon 1 + e3,2\varepsilon 2 + e3,3\varepsilon 3 - (k1)e3,1^2 \\
& - (k2)e3,2^2 - (k3)e3,3^2 + \tilde{\theta}1^T\eta 1\hat{\theta}1 + \tilde{\theta}2^T\eta 2\hat{\theta}2 + \tilde{\theta}3^T\eta 3\hat{\theta}3.
\end{aligned} \tag{28}
$$

At the same time, inequality scaling is performed on the residual term of the neural network approximation and the approximate value of the neural network weight, and the Lyapunov function inequality can be obtained as follows:

$$
\begin{aligned}
\dot{V} \le\ & -\frac{3}{2}\|e1\|^2 - \|e2\|^2 + \frac{1}{2}\|e3\|^2 + \frac{1}{2}\varepsilon_1^2 + \frac{1}{2}\varepsilon_2^2 + \frac{1}{2}\varepsilon_3^2 \\
& + \tilde{\theta}1^T\eta 1\hat{\theta}1 + \tilde{\theta}2^T\eta 2\hat{\theta}2 + \tilde{\theta}3^T\eta 3\hat{\theta}3.
\end{aligned} \tag{29}
$$

Considering $\|\theta i\| \le \theta M, \|\varepsilon i\| \le \varepsilon M, \|\tilde{\theta}i\| \le \tilde{\theta}M, i = 1,2,3,$, we set $ki - 1/2 > 1/2$, and it can be derived from the original inequality:

$$
\begin{aligned}
\dot{V} \le\ & -\frac{3}{2}\|e1\|^2 - \|e2\|^2 - \|e3\|^2 + \frac{1}{2}\varepsilon_1^2 + \frac{1}{2}\varepsilon_2^2 + \frac{1}{2}\varepsilon_3^2 + \frac{1}{2}\eta_1^2\theta_1^2 \\
& + \frac{1}{2}\eta_2^2\theta_2^2 + \frac{1}{2}\eta_3^2\theta_3^2 - \tilde{\theta}_1^T\eta 1\tilde{\theta}1 - \tilde{\theta}_2^T\eta 2\tilde{\theta}2 - \tilde{\theta}_3^T\eta 3\tilde{\theta}3.
\end{aligned} \tag{30}
$$

We assume that the maximum eigenvalue of $S^{-1}(x_1, x_2)$ is less than a constant λ, and the constant λ is greater than zero. The matrix $S(x_1, x_2)$ itself is a positive definite symmetric matrix with uniform positive definiteness. Therefore,

$$\dot{V} \le -\|e1\|^2 - \|e2\|^2 - \|e3\|^2 - \tilde{\theta}_1^T \eta 1 \tilde{\theta}1 - \tilde{\theta}_2^T \eta 2 \tilde{\theta}2 - \tilde{\theta}_3^T \eta 3 \tilde{\theta}3 + C. \tag{31}$$

Among them, $C = 1/2\varepsilon_1^2 + 1/2\varepsilon_2^2 + 1/2\varepsilon_3^2 + 1/2\eta_1^2\theta_1^2 + 1/2\eta_2^2\theta_2^2 + 1/2\eta_3^2\theta_3^2$.

$$V \le +\frac{1}{2}\left(\|e1\|^2 + \|e2\|^2 + \lambda\|e3\|^2 + \tilde{\theta}_1^T \Gamma 1^{-1}\tilde{\theta}1 + \tilde{\theta}_2^T \Gamma 2^{-1}\tilde{\theta}2 + \tilde{\theta}_3^T \Gamma 3^{-1}\tilde{\theta}3 \right). \tag{32}$$

According to the law of comparison, we have

$$\dot{V} \le \frac{-2\min(1, \eta 1, \eta 2, \eta 3),}{\max\left(1, \lambda, \Gamma 1^{-1}, \Gamma 2^{-1}, \Gamma 3^{-1}\right)}V + C. \tag{33}$$

By solving the differential inequality, we can get

$$V \le -\frac{c}{m} + \left(V(0) + \frac{c}{m}\right)e^{mt}. \tag{34}$$

Among them, $m = -2\min(1, \eta 1, \eta 2, \eta 3,)/\max(1, \lambda, \Gamma 1^{-1}, \Gamma 2^{-1}, \Gamma 3^{-1})$.

Therefore,

$$-\frac{c}{m}\|e\|^2 \le V \le -\frac{c}{m} + \left(V(0) + \frac{c}{m}\right)e^{mt}. \tag{35}$$

Thus, it is indicated that the tracking error $e1, e2, e3$ and the weight estimation error index $\tilde{\theta}1, \tilde{\theta}2, \tilde{\theta}3$ converge to zero.

4. Tourism Demand Forecast Based on Adaptive Neural Network Technology

In order to respond to the spatial increase of local tourism demand status, the short-sighted path dependence of the unidirectional flow view and the static destination market concept should be eliminated. Moreover, it is necessary to reconstruct a new tourist destination spatial system with both destination and tourist source functions from a more microscopic perspective (see Figure 1). The spatial reorganization of tourist destinations is explored under the continuous deepening of small- and medium-scale tourism spatial behavior. The system should be a specific organic whole composed of several interacting and interdependent tourism elements within a certain geographical space. It uses the existing borders of jurisdictions as the dividing lines between local and remote areas. This includes not only the part of the spatial system formed by the inflow of tourist from outside the region involved in the original space system into the tourist destination, but also the part of the regional tourism space system such as cities, towns, and rural areas. At the same time, it takes tourist destinations that have both the functions of tourist source and destination as the main body to form a space system with specific order and complementary internal and external space with factors such as regional tourism environment, tourism channels, tourism information, and tourism flow. It needs to be pointed out that the reconstruction of the new tourist destination space system is not a complete denial of the original tourist destination space system, but a supplement and improvement to its system.

When designing the system, the main direction is around the surrounding information of the scenic spot. For example, we need to add functions that allow users to search for, roam, navigate, collect, share, and pay for scenic spots to facilitate users to screen scenic spots and provide the readability of tourism quality and the convenience of transportation. In the process of searching and roaming at scenic spots, tourists can find relevant information such as the ticket limit of scenic spots, travel, and transportation costs. In addition, it should be noted that the platform must take into account both the emotional needs and consumer needs of users. On the one hand, after users have used the travel tools provided by the platform and browsed the target attractions, they will need to communicate with other people on the Internet. On the other hand, users also need to store and classify related information after using the platform. Therefore, we also need to provide a storage and classification function, so that users can save time when using the platform for the second time and quickly find the previously stored scenic spot information. The analysis of user needs is shown in Figure 2.

The analysis of platform function requirements is shown in Figure 3.

Before planning a trip, users need to search for resources effectively. It is necessary to classify the platform's attractions resources, and through the history function, users can easily call up the browsing history. Secondly, after the user has screened the destination, the user needs to understand the surroundings. At the same time, it is necessary to prompt peripheral information such as toilets, ATMs, and hotels during the virtual roaming process. When the platform constructs the framework, it needs to introduce data about city-related information. After the user has searched the surrounding information of the destination, the user needs to pay for the services that can be provided on the Internet. Therefore, the platform needs to add the function of Internet payment. After the travel experience, there must be follow-up emotional expressions, so the platform needs to have a comment function. The fishbone diagram of the platform function requirement analysis is shown in Figure 4.

The terminals involved in this paper include mobile devices and desktop devices. Mobile ports include tablet
FIGURE 1: Spatial system diagram of tourist destinations.

FIGURE 2: Analysis of user needs.

computers and mobile phones, and desktop devices are computer hosts. The network topology is shown in Figure 5.

Space, attribute, and time are the three basic characteristics of geographic phenomena and the three basic elements of geographic analysis. Time information is helpful to explore the movement laws of individual activities and predict future development trends. However, due to the lack of effective analysis methods for massive spatiotemporal data and other reasons, previous studies usually ignore time information. However, time geography introduces "time" and uses the concept of "time and space" to simultaneously analyze the three types of information of time, space, and attributes within the same framework, which bridges the traditional geography's neglect of time. It should be noted that time geography is not the geography of time, but a methodology for studying the relationship between the human behavior and the objective space-time environment. Temporal geography is the geography that studies the temporal and spatial characteristics of individual behavior under various constraints. It believes that the space-time range of individual activities is restricted by a variety of factors in itself and its surrounding environment, which can be summarized into three aspects: ability restriction, combination restriction, and authority restriction. At the same time, time geography borrows the concept of "space-time prism" to describe the space-time area in which individuals can carry out activities under various constraints. The space-time prism image represents the various possibilities of individual activities. The upper and lower vertices of the prism are determined by the time point, and the boundary of the prism is determined by the conditions of transportation.

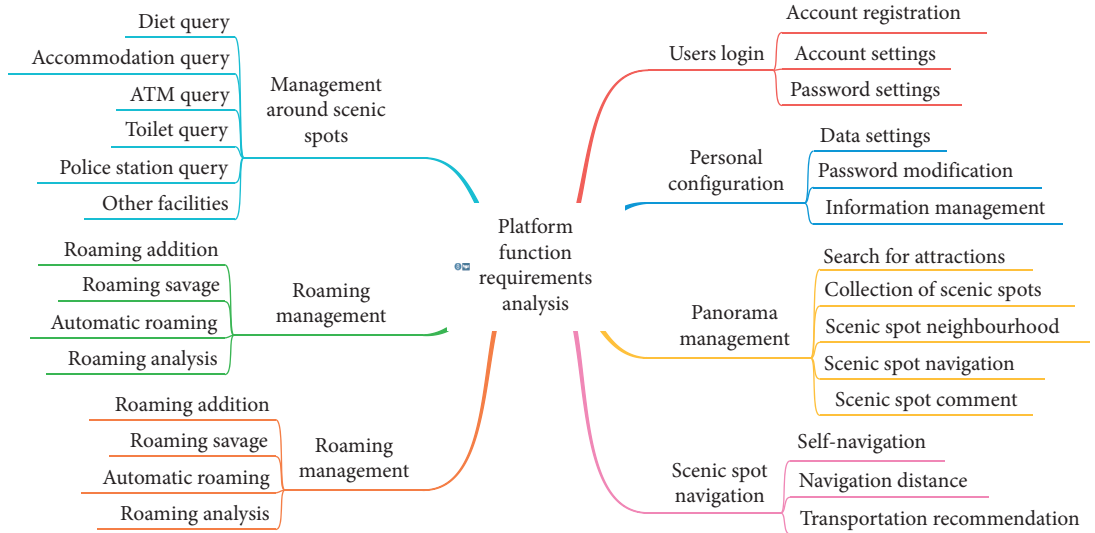
With the quantitative development of time geography, probabilistic time geography began to appear and attracted attention. Although classical time geography borrows space-time prisms to express the uncertainty of individual movement in space-time regions, it assumes that individual objects are evenly distributed within the reach. However, according to the


FIGURE 3: Analysis of platform function requirements.

FIGURE 4: Fishbone diagram of the analysis of platform functional requirements.

FIGURE 5: Network topology diagram.

first theorem of geography, it can be known that the possibility of individual moving objects in different reachable positions is not always uniform. Probabilistic time geography is based on this idea. It is believed that the possibility of moving objects distributed in each reachable position is not always equal, but is distributed within the reachable range with a certain probability value. Moreover, this probability value continues to change over time. Probabilistic time geography advocates the use of probabilistic methods to describe the nonequal possibilities of the reachable locations of mobile objects, which is an extension of classical time geography based on probability. Based on the probability characteristics of variance and other probabilities shown by time geography of different probability models, a time geography probability model of directional movement is constructed based on the Brown Bridge probability and the total probability formula, respectively. Probabilistic time geography is still immature and needs further improvement. However, the idea that the analysis of individual moving objects needs to consider the actual probability distribution provides a theoretical source for this paper to use the probability method to predict the temporal and spatial distribution of tourists in scenic spots. The schematic diagram of the space-time prism with the starting point and the end point in the same spatial position is shown in Figure 6, and the schematic diagram of the space-time prism with the starting point and the end point in different spatial positions is shown in Figure 7.
FIGURE 6: Schematic diagram of a space-time prism with the start and end points at the same spatial position (three-dimensional).

FIGURE 7: Schematic diagram of space-time prisms with start and end points at different spatial positions (three-dimensional).

This paper mainly studies tourism demand forecast based on adaptive neural network and realizes the heat forecast of tourist attractions by fusing the comfort index and specific adaptive neural network forecast algorithms. Moreover, this paper applies the research results to specific engineering practice and establishes a tourist attraction heat forecast system based on the comfort index. The establishment of the system can help tourists better understand the comfort and heat information of a scenic spot, help tourists choose scenic spots reasonably, and also benefit enterprises' decision-making on tourism projects, as well as their recommendation and management of tourists. The system should have three major functions: data collection, data calculation and analysis, and data management and display. The detailed functional modules are data collection

module, comfort index system module, tourism popularity forecast module, background management module, and result display module. The five major functional modules of the system are shown in Figure 8.

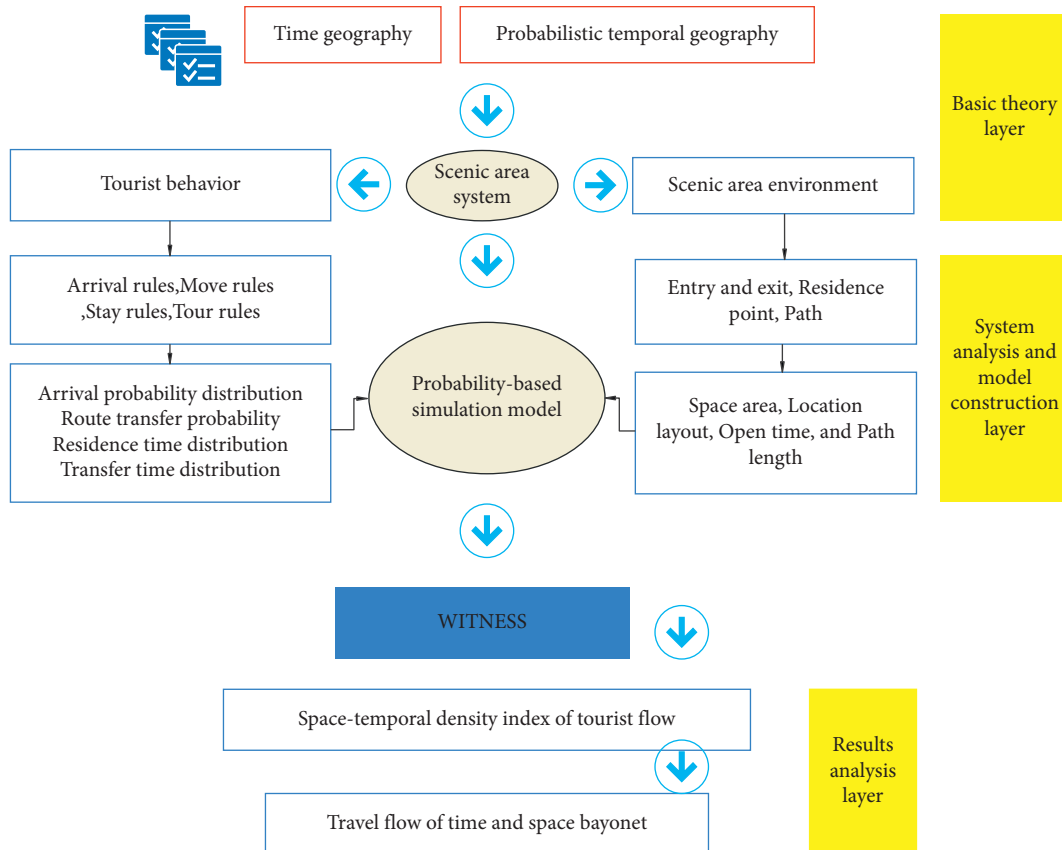
The data acquisition module mainly realizes data acquisition and data preprocessing. The data collection module performs related collection work according to different data requirements. After collection, the data is saved and backed up to the relevant server database, and a data interface is provided to enable other modules to use the travel data. The data collection module should be able to automatically obtain tourist data, weather data, environmental pollution data, road conditions around the scenic spot, etc. according to the configuration. The data acquisition module must have certain data preprocessing capabilities and realize data
FIGURE 8: Functional decomposition of system requirements.


FIGURE 9: Forecast model of travel time and space bayonet.

cleaning and data integration work through programming. The data acquisition module must have a certain degree of anti-interference ability and response speed and provide multithreaded data acquisition and processing capabilities. The configuration administrator can view all the scenic spot information that the system can collect and the scenic spot information currently collecting data and can add and delete the scenic spots collected by the data collection module. When adding tourist attractions to the collection module, the configuration manager can set the time range and time interval for tourism data collection. When the configuration administrator deletes or adds tourist attractions to the data collection module, the delay will take effect until the next day. After adding the scenic spots where the data collection

FIGURE 10: Statistical diagram of the processing effect of spatio-temporal tourism data.
FIGURE 11: Statistical diagram of tourism demand forecast.

module works, the system will query all the URLs of the current scenic spots that collect data by default. The configuration administrator needs to confirm whether all the scenic spots URLs are valid. If they are invalid, they need to be added manually. At the same time, the data collection module requires a built-in web page analysis program. The previous analysis needs are only for China Weather Network, Green Breathing Network, Beijing Meteorological Bureau Network, Beijing Tourism Network, and Nanjing

Tourism Network. When confirming the URL of the scenic spot, we need to ensure that the system can parse the configured URL. At the same time, the configuration administrator needs to configure the collection of API interface information around the scenic spot to ensure accurate acquisition of the road situation around the scenic spot.

This paper integrates time geography and probability time geography theory, system analysis theory, and travel flow spatiotemporal bayonet theory and proposes a research framework based on WITNESS simulation system to predict

travel flow spatiotemporal bayonet. Among them, time geography and probabilistic time geography provide a theoretical basis for establishing a simulation model of a scenic spot system based on probability. According to the system analysis theory, the scenic spot system is analyzed from the two aspects of scenic spot environment and tourist behavior rules, and the scenic spot environment is abstracted and simplified into three categories: entrances and exits, paths, and stop points. The tourist behavior rules are divided into tourist arrival rules, mobile stay rules, and tour rules. According to the results of the system analysis, data on the area of the scenic area, location layout, path length, tourist arrival probability distribution, route transition probability, stay time probability distribution, and travel time of scenic spots are collected. These data provide initial parameters for the probability-based simulation system model, and the model is implemented on the WITNESS simulation software platform. Finally, according to the theory of travel flow time and space bayonet, it is proposed to use the time and space density index of tourism flow as an index to identify the time and space bayonet of tourism flow. The proposed research framework can provide reference and guidance for establishing the same simulation model for other types of scenic spots to predict the spatiotemporal bayonet of tourism flows, as shown in Figure 9.

After constructing a tourism demand forecast model based on adaptive neural network technology, the performance of this model is verified. Based on actual data, this paper uses the simulation platform proposed in this paper to process the time-space travel data, analyze the data processing effect, and obtain the results shown in Table 1 and Figure 10.

From the above analysis, it can be seen that the tourism demand forecast model based on adaptive neural network technology proposed in this paper has good spatiotemporal tourism data processing effects. After that, the tourism demand forecast model based on adaptive neural network technology is evaluated for the effect of tourism demand forecast, and the results shown in Table 2 and Figure 11 are obtained.

From the above research, it can be seen that the tourism demand forecast model based on adaptive neural network technology proposed in this paper performs well in tourism demand forecast and meets the actual demand of modern tourism forecast.

5. Conclusion

The study of factors affecting tourism demand is the key content of tourism demand forecasting. At present, domestic and foreign researches on this aspect have formed a more systematic theory. Quantitative analysis method is currently widely used in foreign countries to study the factors affecting tourism demand. Economic factors can be divided into income, price, leisure time, and marketing. Income includes the personal disposable income and the GDP of the source area; price includes the transportation expenses, the price of products and reading materials in tourist destinations, the price level of competing destinations, and the exchange rate.

Noneconomic factors include consumers' personal preferences, consumption habits, local political factors, travel restrictions, and other social and cultural factors. This article uses adaptive neural network technology to forecast and analyze tourism demand, build a business intelligence model, and improve the prediction effect of subsequent tourism demand. The experimental research results show that the tourism demand prediction model based on adaptive neural network technology proposed in this paper performs well in tourism demand prediction and meets the actual demand of modern tourism prediction.

The in-depth analysis of the strategies for the coordinated and continuous development of population, resources, environment, economy, and society based on the engineering management model is highly important for the sustainable development of the regional economy and society. In this article, a population-economy-resources-environment bilevel optimization model is established based on the economic and social development in a provincial region. The method of bilevel optimization is adopted to introduce the specific bilevel optimization model. The concept and objectives of the bilevel optimization are explained, and its corresponding technical applications are described. In this article, the development in coordinated economic and social development of population, resources, and environment is analyzed and compared based on the bilevel optimization model. In particular, the evolution and changes before and after the implementation of engineering management are studied. Through the results, it can be observed that after the implementation of project management, the coefficient of industry location has presented a downward trend, and the coordinated development of population, resources, environment, economy, and society has become more coordinated.

1. Introduction

With the rapid economic development in recent years, the social resources acquired are getting greater and greater. As a result, it is impossible to sort out these resources based on the previous means and techniques [1]. In this context, the bilevel optimization model has become an important component in the coordinated economic and social development of population, resources, environment, with a low threshold and strong convergence characteristics possessing advantages [2, 3]. In the 21st century, people become more demanding for the relationships in the coordinated development of population, resources, environment, economy, and society. The previous simple economic growth can no longer meet their needs, and the coordinated development of population, resources, environment, economy, and society has slowly shifted from a single nature into an interactive

field [4, 5]. The coordinated development functions allow people to identify useful resources among massive resources. Hence, the combination of the coordinated development function and the coordinated economic and social development of population, resources, environment, and society are useful, and the combination of these two techniques can facilitate a better management of the coordinated economic and social development of population, resources, and environment.

The application of the bilevel optimization model can explain the previous concept of spatial location of production more effectively, while providing the corresponding way to new trade concepts and newly added concepts. After the analysis and evaluation of the basic concepts and techniques of the bilevel optimization model, a special study of the concept is conducted in this article on the situation of regional development in China. Through the study, it is

concluded that the bilevel optimization model has played a crucial role in promoting the coordinated development of population-resource-environment-economy-society regarding the differences in regional development. Finally, this article provides a theoretical basis for the future coordinated development degree of population-economy-resource-environment system in the province and puts forward a strategy to promote the coordinated development of socioeconomic and resource-environment scientifically and rationally, so as to provide a theoretical basis for the sustainable development of economy and environment in the province.

2. Bilevel Optimization Model

In this article, the bilevel optimization model is introduced, and it can be observed that the initialization of the bilevel optimization center can have a serious effect on the bilevel optimization model if the results are not reasonable. This effect requires massive computation time for engineering management under the population, resources, environment, economic, and social subjects intelligent search engine. At the same time, it will also greatly reduce the performance of bilevel optimization, which will eventually lead to inaccurate results obtained.

Based on the working principle of the bilevel optimization model cited in this paper, the method of small-sized samples and multiple sampling are dopated. Through the bilevel optimization model, the scientific and reasonable bilevel optimization center can be obtained so that the initialization stage of the bilevel optimization unreasonable phenomenon can be eliminated based on the big data bilevel optimization model to effectively improve the performance and accuracy of big data bilevel optimization model. The core idea of the model is based on small sample collection, followed by the bilevel optimization model analysis based on the Map-reduce model. The operational framework of the bilevel optimization model is shown in Figure 1.

In the next section, the optimization of the bilevel optimization model K-value is described in detail. The model consists of three main parts: separation model, subcenter elimination, and weight-K value optimization model.

It is assumed that that s stands for the number of samples, x stands for the coordinates, i stands for the ith sample, k stands for the number of clusters, and d stands for the data dimension, the result set of the ith sample cluster is represented in the following form:

$$\left(x^i_{11}, x^i_{12}, \ldots, x^i_{1\,d}\right)\left(x^i_{21}, x^i_{22}, \ldots, x^i_{2\,d}\right)\cdots\left(x^i_{k1}, x^i_{k2}, \ldots, x^i_{k\,d}\right). \quad (1)$$

The matrix form of the results obtained based on the bilevel optimization for all samples is shown as follows:

$$\begin{bmatrix} \left(x^1_{11}, x^1_{12}, \ldots, x^1_{1\,d}\right) & \left(x^1_{21}, x^1_{22}, \ldots, x^1_{2\,d}\right) & \cdots & \left(x^1_{k1}, x^1_{k2}, \ldots, x^1_{k\,d}\right) \\ \left(x^2_{11}, x^2_{12}, \ldots, x^2_{1\,d}\right) & \left(x^2_{21}, x^2_{22}, \ldots, x^2_{2\,d}\right) & \cdots & \left(x^2_{k1}, x^2_{k2}, \ldots, x^2_{k\,d}\right) \\ \vdots & \vdots & \cdots & \vdots \\ \left(x^s_{11}, x^s_{12}, \ldots, x^s_{1\,d}\right) & \left(x^s_{21}, x^s_{22}, \ldots, x^s_{2\,d}\right) & \cdots & \left(x^s_{k1}, x^s_{k2}, \ldots, x^s_{k\,d}\right) \end{bmatrix}. \quad (2)$$

In the above matrix, the arrangement of matrix elements corresponds one to the other based on the similarity of cluster centers. A column matrix corresponds to clusters, in which k clusters are shared. It is assumed that the kth cluster center of the first sample, the first cluster center of the second sample, and the second cluster center of the last sample are subcenters.

$$\begin{bmatrix} \left(x^1_{11}, x^1_{12}, \ldots, x^1_{1\,d}\right) & \left(x^1_{21}, x^1_{22}, \ldots, x^1_{2\,d}\right) & \cdots & \left(x^1_{k1}, x^1_{k2}, \ldots, x^1_{k\,d}\right) \\ \left(x^2_{11}, x^2_{12}, \ldots, x^2_{1\,d}\right) & \left(x^2_{21}, x^2_{22}, \ldots, x^2_{2\,d}\right) & \cdots & \left(x^2_{k1}, x^2_{k2}, \ldots, x^2_{k\,d}\right) \\ \vdots & \vdots & \cdots & \vdots \\ \left(x^s_{11}, x^s_{12}, \ldots, x^s_{1\,d}\right) & \left(x^s_{21}, x^s_{22}, \ldots, x^s_{2\,d}\right) & \cdots & \left(x^s_{k1}, x^s_{k2}, \ldots, x^s_{k\,d}\right) \end{bmatrix}$$
$$\Downarrow \quad (3)$$
$$\begin{bmatrix} \left(x^1_{11}, x^1_{12}, \ldots, x^1_{1\,d}\right) & \left(x^1_{21}, x^1_{22}, \ldots, x^1_{2\,d}\right) & \cdots & (0, 0, \ldots, 0) \\ (0, 0, \cdots, 0) & \left(x^2_{21}, x^2_{22}, \cdots, x^2_{2\,d}\right) & \cdots & \left(x^2_{k1}, x^2_{k2}, \ldots, x^2_{k\,d}\right) \\ \vdots & \vdots & \cdots & \vdots \\ \left(x^s_{11}, x^s_{12}, \ldots, x^s_{1\,d}\right) & (0, 0, \ldots, 0) & \cdots & \left(x^s_{k1}, x^s_{k2}, \ldots, x^s_{k\,d}\right) \end{bmatrix}.$$
FIGURE 1: Framework of the method proposed in this paper at two stages.

In the above matrix (0, 0, ..., 0), which is the bilevel optimization center, is shown as a subcenter. In fact, it is still unknown what cluster centers are suboptimal. Hence, the next topic is to locate and remove the following suboptimal cluster centers.

3. Overview of the Study Area

The population of the province has shown an increasing trend since 1990, and the population growth rate has remained relatively stable, with a small downward trend during this period. The total production in the region of the province is characterized by obvious stage, presenting a gradual trend of growth in the fluctuating gross product of the province in the period from 1960 to 1980. In the period from 1981 to 2000, the gross production in the region showed a trend of annual growth, and in 1995, the gross production in the region exceeded 100 billion yuan with fluctuations. In the period from 2001 to 2014 with the implementation of the policy of revitalization of the old industrial bases in the region, the GDP showed significant growth characteristics until 2014 when the GDP reached RMB 1380.44 billion at the same time, the growth of the regional GDP was maintained at about 0.14%, and the regional economic growth gradually showed a growth trend (Figure 2).

The region is in a period of industrialization transformation and accelerating urbanization. The share of the three industrial structures in the region in 2014 was 11.1%, 52.7%, and 36.2%, respectively. Among them, the value of the primary industry in the regional industrial structure grew RMB 15.457 billion, corresponding to a growth rate of 4.7%. The growth value of the level 2 industry in the region is RMB 728.727 billion, with a corresponding growth rate of 6.7%, and the growth value of the tertiary industry in the region is RMB 499.198 billion, with a corresponding growth rate of 6.8%. The rapid development of industrialization and urbanization will lead to an increase in energy consumption in the city, from which it can be seen that in 2014 the energy consumption in the region was as high as 84.835 million tons, corresponding to a coal consumption rate of 72.5%, which is far above the national average. The majority of the end-use energy consumption is concentrated in the level 2 industry, mainly in coal consumption, while oil, electricity, and heat consumption are also relatively large.

4. Research Method and Data Sources

4.1. Regional Population-Economy-Resources-Environment Scheduling Forecast Model. The dynamics and complexity of the coordinated development of population, economy, and resources and environment in this region cannot be predicted based on a single conventional linear or nonlinear model of its future development trends. In this article, the parameters in the evaluation indexes are optimized by using a bilevel optimization model based on the scheduling and evaluation system of the population-economy-resource-environment association.

4.1.1. Establishment of the Index System and Determination of the Weights. In this article, the development evaluation index system of this region is mainly established with the goal of population-economy-resource-environment coordination, and the division of population development, economic development and resource-environment development is carried out based on bilevel optimization model. The corresponding indexes are combined by qualitative and quantitative methods, as shown in Table 1.

4.1.2. Coordination Degree Model. Coupling refers to the synergistic phenomenon due to the interaction and mutual influence between two or more systems and components, and the degree of bonding is a quantitative description of the degree of interaction and influence between systems and components. The synergistic forecast model for the population, economy, and resource environment established in this paper includes two parts: objective function and constraint conditions.

(1) Objective function: based on the concept of capacitive coupling in physics and the capacitive coupling coefficient model, the coordination degree model of population-economy-resource-environment (3-system) interaction is promoted.

$$D = (C \times T)^{1/2}. \tag{4}$$

In the above equation, D stands for the degree of coordinated development, which is [0, 1]. c stands for the degree of coupling, which reflects the level of synergy between the interactions of systems. T stands for the harmony index, which reflects the overall cooperative effect or

contribution of population, economy, and resource environment. C and T can be expressed as follows:

$$\begin{cases} C = \left\{ \dfrac{f(x) \cdot g(y) \cdot h(z)}{[f(x) + g(y)] \cdot [f(x) + h(z)] \cdot [g(y) + h(z)]} \right\}^{1/3}, \\[2em] T = \alpha \cdot f(x) + \beta \cdot g(y) + \gamma \cdot h(z). \end{cases} \tag{5}$$

In the above equation, the candidate quantities α, β, γ of the population-economic-resource-environment subsystem are finally set in this paper after the review of literature and the consultation of experts. $\alpha = 0.3$, $\beta = 0.2$, $\gamma = 0.5$; $f(x)$ is a function of population effect; $g(y)$ is a function of economic effect; and $h(z)$ is a function of resource-environment effect, which are shown in the following, respectively.

$$f(x) = \sum_{i=1}^{m} a_i x_i', \\ g(y) = \sum_{j=1}^{n} b_j y_j', \\ h(z) = \sum_{k=1}^{q} c_k z_k'. \tag{6}$$

In the above equation, x_i', y_j', and z_k' stand for positive numbers of specific indexes that represent the demographic-economic-resource-environmental characteristics, respectively. The weight of each index. The extreme value method is used for criterialization. The specific methods are described as follows:

$$x_i' = \begin{cases} \dfrac{x_i - \lambda_{\min}}{\lambda_{\max} - \lambda_{\min}}, & \lambda_{\min} \le x_i \le \lambda_{\max}, \quad x_i \text{ is a positive index } (i = 1, 2,), \\[2em] \dfrac{\lambda_{\max} - x_i}{\lambda_{\max} - \lambda_{\min}}, & \lambda_{\min} \le x_i \le \lambda_{\max}, \quad x_i \text{ is a positive index } (i = 1, 2,). \end{cases} \tag{7}$$

The original data processing method for y_j' based on the above method is $j = 1\ 2,3,4, k = 1,2,3,4,5,6$.

(2) Composition of constraint conditions: first, about the economic development constraints, the regional economic development status can be expressed as follows:

$$\text{GDP}_t = \text{GDP}_{t-1}(1 + k_{\text{GDP}}), \\ \text{GDP}_{rj_t} = \text{GDP}_{rj_{t-1}}\left(1 + k_{\text{GDP}_{rj}}\right), \quad \text{GDP}_{rj} \ge A_{\text{GDP}_{rj}}. \tag{8}$$

In the above equation, GDP_t stands for the regional GDP in year t, GDP_{t-1} stands for the regional GDP in year t-1, and k_{GDP} is the growth rate of regional GDP. With regard to GDP per capita in year t, $k_{\text{GDP}_{rj}}$ is the growth rate of GDP per capita, and $A_{\text{GDP}_{rj}}$ is the minimum GDP per capita required for the province.

Emission constraint of environmental pollutants: $W_t = W_{t-1}(1 + k_W), W_t \le W_{t-1}, W_t \le B_t$, in which W_t is the pollutant (SO_2/CO_2) emission in year t, W_{t-1} is the pollutant (SO_2/CO_2) emission in year t-1, k_W is the pollutant (SO_2/CO_2) emission growth rate, and B_t is the allowed pollutant emission in region in year t [4, 6].

Carbon emission intensity: $E_t = E_{t-1}(1 + k_E)$, $E_t \le E_{t-1}$, in which E_t is the carbon emission intensity in year t, E_{t-1} is the carbon emission intensity in year t-1, and k_E is the carbon emission intensity growth rate.

Forest coverage rate: $F_t = F_{t-1}(1 + k_F)$, $F_t \ge F_{t-1}$, in which F_t is the forest coverage in year t, F_{t-1} is the forest coverage in year t-1, k_F is the forest coverage growth rate, through ecological restoration and environmental protection and other measures, the regional forest cover in year $t \ge$ the regional forest coverage in year t-1.

(3) Division of the determination criteria for coordination degree: with regard to 3 major categories and 10 subcategories in the coordinated development of population, economy, and resources and environment association schedule, the transitional coordination, dysfunction and decline, each class based on the size of the population, economy, resources, and environment effect function is the population lag type, economic lag type, energy and environmental lag type, synchronous type four types (the details are shown in Table 2).

(4) Settings of the stages and index parameters: based on the current situation of the economy and society and the future development direction of resources and environment in the province, three stage schemes are established in this paper, that is, the standard stage, the stabilization stage, and the coordination stage, respectively.

(1) Baseline stage: rapid development of population and economy, with moderate improvement in the resources and environment

On the basis of the socioeconomic development in the 11th Five-Year Plan, the population regional production, rapid development of urbanization rate, industry and industry structure has a strong dependence on the level 2 industry coal, oil ratio also remains at a very high level. At this stage, the improvement in the energy efficiency has basically reflected the state of naturally oriented economic development and energy consumption, and it is relatively weak in the implementation of energy conservation and emission reduction measures. Environmental pollutants have yet to be controlled effectively.

- ⋆⋅⋅ population (in 10,000)
- —— Regional GDP (in 100 million yuan, based on the price in the current year)
- ⋅◆⋅ Growth rate of the population
- ⋅⋆⋅ Growth rate of the regional GDP

FIGURE 2: Diagram of demographic and economic development trends in the region.

TABLE 1: Scheduling evaluation index system and weights of the population-economy-resource-environment association in the province.

Target level	Criteria level	Index level	Nature of index	Weight
Comprehensive development level of population, economy, resources, and environment	Population development level	1. Population (million people)	−	0.8100
		2. Urbanization rate (%)	+	0.2100
	Economic development level 1. Gross regional product (in 100 million yuan)		+	0.2280
		2. GDP per capita (10,000 yuan/person)	+	0.1131
		3. Share of the secondary industry (%)	−	0.4710
		4. Share of the tertiary industry (%)	+	0.2280
	Resource and environment development level	1. Share of nonfossil energy (%)	+	0.1100
		2. Energy consumption intensity (t/10000)	−	0.2100
		3. Carbon emission intensity (in 10,000 yuan)	−	0.4100
		4. SO_2 emissions (million t)	−	0.1000
		5. CO_2 emissions (million t)	−	0.1000
		6. Forest coverage rate (%)	+	0.1100

(2) Robust development of population and economy, with a stable improvement of resources and environment: based on the standard stage, the growth rate of economy, population, and urbanization is slowed down, the reliance on industry and traditional primary energy is reduced, and energy-saving and low-carbon technologies are used to optimize the energy consumption structure and accomplish the goal of energy conservation and emission reduction. In this situation, the implementation of relevant energy conservation and emission reduction measures seeks to balance economic development and environmental improvement, which can basically reflect the state of economic development and resources and environment to be achieved by energy conservation.

(3) The coordination stage is highly similar to the stable development of population and economy, with the rapid improvement of resources and environment.

This stage is a comprehensive control stage, in which energy saving and emission reduction activities are carried out in the whole society, and the production and lifestyle of the population is comprehensively optimized. In addition, the economic development pattern and consumption pattern of the residents are improved. The energy structure and industrial structure are further optimized, and major breakthroughs are made in energy conservation and emission reduction measures and economic technologies on all fronts [7, 8]. This is basically an active effort to achieve the goal of economic development and the state of resources and environment.

Based on the above description, 12 index parameters such as population, urbanization rate, total regional production, GDP per capita, level 2 production ratio, tertiary production ratio, energy intensity, and nonfossil energy ratio are parameterized as stage elements (the details are shown in Table 3).

(1) Evaluation index system: based on the actual situation of the economic and environmental development and analytical modeling requirements of the county, the index decision follows the following principles: (1) Comparison of indexes is feasible; (2) identification of indexes is significant in the aspect of significance and differences; (3) indexes are highly independent of each other; and (4) the feasibility of index data collection. Based on the above principles, spatial variable analysis and correlation analysis were used to screen the indexes, as shown in the following equation:

$$C_{ij} = \frac{S_j}{X_j}, \quad (j = 1, 2, \ldots, 20). \quad (9)$$

In the above equation, C_{ij} stands for the coefficient of variation; S_j stands for the criteria deviation; and X_j stands for the mean value.

Based on equation (1) to determine the raw data belonging to the relevant indexes of each district and county, in addition to the indexes with large correlation coefficients, small spatial variation and identification of meaningful differences, the final 8 indexes that can reflect the economic environment and social interrelationship in the county. These are economic index system, environmental index system, and social development index system [9, 10]. The economic indexes include total industrial production ($X1$), gross domestic product per capita ($X2$), and GDP growth rate ($X3$). The environmental indexes include chemical oxygen demand emissions ($X4$), energy consumption per unit of GDP ($X5$), and pollutant emissions per unit of GDP ($X6$). The social development indexes include rural Engel coefficient ($X7$) and unemployment rate (%) ($X8$).

(2) Determination of the weighting of evaluation indexes: upon the determination of the weighting of

evaluation indexes, there will be increasing methods of subjective decision of weighting, such as the AHP method. The evaluation results are sometimes biased based on the subjective factors of human. Based on the information theory, the entropy value reflects the degree of disorder of information, the smaller its value, the smaller the disorder of the system, the greater the utility value of information; the larger that value is, the higher the disorder of the system and the smaller the utility value of the information.

For the initial matrix of n evaluation indexes for the m programs discussed in the above section, as the determination matrix is obviously an information carrier, the orderliness of the system information obtained through information entropy evaluation and its effects are used to determine the index weights eliminating the artificial interference of the weighting calculation if possible so that the evaluation results can be more practically consistent [11]. The calculation sequence is described as follows:

(1) The judgment matrix is established based on n evaluation indexes for m objects as follows:

$$R = (X_j)_{nm}, \quad (i = 1, 2, \ldots, n; j = 1, 2, \ldots, m). \quad (10)$$

(2) The decision matrix is normalized to obtain the normalized decision matrix as follows:

$$b_j = \frac{X_{ij} - X_{\min}}{X_{\max} - X_{\min}}. \quad (11)$$

In the above equation, each item is the most satisfied or the most dissatisfied under the same index (the smaller the better), that is, $X_{\max} X_{\min}$.

(3) Based on the definition of entropy, n evaluation index for m evaluation objects is the entropy of evaluation indexes as follows:

$$\mathrm{Hi} = \frac{1}{\ln m} \sum_{j=1}^{m} f_{ij} \ln f_{ij}. \quad (12)$$

In the above equation, $f_{ij} = b_{ij} / \sum_{j=1}^{m} b_{ij}$. When $f_j = 1$, $f_j \ln f_j$, different from the degree of disorder of information apparently reflected in the entropy, it is equal to 0 and does not match the actual situation. Hence, f_{ij} is further modified as follows

$$f_{ij} = \frac{1 + b_{ij}}{\sum_{j=1}^{m} 1 + b_{ij}}. \quad (13)$$

(4) The entropy weight of the evaluation index is calculated, which is in line with the actual situation.

(3) Establishment of the gray correlation model: for the convenience of analysis, the correlation model is established as follows:

TABLE 2: Determination criteria and classification system for the degree of coordinated development of regional population, economy, and resources and environment.

Classification	Degree of coordinated development	Level 1 criteria	Level 2 criteria
Interval of coordinated development	0.9~1	Superior coordination	
	0.80~0.89	Good coordination	
	0.70~0.79	Moderate coordination	
	0.60~0.69	Basically coordinated	
Interval of transitional reconciliation	0.50~0.59	Barely coordinated	
	0.40~0.49	On the verge of dysfunction and decline	① When $m = \min\{/(x), g(y), h(z)\}$, it is a lagged type, similar to $m = /(x)$, which is population lagged type.
	0.30~0.39	Mild dysfunction and decline	② When $/(x) = g(y) = h(z)$, it is a synchronous type for population, economy, and environment
Interval of dysfunction and decline	0.20~0.29	Moderate dysfunction and decline	
	0.10~0.19	Severe dysregulation and decline	
	0~0.09	Extremely severe dysfunction and decline	

(1) The optimal vector of the series is determined. As the original data are normalized and transformed into positive indexes, the optimal vector is obtained as follows:

$$G = (g_1, g_2, \ldots, g_n) = (f_{11} v f_{12} v \cdots v f_{1m}, f_{21} v f_{22} v \cdots v f_{2m}, \ldots, f_{n1} v f_{n2} v \cdots v f_{nm}). \tag{14}$$

In the above equation, v is the maximum operator.

(2) The gray correlation coefficient equation is used to calculate the correlation coefficient between the jth evaluation index and the optimal vector G, as shown in the following equation:

$$\xi_i(Y_i, G) = \frac{\min_i \min_j |f_{ij} - g_i| + \rho \max_i \max_j |f_{ij} - g_i|}{|f_{ij} - g_i| + \rho \max_i \max_j |f_{ij} - g_i|}. \tag{15}$$

In the above equation, the minimum difference between the two poles and the maximum difference between the two poles ρ-the decomposition coefficient is generally 0.5; that is, $\min_i \min_j |f_{ij} - g_i| \max_i \max_j |f_{ij} - g_i|$.

(3) The correlation R between the ith evaluation object b and the optimal vector G is calculated, as shown in the following:

$$R = \sum_{j=1}^{n} w_j \times \xi_i(Y_i, G). \tag{16}$$

(4) Output of the results: based on the economic environment data of the county in Shaanxi Province from 2000 to 2009, the original data of the indexes are processed dimensionless using official (2) and (3) to obtain the criteria data of the indexes. The entropy value assignment method is used to conduct calculation based on equations (12) and (13), in which

the weight of each index is shown as follows: $W_j = (0.114, 0.117, 0.123, 0.144, 0.128, 0.128, 0.140, 0.105)$.

Based on the normalized data, the series optimal vector $G = (1,1,1,1,1,1,1,1,1)$ tab is obtained. The above correlation coefficients are introduced into equation (16), and the correlation coefficient F is introduced into equation (15) to derive the status of the passing of the values of the coordination index of the economic, environmental, the social system subsystems, and the composite system from 2000 to 2009 (Figure 3).

5. Data Sources

The parameter values of evaluation indexes in this paper are set in accordance with the relevant literature such as the Statistical Yearbook of the Province, the economic and social development goals in the 12th Five-Year Plan, and the historical development experience of world economies.

5.1. Analysis of Results and Discussion. Based on the analysis of the overall development trend in this region, the growth trend in the standard stage and the stability stage from 2011 to 2030 presented a "U-shaped" trend. However, in the coordination stage, it mainly shows a development trend of increases year by year.

5.2. Analysis of Changes in the Time Series of the Coordinated Development Degree. With the gradual improvement of the economic level in the region, the level of science and

TABLE 3: Settings of the relevant parameters in the stage mode.

Classification	Degree of coordinated development	Level 1 criteria	Level 2 criteria
Interval of coordinated development	0.9~1	Superior coordination	
	0.80~0.89	Good coordination	
	0.70~0.79	Moderate coordination	
	0.60~0.69	Basically coordinated	
Interval of transitional reconciliation	0.50~0.59	Barely coordinated	
	0.40~0.49	On the verge of dysfunction and decline	① When $m = \min\{l(x), g(y), h(z)\}$, it is a lagged type, similar to $m = l(x)$, which is population lagged type.
	0.30~0.39	Mild dysfunction and decline	② When $l(x) = g(y) = h(z)$, it is a synchronous type for population, economy, and environment
Interval of dysfunction and decline	0.20~0.29	Moderate dysfunction and decline	
	0.10~0.19	Severe dysregulation and decline	
	0~0.09	Extremely severe dysfunction and decline	

Note: low, medium, and high stand for high growth rate, medium growth rate, and low growth rate, respectively. The parameters of the province are set based on the "12th Five-Year Plan"; the plan refers to the leapfrog plan of the key advantageous industries in the province, the establishment industry development plan of the province, the establishment industry development plan of the province in 2013, and the studies by scholars such as Lin Fude and Fu Jiafeng.

technology has also been developed in an unprecedented speed. In addition, the optimization of energy structure and energy utilization rate is also increasing year by year. In the situation of the coordinated development of the population-economy-resources-environment system, the growth of the regional economy in the standard stage and the stable stage has been improving from the historical low to zero in about 2030. Through comparison with the standard stage and the stable stage, the adjustment stage focuses more on energy saving and emission reduction activities in the whole society and proactively implements the rapid improvement of resources and environment through major breakthroughs in policy, economy, and technology in all aspects, and the degree of coordinated development has been maintaining an upward tendency [12, 13]. By 2030, the growth rate will be 0.64 (basically coordinated), which is 1.4 times that in 2010. The current stage represents the ideal model for the coordinated development of the regional population, economy, resources, and environment in this province (Figure 4).

5.2.1. Baseline Stage. The province is now in a period of steady urbanization. The population keep growing, with an average annual growth rate of about 0.2% and a declining population efficiency function (the details are shown in Figure 5). The economic development model at present is indispensable for the rapid development of industrialization. Under this background, the ratio of level 2 sector in the province is increasing with an average annual growth rate of about 0.6% industrial structure depends on level 2 sector. The economic efficiency is significantly lagging behind. Population and resource environment effects are not obvious. Until 2020, with the implementation of measures such as the improvement of energy use efficiency and nonfossil energy ratio, the emissions of SO_2 have been effectively suppressed with an annual average reduction of -1.14%. With this effect, the resource and environmental effect function increases slightly, reaching a peak in 2019.

However, with the economic and social development, CO_2 emissions increased significantly and offset the resource-environmental effect brought by the reduction of SO_2 emissions. Hence, the resource-environmental effect has been decreasing year by year subsequently.

Based on the analysis in the above sections, the economic development and energy consumption in the region are coordinated based on the baseline scenario development, which has ultimately kept the regional development in a low state, and the corresponding socioeconomic growth pattern is an extensive form. However, with the extension of time, the progress of resource and environment improvement lags far behind the economic and social growth rate, which makes the resource and environment growth efficiency unable to support, ultimately become a hindrance to the coordinated development of population-economy-resource and environment, and have a negative impact on the sustainable development of the whole society in the region.

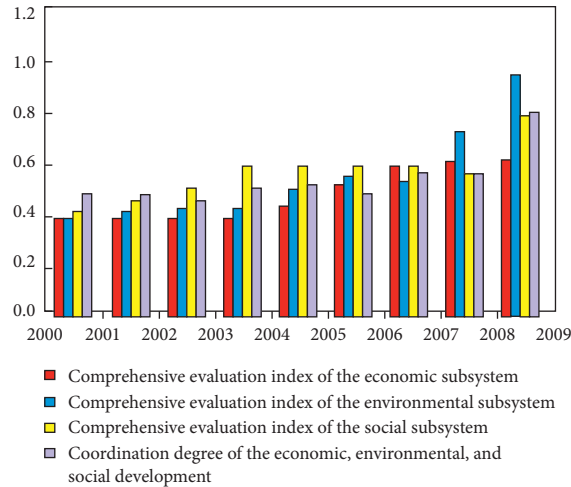
5.2.2. Stability Stage. In the stability growth stage of the region, the population growth trend presents a U-shaped trend of gradual development, as shown in Figure 6. The urbanization rate can be effectively controlled to some extent, and the population growth function can achieve a level lower than the reference value to some extent. The industrial structure can be effectively adjusted. Based on the economic growth of GDP, GDP per capita and the proportion of tertiary industry show an increasing trend every year. The economic growth trend achieved the minimum level of 0.242% in 2020 and started to increase year by year in the later period [14, 15]. The utilization rate of nonfossil energy will be effectively improved, and the growth rate of pollutant emission will be suppressed. The annual average growth rate of SO_2 and CO_2 emission from 2010 to 2020 was reduced from −80% to 2.6%, which was a decrease of 20.5% and 37.2%, respectively, compared with the standard stage, with a more significant effect on resources and environment.


FIGURE 3: Evolution of the economic-environmental-social system coordination index values in the county.

FIGURE 4: Changes in the time series of the coordination development degree at different stages: stages of population-economy-resources-environment scheduling and comparative analysis.

With the joint effect of population, economic, and resource-environmental effect functions, the stability stage of coordinated development degree has the same tendency of change as the baseline stage, with a U-shaped tendency of decreasing first and then increasing. Timing and size of its trough tips are significantly different from those in the baseline stage. Different from the criteria scenario, with the economic benefits of stable development, the value of the trough in 2020 was 0.478. However, by 2027, the value of development within the region will increase to 0.511, after which the development of the region will start to enter the stage of uncoordinated development, when the economic growth rate hits the lowest level among the three. This stage between 2010 and 2026 is on the verge of stagnation in the economic development.

5.2.3. Coordinated Development Stage. Through the overall optimization of production, change of lifestyle, and industrial structure in this region, the effective control of population growth in the region is carried out multiple times. In addition, under the premise of effective control while achieving the increase of urbanization level at the same time, the trend of population growth from 2010 to 2030 does not present a valley phenomenon. However, with the implementation of the resource and environmental improvement policies, the average annual growth rate of the emission of SO_2 and CO_2 is maintained at about -1.1%; and with the significant control of pollutant emissions, the energy efficiency function can always keep a significant growth trend, with the robust improvement in the annual growth. In 2027, the economic efficiency in this region is the lowest among
Figure 5: Changes in the coordination degree at the baseline stage.

Figure 6: Changes in the coordination degree at the stability stage.

the three. However, in 2028 and 2030, the demographic effect and resource environment were eliminated. Hence, the development was the fastest among the three. From 2024 (0.0.6%) to 2026 (0.622%), it will be the period of relatively backward economic development; from 2027 to 2029, it will be the primary coordinated development with backward population, and 2030 will start to enter the primary coordinated development period with stagnant growth in the resources and environment (Figure 7).

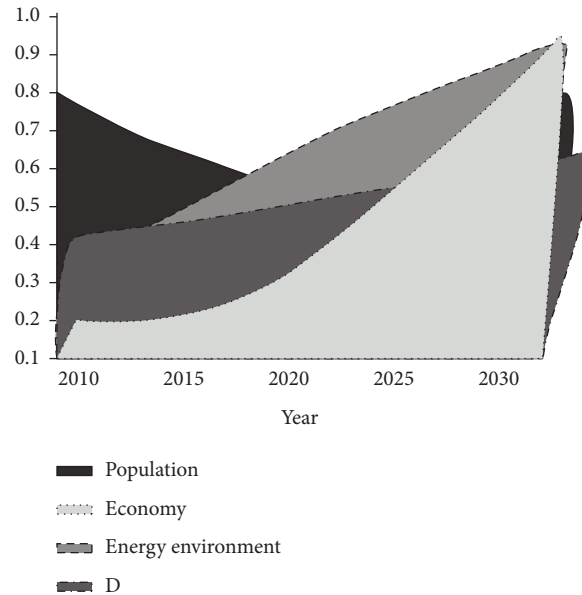
Based on the trend diagram in Figure 7, the coordinated stage development phase occurs at different stages of production effects and profit lag can be obtained. However, as the development trend of population, economy, and resources and environment in the region gradually approaches 1, the evaluation indicates that the overall situation gradually moves towards coordinated development and eventually enters the model of coordinated development of population, economy, resources, and environment.


FIGURE 7: Changes in the coordination degree at the coordination stage.

6. Conclusions

In this article, a bilevel optimization model is used to establish an evaluation system for the coordinated development of population, economy, resources, and environment within the region, and the established evaluation index system is used to carry out accurate forecast for the economic development within this region. Through the experimental analysis, it can be known that for the purpose of achieving the coordinated development of population, economy, resources, and environment in this region, the effective regulation of urbanization development level should be carried out in the aspect of population growth. In the aspect of economic benefits, it is necessary to accelerate the speed of economic transformation in the region and optimize the industrial structure. In the aspect of resources and environment, it is necessary to develop and utilize nonfossil energy effectively and fully improve the utilization rate of resources and energy. In this way, the coordinated and rapid development among population, economy, resources, and environment in the region can be achieved gradually.

Quality Evaluation Model for Smart City Social Sports Information Cloud Service

Lan Zhang [ID]

Department of Sports and Arts, Zhejiang Yuexiu University, Shaoxing 312000, China

Correspondence should be addressed to Lan Zhang; 19992009@zyufl.edu.cn

With the continuous development of social economy, social sport is more and more valued and favored by the people as a universal and nationwide sport, but it should be noted that social sport involves a wide range of aspects, but due to its particularity, it is also constrained by economic development. In view of these needs and limitations, three technical methods of entropy method, RSR (rank-sum ratio), and TOPSIS are introduced, to sort out the development of social sports, national physical development, social sports guidance, and the number of people to be measured in various places based on the relevant technologies of smart cities in this paper, realize the application analysis of social sports in the public service level. This paper aims to provide a scientific evaluation and evaluation method for social sports information cloud services. The results of simulation experiments show that the evaluation of social sports information cloud service quality based on smart cities is effective, and the comprehensive application of methods can be implemented perfectly, and the further promotion and popularization of social sports services can be realized.

1. Introduction

With the continuous development of social economy, physical exercise has become the main way of sports that people are more enthusiastic about, such as running, climbing, and cycling [1, 2]. On the one hand, sports can improve the physical fitness of everyone but also can ensure the popularization of sports methods. For social sports, it is a systematic project, covering a wide range; meanwhile, with the development of the economy, its connotation and corresponding content have changed, especially relative to the subjective judgment of the people [3, 4]. Therefore, how to effectively and objectively evaluate social sports is a problem to which industry scholars attach great importance [5, 6]. Many scholars have tried to conduct evaluation research of social sports from different perspectives, such as constructing a five-dimensional index system of government responsibility, investment, service benefits, social feedback, and value of social sports services. Through iterative calculation of methods, comprehensive evaluation is performed, such as constructing an index system covering

public participation satisfaction, public service input, efficiency, etc., using AHP method to evaluate social sports services, and providing corresponding decision support for government decision-making [1, 7]. In addition, some scholars conduct surveys, statistics, and analysis of different residents based on whether the audiences they serve are satisfied through questionnaires, visits, and consultations and other methods to reflect the popularity of social sports development from the perspective of the audience and whether there are many problems in the enjoyment of the audience, etc. [8, 9].

However, it is worth noting that, due to the restrictions and limitations of data sources, these studies are often conducted based on surveys, visits, questionnaires, etc. The audience's thinking time and response time are relatively concentrated or less, so the survey result may not completely represent their own true feelings [10, 11]. The development of cloud computing, Internet of Things, big data, and other technologies has promoted the continuous improvement of data collection, storage, analysis, mining, and other technologies. To a certain extent, it can solve the problem of

shortage of manpower, less data sharing, unbalanced equipment, and the limited right enjoyed by audience [12, 13]. Therefore, in view of these needs and limitations, the "Internet +" technology is introduced by trial in this paper, through the use of entropy method, rank-sum ratio method, TOPSIS, and other three technical methods, combining the status quo of social sports public services, in order to construct the corresponding social sports service evaluation index, to promote the transformation of social sports from traditional artificialization l to intellectualization, explore and solve the problems encountered by the people in social sports, and aim to improve the quality and effect of the public services of social sports for the people.

2. Research Objects and Methods

2.1. Research Object. The effectiveness of the method under the smart city technology can be verified through selecting certain 11 areas of the experimental area as the research object of the social sports public service level.

2.2. Research Method. By selecting the corresponding latest survey data, the development level of social sports, the number of people to be tested for national physique, the number of sports activities in the year, social sports groups, and other indicators are analyzed, compared, and calculated through selection and integration of corresponding current survey data, integration of Internet mobile phone signaling data, statistical yearbook data, and other data for summary, and the specific statistical results are shown in Figure 1.

For the analysis of social sports indicators, quantitative and qualitative analysis can be carried out in the following ways, including literature method, consultation and interview method, field investigation, and practical analysis method [12, 13]. Among them, the literature method is for summarizing, sorting, and analyzing, to provide a research basis and ideas for quantitative analysis of corresponding indicators by use of existing academic papers, public news reports, and other materials, while the interview method is to obtain the corresponding attitude and understanding of social sports services through the direct communication with audience or corresponding field experts about some questions [14, 15]. On-site inspections are to conduct on-site investigations of residents through visits and reading materials to obtain the most direct evaluation based on the distribution of equipment related to social sports [16, 17]. The logical approach is to conduct analysis and inverting according to the collected relevant data and finally get the corresponding index evaluation analysis.

Figure 1: List of evaluation index values of social sports public service level in some regions.

Based on clarifying the relevant coverage of the index, the corresponding evaluation and analysis are carried out continuously.

2.2.1. Entropy Method. The entropy method is an objective and weight-based method, which is used to confirm and calculate the weight of the corresponding index. For diversified metrics, entropy is a specific method that can determine the weight. Because of these abovementioned characteristics, it can be used to clarify the weight determination of social sports and determine the weight evaluation value of social sports public services through the corresponding data sequence.

To conduct an effective social sports cloud service quality evaluation, the specific steps are mainly as follows:

(1) Orienting at the test area: a diversified evaluation index of social sports is constructed, and a matrix is used to make judgments, among which, $R = (X_{ij})_{nm}$, $(i = 1, 2, \ldots, n; j = 1, 2, \ldots, m)$.

(2) Normalize the judgment matrix R to obtain the normalized judgment matrix $R' = (Y_{ij})_{nm}$.

The larger the value of the evaluation index, the better in this research. Therefore, the calculation formula is shown as follows:

$$Y_{ij} = \frac{x_{ij} - x_{\min}}{x_{\max} - x_{\min}}. \tag{1}$$

According to formula (1), the normalized matrix is calculated as

$$Y_{ij} = \begin{bmatrix} 0.3011 & 0.5861 & 1.0000 & 0.0000 & 0.0203 & 0.3031 & 1.0000 & 1.0000 & 0.3832 \\ 0.5774 & 0.3483 & 0.2853 & 0.1792 & 0.1874 & 0.4492 & 0.0411 & 0.0432 & 0.5661 \\ 0.3962 & 1.0000 & 0.1982 & 0.0255 & 0.0911 & 0.0000 & 0.0072 & 0.0022 & 0.4152 \\ 0.000 & 0.3722 & 0.1113 & 0.7694 & 1.0000 & 0.8104 & 0.0593 & 0.1242 & 0.8862 \\ 0.5771 & 0.2412 & 0.0681 & 0.1532 & 0.0451 & 0.9321 & 0.1360 & 0.0483 & 1.0004 \\ 1.000 & 0.7011 & 0.8243 & 0.6151 & 0.0242 & 0.554 & 0.3392 & 0.3041 & 0.7865 \\ 0.9311 & 0.1511 & 0.0251 & 0.0253 & 0.0372 & 0.5882 & 0.0000 & 0.0000 & 0.4526 \\ 0.8445 & 0.1159 & 0.1586 & 1.0000 & 0.0000 & 0.3956 & 0.1053 & 0.0171 & 0.7422 \\ 0.3792 & 0.1443 & 0.1051 & 0.3331 & 0.0021 & 0.2875 & 0.0064 & 0.0021 & 0.4713 \\ 0.9911 & 0.3235 & 0.3972 & 0.9482 & 0.4011 & 1.0000 & 0.0172 & 0.0012 & 0.5413 \\ 0.3101 & 0.0000 & 0.0000 & 0.1021 & 0.0222 & 0.5314 & 0.0080 & 0.0063 & 0.0000 \end{bmatrix}. \tag{2}$$

(3) The calculation formula for calculating the entropy of the jth evaluation index is shown as follows:

$$H_j = \frac{1}{\ln n} \left(\sum_{i=1}^{n} f_{ij} \ln f_{ij} \right). \tag{3}$$

Among them, it can be calculated by

$$f_{ij} = \frac{1 + Y_{ij}}{\sum_{i=1}^{n} (1 + Y_{ij})}. \tag{4}$$

(4) Carry out the sparse calculation of entropy weight on the basis of formula (4). The specific calculation formula is shown as follows:

$$w_j = \frac{1 - H_j}{m - \sum_{j=1}^{m} H_j}, \tag{5}$$

($\sum_{j=1}^{m} w_j = 1$; $0 \le w_j \le 1$). The calculated entropy weight coefficient is the weight.

Based on the above calculation steps, the determined weights of the evaluation indicators are shown in Figure 2.

2.2.2. TOPSIS Method. The TOPSIS method is a diversified decision-making method, which uses the distance between the positive and negative TOPSIS and the object to be measured for quantitative evaluation and ranks them correspondingly in terms of superiority and inferiority, which is extremely effective in multiobjective decision-making [18, 19].

The TOPSIS method is a multiattribute decision-making method. Its basic idea is to sort the advantages and disadvantages by calculating the distance between the evaluation object and the TOPSIS (X^+) and negative TOPSIS (X^-). According to this method, only each utility function is required to have the monotone increasing (or descending) characteristics, which is a commonly used effective method in multiobjective decision analysis.

2.2.3. RSR Method. The rank-sum ratio method is to obtain a dimensionless statistic RSR through rank conversion in a matrix of N rows and M columns (M evaluation indicators) and rank the advantages and disadvantages of evaluation objects according to the RSR value.

First, a data analysis matrix for different evaluation indicators of social sports oriented at the experimental area is constructed. Because different evaluation indicators have different meanings and dimensions, the indicators are required to be normalized to achieve unified contrast and comparison. The specific normalization processing is shown in the following formula:

$$Z_{ij} = \frac{X_{ij}}{\sqrt{\sum_{i=1}^{16} (X_{ij})^2}}. \tag{6}$$

In the formula, the value range of i is [1, 11], and the value range of j is [1, 9]. According to the above formula and method, the matrix of the normalized evaluation index of social sports public service level is solved, and the specific expression is expressed by Z:
FIGURE 2: Entropy weight of evaluation index for sports public service level.

$$z = \begin{bmatrix} 0.2901 & 0.3844 & 0.7042 & 0.0253 & 0.0242 & 0.1842 & 0.9121 & 0.9453 & 0.1921 \\ 0.3012 & 0.2314 & 0.2013 & 0.1232 & 0.1752 & 0.2438 & 0.0622 & 0.0515 & 0.2752 \\ 0.2941 & 0.6504 & 0.1394 & 0.0413 & 0.0912 & 0.0611 & 0.0321 & 0.0132 & 0.2044 \\ 0.2782 & 0.2471 & 0.0795 & 0.4381 & 0.9023 & 0.3922 & 0.0853 & 0.1261 & 0.4221 \\ 0.3012 & 0.1624 & 0.0482 & 0.1092 & 0.0523 & 0.4424 & 0.1542 & 0.0513 & 0.4723 \\ 0.3181 & 0.4592 & 0.5815 & 0.3565 & 0.0321 & 0.2832 & 0.3352 & 0.2941 & 0.3714 \\ 0.3151 & 0.1062 & 0.0182 & 0.0412 & 0.0442 & 0.3013 & 0.0362 & 0.0141 & 0.2251 \\ 0.3124 & 0.0813 & 0.1121 & 0.5613 & 0.0111 & 0.2223 & 0.1231 & 0.0223 & 0.3523 \\ 0.2932 & 0.1032 & 0.0743 & 0.2054 & 0.0121 & 0.1761 & 0.0341 & 0.0123 & 0.2331 \\ 0.3181 & 0.2181 & 0.2806 & 0.5341 & 0.3632 & 0.4703 & 0.0452 & 0.0142 & 0.2642 \\ 0.2903 & 0.0072 & 0.0002 & 0.082 & 0.0312 & 0.2752 & 0.0362 & 0.0132 & 0.0242 \end{bmatrix}. \tag{7}$$

3. Simulation Experiment

It is not only a reform of business management, but also a reform and improvement of external services $z =$ to introduce cloud computing technology into the social sports management business. The improvement of these two aspects requires the transformation of traditional social sports and services from passive mode to active one. The corresponding social sports intelligent subject service system is designed in this paper, and the specific structure is shown in Figure 3.

According to the overall architecture shown in Figure 3, the social sports smart service system constructed in this article is mainly divided into three parts, which are distinguished as cloud providers, social sports management business personnel, and users according to different object-oriented aspects, respectively. When constructing a social sports smart public service system, full consideration should be given to the application requirements of users as the most basic and the largest number of users.

Based on the overall architecture, it is necessary to consider the hardware and software environment required for deployment. The infrastructure mainly includes hardware environments such as servers and storage, as well as operating network environments, disaster recovery backups, etc. These software and hardware environments need to be

fully utilized; construct the cloud service platform accordingly with this technology. The specific process diagram is shown in Figure 4.

As shown in Figure 5, the first is the cloud layer, which is the layer that relies on cloud infrastructure. It mainly provides storage, hardware, memory, and other environments. With these infrastructures, the integrity and security of the platform can be ensured. Transfer of service providers need to be carried out in the middle of the cloud for the social sports, to coordinate the management of users and service owners and provide external services on mobile terminals or PC terminals through the network environment.

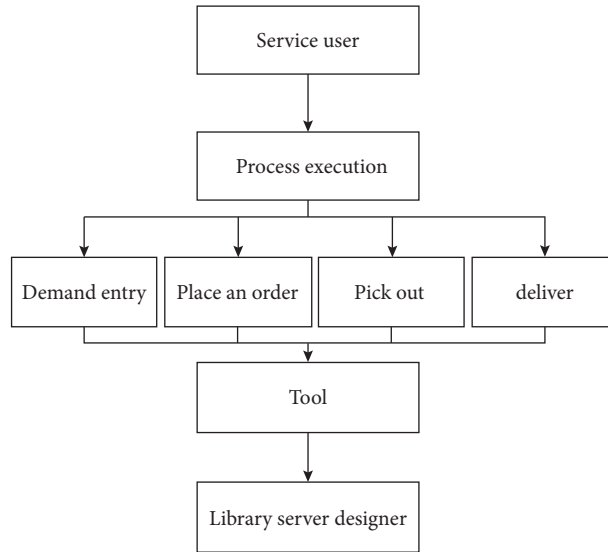
The next is the library layer of the model. This part is to realize the relationship between social sports itself and users. The schematic diagram is shown in Figure 5. Through the analysis of user needs, it ensures that the service has comprehensively changed orientating at the actual social sports and user needs. For the services provided by social sports, users have highlighted individual needs, which requires cloud computing to give full play to its advantages and provide more demanding needs. In this context, based on cloud computing technology, the cloud platform of social sports can analyze user interests, adjust service goals of social sports, and optimize service methods and content based on habits and browsing history of users.


Figure 3: The overall architecture of the cloud service platform.

Figure 4: Cloud service platform model.

The last is the user layer. For social sports, users are the foundation and core of the entire platform. According to users' information sharing and use, to achieve the purpose of learning and creation, their individual needs should be fully considered.

According to the data collected above, the ideal positive and negative solutions in the evaluation indicators of the social sports information cloud service quality of smart cities can be calculated.

3.1. The Low Actual Executive Force of Urban Community Sports Public Service Policies and Regulations. The public

service quality evaluation of social sports according to the corresponding community is shown in Figure 6.

From the results, it can be seen that the proportion of residents being very satisfied is less than 10%, the proportion of being relatively satisfied is about 30%, and the sum of general and dissatisfied residents has exceeded 50%. From the collected data, it can be seen that corresponding policies are not implemented for social sports, and there are some weaknesses in publicity and popularization. Therefore, the residents are not satisfied with the quality of public services of social sports.

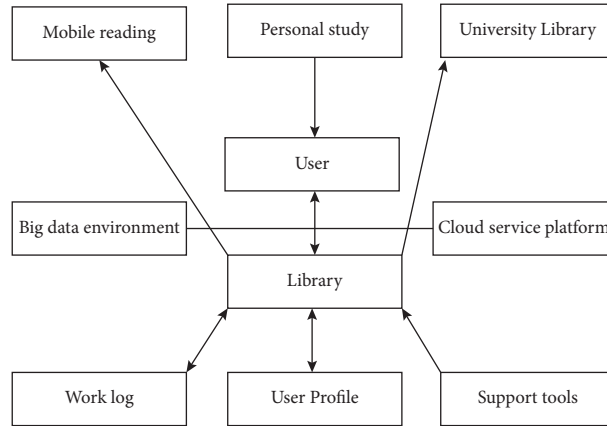
It can be seen from Figure 7 that most of the funding sources of social sports are government investment and


FIGURE 5: Schematic diagram of social sports interaction (taking borrowing sports books from library as an example).

FIGURE 6: Statistics of residents' satisfaction with the quality of public services of community sports ($N = 600$).

FIGURE 7: Main sources of service funding of community sports ($N = 12$).

support, and a small amount of funding comes from corporate donations. Therefore, most of the social sports venues still require a large amount of investment. It is precisely because of the insufficient funding that there are fewer public service facilities for social sports and the reduction of service experience.

3.2. The Low Implementation Speed and Efficiency of Urban Social Sports Public Services.

The so-called implementation efficiency of urban community sports public services refers to whether the principal part of urban community sports public services can efficiently satisfy the public's various sports needs in the process of providing various sports services to the public.

Through investigation and research, it is found that there are obvious regional differences in the quality of social sports public services in cities, which are restricted by local social development. For example, in areas with more developed economies, the efficiency and quality of public services for social sports are relatively satisfactory and can basically meet the needs of social sports of various audiences, but the relative execution efficiency in other areas is significantly lower.

In the construction of cloud service platform guarantee capacity, virtualization technology is the core technology for cloud resource management, scheduling, and transformation into platform guarantee capacity. In platform construction, virtualization technology should be used to realize on-demand allocation and unified scheduling of cloud resources, to strengthen the fine-grained division of infrastructure resources, cloud computing resources, cloud storage resources, cloud system platform resources, and cloud software resources, and to combine services. The characteristics of the object and service content, adopting different management standards, allocation strategies, packaging methods, and usage methods, really strengthen the management and control efficiency of virtual resources; secondly, the application security, reliability, and trustworthiness and reliability of the cloud service platform should be improved. Verification, under the premise of ensuring the cloud service provider has a high degree of credibility and security, realizes the dual identity authentication and security management of the cloud service provider and the platform user; third, the compatibility of the cloud service platform system and software should be strengthened. Availability, support of sports cloud services, availability of cloud applications and databases, cloud service migration capabilities, and capacity building ensure that traditional sports can efficiently, safely, orderly, and economically migrate to the cloud computing environment according to the athletes' cloud use needs. In the construction of the IaaS service platform, the user's ease of use and manageability of IaaS resources should be emphasized to ensure that users can obtain IaaS resources through Web application services. At the same time, administrators can use the IaaS platform monitoring and management system to quickly realize the creation, deployment, allocation, scheduling, management, and monitoring of IaaS resources

and ensure the load balance of the IaaS cloud service platform; secondly, the intelligence of the IaaS service platform resources should be strengthened. Dispatching and automated scheduling capabilities ensure that users can dynamically use resources in an efficient, flexible, scalable, and automatic way according to cloud application requirements and reduce usage costs by paying for usage; third, the IaaS service platform should have a larger system scale and application. Security, through the management and monitoring of resource pools, user resource allocation and scheduling, resource pool architecture optimization, and refined application operations of data transmission guarantee networks and the intensive management of IaaS cloud resources can be realized to ensure the security, efficiency, and efficiency of the IaaS platform, hostable and easy to expand. In the cloud computing environment, the data center has the characteristics of complex infrastructure structure, difficult management of cloud platforms and application systems, increased threats from the Internet, and cloud service platform resources shared by multiple users, and the cloud platform application service system is in a complex network environment middle. At the same time, cloud computing resources are logically divided and shared by multiple users in the distribution and use methods, leading to malicious users who may obtain control rights of the cloud system platform through illegal means and steal important data and user confidential information of the cloud system.

3.3. Failure to Give Full Play to the Role of Sports Clubs and Lack of Fitness Guidance.

With the development of social economy, social sports corporation plays an important role in the important process of sports popularization and sports reform.

As shown in Figure 8, social sports groups do not fully cover the audience. Many residents do not even know about such organizations, accounting for about 30%. A small number of people participate in social sports activities. From the results in Figure 8, it is found that the audience is not very enthusiastic about participating in the corresponding social organizations.

As the core of social sports, social sports instructors play an important guidance role in public services. From the summary results in Figure 9, it can be found that, in the actual guidance process, those exceeding 6 times account for about 15%, which shows the role of social sports instructors in the actual operation process is too weak, which restricts the audience's enthusiasm for participating in sports.

3.4. The Low Type, Frequency, and Participation of Urban Community Sports Public Service Activities.

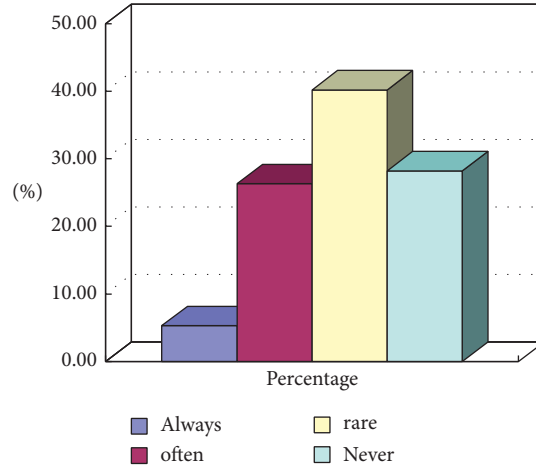
The proportion in population of sports that young people like is relatively small. Due to the limitation of venues and equipment, the development of this type of sports is restricted. Community sports public service departments should consider increasing the construction of venues and equipment to increase the number of people participating in community sports, meet the needs of various groups of people, and


FIGURE 8: Statistics on the frequency of community residents participating in club activities.
FIGURE 9: Statistics of the number of times that city community fitness instructors give community guidance.

continuously improve the quality of urban community sports services.

3.5. Calculate the Distance between Each Evaluation Index Data and X^+, X^-.
The calculation formula for the distance d_i^+, d_i^- between each evaluation index data and X^+, X^- is shown in the following formulae:

$$d_i^+ = \sqrt{\sum_{j=1}^{9} \left(Z_{ij}' - X_j^+ \right)^2}, \qquad (8)$$

$$d_i^- = \sqrt{\sum_{j=1}^{9} \left(Z_{ij}' - X_j^- \right)^2}, \qquad (9)$$

where $i = 1, 2, 3, \ldots, 16$ and $j = 1, 2, 3, \ldots, 8$.

Based on this, the public service level of sports is evaluated and ranked. The specific calculation is shown in formula (10), and some results are shown in Figure 10:

$$C_i = \frac{d_i^-}{d_i^+ + d_i^-}, \qquad (10)$$

where $i = 1, 2, 3, \ldots, 16$.

Through simulation experiments, the results show that the variance consistency between the classifications of each indicator is relatively good, and the differences between the files are statistically significant, and the evaluation of social information cloud service quality under the background of smart cities is effective.

(1) Build a national fitness social sports information service cloud platform that includes public and private clouds, and divide social sports cloud storage into corresponding public cloud storage and private cloud storage: public cloud is built on the Internet,

FIGURE 10: List of C_i values and rankings of sports public service levels in some regions.

and social sports management is built on a private cloud. In the government Intranet, all kinds of social sports management data are published on the Internet and Intranet through the form of services and can be integrated with various services such as government affairs and office running in the local area network and wide area network, so as to achieve the sharing of social sports management information and computing resources. The goal of the cloud platform can also provide a full range and multiangle for different users such as the State Sports General Administration, the Provincial Sports Bureau, the Municipal Sports Bureau, the Sports Guidance Center, the sports fitness site, the fitness team, the sports instructor, the seller, the sports venue, and the general public service.

(2) Build a national fitness social sports big data center, and store site information, social instructor information, training methods, training information, and other structured and unstructured information on a big data platform (HDFS, HBase, etc.) to form an authoritative large-scale database covering all aspects of national fitness and social sports to provide data sources for national fitness management, resource allocation, fitness guidance, and fitness evaluation. An authoritative large database covering all aspects of national fitness and social sports serves as a data source for national fitness management, resource allocation, fitness guidance, and fitness evaluation.

(3) Focus on the four core issues of fitness venues ("where to practice"), fitness people ("who will practice"), social instructors ("who to practice"), and fitness methods ("how to practice"), the design includes basic data management, information collection, data management, data query, data visualization, statistical analysis, data mining, decision support, and other major functions of the city's

national fitness social sports information service system.

(4) Use object-oriented programming language to develop the corresponding C/S mode background management system (C# language), B/S mode online service website (C# language), and mobile phone APP software (Java language), supporting two-dimensional code scanning is free to download and update automatically. Both the website and the mobile APP can quickly access various fitness project guidance materials ("how to practice"), and the management system is responsible for the maintenance and management of "where to practice," "with whom to practice," and "how to practice" related information. The actual application effect of the platform shows that the information platform has completed the foundation of 2,697 fitness sites and 21,295 social sports instructors at all levels in Dalian (84, 1731, 6,989, and 13,421 people at the national, first, second, and third levels). Information management greatly reduces the workload of managers and at the same time provides millions of intelligent information services for tens of thousands of fitness people. Users access the cloud platform through desktop systems, websites, and mobile apps (Android) and use cloud map services and cloud information services among them. In the subject of "who will practice," the public can use interactive applications such as online quick query to solve "where to practice" (find sites/venues), "with whom to practice" (recommend social instructors based on fitness programs), and "how to practice" (push learning materials according to fitness programs). Search for fitness sites, instructors, fitness paths, etc. based on location-based services through maps, and select the best fitness activities, fitness venues, and travel methods.

(5) The social sports service platform designed and constructed based on cloud computing, "Internet +," and other technologies is essentially a loosely coupled architecture, which can be flexibly connected with existing systems and new systems in the future and ultimately can achieve "data in the cloud." The new application service model of "sports by your side, applied in your hands" can satisfy the internal service model and external service model. "Unmanned guidance" issues practically introduce cloud computing, big data, Internet + and other thinking and technical methods into national fitness services, realize the transformation of national fitness services from artificial to intelligent, and effectively improve the public service quality of national fitness.

(6) Provide a reference for building an "Internet +" smart sports information service platform with authoritative data support and persistent services, and ultimately make it a part of smart sports and smart cities.

4. Conclusions

With the continuous development of social economy, people are paying more and more attention to sports. As a national sport, social sports public service industry is valued. Aiming at how to evaluate social sports public services, the relevant technologies of smart cities is introduced in this paper, based on TOPSIS, rank-sum ratio, entropy method, and other methods, social sports instructors, the number of people to be tested, and other analysis index systems are constructed by trial, and they are divided by classifying, to explore the public service level of social sports, aiming to explore the evaluation of cloud service quality of social sports information in the context of smart cities. The simulation results show that the relevant technologies of smart cities are effective, can support the quality evaluation of social sports information cloud service, and can promote the further popularization of social sports.

In this paper, a high-level semantic recognition model is used to parse the video content of human sports under engineering management, and the stream shape of the previous layer is embedded in the convolutional operation of the next layer, so that each layer of the convolutional neural network can effectively maintain the stream structure of the previous layer, thus obtaining a video image feature representation that can reflect the image nearest neighbor relationship and association features. The method is applied to image classification, and the experimental results show that the method can extract image features more effectively, thus improving the accuracy of feature classification. Since fine-grained actions usually share a very high similarity in phenotypes and motion patterns, with only minor differences in local regions, inspired by the human visual system, this paper proposes integrating visual attention mechanisms into the fine-grained action feature extraction process to extract features for cues. Taking the problem as the guide, we formulate the athlete's tacit knowledge management strategy and select the distinctive freestyle aerial skills national team as the object of empirical analysis, compose a more scientific and organization-specific tacit knowledge management program, exert influence on the members in the implementation, and revise to form a tacit knowledge management implementation program with certain promotion value. Group behavior can be identified by analyzing the behavior of individuals and the interaction information between individuals. Individual interactions in a group can be represented by individual representations, and the relationship between individual behaviors can be analyzed by modeling the relationship between individual representations. The performance improvement of the method on mismatched datasets is comparable between the long-short time network based on temporal information and the language recognition method with high-level semantic embedding vectors, with the two methods improving about 12.6% and 23.0%, respectively, compared with the method using the original model and with the *i*-vector baseline system based on the support vector machine classification method with radial basis functions, with performance improvements about 10.10% and 10.88%, respectively.

1. Introduction

With the continuous development of information technology, the way people obtain and store massive video information keeps developing towards diversification, and video information gradually becomes the mainstream multimedia data carrier. In the context of huge video data resources, users face the challenge of how they can efficiently retrieve video resources according to their interests [1]. Therefore, it is necessary to classify and organize the massive video resources intelligently to facilitate users to retrieve according to their preferences. Video semantic analysis technology can annotate and classify important semantic information in videos, and users can retrieve it according to their preferred categories, which improves the efficiency of users' access to information. In addition, the host-based implementation of video semantic analysis technology can replace manual annotation work, reducing many human resources and improving information utilization. Video semantic concept analysis refers to the generalized description of video content after obtaining video sequences, and the content of events, scenes, objects, and so forth is the

multicategory semantic information contained in semantic concepts. A large amount of video data has large intraclass variations for the same action class, which may be caused by background clutter, viewpoint changes, and movement speed and style [2]. In particular, the feature information generated by the deep learning model is very large. Only when the attention mechanism is used in the huge feature space can the model extract more effective features and discard useless information. The high dimensionality and low resolution of the videos further increase the difficulty of designing efficient and robust recognition methods. Although traditional manual annotation methods can achieve the understanding and description of video semantic concepts to a certain extent, the time and labor cost of manual annotation are huge, subjective, and difficult to cross the semantic gap between the underlying features and the semantic understanding of video data, and its annotation speed cannot achieve efficient classification and organization of video data [3]. Therefore, in recent years, researchers have focused their research on how they can automatically access the semantic concepts of video data and annotate, classify, and organize rich video data. This research has significant academic and applied value and helps to improve video management techniques to make them more complete and more efficient.

Video semantic concept analysis is a key and difficult area in the field of machine learning and pattern recognition, where video data can be efficiently and intelligently retrieved and organized by recognizing and understanding the main events, scenes, and objects in the video. In recent years, with the rapid development of technology and the improvement of the computing power of hardware devices, the way of video acquisition has become faster [4, 5]. Video retrieval is the process of finding a match in the video database according to the user's textual description according to a specific algorithm and filtering all videos that match the user's needs according to some qualifying conditions. Group behavior recognition technology can derive labels for crowd scene images that can provide clues for retrieval of images and videos of group scenes. The advancement of group behavior recognition technology is a great boost to crowd scene classification, labeling, and retrieval. With the popularity of electronic devices, especially mobile electronic devices such as mobile phones, the change in people's lifestyles, and the need to record their productive lives, a large amount of image and video data has been generated. However, it is not a simple task to manage and utilize these huge amounts of images and data [6]. A good starting point can not only prevent the gradient descent algorithm from falling into the local extreme point which is difficult to jump out of but also reduce the time to find the global optimal solution, if the initialization point is close enough to the optimal solution. Current video retrieval technology relies heavily on users submitting and sharing videos along with video subject descriptions. This is difficult to achieve in real time, and it is difficult to get down to the specifics, as describing specific details is tedious and time-consuming, and only based on image and video analysis techniques can achieve real-time frame-by-frame analysis. Group behavior recognition techniques are of great interest for real-time frame-level video classification retrieval of crowd scenes.

Classification and detection of video-based actions is an important research topic in the field of computer vision, which has a very wide range of applications in intelligent human-computer interaction, video surveillance, telemedicine, and other fields. The difficulties of traditional action analysis tasks mainly come from several aspects: the differences arising from the same action performed by different people; the influence of environmental factors, such as occlusion, viewpoint changes, lighting differences, and dynamic background interference; and the ambiguity in defining the starting and ending points of the action. However, the existing recognition and detection performance still falls far short of the requirements for accuracy in practical applications. The reason for this is that, on the one hand, the number of action classes in the existing dataset is limited and cannot cover all actions in realistic scenes, and the definition of the classes is relatively coarse, so the models trained on the coarse-scale action classes are not able to analyze increasingly fine-grained action classes. Another important reason is that action classes in existing datasets are usually hand-selected and cropped, resulting in more significant episodic and motion differences between classes, while action boundaries in realistic scenes are usually fuzzy and uncertain, and similarities between actions are often large, often with only minor local differences in the actions. In such cases, more fine-grained action discrimination and detection are required. Therefore, we believe that fine-grained action analysis will facilitate further breakthroughs in the task of action classification and detection, thus promoting the advancement of abstract theoretical research to practical applications in realistic scenes.

2. Related Work

How to represent the behavior in the video is the core problem of behavior recognition research, which determines the recognition performance to a certain extent. There exist many feature representation methods, which can be divided into two categories according to the source of features: handcrafted features and features learned from samples [7]. Handcrafted features are features designed by research experts based on human visual principles. In contrast, features obtained from samples are learned without prior feature design, and suitable feature representations are found directly in training samples by various types of learning algorithms, among which deep learning methods have become the mainstream method for learning features due to their excellent performance [8]. It is pointed out that implicit knowledge is real in the practice of competitive sports, especially in the acquisition of motor skills where implicit cognition plays an important role, and a coping strategy is proposed on how implicit cognition and explicit cognition can be transformed into each other in motor skill learning. Large-scale image retrieval systems necessarily have high demands on the time overhead of retrieval [9]. The performance problem is a difficult problem that must be solved for retrieval on a collection of images of hundreds of millions of sizes [10]. The basis of image retrieval lies in the similarity

calculation between the query image and the database image in the feature space. Calculating the similarity between each vector following a linear traversal is very time-consuming [11].

How to ensure the efficiency of image retrieval systems has been a key research direction in the fields of information retrieval, machine learning, and computer vision [12]. Considering that the image features to be retrieved are not uniformly diffuse in the feature space but in some specific distribution pattern, it is sometimes not necessary to traverse the whole query space to query for the nearest neighbor feature vector. Based on this idea, many kinds of tree-based index structures were proposed to narrow the retrieval domain of the query vector by recursively partitioning the feature space. The vector quantization approach, on the other hand, lies in approximating the original features using quantization to certain representative elements [13]. Deep learning methods can learn multilayer feature hierarchies and automatically construct high-level representations of the original input. A large amount of data is used to drive network training and model optimization to extract more representative semantic features, thereby improving classification performance, making the limitations of traditional manually designed feature extraction methods largely avoided. Using quantization methods, the global features of an image are usually quantized to sparse storage, and the query features are associated with only a small number of relevant quantization points during the similarity calculation, which corresponds to a reduction in the dimensionality of the image features and therefore an increase in retrieval speed [14].

In terms of tacit knowledge measurement methods, most of the relevant results of hierarchical analysis and fuzzy integrated measurement methods are used for specific applications [15]. In recent years, many scholars have started to try to combine the relevant theories of discrete mathematics with multicriteria decision-making to characterize the weight information for multiple scenario comparisons and decision-making. The theory of partial order set, as an important element in discrete mathematical order theory, is a very attractive decision support tool, and the options can be compared and ranked by qualitative weight information. No systematic theoretical system has been developed. Many scholars have addressed the influence of nontechnical factors on athletes' performance from a psychological and philosophical perspective. There are more discussions about implicit learning in psychology, alienation, and sustainable development of competitive sports from a philosophical perspective. The literature applying knowledge management theory to the field of competitive sports practice is occasionally found to be more general. A systematic study of the basic theoretical issues of athletes' tacit knowledge will certainly make up for the lack of research in this field to a certain extent, thus promoting the enrichment and development of the theoretical system of athletes' tacit knowledge.

3. Video Content Analysis of High-Level Semantic Recognition Model Sports under Engineering Management

3.1. High-Level Semantic Recognition Model Design under Engineering Management. Interaction information is an important clue for the task of group behavior identification, and mining the interaction information between individuals is crucial for identifying individual behavior and group behavior. Group behavior can be identified by analyzing the behavior of individuals and the interaction information between individuals. Individual interactions in a cluster can be represented by individual representations, and analysis of the relationships between individual behaviors can be modeled by modeling the relationships between individual representations [16]. It is necessary to extract the appearance representation of individuals, to establish the relationship between individual interaction and individual representation, to analyze the behavior of individuals and to analyze the model of group behavior and individual interaction, and to obtain the group behavior by analyzing individual representation, individual behavior, and interaction between individuals. The attention mechanism is used in the individual fusion of interaction information. After completing the establishment of the index based on the random split rule, we input the automatically mined dance element into each random tree in turn and implement the top-down matching process to find its nearest neighbor in the feature space. By attention mechanism, we mean that the model devotes more attention to the important information and allocates more attention to it. The attention mechanism is essentially designed to pick out the most representative information and discard features with less information. In particular, the feature information generated by deep learning models is very large, and only by using the attention mechanism in large feature space can the model extract more effective features and discard useless information. Attention mechanisms can be used on different dimensions of features, spatial attention to determine which region in the image is more significant and should receive attention, temporal attention to determine which moment in the temporal sequence contains more information, and channel attention to highlight the important role of certain channels in the feature. Achieving attention can be done in both hard and soft ways; the hard attention approach is by completely retaining and completely discarding some information. The soft attention approach generates new states by calculating the weight of information in the new state. Through this form, it is possible to discover the cognitive differences between the two knowledge elements that directly affect the sports performance of the snow sports athletes to provide effective help for coaches to adopt targeted training methods and guidance strategies.

$$\max \phi(w) = \frac{1}{2}\left(w_1 \cdot w^2\right) \tag{1}$$

$$\text{subject to } y_i\left[(w \cdot x_i) - b\right] - 2 \geq 0, \quad i \in N,$$

where x_i and y_i^2 represent the i-vector of the i-th training language sample and the corresponding labels, respectively, and w and b are the parameters of the classification hyperplane to be trained. This is an optimization problem with constraints, and thus it can be optimized using the Lagrange multiplier method, so the following function is defined:

$$L(w, b, \alpha) = \frac{1}{2}\left(w \cdot w^2\right) - \sum_{i=1}^{n} \alpha_i \left\{y_i^2 [w \cdot x] - b\right\}. \tag{2}$$

Since the error back-propagation algorithm is, in fact, a search for states close to the extremum in a large numerical solution state space, a good starting point can both prevent the gradient descent algorithm from getting stuck in local extremes that are difficult to jump out of and reduce the time to find the global optimal solution, if the initialization point is close enough to the optimal solution. Moreover, the response threshold of the activation function is finite due to the nonlinear factor of the model [17]. A good initialization parameter can reasonably activate the activation function so that most parameters are involved in the training, allowing most neurons to participate in the expression without dying, as shown in Figure 1.

The data distribution of the dataset is often fixed and we cannot change the data distribution of the dataset, so the distribution of the parameters directly affects the output response of this network, and if the range of the region of the response is not in the expected interval, then the loss of the model is huge and hard to debug. The parameter-transformed output data should not appear in some uncommon zones, which will make it more difficult to fit the model and reduce its capacity.

$$\begin{cases} \max \|\alpha_i\|_1 & \text{s.t. } x_i = X\alpha_i^2, \\ I^T \alpha_i = 1. \end{cases} \tag{3}$$

The conceptual analysis of video semantics has been a more active research direction in recent years due to the potential applications of an effective understanding of human behavior in video and its interactions in the environment in a variety of domains. To accomplish this challenging task, several research areas have worked on modeling multiple aspects of video semantics (emotions, relational attitudes, behaviors, etc). The other subset contains all the remaining video clips as the natural dataset to be recommended.

In this context, understanding the underlying semantic concepts in videos becomes crucial in interpreting complex video events. In recent years, deep learning methods have played an important role and have been widely used in computer vision tasks such as image segmentation, detection, recognition, and retrieval. In the field of video semantic concept analysis, how to cross the "semantic gap" and establish a mapping relationship between underlying features

and high-level semantics to extract abstract features that are closer to the high-level semantics of video has become a core problem for researchers to solve. Deep learning methods can learn multiple layers of feature hierarchies and automatically construct high-level representations of the original input, using large amounts of data to drive the training of the network and optimization of the model to extract more representative semantic features, thus improving the classification performance, making the limitations of traditional manually designed feature extraction methods largely avoided. Since the feature construction process is fully automated, they are more general.

In our experiment, 10 video clips of each dance type are simulated to the video that the user has clicked on, and the final recommendation result is automatically obtained according to the degree of matching with the dance style excavated from the 10 input videos. Locality-sensitive discriminant analysis is a classical supervised dimensionality reduction algorithm that considers both the discriminant information in the data and the geometric structure of the data. By constructing intraclass and interclass graphs, the method can better characterize the original local features of the data manifold and preserve the original class labels of the data with good discriminability. The sparse constrained autoencoder enables the encoded learned feature representation to better obtain the sparse reconstruction relationship between data by introducing SPP-constructed graph constraints for the nonlinear autoencoder. This pretraining model not only effectively exploits the natural discriminative power of the sparse representation but also largely alleviates the difficulties in the selection of the nearest neighbor parameters.

$$J(f, g) = E(x, g(f(x))) - \frac{1}{2}\partial t \ r\left(H^T G_{\text{spp}} H^2\right). \tag{4}$$

In this framework, to exploit the structural information between images, we wish to obtain the flow information of the previous layer (which can be the input or pooling layer) by constructing locality and sparsity graphs and using the flow information to redesign the mapping relationships between adjacent layers. These graph construction methods make the learned features more stable and discriminative as the network depth deepens, further speeding up the convergence and improving the generalization of the model [18]. The objective function of the localization and sparsity-preserving embedding convolutional neural network of adjacent layers consists of two components: reconstruction error between feature graphs of adjacent layers and graph regularization. After completing the establishment of the random split rule-based index, we input the automatically mined dance elements into each random tree in turn and implement a top-down matching process to find their nearest neighbors in the feature space and recommend dances in the natural dataset based on the cumulative ranking of the matches of such features, as shown in Figure 2.

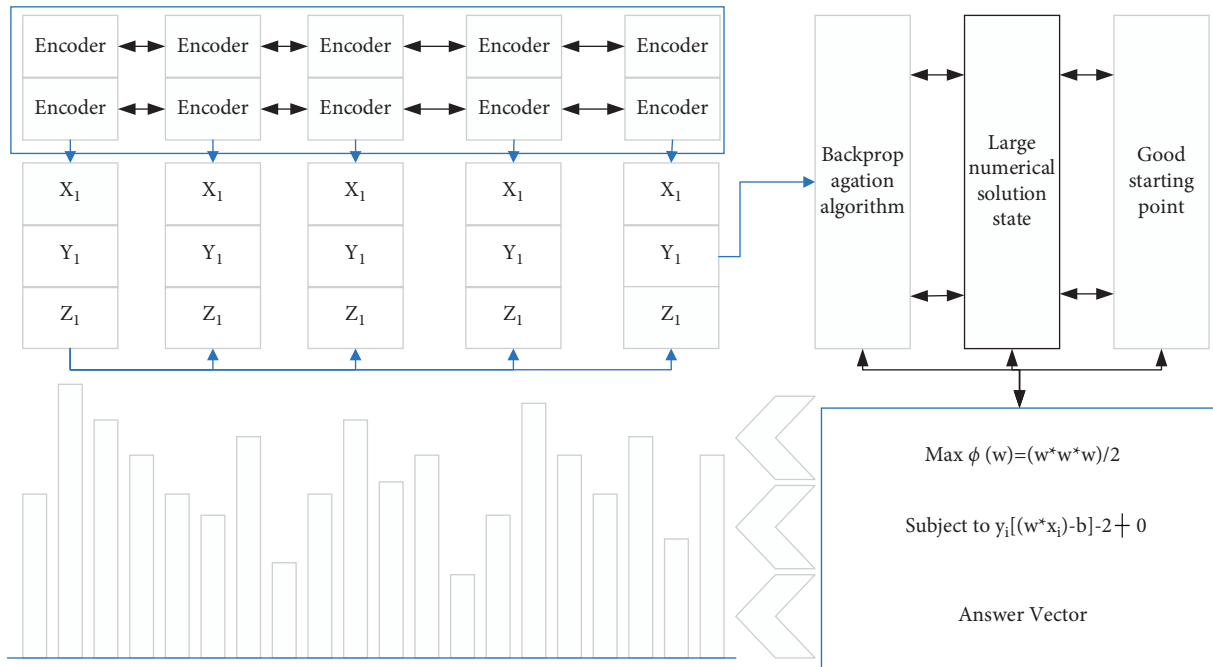
Then the impact of differences like this on the performance of the language recognition model is obvious.


FIGURE 1: High-level semantic recognition model.
FIGURE 2: Campaign engineering management framework.

Depending on the method of selecting spatiotemporal interest points, the current mainstream methods can be divided into spatial-temporal interest point features and trajectory features. Feature detection of local spatial-temporal feature points usually selects spatial-temporal localization and scale by maximizing a specific saliency function, and different detectors usually differ significantly in the type and sparsity of the selected points. Feature descriptors capture shape and motion features in a neighborhood of the

selected point of interest using metrics such as spatial or spatial-temporal image gradients or optical flow.

$$R = \left(I^* g^* h_{gv}\right)^2 - \left(I^* g^* h_{o\ d}\right)^2. \tag{5}$$

Behavioral event interviews, conducted with both high and average athletes in snow sports, reveal the knowledge, qualities, and abilities that snow sports athletes must have to achieve excellent athletic performance, and this is often

implemented by interviewing only the research subjects themselves. However, due to the special nature of sports practice and the role of snow sports athletes, coaches and athletes must spend time together, not only training and competing together but also living together every day and "feeling and fighting" for a few years or more than ten years, and they are in contact with each other, and sports practice activities such as training and competing are done jointly by athletes and their coaches.

Considering the strong complementarity between spatial flow features and optical flow features, choosing a suitable fusion method can effectively improve the performance of video classification. This method first extracts video image frames to form image sequence and optical flow sequence. Therefore, coaches even know their strengths and weaknesses better than athletes. Based on the relevant knowledge information obtained by the snow sport athletes themselves, the behavioral event interviews with their coaches can not only provide a basis for the researcher to confirm the content elements of tacit knowledge but also find out the differences in the cognitive aspects of the knowledge elements that have a direct impact on the athletes' performance in snow sport, to provide effective help for the coaches to adopt targeted training methods and coaching strategies. This will help coaches to adopt targeted training methods and coaching strategies.

The processing of video presents more challenges compared to still images; for example, temporal sequencing is important for behavior recognition in video, but how to reflect temporal information in the representation of behavior still needs further research, as well as issues such as occlusion, background noise, and interclass differences, and further improvements in both hand-designed features and deep learning features, as well as how to fuse multiple features to improve recognition rates, require further research.

3.2. Experimental Design for Video Content Analysis of Sports.

The information in the two hidden layers can well contain the language-related identity information of the speech segment and reflect the nature of that speech segment; that is, it can be considered as the language-related identity information of that speech segment. This representation of speech segments is more exploitable than the LSTM network model. In fact, in the traditional language recognition approach, the i-vector itself is also a representation of the language vector after highly abstracting the high-level semantic information, which is very similar to the nature of the embedding vector. Moreover, the i-vector itself assumes that the sample distribution of language recognition conforms to a Gaussian distribution, whereas LSTM networks do not have such type of assumptions [19]. Therefore, if the i-vector, which reflects the nature of speech segments, can be replaced by the embedding vector and then the investor-based language recognition classification method can be used for classification and scoring, theoretically, it can achieve better results than the i-vector method.

The subset used for dance style mining consists of 10 video segments from each dance genre; another subset contains all remaining video segments as the natural dataset to be recommended. This unbalanced method of slicing the data exactly matches the reality. We know that a user browsing a video on a website selectively selects only a small number of videos to click through, while the amount of data to be recommended in the webspace is huge. A video recommender should then be able to efficiently select videos relevant to the video content that the user has clicked on for recommendation from a large amount of distracting data. In our experiments, 10 video clips of each dance genre are simulated as videos clicked by the user, and the final recommendation results are automatically obtained based on the match with the dance styles mined from the 10 input videos.

$$\text{MAP@}N = \frac{1}{N \sum_{i=1}^{n} (\theta(r_i)/i)} \left(\frac{1}{n} \sum_{i=1}^{n} \frac{\theta(r_i^2)}{i_1^2} \right). \qquad (6)$$

Its purpose is to guide the spatial stream to pay more attention to the foreground area of the human body and reduce the influence of background noise, to better obtain the changes and differences between temporal and spatial features, and to improve the rationality of the network to extract video features. In the AP17-OLR dataset description, the dataset provider also points out that there are some differences between the training data and the test data used for the experiments, and, in the cases of Japanese, Korean, and Russian, the dataset directly gives the sampling environments between the training and test sets, both in quiet conditions and in speech segments mixed with noise. Also, the provider of the dataset points out that the sampling environments of Kazakh, Tibetan, and Uyghur are completely different from the situations of all other languages, and there are some differences between the training and test sets. Whereas DNN-like networks (including LSTMs) are more sensitive to such issues, the impact of differences like these on the performance of language recognition models is obvious if there is no good method for channel compensation, or if existing channel compensation measures are not sufficient to solve the problem. In fact, in the models described in the previous sections of this paper, there is a significant degradation in the recognition accuracy of some of the languages; taking the LSTM-1-MFCC network as an example, the false rejection and false acceptance rates for each specific language in this network are shown in Table 1.

The video semantic concept analysis task is richer and more complex compared to recognition tasks such as image classification, and complex situations such as background dynamic information interference, angle transformation, and target blocking can occur in different scenes. Although convolutional neural networks have achieved great success in image classification and recognition tasks, how to model the spatial-temporal features of videos and obtain the spatial-temporal information contained in videos is still one of the main problems that need to be solved urgently for video semantic concept analysis using deep learning methods. Many works have designed various effective deep

convolutional neural networks for learning and extracting static frame appearance information and motion timing information of videos, such as adding a temporal dimension to the 2D convolutional kernel of convolutional neural networks and expanding it to the 3D convolutional kernel to extract both spatial and temporal dimensional features. Considering the strong complementarity between spatial flow features and optical flow features, choosing a suitable fusion method can effectively improve the video classification performance. As a result, a recognition rate of almost 100% is obtained. When the trajectory feature is used, the trajectory information of the limb movement is captured, which greatly enhances the expression of behavior. Especially when the MBH descriptor is used, the recognition rate of boxing and applause is increased by more than 20%. The method first extracts video image frames to form image sequences and optical flow sequences, then extracts spatial flow features and optical flow features by the convolutional neural network, and introduces optical flow attention layer from temporal flow network to spatial flow network by mining the nearest neighbor relationship and association information between features in the flow embedded spatial flow convolutional neural network to guide the spatial flow to pay more attention to the human foreground region and reduce the influence of background noise. Thus, the variations and differences between spatial-temporal features are better obtained, as shown in Figure 3.

The visual attention mechanism is a unique signal processing mechanism of the human brain; through the observation of the global sample to determine the focus area and area of interest, the key information closely associated with the target will be quickly accessed; attention mechanism frees people from the colorful and complicated information and improves the efficiency of information processing, and it is introduced into the field of computer vision to improve the computer to solve image, video, and other prediction and analysis tasks. Consider that optical flow can be used to direct human foreground attention when appropriate compensation is applied to the movement of the lens. We investigate the combination of spatial streaming embedding CNN and temporal streaming CNN to form a dual-stream convolutional neural network to learn video features [20]. The purpose of introducing an optical flow attention layer from the temporal network to the spatial network is to guide the spatial flow to pay more attention to the human foreground region and to reduce the effect of background noise. Thus, the variation and differences between spatial-temporal features are better obtained and the rationality of the network to extract video features is improved. Attention is a mechanism used to give more weight to a subset of elements,

and the optical flow attention map is directed to foreground regions and helps the spatial flow convolutional network to learn distributed feature representations around these regions to accomplish the label prediction task. In dual-stream convolutional networks, we propose an optical-stream attention layer to model the interaction of the two networks, which can be trained end-to-end using stochastic gradient descent and back-propagation algorithms.

Improve the efficiency of users to obtain information. In addition, the video semantic analysis technology based on the host computer can replace manual annotation work, reduce a lot of human resources, and improve the utilization rate of information. Considering the perceptual wildness of spatial information, the range of neighboring points can be expanded. When building a graph structure, the most extreme case, where the current node can be associated with all other nodes on the graph, can be achieved by the subsequent adoption of attention mechanisms or the amount of information passed. The inclusion of all nodes in the graph, as well as the interconnection of all nodes to each other, is a fully connected graph, constituting a complete graph that allows information about all locations to be perceived by each other. It allows each member to have a large enough perceptual field to recognize a larger range of spatial patterns.

4. Analysis of Results

4.1. Performance Results of High-Level Semantic Recognition Models under Engineering Management. By changing the length of the input sequence from 5 to 10 frames, the accuracy of the model was improved by 0.9%, but as we continued to increase the length of the input sequence to 15 and 20 frames, the accuracy of the model started to decrease. The reason for this phenomenon is that the size of the video dataset is relatively small and overfitting occurs when the input sequence is too long. Since each RGB image frame corresponds to 10 adjacent frames of the stacked optical flow image, the 10-frame input contains 100 consecutive frames of spatial-temporal information in the video clip, which is sufficient to represent the main semantic information of the video clip.

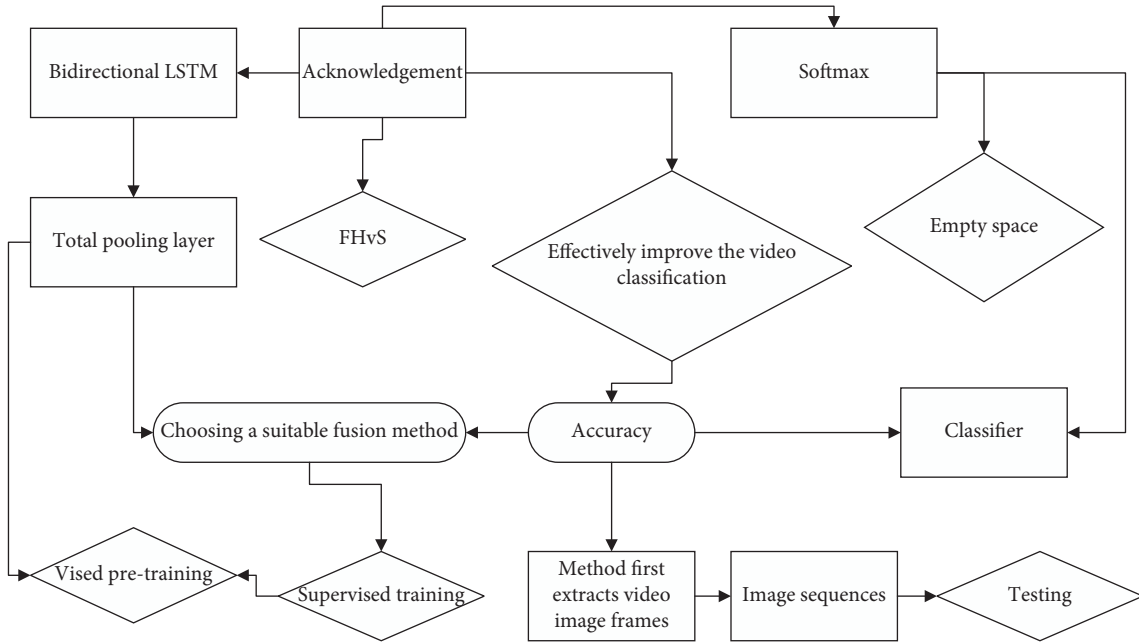
After the selection of the best input sequence is completed, the two-stream network stream embedding parameters and the confidence fusion parameters are set, and the experiments are firstly conducted to search the grid for the two parameters, and the best parameter for stream embedding is obtained as 0.2. After the stream embedding parameters are fixed, the experimental analysis of the effect of the confidence fusion parameter changes on the model


FIGURE 3: Network structure for compensating for mismatches between datasets.

performance is conducted, and the semantic concept detection accuracy based on different confidence fusion parameters is shown in Figure 4.

There is difficulty in designing an efficient and robust identification method. Although the traditional manual labeling method can realize the understanding and description of the video semantic concept to a certain extent, the time and labor cost of manual labeling is huge, and the subjectivity is strong. The vertical coordinate in the Cartesian coordinate system indicates the corresponding video semantic detection accuracy at different confidence parameters. The video semantic concept detection accuracy keeps improving when the values are taken in the interval [0.1, 0.7], which proves that the confidence of the classifier based on the probability error has an important contribution to the final category prediction. The model prediction performance is best when it is 0.7, so this chapter chooses to take a value of 0.7 as the confidence parameter of the dual-stream network classifier. The performance of feature engineering-based algorithms IDT remains competitive; in addition, many methods based on deep learning were combined with IDT to achieve better results, but several video semantic analysis methods with the best model performance are deep convolutional network-based algorithms, and CD methods do not have an advantage over traditional methods due to many model parameters and more difficult training. The basic dual-stream network model has achieved good results by emulating the human visual mechanism and has a better understanding of the spatial and temporal information of the video. The TSN method is built based on the dual-stream network model, which can learn video features efficiently by modeling long time scales and combining sparse sampling strategies and video supervision methods, and it has achieved good results. The proposed method in this paper has 0.4% higher accuracy than TSN.

This shows that the proposed method can better reflect the nearest neighbor relationship between samples and structural features, as well as the complementary relationship between images and optical flow, and the method of confidence fusion classification can effectively obtain video semantic concept features and improve the accuracy of video semantic concept detection, as shown in Figure 5.

The research has important academic significance and application value and helps to improve the level of video management technology, making it more complete and more efficient. In the process of optimal learning of video, features consider the nearest neighbor relationship between samples, association features, and so forth to construct stream shape constraint terms; optical flow attention mechanism was introduced to guide the spatial flow to pay more attention to the foreground region and reduce the influence of background noise, and, to better obtain the changes and differences between spatial-temporal features, in the acquisition of contextual information of video frame sequences, LSTM was introduced to construct stream shape embedding and optical flow attention based dual-stream CNN video semantic concept detection model. The proposed method can better reflect the nearest neighbor relationship and structural features between samples, as well as the complementary relationship between images and optical streams to obtain effective video semantic concept features, and the confidence fusion classification method for the category score results of the two-stream SoftMax layer can more effectively improve the accuracy of video semantic concept detection.

4.2. Experimental Results of Sports Video Content Analysis. As shown in Figure 6, the classification accuracies achieved by different coding and normalization methods are
FIGURE 4: Effect of confidence parameters on model performance.

compared using spatial-temporal interest point features with the number of topics varying between 10 and 100. As the number of topics increases, all coding methods achieve significant performance gains, but after the number of topics is 60, the performance does not change much. The difference between the results obtained when using vector quantization and local soft assignment is small, and the different normalization methods make a limited contribution to the recognition rate, with exponential plus l normalization achieving the best classification accuracy for most of the number of topics. The performance mostly improved as the number of topics increased, and the best performance was obtained when the number of topics reached 80 and then decreased. For soft assignment coding, there was a more significant decrease in classification performance compared to the results for spatial-temporal interest points, and the performance fluctuated by a maximum of more than 15 percentage points using different normalization methods. For both classes of descriptors, soft assignment coding tended to achieve optimal performance in combination with l. Group behavior recognition technology can derive tags of crowd scene images and can provide clues for retrieval of pictures and videos of group scenes. The advancement of group behavior recognition technology has greatly promoted the classification, labeling, and retrieval of crowd scenes.

In Figure 7, the confusion matrix under different features is presented, and it is evident that walking and waving have the highest recognition rate among all cases, and, correspondingly, boxing and clapping have the lowest recognition rate. This is in line with the expectation that, in terms of form movements, boxing and clapping focused on upper limb movements and have a high degree of similarity, while walking and waving, which are more differentiated from the rest of the behaviors, obtain a recognition rate of nearly 100%. When trajectory features are used, the trajectory information of the limb movements is captured, which

substantially enhances the representation of the behaviors, especially when MBH descriptors are used, increasing the recognition rate of boxing and clapping by more than 20 percentage points at maximum.

We obtained a classification accuracy of 89.63% using spatial-temporal interest points, which results in a 6-percentage point improvement. It is reasonable to assume that similar behaviors have similar characteristics and thematic distributions. Describing behaviors with mixed topic probability distributions is superior to the approach of corresponding a topic to a class of behaviors. One advantage of the topic model is that topics can be considered as a mid-level semantic feature and then used to describe more complex behaviors. Inevitably, there are similar form movements in different behaviors; for example, boxing and clapping both have similar upper body movements. Thus, different behaviors share the same themes, and each behavior has its distribution of themes, which enhances the discriminative nature of the features.

Overall, principal component analysis preprocessing of raw features not only reduces the feature dimensionality, thus making it less demanding on computational resources, but also retains most of the discriminative primary information, while having a suppressive effect on noise caused by various reasons, and whitening was also performed in the experiments to reduce the correlation between features, further improving the robust performance of recognition. The difference in the performance of the same action by different people; the influence of environmental factors, such as occlusion, viewing angle changes, lighting differences, and dynamic background interference, etc; and the start and end points of the action are blurred. The use of principal component analysis to preprocess raw features has an important impact on improving the performance of recognition. The principal component analysis projects the original features onto the feature components, which objectively suppresses the
FIGURE 5: Results of different methods on the UCF-101 dataset.

FIGURE 6: Performance comparison of different coding and normalization methods.

FIGURE 7: Content analysis results.

noise to a certain extent but, at the same time, inevitably brings about a loss of information. These two effects cancel each other out; if the noise component is large, the utility achieved by suppressing noise is large, which brings an increase in recognition rate, while the information loss effect is large and the corresponding performance is decreased. On the other hand, the performance of densely sampled features is superior, and the number of features to be processed is increasing, especially for video signals, which are particularly computationally intensive. If PCA is used to preprocess the original features, the number of feature dimensions is significantly reduced while retaining most of the information, resulting in little degradation in classification performance, which will greatly reduce the computational effort and improve the response speed, which is significant for applications that require real-time signal processing.

5. Conclusion

Better performance has been achieved after its introduction into the field of computer vision. In the word-packet framework, it has been shown that different feature encoding methods have an important impact on performance. Inspired by this, the impact of different coding methods combined with normalization methods on the classification performance of probabilistic implicit semantic analysis models is focused on, and it is found experimentally that local soft assignment coding combined with exponential normalization methods substantially improves the recognition performance; the impact of principal component analysis preprocessing raw features on performance is also examined, and when the features contain more noisy components, the computational effort is significantly reduced, while the classification recognition performance is even improved when the features contain more noisy components. However, the performance improvement of the fusion model for the language recognition model is limited. In addition, the idea of this paper is still stuck on the traditional pattern recognition task flow of the feature extraction-classification recognition model, and the two separated links may also affect the performance of the model to some extent. Therefore, a language recognition model based on an end-to-end approach is a very promising problem. Then the spatial flow features and optical flow features are extracted by the convolutional neural network, and the nearest neighbor relationship and association information between features are mined by stream shape embedded in spatial flow convolutional neural network, and the optical flow attention layer from the temporal flow network to spatial flow network is introduced to guide the spatial flow to pay more attention to the human foreground region and reduce the influence of background noise so that the variations and differences between spatial-temporal features can be better obtained. Then the features obtained from the two streams were input in temporal order to learn temporal features, and, finally, confidence fusion was performed on the classifier results of the two streams to detect the video semantic concept categories.

The sublevel caving method without sill pillar is used to improve the cost of mining. The analysis is performed according to unique geographical environment and the current mining technology of the mine. The wireless communication network is used to budget and control the work cost of mining. Simulation operation about unit explosive dosage, fan-shaped deep hole interval, hole bottom distance, and collapse step distance is performed. Experiments have shown that budget and control of the cost of mining workers with wireless communication technology can manage mining data and guide the design of mining data.

1. Introduction

The cost control by mining personnel is a relatively complex system. Due to the continuous changes in the production of mining factories, the cost control of mining personnel needs to consider the overall balance of different links, continuity, and uncertainty, in order to carry out effective identification and optimization, and control the cost of mining personnel of mine engineering. With the rapid development of science and technology, digitization and visualization technology have been widely used in various fields. As the main component of the mine, development plan for cost control of mining personnel is needed, digitizing and visualizing the mining activities, timely and accurately recording and expressing the engineering changes in the mine pit, and improving the mining level and work efficiency [1–3].

The construction of an integer model is used to optimize the location of fans in the network and the selection of structures in this paper. The cost of ventilation is normalized to minimize it. For the same problem, the nonlinear unmixed model covers special constraints and branch constraints, which are the basis for semiconstrained design, and optimizes the answer.

2. Establishment of Operational Research Model

The constrained flow network problem only includes the best deployment location of personnel and building selection to allocate personnel to all predetermined network branches [4–6]. The problem of nonholonomic constraints of the network will face a dual task. In addition to determining the best placement of personnel and the choice of structures, it is also necessary to control the people flowing into unclear branches.

2.1. Constrained Flow Network Problem. Because the distribution of personnel in the network is known, the constrained condition conditions do not need to be discussed, and then the objective function of this problem can be expressed by formula (3), and its constrained conditions are

$$\begin{cases} \sum_{j=1}^{b} \left(R_j |Q_j| Q_j + HR_j - HN_j - HF_j \right) = 0, \\ HR_j, HN_j \geq 0, \quad j = 1, \ldots, b. \end{cases} \tag{1}$$

Obviously, this is a nonlinear programming model, which is transformed into a linear programming model by introducing bivariate Y_j and the objective function is transformed by obtaining this value Y_j.

$$Y_j = \begin{cases} 1, & HF_j > 0, \\ 0, & \text{other}, \end{cases}, C_p Q_j = a_j,$$
$$\text{minimize } Z = \sum_{j \in L} a_j HF_j + \sum_{j \in L} C_j Y_j. \tag{2}$$

The constrained conditions are

$$\begin{cases} \sum_{j=1}^{b} b_{ij} \left(R_j |Q_j| Q_j + HR_j - HN_j - HF_j \right) = 0, \\ HR_j, HF_j \leq 0, \quad j = 1, \ldots, b, \\ HF_j \leq d_j Y_j, \quad j \in L, \\ Y_j = (0, 1). \end{cases} \tag{3}$$

In the formula, $d_j = \max HF_j$. When $HF_j \neq 0$, $Y_j = 1$; when $HF_j = 0$, $Y_j = 0$ 时. So when $Y_j = 1$, $Y_j = 0$, and a larger value may appear in Z.

2.2. Half Constrained Flow Network Problem.

Assume that the minimum value L_j and maximum values U_j of branchers, respectively, flow to ambiguous branchers and are represented by the objective function [7].

$$\text{Min} Z = \sum_{j=1}^{L} C_j Q_j HF_j + \sum_{j=1}^{L} C_j. \tag{4}$$

The constrained conditions are

$$\begin{cases} \sum_{j=1}^{b} a_{ij} Q_j = 0, \\ \sum_{j=1}^{b} b_{ij} \left(R_j |Q_j| Q_j + HR_j - HN_j - HF_j \right) = 0, \\ L_j \leq Q_j \leq U_j, \\ HR_j \geq 0, \\ X_j = (0, 1), \\ Q_j HF_j \geq P_j, X_j = 1, \\ Q_j HF_j = P_j, X_j = 0, \\ j = 1, \ldots, b, \end{cases} \tag{5}$$

where P_j is the minimum power allowed on branch j.

It can be seen from the previously mentioned objective function and constrained conditions that they are all nonlinear. So we need to transform it into a linear programming. During the transformation, the decompression is first

determined, and then, the solutions for each subset are established. All solutions need to form the elements that make up the aggregation L for X_j. Finally, this nonlinear programming is a linear programming, and then, the best solution is selected. The specific method is verified in the following example.

3. Specific Application of Operations Research

Figure 1 is a cost network diagram of a miner. It is composed of nine branches and six nodes, and each wind resistance is constant. According to the specific situation, the personnel can be configured for seven minutes when branching. On 8, the structures are at branches 3, 5, and 8.

The distribution of personnel on each branch is shown in Table 1.

3.1. Problem Solving for Constrained Flow Network.

We select the spanning tree {1, 2, 5, 6, 9}, and the matrix can be obtained b_{ij}

$$b_{ij} = \begin{bmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\ -1 & 1 & 0 & 1 & 0 & -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 1 \end{bmatrix}. \tag{6}$$

Then, the objective function can be expressed as

$$\begin{aligned} \min Z = &\ C_p Q_5 HF_5 + C_p Q_7 HF_7 + C_p Q_8 HF_8 \\ &+ C_5 Y_5 + C_7 Y_7 + C_8 Y_8. \end{aligned} \tag{7}$$

The constrained conditions are

$$\begin{cases} -R_1 Q_1^2 + R_2 Q_2^2 + R_4 Q_4^2 - R_6 Q_6^2 = 0, \\ R_1 Q_1^2 - R_2 Q_2^2 + R_3 Q_3^2 + HR_3 - R_5 Q_5^2 - HR_5 + HF_5 = 0, \\ R_2 Q_2^2 + R_5 Q_5^2 + HR_5 - HF_5 + R_7 Q_7^2 - HF_7 = 0, \\ R_1 Q_2^2 + R_6 Q_6^2 + R_8 Q_8^2 - HF_8 = 0, \\ HF_5 \leq d_5 F_5, \\ HF_7 \leq d_5 F_7, \\ HF_8 \leq d_5 F_8, \\ Y_j = (1, 0), \quad j = 5, 7, 8, \\ HR_j \geq 0, \quad j = 3, 5, 8, \\ HR_j \geq 0, \quad j = 5, 7, 8. \end{cases} \tag{8}$$

After calculation, the best solution is to set up two personnel on branches 7 and 8, respectively, where the wind pressure on branch 7 is 11330.6 Pa, 840.8 Pa of which is shared by branch 8. The main auxiliary equipment is set on branch 3.

The best solutions are usually difficult to be found for the multifunctional optimization problems. Most of them adjust each target in a balanced manner and meet the requirements based on the problem to obtain the best balanced solution
FIGURE 1: Cost network of mining personnel.

TABLE 1: Distribution of personnel in branches.

Branch	Wind resistance R_j	Personnel Q_j	Position of personnel	Structure placement
1	0.34	35.35		
2	0.41	37.02		
3	0.54	18.02		Allowable
4	0.91	20.02		
5	1.43	17.02	Allowable	Allowable
6	1.66	17.35		
7	0.22	35.02	Allowable	
8	0.17	37.35	Allowable	Allowable
9	0.01	72.25		

with certain accuracy and practical significance. Here, the decisive objective function and constraint conditions in the problem are shown. Fuzzy theory is combined with intelligent algorithms to solve chaotic optimization problems. The dark color of more than one thousand targets is most suitable for the best dextrin of the basic thousand single targets. In the fuzzy set of the optimal solution of each target, the solution of each target is satisfied as much as possible.

(1) The objective function of the formula MOP problem is complex and only provides a very large membership function. On the premise of satisfying the constraints as much as possible, the larger the objectives, the better, and there is an upper limit but no lower limit. The upper limit is the best value for each single goal optimization [8–10]. Therefore, the ray shape is selected as the correlation function for each target.

$$\mu(f_k(X)) = \begin{cases} 1, f_k(X) > c_{01}, \\ \dfrac{f_k(X) - c_{0k} + \delta_{0k}}{\delta_{0k}}, c_{0k} - \delta_{0k} < f_k(X) \leq x_{0k}, \\ 0, f_k(X) \leq c_{0k} - \delta_{0k}. \end{cases}$$

(9)

In the formula, $\mu(f_k(X))$ specifies the membership function $f_k(X)$ of the target. The target value $f_k(X)$ for the target optimization of the target monomer c_{0k}. This is the added value of target δ_{0k} accepted by policy makers, and it is determined by scaling to a certain extent on the basis of optimizing the target value into a single target (Figure 2).

The specific solution steps of the wireless communication network method are as follows:

Step 1. Use the following wireless communication network algorithm to find the optimal solution to the constraints of each single-objective function:

$$\begin{cases} \max f_i(X), i = 1, 2, \ldots, p, \\ g_i(X) \leq 0, i = 1, 2, \ldots, m, \\ h_j(X) = 0, j = 1, 2, \ldots, l. \end{cases}$$

(10)

Find the optimal solution of the constraint of the previously mentioned objective function.

Step 2. Stretch each single target value to a certain extent; that is, determine the added value

Step 3. The fuzzy of each objective function, that is, the function that determines the degree of membership of each objective function, is as follows:

$$\mu(f_k(X)), k = 1, 2, \ldots, p.$$

(11)

Define the satisfaction degree of all membership functions as

$$\lambda = \min\{\mu(f_i(X)), \mu(f_2(X)), \ldots, \mu(f_p(X))\}.$$

(12)

Step 4. Substitute c_{0k} δ_{0k} into (3) to obtain expression of p membership function.

Step 5. Based on the max-min law of the fuzzy set theory, the maximum satisfaction degree method is used to convert the multiobjective problem into a
Figure 2: Membership function curve.

single-objective nonlinear problem. The mathematical model is as follows:

$$\begin{cases} \max \lambda, \\ f_1(X) - \delta_{01}\lambda \geq c_{01} - \delta_{01}, \\ \cdots \\ f_k(X) - \delta_{0k}\lambda \geq c_{0k} - \delta_{0k}, \\ \cdots \\ f_P(X) - \delta_{0P}\lambda \geq c_{0P} - \delta_{0P}, \\ 0 \leq \lambda \leq 1, \\ g_i(X) \leq 0, i = 1, 2, \ldots, m, \\ h_j(X) = 0, j = 1, 2, \ldots, l. \end{cases} \quad (13)$$

Step 6. The wireless communication network algorithm is applied to solve the previously mentioned single-objective fuzzy optimization model and find the optimal value of each objective function under a given satisfaction degree (90%).

3.2. Problem Solving for Half Constrained Flow Network. The personnel on branches 3, 4, and 7 are known to be $18.00 \, \text{m}^3/\text{s}$, $20.00 \, \text{m}^3/\text{s}$, and $35.00 \, \text{m}^3/\text{s}$, and a new matrix a_{ij} can be obtained.

$$a_{ij} = \begin{bmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 6 & 8 & 9 \\ -1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 \\ 1 & -1 & 1 & 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 \end{bmatrix}. \quad (14)$$

We define the personnel of branches 7 and 8 as surface personnel and branch 5 as a candidate for underground personnel. The objective function is

$$\min Z = Q_5 HF_5 + aHF_7 + Q_8 HF_8. \quad (15)$$

Suppose $Z_1 = (Q_i + HF_8)/2$, $Z_2 = (Q_8 - HF_8)/2$ and then introduce nonnegative special variables λ_k, u_k, and v_k, so that $\sum_k \lambda_k = 0$, $\sum_k u_k = 0$, $\sum_k v_k = 0$. Then, Z_1, Z_2, and Q_8 can be expressed as $Q_8 = \sum_K \lambda_k Q_{8k}$, $Z_1 = \sum_k u_k Z_{1k}$,

$Z_2 = \sum_k v_k Z_{2k}$. Then, the previously mentioned problem can be transformed into linear programming, and its objective function is

$$\min Z = Q_5 HF_5 + Q_7 HF_7 + \sum_k u_k Z_{1k}^2 - \sum_k v_k Z_{2k}^2. \quad (16)$$

After calculation, the wind pressure on branch 7 is 840.88 Pa, the wind pressure shared by branch 8 is 113.6 Pa, and the wind pressure on branch 5 is 374.35 Pa.

4. The Basic Function and Innovation of the Cost Control System for Mining Personnel

A simulation model of the mine's in-pit visual production system is built according to the actual situation of the specific mine at first, and simulation operation is performed after the model is verified and confirmed. The in-pit production process is observed dynamically in the mine. In addition, the operating status of each stage of the biological flow system of mine can be analyzed in real time. The development logic program of the dynamic optimization policy decision system for the three-dimensional dynamic visualization of underground mine engineering is as follows [11, 12].

(1) Information about mine production systems is collected for specific mines. It contains the parameters related to the tunnel formation system: the logistics process, production capacity, and technical parameters and capabilities of related equipment in the production system of coal mining, ventilation, transportation, drainage, and so on.

(2) Statistical analysis and integration is performed for the previously mentioned collected data related to the cost control system for underground mining personnel.

(3) Analyze the various influencing factors of mine production, define the boundaries of the mine logistics system, and divide the subsystems according to the functions of the logistics process of mine.

(4) On the basis of a large number of field investigations and statistical analysis, the statistical rules and parameters of each part of the mining system are determined.

(5) Through the mine layout system and production system of the built mine, the connection and conversion relationship between the various subsystems of the mine production is found out, the integration capability of the various equipment of the mine production system and the logistics system is established, and a fully visualized underground mine model of mining personnel cost control system is built.

(6) According to the simulation software of WITNESS, the cost control system model of the underground mining personnel of the mine is reasonably converted into a computer simulation model.

(7) The reliability simulation of the simulation model was verified, the interference of random factors was eliminated, the simulation results were statistically analyzed, and unreasonable factors in the system were found.

(8) The model is improved to make it more in line with the actual mine production system.

(9) According to the actual production of mine, the simulation operation of the mine logistics system is carried out. According to the simulation results, the mine logistics system is rationally optimized and integrated, to apply the improvement plan to the mine production practice and compare the improved demonstration operation result with the actual mine production practice effect for evaluation.

Among them, the key issues in the development of the mining personnel cost control system are as follows.

(1) Collect true information about mine production systems for specific mines: the parameters of the tunnel configuration system, coal mining, excavation, ventilation, transportation, drainage, and other logistics process, production capacity, and technical parameters and capabilities of related equipment

(2) Import mine development engineering drawings (Figure 3) into the WITNESS system. The imported engineering drawings will be imported to the prebuilt system modules based on the actual underground mining personnel cost control system process (Figure 4: the mine underground mining personnel cost control system process) to build a simulation model of the mine's in-pit visual production system.

(3) Perform the validity check of the simulation model of the in-pit visual production system in the mine. Transform the parameters of field survey and statistical analysis (including technical indicators such as underground logistics equipment capability, failure rate, repair rate, and other reliability indicators) into computer simulation models. Carry out simulation operation, analyze it combined with the actual logistics system operation, carry out validity check, and ensure the validity of the simulation system.

5. Realization of Cost Control of Mining Personnel

5.1. Projective Transformation. The functions of the wireless communication network-like calculation procedure library cannot directly generate arc surfaces. If the NURBS surface adopted cannot be correctly controlled, it cannot meet the need of explaining the lane. In addition, the complicated program leads to the low operation efficiency. In this study, an arched lane is made by adding a tangent plane. The arched lane is composed of two concentric cylinders with different radii and two concentric circular plates. Projective transformation is an important graphics conversion technique

Figure 3: Mine development engineering drawing (partial).
Figure 4: The process of the cost control system for underground mining personnel.

whose purpose is to define the view. The extra part outside the field of view is intercepted, and the final image is only the relevant part of the visual field.

In perspective projection, the projection close to the point is very large, the projection from the viewpoint is very small, and the projection that reaches the extreme point disappears and becomes the vanishing point. The projection is mainly used for meeting animation requests, visualization and other image display areas. In the mine mining intelligent analysis system, the proportional relationship between the alleys remains unchanged after the projection transformation for a more reasonable use of the relative spatial positions of different projects for the mining project layout of the mine.

5.2. Illumination Treatment. The illumination model of the algorithm is, for example, wireless communication network, radiation, ambient light, diffused light, specular light, and so on. The radiation is emitted directly from the object and is not affected by the light source. Ambient light is scattered multiple times from the light source through the environment, and light that cannot determine its direction is considered to come from all directions. The diffused light comes from a certain direction. It is brighter when it is perpendicular to the object than when it is tilted. After irradiating the object, it will be distributed evenly in all directions. Specular light comes from a specific direction and reflects in other directions.

The purpose of the illumination model is to make the generated graphic image be truly felt by performing complex calculations on normal, light sources, materials, and so on. The command to start the illumination model is glEnbale.

LIGHTING), gDiscable (GL_LIGHTING) turn off the current light.

5.3. Plane Normal Vector. The calculation vector strictly represents the direction between multiple countries. Open GL needs to use the normal vector to calculate the angle of light irradiating the object. In order to generate a three-dimensional image, the normal vector of the object must be defined. The wireless communication network algorithm uses two functions to define the normal vector. The first function means the three component values of the normal vector, respectively, given by the function. Second, define a pointer with three elements. The wireless communication network does not provide a function of the corona calculation method. Therefore, it is necessary to create a corresponding program for the developer. The normal vector algorithm designed in this research is verified by actual data and is accurate and effective.

5.4. Integrated Implementation. The characteristics of the following aspects are mainly reflected in the research and development process.

(1) In order to facilitate the development and use, this system adopts a modular design concept to construct a three-dimensional dynamic visualization system and related equipment modules for the engineering in the pit. Using this modular structure, different mines can be constructed: underground laborers and three-dimensional dynamic visualization simulation to determine the needs of the system.

(2) Regarding the logistics process and flow of the simulation system model, in the CAD engineering drawing of the actual mine production system, such as the introduction of mine development and mining plan, the structure configuration and construction of the simulation system can be fully adapted to the actual system (Table 2).

6. Examples and Results of the Analysis

Miner cost control is one of the important tasks of mining production. Through more accurate miner cost forecasting and control, parameters and mining parameters of the mine blocks are adjusted economically and reasonably, the personnel are arranged, and the personnel costs are reduced to improve results and benefits. The cost of mining personnel is closely related to the entire mining system and is affected by ventilation, drainage, transportation, and mining processes. The factors that affect the cost of mining personnel interact in a complex manner. Due to the complexity of the system, it is difficult to use traditional methods to build accurate and complete prediction and control models.

6.1. Mining Equipment. The equipment used in the mine development includes powdered ammonium nitrate explosive, light oil, detonating cords, explosive tubes, and detonators. The prices are shown in Table 3.

6.2. Mining Technology. When mining, the parameters of the mining process mainly include explosive unit consumption, row spacing, hole bottom distance, and collapse steps. Based on the theoretical and experimental research on the blastability evaluation of metal ore and the optimization of deep hole excavation parameters of the in-pit excavation sites, these parameters need to be considered in the optimal control model of production.

6.2.1. Preliminary Determination of Explosive Unit Consumption. All test blast holes are artificially filled. According to relevant data and experience, the unit consumption q value of the funnel test explosive is taken as $3.25 \, kg/m^3$ and detonated at the bottom of the hole with an explosive tube detonator. After the explosive is filled, it will be severely blocked by taphole clay. After the blast hole is mined, the falling part of the laccolith around the funnel mouth is subtracted to determine the boundary of the funnel mouth. Take the blast hole as the center, take the radii r of nine funnels in different directions directly at 45°, use the average value as the radius r of the collecting funnel, to measure the actual minimum resistance cord w, and calculate the mining action index n. The funnel test data based on test statistics and calculation benchmarks are shown in Table 4.

The average radius r of the mining funnel obtained from Table 4 is 0.88 m, the average minimum resistance cord is 0.65 m, and the actual mining action index $n = r/w = 1.38$. The explosive consumption q value in actual standard unit is in turn calculated as $1.68 \, kg/m^3$ according to the formula of Polis Aube.

The number of columns in each unit consumption value experiment is all 10 columns, and the number of tests is four times. The number of columns corresponding to each detonation is two columns, two columns, three columns, and three columns. The detonation is delayed in milliseconds between the columns, and the time interval should not be less than 50 ms. Table 5 shows the mining test results when different explosives are consumed separately.

Synthesizing the analysis and summary of the mining effect of multiple experiments, the reasonable unit consumption range of the mining area is 0.82–$0.88 \, km/m^3$, and the unit consumption value is set to $0.86 \, km/m^3$ in the mining design. The actual unit consumption is controlled within the range of 0.82–$088 \, kg/m^3$. The effect after mining is ideal, and the volume fraction is low (3%–25%). Afterwards, its impact on the construction is very small.

6.2.2. Selection of the Distance between the Row Spacing of Fan-Shaped Deep Hole and the Hole Bottom. In the collapse of mining place, the interval between the fan-shaped deep holes is the minimum resistance line, which is usually determined by the diameter of the hole, the characteristics of the ore, the power of the explosive, and the degree of rock fragmentation. The distance between the bottom of the hole is the vertical distance between relatively shallow hole bottom and the deep blast holes. The blast hole density factor is the ratio of the bottom hole distance to the minimum resistance line, that is,

TABLE 5: Mining test results of different explosive unit consumption.

Unit consumption/kg/ m3	Row spacing (m)	Hole bottom distance (m)	Mining effect	Open wiring condition	Top board situation	Two side-wall situation	Rear blast hole situation
091–095	16	20	Overgrind of ore	Damaged severely	Lots of falling lumps and pumice	More slanting side-wall	Serious blocking of holes and dislocation
086–091	16	20	Small lumpiness, partly fine ore	Small damage	More pumice	Less slanting side-wall	More plugged holes, less dislocation
082–086	16	20	Uniform lumpiness, less fine ore	Less damage	Partial pumice and falling lumps	Less slanting side-wall	Less plugged holes and dislocation
075–082	16	20	Uneven lumpiness, high lump rate	Less damage	Less pumice and falling lumps	Rarely slanting side-wall	Occasionally plugged or misplaced

selection of these three parameters is correct will directly affect the economic and technical indicators in the mining process.

Combining the experience of various metallurgical mines, the blast hole density coefficient can be $m = 1.0 \sim 2.0$. The relationship between the minimum resistance line w and the blast hole diameter d can be selected for reference from the actual data of the relevant mine. The value of the minimum resistance line used in mines is roughly as shown in Table 6 [13–15].

After the previously mentioned analysis, the design unit consumption is 0.85 kg/m^3, and the actual unit consumption is mining tests with different distances and intervals in the range of 082–087 kg/m^3. In the test, the hole bottom distances are divided into five groups, namely, 1.8 m, 2 m, 2.3 m, 2.4 m, and 2.5 m, respectively. Each group corresponds to seven kinds of intervals, 14 m, 15 m, 16 m, 18 m, 19 m, 20 m, and 21 m, respectively. The test site is located on the 2280 floor on the reexcavation channel of no. 23–25 detection line and the no. 19 detection line. Part of it is arranged on the return way of the no. 19 exploration line on the 2265 floor.

After mining, the mining effect records and analysis of seven different intervals are performed corresponding to five different hole bottom spacings. As the hole bottom distance and discharge interval increase, the impact of front row mining on the rear row of blast holes becomes more and more serious. The blast holes in the back row are blocked and misaligned more and more. The destruction of the eyebrow line gradually became apparent. The ceiling and the two groups will also be increased if they are missing. Obviously, the progress of the next mining project has slowed down. In the case of a certain hole bottom distance, as the cannon hole density coefficient increases, the volume rate after mining gradually decreases. If the big blast hole density coefficient increases to a certain range, a larger volume rate will be maintained. The relationship is shown in Figure 5.

Considering the comprehensive mining effect and project progress, the reasonable row spacing is 1.6–1.8 meters, and the reasonable hole bottom distance is 2–22 meters.

6.2.3. Determination of the Step Pitch of Ore Caving. According to the results of multiple mining tests and the determination of the loss of ore drawing poverty, if two roads are used for collapsed mines simultaneously, the step distance of collapsed mines should preferably be three rows in each direction; that is, the stepped distance of collapsed mines is about 53 m. When a one-way road falls into a mine, the collapsed mines steps are preferably four columns per road. In other words, the collapsed mine step is about 7 meters.

Through a large number of field mining tests, mining parameters can be selected from Table 7.

6.3. Design of Wireless Communication Network. Compare the ratio of the amount of ore mined at one time to the cost of material used for mining 1 m^3. The price performance ratio is considered as a measurement index, and cost performance is used as the output point of the model. In this way, the cost of equipment and personnel required for the volume of ore of the mining unit and the mining parameters are considered as the influencing factors of the system. This neural network model has nine input nodes. *Influence*. In other words, the model has nine input nodes. Due to the cost performance as the output of the model, the model has only one output node.

We collected a total of 20 learning samples, as shown in Table 8.

The first nine items in Table 6 are the input factors of the learning sample, and the last item is the output quantity. Use the samples in Table 8 to train the network. Before training, you should normalize the data not in [0, 1].

The model training, prediction, and appropriate program design calculations are carried out,. The model accuracy during training is 0.001, and the learning step is selected as 0.05. After 17 repetitions, the accuracy reached the requirement and the training was completed. Figure 6 shows the error variance curve during model training. At this point, the connection weight of each node of the model has been determined. The same type of samples can be predicted at any time.

According to the range of mining equipment and mining process parameters, each element of the model is valued

using interval intensive scanning technology in turn, which is used as the prediction sample of the model. Due to the large number of input factors and prediction samples, in order to ensure the comprehensiveness of the prediction samples, a computer is used to obtain values for the nine elements in sequence. Unsolicited data is automatically deleted. The selected prediction samples can be directly input into the model for prediction, and the performance-to-price ratio of all prediction samples can be obtained. Table 9 shows the results of the inverse normalization after the prediction of the seven groups of prediction samples of the model.

According to the prediction results in Table 9, the deviation between the prediction and the actual situation is relatively small, and the prediction and actual results of the third and seventh groups are relatively high. Multiple production practices and wireless communication networks are combined to predict and control the cost of miners. This lead mine uses the best mining parameter values of the collapse method without sill pillar division. The explosive unit consumption is 0.87 kg/m^3, the row spacing is 1.76 m, the hole bottom distance is 2.2 m, and the collapse step is 5.26 m. At this time, the actual price ratio of development reaches 33.78/yuan, which meets the production requirements.

7. Conclusions

In this paper, experiments on the budget and control of the cost of mining workers by wireless communication network technology have been carried out to prove that the characteristics of sandstone deposits are used to optimize the data, and the budget and control model of the cost of mining workers through wireless communication network technology are summarized. The method can accurately improve the mining work, guide the new direction of the mining design work, and provide favorable experience and data for mining similar mines.

Building information modeling (BIM) is evolving as a digital infrastructure model for innovation in the construction field. The innovation-enabling potential of BIM has been highly neglected in the literature. This study explores the innovative potential of BIM, specifically its value in enabling construction innovation (CI). Through reflective research and a literature review, the relationship between BIM and CI is redefined, BIM-CI's value spectrum and underlying mechanisms are mapped and their required resources and activities are illustrated. The results indicate that different BIM applications provide various proinnovation environments wherein CI may flourish. Extra attention should be paid to BIM-enabled systematic collaborative innovation and digital innovation ecosystems with BIM as the core infrastructure that integrates the physical space with cyberspace to accelerate radical innovation. This study extends BIM management research by considering digital innovation and providing a new perspective for CI management theory and practice. The results will provide academics with a solid point of departure for developing relevant research and serve as a reference for practitioners who intend to utilize BIM for efficient innovation in construction projects.

1. Introduction

Since it was first proposed in the 1970s, building information modeling (BIM) has become the newest trend in the construction field. An effort has been devoted to pursuing the potential of BIM. Some have focused on the functionality provided by BIM (e.g., clash detection and energy analysis), while others have emphasized productivity and efficiency achievements enabled by BIM, such as existing construction management tools being integrated with open BIM to extend their capabilities in construction ecosystems [1] as well as integrating and enabling BIM capabilities to improve

construction projects in combination with other innovations (e.g., new materials and new technologies such as three-dimensional (3D) printing, cloud computing, and robotics). These have led to advancements in the recognition and application of BIM.

However, regardless of the benefits related to productivity improvement in particular activities, the innovative capability of BIM has been highly neglected in the literature [2, 3]. Innovative capability involves the ability of BIM in enabling its user or organization/network to work differently (i.e., innovate) for improvement [2]. Evidently, construction innovation (CI) is pivotal to the ultimate success of

construction projects and is key to the sustainable development of the construction sector [4]. Although the construction industry is often perceived as conservative, its inertia characteristics (e.g., stakeholder complexity, fragmentation, low profit margins, and low productivity rates) render it "ripe for digitization" [5, 6]. It has been demonstrated that due to the characteristics of digital technologies (i.e., convergence and reprogrammability), tremendous benefits are expected from digital technologies for CI. There are very few researchers who have noticed this aspect of the potential of BIM, and most relevant research has used case studies to describe the process or the outcome of CI enabled by BIM through the application of specific functionality (e.g., 3D representation) during certain stages (e.g., the design phase) of construction projects [2, 6]. Systematic research on the innovative capabilities of BIM is extremely scarce.

The essential reason for this lack of academic research and untapped practical potential may be the absence of a holistic picture of the value of the innovative capability of BIM in construction projects. Thus, the purpose of this conceptual study is to map a value spectrum of the ability of BIM to enable innovation in construction projects. To achieve this goal, reflective research and a qualitative literature review were conducted to reidentify the relationship between BIM and CI. By coupling CI classifications and BIM application modes, a value spectrum depicting a holistic picture of the innovative capability of BIM is mapped and analyzed, and its underlying mechanisms and required resources and activities are also illustrated.

Innovation-related research in the BIM management field mostly considers BIM as an innovative application or technology and examines its adoption, application, and implementation based on innovation diffusion theory or the technology acceptance model [3, 7]. A BIM application is an evolving, dynamic, and complex sociotechnical process. Indeed, BIM is more like an innovation engine rather than simply a technological innovation in the construction field. By exploring the innovative value potential of BIM and analyzing the value spectrum of innovations that enable BIM in construction projects, this study contributes to the body of knowledge by extending the scope of BIM management research considering digital innovation management. Furthermore, this study provides a new perspective for CI management theory and practice. Reshaping the relationship between BIM and CI and creating a value spectrum of the innovative capability of BIM will serve as a solid departure point for developing relevant research and guiding practitioners in executing project management based on BIM to develop innovative solutions in order to address engineering problems, improve efficiency, and build better projects.

2. CI in the Digital Era

The construction industry is a diverse, project-based sector [8]. Architecture, engineering, and construction (AEC) projects are distributed (i.e., designed and constructed by multiple, autonomous actors), heterogeneous (i.e., comprising communities with distinct skills, expertise, and interests), and sociotechnical (i.e., requiring trust, values, and norms as well as information technology (IT) capabilities and complex fabrication processes) [6]. The construction industry has always been regarded as a conservative economic sector because it involves large volumes of repetitive work. However, the completion of iconic mega projects, such as the Burj Khalifa Tower in Dubai and the Hong Kong-Zhuhai-Macao Bridge, also underscores the immense innovative potential of this sector.

Currently, the digitization of the construction industry is overwhelming. The inertia characteristics of the construction industry (e.g., stakeholder complexity, fragmentation, low profit margins, and low productivity) render it "ripe for digitization" [5, 9]. In the new digital era, the construction industry is required to build better buildings and offer better service in a shorter time and with tighter budgets, which pose more challenges to CI and make the improvement of its efficiency imperative [3]. Under such circumstances, digital technologies claim to be a promising new path for improving CI efficiency. Today's construction technology landscape offers a wide variety of innovative digital solutions for optimizing project constraints in terms of scope, time, cost, quality, and resources [5]. Based on the findings reported by the World Economic Forum regarding the likely impact of new technologies and global drivers influencing the future of construction, digitization-enabled innovation—which includes a range of capabilities such as data creation, management, reality capture, analytics, and automation control and tracking—is one of two broad technical trends [10]. The other trend is innovation in building materials, which is not included in the scope of this study [11].

Digital innovation involves the use of digital technology during the innovation process. Nambisan et al. [12] conceptualized digital innovation as the creation of, and the consequent change in, market offerings, business processes, or models resulting from the use of digital technology. Boland and Lyytinen [6] indicated that the two fundamental properties of digital technology are their reprogrammability and data homogenization. Together, they provide an environment of openness and flexibility that is used to create convergent and generative innovations [6]. By overviewing the evolutionary process of CI, Skibniewski and Zavadskas [13] indicated that advanced information and communication technologies develop rigidly and rapidly to ensure the realization of innovative solutions for emergent, dynamic, and complex engineering problems. BIM appears to be at the center of most advancements in digital construction [11]. After the implementation of BIM, a series of innovations, whether incremental advancements toward design and construction management or more radical advancements toward robotics or direct digital construction, will emerge and thus improve management efficiency [11]. Up until this point, BIM has been a prospective solution for improving the efficiency of CI [5].

2.1. Innovative Capability of BIM in Construction Projects. In the digital economic era, BIM is considered the main paradigm of the construction industry's technological

transformation [14]. The BIM concept was originally proposed by Charles Eastman in the 1970s. Since then, issues related to BIM have attracted much attention. Research shows that innovation is one of the most popular topics in BIM management research [7].

Liu et al. [3] conducted a thorough bibliometric analysis of the BIM literature focused on innovation-related topics to investigate the latest status and trends. The results of the bibliometric analysis showed that the number of innovation-related articles in BIM research publications has increased over the past decade, while relevant research mostly depicted BIM as an innovative IT system and investigated its adoption, implementation, and performance based on innovation diffusion theory or the technology acceptance model from a technology-centered perspective. The characteristics of the ability of BIM to enable innovative action have generally been the focus of research. Innovative capability is the ability of technology to enable its users to pursue innovative activities [2]. Selçuk Çıdık et al. [2] highlighted that most relevant research still focused on what BIM technology can provide as a technological window of opportunity in construction projects. The topic of what and how people use BIM on a daily or routine operational basis to improve construction projects remains underresearched, which means that there is ambiguity regarding the innovative capability of BIM in construction projects. In other words, the ability of BIM to enable a construction project network to build or possess the ability to work differently (i.e., to innovate) in order to improve performance has been highly neglected. Thus, a clear illustration of the enabling capability of BIM for CI, that is, a clearly defined relationship between BIM and CI as well as a thorough analysis of the value level of the ability of BIM to enable CI, is highly necessary.

3. Methodology

Recently, there have been an increasing number of researchers claiming that divergent thinking and creative research methods are required for construction research [11]. In particular, conceptual advances are considered critical to the vitality of scientific research, which should be encouraged for prosperity [11, 15].

Research design and method selection are extremely effective and have the greatest potential for innovation when they match the nature of the research question [16]. In this study, the research question concerns the value spectrum of the ability of BIM in enabling CI. The purpose is to establish a conceptual or structural framework and detail, articulate, chart, describe, and depict the innovative capability of BIM. A conceptual study with a delineation goal can serve this research purpose [15].

Conceptual articles are devoted purely to thought-based conceptions and are devoid of data [15]. If inductive and deductive reasoning becomes difficult, and empirical data are either not available, are too costly for exploration, or are not particularly useful, then reflective research is a valid qualitative research method that is suitable for abductive topical reasoning and resolving this paper's research question [11]. Reflective research methodologies are frequently used in research groups; however, they are less often applied to academic research in the construction field. Nevertheless, Singh [11] claimed that this kind of exploratory research could benefit the research community by identifying outliers that are not limited by methodological rigor or statistical evidence [11]. In this research, the concept and characteristics of the innovative capability of BIM were perceived and constructed by thoroughly reviewing the relevant literature, including books, reports, and other sources. Given that CI enabled by BIM is a dynamically evolving, complex process, aside from literature reviews, authors have discussions with colleagues and attendees of international conferences to delineate the innovative value of BIM. Further, thought experiments have been utilized to map the value spectrum.

Actor network theory (ANT), path creation theory (PCT), trading zone theory (TZT), and digital innovation theory have been applied to assist the research process. Based on ANT, technology and other artifacts are regarded as actors shaping roles and relationships in networks [17]. Under this perspective, we can take BIM application in construction projects as a rearrangement of an innovation network. BIM, as the equivalent of other innovation actors, breaks the behavioral and interactional modes between innovation networks and provides a transparent and synchronizing information-sharing channel, thus cultivating propitious conditions for innovation to occur. Although the initial development of digital innovation theory in the context of an information system or the organizational science discipline is still in its infancy [12], the overwhelming development and application of pervasive digital technologies in various industries have challenged the underlying logic of traditional innovation theory. New logic for understanding the novel paradigm of innovation induced by pervasive digital technologies has been provided, for example, taking digital innovation management as a sporadic, parallel, and heterogeneous process of forking, merging, terminating, and refining problem-solution design pairs; shifts in participant cognition and sense-making in emerging distributed innovation as well as the importance of digital platforms with orchestration mechanisms [12, 18]. All the aforementioned examples provide a proper theoretical framework on which our reflective study may build. Regarding the driving mechanism under CI enabled by BIM, this study takes advantage of PCT and TZT to demonstrate how BIM stimulates innovation on the individual actor level and from the interaction perspective among multiple innovation network actors.

4. Redefining the Relationship between BIM and CI

Indeed, BIM is much more than a purely simple innovative technology; rather, it is an engine that promotes CI [19]. With the emergence of the digital economic era, BIM is considered the heart of smart/digital construction, and it will evolve as a digital infrastructure/platform for innovation in the construction field [9, 19]. Research has established BIM as a significant innovator [20]. The use of BIM can generate both technological and organizational innovation and

enable potentially radical innovation that could disrupt the entire industry [9].

The current innovative capability of BIM has attracted the attention of researchers. For instance, Selçuk Çıdık et al. [2] proposed a conceptual continuum by synergizing the polarized functionalist (i.e., technology-centered) and nonfunctionalist (i.e., human-centered) perspectives on BIM to analyze its innovative capability. Boland and Lyytinen [6] found that BIM implementation in Frank O. Gehry's projects instigated diverse innovations, each of which created a wake of innovation. They concluded that Gehry's adoption of 3D BIM as the representational tool disturbed the ecology of interactions and stimulated innovations in his project networks by providing path-creating innovation trajectories in separate communities of practice, creating trading zones in which communities could create knowledge about diverse innovations, and offering a means for intercalating innovations across heterogeneous communities [6].

The aforementioned research concerning the innovative capabilities of BIM primarily focuses on the scope of design practice. Increasingly, the enabling effect of BIM on CI has been expanded to the project life cycle or beyond. In a deductive case study, Holmström et al. [19] investigated how sociotechnical actions such as adoption, reuse, and recombination of designs and processes empower the users of BIM tools to not only achieve productivity improvement in particular activities but also build system capabilities that enable new ways of working. Recently, the incorporation of BIM within the life cycle project management system in the construction field has been highlighted [21, 22]. All of the evidence previously shown demonstrates that the collaborative application of BIM throughout the entire life cycle of a construction project will disrupt the CI ecosystem and provoke the emergence of new innovation patterns, the reduction of communication costs, and the creation of digital convergence that may lead to new interactions and relationships between innovators. New knowledge, skills, and innovative possibilities, accompanied by the associated cognitive and social translation, can occur through the penetration of boundaries [23]. Therefore, by considering the life cycle project management theory and aligning it with the analytical framework used by Boland and Lyytinen [6], this study redefines the relationship between BIM and CI (Figure 1).

CI represents the engineering of problem-oriented innovation activities on the construction project level, which are usually completed collaboratively. The path for CI can be illustrated as a dynamic problem-solution matching process from both an individual organizational perspective (i.e., path creation) and a cross-organizational perspective (i.e., collaborative innovation). During these processes, the embeddedness of BIM serves to activate an individual organization's subjective initiative and accelerates collaboration between organizations to support CI.

A CI network enabled by BIM can be considered a digital ecosystem, a concept that Sawhney et al. [24] defined as a complex intermeshing of an interdependent group of organizations, people, products, and things that work on a shared digital platform for a mutually beneficial purpose and value creation. In this digital ecosystem, BIM, as a shared digital platform or orchestrator, as claimed by Nambisan et al. [12], offers a convergent approach to make project data available for multiple construction technology use cases (e.g., design management, document management process simulation, and project scheduling), thus becoming a key driver of innovation, emergent ecosystem behavior, and value creation [24, 25].

As demonstrated in Figure 1, BIM provides a window of opportunity for people to work differently to improve (i.e., innovate) on an operational level in separate practice communities [26]; path creation enabled by BIM provides innovation trajectories for actors within their organizational boundaries. For example, triggered by the demands and opportunities of high-profile projects and the state of development within each firm, participants in innovation networks enabled by BIM could mindfully invent their own innovation trajectories at different paces. Moreover, some could be more collaborative in their project organization, whereas others could be more experimental with materials and work practices [6].

According to Galison [27], when community boundaries cross or overlap during a project, a trading zone emerges. Owing to certain occasions or specific project tasks, various innovations can be interplayed in trading zones supported by BIM at permeable boundaries (shown in Figure 1 as the circles of dotted lines). In these trading zones, owners, designers, and contractors take artifacts (e.g., the BIM model) authorized by BIM as boundary objects or a common language to constantly refine and mutually adjust their interrelationship, thereby establishing a new interdependent network system so they can work together to produce innovative solutions for various design, construction, and delivery tasks. For example, based on a BIM platform, a construction company can work with trade contractors and third-party software developers to develop a tool for the real-time monitoring of construction workers to track worker safety, productivity, and well-being [24]. Path creation and the interplay of various innovations in trading zones will together lead to the so-called "wakes of innovation" enabled by BIM among the construction project network [6]. During these processes, knowledge evolves, learning occurs, and new action patterns are constructed.

Although BIM is an overall approach, BIM application is a dynamically evolving elaboration, because there are various functional specifications that can be implemented at different phases of a project's life cycle that can bring distinctive benefits and costs [26]. In reality, the application of BIM shows various possibilities with different functions (i.e., what BIM can do)—depending on when, where, and how people use it—and the interactions among individuals during its implementation (i.e., what people can do with BIM) [2]. Therefore, different types of BIM implementation will provide various levels of enabling effects on CI. However, people realize that BIM application has innovative value for construction projects and its users; however, the problem lies in how much value it brings and, particularly, how and in which situation the application of BIM can contribute to improving innovation efficiency for actors and
Figure 1: Relationship between BIM and CI.

networks of construction projects. This vagueness on the innovation value spectrum of BIM will consequently hinder construction projects in terms of taking full advantage of BIM to assist CI [26].

5. Value Spectrum of the Ability of BIM to Enable CI

5.1. Application Modes of BIM for Construction Projects. As previously mentioned, there are many possibilities of the application of BIM in construction projects, or various so-called "BIM application modes," which are highly dependent on the type of interactions and relationships between the participants and how BIM is used [28]. Based on a case study of 25 BIM projects, Taylor and Bernstein [29] identified 4 BIM application modes—the visualization, coordination, analysis, and supply chain integration modes—which are consequently incrementally involved in the BIM experience. From the interoperability perspective, Grilo and Jardin-Goncalves [28] acknowledged that various interaction styles between project network actors can lead to different kinds of BIM utility, namely, communication, coordination, cooperation, collaboration, and channels. To sum up, because of the heterogeneous and systematic characteristics of BIM, BIM allows various application statuses to coexist in the construction industry. In this study, grounded on the aforementioned literature coupled with validation from senior BIM experts, the BIM application modes finally include the visualization, coordination, analysis, collaboration, and infrastructure modes.

5.2. Classification of CI. The classification of CI made by Slaughter has been commonly acknowledged in this field [8, 20], which will be applied to be the framework measuring the innovation value level of BIM in this study. As per changes regarding the concept and its linkage to other components, Slaughter classified CI into five

clusters—incremental, modular, architectural, system, and radical—as shown in Figure 2.

According to Figure 2, incremental innovation is a small improvement to the standard practice based on existing experience and knowledge that influences the constraints of a specific element. Incremental innovation is usually more frequent in the construction industry than in other industries, such as the manufacturing industry. Actors from the entire value chain of a construction project can generate incremental innovation, for instance, by improving the products provided by a supplier or modifying the on-site construction process. Modular innovation is a relatively large change on the concept level within a component that has limited influence on the links to other elements or systems. The replacement of drawing with hands with computer-aided design (CAD) is a typical example of modular innovation, which only changes the way people design or draw in terms of the concept of design drawing; the changes to the relationships between design groups are very limited (i.e., they are still done using 2D paper drawings). Contrary to modular innovation, architectural innovation requires only trivial modification of concepts/elements but substantial revisions of the linkages with other elements/ systems, such as incorporating self-compacting concrete. There is no obvious change to the concrete technique itself; it is the fact that under gravity, the fluidity, density, and homogeneity of concrete can be achieved without additional vibrating process changes in the interaction and interconnection between the activities related to this work. To achieve new functions or levels of performance, system innovation involves the integrative innovation of multiple innovations that requires the effective rearrangement of the subsystems comprising the system and relative changes in corresponding elements/systems. One example is the application of ballastless tracks in railway construction. The realization of systematic innovation, such as a ballastless track, requires the integration and coordination of multiple independent innovations (e.g., new orbital technology, new
Figure 2: The classification of CI adapted from Slaughter [4].

roadbed construction technology, and new maintenance technology). Radical innovation is a rare and unpredictable breakthrough in science or technology that might lead to the essential reform of an entire industry. For instance, the realization of the so-called digital twins (DT) mode may overturn the overall working logic for the construction industry.

The five types of innovation presented through the model can be arranged as per the scale of required change from the current state-of-the-art practice as an incremental, modular, architectural, system, and radical [4] (see Table 1).

The innovation classification system proposed by Slaughter [4] is utilized as the innovation value metric for measuring the innovative capability of BIM. On the one hand, the enabling effect of the application modes of BIM on CI is highly dependent on the willingness of actors in distinct communities (innovation path creation for concept change) and the interaction mode and interrelationship between various project network communities (linkage changes based on trading zones). On the other hand, assuming that innovation provides improvement through change, an innovation classification model based on the degree of change is appropriate. As demonstrated in Table 1, it is easier to describe the specific resources and activities (e.g., the timing of commitment, degree of coordination within the project team, need for special resources, and type and level of active supervision) [4] required for the application of BIM to enable the relevant level of CI. The alignment of the application of BIM with the classification of CI in exploring the value of the innovative capability of BIM is demonstrated in Table 1.

5.3. Analyzing the Value Level of BIM in Enabling CI. Based on the combination of Slaughter's [4] CI classification system and the BIM application mode summarized in this study (as shown in Table 1), the value spectrum for the innovative capability of BIM will be analyzed as follows (Figure 3). In Figure 3, the x-axis represents the evolution of BIM application modes, while the value of the innovative capability of BIM is demonstrated on the y-axis. As the scope and maturity level of a BIM application evolves, BIM application modes become more innovation-friendly environments. In other words, in different application modes,

BIM provides different levels of innovation value. The wider the scope and the more mature the implementation of BIM, the higher the innovation value of its application in a construction project. Thus, the BIM application mode can be arranged according to the innovative value level of aspects such as visualization, coordination, analysis, collaboration, and infrastructure, as illustrated in Figure 3. This value proposition is not very solid and rigorous because incremental innovation to some actors may be considered modular or systematic innovation to other actors. Thus, the analysis and results herein are conducted on the construction project level and depart from the perspective of general project benefits.

5.3.1. Visualization. Since the 1990s, the visualization mode of BIM has been widely applied in the construction industry, mainly for marketing or aesthetic requirements. The application of BIM visualization demonstrates a great effect on the design and construction phase. First, 3D models of BIM designed on the basis of a 3D entity component provided by suppliers highly improve the designing efficiency. Second, the application of BIM makes communication between designers and owners regarding design intentions more convenient, thus enabling effective information to be correctly conveyed to the relevant team member. In a virtual environment based on BIM, many kinds of "what ifs" can be demonstrated and compared intuitively, which can accelerate the optimization of design solutions by smoothing the communication and cooperation targeting design objectives and solutions. On the construction stage, compared to two-dimensional (2D) painting, 3D models enable contractors to more easily and clearly understand the owner's actual design requirements and intentions, which consequently reduces changes and requests for information subsequently in the project's life cycle.

The BIM visualization mode is essentially the transformation from 2D to 3D presentation technology. Therefore, the visualization mode of BIM application accelerates incremental innovation in construction projects at any time during the project. Incremental innovation enabled by BIM based on the visualization mode only involves small improvements and most of time is constrained by the scope of a single organization with no special resources or coordination required. The related supervision of the individual task level focuses on improving the notification manner and the supervisory competencies of the specific improved product, process, or service.

5.3.2. Coordination. The coordination mode of BIM creates mutual benefits and avoids gaps and overlaps to connect various project activities and efficiently realize project objectives [28]. The coordination of the designing documents (e.g., structuring, plumbing, designing, and drawings) is an important example of this application mode. The coordination of complex systems is a common application in construction projects. The virtual 3D model is completed by various team members. No matter who the consultant is, a specialty manufacturer or a subcontractor, every team

Table 1: Alignment of innovative capabilities of BIM with innovation models for construction adapted from Slaughter [4] and Murphy [20].

| Type of CI	Definition	Scale of change	Example	Timing of commitment	Resource and activities required by BIM-enabled CI						BIM application mode
					Degree of coordination within the project team	Need for special resources	Supervision organizational level	Supervision type	Supervision competency	Enabling mechanisms	
Incremental	A small improvement to the standard practice based on existing experience and knowledge	Small	Modified construction process conducted on-site	At any time	None	None	At locus of improvement	Notification	Specific product or process		Visualization
Modular	A significant change in concept within a component but one that leaves the links to other components and systems unchanged		Computer-aided design (CAD)	At the design stage	None	For concept change	At design level	Notification, review	Technical competency	Path creation oriented	Coordination
Architectural	A small change within a component but a major change in the links to other components and systems		Self-compacting concrete	At the design-to-implementation stages	Among affected parties	For complementary changes	At the affected system level	Notification, agreement, review	System competency		Analysis
System	Multiple integrated innovations that complement each other to achieve new functions or levels of performance		Ballastless track	At the conceptual design stage	With all project team members	For integration of set of innovations	At top engineering management level	Project scope, agreement, review	Technical, system competency and organizational authority	Trading zone building oriented	Collaboration
Radical	A breakthrough in science or technology	Major	DT	At the technical feasibility stage	With top management from all involved organizations	For breakthrough	At top management level	Project objectives and scope	Specialized technical competency	Trading zone building + path creation oriented	Infrastructure
Figure 3: The value level of the innovative capability of BIM in construction projects.

member will create their own model for their work purpose in a project. The general contractor will integrate these independent models to form a more holistic composite model that represents the overall picture of the project. Based on the coordination of the constituent components of the composite model, possible conflicts can be identified and resolved before execution; thus, this mode is also known as the conflict detection mode.

The coordination mode of BIM application invokes conceptual change of coordination issues in construction projects (e.g., design checks and clash detection) while having little influence on other systems. In this mode, innovative solutions are likely to be created in order to realize conceptual goals. Thus, the value level is in modular innovation. Modular innovations enabled by BIM are usually created during the design and bid stages. Because changes to the links to other components or systems are rare, very little explicit or implicit coordination within the project team is required. The resources required for a conceptual change must be prepared to conduct modular innovation enabled by BIM, such as the training required to install and maintain a component embodying a modular innovation. Relative supervisory activities (i.e., notification and review and technical competency) are required on the design and bid levels to ensure modular innovations enabled by BIM meet project objectives.

5.3.3. Analysis. The analysis mode of BIM application realizes mutual benefits through sharing and cooperation. In the 3D virtual project environment based on BIM, the constructability and construction sequence can be clearly simulated. The entire arrangement of any specific task can be visualized in a 3D virtual environment based on BIM so that the schedule can be properly allocated. The BIM analysis mode provides the possibility to moderate and analyze construction costs and operations from the whole life cycle perspective. Moreover, BIM possesses many potential analytical capabilities for construction projects (e.g., energy consumption and lightning, wind flow patterns, and greenness). Theoretically, one central BIM model could be

formed with all of the information needed by all contractors and consultants—information that contractors previously had to create independently from an architect's 2D blueprints [6]. The application of the analytical functionality of BIM requires construction project stakeholders to correctly and timely renew the information in the BIM model and share relevant information, which overturns adversarial relationships between project team workers and persuades them to constantly optimize project solutions from a holistic perspective. Indeed, the BIM analytical mode has not changed the way relevant analysis is done; however, it changes the interactions and links between different analysis systems: the data used for analysis can be retrieved if team workers correctly and timely input and share the BIM model information rather than repeatedly manually measure and calculate them.

In this BIM application mode, there is more potential for architectural innovation to occur, which requires the support and encouragement of organizations at the system level with strong management and control capabilities. For major changes to system or component links, architectural innovation enabled by BIM may require a greater degree of supervision and coordination among the affected parties. To ensure high-level performance from the completed system, the supervisory activities required include notification, agreement, and constant review and revision. Coordination among project team members based on BIM includes both official contract changes (e.g., if architectural innovations based on BIM lead to new project deliverables) and unofficial coordination (e.g., commitment to cooperate). Small conceptual changes may lead to a wide scope of BIM-enabled architectural innovations, from design-to-implementation, with special resources associated with complementary changes.

5.3.4. Collaboration. The collaboration mode involves the full application of BIM in a construction project. Collaboration in a construction network based on BIM is a nonadversarial, team-based environment of mutual trust in which key participants are jointly involved in developing and augmenting the central BIM model throughout the life cycle of the project and where everyone understands and respects the input of others. The BIM model, as a central information resource, is a collaboration platform based on which the project's life-long activities are conducted (e.g., the owner develops an accurate understanding of the nature and needs of the project; the designer designs, develops, and analyzes the project; the contractor manages the construction of the project; the asset manager administers the operations of the project during the operation and decommissioning phase) [28, 30]. Through the collaborative application of BIM, the key participants jointly maximize the value of a construction project by mutually solving problems using proper contracts and fair risk/benefit sharing mechanisms. This application mode is pivotal to the formation and synergy of CI networks. The collaboration of a CI network based on BIM can bring about a synergistic effect that a single or a few functionalities or software programs

cannot establish. The integrative application of BIM over the whole life cycle of a construction project provides reliable information and a knowledge-sharing platform for decision-making. Based on this, joint goals, joint responsibilities, and mutual understanding and respect are easily formed; team workers can communicate fluently and work together for innovative solutions rather than simply for efficient and similar results as in traditional approaches, thus creating a context for system innovation [3, 28]. With the execution of the collaboration BIM application mode, systematic CI has rich grounds to flourish upon.

Commitment to systematic innovation enabled by BIM is usually made during the conceptual design phase because it often involves new functions or increased levels of performance of an entity or a facility as a whole [4]. During the conceptual design phase, the collaborative innovation network enabled by BIM was designed, which facilitates the integration of a set of innovations. Coordination among network actors is assigned through official contracts or unofficial negotiations to reach a common sensibility of the information sharing and resources related to each innovation and their integration. The integrated project delivery method, or the design assistant kind of contract, is used by all project team members. The risk associated with system innovation may require active supervision by top engineering managers who are concerned with incorporating it into the project scope, obtaining agreements, and constantly reviewing its implementation and performance. These supervisors require technical and system competencies to assess the complementary changes needed to effectively implement the system innovation combined with organizational authority in order to ensure collaboration and integration. Professionals not only need to possess knowledge related to the individual innovation and its integration but must also master relevant collaboration knowledge concerning system innovations enabled by BIM [30].

5.3.5. Infrastructure. With the coming digital economic era, the Internet 3.0 has enabled various possibilities for many different industries. In contrast to previous technological changes in the AEC industry, Morgan [9] claimed that the application of BIM has the potential to generate radical innovations that could disrupt the entire construction industry. The infrastructure application mode of BIM is more of a vision for the near future of the construction industry in the digitalized era wherein BIM is perceived as the most stable digital infrastructure [9, 19]. With BIM as the core digital infrastructure, the combination of divergent digital technologies (e.g., Internet of Things, 3D printing, and robotics) will thoroughly reform the productivity of the construction industry by welcoming the smart and digital construction era.

Radical innovation enabled by BIM entails not only financial and project risk but also the potential for technical failure, meaning that the commitment to this kind of innovation must be completed as early as possible, most often before the project is initiated (e.g., during the technical feasibility stage). Correspondingly, coordination of explicit and implicit cooperation and relative supervision requires the support of top management of all involved organizations. Consequently, the objective and scope of construction projects must be redefined, and the special resources required for radical innovation related to scientific or technological breakthroughs enabled by BIM might bring new challenges for top managers in terms of technical competencies in the specific scientific or technological area to monitor the implementation process and adjust the innovation activities accordingly [4].

6. Discussion and the Future BIM Agenda

Industry practitioners and academia mostly perceive BIM as a tool and an application and occasionally as a methodology. Consequently, research related to BIM mostly focuses on practice and application. BIM theory-building has been vastly limited [11]. Therefore, analogous to the development of management information systems as a discipline, Singh [11] claimed that there is a need to rethink the scope of BIM as a discipline emerging at the interface between construction, computer science, information management, and social science domains. The underpinning theoretical and conceptual questions regarding BIM have not been sufficiently investigated. Thus, our study joins this conversation by extending the BIM management research to the digital innovation management area by incorporating BIM into the domain of CI from a sociotechnical perspective [12]. In a CI network based on BIM, BIM may not only be an actor (i.e., a node) but also a relationship (i.e., a link) between elements or actors depending on the functionality used. This provides a new perspective for theory-building and practice of CI management. The underlying mechanisms for CI enabled by BIM will be analyzed based on path dependence theory and TZT in the following section. From the management information systems perspective, digital innovation and BIM-enabled digital innovation ecosystems will be utilized to describe the radical innovation value that BIM might be able to provide.

6.1. Mechanisms Underlying CI Enabled by BIM. As is depicted in Table 1, the enabling mechanism of incremental and modular innovation enabled by BIM based on the visualization and coordination modes is mainly path creation. The innovation trajectories of the involved actors are stimulated by the demands and opportunities of high-profile projects and the development status of each organization. Across the spectrum of engagement in path creation, actors may move at different temporal paces following their own logic and structure. The areas that incremental or modular innovation conduct are dependent on the professional identity and economic interests of the specific organization or community. Thus, they are sometimes more advanced in their use of technologies or are more experimental with their materials and work practices [6]. As the scope of change increases, the depth and width of the application of BIM in the analysis, collaboration, and platform modes rise. Aside from path creation, the innovating mechanism based on BIM focuses more on building trading zones. In these newly

created interactive trading zones, the innovative level is aligned with the intensity of the interactions enabled by BIM. The infrastructure mode of the application of BIM leads to brand new innovation paths and disturbs the existing construction industry ecosystem, bringing new interaction modes among construction project-level innovation networks. As the establishment of trading zones becomes the dominant innovating mechanism, innovators of the CI network enabled by BIM gradually tend to innovate based on a shared identity, common vocabularies, and mutual understanding. In this situation, the innovation trajectories of separate actors or communities cross with those of others. Such interplay of innovations not only invokes new knowledge and skills for system innovation but also provide occasions for further upgrading of their separate innovation paths. To achieve higher value levels from innovation activities enabled by BIM, their tempo, structure, and logic should be aligned with a coherent and synchronized plan [6].

6.2. Systematic Innovation Enabled by BIM Based on Collaboration.

The collaborative BIM application mode is the current goal of BIM implementation in a construction project. Collaborative BIM applications can reap value from incremental to system innovation, as shown in Figure 3. However, systematic innovation based on BIM through collaboration has not been thoroughly investigated in the literature [3].

BIM-CI is a dynamic problem-solution pairing process [12]. The implementation of BIM will change the interaction mode between the elements and actors involved and accelerate the formation and synergy between CI networks, thereby improving the innovative capabilities of BIM-CI networks [3]. BIM-CI networks are not designed but emerge from the interaction of individual social or technical elements or actors [31]. As an orchestrator, BIM plays the role of collaborative innovation platform, leading the innovation network to realize the synergistic effects of resource integration, effective communication, and common vision-building. The evolving and the emerging mechanism underlying this synergistic effect deserves further exploration.

Given the critical position of systematic innovation enabled by BIM in the value spectrum of the ability of BIM to enable innovation in construction projects, Liu et al. [3] proposed an inclusive systematic theoretical framework for collaborative CI enabled by BIM (also known as an "innovation pyramid"). This dynamic and evolving socio-technical system contains six interdependent subsystems—contexts, actors, artifacts, processes, structures, and innovative tasks—as illustrated in Figure 4. In this system, actors possessing varying attitudes, requirements, and abilities use a range of technologies and tools (classified as artifacts) and work within a context with structures and a regulatory framework to take advantage of all of the resources (processes) to achieve the assigned innovative tasks [3].

To reach the synergistic effect of a BIM-CI network, the subsystems must fulfill enormous emerging requirements

Figure 4: Collaborative innovation enabled by BIM in construction projects by Liu et al. [3].

and overcome many challenges [32]. For example, new professional roles and skills are needed; when innovative new tasks (e.g., some construction companies have started to sell "Building as a Service") for a new service emerge, the structure of the BIM-CI network (i.e., relationships and interrelationships, etc.) must be adjusted. Novel processes for the new form of business are required to implement workflow changes [33]. Further research should systematically examine the new problems faced by each subsystem. Additionally, the interactions, interrelations, and mutually adjusting effects of the subsystems on a macrolevel should also be investigated [3].

6.3. BIM as the Infrastructure for a Digital Innovation Ecosystem in Construction 4.0.

Through collaboration, CI enabled focuses on reaping the systematic innovation value of BIM within the confines of a construction project. The extensive digitization of the construction industry persuades us to consider the bigger picture on an interproject and an industrial level and beyond.

Industry 4.0 has introduced digital technologies, sensor systems, intelligent machines, and smart materials to the construction industry [1]. This transformation is known as "Construction 4.0" [34]. With the adoption of advanced technologies, the processes and outcomes of CI have been gradually digitalized, thereby upending existing theories on innovation management by calling fundamental assumptions into question, such as the following: Are innovation boundaries definitional? Can innovation actors be predefined? Can innovation processes and outcomes be separated? [12].

Under such circumstances, the CI enabled by digital technologies urgently requires specific attention. The concept of digital innovation proposed in the information systems management field can be applied here. As explained by Khin and Ho [35], digital innovation is the development

of new products, services, or solutions using digital technology (e.g., big data, Internet of Things, cloud computing, ontology, blockchain, data analytics, laser scanning, augmented and virtual reality, artificial intelligence, machine learning, and cyber-physical systems), in other words, in digital innovation, digital technologies and the associated digitizing processes form an inherent part of the new idea and its development, diffusion, or assimilation [12].

Digital innovation research brings digital technologies into the foreground of innovation management [31]. On the radical innovation value level, the DT mode is a revolutionary idea for realizing smart construction and Construction 4.0 [36, 37]. The key point for DT or Construction 4.0 is using BIM to connect virtual and actual building activities [35]. For the integration of this autonomous and synchronized cyber-physical system, BIM must collaborate with other cutting-edge Construction 4.0 technologies that embrace digital construction by transforming the construction industry into a dynamic environment [38].

To do so, a digital technologies ecosystem with BIM in the center as a common data infrastructure for enabling radical CI should be established. This "digital innovation ecosystem" refers to a dynamic, evolving network comprising heterogeneous elements [31]. The combined effects of several digital innovations in this ecosystem will bring about novel actors (and actor constellations), structures, practices, values, and beliefs that change, threaten, replace, or complement existing rules within organizations and fields [39]. How do we achieve an effective orchestration of these digital innovations? [12]. What is the structure of this complex, emerging, dynamic network? What are the emerging mechanisms underlying such digital innovation ecosystems? These are all equally significant issues that require examination. As digital technologies play an increasingly important role in construction and innovation activities, a challenging but fascinating set of security-related, ethical, legal, and regulatory issues also arise. How do we mitigate any potential negative influence while reaping the benefits of such digital technologies [40]? This is another research concern regarding digital innovation governance that should be investigated in future research.

7. Conclusions

This study explores a neglected area—the innovation-enabling potential of BIM in construction projects. Specifically, it analyzes and evaluates the value level of the ability of BIM to enable CI. The relationship between BIM and CI was redefined as shown in Figure 1. Besides the fact that BIM is often perceived as a typical construction innovation that offers efficiency and productivity improvements through its various functions or by extending BIM applications, BIM is instead an engine of CI. The main enabling mechanisms of BIM in terms of CI are path creation and trading zone building. Based on this fact, the value spectrum of the innovative capability of BIM was determined by coupling Slaughter's [4] CI classification system and BIM application modes in construction projects, as illustrated in Figure 3, with the resources and activities required to promote CI

enabled by BIM. Additionally, the underlying innovating mechanisms are described in detail in Table 1. Various BIM applications provide different proinnovation environments wherein various levels of innovation may occur and flourish. The results indicate that extra attention should be paid to systematic innovation enabled by BIM based on collaboration and digital innovation ecosystems with BIM as their core infrastructure that integrates cyberspace and physical space to accelerate radical innovation.

Theoretically, this research extends the scope of the BIM management research considering digital innovation management issues and provides a new perspective for CI theory-building and management practice. The relationship between BIM and CI and the mapping of the value spectrum of the innovative capability of BIM provides researchers in this field with a novel perspective on the innovative capabilities of BIM. Relevant research should take the relationship structure and value spectrum map as departing points to design and develop further research. For practitioners, the detailed resources and activities required and the enabling mechanisms for relative levels of BIM-enabled CI can serve as good reference points to guide and inspire BIM-based project management practitioners to develop innovative solutions, solve corresponding engineering problems, improve efficiency, and build better projects.

However, regardless of its contributions, this study also has some limitations. This conceptual study is an initial exploration of the value spectrum of the innovative capability of BIM. Because the goal of this study is to conceptually delineate the innovative capability of BIM, the main research methods applied in this study were the literature review, reflective thinking, and thought experiments, during which abductive and logical reasoning was required, and traditional qualitative research methods (e.g., ground theory) were not utilized, which may cause some concern regarding the validity of the results. Thus, future qualitative and quantitative exploration of the value spectrum map of the innovative capability of BIM is required. In other words, these also create future opportunities to research BIM-enabled CI or digital innovation in the construction field. For instance, further research can apply more quantitative or mixed-methods research to validate the corresponding relationships between BIM and CI and develop relevant research questions, such as the following: Is there a corresponding relationship between the BIM application mode and the level of CI? Do the strategy and resources for enabling relative BIM-enabled innovation illustrated in this study suffice? Is the match between BIM and CI influenced by the delivery mode or owner involvement? How can the innovative capability of BIM in construction projects be activated?

As overwhelming as the development of Industry 4.0 was, the new concept of Industry 5.0 has also been recently proposed [41]. Industry 5.0 highlights the importance of human-centricity, sustainability, and resilience in addition to digitalization itself. Accordingly, the new paradigm of Construction 5.0, the construction industry's version of Industry 5.0, should be put on the agenda. As BIM plays a core role in this transformation, BIM/digital innovation-

related research should pay extra attention to human-centered, environmentally friendly, and risk-related issues to promote the sustainable development of the construction industry.

Data Availability

No data were used to support this study.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

Authors' Contributions

Conceptualization was done by Hui Liu and Qianqian Ju; methodology was provided by Hui Liu and Miroslaw J. Skibniewski; resources were provided by Na Zhao and Hujun Li; the original draft was prepared by Hui Liu; review and editing were done by all authors. The authors have read and agreed to the published version of the manuscript.

Smart Garden Planning and Design Based on the Agricultural Internet of Things

Yi Xun and Guangpei Ren (iD)

School of Art and Design, Guangdong University of Technology, Guangzhou, Guangdong 510060, China

Correspondence should be addressed to Guangpei Ren; ren20171220@gdut.edu.cn

To improve the effect of urban agricultural garden landscape planning and design, this paper combines the agricultural Internet of Things technology to construct a smart garden planning and design system. Moreover, this paper selects the LEACH protocol that can support monitoring for a long time according to actual application needs, introduces the latest swarm intelligence optimization algorithm, the gray wolf algorithm, to optimize some of the problems in the LEACH protocol, and conducts simulation experiments on the improved algorithm. The simulation experiment results show that the improved algorithm has obvious advantages in cluster head selection, data transmission within the cluster, and route maintenance. After constructing a smart garden planning system based on the agricultural Internet of Things, the effect of the agricultural Internet of Things data processing in this paper is evaluated. Finally, this paper constructs a garden simulation system and analyzes the performance of the system. The results verify that the agricultural Internet of Things has a good effect in the planning and design of smart gardens.

1. Introduction

Ecological culture is a new cultural outlook that represents new trends and trends in the world. It represents the awakening of human beings from the ignorant concept of ruling and conquering nature, seeking a way to respect and coexist in harmony with nature. It is the "ecological" and "natural" transformation of the central values of mankind [1].

Regarding the definition of the term landscape, many scholars have put forward different interpretations. In the field of landscape ecology, it studies the ecosystem of the entire natural world, and it focuses on the interaction between ecological subsystems such as climate, geology, soil, vegetation, hydrology, animal and human activities, and their impact on nature. In addition to studying the characteristics of the objective laws of the generation, development, and evolution of the landscape ecosystem itself, it also seeks measures and ways to rationally utilize, protect, and manage the landscape. The field of landscape geography focuses on the changes of natural landscape morphology,

emphasizes the natural characteristics of the landscape, and pays attention to the development and evolution of landscape morphology and landform. From the perspective of landscape architecture, it focuses on the relationship between humanity and nature from the relationship between human and landscape and social attributes. The connotation of the landscape shows obvious characteristics of dynamic changes with the influence of human activities and the change of regional form. From the perspective of the entire development history of human society, the landscape on the Earth is the result of human adaptation and transformation of the natural world [2]. From the definitions of the three major disciplines mentioned above, it can be summarized that landscape is the trace left on the land by human activities or the interaction between humans and nature. The landscape can be regarded as an organic collection composed of a series of symbolic landscape elements. The landscape elements are the unit elements that make up this large collection of landscapes. Therefore, landscape elements can be divided into two categories: natural landscape elements and artificial landscape elements. Natural landscape

elements include terrain, soil, vegetation, and Fengshui patterns, and artificial landscape elements include road paving, sketches, and buildings [3].

In recent years, rural revitalization has been a key work and policy measure in my country. Rural complexes are an important measure to realize rural revitalization. Since the concept of rural complexes was put forward, many cities and towns in my country have been put into practice. However, research on rural complexes and the development of on-site projects is not perfect, and the aspects involved are relatively limited, mainly including leisure and entertainment, physiotherapy, sightseeing agricultural picking, and specialty catering. There are relatively few research studies and analyses on building a smart pastoral complex from the perspective of global tourism combined with the Internet of Things. Global tourism is not the same as previous tourism, blindly pursuing the growth of tourist visits, but focusing more on the improvement of tourism quality. Above all, global tourism aims to build tourism into tourism that can improve people's quality of life and also pursue the value of tourism in people's new wealth revolution.

Taking the agricultural pastoral as the theme, this paper combines the agricultural Internet of Things technology to carry out smart garden planning and design, so as to promote the development of the industry and raise people's awareness of ecological protection and bring people a good pastoral scenery experience.

2. Related Work

With the continuous development of spatial geographic information acquisition technology and computer communication technology, the amount of geographic information data continues to expand, and the difficulty of information extraction and analysis continues to increase. Geographic information has gradually changed from a "digital city" to a "smart city" [4]. At present, various countries are developing smart city projects in line with their own national conditions, such as smart grids in the United States and smart communities in the European Union. With the gradual maturity of 3D geographic information technology, 3D geographic information data have finally entered a wide range of applications in recent years, new stage [5]. In terms of data acquisition methods, noncontact rapid batch acquisition of large-scale data has been achieved at home and abroad. Oblique photography technology, which uses multisensor or dynamic sensors to synchronously collect images from the air, can collect rich high-resolution texture data on the surface and side of buildings and is an upgrade to the traditional single-sensor acquisition method of aerial photography [6]. Literature [7] shows a 3D map made with oblique photography data. At present, the AOS system in the United States, the Penta-DigiCam system in Germany, the A3 system in Israel, and the RCD30 in Leica in Germany are widely used internationally [8].

With the popularization of drone technology, tilt photography technology has also shown explosive growth [9]. Now, in the smart city 3D modeling project, the oblique photography 3D modeling program has taken a place [10].

In addition, LiDAR technology, namely, laser scanning, has also emerged in many fields. It can quickly obtain high-precision point cloud data and is widely used in many fields such as surveying and mapping, architecture, deformation monitoring, mechanical engineering, archaeology, cultural relics protection, and autonomous driving [11]. At present, common international laser scanners include German ATOS 3D optical scanner, Swiss Leica 3D laser scanner, Austria RIEGL laser measurement system, and American Trimble 3D laser scanner [12].

In recent years, high-resolution satellite remote sensing technologies have also been continuously developed, such as QuickBird and WorldView in the United States. In my country, the Chinese "High Score Family" represented by Gaofen No. 2, No. 3, and No. 4 also provides reliable DOM (Digital Orthophoto) and DEM (Digital Elevation Model) for smart city 3D modeling projects data [13]. In the use of oblique photography data for 3D automatic modeling, there are foreign Smart3DCapture, Pixel Factory, PhotoMesh, PohtoScan, etc., which are all powerful tools suitable for the rapid production of smart city 3D models [14]. In the use of laser point cloud data for 3D automatic modeling, the current use of refined reverse engineering modeling software is mainly not suitable for the automatic production of large-area smart city 3D model data [15].

The massive data of smart cities need to be supported by software platforms with spatial management and analysis functions, such as SkylineGlobe, ArcGlobe, CityEngine, etc., which are all currently used smart city geographic information platforms [16].

Smart city 3D models have a wide range of data sources, different production methods, and data structures. Only when a unified standard specification is formulated, can the data interoperability be realized [17]. The Open Geospatial Consortium (OGC) has established the 13S standard as a new international three-dimensional standard, which is a standard specifically designed for three-dimensional spatial geographic information data [18].

3. Agricultural Wireless Sensor Network Model

In order to make the research on wireless sensor networks more targeted, the research content in this article is based on the following assumptions:

(i) The sink node is located in the monitoring area, and its energy is continuously supplied by an external power source. It has stronger computing and storage capabilities than ordinary nodes, can connect to the external network, send data to remote observers, and maintain communication with at least one node in the network.

(ii) The scale of the sensor network is designed to be 200 nodes, and they are randomly and evenly distributed in the monitored area. The nodes have limited energy and are supplied by their own batteries. They have certain computing and storage capabilities, and can sense their own remaining energy, and follow the network operation. As time progresses,

the energy consumption of each node is not the same, and the energy of the nodes will be inconsistent.

(iii) After the node is deployed, once the network is started, the position of the node will no longer change, and the node can know the distance between itself and other nodes through RSSI.

(iv) All nodes have similar communication capabilities and data processing capabilities, there is no super node, the channels between the nodes are symmetrical, the node's transmission power is limited, and it has a unique ID code.

(v) The communication success rate of all nodes conforms to formula (1). There is a communication path with a hop count of h in the network. If it is assumed that the communication distance of the i-th hop is d and the effective communication distance of the node is r, then the communication success rate obeys the following formula [19]:

$$P_{\text{suc}}(h) = \prod_{i=1}^{h} p(d_i) = \frac{(0.2)^h d^h, d^h, \ldots, d^h}{r^h} \leq 0.2^h. \quad (1)$$

It can be seen from formula (1) that the fewer the number of hops, the shorter the path and the higher the communication success rate [20].

The wireless sensor network communication channel is a random channel.

$$E_{\text{Tx}}(k\ d) = E_{\text{elec}}(k) + E_{mp}(k\ d) = \begin{cases} kE_{\text{elec}} + k\varepsilon d^2, & d \leq d_0, \\ kE_{\text{elec}} + k\varepsilon d^4, & d \geq d_0. \end{cases} \quad (2)$$

Here, E_{elec} is the receiving module to complete a complete transceiver, ε_{fs} and ε_{mp} depend on the parameters of the transmitting circuit and the receiving circuit, d is the distance between the transmitting node and the receiving node, and the calculation formula of d_0 is as follows:

$$d_0 = \sqrt{\frac{\varepsilon_{fs}}{\varepsilon_{mp}}}. \quad (3)$$

d_0 is the distance threshold. When d is less than d_0, the communication of the node obeys the free space model.

$$E_{rx}(k) = kE_{\text{elec}}. \quad (4)$$

The LEACH protocol is a WSN hierarchical routing protocol, which occupies a very important position in the research of WSN routing protocol. Figure 1 is a schematic diagram of LEACH protocol clustering. Clustering algorithms such as DCHS, TEEN, and APPTEEN, all borrow the idea of LEACH algorithm. The LEACH algorithm first puts forward the idea of "round." Each round is divided into two stages: cluster establishment and data transmission.

During the formation of the cluster, if the node randomly chooses a number between 0 and 1 and if the selected number is less than the threshold $T(n)$, it is selected as the cluster head. The calculation formula of $T(n)$ is as follows [21]:

FIGURE 1: Schematic diagram of LEACH protocol clustering.

$$T(n) = \begin{cases} \dfrac{x}{1 - x(r \bmod (l/x))}, & \text{if } n \in S, \\ 0, & \text{otherwise.} \end{cases} \quad (5)$$

At this point, one cycle is over and preparations for the next cycle are started.

Figure 2 is the LEACH protocol flowchart. First, the algorithm selects the cluster head node. After this cluster head is determined, a broadcast message is sent to other nodes. The message includes the cluster head location, cluster head ID, and energy information. The noncluster head node selects the cluster head closest to its position to join according to the received message to form a cluster, and the cluster establishment phase is completed. The cluster head manages the nodes in the cluster, collects data collected by the members, and establishes a TDMA timing table for the member nodes. Then, send the timing table to the nodes in the cluster. All nodes send the collected data to the cluster head according to the time slot specified in the timetable. The cluster head performs simple preprocessing on the data in the cluster and then sends it to the upper node. At this point, one "round" is over and the next cycle begins.

Although the LEACH protocol has a very good performance in long-term monitoring, it also has some shortcomings, mainly including the following aspects:

(1) In each round of cluster establishment, all nodes must participate, and the amount of calculation is very large, which is a great waste of resources

(2) The selection of the cluster head is random

(3) All cluster capitals communicate directly with sink nodes and do not consider the resource loss caused by long-distance communication between cluster heads far away from sink nodes

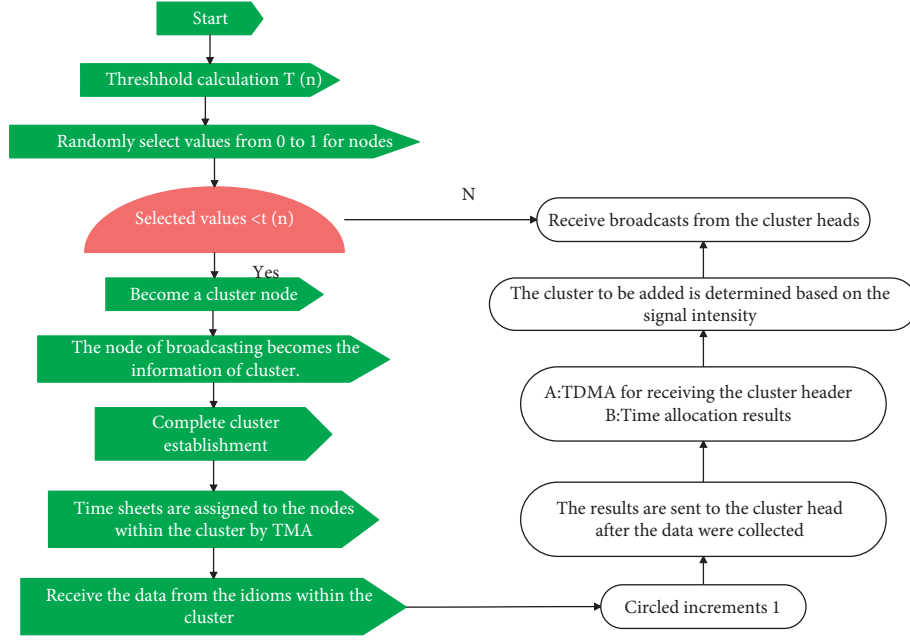
This paper introduces a new meta-inspired optimization algorithm—gray wolf algorithm—to solve the above-mentioned problems of LEACH algorithm, so that it can better serve agricultural applications. Meta-heuristic algorithms are favored by researchers because of their simplicity and flexibility. The gray wolf (GWO) algorithm is currently the


FIGURE 2: LEACH protocol flowchart.

most popular meta-heuristic algorithm in theoretical research. The main idea of the algorithm is to simulate the social hierarchy and group hunting behavior of the gray wolf family in nature. Gray wolves belong to the canine family and like to live in groups. On average, each group consists of 5–12 gray wolves and follows a strict hierarchy, as shown in Figure 3.

The social status of wolves in the gray wolf family can be divided into 4 levels from top to bottom, namely, α wolves, β wolves, δ wolves, and ω wolves. Alpha wolf is a wolf, mainly responsible for deciding the time and place of sleeping, hunting, and tactics. The second level of the gray wolf class is β wolves. β wolves are subordinate wolves, mainly responsible for assisting the wolves to manage the wolf pack. When the wolf pack lacks alpha wolves, beta wolves will replace alpha wolves. The delta wolf is on the third level. The delta wolf obeys the instructions of the alpha wolf and the beta wolf, but it can command the ω wolf at the bottom. The ω wolf is mainly responsible for balancing the relationships within the population.

The collective hunting of gray wolves is an important part of the social activities of gray wolves. Scholars such as Muro have introduced the hunting behavior of gray wolves in detail in the literature, as shown in Figure 4.

Mathematical model of gray wolf algorithm: (1) to establish a mathematical model of gray wolf's social hierarchy, we named the solution with the best fitness as α wolf. Therefore, the second and third best solutions are named β wolves as well as ω wolves, respectively.

3.1. Hunting Model.
In order to simulate the encircling behavior of gray wolves with a mathematical model, equations (6) and (7) are introduced.

$$\vec{D} = \left| \vec{C} \vec{X_P}(t) - \vec{X}(t) \right|, \tag{6}$$

$$\vec{X}(t + l) = \vec{X_p}(t) - \vec{A}\vec{D}. \tag{7}$$

The calculation formulas for vectors $\vec{A}$ and $\vec{C}$ are as follows [22]:

$$\begin{aligned} \vec{A} &= 2\vec{a}\vec{r_1} - \vec{a}, \\ \vec{C} &= 2\vec{r_2}. \end{aligned} \tag{8}$$

3.2. Attack Model.
GWO hunts are led by α, and β and δ occasionally participate. In order to mathematically simulate the hunting behavior of gray wolves, we assume that α (the best candidate solution) and β and δ have a more accurate understanding of the potential location of the prey. Therefore, the algorithm saves the first three optimal solutions obtained so far and forces other search agents (include o) to update their positions according to the position of the best search agent. And its update formula is as follows:

$$\vec{D_\alpha} = \left| \vec{C_1} \vec{X_\alpha} - \vec{X} \right|, \tag{9}$$

$$\vec{D_\beta} = \left| \vec{C_2} \vec{X_\beta} - \vec{X} \right|, \tag{10}$$

$$\vec{D_\delta} = \left| \vec{C_3} \vec{X_\delta} - \vec{X} \right|, \tag{11}$$

$$\vec{X_1} = \vec{X_\alpha} - \vec{A_1}\left(\vec{D_\alpha} \right), \tag{12}$$

$$\vec{X_2} = \vec{X_\beta} - \vec{A_2}\left(\vec{D_\beta} \right), \tag{13}$$
FIGURE 3: Schematic diagram of the gray wolf population hierarchy.

FIGURE 4: Gray wolf hunting behavior. (a) Chasing, approaching, and tracking prey. (b) Pursuit, harassment, and encirclement. (c) Static state and attack.

$$\overrightarrow{X_3} = \overrightarrow{X_\delta} - \overrightarrow{A_3}\left(\overrightarrow{D_\delta}\right), \tag{14}$$

$$\overrightarrow{X}(t+l) = \frac{\overrightarrow{X_1} + \overrightarrow{X_2} + \overrightarrow{X_3}}{3}. \tag{15}$$

Equations (12) to (14) define the length and direction of the advancement of ω wolf toward α, β, and δ, respectively. Equation (15) represents the current α position. And the specific process is shown in Figure 5.

The general steps of the GWO algorithm are as follows:

Step 1: the algorithm initializes the wolf pack

Step 2: the algorithm calculates the fitness value of each wolf

Step 3: the algorithm selects the top three wolves with the best fitness as α, β, and 8

Step 4: the algorithm uses formulas (9) to (14) to update other wolves (ω)

Step 5: the algorithm updates parameters, a, A, and C

Step 6: if the end condition is not met, the algorithm goes to step 2

Step 7: the algorithm outputs the position of α

In this paper, sensor nodes represent individual wolves, and base station BS represents prey.

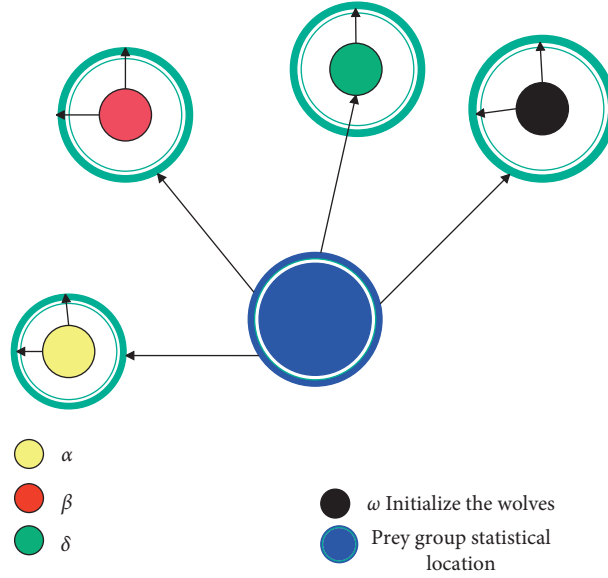
HCGW adopts a round-robin mechanism similar to LEACH, and each round performs the following steps: ①According to the relationship between signal reception and transmission and distance, the simulated gray wolf algorithm divides the network into multiple layers. Each node determines which layer it is in based on the distance between its position and the base station. ②The fitness function includes the remaining energy of the node. ③After the cluster head is determined, all member nodes choose the cluster head to form a cluster. ④ The GWO communication route is established between the cluster heads to avoid long-distance transmission. ⑤Establishes a new route for route maintenance.


Figure 5: Schematic diagram of the gray wolf algorithm.

3.2.1. Network Layering. As shown in Figure 6, this paper assumes that the network can be divided into L layers. According to energy model formulas (2)–(4), nodes with a distance less than d_0 from the base station are classified as the first layer, and they are marked as layer α according to their priority. And the rest are β layer and 6 layer in order.

The node SN_i is in the lth layer:

$$l = \left[2 \times \frac{d_i}{d_0} \right]. \tag{16}$$

By layering the nodes, the communication distance between cluster heads is less than or equal to d_0 during data transmission, which can effectively avoid the energy loss caused by long-distance communication.

3.2.2. Cluster Head Selection Method Based on Fitness Principle. After the sensor nodes are layered, in each layer, the fitness function and fitness rules are used to calculate the fitness of the node, and one or several nodes with high fitness are selected as the cluster head of this layer.

(1) Node Remaining Energy. The node's remaining energy E_{RE} represents the maximum energy left by the node after a number of rounds in the network.

$$E_{RE} = E_{init} - E_r. \tag{17}$$

(2) Node Density. The greater the node density, the more neighbor nodes of the node, and the less energy it consumes when exchanging data with surrounding nodes. The node density is represented by P_{SN_i}, and its calculation company is as follows:

$$P_{SN_i} = \frac{N}{\pi \cdot d_0^2}. \tag{18}$$

Here, N is the number of nodes in the communication range of d_0.

(3) Node Centrality C. The centrality C represents the average distance between a certain node SN and its neighboring nodes. The smaller C is, the closer it is, the less energy is needed for communication, and vice versa.

$$C_i = \sqrt{\left(x_i - \frac{1}{n} \sum_{j}^{n} x_j \right)^2 + \left(y_i - \frac{1}{n} \sum_{j}^{n} y_j \right)^2}. \tag{19}$$

Here, x_i represents the abscissa of node SN_i, and y_i represents the ordinate of node SN_i.

(4) Fitness Function. The cluster head selection is determined by the fitness function. In the GWO algorithm, the fitness function plays a very important role in finding the prey mechanism. The input of this function is the characteristics of the node, including node residual energy (E_{RE}), node density, and node centrality. And, the output is the fitness value of whether the node can become the cluster head.

$$f(CH_i) = q_1 \left| \frac{P_{SN_i}}{C_i} \right| + q_2 \sum E_{RE}. \tag{20}$$

Here, q_1 and q_2 are random numbers in the range of [0, 1]. A certain threshold is set for the fitness, and the node with a fitness value greater than this threshold will be selected as the cluster head.

(5) Fitness Rules. The HCGW algorithm uses adaptive criteria for comprehensive evaluation. The nodes with more residual energy, higher node density, and higher centrality have very high priority. HCGW contains a total of 3 $3 * 3 * = 27$ fitness criteria, as shown in Table 1.
FIGURE 6: Schematic diagram of network layering.

3.2.3. Formation of the Family. After receiving the Invite.Msg message, the member node calculates the approximate distance d from itself to each CH and selects the cluster head with the smallest distance to join to form a cluster structure.

3.2.4. Route Establishment and Maintenance. The cluster head performs preprocessing steps such as compression and optimization of the data. Then, the algorithm sends the data head node of the upper layer with higher priority according to the priority order of the hierarchy and then transmits it in turn until the first layer. At this time, a multihop routing similar to the gray wolf hierarchy is established.

After a long enough time T, the routing of the entire network will be updated. Compared with the LEACH protocol's global mechanism, proposed by the HCGW algorithm, it can greatly save computational and broadcast costs and at the same time achieve local optimality.

4. Smart Garden Planning and Design Based on the Agricultural Internet of Things

The process for the smart garden information management platform to access and call basic geographic data is as follows: (1) The smart garden information management platform sends a graphical call request to the basic geographic information sharing service platform. (2) After receiving the graphic data query request, the basic geographic information sharing service platform will execute the relevant graphic data query process, package the query results (map images or JSON format attribute data), and return them to the smart garden information management platform. (3) After receiving the query result, the intelligent garden information management platform displays it in the map window of the platform. The thematic geographic data of landscaping is directly accessed and invoked on the platform and can be displayed superimposed with the basic geographic information sharing service. The schematic diagram of the business data interface model (process) of the smart garden information management platform is shown in Figure 7.

After constructing a smart garden planning system based on the agricultural Internet of Things, the effect of the data processing of the agricultural Internet of Things in this paper is evaluated, and a garden simulation system is constructed to analyze the performance of the system. The network nodes of the simulation system are shown in Figure 8.

Through the performance verification of the above model, the data processing effect of the agricultural smart garden is shown in Table 2 and Figure 9.

The above model verifies the data processing effect of the agricultural smart garden system.

On this basis, the planning and design effects of agricultural smart gardens are carried out, and the results shown in Table 3 and Figure 10 are obtained.

The above analysis verifies that the smart garden planning and design system has a good planning and design effect.

5. Conclusion

People can intuitively watch the objects in the real environment scene through the network platform and can select corresponding operations on the network client to perform corresponding operations on the real objects in the real environment. Virtual experience is dependent on computer and Internet of Things technology. Compared with real experience, virtual experience has some inherent characteristics, such as virtual experience, virtual experience with uncertainty, and virtual experience with globality. This paper combines the agricultural Internet of Things technology to carry out smart garden planning and design. With the theme of agricultural pastoral, it promotes industrial development and raises people's awareness of ecological and environmental protection and brings people a good pastoral scenery experience.

In order to improve the effect of financial data classification and extract effective information from financial data, this paper improves the data mining algorithm, uses linear combination of principal components to represent missing variables, and performs dimensionality reduction processing on multidimensional data. In order to achieve the standardization of sample data, this paper standardizes the data and combines statistical methods to build an intelligent financial data processing model. In addition, starting from the actual situation, this paper proposes the artificial intelligence classification and statistical methods of financial data in smart cities and designs data simulation experiments to conduct experimental analysis on the methods proposed in this paper. From the experimental results, the artificial intelligence classification and statistical method of financial data in smart cities proposed in this paper can play an important role in the statistical analysis of financial data.

1. Introduction

With the acceleration of economic globalization, financial information has become more transparent and authentic. In this context, accounting standards are converging faster and faster globally. According to incomplete statistics, there are nearly 120 countries and regions that have adopted the International Financial Reporting Standards (IFRS) in the global plan or have adopted the International Financial Reporting Standards (IFRS). The international financial crisis that broke out in 2008 made people realize that improving the transparency of accounting information and formulating a set of globally unified and high-quality accounting standards are vital to the stability and healthy development of the global financial system and capital markets. In this context, countries and regions have accelerated discussions and research on the international convergence of accounting standards [1].

Because keyword retrieval technology cannot meet the needs of some occasions, in recent years, some new researches have begun to focus on improving the efficiency and accuracy of information retrieval technology. Information extraction technology is one of the technologies for obtaining specific events or the relationship between events and events. It is a process of extracting structured and unambiguous information from unstructured free text or other information resources. Information extraction technology can not only filter out information that is not useful to users, but also generate specific information that users are interested in. Information extraction technology integrates artificial intelligence and natural language processing technology and plays an indispensable role in the field of information retrieval. To evaluate the market value of a company, such as the evaluation of intangible assets, all financial data of the company and the financial data of the industry are required, including the company's financial statements and notes to the statements, relevant industry financial news, and macro- and microeconomic data [2]. Most of these data are stored on the Internet in formats such as web pages (HTML) and PDF and are distributed on various websites that provide financial information. At present, people can only manually collect and sort relevant financial data from different data sources, carefully sort and analyze and filter out the data they want, but there is no place to directly get all the data they want. This takes a lot of manpower and time, and most of the work is repetitive work.

According to the preestablished evaluation model, the financial data evaluation results are obtained, which will greatly improve the efficiency of decision-making and provide support for financial-related decisions such as stock investment, mergers and acquisitions, and financial risk assessment [3].

This article combines big data technology to conduct financial data classification research and explores intelligent methods suitable for contemporary financial data classification.

2. Related Work

The literature [4] put forward some suggestions on the classification of financial assets. It includes two parts: one is the understanding of the different levels of financial transactions, and the other is how to deal with the various levels of relationships in the classification of financial instruments during the transaction process. The literature [5] conducted a comparative analysis on the four categories of financial assets and believed that financial assets should also be included in the foreclosed assets, and the financial assets in this part should be handled in accordance with the relevant regulations in the four categories. The literature [6] specifically analyzed and explained the revision of the classification of nonfinancial assets and financial assets in the national economic accounting system. The literature [7] studied the classification of financial instruments and the measurement model of financial instruments, explored the standard and root causes of the classification of financial instruments, and studied the future direction of the classification standard. According to the current classification standards of financial instruments, the literature [8] elaborated the classification standards of held-to-maturity investments in detail. The literature [9] believed that, under the current standards, the main reason for the strong subjectivity of the classification of financial assets lies in the intention of the management. Therefore, there may be errors in the classification of financial assets in actual work, and the relevant discrimination methods are given in the article.

With the changes in the economic environment, follow-up measurement issues and other related issues derived from the classification of financial assets have gradually emerged, and scholars have launched relevant discussions on these issues. Since the promulgation of the new accounting standards and the full implementation of the financial instrument standards, many scholars have begun to pay attention to whether the problem of financial asset classification will bring earnings management opportunities to enterprises. Therefore, most of the research and discussion on this issue have been concentrated in recent years. Literature [10] believes that the current research does not clearly define the criteria for the classification of financial assets, especially for transactional financial assets and available-for-sale financial assets, which only require classification according to the holding intention and ability of the enterprise. Therefore, companies can make full use of the subjectivity of financial asset classification to manipulate corporate profits. Literature [11] made a specific analysis on

the impact of the classification of equity financial assets on the basis of a full analysis of corporate equity financial assets. Literature [12] conducted an empirical study on the classification of listed companies' financial assets under the new standards. The research perspective is management, accounting policies, and earnings management. Studies have shown that when the initial classification of financial assets is performed, listed companies have obvious intentions to hold financial assets and can be clearly classified; however, during the holding period of financial assets, listed companies have more room for profit operation. The accounting treatment of available-for-sale financial assets can be managed according to the management's wishes. Literature [13] analyzed the classification standards of financial instruments of listed companies and concluded that because the classification of financial instruments is subjective and selective, holders will choose according to their own interests to maximize the reliability of financial information. Literature [14] investigated and studied the classification of financial instruments of listed companies and concluded that the classification of financial instruments of listed companies has a certain tendency according to the wishes of management. It can be found that many scholars have discovered in their research that the classification of financial assets will indeed bring opportunities for companies to manage earnings. The classification of financial assets is closely related to fair value measurement, and some scholars have discussed this. Literature [15] puts forward new insights in the classification, reclassification, and measurement of financial assets to prevent corporate management from adjusting corporate profits at will. Research in this area also exists in the field of practice. Literature [16], in studying the classification of financial instruments of securities companies and the fair value of financial instruments, concluded that the accounting information disclosure system of enterprises on financial instruments is still not perfect. Commercial banks hold the largest scale of financial assets, so some scholars have carried out research on the impact of financial asset classification on commercial banks' profits. Literature [17] analyzed the classification of financial instruments of commercial banks and concluded that the management of the enterprise has a risk appetite for the classification of financial instruments, and it replaces liquidity with robustness. Literature [18] uses the data of Liangmianzhen, Minmetals Development, and Qianjiang Biochemical Company as examples to discuss the earnings management of listed companies based on the perspective of financial asset classification and accounting confirmation differences. Literature [19] compares the differences between IFRS9 and the current accounting standards in the classification of financial assets and analyzes the differences between IAS39 and IFRS9 financial asset classification of 16 listed banks, showing the possible impact of commercial banks in the future. Financial asset standards are closely related to the financial environment. Literature [20] puts forward suggestions for strengthening supervision and protection. Literature [21] discusses the problems that financial asset reclassification may bring to corporate profits and losses, including the recognition of corporate profits and losses in

financial asset holdings, the impact of financial asset impairment on profits and losses, and the possible problems of financial asset reclassification.

3. Financial Data Intelligent Mining Classification Method

We assume that there are p indicators in the actual problem under discussion, and we regard these p indicators as p random variables, denoted as $X_1, X_2, \ldots, X_p$. Principal component analysis is to transform the problem of p indicators into a problem of discussing the linear combination of p indicators. These new indicators $F_1, F_2, \ldots, F_k (k \leq p)$ fully reflect the information of the original indicators in accordance with the principle of preserving the amount of main information and are independent of each other.

This process of reducing multiple indicators to a few comprehensive indicators is mathematically called dimensionality reduction. The usual method of principal component analysis is to seek the linear combination F_i of the original indicators.

$$
\begin{aligned}
F_1 &= \mu_{11}X_1 + \mu_{21}X_2 + \cdots \mu_{p1}X_p, \\
F_2 &= \mu_{12}X_1 + \mu_{22}X_2 + \cdots \mu_{p2}X_p, \\
&\cdots \\
F_p &= \mu_{1p}X_1 + \mu_{2p}X_2 + \cdots \mu_{pp}X_p.
\end{aligned}
\tag{1}
$$

It satisfies the following conditions:

(1) The sum of the squares of the coefficients of each principal component is 1, that is,

$$
\mu_{1i}^2 + \mu_{2i}^2 + \cdots \mu_{pi}^2 = 1.
\tag{2}
$$

(2) The principal components are independent of each other; that is, there is no overlapping information, that is,

$$
\mathrm{Cov}\left(F_i, F_j\right) = 0, \quad i \neq j, i, j = 1, 2, \ldots, p.
\tag{3}
$$

(3) The variance of the principal components decreases successively, and the importance decreases successively, namely,

$$
\mathrm{Var}\left(F_1\right) \geq \mathrm{Var}\left(F_2\right) \geq \cdots \geq \mathrm{Var}\left(F_p\right).
\tag{4}
$$

The conclusion of the two linear algebras is as follows:

(1) If A is a real symmetric matrix of order p, then an orthogonal matrix U must be found to make

$$
U^{-1}AU = \begin{bmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_p \end{bmatrix}_{p \times p}.
\tag{5}
$$

Among them, $\lambda_i (i = 1, 2, \ldots, p)$ is the characteristic root of A.

(2) If the unit eigenvector corresponding to the characteristic root of the above matrix is $\mu_1, \ldots, \mu_p$,

$$
U = \left(u_1, u_2, \ldots, u_p\right) = \begin{bmatrix} u_{11} & u_{12} & \cdots & u_{1p} \\ u_{21} & u_{22} & \cdots & u_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ u_{p1} & u_{p2} & \cdots & u_{pp} \end{bmatrix}.
\tag{6}
$$

Then, the eigenvectors corresponding to different eigenvalues of the real symmetric matrix U are orthogonal, that is, $U'U = UU' = I$ [22].

Conclusion: $\sum x$ is the covariance matrix of the random vector $X = X_1 + X_2 + X_3 + \cdots + X_p$. It has eigenvalue $\lambda_1, \lambda_2, \ldots, \lambda_p$ and eigenvector $u_1, u_2, \ldots, u_p$, where $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_p$. Then, the principal components are

$$
\begin{aligned}
F_1 &= \mu_{11}X_1 + \mu_{21}X_2 + \cdots \mu_{p1}X_p, \\
F_2 &= \mu_{12}X_1 + \mu_{22}X_2 + \cdots \mu_{p2}X_p, \\
&\cdots \\
F_p &= \mu_{1p}X_1 + \mu_{2p}X_2 + \cdots \mu_{pp}X_p.
\end{aligned}
\tag{7}
$$

At this time, $\mathrm{Var}(F_i) = U' \sum xU = \lambda_i$, $i = 1, 2, \ldots, p$. $\mathrm{Cov}(F_i, F_j) = 0, i \neq j, i, j = 1, 2, \ldots, p$.

It is written in matrix form: $F = U'X$.

$$
U = \left(u_1, \ldots, u_p\right) = \begin{bmatrix} u_{11} & u_{12} & \cdots & u_{1p} \\ u_{21} & u_{22} & \cdots & u_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ u_{p1} & u_{p2} & \cdots & u_{pp} \end{bmatrix},
\tag{8}
$$

$$
X = \left(X_1, X_2, \ldots, X_P\right).
$$

The two basic concepts are as follows:

(1) Contribution rate: the proportion of the variance of the i-th principal component in the total variance, $\lambda_i / \sum_{i=1}^{p} \lambda_i$, is called the contribution rate, which reflects how much information the original P indicators have and how comprehensive they are.

(2) Cumulative contribution rate: the comprehensive ability of the first k_i principal components is described by the variance of these k principal components and the proportion $\sum_{i=1}^{k} \lambda_i / \sum_{i=1}^{p} \lambda_i$ in the total variance, which is called the cumulative contribution rate.

One of the purposes of our principal component bond analysis is to replace the original p indicators with as few principal components $F_1, F_2, \ldots, F_k (k \leq p)$ as possible. In actual work, the number of principal components depends on the amount of information that can reflect the original variable, that is, the cumulative contribution rate.

Principal component analysis is a method that converts multiple indicators into a few indicators and can maintain the correlation of the largest original data. The more important variance contribution $\beta_i (i = 1, 2, \ldots, k)$ in principal component analysis represents the maximum value of the

variance contribution of the i-th common factor after eliminating the influence of $(i-1)$ common factors. It is mainly used to measure the importance of the i-th common factor. Therefore, the corresponding evaluation model can be established with β as the weight: $F = \beta_1 F_1 + \beta_2 F_2 + \cdots + \beta_k F_k$. Among them, $F_1, F_2, \ldots, F_k$ is the corresponding k common factors used to comprehensively describe the original indicators, and the comprehensive score is calculated and sorted.

In summary, the calculation process of finding the principal components has the following steps. We set n samples, where each sample has m data, denoted as

$$X = \begin{bmatrix} x_{11} & \cdots & x_{1m} \\ \vdots & \ddots & \vdots \\ x_{n1} & \cdots & x_{nm} \end{bmatrix}. \tag{9}$$

(1) Standardization of sample data: in order to achieve the standardization of sample data, the mean and variance of the sample data need to be required. The standardization of sample data is based on the mean and variance of the data. The essence of standardization is to transform the sample into standardized data with a mean value of 0 and a variance of 1. That is, the normalized transformation of the column is

$$x_{ij}^{\bullet} = \frac{\left(x_{ij} - \overline{x}_j \right)}{\delta_j}. \tag{10}$$

Among them,

$$i = 1, 2, \ldots, n,$$

$$j = 1, 2, \ldots, m,$$

$$\overline{x}_j = \frac{1}{n} \sum_{i=1}^{n} x_{ij}, \tag{11}$$

$$\delta_j^2 = \frac{1}{n} \sum_{i=1}^{n} \left(x_{ij} - \overline{x}_j \right)^2.$$

The resulting standardized matrix $X^{\bullet}$ is written as

$$X = \begin{bmatrix} x_{11} & \cdots & x_{1m} \\ \vdots & \ddots & \vdots \\ x_{n1} & \cdots & x_{nm} \end{bmatrix}. \tag{12}$$

(2) Calculation of the correlation matrix: for given n samples, we use a computer to calculate the correlation coefficient matrix of the indicator variables:

$$R = \begin{bmatrix} r_{11} & \cdots & r_{1m} \\ \vdots & \ddots & \vdots \\ r_{m1} & \cdots & r_{mm} \end{bmatrix} = \frac{1}{n} X' X. \tag{13}$$

Among them,

$$r_{ij} = \frac{1}{n} \sum_{i=1}^{n} X_{ij} X_{ik} = \frac{1}{n} x_j' x_k, \quad j, k = 1, 2, \ldots, m. \tag{14}$$

(3) Find eigenvalues and eigenvectors. The obtained correlation matrix is R to solve the characteristic equation:

$$|R - \lambda f| = 0. \tag{15}$$

By solving the characteristic equation, k eigenvalues $(i = 1 \sim m)$ and the eigenvector corresponding to each eigenvalue can be obtained:

$$Q_i = \left(a_{i1}, a_{i2}, \ldots, a_{ip} \right), \quad i = 1 \sim k. \tag{16}$$

And the eigenvectors corresponding to $\lambda_1 > \lambda_2 > \lambda_3 > \lambda_k > 0$ are orthogonal to each other.

By the above method, k $(k \leq p)$ principal components can be obtained. $\lambda_i / \sum_{i=1}^{k} \lambda_i$ is the contribution rate of the i-th principal component, denoted as β_i, which is

$$\beta_i = \frac{\lambda_i}{\sum_{i=1}^{k} \lambda_i}. \tag{17}$$

Among the k principal components, the sum of the contribution rates of the first q principal components is the cumulative contribution rate of the first q principal components, denoted as α:

$$\alpha = \frac{\sum_{i=1}^{q} \lambda_i}{\sum_{i=1}^{k} \lambda_i}. \tag{18}$$

The number of principal components can be determined by the cumulative contribution rate. Usually the cumulative contribution rate $\alpha \geq 0.85$ as the standard. For the selected q principal components, if the cumulative contribution rate reaches 85%, that is, $a \geq 0.85$, the principal components can be determined as q. It represents the selected q principal components and basically retains the information of the original p variables. When determining the number of principal components, the number of principal components should be minimized under the condition of the cumulative contribution rate constraint.

(4) Find the factor load α_i:

$$\alpha_i = \sqrt{\lambda_i} \alpha_i. \tag{19}$$

According to formula (19), we calculate the factor loading matrix and then calculate the score of each factor:

$$F_i = \alpha_i x, \quad i = 1, 2, \ldots, k. \tag{20}$$

(5) According to the numerator of the factor and the size of the contribution rate, we calculate the comprehensive score:

$$F = \beta_1 F_1 + \beta_2 F_2 + \cdots + \beta_k F_k. \tag{21}$$

Finally, it is sorted according to the comprehensive score. PCA analyzes the system with fewer q indicators instead of the original p indicators, which brings great convenience to the comprehensive evaluation of the system.

A large amount of original detection value data flow information is used to detect lag correlation using the BRAID method, and a series of time series with lag correlation can be found, and the lag time of each time series relative to the original reference series can be calculated.

We assume that there are n time series with a lagging correlation after the detection of the BRAID method. Each time series has a piece of data. Since the original detection data are data values obtained at equal intervals of time, a time variable t is introduced in the representation of the time series, and the data value corresponding to each time point is $x(t)$. Then the original multidimensional data flow is denoted as

$$X = (X_1(t), X_2(t), \ldots, X_n(t)), \quad t = 0, 1, \ldots, m - 1. \tag{22}$$

This can be written in matrix form, namely,

$$X = \begin{bmatrix} x_1(0) & x_1(1) & \cdots & x_1(m-1) \\ x_2(0) & x_2(1) & \cdots & x_2(m-1) \\ \vdots & \vdots & \ddots & \vdots \\ x_n(0) & x_n(1) & \cdots & x_n(m-1) \end{bmatrix}. \tag{23}$$

The lag time is recorded as $\Delta t_1, \Delta t_2, \ldots, \Delta t_n$.

Among them, $\Delta t_1 = 0$ (that is, x is the original reference sequence), and $\Delta t_2, \ldots, \Delta t_n$ is the lag time of the sequence $x_2, \ldots, x_n$ relative to the sequence x_1.

The first principal component analysis method is applied to "aligned" data streams; that is, the data is synchronized. This article discusses the lag-related multidimensional data flow. The data that needs principal component analysis is not synchronized, but has a certain lag time relative to the original time series. Therefore, it is necessary to perform principal component analysis on the detected multidimensional data stream with lagging correlation. The first task is to remove the lagging part of each time series, and "align" the data flow, that is, temporarily ignore the time parameters, and only keep the parts with similar changing trends in each time series, in order to achieve the purpose of multidimensional data flow synchronization. Figure 1 shows the unsynchronized time series, and Figure 2 shows the synchronized time series.

If the data corresponding to w time points in each data stream are obtained, the synchronized multidimensional data stream is recorded as

$$X = \begin{bmatrix} x_1(0) & x_1(1) & \cdots & x_1(w-1) \\ x_2(\Delta t_2) & x_2(\Delta t_2 + 1) & \cdots & x_2(\Delta t_2 + w - 1) \\ \vdots & \vdots & \ddots & \vdots \\ x_i(\Delta t_i) & x_i(\Delta t_i + i) & \cdots & x_i(\Delta t_i + w - 1) \\ \vdots & \vdots & \ddots & \vdots \\ x_n(t_n) & x_n(\Delta t_n + i) & \cdots & x_n(\Delta t_n + w - 1) \end{bmatrix}. \tag{24}$$

That is, $X = (X_i(\Delta t_i), X_i(\Delta t_i + 1), \ldots, X_i(\Delta t_i + w - 1))$, where $i = 1, 2, \ldots, n$.

For the above synchronized multidimensional data stream with delayed correlation, we apply the principal component analysis method to find the principal components. The steps of calculating the principal components include standardizing the sample data, calculating the correlation matrix, finding the eigenvalues and eigenvectors, and finding the principal components.

(1) Standardize multidimensional data streams. In order to achieve the standardization of multidimensional data streams, we should find the mean and variance of each data stream. The standardization of the data stream is based on the mean and variance of each data in the data stream. The essence of standardization is to transform the data stream into standardized data with a mean value of 0 and a variance of 1, which is to perform a standardized transformation on the column of X:

$$x_i^\bullet(j) = \frac{\left(x_i(j) - \overline{x(j)}\right)}{\delta_j}. \tag{25}$$

Among them,

$$i = 1, 2, \ldots, n,$$

$$j = 1, 2, \ldots, m,$$

$$\overline{x(j)} = \frac{1}{n} \sum_{i=1}^{n} x_i(j), \tag{26}$$

$$\delta_j^2 = \frac{1}{n} \sum_{i=1}^{n} \left(x_i(j) - \overline{x(j)}\right)^2.$$

Then we get the standardized matrix, denoted as

$$X = \begin{bmatrix} x_1(0) & x_1(1) & \cdots & x_1(w-1) \\ x_2(0) & x_2(1) & \cdots & x_2(w-1) \\ \vdots & \vdots & \ddots & \vdots \\ x_n(0) & x_n(1) & \cdots & x_n(w-1) \end{bmatrix}. \tag{27}$$

(2) Calculate the correlation matrix. For the w data streams with lagging correlations that have been detected, we use a computer to calculate the correlation coefficient matrix of the indicator variables:
FIGURE 1: Unsynchronized time series.

FIGURE 2: Synchronized time series.

$$R = \begin{bmatrix} r_{11} & \cdots & r_{1m} \\ \vdots & \ddots & \vdots \\ r_{m1} & \cdots & r_{mm} \end{bmatrix} = \frac{1}{n} X' X. \qquad (28)$$

Among them,

$$r_{ij} = \frac{1}{n} \sum_{i=1}^{n} X_{ij} X_{ik} = \frac{1}{n} x_j' x_k, \quad j, k = 1, 2, \dots, m. \qquad (29)$$

(3) Find eigenvalues and eigenvectors. The obtained correlation matrix is R to solve the characteristic equation: $|R - \lambda f| = 0$.

By solving the characteristic equation, w eigenvalues can be obtained, and the eigenvector corresponding to each eigenvalue: $U_i = (u_{i1}, u_{i2}, \dots, u_{iw})$, $i = 1 \sim w$, and $\lambda_1 > \lambda_2 > \cdots > \lambda_w > 0$, and its corresponding eigenvector are orthogonal to each other.

(4) Find the principal components. The algorithm can obtain w principal components by the above method. $\lambda_i / \sum_{i=1}^{w} \lambda_i$ is the contribution rate of the i-th principal component, denoted as β_i, namely,

$$\beta_i = \frac{\lambda_i}{\sum_{i=1}^{w} \lambda_i}. \qquad (30)$$

Among the w principal components, the sum of the contribution rates of the first k principal components is called the cumulative contribution rate of the first k principal components, denoted as α:

$$\alpha = \frac{\sum_{i=1}^{k} \lambda_i}{\sum_{i=1}^{w} \lambda_1}. \qquad (31)$$

The number of principal components can be determined by the cumulative contribution rate. This paper takes the cumulative contribution rate $\alpha \geq 0.85$ as the standard. For the selected k principal components, if the cumulative contribution rate reaches 85%, that is, $\alpha \geq 0.85$, then the principal components can be determined as k. It means that the selected k principal components basically retain the information of the original w variables. When determining the number of principal components, the number of principal components should be reduced as much as possible under the condition of $\alpha \geq 0.85$.

Using the obtained k principal components to linearly combine them can express the original multidimensional data flow of the lag correlation, namely,

$$
\begin{aligned}
F_1(t) &= u_{11}x_1(t) + u_{12}x_2(t + \Delta t_2) + \cdots + u_{1i}x_i(t + \Delta t_i) + \cdots + u_{1k}x_k(t + \Delta t_k), \\
F_2(t) &= u_{21}x_1(t - \Delta t_2) + u_{22}x_2(t) + \cdots + u_{2i}x_i(t + \Delta t_i - \Delta t_2) + \cdots + u_{2k}x_k(t + \Delta t_k - \Delta t_2), \\
&\cdots \\
F_i(t) &= u_{i1}x_1(t - \Delta t_i) + u_{i2}x_2(t - \Delta t_i + \Delta t_2) + \cdots + u_{ii}x_i(t) + \cdots + u_{ik}x_k(t - \Delta t_i - \Delta t_k), \\
&\cdots \\
F_n(t) &= u_{n1}x_1(t - \Delta t_n) + u_{n2}x_2(t - \Delta t_n + \Delta t_2) + \cdots + u_{ni}x_i(t - \Delta t_n + \Delta t_i) + \cdots + u_{nk}x_k(t + \Delta t_n - \Delta t_k).
\end{aligned}
\tag{32}
$$

Furthermore, the algorithm obtains a comprehensive evaluation function:

$$
F = \beta_1 F_1 + \beta_2 F_2 + \cdots + \beta_k F_k. \tag{33}
$$

It can be seen that, by performing principal component analysis (PCA) on the lag-related multidimensional data stream, the original multidimensional data stream represented by the data corresponding to the larger m time points can be converted into the smaller k principal components to represent the original multidimensional data stream, which brings great convenience to the storage and use of data stream and also provides help for the analysis and reconstruction of lag-related multidimensional data stream.

4. Classification and Statistics of Financial Data in Smart Cities Based on Artificial Intelligence

The overall framework of financial asset classification is shown in Figure 3.

There are three major factors in sequence analysis. (1) Sequence duration: it refers to the length of the analyzed sequence in the time dimension, such as the time period during which user behavior occurs. (2) Time folding window: it means that a series of actions occurring within a certain period of time will be regarded as occurring simultaneously. (3) Time interval: it refers to the time interval of the discovered time series model. An example of the data mining process is shown in Figure 4.

The fast hierarchical clustering algorithm based on root finding is based on the following assumption: a data set can be divided into several clusters, and there is a core point in each cluster, and this point can represent other points in the cluster. This core point is not necessarily the center of mass of the cluster; it exists in an area where the data is densely distributed. The area with dense data distribution here refers to the closest distance between the data points in this area relative to the surrounding neighborhood of this area. We call the core point of the cluster the root node, as shown in Figure 5.

The structure design of the financial data classification system is shown in Figure 6. The system obtains sample files from the sample database after data extraction and preprocesses the sample files into training samples and test samples. The training samples are used to train the classifier, and the test samples are used to evaluate the classification performance of the classifier, and the training process of the classifier is adjusted according to the evaluation results to obtain the final classifier.

The evaluation process of the classification effect is shown in Figure 7. The source of the test sample is the same as the training sample. It is taken from the sample database and preprocessed. The test sample also carries the actual category label.

The simple understanding of financial data classification task refers to the process of categorizing financial data of an unknown category based on its content when the classification system is known. Financial data classification is essentially a process of identifying the characteristics of financial data patterns. After the financial data is preprocessed and expressed as a feature vector, it is input into the classifier, and the model is trained. For the financial data to be classified, it is also expressed as a feature vector and then input into the classifier for classification. Figure 8 shows the principle of financial data classification. Financial data content processing will be introduced in detail later.

As shown in Figure 9, we have given a basic model framework based on rough set and KNN text classification. In this model framework, we can clearly see that this model is composed of three parts: rough set-related preprocessing module, KNN classification algorithm module, and quality evaluation module. First, in the text collection stage, the relevant web text data is obtained from the internet, and the relevant data is used as the training set and test set of the web text for subsequent operations, and then the next step is entered.

After constructing the above intelligent model, this paper conducts statistical analysis of the intelligent model and evaluates the effect of financial data mining and financial data classification, and the results are shown in Figure 10.

It can be seen from Figure 10 that the intelligent algorithm proposed in this paper can play a certain role in financial data processing. After evaluating the intelligent data decision in this paper, the results are shown in Figure 11.
FIGURE 3: The overall framework of financial asset classification.

FIGURE 4: The data mining process.

FIGURE 5: A possible result of finding the root node on the sample data set.

Figure 7: Classification and evaluation process diagram.

Figure 8: Principles of financial data classification.

FIGURE 9: Financial data subsystem model framework.

FIGURE 10: Evaluation of financial data processing effect.

Figure 11: Intelligent data decision statistics.

From the above research, we can see that the artificial intelligence classification and statistical method of financial data in smart cities proposed in this paper can play a certain auxiliary role in financial decision-making.

5. Conclusion

The prediction problem of financial data processing is mainly the prediction of financial time series. Financial time series can be regarded as a special time series, which has the following three characteristics. (1) The generation process of financial time series is more complicated, and there are many influencing factors. (2) Most financial time series contain a large number of unpredictable influence factors. (3) The composition of the data in the financial time series is relatively complex and usually exhibits nonlinearity. Artificial intelligence information processing methods such as neural networks, chaos theory, and genetic algorithms can well adapt to these three characteristics, which have become advanced methods to solve financial data processing problems. This paper combines big data technology to carry out financial data classification research and extracts financial data from different data sources in an automatic and intelligent way. Users can not only get the data they want in the shortest time, but also improve the accuracy and effectiveness of the data. Through experimental research, we know that the artificial intelligence classification and statistical method of financial data in smart cities proposed in this paper can play a certain auxiliary role in financial decision-making.

Accidents of various types in the construction of hydropower engineering projects occur frequently, which leads to significant numbers of casualties and economic losses. Identifying and eliminating near misses are a significant means of preventing accidents. Mining near-miss data can provide valuable information on how to mitigate and control hazards. However, most of the data generated in the construction of hydropower engineering projects are semi-structured text data without unified standard expression, so data association analysis is time-consuming and labor-intensive. Thus, an artificial intelligence (AI) automatic classification method based on a convolutional neural network (CNN) is adopted to obtain structured data on near-miss locations and near-miss types from safety records. The apriori algorithm is used to further mine the associations between "locations" and "types" by scanning structured data. The association results are visualized using a network diagram. A Sankey diagram is used to reveal the information flow of near-miss specific objects using the "location ⟶ type" strong association rule. The proposed method combines text classification, association rules, and the Sankey diagrams and provides a novel approach for mining semi-structured text. Moreover, the method is proven to be useful and efficient for exploring near-miss distribution laws in hydropower engineering construction to reduce the possibility of accidents and efficiently improve the safety level of hydropower engineering construction sites.

1. Introduction

Construction is a high-risk industry, and until recently, construction sites have continued to pose a serious threat to workers' lives and health [1]. In particular, hydropower engineering construction leads to various types of casualties due to the frequent cross-work of construction equipment, the dynamic construction work environment, and high-risk site operations [2]. For example, in March 2020 alone, there were two hydropower accidents in Sichuan Province: a scaffolding collapse and high falls caused by burnt-out safety belts led to 3 deaths and 4 injuries, according to China's National Energy Administration [3].

Near misses have been defined as a dangerous state in production that may lead to accidents, such as the unsafe behavior of people, an unsafe state of things, unsafe factors in the environment, and defects in management [4]. In particular, there is a wider variety of near misses in the construction of hydropower engineering, leading to a sharply increased probability of serious accidents. An accident is a fait accompli and cannot be undone. In contrast, near misses still have remedial leeway [5]. Therefore, to improve the safety situation, it is a key part of safety management to determine the potential laws of near misses and take safety measures to eliminate near misses in the construction of hydropower engineering projects.

With increasing attention to safety issues in the hydropower industry, the frequency of safety inspections has increased rapidly, and numerous near-miss text data have been accumulated. However, text data are both semistructured and unstructured; accordingly, traditional methods of mining text data are time-consuming and laborintensive. With the development of artificial intelligence (AI) technology, automatic mining and analysis of near misses will inevitably replace relying on manual work to structure text data and find near-miss laws [6]. Thus, it is of great significance to study the data mining of near-miss text data, especially the mining of near-miss distribution laws relying on AI technology.

In the field of construction, text mining application research mainly adopts text classification methods to classify housing construction accidents, subway construction near misses, and construction contract documents. Shallow machine-learning algorithms, such as the support vector machine (SVM), naive Bayes (NB), and K-nearest neighbor (KNN) algorithms, have been used to classify housing construction accidents [7] and construction contract documents [8]. Such algorithms require manually combining lexical, syntactic, and semantic features. These are limited by the domain knowledge of individuals, resulting in poor performance in feature representation.

In contrast, deep learning algorithms (e.g., convolutional neural networks (CNNs) [9], Bidirectional Encoder Representations from Transformers (BERT) for language understanding [10], and convolutional bidirectional long short-term memory (C-BiLSTM) [11]) can automatically identify features and use existing tagged data to train the classification model of house-building construction accidents and near-miss subway construction. The above research proves that deep learning has a better effect on the classification of construction of short texts than shallow machine learning.

Previous text information expression and big data mining technology have laid a very important foundation for intelligent analysis of text information. All kinds of text intelligent analysis technology have been widely used in housing construction, subways, and so on. However, there are few studies on the intelligent analysis of big data in the field of safety knowledge in hydropower engineering construction addressed in this study. Although the core algorithm of text big data analysis has not changed much, due to the unique characteristics of safety knowledge in hydropower engineering construction, the data analysis framework that focuses on hidden trouble needs to be reformulated. The main reason is that hydropower engineering construction involves a wide range of engineering types, and there are huge differences between different engineering types, leading to the necessity of reexploring the distribution of near misses in this kind of engineering. Moreover, these studies only classified the text without discussing how to further mine the more detailed construction knowledge contained in the classified text. Safety managers cannot intuitively and quickly acquire near-miss knowledge due to the poor visualization effect of near-miss distributions.

Against this contextual backdrop, we develop a near-miss classifier based on a CNN, associate the classified results, and visualize them with a network diagram [12] and a Sankey diagram so that safety managers can easily find the key points of massive near misses [13]. First, to structure text data, a CNN-based classifier that incorporates a deep learning method is developed to generate structured classification results of near-miss information within safety records. The classifier can capture semantic features in a near-miss text to automatically classify near-miss locations and the near-miss descriptions into predefined "location" and "type" categories, which can generate structured data for statistical analysis. An apriori algorithm is then used to quantify the frequency and trustworthiness of the association rule "location ⟶ type." The network diagram visualizes the quantification of the association rule "location ⟶ type." Finally, after integrating all texts corresponding to each category of strong association rules, the Chinese word segmentation is carried out on these texts. A Sankey diagram is drawn with word frequency as the size of the information flow.

A classifier based on deep learning and a CNN combined with the apriori algorithm and a Sankey diagram can automatically classify text and associate the "location" and "type" of the classification results. Consequently, safety management personnel can implement corresponding near-miss measures for specific near-miss locations, eliminate near misses in advance, and improve the safety level of hydropower project construction.

2. Related Work

2.1. Accident Prevention in Hydropower Engineering Construction. Hydropower engineering construction has the characteristics of a complex construction environment, including a wide range of cross-work and high labor intensity. Moreover, it has a low level of safety management and, more generally, a lack of safety supervision and personnel training [14]. Accidents occur frequently in hydropower project construction. There are many studies on accident prevention in hydropower engineering construction. Zheng et al. [15] applied the Human Factor Analysis and Classification System (HFACS) to study the evaluation of human factors in high-risk operations and finally obtained the evaluation value of faulty behavior risk (FBR) in hydropower engineering construction. Zhou et al. [2] integrated the methods of the decision-making trial and evaluation laboratory (DEMATEL) and the analytic network process (ANP), taking into account the interaction between factors and their self-feedback. The deduced causal diagrams provide suggestions for the safety management of high-risk working systems in several large hydropower projects. Zheng et al. [16] adopted the HFACS framework, collected 869 accident investigation reports, determined the first three accident types by frequency statistics, and determined the accident path by analyzing the correlation between different human factors. All the above studies focus on the prevention of accidents, but the study of near misses can advance the link of accident prevention and reduce the probability of accidents by eliminating near misses.

2.2. Text Classification and Machine Learning. Natural language processing (NLP) is a technology in which a computer is used to process and analyze human language, including text classification, information extraction, and information retrieval [17]. Text classification is a common task of NLP, which concerns training mathematical models to gain a certain generalization ability by inputting a group of texts with relevant classification labels so that the model can better predict the categories of other texts in the same field [18]. Text classification has been widely used in various fields as an efficient information processing technology [19].

Machine learning is a popular method to realize text classification [20]. For instance, Bertke et al. [21] identified the three "claim cause" categories of workers' medical compensation claims using the NB classifier. Ubeynarayana et al. (Ubeynarayana. and Miang., 2017) used a support vector machine (SVM) classifier to classify the Occupational Safety and Health Accident (OSHA) dataset. Similarly, Mahfouz [8] utilized an SVM to classify unstructured information in contract documents. Maia et al. [22] used the random forest (RF) method to classify complaint texts and achieved good results. All of the above studies used shallow machine learning, which can only obtain simple functions through a linear combination of feature parameters of training data. However, simple functions poorly classify the complex and changeable near-miss text of hydropower project construction.

Deep learning (DL) can learn complex functions and extract higher-dimensional features from input data. The DL method has been identified as an appropriate method to automatically extract features for text classification without manually creating features [23]. Compared to shallow machine learning, DL can effectively extract word order features and learn from the semantic information contained in text [24].

CNNs have been applied in NLP and have achieved good results in semantic processing [25], sentence modeling [26], and search query retrieval [27]. Researchers are increasingly interested in the application of CNNs in text classification. Arora et al. [28] proposed a text normalization algorithm based on deep convolutional character level embedding (the Conv-char-EMB neural network model) for sentiment analysis (SA) of unstructured data. He et al. [29] proved that CNN architecture with multiple pooling operations can extract the most significant features of a convolutional filter by convolution, activation, and pooling operations and effectively classify medical relations.

Do [30] proposed a CNN model that can use both a word vector adjusted for a specific task and a static pretrained word vector for the sentence-level text classification task. Yoon et al. [31] used a CNN to classify sentences preprocessed by word embeddings and suggested that only one layer of convolution can classify sentences effectively. The above studies have laid an important foundation for text big data mining, but the laws contained in text big data of near misses in hydropower project construction need to be further explored. Due to the large difference in the characteristics of various subprojects for hydropower projects, the types of near misses in different locations are also very different and present great trouble in the analysis of hidden danger data. The text intelligence analysis method commonly used in other projects has difficulty addressing this challenge.

2.3. Association Rules and Sankey Diagram. Association rules contain the rules of occurrence between things. It is imperative for people to understand detailed information about the research object. Agrawal [32] proposed an association rule algorithm for mining the potential association between transactions in a transaction database. The apriori algorithm is the most famous association rule algorithm. It can prune item set trees to prevent the exponential growth of candidate item sets, reduce the amount of data, and improve operation efficiency [33].

Association rule mining has been widely used in construction safety fields. Cheng et al. [34] used association rules in analyzing 1347 accidents to identify potential hazards in Taiwanese construction projects. Guo et al. [35] found the association rules of workers' unsafe behavior, worker type, and construction phase in the construction industry using the apriori algorithm. Qiu and Wang [36] proposed the "cause ⟶ emergency measure" association rule algorithm based on construction accident cases to find all possible accident cause chains. Mingyuan et al. [37] used the apriori algorithm to mine a dataset of near misses in construction and obtained the correlation between the hazard sources in the internal and external environments of a construction site.

Using the apriori algorithm for data mining, these researchers obtained valuable association rules that are difficult to find by subjective experience. The algorithm involves counting the number of terms. For unstructured text, items that have the same meaning but different expressions are considered different when they are counted. Therefore, items with the same meaning need to be classified into the corresponding preset categories to obtain structured text. Finally, the number of items in each category is counted as the operation data of the apriori algorithm. However, the association rule algorithm is only applicable to mining structured data, it is necessary to carry out structured data tasks to mine unstructured text, and text classification plays such a role. Since the near misses of hydropower projects are recorded artificially, they are random and nonstandard, and all belong to unstructured texts. To mine the association rules of near misses of unstructured texts, it is necessary to obtain structured texts that are easy to calculate by classifying near misses.

A Sankey diagram is a data flow diagram that shows the flow of information among multiple attributes [38]. The Sankey diagram is a fashionable tool in energy system analysis [39], and it can clearly show the energy flow process. There are also some applications of the Sankey diagram in civil engineering. For example, Abdelalim et al. [40] used a Sankey chart to carry out data visualization and analysis of energy flow at the multizone building scale. Goswein et al. [41] used a Sankey diagram to represent the relationship between building stock and its driving factors. Ioannidou

et al. [42] visualized the economic flow of construction projects through a Sankey diagram. These studies took advantage of the characteristic that the Sankey diagram can represent information flow. The distribution law of near misses also has the characteristics of information flow, so the Sankey diagram can be used to show the flow of specific near-miss objects between near-miss locations and near-miss types.

3. Data Preparation

The data preparation section is divided into 4 steps: (1) collecting near-miss data from the Crane Beach Hydropower Station projects and storing them in the database, (2) cleaning up noncompliance data and obtaining word segmentation, (3) labeling the training data, and (4) assigning the labeled dataset for training the model. This process is shown in Figure 1.

3.1. Source of Data.

The 32,370 safety records of the Crane Beach Hydropower Station from 2015 to 2020 were taken as the data source. The 24,325 collected semi-structured records were uploaded by the site construction operator through WeChat-based near-miss check software. The 8045 paper unstructured records were collected from the safety management personnel at the construction site and manually entered into the database. Some examples of raw data are shown in Table 1.

Each near-miss record includes its check date, near-miss description, and near-miss location. In the near-miss records, "description" and "location" belong to semi-structured data, which are characterized by lengthy sentences and inconsistent expressions. The fields of a semi-structured record are related to each other, but the data stored in the fields are unstructured text. The "description" contains the information of the type of near misses, and the "locations" contain the information of the near-miss places. However, the information is unstructured text and cannot be associated with the association rule algorithm. To automatically find the association rules between the near-miss type and the near-miss location, these two fields need to be transformed into structured text. The CNN DL algorithm is used to transform these two fields into structured data, which are 11 near-miss types and 35 near-miss locations.

3.2. Data Preprocessing.

The training effect of the model can be improved by preprocessing data to reduce data noise. The data preprocessing steps are as follows:

(i) Empty items, numbers, and punctuations such as "3#," "/," "," and "6–2" in a sentence are considered noise, and regular expressions (REs) are used in Python to remove the noise. In particular, "3#" describes the location information of hydropower projects in a more specific way. In different # hidden trouble locations, the impact

on hidden trouble types can be ignored, so 3# is not considered.

(ii) Jieba [45] (Chinese word segmentation software based on Python) is employed to carry out word segmentation to better express the features of Chinese sentences.

(iii) One-character words that are not rich in meaning are deleted.

3.3. Label Definition.

Since a supervised learning model is proposed, it is necessary to label the classified data accurately. According to 20 accident types that a near miss may cause [44] and combined with the description of the near misses in this study, the near misses are divided into 11 types for hydropower engineering construction. Due to the differences in construction organization plans in each near-miss location, we define a total of 30 near-miss location labels. The text datasets are manually tagged by experienced safety management personnel on-site and then reviewed by experts in the field of hydropower engineering construction to ensure the accuracy of the labels. Partial labels are listed in Table 2.

3.4. Dataset Division.

To obtain the classification model, the labeled datasets need to be divided into a training set, test set, and validation set. Among them, the training set optimizes the model, the validation set selects the parameters of the optimization model, and the test set evaluates the performance of the established model. The two datasets of "location" and "description" are arranged in proportion as follows: training set: test set: validation set = 10 : 1 : 1. The numbers of training sets, validation sets, and test sets for the "location" classifier are 14,995, 1515, and 1500, respectively. The numbers of training sets, verification sets, and test sets for the "type" classifier are 16,018, 1545, and 1580, respectively.

4. Near-Miss Text Mining Approach

The data mining model is divided into 3 parts: (1) CNN classification: the "type" classifier and "location" classifier are obtained by training the tag dataset. (2) Association analysis: the trained classifier classifies the "type" and "location" of new near misses to generate structured data of "type" and "location" for statistical analysis. An association rule network diagram is created to visualize the mining results. (3) Sankey diagram: the Sankey diagram adds detailed rules to the near-miss association rules. The specific steps are shown in Figure 2.

4.1. CNN-Based Classifier.

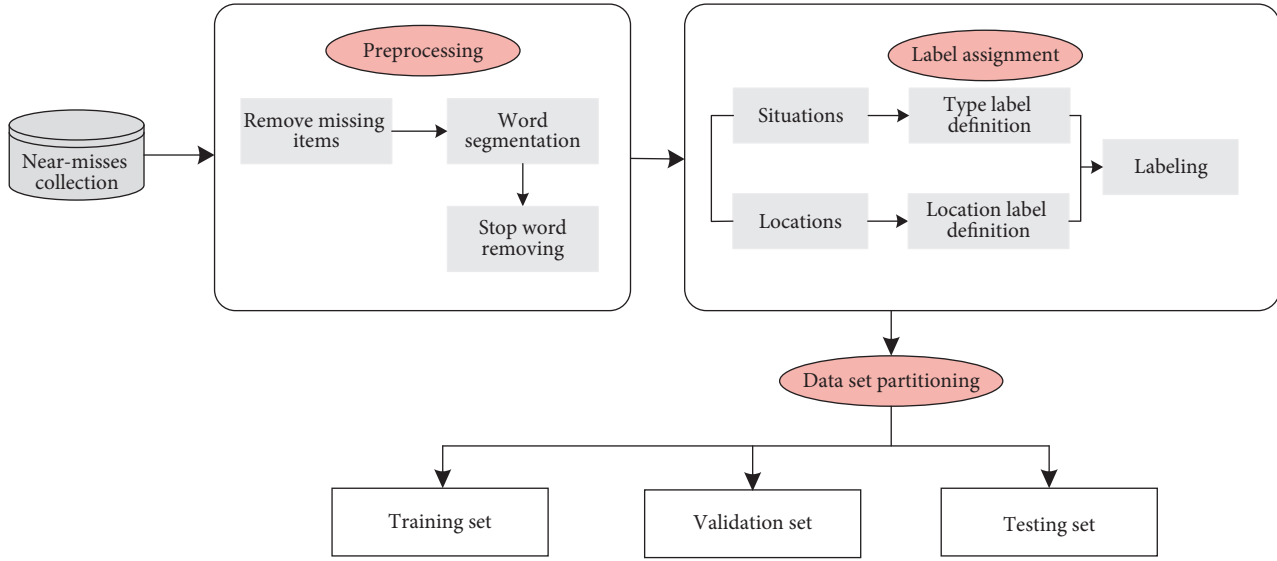
The CNN is a supervised learning method in DL. The weight sharing of a convolutional layer in a CNN can reduce the number of trainable parameters in the network and the complexity of the network model. A text classification method based on CNN can learn complex functions and related features from a given text without the need to select effective features through tedious manual text


FIGURE 1: Data preparation process.

analysis. This can greatly save on labor and time [9]. With the proposal of the word2vec method, word embedding training can be carried out on a large scale. This lays a foundation for CNN's extensive application in text classification [45].

The context information of each word in the near-miss text is crucial for the CNN model to capture the near-miss features. By introducing word2vec to the input layer, the near-miss text is transformed into a word embedded with a specific numeric expression containing the relationship between words in a near-miss text. This serves as the input layer of the CNN model. In the convolutional layer, the feature mapping of near-miss text is learned in parallel using different sizes of convolution kernels. A fixed-length near-miss feature mapping is acquired by performing the max pool operation at the pooling layer. The final near-miss
FIGURE 2: Text mining process of hydropower engineering construction near misses.

classification task is handled by the full connection layer. This is equivalent to classifying the features extracted by the convolution layer and pooling. The model structure is shown in Figure 3.

4.1.1. Word Representation. To make full use of the word characteristics, 19,143 "description" and 18,010 "location" instances in the dataset are divided into multiple words separated by line breaks with Jieba. Different words in the "description" and "location" datasets constitute the "description" word vector space and "location" word vector space, respectively. The numbers of words in the two word vector spaces are $V_{\text{description}} = 8001$ and $V_{\text{location}} = 1919$.

The text dataset of hydropower project construction near misses has the characteristics of a large word space, short sentences, and high frequency of professional vocabulary [46]. To better express the near-miss texts, we use word embedding to pretrain the near-miss words. In embedding spaces, different words that are semantically similar are likely to form semantic groups in which words with different properties are close together in distance. The continuous bag of words (CBOW) is a common model for word2vec [47]. The model is suitable for word embedding training in text datasets with fewer low-frequency words and more short sentences [48].

The main idea of the CBOW model is to use context words $\{x_1, x_2, ..., x_C\}$ to predict the central word W_i, where C is the window value (set to 5), W_i is the i word in word vector space, and $\{x_1, x_2, ..., x_C\}$ is the one-hot coding (the corresponding index position of the word is 1, and the others are 0). The model calculation is divided into two processes: forward propagation and back propagation.

(1) Forward propagation.

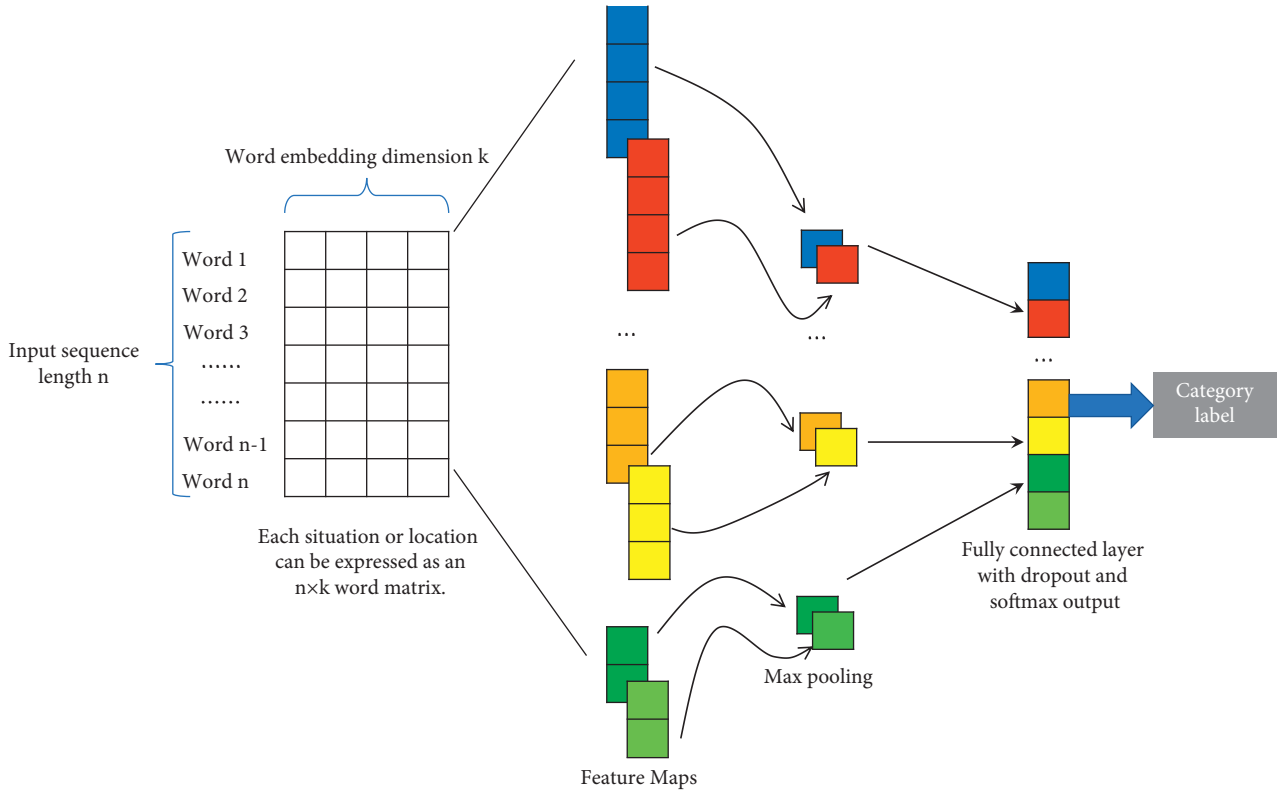
Figure 4 shows the calculation process of forward propagation, where "氧气(oxygen)/乙炔(acetylene)/瓶(bottle)/无 (no)/安全(safety)/距离(distance)" is taken as the


Figure 3: CNN classifier model framework.

Figure 4: CBOW forward propagation flowchart.

dataset for illustration, and "bottle" is the predicted central word. Forward propagation is divided into two steps.

Step 1: Calculate the hidden layer H, which is a $1 \times N$-dimensional vector. N is the dimension of each word vector. The value is set to 100. The calculation formula is described as follows:

$$H = \frac{1}{C} W_0 \cdot \left(\sum_{i-1}^{C} x_i \right), \tag{1}$$

where W_0 is a $V \times N$-dimensional matrix that connects the input vector and hidden layer, and V is the size of the word vector space. In the figure, the value is set to 6.

Step 2: Calculate the output vector Y of size $1 \times V$. Y (the word vector for "bottle" in this image) is a distributed representation of the predicted central word. To facilitate the calculation of errors during back propagation, the *softmax* function is used to normalize $H \times W_1$. The calculation formula is described as follows:

$$Y = \text{softmax}(H \cdot W_1), \tag{2}$$

where W_1 is the weight matrix with a size of $N \times V$ to connect the hidden layer and the output layer.

(2) Back Propagation. The back propagation error is calculated according to Y of the center word and the one-hot encoding vector of this word. The values of W_0 and W_1 are continuously adjusted using the gradient descent method. During the training, each word is used as a central word; that is, W_0 and W_1 are modified V times. After the training, the one-hot coding vector of each word is computed in steps 1 and 2 and united with the trained W_0 and W_1 to accomplish the word vector of all words in the entire dataset.

4.1.2. Convolution Layer. In the NLP domain, since the width of the convolution kernel is generally equal to the dimension k of the word embedding, the convolution kernel slides in only one dimension. We illustrate the process of convolution in Figure 4. In the example, the window value (the local word order length per convolution) h is set to 4. The process is divided into three steps. Step 1: the 4×4 matrix $X_{1:4}$ corresponding to "氧气(oxygen)"/"乙炔(acetylene)"/"瓶(bottle)"/"无(no)" and convolution kernel W are substituted into formula 1 to obtain the feature mapping C_1.

Step 2: due to the sliding step s = 1, the window slides down one slot. We perform the same calculation by replacing $X_{1:4}$ with $X_{2:5}$ corresponding to "乙

炔(acetylene)"/"瓶 (bottle)"/"无 (no)"/"安全 (safe)." Step 3: according to the first and second steps, an iterative operation is performed to obtain the feature mapping matrix C: 3×4. The calculation formula is described as follows:

$$c_i = f\left(w \cdot x_{i:\ i+h-1} + b\right), \tag{3}$$

where w is the convolution kernel matrix representing the shared weight, and $x_{i:\ i+h-1}$ is the connection matrix of the word embedding from the i word of a "description" or "location" to the $i + h - 1$ word. b is an offset term. f is a nonlinear function, and in this study, f is set to a rectified linear unit (ReLU). Figure 5 shows the convolution process.

4.1.3. Pooling Layer and Full Connection Layer. To represent richer features, the convolution kernel is set to different windows, and the same convolution kernel will run parallel operations [49]. Therefore, a sentence will generate feature vectors with different dimensions. The advantage of pooling is that it outputs a fixed-size matrix, reduces the dimensions of the output, and retains significant features with the maximum value $P_i (i = 1, 2, \ldots, m)$. P_i is the maximum value of the vector by the i convolution operation, and m is the number of convolution kernels.

Dropout technology is adopted in the fully connected layer to prevent hidden layer neurons from self-adapting and

to reduce overfitting [50]. The weight parameters of the fully connected layer are combined with $P = \{P_1, P_2, \ldots, P_m\}$ to calculate $Y = \{Y_1, \ldots, Y_t\}$. In this study, t is $t_{\text{description}}$ (the number of "descriptions" tags) and $t_{location}$ (the number of "locations" tags). After vector Y passes through the softmax layer, the probability distributions $L = \{L_1, L_2, \ldots, L_3\}$ of different labels are acquired by normalization calculations. Figure 6 shows the process of pooling to the fully connected layer.

4.1.4. Parameter Settings. According to the hyperparameter settings of CNN text classification in existing studies and through multiple comparison tests, the hyperparameters of this study are determined as shown in Table 3.

4.1.5. Evaluation Metric. In this study, accuracy, recall, precision, and F_1 score are used to evaluate the performance of the DL classification model. Formulas (4)–(7) define these metrics. Among them, recall can be understood as the ability to find crucial instances in the dataset, and precision represents the proportion of data points found by the model that is relevant to reality. The F_1 score is a comprehensive evaluation of the model combined with recall and precision [51].

$$\text{accuracy} = \frac{\text{the number of correctly classified categories}}{\text{the sum of classified data}} \times 100\%, \tag{4}$$

$$\text{precision} = \frac{TP}{TP + FP}, \tag{5}$$

$$\text{recall} = \frac{TP}{TP + FN}, \tag{6}$$

where TP is the number of positive samples predicted correctly, FP is the number of positive samples predicted incorrectly, and FN is the number of negative samples predicted incorrectly.

$$F_1\text{score} = \frac{2 \times precision \times \text{Recall}}{\text{precision} + \text{Recall}}. \tag{7}$$

4.2. Association Mining. This study utilizes the apriori association rule algorithm to analyze the associations between "type" and "location" classified by a CNN-based classifier. D is a set of all "types" and "locations." If there is an association rule "location1 $\longrightarrow$ type1" in which "location1" contains the "pipeline" item and "type1" contains the "electric shock" item, then there is a high probability of an electric shock accident occurring in the pipeline. "Location 1" and "type 1" (hereinafter abbreviated as P_1 and T_1) are both near-miss data item sets.

For association rule "$P_1 \longrightarrow T_1$," its support $\sup_{(P_1 \longrightarrow T_1)}$ is used to measure the frequency of

"$P_1 \longrightarrow T_1$," and the calculation formula is described as follows:

$$\sup_{(P_1 \longrightarrow T_1)} = \frac{\text{count}(P_1 \cap T_1)}{\text{count}(D)}, \tag{8}$$

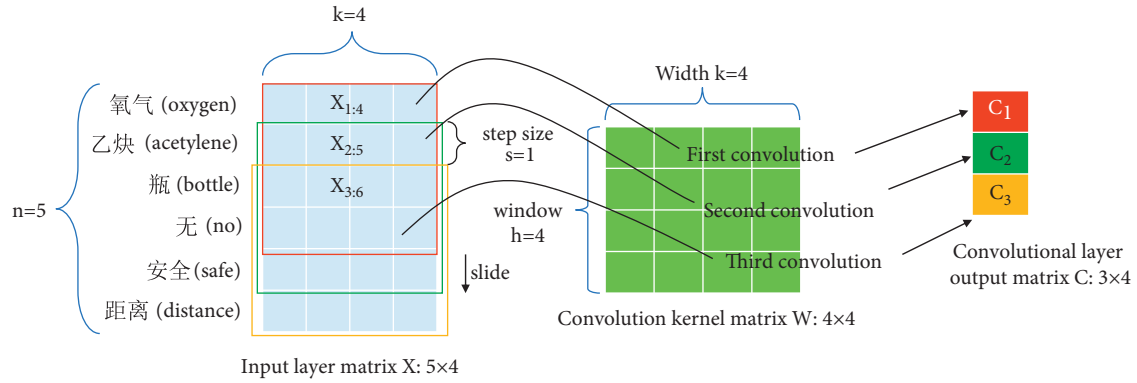
where $\text{count}(P_1 \cap T_1)$ is the number of simultaneous transactions between P_1 and T_1, and $\text{count}(D)$ is the total number of transactions.

Confidence $\text{conf}_{(P_1 \longrightarrow T_1)}$ measures the degree of credibility of "$P_1 \longrightarrow T_1$":

$$\text{conf}_{(P_1 \longrightarrow T_1)} = \frac{\text{count}(P_1 \cap T_1)}{\text{count}(P_1)}, \tag{9}$$

where $\text{count}(P_1)$ is the number of transactions occurring in P_1.

Rules whose support and confidence are both greater than a given threshold are called strong association rules [52].

In this study, the front and back items of association rules are "locations" and "types," respectively, and each near-


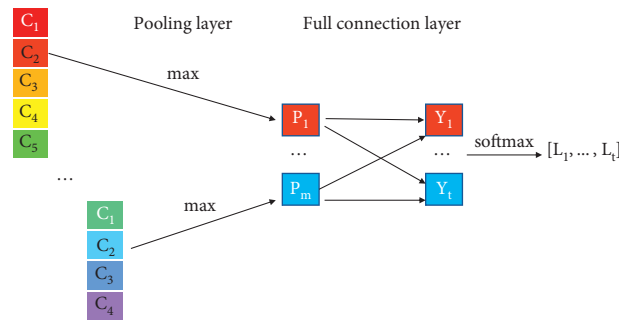


FIGURE 5: CNN convolution computation process.

FIGURE 6: Process of pooling to connection.

TABLE 3: Setting of CNN model hyperparameters.

Embedding dimension	Filter size	Number of filters	Dropout probability	Learning rate
100	5	128	0.5	0.8

miss record is a single safety check record. The front and back items of association rules are limited. That is, there is only one item. Therefore, the algorithm can be improved to reduce the time cost of scanning by lowering the number of scans.

This algorithm can be divided into two steps as follows:

(i) Step 1: When finding the frequent 1-item set (the number of items contained in the frequent item set is 1), different from the traditional apriori algorithm, only the "location" item set is scanned instead of the item sets of "type" and "location" at the same time, thus saving scanning time. The corresponding support degree of each item is calculated, and an item set below the support threshold value is cut off to obtain a frequent 1-item set. The frequent 1-item set is connected with the "type" item set to obtain the candidate frequent 2-item set, and the candidate frequent 2-item set below the support degree is screened out to obtain the frequent 2-item set and its item statistics.

(ii) Step 2: According to all frequent item sets mined in step 1, the confidence of each frequent item set is filtered whose value is greater than the small confidence; then, the frequent item set is a strong association rule.

This study explores what types of near misses may occur in a specific "location." To show the relationship between them more intuitively, a network diagram is used to visualize them, as shown in Figure 7. The thickness of the line in the network represents the degree of correlation, and the size of the circle indicates the frequency of occurrence. The thickness is determined by the weight calculated from the support and confidence of the association rule. The weight is calculated in two steps: (1) normalizing "support" and "confidence" and (2) calculating the sum of the normalized "support" and "confidence" and then normalizing the result of the sum. The normalization can be calculated by formula (10). This solves the problem of inaccurate evaluation caused by different orders of magnitude of evaluation indexes. The statistical quantity of near-miss locations and near-miss types in hydropower projects is evenly distributed. If the support degree and confidence degree are set higher, some rules with strong practical relevance will be lost. In addition, the data in this study are large, so more valuable association rules can be obtained by setting these two values to smaller values. We set the support degree and confidence degree to be lower at 0.001 and 0.01, respectively.
$$y = \frac{x - x_{\min}}{x_{\max} - x_{\min}}, \tag{10}$$

FIGURE 7: Precision, F_1 score, and recall of "location" classification results.

where x and y are the values before and after normalization, respectively, and x_{max} and x_{min} are the maximum and minimum values of the samples, respectively.

4.3. Sankey Diagram. The apriori algorithm can determine the strong association rule of "location $\longrightarrow$ type" but cannot determine the distribution law of specific near-miss objects. The text corresponding to categories in strong association rules is processed by the Chinese word segmentation to obtain a more detailed near-miss distribution. For example, for "dam shoulder slot $\longrightarrow$ fall from height," (1) all descriptions of this association rule are collected as shown in Table 4, (2) the Jieba word segmentation package is used to segment the description in Chinese, and (3) words with large word frequency and significance as specific near-miss objects are selected to connect "location" and "type." A Sankey diagram is drawn to describe the information flow of multiple strong association rules, in which the word frequency is used as the flow size.

5. Results and Discussion

5.1. CNN-Based Classification. To train the "location" and "type" classifiers with strong generalization ability, the dataset allocated according to section 3.4 is input into the constructed CNN DL text classification model. Furthermore, the model is evaluated by the accuracy, recall, precision, and F1 score.

The 8990 "description" data and the corresponding "location" data without labels generated in the Crane Beach Hydropower Station are taken to classify the "type" and "location," respectively, using the "type" classifier and the "location" classifier. The 8990 structured data are obtained for mining association rules "location $\longrightarrow$ type."

The average accuracy, average precision, average recall rate, and average F1 score rate of the "location" classifier were 90.19%, 81.90%, 84.43%, and 81.93%, respectively. The evaluation results of each category of the "location" classifier are shown in Figures 7 and8. The evaluation results of each category of the "type" classifier are shown in Table 5 and Figure 9.

In Figure 7, some categories are less effective, such as No. 28 "curtain" and No. 11 "drowning." The similarity of drowning words is high, and the sample size is extremely small, which leads to a higher precision but lower recall. The sample size of the "curtain" is very small, leading to all evaluation metrics being 0. No. 1, No. 4, and No. 6 have higher recall but lower precision. This is because the texts tagged in these categories are similar to the texts tagged in other categories, and more other tags are classified as these.

In Table 5, "mechanical damage," "collapse," and "drowning" have higher precision but lower recall. The reason is that these categories have strong text features; thus, the classification precision is better, but the small sample size leads to a low recall.

Although precision, recall, and F_1 scores indicate that the CNN performs better than other algorithms, they are unable to provide any information about how each category of "type" and "location" is misclassified. Thus, confusion matrices are introduced to focus on categories that are misclassified. In Figures 8 and 9, rectangles in the diagonal position represent the correct classification, while other rectangles represent the incorrect classification. Each row represents the actual category, and the column represents the predicted category.

As shown in Figure 8, since the descriptions of "No. 28" ("tunnel entrance") and "No. 13" ("inside tunnel") are extremely similar, it is easiest to misclassify them. The top misclassified "type" shown in Figure 9 is "drowning." The probability of "drowning" being misclassified as "civilized construction" (row 11, column 9) is 0.53. In the description of "civilized construction," there is a large amount of "surface ponding." Furthermore, the most striking feature that "drowning" describes is also "surface ponding," so CNN classifiers easily confuse "drowning" with "civilized construction." In addition, "collapse" has a 0.22 probability of being misclassified as "struck by objects" (row 8, column 10). After a collapse, there is a high probability of an object striking by accident. Therefore, the confusion between "collapse" and "struck by objects" can be explained by the symbiotic tendency. For a small number of categories that are easily confused, manual inspection is used for secondary classification to ensure classification accuracy.

5.2. Contrast Tests. Existing studies show that the short text classification effect of shallow machine learning is worse than that of DL [53]. Consequently, we do not consider shallow machine-learning algorithms and only compare

TABLE 4: Near-miss descriptions about "dam shoulder slot ⟶ fall from height."

| "Location"	Description	"Type"
Dam shoulder slot	坝肩槽EL635-EL625高程中间爬梯扶手焊点开裂2处, 存在安全隐患。(there are 2 cracked solder joints of the middle ladder handrail in the dam abutment grooves of EL635-EL625 that have safety risks.) 临边防护及警示缺失。(lack of border protection and warning.) … 坝肩槽EL74O通道端头未封闭开放, 存在坠落风险 (the end of the EL74°channel of the abutment groove is not closed and open, and there is a risk of falling.)	Fall from height
FIGURE 8: Confusion matrix of "location" classification results.

four typical DL classification algorithms: recurrent neural network (RNN) [54], BERT [10], fast text [55], and long short-term memory (LSTM) [56].

Near-miss short texts on hydropower engineering construction have the characteristics of limited sentence length, compact structure, and independent expression, which make it possible for CNNs to handle such tasks [57]. Five DL classification algorithms classify the same dataset in the comparison test, and the same trained word embedding layer is used as the input layer.

As the number of categories classified in this study is too high to fully display the evaluation metrics of each category, the average value of each evaluation metric of the classifier is

used for comparison with the CNN algorithm and other DL methods. As can be observed from Table 6, all metrics of the CNN algorithm are superior to those of other DL classification algorithms. Therefore, the CNN algorithm is adopted to classify the short text of near misses in hydropower engineering construction.

5.3. Association Rules. To acquire more objective association rules, labeled data are added to the association analysis dataset for more comprehensive data. Due to the large amount of data and the large number of label categories, the threshold of support and confidence were set at low levels of

TABLE 5: Precision, F1 score, and recall of "type" classification results.

| No.	Label	Precision	Recall	F1 Score

FIGURE 9: Confusion matrix of "type" classification results.

0.02 and 0.20, respectively. A total of 31 strong association rules were mined. Some of the results are shown in Table 7.

To display more association information using a network diagram, we set the support degree and confidence degree lower at 0.001 and 0.01, respectively, and a total of 235 association rules are output. As shown in Figure 10, the larger circles of "civilized construction" and "struck by objects" indicate that these types of accidents are more likely to occur in the construction of hydropower engineering projects. According to the thickness of the line, "inside the tunnel" is prone to "collapse," "vehicle injury," "fire," and other accident types, while "underground chambers" are prone to "fall from height," "struck by objects," "fire," and other types of accidents.

Knowing which places are prone to accidents, safety managers can search for the corresponding original near-

FIGURE 10: "Location ⟶ type" network graph.

miss description data and perform a more in-depth and detailed analysis based on the specific association rules. For example, a tunnel is prone to collapse due to arch cracking, no anchor, nonstandard support, and so on. More valuable near-miss prevention objects can be learned by combining raw near-miss data with an association rule network.

Compared with the network diagram, the Sankey diagram displays more detailed and specific content and visually presents the frequency distribution and information flow of the specific near-miss objects, near-miss locations, and near types. We exhibit one of the Sankey diagrams in Figure 11 using 6 pairs of strong association rules. Some

valuable hidden danger rules can be analyzed from the figure. For example, electric shock near misses are likely to appear in "dam shoulder slots" and "tailrace tunnels" due to the "inside of the distribution box." Referring to the original text related to "inside the distribution box," we can understand that "there is debris in the distribution box" is the cause of electric shock near misses, and it is more likely to appear in the "tailrace tunnel" and "dam shoulder slot."

In addition, the "traffic ladder" of the "dam shoulder slot" has great potential to cause near misses of "falling from height." Referring to the "traffic ladder" in the original text, we can find that the main reason for "fall from height" is that
FIGURE 11: Sankey diagram of association rules.

"there is no traffic ladder," "the traffic ladder handrail is missing," and "the traffic ladder has no protective railing." Safety managers can quickly find the details of near misses and implement measures to prevent the emergence of these near misses through the Sankey diagrams combined with original text data.

6. Conclusion

The construction safety management of hydropower engineering is mainly based on the analysis of safety text data, but the recorded data are often inconsistent and messy data, so it is particularly difficult to directly obtain knowledge that can guide safety early warnings. In recent years, NLP technology combined with AI has provided the possibility for rapid and automatic analysis of text data in all walks of life.

To mine the valuable information hidden in the data of hydropower engineering construction near misses, this study developed a new model combining text classification

and association mining. The purpose of text classification is to aggregate near misses in the same category and lay the foundation for subsequent data statistics. The association algorithm can be used to calculate the results of structured classification and find the association rules with strong practical significance.

To overcome the shortcoming that the association algorithm cannot analyze the near-miss description field that contains the most near-miss information, the method of word segmentation combined with the Sankey diagram was used to add abundant near-miss information to the association rules. Intuitive near-miss distribution visualization helps safety managers quickly find the causes of near misses and take measures to control them to reduce the possibility of accidents and improve the safety level of hydropower engineering construction sites. The model can mine massive texts and obtain more detailed rules and is also applicable to other fields of text mining.

Our research can better examine near-miss associations, but there are still some limitations. First, the work of making

near-miss labels is completed by different people, which may lead to different classifications of the same near-miss types due to respective subjective opinions. Second, it is still necessary to manually check the near-miss classification results with poor performance in the classifier to ensure the accuracy of data involved in association rule mining. Third, the CNN-based model proposed was only used to evaluate the near-miss text dataset obtained from the Crane Beach Hydropower Station project. Future study is required to use unsupervised learning to improve the accuracy of near-miss data classification. In addition, the consistency of near-miss dataset classification models for different hydropower engineering projects can be further discussed.

With the continuous development of the global economy, the degree of internationalization and openness has gradually deepened. Higher English internationalization education also needs to keep pace with the times and keep pace with international development. At this time, it is necessary to build a multi-source information fusion algorithmic higher English international education model and evaluation index system to better adapt to the trend of higher English international education in the future. In the current higher English teaching process, it is necessary to change the traditional teaching concepts, change the previous teaching ideas, continuously expand the horizons, build an international and diversified English teaching training program, and actively absorb excellent education concepts from foreign excellent teaching models, which has better promoted the development of English teaching.

1. Introduction

English classroom education is mainly centered on the exchange activities between teachers and students. It is a system with significant social characteristics. The corresponding evaluation index system and teaching model together constitute the education level weighed by the higher English evaluation index [1–3], according to the principle of combining pre-teaching appointments and post-teaching satisfaction. At present, cloud computing, computer technology, big data analysis, and hypermedia technology are the basis for promoting the continuous development of modern information technology; it can provide English learners with virtualized teaching services and fast teaching services, which are generally interconnected, intelligent, and huge. Data-scale data information mining, image-friendly learning interface, and other data information technology services can not only effectively improve the environment of higher English teaching, but also change the previous views and

learning styles of English teaching. The relationship between teachers and students can apply higher English learning to the actual era of information development, and it has become the main factor that can realize the "structural reform" of higher English education. Education itself is to cultivate high-quality people, who are useful to society. Traditional education is centered on teachers. Teachers dominate and students passively participate. Students trained in this model rarely have innovative thinking. They are obedient and dependent. Learning is not so enthusiastic, and there is rarely a rich imagination, and scientific research and creation all need imagination as a support. Therefore, cultivating students' imagination and innovating their thinking ability is the motivation and purpose of our research. Through research, it is found that multimedia education is based on traditional education, which is obviously more advantageous and can stimulate students' enthusiasm. It is full of enthusiasm for learning and let students take the lead in learning. Therefore, multimedia support education is not

only a tool to assist education, but also a transformation of modern education for the improvement and reconstruction of learning methods, which is a leap in the quality of traditional education.

By constructing a higher English international education model and evaluation index system, this paper analyzes the key factors of the higher English international education system in the current information age in detail. It mainly initializes teaching information from the perspective of English teaching evaluation and analyzes the international English education in colleges and universities' level and quality.

2. Classroom Evaluation Health: A New Vision of "Effective Teaching" Evaluation Research

Learning is based on a certain English environment, with the help of others and multimedia, that is to say, the process of meaning construction achieved through cooperation activities between people. Therefore, in this mode, "condition, cooperation, dialogue, and meaning construction" are the four elements in the learning environment. The characteristics and functions of multimedia technology are conducive to fully embodying the four elements. In order to provide a supportive education model, it provides the necessary conditions for effective use in English classrooms. Based on the above viewpoints, the multimedia support English education model is the specific application of constructivist learning theory in multimedia English education. Multimedia support education is to teach knowledge before class in traditional classrooms, and the internalization of knowledge is to carry out work activities after the original class and then transfer to learning activities in the classroom. Combined with the concept of multimedia-supported education, a multimedia-supported education model with four stages of education preparation, memory, application analysis, and comprehensive evaluation of education was designed. Take university English as an example, try the composition, and establish higher vocational education. The college English multimedia-supported teaching model divides the college English multimedia-supported teaching into two stages: pre-education and classroom. Discussions on knowledge extraction, online learning, and classroom problem-solving are given in Figure 1. See the figure for the four links of evaluation and feedback.

The development of students is divided into two stages. The first stage is the individual differences of students. The results are different. The second stage of development is under the guidance of teachers, and students can dig out the potential level of development. Use this to verify. In the case of underachievers, some students have average grades at the beginning of their studies. As long as their teacher provides reasonable guidance, this student can make great progress. Therefore, the educational model has an important influence on the development of students. Therefore, teachers should formulate educational plans around students' learning conditions.

In the knowledge extraction link, the teacher selects the main points of knowledge according to the students' knowledge level, learning foundation, learning ability, and learning habits; determines the teaching goals, teaching difficulties, and learning tasks of each unit; and refines enlightening and guiding questions. The online learning link is under the guidance of the teacher's questions; students can watch teaching videos in groups or independently by themselves to learn the main language, sentence structure, cultural background, and text structure. At the same time, with the help of the group leader, they can understand the main knowledge points as much as possible and bring the unsolvable knowledge content to the classroom. In the classroom discussion problem link, students expand their self-learning language and culture knowledge in groups or individually and apply them to various activities and tasks of classroom teaching to promote the students to absorb, internalize, and apply the knowledge they have learned. In this link, students need to complete the exercises and exercises related to online learning tasks, as well as activities such as after-reading feelings, situational dialogues, role-playing, keynote speeches, and hot topic discussions. In addition, for common problems, teachers should organize students to collaboratively solve and summarize. For personality problems, teachers should inspire and guide students to solve them independently and give individual guidance; the evaluation feedback link is given after the completion of the first three links; then the teacher will conduct a summary evaluation of the strengths and weaknesses of the learning situation and performance and propose improvement measures and future directions for efforts. Through the implementation of this link, students can further consolidate and improve the knowledge they have learned and have a better understanding of the problem.

To accurately evaluate the internationalization of higher English education, we first need to build an evaluation model of English education model. Combining nonlinear information fusion methods and time series analysis methods, statistical analysis of the teaching ability of English international education is performed. Higher English internationalization education model and evaluation ability constraint index parameters are a set of nonlinear time series. Constructing a high-dimensional feature distribution space represents the distribution model of higher English analysis and evaluation parameters, and its main index parameters restrict the teaching ability of English international education, teachers' level, investment in educational facilities, and policy relevance. Construct differential equations and construct an information flow model that expresses the constraint parameters of English international education ranking ability [4–7].

$$x_n = x(t_0 + n\Delta t) = h[z(t_0 + n\Delta t)] + \omega_n. \tag{1}$$

In the formula, $h(\cdot)$ is the multiple value function of the analysis and evaluation of English international education. ω_n is an evaluation error measurement function. In the high-dimensional feature distribution space, the solution vector of
FIGURE 1: Multisource information fusion diagram of college English in higher vocational colleges.

the analysis and evaluation in the English international education teaching is calculated by the correlation fusion method, and the feature training subset $S_i (i = 1, 2, \ldots, L)$ of the education analysis and evaluation is obtained, and the following conditions are met:

(1) $\Sigma = \text{diag}(\delta_1, \delta_2, \ldots, \delta_r)$, $\delta_i = \sqrt{\lambda_i}, \forall i \neq j$

(2) $\cup_{i=1}^{L} S_i = V - v_s$

where $x_{n+1} = \mu x_n (1 - x_n)$ indicates that the evaluation index of higher English internationalization education adopts the conjugate solution of the statistical information model, which can reach the decomposition condition $U = \{u(t)|u(t) \in X, \|u\| \leq d, t \in I\}$ of the initial value, among which $(I_i)_{i \in N} = \{x_1, x_2, \ldots, x_m\}$. For multiple variable groups, the characteristic distribution sequence $x(n)$ corresponding to the evaluation statistics of higher English internationalization education can be used to construct a higher English internationalization education model based on the measured value of the previous teaching level.

$$c_{1x}(\tau) = E\{x(n)\} = 0,$$
$$c_{2x}(\tau) = E\{x(n)x(n+\tau)\} = r(\tau), \quad (2)$$
$$c_{kx}(\tau_1, \tau_2, \ldots, \tau_{k-1}) \equiv 0, \quad k \geq 3.$$

When $Q = 2$, the teacher's strength level and the distribution level of educational resources in the higher English classroom evaluation meet the $(2 + 1)$ dimensional continuous letter writing condition [8–10]. In other words, the courses of English internationalization education should be analyzed and evaluated.

$$\psi_x(\omega) = \ln \Phi_x(\omega) = -\frac{1}{2}\omega^2 \sigma^2. \quad (3)$$

The exclusive analysis and evaluation data information flow model of English international education it provides an accurate data input basis for the teaching analysis and evaluation of English international education and constructs a set of scalar sampling sequence components.

The multi-source information fusion algorithm is used to analyze the big data information model of the higher English international education model and the evaluation index system, and the control objective function for constructing the prediction and estimation of the ability of the higher English international education model is

$$\max_{x_{a,b,d,p}} \sum_{a \in A} \sum_{b \in B} \sum_{d \in D} \sum_{p \in P} x_{a,b,d,p} V_p, \quad (4)$$

$$\text{s.t.} \sum_{a \in A} \sum_{d \in D} \sum_{p \in P} x_{a,b,d,p} R_p^{bw} \leq K_b^{bw}(S), \quad b \in B. \quad (5)$$

Therefore, a specific analysis is made on the health evaluation index system of high school English teachers in the information learning environment.

3. The Health Evaluation Index and Measurement Analysis of College English Classroom Evaluation under the Information Environment

3.1. The Evaluation Index of College English Classroom Teaching System in the Information Learning Environment. According to the knowledge theory of health review, the motivation of the teaching system comes from the passage of English teachers and students in the system. The motivation of the English teaching and activity input system is mainly to promote the change of higher English international education mode, which needs to be measured indirectly through the obvious teaching mode of the outside world [11–13]. According to the analysis of the teaching process between the higher English teaching teachers and students, the types and characteristics of teaching activities are used to evaluate the health index system of higher English teachers. The higher English internationalization education model mainly prepares English teachers and English classroom education and provides special tutoring. The types of student education activities include students studying with teachers, and mutual help among students within teachers. The characteristics of higher English international teaching activities can use teacher enthusiasm and teaching. The time used by the process is measured. The characteristics of the student's learning model can be explained by the student's enthusiasm for learning and the amount of time spent on learning. The teaching enthusiasm of higher English teachers is used to evaluate the degree of effort of teachers in English teaching activities, and it is also an active psychological activity that appears in higher English teaching as a teaching model. Under the modern information, the motivation to input the evaluation system of higher teachers, in addition to the two

main teaching models of teachers and students, is the evaluation basis of the evaluation system under data informatization. In the past, higher English education needed a teaching model shared by teachers and students. As the teaching model of the education system, modern informatization mainly uses informationized teaching resources and higher English international teaching.

3.2. Organizational Structure Measurement Indicators for College English Classroom Teaching Evaluation in an Information Learning Environment. The higher English teaching evaluation index is used as a teaching model for English teachers and students individually, and the input energy from teaching is rationally allocated as an international teaching system. A certain teaching model can be constructed to ensure smooth energy flow and high efficiency. The teacher evaluation system can run the sequence in a healthy manner [14, 15]. In the modern information environment, the teacher evaluation system includes the interaction between the teachers, students, and teaching resources, and detailed teacher learning and classroom learning can explore the learning motivation of students and ensure that the input system energy meets the characteristics of all aspects in these mutual exchanges. The measurement is suitable for the organizational structure of higher English internationalization evaluation to construct teaching evaluation indicators. Teachers and students need to meet the needs of each other, and their mutual adaptability is very high. According to their own teaching activities to supervise each other's work, the way of energy transfer between each other has become more fluent, and the number of energy conversions has increased. On the whole, fitness satisfies the three aspects, namely, purpose fitness, content fitness, and method adaptation. Teaching attitude plays an important role in the evaluation system of higher English teachers. The purpose of different activities, teaching content, and learning attitudes are in line with the teaching levels of both parties.

3.3. Resilience Index of College English Classroom Teaching Evaluation in an Information Learning Environment. The resilience of the English curriculum evaluation system refers to the ability of the teaching evaluation system to be threatened by the outside world and to maintain the system's ability to create and function normally. In order to maintain the normal operation of teaching evaluation, the evaluation system can play an overall adjustment role and strengthen the protection elements to reduce the risk. This requires higher English teachers to have a sense of self-reflection in the teaching process and be able to consciously correct the existing risk factors in time. The main influencing factors in the evaluation system are the teaching fatigue of the English teachers in the teaching process, the lack of motivation of students, and the information incompatibility existing in the environment of globalization, and the teaching organization structure is threatened from the outside. This will be caused by teachers' fatigue, the interaction between student's learning and teacher's teaching activities, goals, teaching

content, teaching attitudes, and teaching methods that cannot meet their needs. It is not suitable to be applied to the modern information teaching environment. It needs to constantly overcome the existing problems. Teachers and students need to have the ability to reflect, detect the existing dangerous factors, and take corresponding measures to overcome the existing difficulties. This will enable teachers' and students' educational abilities to be effectively used, and the existing risk factors can be detected. The good state of learning motivation and organizational teaching structure is equivalent to the key protective factors in the English classroom evaluation system, in order to effectively promote English teachers, and the embodiment of the education level of the students ensures that the students have better learning ability.

4. Realization of Optimization of Higher English Internationalization Education Model and Evaluation System

Constructing a binding parameter index analysis system for higher English internationalization education model and evaluation analysis, using multisource information fusion for higher English internationalization education model and evaluation based on the analysis of big data information system, in order to improve the quantitative assessment ability of higher English classroom scheduling level, we propose a higher English classroom teaching analysis method based on a fuzzy greed algorithm and information fusion, analyze higher English classroom teaching, and transform the evaluation problem into a least-square estimation problem of the K-means cluster objective function. The least-squares problem is to find the consistent estimation value of the higher English internationalization education model and the evaluation resource constraint vector β so that $\|Y - X\beta\|$ can be minimized, where $\| \cdot \|$ is the F-norm in the European algebra norm, and obtains the constraint characteristics of the ability of advanced English classroom scheduling. The entropy feature extraction value of the information is

$$P_{\text{loss}} = 1 - \frac{1 - p_0}{\rho} = \frac{p_0 + \rho - 1}{\rho} = \sum_{n=1}^{N} p_{k,n}. \tag{6}$$

Given that d_i is the perturbation feature vector for teaching analysis and evaluation, the estimating formula of higher English classroom arranging ability is transformed into the least square solution

$$z(t) = x(t) + iy(t) = a(t)e^{i\theta(t)} + n(t), \tag{7}$$

where $x(t)$ is the real part of the time series for evaluating the distribution of big data, and $y(t)$ is the imaginary part of the higher English international education model and evaluation constraint index sequence.

Using surrogate data method to randomize the teaching ability of higher English classrooms can also disturb the empirical distribution data of the kth education analysis and evaluation of functional, and obtain the kth subgroup, which

represents the utilization rate of the resource distribution of higher English classrooms.

$$U_{\text{util}} = \gamma \overline{X}. \tag{8}$$

Constructing a hierarchical tree, using big data analysis methods, establishing the main component characteristics of the analysis and evaluation outside the teaching time of higher English classrooms, and using ambiguous close filling methods can solve the similarity of the distribution of educational resources.

$$\text{Sim}_1\left(d_i, d_{1j}\right) = \frac{\sum_{k=1}^{M} W_{ik} \times W_{1jk}}{\sqrt{\sum_{k=1}^{M} W_{ik}^2} \cdot \sqrt{\sum_{k=1}^{M} W_{1jk}^2}}, \tag{9}$$

where d_i is the prior distribution feature vector of higher English internationalization education model and evaluation and d_{1j} is the K-means clustering center vector of the first-level big data.

Combining the fusion method of linear correlation characteristics, the clustering, and integration of the index parameters of the higher English classroom teaching evaluation are realized, and the fusion formula of the output education resource information is as follows:

$$P(w|x) = \frac{P(x \mid w)}{P(x)}. \tag{10}$$

If the quantitative recursive feature $(N(i) \bmod L) < m$, the probability density feature $p(i) = \lfloor N(i)/L \rfloor$ of the distribution of teaching resources, the higher English internationalization education model, and the evaluation big data stream $X(i)$ are divided into $p(i)$ submatrices $N_{ij} \times m$ with the size of X_{ij}, and they are aggregated by index parameters, classes, and integration, and compile appropriate teaching evaluation contents, so as to realize the evaluation of international higher English education model.

5. Improvement Strategies for Higher English Internationalization Education under the Background of Multi-Source Information Fusion

5.1. Adjust Teaching Goals. If information processing methods and big data analysis methods are used to adjust teaching evaluation and resource utilization, the quantitative control of teaching progress will be improved and it will play an important role in the level of planning ability. Therefore, it aims at the background analysis of higher English teaching ability assessment. Because of the influence of many factors, the evaluation of higher English teaching ability first conducts experiments and researches on higher English teaching level, establishes a data system and resource analysis system for higher English teaching level, and uses information combination and clustering solutions to solve higher English. The evaluation of teaching ability and the establishment of the target and statistical system of English teaching ability evaluation can significantly improve the quantitative budget ability of higher English teaching ability evaluation. In the higher English international education model and evaluation index system, the effect of the international education model and evaluation index system is affected by the order of courses. It can be seen from the effect of the order of courses that the arrangement of higher English classrooms in a college is reasonable, and what is the effect of college education. The ranking of higher English classrooms represents the feasibility of the entire class schedule of this college.

5.2. Strengthen the Design of Higher English International Education Courses. For the traditional international education model and evaluation index system ability evaluation calculation, there is a situation of inaccurate classification. Based on this situation, research scholars have proposed an international education model and evaluation index system ability evaluation calculation method on the combination of fuzzy greedy calculation method and information. First, set up a research system for constrained parameter indicators, then use quantitative recursive methods to evaluate the ability of the data information system to achieve the ability to control the acquisition of characteristic resources, complete the classification and summary of the index parameters of the international education model and the ability of the evaluation index system, and edit the corresponding the teaching resource plan. Complete the evaluation of the ability of the evaluation index department. Using this calculation method to carry out the evaluation of the ability of the international education model and the evaluation index system, the information integration and analysis ability is high, the accuracy of the teaching ability evaluation is greatly improved, and the efficiency of the use of educational resources is improved.

5.3. Improve the Teaching Test and Evaluation System. For a long time, the evaluation of China's higher English internationalization education is based on final evaluation, with final exams and CET-4 and CET-6 as the main test methods, but students' evaluation of the English learning process is relatively neglected. Do not pay attention to the assessment and evaluation of students' learning methods, knowledge application ability training, and other key skills. CET-4, CET-6, CET-4, and CET-8 all emphasize achievement and pass rate. It has brought many negative effects to students' English learning. The question type of the college English test has a big flaw in its design. Not only is there a big deviation in the basic internationalization of college English education, but also the review of many contents cannot fully reflect the comprehensive language application ability of college students. In particular, the review of oral skills and translation skills has weakened. The phenomenon of dumb English with poor ears is still relatively serious. Therefore, it is necessary to reform the current higher English international education testing and evaluation system. On one hand, increase the proportion of formative evaluation and ask students to speak, read, write, and perform comprehensive test translation and other language skills to promote students' application skills of English knowledge. On the other hand, make corresponding changes in the form of

English examination questions and improve the effectiveness and accuracy of the review process. If objective problems can be reduced, questions such as conversational tests and subjective questions will be added, focusing on cultivating students' ability to use English language thinking skills and English knowledge to solve practical problems.

5.4. Pay Attention to the Construction of the Teaching Staff. In order to further accelerate the internationalization of higher English education and the process of internationalization of education, we must pay attention to the direct impact of the construction of the teaching staff. In the context of multisource information integration in higher education, the construction of the teaching team is ensured. The key to the smooth progress of the reform of higher English international education is to improve the professional quality of high school English teachers and to further improve the education level and quality of education. In order to better meet our country's actual needs for training international English talents. At present, college English teachers regularly participate in educational seminars, and training is the main way to build the teacher team. However, this is obviously insufficient for cultivating new international talents. On the basis of strengthening in-service teacher training, the university encourages students to participate in foreign language education seminars at home and abroad. If conditions permit, teachers can be given more opportunities for overseas exchanges and training. Expand the horizons of teachers' international education and form the ability of international thinking and practice in English education. In addition, on the basis of accumulating their own professional knowledge, college English teachers have been extensively involved in pedagogy, linguistics, psychology, sociology, anthropology, and other related subject knowledge, improving personal comprehensive quality and accelerating the accumulation and integration of and subject experience, so as to improve the quality of English international education.

6. Experimental Process and Results

This experiment will use this indicator system to analyze the results of the experiment. First, establish a hierarchy, based on the levels and elements of the learning ($a1$) part of the higher English international education model in Table 1; English learning input ($b1$) and English learning output ($b2$) are contained in it, and $c1$ is the visible learning level indicator. Adopt the sum of compulsory and elective hours, and the evaluation criteria are over 150A, 120–150B, 90–120C, 60–90D, E under 60, converted into a percentage system A 100 points, B 85 points, C 70 points, D 55 points, and E 40 points; $c2$, the invisible learning indicator calculates the level and number of students participating in competitions, participation in English-related lectures and activities, participation in international academic exchanges, and English-related practical activities, which are converted into a hundred-point

Table 1: *a-b* comparison judgment matrix.

| a_1	b_1	b_2	w
b_1	1.5	1.5	1
b_2	1.5	1.5	1

Figure 2: *a-b* matrix diagram.

Figure 3: b_1-*c* matrix diagram.

system; $c3$ indicators are degree courses and evaluation standards. It is a percentile system with a score of 7 : 3 on the roll and usual; $c4$ is the accumulation of other output such as awards in the National College English Contest and submission and publication of English papers (assigned according to ISTP, EI equal levels), etc. and is converted into a percentile system. Secondly, the corresponding questionnaire was compiled, and opinions were solicited from 20 teachers engaged in English teaching for non-English major graduate students to confirm the final judgment matrix and form the weight coefficient, as shown in Figures 2–4 and Tables 1–3.

When λmax = 1.5, when CI = 0 is satisfied, the obtained matrix has complete consistency (Figure 2).

When λ_{max} = 2.0, when CI = 0 is satisfied, the obtained matrix is completely consistent (Figure 3).

When λ_{max} = 2.5, when CI = 0 is satisfied, the obtained matrix has complete consistency (Figure 4).

The results of the 2019 higher English internationalization teaching courses are selected in order of 67–74 points, of which there are 50 students, 25 boys and 25 girls. The selected student targets have no significant difference

Figure 5: Distribution of English comprehensive ability assessment results.

in age. The detailed distribution is shown in Figure 5. As shown, in the evaluation of the quality of the teaching model, this single result obviously cannot be used to objectively evaluate the 50 students with insignificant differences in scores.

From the analysis of the experimental results, it can be seen that the higher English internationalization education index assessment constructed in this article has a good degree of discrimination, can more reasonably evaluate the higher English internationalization teaching ability, and can also make the evaluation process more objective and scientific. This provides a scientific basis for follow-up teaching quality evaluation.

7. Conclusions

According to the above analysis, it can be seen that there are many problems in the teaching process of higher English international education based on the multisource information fusion algorithm. The English teachers of colleges and universities need to reform according to the teaching level, mainly from the English teaching goals and English courses. Design standards, teaching content compilation, teaching quality evaluation, and English teacher team construction are analyzed from different perspectives to realize the adjustment and innovation of previous higher English nationalization teaching programs and effectively

enrich the role and functions of higher English international education. Improve the teaching level of English internationalization and better adapt to the development trend of the internationalization of higher education and economic globalization.

In order to improve the construction effect of intelligent buildings, this paper combines the BIM digital twin technology to construct the overall structure of the building construction operation and maintenance system driven by the BIM digital twin. Moreover, this paper conducts intelligent simulation of the construction process of the building and combines the construction process of the intelligent building to apply the BIM digital twin technology to the construction management of the intelligent building. In addition, this paper uses BIM to simulate the construction process. After the construction management plan is developed, BIM can be used to simulate the construction, find the problems in the construction, and formulate a reliable construction management plan in time. Through simulation experiment research, it can be known that the intelligent building construction management model based on BIM digital twin proposed in this paper can help the deployment of intelligent building construction process in many aspects and help improve the efficiency of building construction management.

1. Introduction

One of the largest network interconnection tools in the world is the Internet. The Internet uses some specific technical means and facilities connecting various types of related networks well and then connects these established connections to the Internet backbone network [1]. Generally speaking, the Internet technology we are talking about is the integration and synthesis of various technologies such as network, computer technology, multimedia technology, information data exchange, and communication technology, etc., to form a systematic information technology. Internet technology can be called a universal technology without exaggeration. It is a kind of integrated information technology. Moreover, it can perform a near-real simulation restoration of various activities, things, and situations in the real world, and it can also present various concepts of people on the computer in a virtual way [2].

The construction project management system is a newly built system. Therefore, the fourth-generation development environment construction system that can quickly generate prototypes is used in development, and it can be continuously improved and improved during operation, making it an ideal project management system [3].

BIM technology, simulation analysis technology, and monitoring technology have been widely used in the construction process of buildings [4]. BIM uses all the information of the engineering project as the database of the model, which can be used for visualization of the construction plan, construction simulation, and project management during the construction phase. Simulation analysis technology can simulate the mechanical performance and deformation state of the building structure at different times during the construction process. Large-scale finite element software is usually used to realize the simulation analysis of the structure, but the analysis of complex buildings requires secondary development. Moreover, through real-time construction monitoring of the construction process, especially the important parts and key procedures, it is possible to know the stress and operating status of the structure in time during the construction process. Whether the construction monitoring technology is advanced and reasonable, plays a vital role in construction control and is also an important part of the informationization of the construction process.

2. Related Work

Literature [5] defined BIM as integrating building component information into the building model by means of parametric modeling. At each node in the project life cycle, project participants can transmit and exchange project information through the model. BIM is used by all parties in the industry. With the continuous development of BIM standards, the continuous research of information exchange formats, and the continuous exploration of actual projects, BIM technology has been continuously improved [6]. For the intelligent management of construction sites, literature [7] is dedicated to the development of hybrid artificial intelligence tools, which have been successfully applied in many construction industries. In particular, in the field of construction management, CAPP software is used to determine important project success factors, and the developed Evolutionary Fuzzy Hybrid Neural Network (EFHNN) is used to evaluate project success. In terms of construction site informatization management, Japan has relatively standard regulations in the implementation of construction industry informatization, and Japan has fully implemented the full life cycle informatization of construction projects. On the basis of computer-aided design (CAD), a unified IT platform is provided for interaction, and electronic drawings and diagrams are used to illustrate the construction of the project, which proves that, in the case of three-dimensional electronic drawings, the realization of visualization is the most effective [8]. Literature [9] proposed a model for designing a visual management system. According to the degree of integration of the management process, the research proposed a set of guidelines for designing and implementing a visual management system and a virtual machine practice classification method.

Literature [10] proposed an Intelligent Scheduling System (ISS); project managers can use this system to find a near-optimal scheduling plan under project goals and project constraints. The ISS system integrates most important construction factors, including schedule, cost, space, manpower, equipment, and materials, etc. and uses simulation technology to allocate resources. The system assigns different levels of priority to different activities in each simulation cycle to find a near-optimal solution, so that the final progress is closer to the optimal. There are also various tools for the development of informatization in the construction industry in Germany. One of them is called the SWLMing project, which is called the energy-saving building information management semantic Web technology.

Using BIM, the construction process can be virtualized and visualized, and the construction progress, cost, resource allocation, etc. can be simulated, and the construction plan can be continuously improved, and the rationality of the construction can be improved [11]. Literature [12] proposed and verified the method of 4D model creation and the advantages of using 4D model; the use of 4D model in construction is conducive to project schedule and control. Finally, suggestions and precautions for using BIM in the process of 4D model creation are given. Literature [13] proposes a BIM-based automatic schedule plan generation method. Managers can use the schedule information model to compile a construction schedule. The two are linked for 4D simulation to increase the practicability of the schedule and reduce the number of managers and systems in subsequent construction. Literature [14] studied the BIM-based schedule planning model, which can automatically count the activity engineering quantity and calculate the duration and then schedule the schedule according to the duration. Based on the analysis of BIM-based schedule planning and BIM functions, a schedule planning method based on BIM to build an AEC + FM integrated framework is proposed.

Literature [15] deeply studied the benefits and value of applying BIM to prepare schedule and control the schedule and finally simulated the application of BIM technology to prepare schedule. Literature [16] conceived a BIM-based schedule management system framework. On the basis of this framework, a general and detailed secondary, weekly, and daily schedule plan was formulated. This action can realize the visualization of schedule management and the basis of information integration. Collaborative optimization to achieve multiple goals enriches schedule management theory, broadens schedule management practice ideas, and has guiding significance. Literature [17] uses BIM to study the automatic generation of schedule plans, with BIM technology as the main line and foundation, and on the basis of schedule planning process analysis, it integrates the establishment of expert knowledge and experience knowledge base in the field of construction and uses rules to conduct BIM-based automatic generation of schedule. BIM can be used as a database collection of component three-dimensional geometric information and other functional information. The advantage of RFID technology is that it can track and collect component progress status information, combine the advantages of the two to complement each other, and apply it to progress management, creatively solving the real-time progress. Tracking and progress monitoring are the core issues of construction progress management [18]. Literature [19] studied the application of the Internet of Things and BIM to the construction progress of the project, through radio frequency identification, global positioning, and remote understanding, command, and scheduling of construction.

3. Overall Structure of Building Construction Operation and Maintenance System Driven by BIM Digital Twin

Digital twin technology can be applied to a wide range of objects in the construction field, including buildings, work units, construction lines, workshops, etc. It should be noted that, in the digital twin general model architecture, when an object on the Y-axis (object level) is projected to the XOZ plane (system level-life cycle plane), it can be driven by the digital twin to realize the new idea of cyber-physical integration and intelligent operation of the object during its entire life cycle. Specifically, taking the building automation assembly construction line studied in this subject as an

example, when it is projected along the Y-axis XOZ plane in the three-dimensional digital twin architecture, the overall structure of the construction line operation and maintenance system driven by the digital twin can be obtained, as shown in Figure 1.

Among them, the building construction site as a physical entity layer is the basis for realizing virtual and real interaction. During the construction process, various sensors on the construction site transmit construction status information and equipment parameters to the virtual model layer through the digital tie layer. The virtual mirroring continuously updates the data and calls the geometry, physics, behavior, and rule models to simulate the status and performance of the construction line in real time and then feeds back the simulation analysis results to the physical layer and optimizes the control of the construction site through the controller. At the same time, the data link layer transmits the construction site conditions and simulation analysis results to the service application layer. On the one hand, the service application layer integrates modules such as building quality display, construction process monitoring, abnormal situation handling, construction progress feedback, equipment fault diagnosis, health status assessment, equipment life prediction, and maintenance plan generation. It displays the operation and maintenance status of the construction line on multiple platforms. On the other hand, enterprise management information systems such as ERP, MES, PDM, and PLM will also support various functional modules in the service application layer and provide them with construction-related information through data sharing. In addition, users can issue instructions through the service application layer to optimize the control of the building construction process, which also reflects from the side that the digital twin-driven construction line operation and maintenance system have good human-computer interaction performance.

In building construction activities, factors such as building structure, process flow, and technical indicators are closely related to construction efficiency and quality. Therefore, the focus of research and development of the building automation construction line is to reasonably carry out construction line layout, key mechanism structure design, and control system scheme design based on the analysis of construction elements and complete the automated construction of the building through the cooperation of reasonable and effective mechanical structure and stable and reliable control system. From the three aspects of construction element analysis, layout and structural design and hardware system design, the overall research and development idea of the design and development of the building automation construction line is shown in Figure 2.

The overall layout of the construction line is a prerequisite for development, so the overall layout of the construction line should be combined with the current situation and needs of the enterprise. As shown in Figure 3, the construction area is divided into areas such as storage of materials to be processed, storage of tooling and tools, and construction. Among them, the building construction area includes the main construction line and the automatic

feeding area, and the specific location of each station in the construction line can be determined according to the analysis of the process flow.

The virtual model of the traditional construction line mainly focuses on the visual expression, lacks the description of the characteristics, behavior, and rules of the construction line, cannot realize multidisciplinary, multiphysical, multiscale, and multiprobability simulation, and cannot meet the technical requirements of digital twins. Therefore, in the digital twin virtual model layer, researches are mainly conducted on the construction of geometric models, the standardized description of behavior models, and the evaluation of rule models.

As shown in Figure 4, in the construction of geometric models, the expression of key attributes such as physical entity size, shape, and assembly relationship is still the focus of research. Therefore, the node information will be planned based on the analysis of the structure and movement characteristics of the key elements of the physical construction line. And then use Open Inventor to build the geometric model of the object and express it visually. In terms of behavior model description, considering that the physical construction line is a construction system that integrates multidisciplinary and multidomain knowledge, there is currently no standardized description method for behavior models, and the modeling scope of AutomationML covers multidisciplinary data information, with descriptions. The ability of the behavior model and the construction line behavior model is related to the building, resources, and technology, so the standardized description of the behavior model will be studied based on AutomationML. Since the stability and reliability of the construction line's operating state are related to the key point information, the association rules of discrete data information will be mined, and the association rules will be quantified through the information entropy method, and the construction line health rule model will be established and collected through the construction site. The temperature data analyzes and evaluates the health of the construction line to verify the accuracy of the model.

At present, digital twin technology is still in its infancy, with few applications in services, and the advantages it brings are unclear. It can be seen that, through the development of the digital twin service application layer operation and maintenance system, it is very necessary to reflect the advantages of this technology in monitoring and evaluating the operation status of equipment in the construction field. The overall plan of the operation and maintenance system is shown in Figure 5. Based on the research of the physical entity layer and the virtual model layer, the key point data of the discrete construction line system is collected through the field bus to monitor the working conditions of the automated construction line at multiple construction sites. Establish a workshop Web network database server, integrate the physical entity layer construction database and the virtual model layer simulation database into the Web-core BS structure model, use the Web server to feed back the real-time construction situation and maintenance strategy of the construction site to the decision makers, and provide basic information query function. The construction information
Figure 1: The overall structure of the construction line operation and maintenance system driven by digital twins.

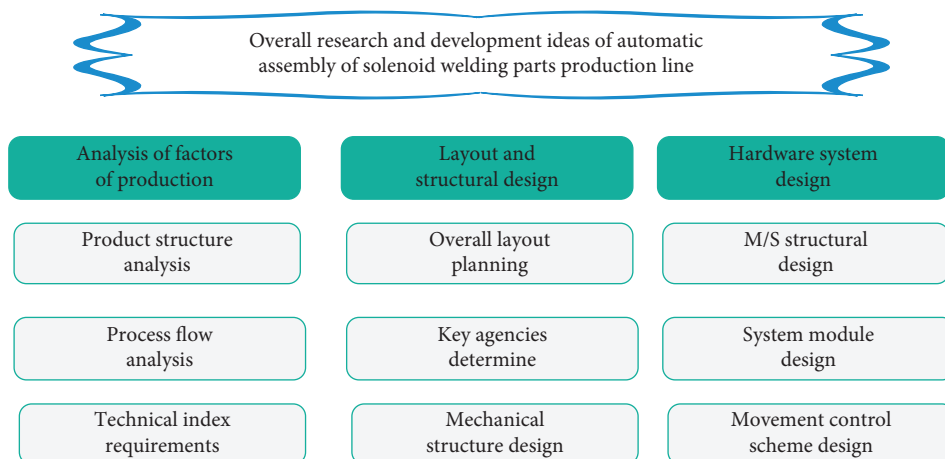

Figure 2: Overall research and development ideas of building automation construction line.

query and construction object information query functions build a unified and simple interaction method for the digital twin service application layer, physical entity layer, and virtual model layer that is independent of the user platform.

With the increase of construction line construction system equipment and the increase of uncertain factors in the construction environment, there will be complex coupling relationships within the system, which will seriously

FIGURE 3: Overall layout of building automation construction line.

$$MVE=\{Gy, By, Ry\}=\begin{Bmatrix} Bvl & Gvj & Rvj \\ Bva & Gvw & Rve \\ Bvt & Gwh & Rvo \\ .... & .... & .... \end{Bmatrix}$$

Construction of the production geometric model based on Open Inventor

Standardized description based on the AutomationML behavioral model

FIGURE 4: The main research content of the virtual model layer.

affect the reliability and stability of the construction system. Therefore, it is necessary to quantitatively evaluate the uncertain factors in the operation of the complex construction production line system. Taking into account that the digital twin rule model includes rules such as constraints, associations, and derivations, the mirroring of the virtual

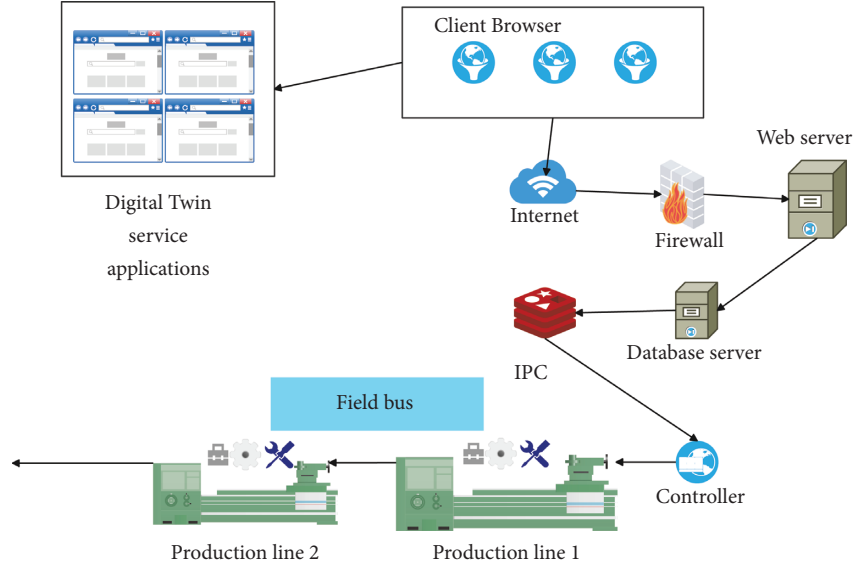
space can be equipped with functions such as judgment, evaluation, prediction, and optimization. Therefore, this paper defines the digital twin rule model, combines it with the health assessment of the construction line system, and uses the real-time data collected by the physical entity layer sensor as the input of the rule model. Moreover, this paper


FIGURE 5: The overall scheme design of the service application layer operation and maintenance system.

uses quantitative association rules to output health and judge, evaluate, and optimize the working status of the construction line.

When any construction system works, there will be corresponding behavior patterns, and the collection of all behavior patterns represents the construction capability of the system. Although the behavior mode of the system is the result of the interaction of different attributes, the reliability of the system operation can be obtained by analyzing it, but the complex construction system often contains more attributes with coupling relationships, which increases the difficulty of identifying the internal behavior mode. It should be noted that the real-time data collected on the construction site can effectively reflect the construction status of the resource equipment. Therefore, it is the main research direction of the digital twin rule model to obtain the health of the construction system by analyzing the real-time data stored on the construction site and quantifying the relationship between different attributes.

Since the key point monitoring data of the construction line transmitted by the digital tie layer in real time is a data sequence $x_1, x_2, x_3, ..., x_n$ that arrives continuously at a fixed speed, the sliding window model can be used to evaluate the data, that is, to analyze the collected data updated over a period of time. The data to be processed in the digital tie layer can be expressed in the form of a matrix [20]:

$$D_{DT} = \begin{bmatrix} D_{DT\,1} & D_{DT\,2} & \cdots & D_{DT\,n} \end{bmatrix} = \begin{bmatrix} d_{11} & d_{12} & \cdots & d_{1n} \\ d_{21} & d_{22} & \cdots & d_{2n} \\ \vdots & \vdots & \vdots \\ d_{m1} & d_{m2} & \cdots & d_{mn} \end{bmatrix}.$$

(1)

.

In the formula, Dpr represents the digital tie layer data matrix, which is composed of n elements representing different attributes, which can describe the temperature, force, and other attributes of the key equipment of the construction line, and the value corresponding to the attribute is represented by d_{mn}. In the solenoid assembly line system, the digital tie layer data matrix mainly includes attributes such as welding temperature and hot riveting temperature.

Next, we use the digital tie layer data matrix to analyze the relationship between the data. Among the n attributes of the matrix ($n > 2$), two are selected arbitrarily as the X and Y axes to establish a two-dimensional scatter plot, and the extreme value in the data is used as the boundary of the two axes. At this time, a rectangular area containing all data points is obtained. According to the permutation and combination calculation formula, a data matrix with n attributes produces a total of $n(n-1)$ scatter plots. Since the data in the scatter chart represents the attributes of the object and its related operating modes, in this paper, the scatter chart is called the attribute pattern chart.

Because the continuous data stored in D_{DT} is not conducive to analysis and calculation, there is a problem of low calculation efficiency, which will affect the real-time simulation evaluation of the digital twin rule model, so these continuous attribute data need to be discretized.

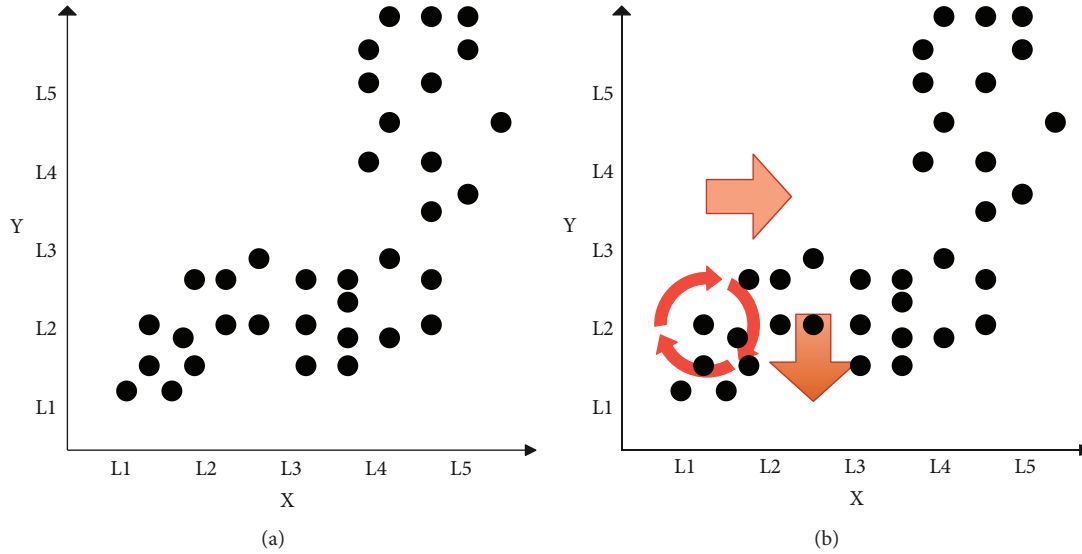
This paper uses the equal interval method to discretize the data and divide the data area. First, this paper determines the number of intervals to be divided. The number of intervals usually takes a value of 5–9, which represents the health assessment accuracy (EA). To facilitate analysis, the coordinate axis of the data to be analyzed is divided into five intervals, which are represented by L1, L2, L3, L4, and L5, as shown in Figure 6(a). Next, this paper conducts correlation mining on variables to study the changing trend of the system state when a certain attribute is disturbed. The figure is divided into 25 cells, and the cells containing data may represent the next operating state of the system. Therefore, the cells can be selected in turn as the reference grid, and the


FIGURE 6: Attribute pattern diagram and association rule mining. (a) Attribute pattern diagram. (b) Association rule mining.

data can be disturbed, and the changes of other attributes can be analyzed. The mining of association rules can be expressed as [21].

$$X + \Delta X = \gg \Delta Y (\Delta X = \pm L). \tag{2}$$

This formula expresses applying a unit disturbance on the X-axis and observing the changes on the Y-axis. When mining association rules, relevant indicators need to be used to determine whether the rules are valid. Here, the two concepts of confidence coefficient (Con) and support coefficient (Sup) are introduced, which, respectively, represent the degree of reliability and the degree of support. Confidence coefficient and support coefficient can be expressed as the ratio of the number of data in the reference grid to the total number of data in the current data interval, and the ratio of the number of cell data after being disturbed to the total number of data intervals occupied. In the calculation process, the minimum values of the above two coefficients are both set to 2/EA, as shown in equations (3) and (4). Taking the above attribute pattern diagram as an example, since its evaluation accuracy is 5, the minimum confidence coefficient and support coefficient are set to 40%. If the minimum confidence coefficient is met, it means that the system has enough probability to fall into this state during operation. Satisfying the minimum support coefficient indicates that, after being disturbed, the system state has enough possibility to change to another operating state.

$$\min\_\mathrm{Con} = \frac{2}{\mathrm{EA}}, \tag{3}$$

$$\min\_\mathrm{Sup} = \frac{2}{\mathrm{EA}}. \tag{4}$$

Taking Figure 6(a) as an example, the selected cell (2, 3) is the reference grid, which contains 8 data points, and there are 16 data points in the X-axis L2 interval, so the confidence coefficient is 50%. It satisfies the minimum confidence

coefficient requirement; that is, during the operation, the state of the system may be the state pattern represented by the cell. When a positive disturbance is applied to the reference cell, the support coefficient of each cell on L3 is calculated, which is 6.25%, 62.5%, 31.25%, 0, 0, respectively. It can be seen that the cell (3, 2) meets the requirement of the minimum support coefficient. That is, when the system is in the state represented by cell (2, 3), if the attribute represented by the X-axis is disturbed in the positive direction, the system is likely to change to the state corresponding to cell (3, 2). By analogy, when negative interference is applied, the cells (1, 1) and (1, 2) meet the requirements of the support coefficient. The mining of the above association rules is shown in Figure 6(b).

After obtaining the association rules, in order to visually indicate the strength of the association rules, it needs to be quantified, and the health of the system can be obtained on this basis. Considering that entropy represents the degree of disorder of a data set and is directly related to the amount of information it contains, information entropy can be used to describe the strength of association rules. The information entropy of continuous variables can be expressed in the following form:

$$H(X) = -\int p(x)\log p(x)\mathrm{d}x. \tag{5}$$

However, to calculate the information entropy through this formula, the probability density function $p(x)$ needs to be obtained first, which is more difficult in some cases, so it needs to be discretized. The information entropy after discretization is

$$H(X) = -\sum_{i=1}^{n} p(x_i)\log_s p(x_i). \tag{6}$$

In the formula, $p(x_i)$ represents the probability when X takes the value xi, $i = 1, 2,...,n$.
Figure 7: Flowchart of progress management based on BIM technology.

In addition, mutual information represented by entropy is a useful information measure in information theory, which can measure the degree of association between two variables, and its form is shown in formula (7). Among them, the mutual information of the two variables is equal to the sum of the respective entropy minus the joint entropy. Mutual information can describe not only linear correlations between variables but also nonlinear correlations, but its values are not normalized, so mutual information needs to be normalized. This article uses generalized correlation function to quantify the relationship, such as formula (8). Among them, the value of R_g is between 0 and 1. The closer R_g is to 1, the stronger the correlation between the two attributes.

$$I(X, Y) = H(X) + H(Y) - H(X, Y), \qquad (7)$$

$$R_g = \frac{I(X, Y)}{\sqrt{H(X)H(Y)}}. \qquad (8)$$

When different cells are used as the reference grid, the subpatterns mined may be the same effective area, so the confidence coefficient of each reference grid needs to be considered. For a certain mode, the health degree can be expressed by the sum of the product of each submode and the confidence coefficient:

$$U(D_x, D_y) = \sum_{i=1}^{EA} \sum_{j=1}^{EA} \text{con}(i, j) R_{i,j} | C_{D_x, D_y}. \qquad (9)$$

Among them, $R_{i,j}$ is the generalized correlation coefficient of the subpattern mined in the cell (i, j), and C_{D_x, D_y} indicates that the calculation comes from the coordinate system composed of the Dx and Dy attributes in the digital tie layer data matrix.

For any construction system, each variable will become a benchmark attribute for analyzing the possible association relationship with other variables, and at most $n\,(n-1)$ patterns can be obtained. The collection of the above modes can reflect the operating rules of the entire system. Therefore, the system health should be a collection of all modes

$$
\begin{aligned}
U &= \sum_{x=1}^{n} \sum_{y=1, y \neq x}^{n} U(D_x, D_y) \\
&= \sum_{x=1}^{n} \sum_{y=1, y \neq x}^{n} \left(\sum_{i=1}^{EA} \sum_{j=1}^{EA} \text{con}(i, j) R_{i,j} | C_{D_x, D_y} \right).
\end{aligned}
\qquad (10)
$$

4. Intelligent Building Construction Management Based on BIM Digital Twin

Compared with traditional schedule management, construction schedule management combined with BIM technology provides a communication platform that integrates multiparty information, including schedule, cost, and materials. When making schedules, it uses relevant software to simulate the project before construction to find and solve problems. During the implementation of the plan, it is possible to analyze and adjust the problems that occur efficiently and conveniently, so as to avoid missing the best time to solve the problems and affect the construction. The flowchart of the progress management based on BIM technology is shown in Figure 7.

The schedule preparation process is shown in Figure 8.

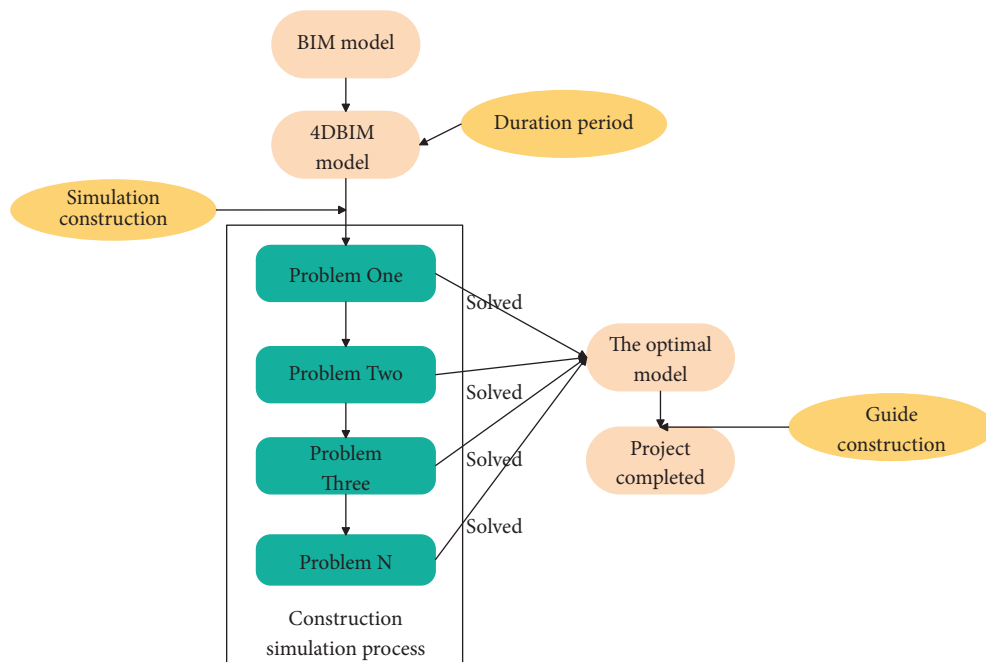
The schedule preparation and implementation procedure under BIM technology is shown in Figure 9 below. Under the BIM technology, through the early visual


Figure 8: Schedule preparation process.

FIGURE 10: The effect of intelligent building construction management based on BIM and digital twins.

operation, the problem is first discovered, then rectified, and finally implemented.

After constructing the above model, the practical effect of the intelligent building construction management model based on the BIM digital twin is studied through experiments. This article explores the effectiveness of the intelligent building construction management model based on the BIM digital twin from the aspects of construction safety, equipment management, material management, site management, operation management, and quality management. The experimental results obtained through simulation research are shown in Table 1 and Figure 10.

It can be seen from the above research that the intelligent building construction management model based on BIM digital twin proposed in this paper can help the deployment of the intelligent building construction process in many aspects and help improve the efficiency of building construction management.

5. Conclusion

The calculation model, material properties, construction method, construction load, temperature change, etc. of the building structure from the start to the completion stage can affect the construction quality to varying degrees. This leads to a large deviation between the actual state of the structure and the ideal state, which requires strict control of the adverse effects during the construction process. For complex structures, the mechanical properties and safety control requirements during the whole construction process are no longer what the traditional construction control technology can meet. Then, how to consider the impact of unfavorable factors on the construction status during construction and carry out real-time identification and adjustment, how to reasonably and accurately simulate the time-varying process of the structural system in each stage of construction, how to arrange the construction and schedule reasonably, and how to control the stress and strain state of the structure during construction within the allowable range are the contents and technologies that are urgently needed in the current construction field. This paper applies BIM digital twin technology to intelligent building construction management and simulates the construction process through BIM. After the construction management plan is formulated, the construction simulation can be carried out through BIM, and the problems existing in the construction can be found, and a reliable construction management plan can be formulated in time.

With the application of engineering management in smart city construction under Industry 4.0, the intelligent design of urban street landscape has attracted extensive attention. Affected by the low intelligent level of traditional landscape design, the existing urban landscape composite system has difficulty in meeting the needs of smart city construction. Therefore, this paper proposes the construction of street landscape big data-driven intelligent decision support system based on Industry 4.0. Based on the complex network theory, this paper analyzes the structure, links, nodes, driving forces, and functional requirements of urban street landscape and then puts forward the construction content and implementation method of urban street landscape intelligent decision support system. The system consists of four aspects: intelligent infrastructure, service, protection and maintenance, and management and evaluation system. Its implementation not only reflects the cooperation and effective application of intelligent technology in each stage of street landscape construction, but also provides reference for the application of engineering management in other fields under Industry 4.0.

1. Introduction

Based on the connectivity provided by the Industrial Internet of Things (IIoT) and the use of a variety of digital technologies such as cloud computing, big data, and artificial intelligence, Industry 4.0 is proposed as a new stage of industrial maturity [1, 2]. These technologies have produced an industrial method of automation and interconnection involving objects, products, and people, thus achieving a higher level of industrial performance [3]. With the application of engineering management in smart city construction under Industry 4.0, the intelligent design of urban street landscape also rises and develops rapidly. Meanwhile, "intelligent" development has become the new trend in modern society due to the advancement of information technology represented by the Internet. The smart city emerges in this context, which can detect, analyze, and integrate the key information of urban core operating systems using information and communication technologies, thus making intelligent responses to various needs covering people's

livelihood, environmental protection, public security, urban services, and industrial and commercial activities [4]. The intelligent urban management and operation relying on advanced information technologies can effectively solve the complex urban problems and promote the harmonious and sustainable urban development [5].

As an important part of smart city construction, landscape architecture is also facing opportunities and challenges brought by the intelligent process. Smart gardens changing the construction, operation, and management modes of traditional gardens can effectively improve the efficiency in landscape garden industry, realizing the normalization, standardization, digitization, networking, and intelligence of garden construction [6]. The typical scenario of urban street landscape has significant effects on shaping the urban image. By selecting street landscape as the entry point of smart gardens, this paper aims to explore the needs of urban street landscape and discuss the intelligent system construction and implementation means, in order to provide reference for the construction of urban street intelligent systems [7, 8].

However, under Industry 4.0, in the process of intelligent city construction, how to effectively use new technologies such as big data and Internet of Things, as well as the interconnection between urban street landscapes after 5G network integration, has attracted people's attention to the security and anti-network attack stability of these systems.

2. Related Works

In the construction of urban street landscape intelligent system, "urban street" refers to the urban road equipped with sidewalks, municipal utilities, and various buildings on both sides in the overall length or most sections. As one of the subsystems under the future urban open complex giant system, the nature, function, form and structure of urban street are more complex than traditional urban road. Urban street serving as the most basic public urban space focuses on the citizens' life and humanized experience, which facilitates the interpersonal communication and interactions via emotional sustenance as well as playing an irreplaceable role in shaping the urban charms and vitalizing the economic development [9, 10].

Relying on the complex network theory and "Internet +" thinking, the smart landscape cooperates with new-generation information technologies such as Internet of Things, big data cloud computing, mobile Internet, remote sensing, and information intelligent terminal, obtains time-domain advantages, and responds quickly to social and natural activities carried in the landscape space. Integrating the spatial domain of modern ecological landscape into the large database achieves the intelligent connection between scattered social activities and needs of human beings, nature and landscape space for the interactive perception, and cognition and communication and improves the utilization and sharing rate of various scattered landscape resources, thus promoting the intelligent construction, service, and management of landscapes [11, 12].

The design of intelligent street landscape systems shall be based on the comprehensive consideration of user needs, greening landscapes, and basic street functions, through the Internet of Things, web services, and virtualization technology. The basic attributes, characteristic parameters, status, and other information of various street landscape elements are dynamically and intelligently sensed and accessed in real time, to build street space intensively. Through processing the information perceived by the landscape intelligent system, data collection, integration, analysis, processing, and feedback are realized under the mapping of landscape resources in urban streets. On the premise of ensuring the basic functions of the road, people's travel safety, life, and social security should be guaranteed, which provides conditions for the scientific, rapid, comprehensive, and visual development of urban street landscape design and management.

The construction of intelligent systems for urban street landscape based on complex network theory and the integration of smart landscape concept into the traditional urban street landscape indicate further improvement, which shall meet the requirements for intensive intelligent spaces, multiple interactive experience, and green ecology of energy conservation [13, 14].

3. Composition of Intelligent Systems for Urban Street Landscape

In order to cope with the multiple landscape needs under the complex system of urban streets, the intelligent street landscape system based on the complex network realizes the intelligent supply-demand matching of street landscape space services from the three levels of landscape facilities Internet of Things, service Internet, and user Internet.

The construction of street landscape intelligent system mainly involves four aspects: intelligent infrastructure, intelligent service, intelligent protection and maintenance, and intelligent management and evaluation.

3.1. Intelligent Infrastructure. Intelligent infrastructure is the physical layer and the foundation of street landscape intelligent systems. The infrastructure of street landscape intelligent systems shall proactively provide the information and services desired in addition to the basic functions and be available to correlate with other facilities and even users for the formation of a complete intelligent network featuring information interaction and function linkage, thus completing the virtualization and service-oriented information interaction and functional linkage of the intelligent information system.

3.1.1. Information Infrastructure. Information infrastructure is the basis of intelligent street landscape, covering the electric information screen shown in Figure 1, multimedia touch screen terminal shown in Figure 2, intelligent monitoring, intelligent broadcasting, help facilities, security facilities, and landscape performance facilities. The foundation of infrastructure construction lies in the sound network transmission and communication networks, and relevant facilities shall be arranged in the densely populated areas (e.g., road entrances, parking lots) to facilitate the service provision such as information inquiry and satisfy the important requirements of easy identification and convenient use. The service scope of facilities with special functions (e.g., help facilities and security facilities) shall cover the entire street area, as well as focusing on the locations along main/secondary trunk roads and various open spaces, activity sites, and surroundings of green landscapes [15].

3.1.2. Data Infrastructure. Data cognition is the core of intelligent street landscape development. The data infrastructure is used to collect and integrate street landscape data, achieving the intelligent street landscape construction by providing the users and managers with comprehensive and intuitive information based on the integration and analysis of multisource data (basic/business/service databases).

Figure 1: Electronic information screen.

Figure 2: Multimedia touch screen terminal.

Basic database clarifies the spatial location and surrounding environment of urban street landscape for the precise positioning of smart landscape. Business database has multiple subdatabases covering the special data, system planning and management, monitoring management, and industry management available for the precise and whole-process collection of street landscape data. Service database can provide the popular science knowledge about smart street landscape for the public and facilitate the review of various urban green spaces and scenic spots by potential travelers [16].

3.1.3. Observation Points of Street Green Space Ecosystem. Based on the ecological requirements of the street landscape intelligent system construction, ecological observation of the street is an effective measure to achieve this goal. Using RFID (radio frequency identification) technology, the real-time update of spatial ecological information of street landscape can be realized, and the location of vegetation, structures, and buildings can be monitored online. Special

sensors and wireless sensor networks for street landscape ecological observation can effectively realize real-time data acquisition and transmission. Real-time monitoring of the street green space ecosystem can help with maintenance and management of the green landscape. Furthermore, the obtained ecological econometric characteristic data can aid in the formation of quantitative analysis results of the street landscape space, resulting in better landscape and ecological effects from green space maintenance and management, Figure 3.

3.2. Intelligent Service. The service object of the intelligent street landscape systems is the streetscape users. The construction of intelligent service system is based on Internet functions, which can realize the dynamic matching of the user's needs. From the perspective of users, in the process of system construction, our goals and demand motivation can be evaluated, and the service content can be derived dynamically.

In terms of qualitative or quantitative data, managers could be provided with genuine feelings, opinions, and suggestions generated by the public in the service experience. With the help of dynamic characteristics analysis of smart infrastructure, a reliable method for demand forecast management is provided. Thus, public involvement can be achieved, and the quality of the service improves continuously [17].

3.2.1. Network Service Platforms. Network service platforms are the basis for intelligent service and the guarantee for intelligent linkage with other service facilities. The construction of portals serving the public shall cover various services such as bus routes, e-maps, traffic notices, travel tips, and road service calls. In addition, the construction of mobile-based network service platforms (e.g., mobile apps, WeChat public accounts) shall also be emphasized to ensure the real-time content update and provide mobile users with street information services based on the shared portal resources.

3.2.2. Basic Street Services. Basic street services are mainly the traffic, lighting, and other necessary basic services. For instance, the smart parking management system achieves the real-time monitoring of parking spaces and the intelligent guidance about available parking spaces based on the information inquiry of parking lots and spaces through various intelligent terminals such as smart phones. The construction of public transportation system shall ensure the timely release of bus information and certain functions (e.g., multimedia information release, passenger complaint) in combination with the special bus signal system for important bus corridors and the intelligent bus stations. The streets with heavy traffic flows shall be equipped with smart toilets, which are available for the information inquiry of location and real-time usage through various intelligent terminals (e.g., smart phones, multimedia touch screens). In addition, the intelligent lighting system subject to the independent

Figure 3: Ecosystem observation facility.

sensing, timing, voice control, or remote control of intelligent terminals shall also be arranged for the smart control of landscape lighting in different areas [18], Figure 4.

3.2.3. Road Navigation. The intelligent terminals (e.g., smart phones, multimedia touch screens) and multilanguage terminals for self-service navigation shall be arranged to facilitate the inquiry of street and surrounding-area e-maps and tour route planning as well as the scenic spot/plant introduction using QR code/RFID technologies [19].

3.2.4. Information Release. An interactive information system shall be established to provide life, service, business, and medical information for citizens, with various network service platforms serving as the channels for street information release, covering the street information, real-time road conditions, toilet usage, spare parking spaces, restaurant usage, and other basic information; climatic information (e.g., street temperature, humidity) and health information such as negative oxygen ion content in key areas Figures 5, flowering phase, and news and cultural event notices (e.g., lectures, exhibitions, festival activities, fitness events) at sites along the street; and information of emergency responses.

3.2.5. Personalized Services. Personalized services available at various network service platforms can meet the street use demands of different people [20], for instance, the online adoption of plants along the street, and regular pushing of plant growth status and daily conservation information; pushing of intelligent infrastructure, location awareness, environmental monitoring index analysis, online security, and health information via the Internet; and application of

intelligent technologies based on the users' different needs of travel and fitness.

3.2.6. Consulting/Complaint Services. Compared with the traditional consulting/complaint services, the services provided through the intelligent system are more convenient and efficient, and multiple channels (e.g., street intelligent terminals, consulting/complaint pages, mobile terminals) are available for the public. The intelligent system of linkage service can achieve the unified receipt and instant feedback/response to consultations and complaints from telephones and network terminals.

3.2.7. Virtual Experience. In order to improve the user experience, a multimedia experience center focusing on historical districts shall be constructed using multiple technologies (e.g., GIS, VR, and multimedia) for the display of historic landscapes, original natural features, and historical changes. The 3D panorama/reality enhancement display technology and 360°/720° real-life photos or videos can be utilized to create the virtual blocks for digital virtual tours that are available at portals and terminal devices (e.g., multimedia touch screens, smart phones) [16, 21].

3.3. Intelligent Protection and Maintenance. Intelligent protection and maintenance are the function expansion of the user Internet based on the Internet of Things of landscape facilities. Dynamically generate landscape maintenance needs based on smart infrastructure, and dynamically match landscape maintenance needs with landscape maintenance services through the Internet of Things technology. Realize the informatization and intelligence of the protection and maintenance process, provide visual guidance on daily maintenance process and key technology, and the responsible personnel and stages could be specified for the real-time recording of maintenance process and information [22].

3.3.1. Green Space Protection and Maintenance. Green space protection and maintenance are the key to intelligent protection and maintenance, covering the digital recording, monitoring, and control of boundaries and green resources including the main plants and facilities. The important spots and key facilities shall be equipped with 3D scenes for inspection and comparison via intelligent terminals, mainly involving the plant irrigation and fertilization, pest and disease and freezing damage management, and intelligent cultivation.

Environmental monitoring and intelligent irrigation system can provide effective services for intelligent plant irrigation and fertilization management. The digital data processing of soil nutrients can maximize the effects of water-saving and precise irrigation, scientific management, and low-carbon maintenance [23, 24]. The construction of soil monitoring subsystem is available for the real-time monitoring of ambient temperature and humidity, wind direction, rainfall, and illuminance in the
FIGURE 4: Basic street services.

FIGURE 5: Street climatic information and health information.

surrounding environment Figure 6, with the sensing facilities adopted for real-time detection of soil moisture, fertility, and other green space indexes. Maintenance decision-making depends on the IoT-based intelligent analysis and sorting of monitoring data received by servers [25]. In addition, the sprinkling and dropper systems are used for the automatic irrigation and fertilization and other intelligent applications, and the landscaping personnel can also search and receive monitoring data and warning information via computers and mobile phones Figure 7.

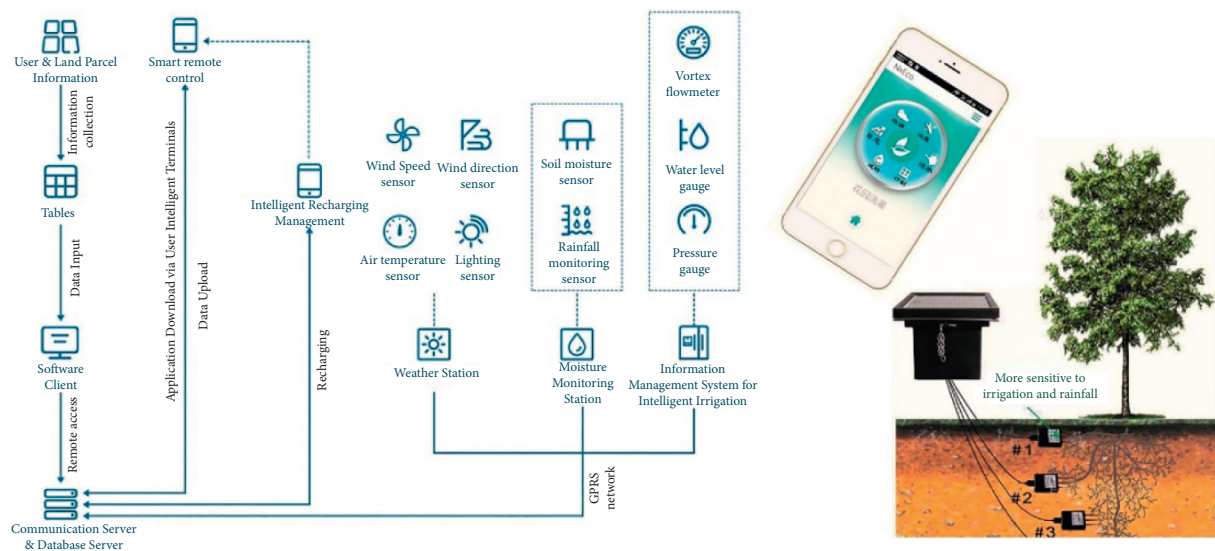
The GPS positioning and FRID technologies shall be adopted for the control of plant diseases and pests, with the dynamic tracking system established to ensure the dynamic protection and monitoring of green plants as well as help technicians locate the areas of pests and diseases at first time. The implementation of "prevention-first" principle by each institution responsible for plant management and protection targeting the necessary early warning of pests and diseases within all periods can greatly reduce the prevention costs and probability of large-scale pests and diseases [26]. Early warnings for the freezing damage management shall be


Figure 6: Soil monitoring subsystem.

Figure 7: Intelligent irrigation system.

issued in advance based on the weather conditions, providing the scientific basis and guidance for plant winter protection.

The intelligent technology-based seedling planting and cultivation shall make full use of the IoT and spatial information integration technologies. The partitional measuring of regional soil quality, hydrological conditions, and microclimate factors at the stage of planting planning provides the definite data basis for breeding and rapid formulation of cultivation schemes. At the same time, a tree full cycle database shall be established for plant tracking and data sorting in the whole process, as well as the records of seedling archives, tree transplantation, and maintenance information. Intelligent cultivation can effectively prevent the challenges faced by the traditional seedling cultivation (e.g., improper layout of trees, unsatisfactory production or waste of seedlings).

3.3.2. Heritage Protection and Maintenance.
Both natural heritage and cultural heritage involve heritage protection and maintenance, including ancient and famous trees and cultural relics. For the ancient and famous trees, the high-definition photos shall be obtained based on the precise coordinate positioning via monitoring and RFID technology in addition to the normal maintenance measures, and mastering relevant detailed information will facilitate the data calling, plant protection, document management, maintenance, and rejuvenation monitoring. Digital modeling based on the growth environment of ancient and famous trees also facilitates the accurate analysis of protection measures Figure 8. For the cultural relics and historical sites surrounding the street, the 3D data model shall be constructed to enhance the protection. The ancient buildings shall be equipped with stress-strain sensors for deformation monitoring and risk assessment [27].

3.4. Intelligent Management and Evaluation System.
Scientific and comprehensive management measures are an important prerequisite for realizing the sustainable development of streetscapes. Quantitative evaluation mechanism is an effective objective to judge the effectiveness of streetscapes.
FIGURE 8: Digital monitoring of ancient and famous trees.

How to effectively integrate various scattered landscape management resources and coordinate various quantitative evaluation parameters to achieve the best match between street landscape management and demand is the key problem. Hence, quantitative data-driven evaluation and control system is ultimately conducive to the continuous optimization of landscape effects.

3.4.1. Intelligent Management. The comprehensive and scientific management shall take account of internal office work, gardening business, street security, and other related factors.

Office automation (OA) system can improve the overall efficiency of internal office work, covering process management, e-mail, document management, document circulation, approval management, working calendar, notice announcement, personal information maintenance, conference management, and attendance management.

In terms of the gardening business management, video monitoring, RFID, and infrared sensing technologies shall be adopted for the real-time perception of changes in street green resources, infrastructure, and traffic flows, as well as the automatic collection, adjustment, and update of street landscape data. The real-time monitoring of street landscape can achieve precise management and prevention against vandalism and damage caused by natural disasters.

Street security cannot be neglected considering the special traffic function of urban street with public spaces. The construction of integrated street control platform makes the daily operation monitoring and emergency command and dispatching possible, providing basic support for navigation and guidance based on the location services of GIS and satellite positioning systems [28]. Nowadays, the rapid development of information technology also facilitates the dynamic monitoring of public opinions released via key media, forums, blogs, and Weibo platform; extraction of relevant information; and timely warning/treatment of potential crisis events in accordance with predetermined strategies.

3.4.2. Intelligent Evaluation System. The evaluation of self-diagnosis by intelligent evaluation system aims to provide reference for further development. Moreover, reasonable performance evaluation can not only measure the achievements of street landscape construction and find out

the existing problems, but also provide important guidance for the continuous improvement of street landscape intelligent system.

Establishment of the complete, scientific, and effective evaluation system shall be based on the existing urban gardening standards, with the relevant street smart landscape indicators integrated into the system by means of spatial layers, forms/tables, document uploading, and image attachments for real-time computing and result judgment/analysis [29], Table 1.

4. Technical Means of Intelligent Systems for Urban Street Landscape

Intelligent technology refers to a specific technology or method used in the construction of an intelligent urban streetscape system. Internet of Things, spatial information integration, virtual reality and visualization technology, digital technology, etc. can solve the following problems in the construction of streetscape system under the condition of urban complex giant system:

(1) How to manage, digitize, and integrate information from scattered roads efficiently and precisely, in order to realize the effective distribution and dynamic overall grasp of the streetscape service capabilities.

(2) How to coordinate the relationship between the geographic space, data flow, time distribution, hardware network, and user needs of the streetscape intelligent system, in order to realize the spatial mapping between complex streetscape resources and intelligent system service capabilities [30].

Emergence of the most representative IoT technology in the intelligent process has led the transformation of information age into an intelligent era. The all-inclusive IoT technology involving radio frequency identification (RFID), infrared sensor, and sensor-laser scanner solves numerous urban problems via interconnection of things after the Internet-based information connection [31].

Spatial information reflects the spatial distribution characteristics of geographic entities, and the spatial information integration technology involving remote sensing (RS), geographic information system (GIS), and global positioning system (GPS) can reflect the topographical features of all sites more concretely and objectively at the

TABLE 1: Intelligent evaluation index.

Target layer	Control layer			
	Evaluation object	Weights	Indicator layer	Weights
Evaluation of intelligent urban street landscape (A)	Material element (B1)	0.38	Functional facilities (C1)	0.35
			Recreation facilities (C2)	0.3
			Plant landscape (C3)	0.15
			Paved landscape (C4)	0.2
	Open space (B2)	0.28	Spatial scale fitness (C5)	0.3
			Environment comfort (C6)	0.25
			Landscape interface suitability (C7)	0.23
			Activity type richness (C8)	0.12
			Activity time richness (C9)	0.1
	Environmental ecology (B3)	0.34	Landscape sensitivity (C10)	0.35
			Landscape suitability (C11)	0.33
			Landscape health (C12)	0.32

macro level and achieve precise quantification and data digitization for in-depth research and analysis [32].

VR technology integrates multiple techniques features in good experience of immersion, interaction, and conception, covering the real-time 3D computer graphics, 3D wide-angle (wide-field) display, tracking of the viewer's head/eyes/hands, tactile/force feedback, stereo effects, network transmission, and voice input/output [33].

The basic process of digitization involves the transformation of all complex and changeable information into measurable data, digital data modeling for binary code conversion, and input into the computer for unified processing [34]. At present, the digital technology is widely used in various industries, and the digitization serving as the predecessor of intelligent technologies shall be utilized continuously in the intelligent era.

5. Prospects of the Construction and Application of Intelligent Systems for Urban Street Landscape

To achieve the successful construction of street landscape intelligent systems, the mutual mapping of complex system and complex network of street landscape needs to be realized. Therefore, the above intelligent means must be implemented combined with the actual stages of street landscape construction in practice.

5.1. Planning and Design Stage. The early stage of planning and design provides direct guidance for the mid-term construction and post-management of landscape construction. The application of intelligent means such as the Internet of Things, virtual reality, and visualization technology at the planning and design stage can realize more scientific and rational street landscape design.

In terms of on-site investigation, the traditional investigation methods have large workload and large error, and most of them are completed on the basis of on-site inspection and surveying and mapping, combined with the existing data. In addition, the traditional street design focusing on-site plane lacks the 3D-space and humanized thinking in terms of vertical design, construction scale, and

detailed design. On the contrary, the intelligent landscape construction can realize the targeted integration of IoT and spatial information technologies into the site survey, with the precise positioning of street location and surrounding land uses utilizing the IoT sensing nodes [35]; moreover, the spatial information technology enables the designer to understand the connections between overall street appearance/style and urban image more comprehensively and accurately Figure 9.

5.2. Construction Stage. The construction quality directly affects the smooth implementation of the preliminary design and the cost of later maintenance and management. Due to the problems of inaccurate calculation of quantities, unconstrained construction, and limited professional quality of most construction personnel in traditional garden construction, there are often some deficiencies in construction quality compared with the expected effect.

The intelligent street landscape construction can ensure the rational resource allocation and construction efficiency through the in-depth survey of on-site environmental factors (e.g., soil quality, hydrological conditions, wind force, atmospheric pressure) using the sensing and RFID systems of IoT technology and the corresponding construction schemes and regulations. The application of spatial information integration technology and sensing system makes precise and rapid data positioning based on construction drawings possible at the stage of fixed point setting-out. The multispace model using VR technology enables the construction personnel to understand the design intention in an intuitive manner during construction, thus ensuring the realization of design effects. The application of IoT sensing system upon project acceptance for data measurement and quantitative analysis of engineering effects, combined with the direct data transmission to the auditor's mobile devices using mobile Internet technology, guarantee the strict project acceptance [36], Figure 10.

5.3. Green Plant Cultivation and Conservation Stage. Conservation management can maintain and guarantee the landscape effects after gardening construction. The
Figure 9: Application of intelligent technologies at the planning and design stage.

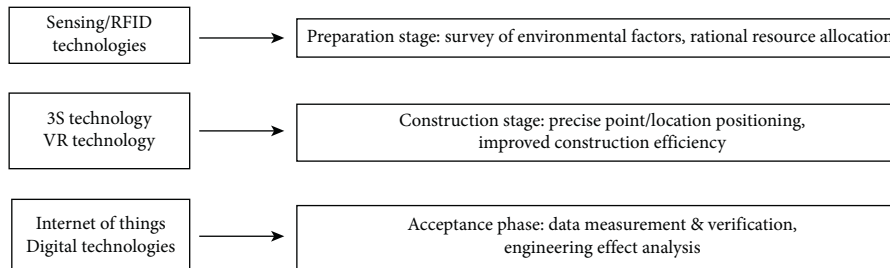

Figure 10: Application of intelligent technologies at the construction stage.

Figure 11: Application of intelligent technologies at the green plant cultivation and conservation stage.

traditional plant cultivation and conservation have certain shortcomings, e.g., unsatisfactory professional quality of management personnel and conservation measures of low technical contents.

The intelligent plant cultivation and conservation integrating IoT technology ensure the effective improvement of conservation efficiency and effects with reduced cost. In order to make proper use of local conditions, the sensors shall be used to measure environmental factors (e.g., humidity and soil quality) at the cultivation stage, and the original manual sprinkling shall be replaced by the sprinkling/drip irrigation system with time-frequency sensors to detect the soil moisture and facilitate the intelligent control [37]. In terms of fertilization, winter protection, and wind protection, the digital model established based on the plant growth environment can realize the precise analysis of proper measures in different periods to ensure the normal plant growth and optimal effects Figure 11.

6. Conclusion

Applying intelligent means in urban street landscape design and integrating street landscape intelligent system into smart city construction can actively promote urban development. Procedures starting from scheme design and project construction to maintenance management,

technology introduction, and formulation of comprehensive and effective strategies are the key to the successful construction of street landscape intelligent system based on complex network. In addition, the construction of street landscape intelligent system also provides a platform for public participation and governance. The public can easily and quickly obtain information through such intelligent systems and use improved consultation/complaint services to give timely feedback to managers, which indicates that public participation has been significantly improved [7, 38, 39]. In short, the street landscape intelligent system based on complex network theory provides an advanced and sustainable construction mode for the future urban complex street system. In the context of Industry 4.0, with the rapid development of big data and the Internet of Things, more in-depth research in the future should aim to integrate the street landscape intelligent system into the construction of smart city and build a perfect street landscape intelligent system.

Urban Public Sports Information-Sharing Technology Based on Internet of Things

Youliang Li, Fenglei Li ⓘ, and Yujun Xiong

School of Physical Education, East China University of Technology, Nanchang 330013, China

Correspondence should be addressed to Fenglei Li; 201960251@ecut.edu.cn

With the continuous development of social economy, sports has become one of the important ways of physical exercise, and the demand for corresponding sports facilities is also increasing. The Internet of Things technology is introduced in this paper. Through combining the current status of urban public sports, an urban public sports sharing system is built by trial, to promote the sharing of urban public sports information through the continuous development of new technologies such as the Internet and improve the publicity and popularization of public sports information. Simulation experiments prove that the Internet of Things technology is effective and can effectively support the sharing of urban public sports information.

1. Introduction

With the continuous development of social economy, modern society has gradually transformed into a "data society," and all walks of life are subject to important influences and innovations related to informatization [1, 2]. The continuous progress of society has promoted the healthy development of human beings, but how to conduct sports or physical exercise is an issue that people are extremely concerned about, especially about the existence of surrounding stadiums and public welfare sports facilities, vacant venues for the badminton courts, etc. [3, 4].

From digital cities to smart cities, the construction of informatization has had a profound impact on various industries, and data have also grown in an explosive manner. However, disorderly and messy data often bring about important loads of hardware storage and network transmission and have become a burden on users [5, 6]. However, what needs to be valued is how to reasonably process, orderly process, and classify and extract these data, realize the reuse of data, tap its potential value, transmit potential information, realize the maximum sharing of data and information, and save the cost of data and information and various construction costs [7, 8]. The continuous construction and development of smart cities have gradually introduced a series of new technologies and methods such as the Internet of Things, the Internet, CloudNative, and Fog Computing, aiming to solve urban sickness such as urban congestion, environmental pollution, population agglomeration, and other cities in the process of urbanization [9, 10].

For sports, it is necessary to further consider its limitations and needs in the actual implementation process, how to select the location of sports facilities, how to release it to the public, when will the corresponding venue information be opened, how many visitors access the venues currently in real time, and so on [11, 12]. According to the different seasons, some information is extremely valued such as opening college swimming pools and badminton halls to the public, related matters, and public opening hours, to prevent the public from entering disorderly. In response to these needs and limitations, the new technologies such as the Internet of Things is introduced in this paper, and an urban public sports information-sharing architecture system is built by trial. Through the Internet and other technologies, information is continuously processed, extracted, and shared, and finally, information sharing is realized, aiming to improve the quality of public sports, realizing "one-time processing and analysis, and multiple times' sharing applications."

2. The Status Quo of the Co-Construction and Sharing of Sports Information Resources in China

The advent of the information age has given birth to the increase and enrichment of various information resources. As far as the sports industry is concerned, its information resources are an important branch of related information resources, which have the extensiveness and imbalance of traditional information resources. Similarly, sports resource information still contains a lot of content, but the quality is difficult to be guaranteed. Because sports has penetrated every walk of life, such as sports channels, sports pages of web news, sports sections in micromedia, sports bloggers, and various sports magazines, there are various carriers of sports information resources, even new media such as Douyin and Kuaishou, have a large amount of sports information resources. This aspect is due to the continuous development of information technology and the continuous enrichment of carriers. On the contrary, sports have become the focus of daily life and gradually attract more and more people's attention. How to provide important sports information to the public has become a problem and direction worthy of attention in the industry and academia [13, 14]. Therefore, it is necessary for all sports-related industries to work together to improve business capabilities and realize the sharing and co-construction of sports resources.

2.1. Outdated Concepts and Weak Consciousness. As a public welfare direction, usually sports does not receive too much guarantee in terms of policies, especially funding guarantees; it is difficult to be guaranteed completely. According to the research statistics of relevant experts, in the sports industry, construction of informatization for the related sports scientific research projects is hardly valued. On the one hand, the construction of sports facilities requires a high cost; on the other hand, it is difficult to keep up with management concepts and awareness. The relevant expert often meets with the trouble in calling for the strengthening of the co-construction and sharing of related information-based sports resources. On the one hand, information-based resources are less; even if they are shared, they cannot meet the requirements; on the other hand, institutions engaged in corresponding sports scientific research have few projects of related research and conducted few informatization research studies [15, 16]. In addition, managers in the actual sports industry still cannot have this kind of thinking or courage to realize the direct sharing of relevant information. On the one hand, the requirement and support from the relevant industry authorities are lacked. On the other hand, most industry managers believe that they have no obligation to provide information resources to other units. This has great limitations on information management and urban management, and it is not conducive to the sharing of sports resource information for urban residents.

2.2. Barriers Exists and Each Does Things in His Own Way. As far as the administrative authorities are concerned, the resource information is controlled by the corresponding competent authority; the physical education colleges for college students have relevant information resources, so the corresponding sports information center, scientific research institute, or university sports library are all carrying out their respective construction of informatization, in which there are not only technical gaps in the underlying system development but also differences in operating networks, all of which cause more trouble for information sharing to form an information barrier [17, 18].

2.3. Lack of Talents, Low Development, and Integration Capabilities. For a long time, because the construction and development of sports informatization have not been valued correspondingly, there are fewer composite talents with related sports knowledge in the field of sports informatization, including computer network technology, especially the high-quality sports services are less such as technical consultation sports characteristic databases and network academics [19, 20].

3. Conditions for Constructing a Platform for the Co-Construction and Sharing of Sports Information Resources in China

3.1. The Continuous Growth of Sports Digital Resources Provides a Resource Base. With the continuous development of the social economy, the sports information resource database has also been continuously enriched, which lays a solid foundation for the construction of a corresponding sports information resource-sharing platform. With the use of networked and electronic related technologies, the more demand emerges to use a unified portal for unrestricted access to corresponding information resources. Therefore, it is extremely important to establish corresponding sports shared information service platform. The continuous development of computer technology and network transmission technology can realize the integration of resources and one-stop fast service.

3.2. Coordination of Supply Entities. For most entities, the governance of collaborative information becomes possible because public sports services can involve multiple objects, such as the government, users, and markets, and require multiple parties to conduct collaborative management, which is mainly reflected in multiple aspects, such as under the background of informatization; multiple entities realize the supply and service of sports public services and realize the improvement of the overall quality of urban sports public services. Ensure that the form of government tends to be flat vertically; horizontally, we achieve coordination, unification, and cooperative management and governance between governments, focusing on solving the problem of fragmentation.

In addition, big data technology can ensure that online sports services are possible and clarify the further enhancement of the entity service. The traditional sports supply is managed by different administrative departments according to different responsibilities, giving full play to the

advantages of technology and knowledge, so that all aspects are all in the state of co-construction and sharing. However, what needs to be valued is that various factors such as the positions of various units, the cost of information sharing, and the different technical standards have caused various departments to form different service models. Therefore, the corresponding departments should be linked to realize the virtual cooperation in demand for sports public services, to ensure that the individual's management and service capabilities are improved, to achieve a more fragmented and detailed public sports services, to achieve the refinement of the tasks of the public service entity, to remove the traditional steps designated by the higher level, to optimize the organizational relationship, and to achieve flattening.

In the era of big data, there is a clear gap between the public and the actual supply of sports services. On the one hand, the public cannot accurately express the demand for sports facilities, and on the other hand, there is a structural dislocation in the demand for sports public services.

Before the era of big data, there is often a clear gap between people's expectations for public sports services and the supply of public sports services. The reasons are that the public's demand for public sports services is not fully and clearly expressed, the government's decision-making model is not sufficient, and there is a structural dislocation between the demand for sports public services and the supply. In the era of big data, public sports services are becoming more and more inventory oriented. The total public demand for sports and configuration needs of the people are clearly expressed, and they are realized through the intelligent perception of sports public service needs and service data decision-making.

First of all, the intelligent perception of sports public service needs. To fully and clearly express the people's sports service needs, the government can increase interaction with the society through open methods and can also use big data technology to intelligently acquire and perceive the people's public sports needs. The mainstream web3.0 technology of big data solves the inaccessibility of people's information technology and greatly reduces the cost of information and data transmission. The public can also use various terminals such as websites, Weibo, WeChat, and application software to express their needs for sports services; the government uses intelligent-sensing technology to gather these micro-data reflecting people's needs and aggregate them into the big data needed for statistics. Relying on big data analysis and mining technology, data are processed and people's specific needs are analyzed for sports public services. Second is data decision-making for the provision of sports public services. The total amount of services and the allocation of resources are the main content involved in the supply of sports public services; in the final analysis, it is a matter of decision-making. At present, the supply of sports public services is not balanced. The key factor is that the government's decision-making model is not perfect; the factor that the government's decision-making model is not perfect is that the decision-making body often makes decisions based on their own interests and preferences and does not fully consider the people's sports needs; with comparison of decision-

making methods, subjectively, it is difficult for the government to make scientific decisions in the absence of samples and data information. The use of big data largely solves the problems of data complexity, uneven levels, and in-depth data analysis. Data-driven decision-making has gradually become an important model for the precise supply of sports public services. Third, the supply of public sports services tends to be inventory based. The supply of sports public services covers the overlap between supply and demand. The supply is related to the financial situation of the local government, the level of social and economic development, and the realization of government functions. The cloud platform can be used to systematically integrate. The big data of the database are sorted out, and the supply of sports public services is accurately mined with the help of MapReduce technology. Demand refers to the type and quantity of people's needs for sports public services, which requires big data technology to collect social information more intelligently and comprehensively, such as through websites, Weibo, WeChat, and other terminals. With the help of big data technology and analysis technology, realize mining and evaluation.

With the help of big data resources and technology, we can effectively predict the total amount of sports public services and optimize their configuration to alleviate the problem of unbalanced supply on the demand side. At the same time, big data have also become an efficient and intelligent tool for the main body (government) on the supply side of sports public services, making the supply of sports public services more intelligent, precise, and simple, thereby realizing the government's modern governance goals.

First, the supply of sports public services is smarter. First of all, the auxiliary equipment for sports public services has realized intelligence. Big data promote APP-based terminal applications. By integrating government websites and government service AGM and other auxiliary equipment, the intelligent model can be used to reach all distances of sports public services. Secondly, the willingness to supply sports public services has become intelligent. Before the era of big data, government websites were mainly based on supply-oriented service models that only responded to requests. This model was relatively passive, and government supply usually did not match the people's sports needs. In the era of big data, the government can use online analysis tools such as Google Analytics, Urchin, and SiteCastalyst to collect and analyze data information such as the types and characteristics of search keywords and use Hadoop and other tools to analyze people's search behaviors, effectively based on people's points of interest. Push the corresponding sports service. Second, the supply of sports public services is more precise. Individual needs in the era of big data have become the focus of attention of enterprises, society, and government. Big data advocate the concepts of information openness, sharing, fairness, and information decision-making. Its mining analysis technology not only analyzes the sports public service database but also effectively analyzes the data of the Internet and mobile terminals and uses natural language decryption software to analyze unstructured data. The data can be used to identify the potential actions of users, so as to provide targeted sports services for them, and "let the data

speak" so that both the supplier and the demander can see the visualized results. Third, the supply of sports public services is more concise. Before the big data era, the supply of sports public services was based on the division of labor based on professionalism, and the operation process was constructed in the form of bureaucracy. In this way, a very complete sports public service chain was divided into countless broken links to make its service process more messy. The fragmented work process caused not only delays in service work but also an embarrassing situation in which operating costs exceeded benefits. Integrating resources is the important significance of the existence of big data, and the supply of sports public services under big data should also be transformed from the traditional multichannel model to a simplified model, integrating the application layer, data layer, and platform layer of different government functions in the background. In order to better provide resources and system support for the front end, we build an application system at the application layer to achieve connection and communication, establish a government department database at the data layer and open data information, establish a platform for government business support at the platform layer, and integrate sports at the front end. The public service client is integrated to provide a way of integration for the background. Unify the website port with the mobile port to provide simplified public sports services.

3.3. Principles of Sports Information Resource Sharing.
Assume that the subtask sample dataset of n platform data traffic shunt is

$$T(n) = \{t_1, t_2, \ldots, t_n\}. \tag{1}$$

Among them, $n \in N$ and t_i represents the ith shunt subtask $(i = 1, 2, \ldots, n)$ in the set. The corresponding attribute vector of the shunt task t_i is expressed by

$$t_i = \left(t_{id}^i, t_{mi}^i, t_{fee}^i, t_{deadline}^i, t_{memory}^i, t_{bw}^i, t_{submit}^i\right). \tag{2}$$

Among them, t_{id}^i represents the unique tag number of the task, t_{mi}^i represents the size of the platform data traffic task, which reflects the number of tens of millions of instructions (MI) of the task, t_{fee}^i represents the cost of the user's desired task, $t_{deadline}^i$ represents the deadline of the user's desired shunt task, t_{memory}^i represents the memory size requirement of the shunt task, t_{bw}^i represents the bandwidth requirement of the shunt task, and t_{submit}^i represents the time when the network user submits the shunt task.

Assume that the sample dataset of m virtual machine platform data traffic resources is

$$VM(m) = \{vm_1, vm_2, \ldots, vm_m\}(m \in N). \tag{3}$$

Among them, vm_j represents the jth virtual machine $(j = 1, 2, \ldots, m)$, to calculate the corresponding attribute vector of the virtual machine resource:

$$vm_j = \left(vm_{id}^j, vm_{capacity}^j, vm_{bw}^j, vm_{memory}^j\right), \tag{4}$$

where vm_{id}^j represents the unique tag number of the data traffic data center of the platform where the virtual machine is located, $vm_{capacity}^j$ represents the processing capacity of the virtual machine resources, vm_{bw}^j represents the bandwidth provided by the virtual machine, and vm_{memory}^j represents the memory size of the virtual machine, and ETC_{ij} is utilized to reflect the expected execution time of platform data traffic shunt subtasks t_i on virtual resources vm_i:

$$\text{ETC}_{ij} = \frac{t_{mi}^i}{vm_{capacity}^j}. \tag{5}$$

Let be_j represent the initial time for execution on different virtual machines and ETC_{ij} represent the expected completion time of the shunt task executed on the virtual machine vm_{ij}:

$$\text{ECT}_{ij} = be_j + \text{ETC}_{ij}. \tag{6}$$

The completion time of all platform data traffic shunt tasks is denoted as Makespan; then,

$$\text{Makespan} = \max\{\text{ECT}_{ij}\}. \tag{7}$$

Formula (8) is used to express the objective function and constraint conditions of the platform data traffic offload task:

$$\begin{cases} \min\{\text{Makespan}\}, \\ \begin{cases} t_{memory}^i \leq vm_{memory}^j, & i = 1, 2, \ldots, n, \\ t_{bw}^i \leq vm_{bw}^j, & j = 1, 2, \ldots, m. \end{cases} \end{cases} \tag{8}$$

In the form of linear programming, the objective function given by equation (8) is solved. Assuming that equation (8) is established, ω' is the optimal solution for the current platform data traffic shunt task, and equation (9) is used to establish a cloud platform data traffic management model:

$$\begin{cases} \omega' = \omega + \dfrac{(1-p)(1-\text{rand})}{e^y}, \\ 1/e^{\Delta y/(1+T_i)} > \text{rand}(), \end{cases} \tag{9}$$

where rand () is a random number in the interval $[0, 1]$, p is the mutation probability, and T_t represents the completion time of different subtasks in the objective function constraint condition determined by Makespan.

Assume that the set of platform data traffic shunt subtasks composed of sample data of k platform data traffic shunt subtasks is

$$c = [c(0), c(1), \ldots, c(e-1)]^k. \tag{10}$$

Among them, to satisfy the conditions of $a \sim g(c, s)$, $g(s|c)$ represents the distribution probability of subtasks in the shunt task, and we calculate the shunt task load of total platform data traffic:

$$\widehat{s} = \varepsilon \arg\min_{q \in \varepsilon} \sum_{s=1}^{+\infty} H(\widehat{s}, s) g(s|c), \tag{11}$$

where $H(\widehat{s}, s)$ represents the cost function in the shunt task and ε represents the set of all subtasks in the shunt task:

$$\varepsilon = \{\widehat{s}|c_1 + 2c_r \le \widehat{s} \le S\}, \tag{12}$$

where S represents the maximum value of the task in the process of shunting tasks, and the cost function is calculated using

$$H(\widehat{s}, s) = (\widehat{s}, s) = (\widehat{s} - s)^2, \tag{13}$$

where $\widehat{s}$ represents the mean value of the time required for the shunting process. Assuming that the diversion time meets the condition of $\sum_{s=1}^{s} \widehat{s}(s|c) = 1$, the estimated function can be obtained:

$$H(\widehat{s}, s) = |\widehat{s} - s|. \tag{14}$$

Substitute formula (13) into (11), the following results can be obtained:

$$\widehat{s} = \arg\min_{s} \widehat{s}\left(\sum_{s=1}^{s} s(s|s) - \sum_{s=s}^{s} s(s|c)\right). \tag{15}$$

Realize the calculation of the amount of subtasks in the process of platform data traffic shunting:

$$s = \arg\max_{s}(\overline{s}|c). \tag{16}$$

In summary, the amount of subtasks in the platform data traffic offloading task can be calculated, and the dynamic priority task of the platform data traffic shunt task can be obtained, which provides an accurate data foundation for the establishment of the data traffic optimization management model of the big data cloud platform.

To ensure that sports information play the role of co-construction and sharing, therefore, a co-construction and sharing platform is built by trial to realize the sharing of platform information in this paper.

According to the experience of various successful examples, the co-construction and sharing system platform is based on a library with rich digital resources and power (information centers) as the "leader" in a region (or industry), which leads everyone in the construction.

The first is to integrate existing digital resources, including local mirroring resources and remotely accessible resources, as shown in Figure 1, such as Chinese and foreign language collection catalogs, e-books, e-journals, and video materials.

The second is the division of labor and cooperation. The corresponding characteristic database is established based on different data. If the corresponding information resource database is constructed according to the sports items, the corresponding sports resource database will be formed, and continuous incremental updates will be carried out.

4. Simulation Experiment

4.1. Overall Objectives. Based on the development needs of the city, starting from the sharing of urban public sports information technology, technologies such as the Internet and the Internet of Things are introduced as an emphasis, to realize the relevant sharing of sports information by building a corresponding technical platform.

4.2. Overall Thinking. According to the urban public sports information sharing, the corresponding framework is realized, as shown in Figure 2.

In the higher vocational physical education class, the online and offline hybrid teaching mode is used, and the general process of using urban public sports information is carried out, as shown in Figure 2.

(1) The first stage: online learning before class.

According to the educational programs, the teacher before class organizes the learning materials online and uploads them to the learning and exchange group.

(2) The second stage: offline learning in class.

In the classroom, teachers can give targeted explanations based on students' preclass learning situation to improve classroom efficiency. Meanwhile, teachers should help the students carry out the explorative study, solve preclass questions, and consolidate knowledge and skills.

(3) The third stage: online consolidation after class.

After class, teachers continue to interact with students in the online learning platform to help students solve problems encountered in the learning process. Meanwhile, teachers improve and enrich learning materials and improve teaching methods based on students' feedback.

4.3. Establishment of Database. Using urban public sports information, the original data of 23,001 students from freshman to junior year are removed and cleaned and missing value data were purged, and data of 21,089 students were retained. A model of "the association between the physique test grade and each individual index" is established, as shown in Figure 3, to study the influence of each individual index of the physique test on the overall physical fitness assessment.

A large number of association rules are excavated, and the typical correlation rule is screened out, as shown in Figure 4, which will be beneficial to the decision support of this research goal.

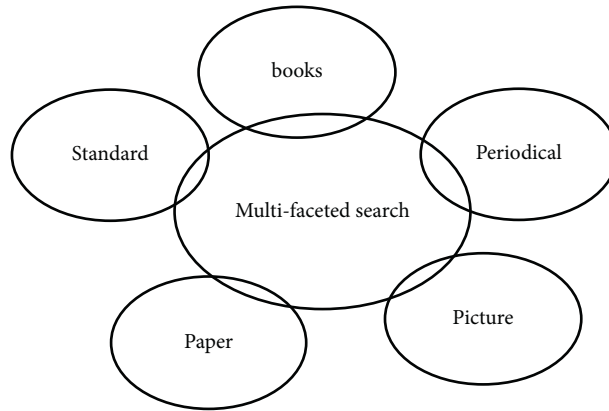
41% of the senior girls are rated as with excellent physiques and with excellent speed and flexibility. Rule 2 shows that 48.5% of girls are rated as excellent with excellent speed and vital capacity and body mass index. Rule 3 shows that


Figure 1: Searching and sorting out of existing digital resources.

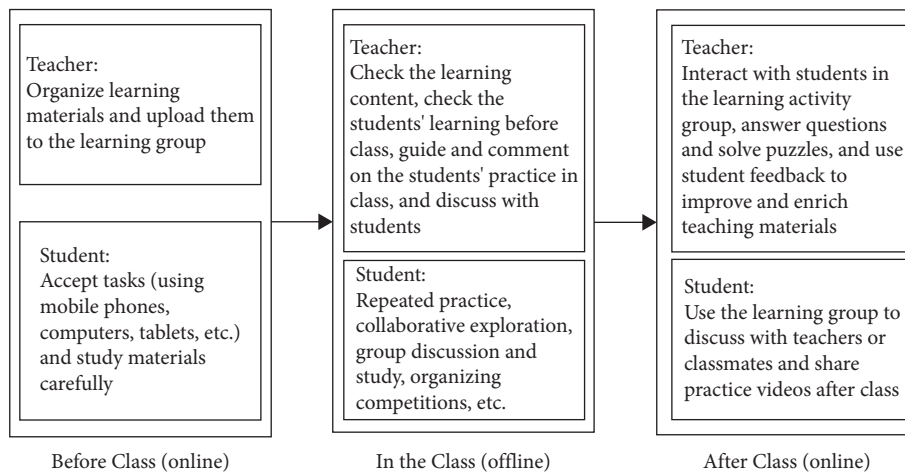

Figure 2: Procedure diagram of the online and offline mixed teaching mode of higher vocational physical education.

Figure 3: Topological structure diagram.

Figure 4: Some part of the results of association rule mining.

82.4% of the senior girls who passed the overall evaluation score failed in speed, but had excellent flexibility, with an importance of 0.877025, indicating that even though the body has good flexibility, while the speed is poor, the overall evaluation results are only qualified. Rule 4 shows that the physical flexibility and BMI of the failed sophomore girls are both unqualified. The probability and importance are 0.44 and 0.94, respectively. It can be seen that the body shape and flexibility have a huge impact on the physical fitness test level. Rule 5 shows that even if the endurance score passes, the sophomore girl with poor vital capacity is unqualified and the probability and importance are 0.46 and 0.98, respectively. According to the comprehensive analysis of the results of urban public sports information sharing, girls with excellent physique evaluation have excellent speed, flexibility, and vital capacity. However, girls with poor physique evaluation are mainly caused by poor performance in speed, endurance, and vital capacity. Simulation experiments prove that technologies such as the Internet of Things and the Internet are effective and can support the sharing of urban public sports information.

5. Conclusions

With the advent of the era of big data, how to share urban public sports information has become an increasingly important issue. The status quo of the co-construction and sharing of sports information resources are sorted out by introducing related technologies such as the Internet of Things, the Internet, and artificial intelligence, and the needs and difficulties of co-construction and sharing of sports information resources are analyzed and constructed by trial in this paper. The aim is to promote the openness and popularization of public sports information by realizing the corresponding sharing scheme. Simulation experiments prove that the Internet of Things technology is effective and can effectively support the sharing of urban public sports information.

Data Availability

Data sharing is not applicable to this article as no datasets were generated or analyzed during the current study.

Network open curriculum provides a new solution for general education in local colleges and universities, which makes the network curriculum widely popularized and applied in colleges and universities. However, due to the lack of good curriculum learning evaluation, it is inconvenient for learners to choose. Therefore, this paper proposes to use the BP neural network model to evaluate the learning process of network general education course. Based on the course and user data provided by the existing platform, this paper constructs an online course learning evaluation model and studies the structure and effect relationship among learning experience, learning investment, and learning performance of ordinary online courses based on the preaging process product (3P) model and structural analysis method. Our research shows that curriculum quality is a key factor in analyzing and predicting learning results, which has a great impact on learning achievement. Learning experience is a direct factor affecting academic achievement. Learning experience, as an intermediary variable, indirectly affects e-learning performance. At the same time, it puts forward some suggestions to optimize the learning effect of ordinary online courses. On the one hand, the evaluation model provided in this paper can provide a reference for learners to select online courses; on the other hand, it can also be used as a supplement to the existing subjective evaluation model.

1. Introduction

General course aims in providing a broader and more comprehensive education for college students and enriches them with necessary knowledge and abilities for postgraduate practice. This concept originated from Europe, developed in the United States decades ago, especially after the Harvard committee established and published the "General Education in a Free Society" (the Harvard Redbook, 1945) [1, 2]. It caused an applauded response in the American higher education society and boomed around the world later. After the Chinese Economic Reform in 1978, the higher education in China started a progressive qualitative education reform and addressed the connection between vocational education and general education. Recently, colleges in China are exploring novelties and possibilities in general education theoretically and practically. Outstanding accomplishments were achieved, and some adapted general education models was established. These achievements have a significant impact in Chinese higher education [3].

Compared with first-class universities, regional colleges have some shared problems such as lacking faculty and staff, unbalanced course arrangement for different subjects, and setting up courses by number of students [4]. With the development of online open course, these problems are well relieved. Currently, there are more than 2000 universities, and more than 10 million students are using online learning platform in China. The online learning platform has become an important carrier for general education of regional college. However, challenges emerged with the succeeding of online teaching at the same time. For example, misunderstanding of course content during course selection, impure motivation in learning, imperfection of course assessment, assurance of course quality, marginalized course management, and plagiarisms. Based on a case study in our college, start from spring 2020, 400 modelized open general courses were offered for all students. Data for latest two years are given in Table 1. It is easy to find the "high selection rate-low complete rate-high excellent rate" pattern in Table 1. This led to questions on providing qualitative online general course.

TABLE 1: Operation data for online general course in Zhejiang Shuren College.

Semester	Course number	Course selection number	Pass rate (%)	Excellent rate (%)
Spring 2021	371	18836	88.67	71.46
Fall 2020	366	18745	89.86	71.38
Spring 2020	369	15184	86.29	68.96
Fall 2019	12	8278	92.81	71.92

How was the students' learning experience in the online general course? How to accurately control learning performance and its key factors? How to optimize the learning performance? Many scholars considered learning experience, learning engagement as the major factors for online learning [5, 6]. As a result, this study was theoretically based on the Dr. Bigg's "presage-process-product" model. We applied the structural equation modeling analysis method and discussed the structure and effect between learning experience, learning engagement, and learning performance for online general course. We were also aiming at optimizing the online learning performance, improving the general education quality, and providing future considerations on online general course in China.

2. Method and Modeling

Biggs pointed out that the early variables include student's personality and learning experience, and process variables include learning engagement and feeling to the course content in the learning process [7]. Based on the 3P theory, we provide an online general course learning relationship model (Figure 1). Taking the online learning experience as the main factor in the presage stage, taking the online learning engagement and course content quality as main factors in the process stage, and taking the online learning performance as the key factor in the product stage, the interaction between different factors forms a dynamic model.

2.1. Variables in Presage. Presage variables determine the attitude and method of the learner which further determines the learning product. As the direct participant and experiencer, students who attend the online course are affected by various factors such as the perception and experience for learning process and product.

Online learning experience positivity influences the online learning performance. Study shows strong correlation for the online learning experience and individual specialties of the students [8]. The individual specialties usually include willingness and motivation of learning, self-regulation ability, and information attainments [9, 10].

In this case, we propose that H1-H2, online learning experience has positive effect on online learning engagement and online learning performance.

2.2. Variables in Process. Process variables in online learning are mainly discussing whether the learning method could satisfy the learner's experience and whether the online learning performance could reach the preset goals. Course

content quality control is one of the key targets for the online learning management. Online learning engagement affects the learning quality greatly as well. Both of them affect the learning process significantly [11]. In this case, we investigated the online learning engagement and course quality as the major process variables.

Course content quality actively affects the online learning experience. Study shows the content and experience are in the relationship of demand and satisfaction [12]. Qualitative course content satisfies the learner with a higher learning experience, incites their mind and feeling, emotional, and positively gains them knowledge. Factors for online learning experience include online course anxiety, course content quality, perception of the usefulness of the course, flexibility of the course [13]. Course quality has positive impact on the online learning engagement. Study shows the interaction between learner and course content deeply reflects the degree of perception for learning engagement [14]. Modeling of online learning theory should focus on the positive learning experience and learning engagement concentration of the learner in an organic and unified information environment, paying attention to the thinking and interestingness of the content. Online course quality will have a positive impact on online learning performance. Research shows that appropriate course content is a key factor in the performance of teaching and online learning. Quality perception has a great impact on academic achievement. At the same time, the learning performance is directly affected by the perception of course value.

Online learning engagement has positive impact on online learning performance. Study shows increasing learner's learning engagement promote the learner's further in-depth processing, speculation, analysis reasoning, and argumentation of the learning content. It has significant impact on the learning performance as well [15–17]. Other classification research on the relationship between online learning engagement and performance in distance education shows positive relationship between online learning engagement and online learning performance in 60% of the learners [18].

Therefore, we assume (a) course content quality has positive effect on online learning experience, online learning engagement and online learning performance (H3-H5); (b) online learning engagement has positive effect on online learning performance (H6).

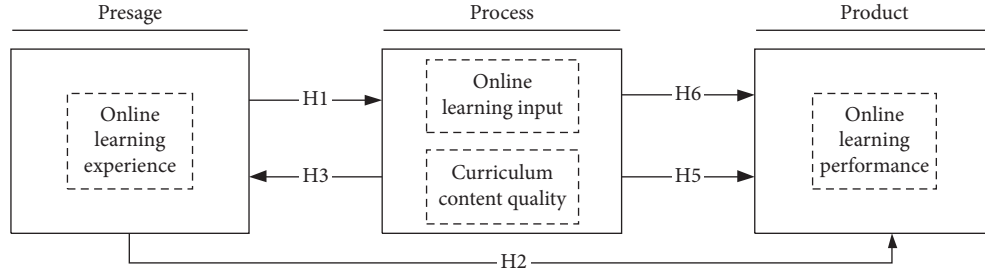
2.3. Variables in Product. Variables for learning product mainly include the performance and product of learner, they are directly affected by presage variables and process variables. Online learning performance, also called E-learning performance or digital learning performance, is both (a)


Figure 1: Online general course learning influential relationship model.

learning grade and performance achieved by the learner, and (b) information literacy consciousness, knowledge and skill improvement, learning experience satisfaction [19], etc. Currently, comprehensive, systematic, and in-depth studies on online learning performance have been carried out internationally. Overall, low online learning performance, low online course quality has significant long-term impact on college education. It is theoretically and practically important to figure out the factors for online learning performance [20]. This study uses online learning performance as the course product variable. We have added requirements for student abilities and emotions considering the online general courses are basic, accommodating, and profound. For instance, through the online general courses, students have formed general sense abilities, positive emotion, and attitude. This outcome aligns with our goal and highlights characteristics of general education.

The variable relationship among learners, learning process variables, and learning performance is shown in Figure 2.

2.4. Implementation Process of the BP Neural Network.
BP neural network, also known as back propagation neural network, its main working principle is to use machine learning to continuously iterate the training model, adjust the weight in the network structure, gradually optimize the model structure, make the error function decline along the negative gradient direction, and make the output value of the model constantly close to the expected value. The input layer described in this paper includes the following nodes: online learning experience, online learning engagement, course content quality, and online learning performance. The output layer has only label degree, that is, the output layer is one node. The number of nodes in the hidden layer is l, which is obtained through the analysis of training experiments.

In order to eliminate the influence of different dimensions among the four evaluation indicators: the number of course interaction, the number of course selection schools, the number of course selection and the number of viewers, the data are standardized. The index variables are mapped to [0,1] through normalization, and the formula is as follows:

$$p_i^m = \frac{P_i^m - P_{i\min}}{P_{i\max} - P_{i\min}}, \tag{1}$$

where $i = 1, 2, \ldots, 4$, $m = 1, 2, \ldots, 400$, $P_{i\max}$ and $P_{i\min}$ are the maximum and minimum values in the m-th original data, and p_i^m ($m = 400$) is the normalized data. 80% of the data are randomly selected from the normalized data set as training data and the remaining 20% as test data.

Input the training data into the neural network, and the output value of the hidden layer can be obtained through equation (2), shown as follows:

$$l_j^m = \sum_{i=1}^{4} w_{ij}^{(z)} P_i^m + h_j^{(z)}, \tag{2}$$

where $j = 1, 2, \ldots, n$, n is the number of nodes in the hidden layer, $w_{ij}^{(z)}$ is the connection weight between the input layer and the hidden layer, and $h_j^{(z)}$ is the threshold of the hidden layer.

2.5. Construction of the BP Neural Network Model.
In order to explore the internal relationship between different evaluation objects and indicators, the BP neural network model can be constructed based on the existing sample data. This paper will fully consider and reasonably determine the key factors such as the structure, algorithm, neuron number, and error accuracy of the network model and make the model have a certain generalization ability. The BP neural network model structure for analyzing the relationship among learners, learning process variables, and learning performance is shown in Figure 3.

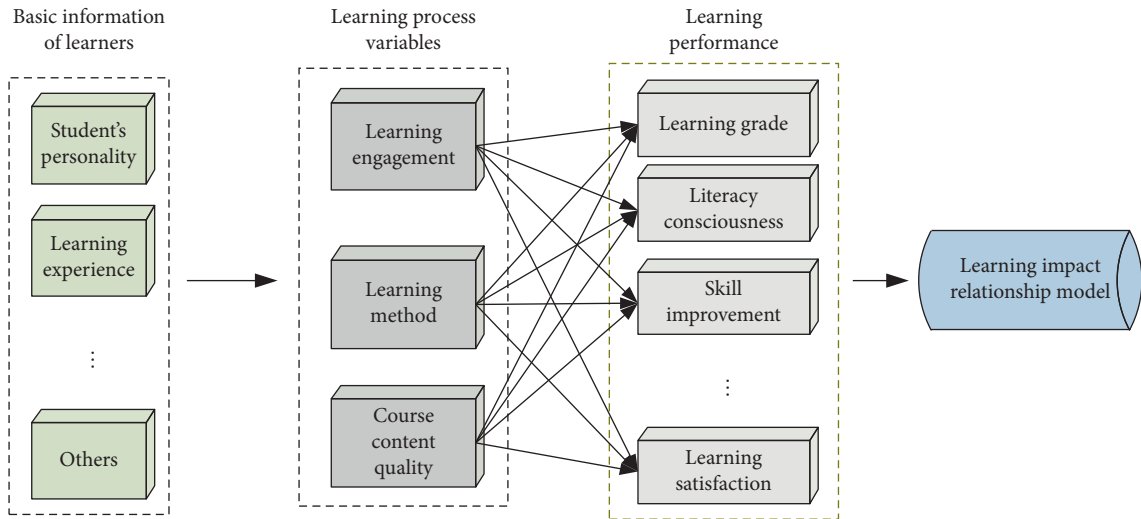
Because the number of neurons in the input layer depends on the number of variables contained in the problem, this study involves learners, learning process variables, and learning performance. The output layer mainly depends on the research results. After comprehensive analysis and judgment, select the number of neurons in the output layer. The output of this study is the relationship among learning performance, learners and learning process variables. Therefore, this paper sets the number of neurons in the output layer to 1. From the above analysis, the BP neural network constructed in this paper contains only one hidden layer. Because the number of hidden layer neurons will directly affect the accuracy of network training, the number of neurons should be considered according to needs. If the number of hidden layer neurons is too small, it will greatly reduce the fault tolerance of the network model and the accuracy of sample recognition. If you set too many times, the network training time will be too long, and the fitting


FIGURE 2: Schematic diagram of online learning impact relationship.
FIGURE 3: BP neural network model structure for analyzing the relationship between learners, learning process variables and learning performance.

degree of the network model will be greatly improved, resulting in overfitting problems.

3. Research Design

3.1. Research Content. Based on previous research results and 3P model, this study empirically explored the structural and effect relationship among online general learning experience, engagement, and performance in regional undergraduate schools from the perspective of general education, to explore ways and methods of which promoting teaching quality of online general course. This study focuses on the following issues: (a) validation of the theoretical model of online learning experience, online learning engagement, course content quality, and online learning performance; (b) if validated, the effects among each factor

in the model and the degree of effectiveness of the online general course.

3.2. Research Target. This study used convenience sampling on undergraduate students from five regional colleges in Zhejiang, China. We used the questionnaire survey method to collect relevant data and information. 685 questionnaires were successfully returned and analyzed. After screening by three standards: (1) no learning experience of online general course; (2) variable answers were all the same for variables; (3) answers for the variable items are missing, a total of 583 valid samples remained, with an effective rate of 85.11%.

Sample compositions are listed as follows:

Male: 257 (44.1%), female: 326 (55.9%)

Freshman: 162 (27.8%), Sophomore: 211 (36.2%)

Junior: 139 (23.8%), senior: 71 (12.2%)

Science and engineering: 189 (32.4%), literature/economics/financial/management: 154 (26.4%), agriculture and medicine: 78 (13.4%), art and edu: 92 (15.8%), law/history/philosophy: 70 (12%)

Course attended: 1 course: 75 (12.9%); 2-3 courses: 125 (21.4%); 4-5 courses: 245 (42%); more than 5: 138 (23.7%).

3.3. Research Method. SPSS 25.0 was used for data descriptive statistics and correlation analysis. AMOS 24.0 was used to establish the structural equation model. Maximum likelihood estimation method was used to evaluate the fitness of the model. Relative path analysis was combined to define the model.

3.4. Research Tool. In this study, a scale was developed to measure students learning status by literature reviews and student interviews. The scale includes two parts: learner's basic information (4 items) and survey on online general course (35 items). Each item in the second part was designed from the Likert's five-point scale (1 = strongly disagree, 5 = strongly agree). As shown in Table 2, the survey items are mostly referred to domestic influencing factor scales for various studies on general education.

To guarantee reliability and validity of the model, we used T-test for project analysis; we adopted internal consistency method for reliability evaluation; we used factor analysis method for construct validity test; we deleted one item from the learning engagement subscale, kept 34 items; and we deleted latent variables with a loading less than 0.5. Finally, dimensionality reduction was performed by calculating variables to determine 4 latent variables and 28 observed variables.

4. Results and Discussion

4.1. Measurement Model Testing. SPSS25.0 was used to perform reliability and validity test on the measurement model. In the model's reliability test, as shown in Table 3, from the view of average value, each latent variable is higher than the theoretical median (3 point). This indicates that learner's evaluation tends to be positive. Further improvement in online learning engagement is expected. From the view of standard deviation, the fluctuation of online learning engagement is high. Cronbach's α value is greater than 0.7, which implies data are reliable with high confidence. All average variance extracted (AVE) values are greater than 0.5, and all combination reliability (CR) is greater than 0.8, which indicate that the inherent quality of latent variables is good, and convergent validity is ideal. As a conclusion, the reliability of this measurement model is good.

In the model's validity test, as shown in Table 4, this model passed Bartlett's test. KMO >0.8, $P < 0.000$, and passed the significance test. This indicates the latent variables are suitable for factor analysis. The factor loadings of the observed variables are all greater than 0.7, eigenvalues are greater than 3, and cumulative variance explained rates are greater than 70%. As a conclusion, the overall validity of the measurement model is good.

4.2. Structural Model Testing. AMOS24.0 was used for confirmatory test on the structural model. The result shows the fitting index of the model is good. $X^2/df = 2.859$, RMSEA = 0.056, NFI = 0.868, RFI = 0.848, CFI = 0.903, IFI = 0.904, and TLI = 0.952. The discriminative validity test results for the structural model are shown in Table 5. The absolute values of the correlation coefficients of the observed variables are all less than 0.5 and are all less than the square root of the corresponding AVE. This indicates the model has an ideal discriminative validity.

4.3. Hypothesis Testing. This section uses hypothesis testing in the model to analyze the effect and relationship between course content quality, online learning experience, online learning engagement, and online learning performance. As shown in Table 6, course content quality has a significant positive impact on both online learning experience ($\beta = 0.724$, $P < 0.001$) and online learning performance ($\beta = 0.507$, $P < 0.001$), respectively, indicating that high-quality course content leads to high learning experience. This will not only help to improve the sense of achievement and satisfaction of learning but also improve general skills and better achieve knowledge, ability, and emotional goals. Course content quality has no significant effect on online learning engagement ($\beta = 0.124$, $P > 0.005$). Through communications and interviews with students, blind course section and the improper course selection phenomenon are existed. As a result, students have less course engagement or even drop the course in the midterm. These are the main reasons for the low completion rate of online general course. Online learning experience has a significant positive impact on both online learning engagement ($\beta = 0.493$, $P < 0.001$) and online learning performance ($\beta = 0.484$, $P < 0.001$). This indicates that good online learning experience can help students build a sense of self-worth, belonging, realize high-level cognitive activities, and improve learning performance. Online learning engagement has a significance positive effect on learning performance ($\beta = 0.671$, $P < 0.001$). This result indicates the positive attitude of learning engagement is an important cornerstone and guarantee for achieving excellent learning performance.

4.4. Effect Analysis. This section mainly analyzes the interaction mechanism between course content quality, online learning engagement, online learning experience, and online learning performance by total effect, direct effect, and indirect effect of the variables.

4.4.1. Overall Effect and Direct Effect Analysis. The total effect results between each variable in the modified structural model are shown in Table 7. Online learning engagement only has a direct effect on online learning

Table 2: Examples for survey item design and references.

1st dimension	2nd dimension
Online learning experience	Social interaction, support and service, evaluation method, input and output, teaching method [21]
Course content quality	Appropriateness, scientific, thinking, balance, fun, cutting-edge [12, 22]
Online learning engagement	Behavioral, cognitive, and emotional engagement, learning motivation [11]
Online learning performance	Self-efficacy, knowledge goals, ability goals, emotional goals, learning satisfaction [22]

Table 3: Measurement model's reliability test results.

Latent variable	Average	Standard deviation	Cronbach's α value	Average variance extracted (AVE)	Combination reliability (CR)
Course content quality	3.899	0.674	0.869	0.8419	0.8696
Online learning experience	3.819	0.751	0.913	0.7759	0.8453
Online learning engagement	3.618	0.802	0.840	0.7518	0.9135
Online learning performance	3.900	0.681	0.872	0.8665	0.8701

Table 4: Measurement model's validity test results.

Latent variable	Observed variable	Factor load	KMO	Approximate Chi-square and P	Eigenvalue	Cumulative variance explained rate (%)
Curriculum content quality	Appropriateness	0.874	0.892	874.048 ($P < 0.000$)	4.329	72.148
	Practicality	0.833				
	Cutting edge	0.840				
	Thinking	0.842				
	Systematicness	0.826				
	Fun	0.819				
Online learning experience	Social interaction	0.838	0.811	617.918 ($P < 0.000$)	3.321	71.424
	Input and output	0.784				
	Learning support and service	0.803				
	Evaluation methods	0.816				
	Teaching methods	0.811				
Online learning investment	Behavioral investment	0.846	0.844	595.826 ($P < 0.000$)	3.471	69.772
	Learning motivation	0.774				
	Cognitive investment	0.848				
	Emotional investment	0.893				
Online learning performance	Learning satisfaction	0.927	0.879	727.379 ($P < 0.000$)	3.707	74.136
	Self-efficacy	0.894				
	Knowledge goals	0.891				
	Ability goals	0.866				
	Emotional goals	0.917				

Table 5: Discriminative validity results.

	Course content quality	Online learning experience	Online learning engagement	Online learning performance
Course content quality	0.842			
Online learning experience	0.433	0.776		
Online learning engagement	0.394	0.383	0.752	
Online learning performance	0.429	0.413	0.433	0.867
Square root of AVE	0.918	0.881	0.867	0.931

performance ($\beta = 0.311$), indicating that the continuous and positive state displayed by students during learning is especially critical to achieve an excellent grade. The degree of total effect of online learning experience on each factor from high to low is online learning performance ($\beta = 0.637$) and online learning engagement ($\beta = 0.493$). And, it only has a direct effect on online learning engagement. This indicates that a successful online learning experience, such as learning

TABLE 6: Model parameter test values and research hypothesis testing results.

	S.E.	C.R.	P	Hypothesis testing
H1 Content quality ➔ learning experience	0.059	11.798	***	Yes
H2 Content quality ➔ learning engagement	0.123	0.203	0.839	No
H3 Content quality ➔ learning performance	0.111	4.267	***	Yes
H4 Learning experience ➔ learning engagement	0.142	3.634	***	Yes
H5 Learning experience ➔ learning performance	0.096	5.217	***	Yes
H6 Learning engagement ➔ learning performance	0.514	3.729	***	Yes

Note: $***P < 0.001$; $**P < 0.01$; and $*P < 0.05$.

TABLE 7: Total effect values between variables.

Dependent variable independent variable	Online learning experience	Online learning engagement	Online learning performance
Online learning engagement			0.311
Online learning experience		0.493	0.637
Course content quality	0.724	0.357	0.968

community, input and output, and learning support and service can help in reinforcing learning interest and motivation and getting a good grade by behavioral externalization. The degree of total effect of course content quality on each factor from high to low is online learning performance ($\beta = 0.968$), online learning experience ($\beta = 0.724$), and online learning engagement ($\beta = 0.357$). And, the total effect on online learning experience only has a direct effect, and the total effect on online learning engagement only has an indirect effect. This indicates that course content's appropriateness, practicality, cutting-edge, thinking, systematic, and fun are important to satisfy a good learning experience. Even if the result of course selection does not meet the expectation, it can also transform experience into self-driving force of learning, stimulate learning motivation, and improve learning achievement.

4.4.2. Medium Variables Effect Analysis. In the intervening effect variable analysis, the most used intervening effect value is the ratio of indirect effect by total effect. In this section, there are two intervening variables: online learning engagement and online learning experience (Table 8). In the intervening variable of online learning engagement, online learning performance changes by 0.637 standard deviations when online learning experience changes one standard deviation. Among these, online learning experience influences online learning performance through the intervening variable online learning engagement when effect value is 0.153. However, when effect value is 0.484, online learning experience has a direct effect on online learning performance. The intervening effect accounted for 24.02%, and this indicates the online learning engagement is a significant factor for the online learning performance. However, it is not the key role. In the intervening variable of online learning experience, online learning performance changes by 0.968 standard deviations when content quality changes

one standard deviation. Among them, 0.461 indicates the content quality influences online learning performance through the intervening variable online learning experience. However, the remaining 0.507 indicates the content quality has a direct impact on the online learning performance. The intervening effect accounted for 47.62%, which closes to the standard of important influential intervening variable, and this indicates the need to actively improve learning experience, motivate students to adopt in-depth learning ways, and improve learning performance in the online learning process.

4.4.3. Online Learning Performance Effect Analysis. As shown in Figure 4, from the perspective of total effect, the degree of effect of each factor on online learning performance from high to low is course content quality, online learning experience, and online learning engagement. From the perspective of direct effect, the degree of effect of each factor is consistent with total effect. From the indirect effect, the direct effect of curriculum content quality is higher than the intervention effect of e-learning experience. This result shows the key to the online learning performance of the online general course is course content quality and online learning experience. High-quality, satisfying, and demanding teaching content can enable learners to gain a high-level experience, spend more time and energy, and gain more.

5. Suggestions

5.1. Value the Effect of Course Content. Course content quality is the embodiment of course value. The result of this study revealed the course content quality plays a decisive role on the online learning performance of online general course. Additionally, the perceptual impact of content appropriateness is the most significant one. In another word, the course content should highly fit the learning goals.

TABLE 8: Intervening effect between online learning engagement and online learning experience.

| Intervening variable	Path	Effect value	Percentage (%)
Learning engagement	Learning experience ➡ learning performance	0.484	75.98
	Learning experience ➡ learning engagement ➡ learning performance	0.153	24.02
Learning experience	Content quality ➡ learning performance	0.507	52.38
	Content quality ➡ learning experience ➡ learning performance	0.461	47.62

FIGURE 4: Online learning performance factor's performance.

Therefore, firstly, set up "general education introduction course" for students to understand school's general education objectives, course system, courses selection strategy, and how to deal with general education, etc. Also, developing general literacy test and evaluation helps the students effectively understand their general literacy's advantage and disadvantage, gain personalized resource that can effectively remedy their shortcomings, and further guide course selection to fit their own learning goals. Secondly, value the thinking and cutting-edge facts in the course content when develops and introduces online general courses. Focusing on learning objectives, this paper discusses the evaluation value of learners' perspective in content perception. Moreover, design and research relevant quality analysis tools in order to improve the quality of curriculum content.

Carrying out a separate, specialized and normalized, precise online general course content quality evaluation comprehensively assesses the fitness and effectiveness of existing course and general literacy training in school. Sort by category on a basis of survival of the fittest, building "high-quality" general courses, establishing, and improving a general education course system that meets the quality requirements of the school's students. Practically improve teaching quality of general courses. For example, starting from the goal of talent training and actual school situation, Tianjin University explored a school-based course operation mode from various aspects such as course selection recommendation, process control, assessment setting, test paper customization, and teaching assistant. Lanzhou University used the general literacy assessment to grade the learning difficulties of the courses, let students "check their

seats," scientifically evaluated the implementation effect of general education and made timely adjustments. Sanjiang College took courses and activities as the starting point and constructed a "closed-cycle" application-oriented general education system in colleges and universities of "general course system + classic reading system + series of activities + cultural infiltration."

5.2. Focus on the Medium Effect of Online Learning Experience and Engagement. Results show that the online learning experience can not only directly affect online learning performance but also indirectly affect online learning performance through content quality as a key intervening variable. The most influencing factors on online learning experience are social interaction and evaluation methods. Therefore, firstly, the teachers should guide the students to participate in group discussion, learning, communication, sharing, strengthening their social connections, building a modular and diversified learning community for collaborative learning, and creating learning atmosphere of mutual assistance, mutual learning, and continuous interaction. The cultivation of a good learning community is of great significance to promote the general education, the students' overall training, and the teachers' growth. Secondly, according to course characteristic, clearly defining evaluation methods, designing a scientific course evaluation scale, adopting a multilevel and multitype dynamic assessment mode to evaluate students' comprehensive qualities comprehensively and objectively such as knowledge, abilities, and personal sentiments. Pay more attention to usual performance rather than test scores so that the students can truly enjoy general education.

The experimental results show that online learning investment not only directly affects online learning performance but also indirectly affects online learning performance through learning experience. The most influencing factors for online learning engagement are emotional engagement and cognitive engagement. Therefore, consideration of emotional elements is required while designing the course. Perform emotional design around sensory interaction, behavioral experience, and inner thinking to realize the intervention of learning, thereby promoting student's in-depth learning. In terms of cognitive engagement, using learning analysis technology to collect the feature vector of learner's personality cognition. Design different learning paths, recommending personalized resources and services. The cognition and attitude of learners towards general education are important factors affecting implementation and quality of general education. Good general education should be established on this foundation

and try its best to promote students' understanding and cognition towards general education; let them deeply understand the true value and significance of general education, to actively study and grow.

6. Conclusion

This paper takes online learning experience, online learning participation, course content quality, and online learning performance as the input layer of neural network and establishes the learning evaluation system of network general education course based on the BP neural network model. This study was based on the 3P model "Presage-Process-Product," a structural equation model was applied to analyze the structural and effect relationship among learning experience, learning engagement, and learning performance in the online general course. We found that the course content quality is the key factor on analyzing and predicting the early stage and product of learning, and it has the greatest impact on online learning performance. Appropriateness and thinking of content are the key factors affecting content quality. Online learning experience is the important factor which directly affects the online learning performance. It acts as a key intervening variable indirectly affects online learning performance through content quality. Social interaction and course evaluation methods are key factors which affect the online learning experience. Online learning engagement can have a direct and positive effect on the online learning performance. Emotional engagement and cognition engagement are key factors that affecting the online learning engagement. The above conclusions have a certain reference meaning for further optimization of learning effect of online general course. The experimental results show that the method proposed in this paper can effectively detect and evaluate the concentration of students in online course learning and analyze the relevant data. In future research, we will further enrich the variables of early stage and learning process from the aspects of general literacy, in-depth learning strategies, and knowledge acquisition, in order to make the learning impact relationship model of online general education curriculum more comprehensive [23]. In addition, we will combine simulation to prove the robustness of the method.

Correspondence should be addressed to Jie Wu; 20160735@ayit.edu.cn

Products no longer exist simply as carriers of useful functions, but more and more consumers are beginning to pay attention to the spiritual aspects of the feelings brought by products. This paper brings machine learning algorithms to the discipline of industrial design and proposes a method to evaluate the design of product shapes using a multilayer perceptron genetic algorithm neural network (GA-MLP-NN) algorithm, quantifying the product shape, using computer-aided design technology to achieve shape optimization, shape, and color scheme generation, and using interactive feedback with users to finally generate a product shape with market demand. In this paper, we use the combinatorial innovation method to arrange and combine the detail elements in the solution library to generate the modeling solution, combine the multilayer perceptron genetic algorithm neural network algorithm with product modeling, and establish the interactive genetic modeling system for the product, use this system to design the product modeling solution, and finally get the product modeling solution satisfied by the target users; using the multilayer perceptron genetic algorithm neural network method to evaluate the product modeling items. The mapping relationship model between morphological feature space and imagery cognitive space was constructed based on multiple linear regression equations, and the multiple regression model for each affective dimension was ideal. The results show that the model performance is reliable. The weights are calculated, and the appropriate people are selected to score and calculate the modeling scheme, and finally, the satisfactory product modeling scheme is obtained.

1. Introduction

Along with the progress of social history and the continuous improvement of human industrial civilization, people's living standards and consumption concepts have also undergone great changes. The esteem for material functions has gradually evolved into a strong pursuit of the field of spiritual consciousness. With the intersection and integration of various disciplines, many researchers have brought genetic ideas from biology to the discipline of industrial design; with the rapid development of computer and electronic information technology, the field of computer-aided industrial design has also gradually developed, and this design trend has led to more and more advanced algorithms to control the design process, resulting in many new design models [1]. These have brought a new idea in product design, i.e., how to assist in the design and optimization of product shape with the help of computers to produce products that are competitive in the market. Therefore, this thesis is based on a multilayer perceptron genetic algorithm neural network based on a computer-aided designer to design and optimize the product shape and find more possibilities and innovations to make the designed product more unique and selling point.

Neural networks are a research hotspot in the field of machine learning. Artificial neural networks have features such as massively parallel processing, distributed information storage, and good self-organization and self-learning ability. Artificial neural networks have been successfully applied to many fields such as signal processing, pattern recognition, and intelligent control [2]. At the same time, neural network learning also suffers from the disadvantages of easily falling into local minima, slow convergence of network learning, and complex network topology design,

which hinder its application. A multilayer perceptron neural network is a forward-structured artificial neural network also called a multilayer feedforward network, that maps a set of input variables to a set of output variables and gives a prediction of the outcome of the output variables as well as a prediction model based on the input variables. Structural characteristics of multilayer feedforward networks: (1) There is no connection between neurons in the same layer. (2) There is full connectivity between neurons in two adjacent layers. (3) There is directionality in information transfer. The feedforward computation is performed layer by layer from the input to the output. The idea of a genetic algorithm is derived from the biological evolutionary process in nature and is an optimization algorithm for solving complex problems. Intelligence and essential parallelism are the biggest differences between evolutionary computation and traditional optimization methods. Evolutionary computation does not require the objective function of the object to be continuous and differentiable, and these advantages it has made it more suitable for solving complex optimization problems, and it can also be used to avoid various defects of traditional neural networks themselves [3]. By combining the multilayer perceptron neural network algorithm with a genetic algorithm, different features are obtained by different feature extraction methods for the characteristics of product modeling design, and then the genetic optimization algorithm is used to optimize the selection of the extracted features, and the classifier is trained by MLP, and the results show that the combined model achieves the expected classification effect with a high accuracy rate. Nowadays, with the development of electronic information technology, the methods for signal processing are even more endless and become more and more efficient, and people will be more thorough in the study of feature signals to make new contributions to the future development of product modeling design [4].

2. Status of Research

There is a lack of information on the direction of machine learning algorithms combined with product form design. Many scholars and experts in the research of product morphology design theory and machine learning have made great contributions to these fields. Literature [5] first proposed a morphological analysis method, which encodes the main morphological elements and components of a product and forms different morphological products by arranging and combining them. This approach aims to generate new design solutions through "reconfiguration" and has since been widely used in product form design and related fields. Form quantization, proposed in [6], is characterized by the concept of averaging and complementing a set of similar product forms with low correlation, extracting representative forms, giving them different weights in the process, and then deriving new forms. In terms of morphological expansion, literature [7] considers the shape as a finite arrangement of lines and sets some conditions on the shape, such as position, size, and direction, through the concept of Euclidean transformation, to generate new shapes. The

imagery diagram method proposed by [8] suggested that the pictures and information can be studied by classifying them according to certain rules to establish the target scenario as a way to help the designer in designing. However, this method can only help designers to organize their thoughts to promote the association and is only an auxiliary technique before designing. Literature [9] proposes a product form design method based on the user's behavioral imagery capabilities, compared to traditional research methods that do not integrate user experience into product form design, through the study which found that the experience brought to the user by the product form has an impact on the consumer's purchase process and even plays a decisive role in the purchase decision. Literature [10] constructed a user semantic driven approach for product form prototyping and argued that semantics is the chain between people and things, and through the analysis of user semantics, it can improve user satisfaction with the product and promote the iteration of enterprise products. In addition, literature [11] proposed a theory of pan-community product form design approach based on shape literature and integrating anthropological and psychological theories. This theory first analyzes the product form elements and divides the homogeneous products and heterogeneous products and then deduces the shape grammar for both the homogeneous products and heterogeneous products and filters them to get a satisfactory solution. Literature [12] proposed a discrete neural network model with fully interconnected network topology and successfully solved the traveler problem using energy function. Literature [13] proposed a continuous neural network model, stating that neurons can be implemented with operational amplifiers and stating that the connections of all neurons can be simulated with electronic circuits, called continuous Hopfield networks. Literature [14] provides an exhaustive analysis of the error backpropagation algorithm for multilayer feedforward networks with nonlinear continuous transfer functions, which is known as the BP algorithm. Literature [15] simulates the consumer's imagery evaluation pattern for product color matching based on BP networks and generates offspring to optimize the color matching design by genetic algorithm to speed up the design process. Literature [16] incorporated genetic and biological coding methods into product color scheme design, proposed to form codes in terms of product formation, and created a PCIDBMT prototype system based on the above theory; based on interactive genetic algorithm, in [16] Yuan and Moayedi used techniques such as color merging and primary color extraction to establish an automatic mapping mechanism of color schemes from flat images to three-dimensional models of products; literature [17] introduced color matching case and grayscale correlation analysis into color matching design and used a scissor lift as an example to demonstrate that the described method can realize the conversion between case color matching and target color matching. Literature [18] proposes an orthogonal-interactive genetic algorithm, which reduces the genetic race space by orthogonal analysis to increase the convergence speed while reducing the psychological burden of fatigue to the user by reducing the number of user

interactions, producing a higher adaptation value that meets the needs of product styling design.

3. Product Styling Design Evaluation Method Based on Multilayer Perceptron Genetic Algorithm Neural Network Algorithm

3.1. Principle of Multilayer Perceptron Based Genetic Algorithm Neural Network Algorithm. A perceptron is a neural network with a single layer of computational units, which is a feedforward network with no connection between neurons within the same layer and no feedback between neurons between different layers, and the signal is transmitted from the lower-layer neurons to the upper-layer neurons. Its input and output are discrete values, and the neuron determines its output by a threshold function after the weighted summation of the inputs. The perceptron is a simple nonlinear neural network with a threshold function added to the linear neurons, also known as linear threshold elements. It can accept real type signals while outputting binary discrete quantities (0, 1). The main feature of the multilayer perceptron genetic algorithm neural network is to calculate the adaptation value based on the user's interaction evaluation rather than a function formula. Because of the combination of user evaluations as well as specific function formulas, it excels in problems where it is difficult to build adaptation functions, such as in the fields of product design, image retrieval, and design evaluation. The single-layer perceptron model has only two layers of neurons, the input and output layers, which are directly connected. It is designed as follows: first step: initialize the connection rights and thresholds; the initial values of both are generally set to smaller nonzero random numbers. Step 2: The input signals are fed into the network, the connection weights of all the input signals are weighted and processed, and the result of the calculation is used as the actual output of the network. Step 3: Adjust the weights. If the actual output of the network differs significantly from the desired output, the connection weights parameter is adjusted, and the adjustment process relies on the perceptron learning algorithm automatically [19]. Step 4: Perform step 3 repeatedly until the difference between the actual and desired outputs of the network meets the predesigned requirements.

In a neural network, perceptrons can be viewed as individual nodes in the neural network. The design idea of a parameter learning scheme for a multilayer perceptron network is that, in a multilayer perceptron network, the weights of all neurons except the last neuron are set in advance, and then the perceptron learning algorithm is used to learn the weights of the last neuron. Because the weights of the first layer neurons are set artificially, the degree of excellence of the first layer neuron design will directly affect the performance of the multilayer perceptron model. The design of the first layer neuron depends on the level of understanding of the problem faced and the data, which leads to the fact that there is no general approach to the design of parameters for the first layer neural network in solving a variety of different problems. As can be seen from Figure 1,

the structural characteristics of multilayer feedforward networks are (1) no connections between neurons in the same layer, (2) Full connectivity between neurons in two adjacent layers, and (3) there is directionality in information transfer. The forward calculation is done layer by layer from the input to the output [20].

The genetic algorithm improved multilayer perceptron neural network model is essentially the application of the genetic algorithm to extensively search the solution space of the target information, followed by locating the better multilayer perceptron neural network form searched by the genetic algorithm and then by training to obtain the optimal result of the prediction problem. Artificial neural networks are characterized by massively parallel processing, distributed information storage, and good self-organizing and self-learning capabilities. The process of genetic algorithm optimized multilayer perceptron neural network includes three parts: determining the multilayer perceptron neural network connection structure, determining the genetic algorithm optimized multilayer perceptron neural network weights and thresholds, and multilayer perceptron genetic algorithm neural network model prediction, the main steps are as follows (Figure 2): (1) determine the multilayer perceptron neural network structure based on the training sample data; (2) BP neural network hidden layers and layers are determined; (3) the length of the individual coding of the genetic algorithm is determined, and this value is determined by combining the number of parameters of the multilayer perceptron neural network; (4) the fitness value is optimized, and this value is optimized according to the error obtained from the training of the multilayer perceptron neural network; (5) the optimal solution is determined by the cyclic operation (4); (6) the optimal threshold weights are redetermined even more for the optimal solution; (7) the optimal weights and thresholds are assigned to the multilayer perceptron neural network model; (8) error calculation judgments on the new weights and thresholds are done to carry out multilayer perceptron neural network model training prediction; and (9) prediction result analysis is done, comparing the prediction results of multilayer perceptron neural network and genetic algorithm neural network.

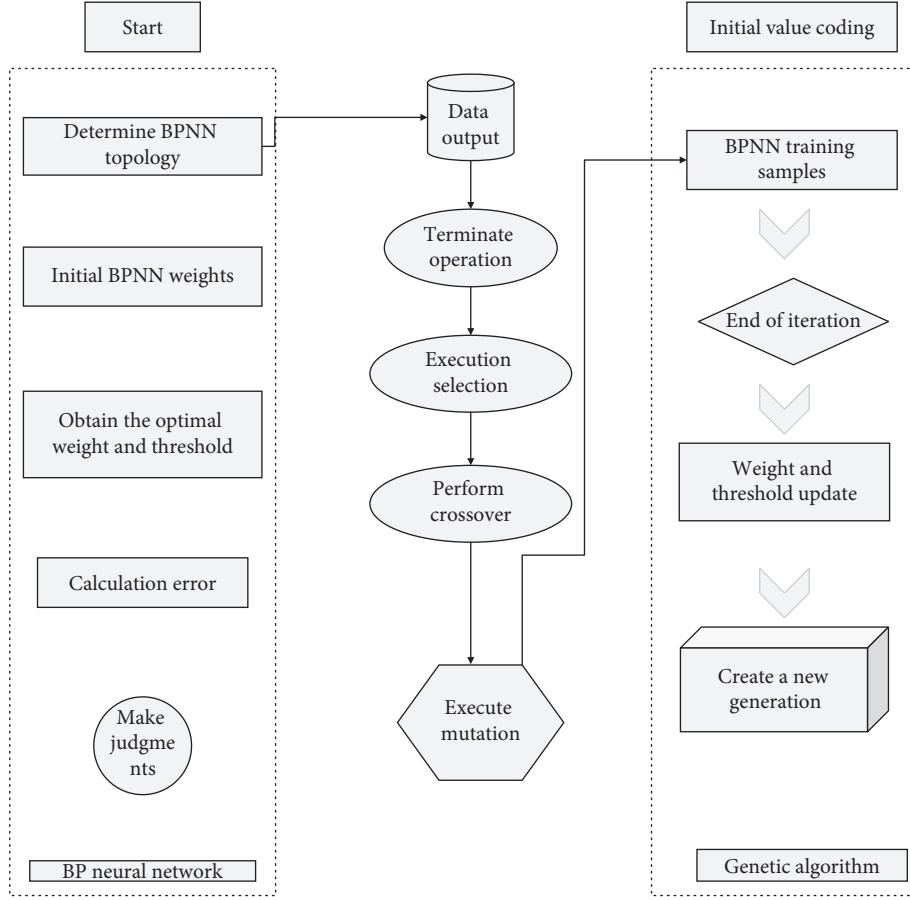
Thresholds and weights of the multiperceptron neural network are cascaded according to a specific order, and the weights and thresholds of the multiperceptron neural network are cascaded according to the order; namely, N chromosomes are generated randomly; implicit and output layer thresholds; input and implicit layer thresholds; implicit and output layer weights; input and implicit layer weights; the fitness function selects the mean square error, and the fitness of the chromosomes is recalculated according to the mean square error function to judge whether the prediction results meet the target requirements and generate new individuals if they do not meet the requirements; the specific operation is to perform variation operation, crossover operation, and replication operation on the individuals that meet the requirements of the fitness value and judge whether the new individuals meet the requirements of the mean square error value function if they meet the requirements [21]. There are four mutation operations in the evolution of a multilayer perceptron genetic algorithm neural


FIGURE 1: Topology of multilayer perceptron neural network.

network: adding connections, adding nodes, correcting connection weights, and changing the excitation function response. If the requirement is not met, the fitness of the chromosome is calculated again according to the mean square error function, and if the requirement is met, the optimal individuals are sequentially split and the threshold and weights applied to the multisensors neural network are updated; then the multisensors neural network is forward propagated, the global error is calculated, the weights and thresholds of the network parameters are adjusted and corrected, and the multisensors neural network learning training is cycled until the set learning times or accuracy requirements, the calculation is terminated, and the results are output.

Let the input layer of a multilayer perceptron genetic algorithm neural network have n one input neuron, the layer has m one output neuron, the hidden layer has q one hidden layer neuron, the connection weight between the hidden layer and the output layer is w_{ik} the v_{ik} connection weight between the input layer and the hidden layer is f_2, the transfer function of the hidden layer is f_1, and then the output of the hidden layer neuron is calculated as follows:

$$E(w_{ik}) = n \times f_1(q) \times f_2^m(v_{ik}) + C_v. \tag{1}$$

The output of the output layer neurons is calculated as follows:

$$\varphi_0 = F\left(f^P(i), f^Q(j+1)^2\right). \tag{2}$$

At this point, the multisensors genetic algorithm neural network completes the forward propagation process and establishes the mapping n from dimensional space vector to m dimensional space. For all the training samples in the BP neural network, the global error of the network is noted as G and is calculated as follows:

$$G = f^P(i) \oplus f^Q(j) = f(P_i) f^Q(j)^T. \tag{3}$$

The variation in the output layer weights of the multisensory layer genetic algorithm neural network is noted as L and is calculated as follows:

$$L = \sum_{(i,j,k)\in D} -\ln \sigma(z_{ij} - z_{ik}). \tag{4}$$

The formula for adjusting the weights of each neuron in the output layer is obtained as

$$R_{n+1} = R_n^2 - \sum P_{ij}. \tag{5}$$

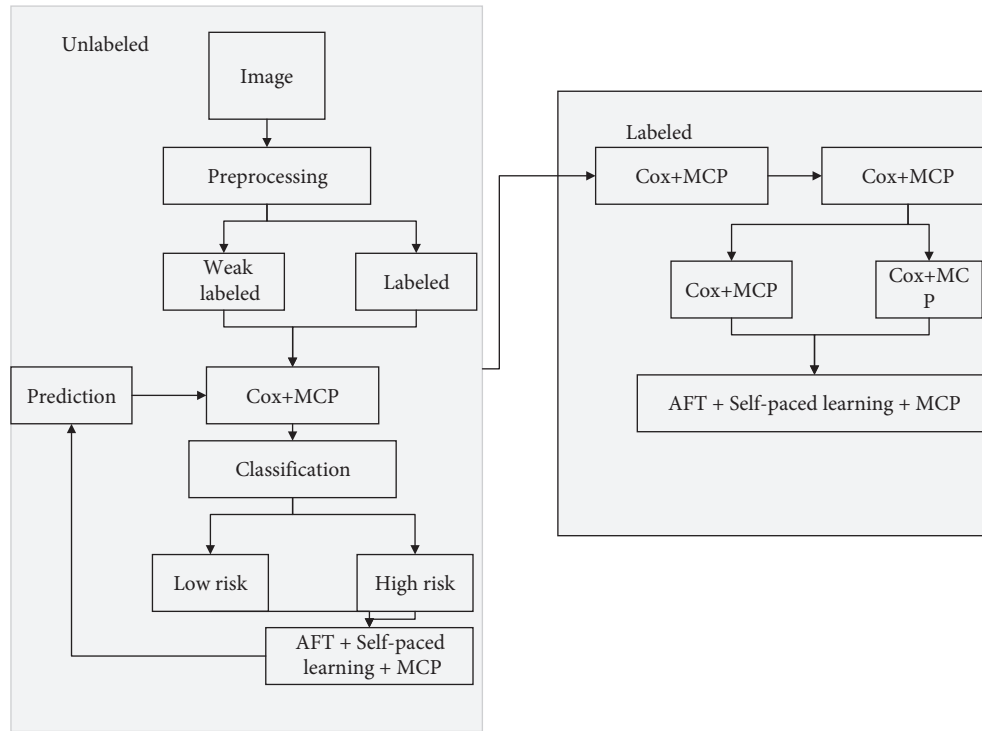
Fixed topology evolution must be done artificially to design the topology of the neural network. In contrast, topological weight evolution methods can automatically evolve the correct network topology. In addition, there is no general set of laws that guarantee excellent performance of


FIGURE 2: Computational flow of neural network of multilayer perceptron genetic algorithm.

artificially designed neural networks, so the topology of multisensory neural networks evolved based on genetic algorithms tends to outperform artificially designed solutions in terms of performance. This phenomenon is particularly evident in keeping network complexity to a minimum [22]. Although topology weight evolution methods perform better compared to fixed topology evolution methods, they also face many problems that do not exist in fixed topology evolution methods. There are four mutation operations in the evolution of a multilayer perceptron genetic algorithm neural network: adding connections, adding nodes, correcting connection weights, and changing the excitation function response. Before the mutation operation, we set a mutation probability, and the mutation of connection weights is done by correcting all connection weights according to the set mutation probability. In special cases, it is also possible to disregard the mutation probability and directly turn the original weight into a new weight. The mutation is used to change the weights and the network structure. Mutation of connection weights is done by adding a floating-point number (either positive or negative) to each weight with a fixed probability that matches a normal distribution. The network structure is mutated in two ways: mutation by adding nodes and mutation by adding a connection between two nodes.

3.2. Product Styling Design Evaluation Methods Based on Machine Learning Algorithms.
The so-called modeling is to point, line, surface as the basic elements, according to certain rules of mutual transformation, organic to produce new organic form. In the process of styling, the use of more

organic forms of free-form products can increase the uniqueness and innovation of products, of which, "selection" and "change," as two major modeling laws, are often applied. The so-called selection is to choose the basic type according to the use of function, maneuverability, and other conditions. There are two types of basic shapes, geometric and organic. Geometric forms are some common geometric shapes in mathematics, while organic forms are streamlined, bionic, or free-form. Transformation is the operation of dividing, cutting, accumulating, merging, stretching, extruding, bending, etc., in the form of the basic type. Splitting: It is in the form of "loss" or "separation." Usually, when cutting, it will be divided according to the golden ratio; for example, we commonly see the ratio of wheelbase to the total length of cars and the ratio of screen to the key distribution of flat panel products, etc., which are all golden ratios. Cutting: The basic type is partially cut to produce a face change in shape. The idea of the genetic algorithm comes from the biological evolution process in nature and is an optimization algorithm for solving complex problems. Intelligence and essential parallelism are the biggest differences between evolutionary computing and traditional optimization methods. The position, curvature, and depth of the cut all make the product produce different new shapes. Accumulation: The same or similar monoliths are stacked in size, position, number, and direction to produce a regular stack. The fruit plate, for example, is a shape produced by the accumulation of a basic type. (4) Merging: It is taking two separate individuals and creating a new shape by intersecting, cutting, or superimposing them. This type of shape can usually be seen in mechanical parts. (5) Stretching: As the name suggests, this is taking a base shape and dragging it

outward in a given direction to produce a new shape. This type of molding is seen everywhere in life; for example, refrigerator and cabinet air conditioner molding are applications of this method. (6) Extrusion: On the surface of a monolith, stretching in the direction of centripetal force is called extrusion.

With the vigorous development of computer technology, parametric and quantitative technology has become a hot spot for research in various academic fields and is also gradually applied to product form design. Most of the product form design is an improved design based on the original shape, and its parameters have a clear correspondence with the size of the design object. Therefore, the parametric design brings a more efficient design process to product design, which can use the previously accumulated and established models and modify them on this basis. The principle of parametric design is that the parameters of a line or a figure correspond to the control dimensions of the design object, and when different values of the parameter sequence are given, the design result changes, i.e., a new geometry is obtained under the drive of the parameters. At present, the application of parametric design in morphological design is more extensive, and its scope is gradually extended to the whole life cycle of the product, including two-dimensional organization, three-dimensional entities, accessories intermediate relations, product features expression, and other product-level designs.

Product styling is a process of multiple solution selection, and at the same time, styling is a field full of emotions. If traditional machine learning algorithms are involved in the design process, the nonoptimal individuals are completely discarded while the good individuals are retained. However, in the design domain, nonoptimal individuals can still have some influence and contribution to the final solution product even if they fail to satisfy some specific requirements. Therefore, this requires the introduction of multilayer perceptron neural networks to control the genetic algorithm. The main feature of the multilayer perceptron genetic algorithm neural network is to calculate the adaptation value based on the user's interaction evaluation rather than a function formula. Since users' visual cognition of products is mainly reflected in the form of perceptual information, designers should take the initiative to obtain information about users' perceptual preferences and understand how users decode their cognition of products and their perceptual preferences, to ensure success of design coding. Because of the combination of user evaluations as well as specific function formulas, it excels in problems where it is difficult to build adaptation functions, such as in the areas of product design, image retrieval, and design evaluation. For example, Figure 3 shows the flow chart of the product interactive styling design model.

In the conceptual stage of product design, the principle of combinatorial innovation is often used to generate new shapes. Combinatorial innovation, as it means, is the process of segmenting and analyzing a product based on a certain aspect, so that the modules can be combined to produce a new product shape, based on, but not limited to, function, shape, structure, man-machine, material, etc. The process of

design is always accompanied by many uncertainties, how to translate the subjective design activities into the digital language to analyze and quantify the emotions and demand preferences, need to analyze, process, and integrate all kinds of complex elements with the help of scientific and effective evaluation methods. Hierarchical analysis (AHP) is commonly used to measure the emotional factors of a product, simplifying complex decisions, or apply the principles of perceptual engineering theory to establish and determine the final evaluation index through semantic difference hierarchical evaluation. Product design evaluation is to use specific rules to evaluate the attribute values of each solution in a limited set of solutions and then use the specific rules to obtain a comprehensive evaluation value and finally rank all solutions based on the comprehensive evaluation value and obtain the optimal solution. It generally includes three steps: (1) normalize the evaluation matrix; (2) determine the weight size of each solution; (3) rank all alternatives. Commonly used design evaluation methods include the simple linear weighting method, efficacy coefficient method, hierarchical analysis method, approximate ideal solution ranking method, gray correlation analysis method, etc. The simple linear weighting method is a common multiobjective evaluation method; this method is based on the actual situation; first, determine the evaluation attribute weights, and then standardize the decision matrix, find out the average value of the linear weighting index of each option, and use it as the judgment basis of each feasible option ranking. The efficacy coefficient method converts the dissimilarity measures of each attribute into corresponding dimensionless efficacy coefficients and then performs a comprehensive evaluation. TOPSIS is a ranking method that approximates the ideal solution, which is characterized by full utilization of the original data, low error, and high reliability. The optimal solution is the one closest to the positive ideal solution and farthest from the negative ideal solution, to evaluate the optimal solution. The gray correlation method is a multifactor statistical analysis method, which is based on the sample data of each factor and analyzes the correlation size between each component factor and the whole and reflects the similarity of the solution to be evaluated and the optimal solution in terms of shape. Based on the multilayer perceptron genetic algorithm neural network, these evaluation indexes can be connected in series to evaluate the product shape design in a multifaceted way.

4. Experimental Verification and Conclusions

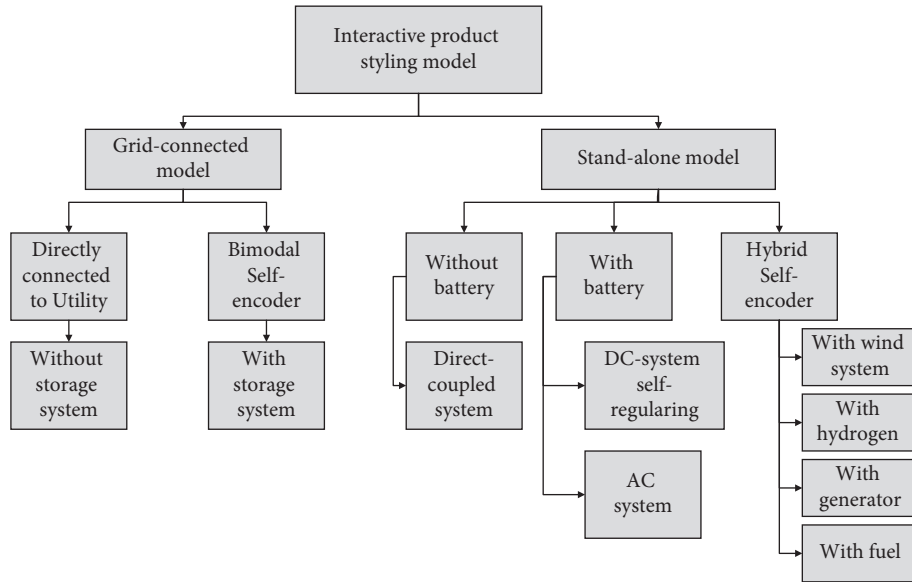
To verify the feasibility and effectiveness of the proposed method, a series of experiments are conducted to illustrate this paper. The main steps include the following: (1) constructing an evaluation system using perceptual engineering and hierarchical analysis; (2) using hierarchical analysis to obtain subjective weights; (3) using entropy weighting to obtain objective weights; (4) using game theory to obtain comprehensive weights; (5) using SD method to build a perceptual decision matrix; and (6) using KE-GRA-TOPSIS method to rank the alternative products.


FIGURE 3: Flowchart of an interactive product styling model.

A comprehensive evaluation system for the product was developed using perceptual engineering and hierarchical analysis. The target level has only one element, i.e., the selection of the product solution. Six criteria and 12 indicators were identified based on the TF-EPA method. The product perceptiveness was evaluated in 6 dimensions: gender perspective, acceptance, structural characteristics, duration, weight characteristics, and technical characteristics, respectively. Two indicators were included under each criterion and the indicators consisted of a pair of perceptual words.

The relative closeness trends of the three methods MLP, GA, and GA-MLP-NN regarding the 14 alternatives were obtained based on the experiments, and the comparison graphs shown in Figure 4 were drawn. In the GA method, the relative closeness gap of the alternatives is larger because the GA method only considers the distance of the alternatives in space and magnifies the evaluation results; the gap of the alternatives in the MLP method is smaller because the method focuses on the association between indicators but ignores the distance of the evaluation alternatives in space. Introduce the preference information in the user's multidimensional perceptual preference space directly into the design conception. The information transfer and transformation efficiency in the process is improved. The GA-MLP-NN method is an integration of the GA method and MLP, which considers the relative closeness derived from this method is more realistic as it considers both the degree of association between evaluation options and the gaps between options.

The results of DM selection were also compared with those of the MLP method, GA method, GA-MLP-NN method, and TOPSIS method, and the comparison results are shown in Figure 5. The KE-GRA method was not included in this comparison test because its accuracy was too low. The GA-MLP-NN method had an accuracy of 78.6%, followed by the MLP method with 57.2%. Also, the accuracy

FIGURE 4: Comparison of relative posting progress trends.

of the GA method and TOPSIS method was 7.2% and 0. Observing Figure 5, it can be seen that the results of the GA-MLP-NN method and MLP method were similar, while the GA method and TOPSIS method were similar. In addition, the results of the GA-MLP-NN method and the MLP method are roughly consistent with the choice of DM. This experiment verifies that the TOPSIS method and its extensions cannot be directly used for the perceptual ranking of products.

To verify the validity of the proposed method, 10 additional participants were invited to repeat the experiment. Figure 6 shows the results of preferences and alternatives ranking given by the participants. It is worth noting that the subjective weights in the hierarchical analysis method are adjustable. The comparison results of the subjective choice
FIGURE 5: Results of comparison of program ranking.

FIGURE 6: Results of participant preferences.

results of the 10 participants with the GA-MLP-NN method and the MLP method are shown in Figure 6, which contains the comparison of the number of correct rankings and the comparison of the accuracy rate. In this case, the bar graph represents the number of correct rankings and the line graph represents the accuracy rate. In the GA-MLP-NN method, the accuracy rates of U1 to U10 are 85.7%, 100%, 85.7%, 100%, 100%, 100%, 85.7%, 100%, 100%, and 100%, in that order. The average accuracy was calculated to be 95.7%. In the MLP method, the accuracy rates of U1 to U10 were 85.7%, 85.7%, 85.7%, 85.7%, 85.7%, 85.7%, 85.7%, 71.4%, 85.7%, 100%, and 85.7% in that order. The average accuracy rate was calculated to be 85.7%. In terms of accuracy, both

the GA-MLP-NN method and the MLP method performed well, and the GA-MLP-NN method was more accurate. The above results show the feasibility of the perceptual decision matrix and that the proposed GA-MLP-NN method can accurately rank products according to users' personalized preferences.

In Figure 7, True Positive (TP) indicates the number of positive samples classified as positive; True Negative (TN) indicates the number of negative samples classified as negative; False Positive (FP) indicates the number of negative samples classified as positive, and False Negative (FN) indicates the number of positive samples classified as negative. The commonly used evaluation metrics, including Accuracy, Precision, Recall, False Discovery Rate (FDR), and False Positive Rate (FPR), are listed in Figure 7. 30 product images are arbitrarily selected as a content map and 10 images as style map; 300 new product images were generated. After mixing 100 real images and 300 generated images, the 30 users in Section 3.4.2 were invited to distinguish the truth from the falsehood of 400 images. Since the product images generated by the GA-MLP-NN method are only used to inspire designers or users and are not final design renderings, to weaken the detailed features of the generated images, 30 users (with normal vision) observe the images at a distance of 1 m from the display (resolution of 2560×1440) with a maximum display size of about 8 cm on one side (width or height) of the images and each image. The dwell time does not exceed 2 s. The purpose of this experiment is to evaluate the user's ability to distinguish between real and generated images and to reflect the quality of the generated images. FDR is the proportion of actual negative samples among positive samples, and FPR is the proportion of actual negative samples among positive samples. FDR and FPR are positive indicators. The calculated FDR and FPR are 69% and 67%, respectively, indicating that the generated images are of good quality and can be used to display and inspire designers.

Due to the relationships of relevance, subordination, redundancy, and similarity between adjectives, two perceptual words with similar concepts and opposite meanings are more reflective of user psychology. Therefore, perceptual words are selected in this chapter to describe the user's psychological feelings. The importance of a word is proportional to the number of times it appears in a text, and if a word appears repeatedly in the text under study, it can be used to characterize the dominant tendency of the text. Considering the one-sidedness of the traditional method of selecting sentiment words by considering only word frequency or user preference in sentiment engineering, this chapter proposes a GA-MLP-NN-based method for selecting sentiment word pairs based on the characteristics of word frequency and EPA dimensions. Text sentiment analysis is the use of computer analysis of text with subjective feelings in user comments for polarity classification, which is usually classified as positive (positive), derogatory (negative), or neutral. Sentiment classification methods can be divided into two categories: machine learning-based methods and lexicon-based methods, the latter of which discriminate text sentiment by sentiment lexicons such as
FIGURE 7: Partial sample attribute parameter rank distribution.

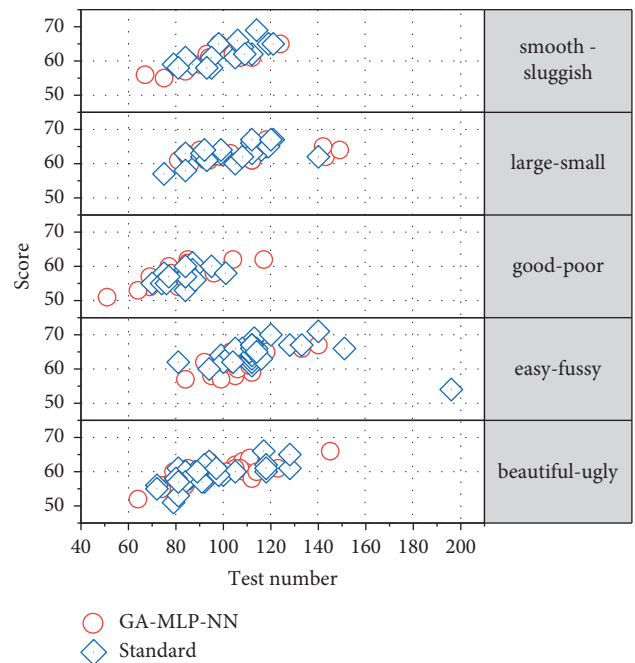
WordNet and HowNet, which rely on the quality and continuous improvement of sentiment lexicons. In this chapter, the sentiment dictionary-based approach is used to determine the sentiment tendency of sentiment words in online reviews. The HowNet dictionary and synonym word forests are searched to obtain the results of sentiment tendency judgment of sentiment words. The score of sentiment unit EO is the product of sentiment polarity EP and sentiment intensity EI, and the sentiment evaluation of the whole text is characterized by aggregating the sentiment units in the text. The sum of the sentiment tendency scores of independent positive and negative sentiment words in a sentiment pair is used as the evaluation value of a set of sentiment word pairs. Commonly used design evaluation methods include the simple linear weighting method, efficacy coefficient method, hierarchical analysis method, approximate ideal solution ranking method, gray correlation analysis method, etc. The perceptual evaluation values of the six sets of perceptual words are obtained by traversing the product reviews according to the perceptual evaluation value calculation process, where positive values indicate that the sample ratings are biased towards positive perceptual words, negative values indicate that the sample ratings are biased towards negative perceptual words, and the absolute values of the ratings indicate the degree of deviation. In the perceptual evaluation of the sample in Figure 8, the perceptual word "good-poor" is rated as 0.949, indicating the overall product evaluation preference; "beautiful-ugly" is rated as 2.133, indicating the product. The "smooth—sluggish" rating of −1.005 indicates that the system is sluggish to use. The perceptual rating for sample 2 was medium, with a "large-small" rating of 1.957, indicating a large product size. The perceptual rating for sample 3 was medium, with a "large-


FIGURE 8: Partial sample perceptual evaluation.

small" rating of 2.127, indicating a large product size. Sample 4 had a medium perceptual rating of 4.0 on the "large-small" scale, indicating a large size, and a −1.121 on the "easy-fussy" scale, indicating that the product was fussy to use. The "Smooth-Sluggish" rating of 3.0 indicates that the system is smooth to use. The perceptual rating for sample 5 was medium, with a rating of 2.5 for "beautiful-ugly" indicating a beautiful product, and 2.589 for "large-small" indicating a

large product size. The "Flow-Sluggish" rating is 0.953, which indicates smooth system usage. The model predicted by GA-MLP-NN and the actual value model almost agree, indicating that the GA-MLP-NN model has high accuracy.

With the widespread application of the Internet of Things, Internet, and automation technologies, products are developing in the direction of intelligence and information technology, and the whole product life cycle process is becoming more and more open and transparent. The product life cycle is the whole process from product development to end-of-life, including product design, production and processing, transportation and supply, and sales and use. The data generated from the whole product lifecycle includes data in the database of enterprise information management system such as enterprise resource planning, CRM, manufacturing enterprise production process execution system, product data management, and supply chain management, as well as data generated by users in the Internet and e-commerce system such as browsing, clicking, purchasing, and reviewing, etc. These data have the typical characteristics of big data, i.e., many data types, large data volume, low-value density, and high commercial value. These data have the typical characteristics of big data, namely, many data types, large data volume, low-value density, and high commercial value. Among them, the data types include text data, image data, voice data, video data, and log data. These product-related data grow exponentially every day to form the product life cycle big data. The multilayer perceptual genetic algorithm neural network based on this paper can make full use of the characteristics of big data with low-value density and high commercial value to extract valuable information from large-scale data and the value of the most core part. The value of big data depends on the role that the data analysis results play in the application. The field of product design has received slightly less attention than other applications of big data, but there is no shortage of roles it can play. For example, by collecting product reviews in e-commerce systems, it is possible not only to detect changes in user needs but also to improve product defects based on user feedback, thereby increasing user satisfaction. Image big data can intuitively inspire designers and facilitate product styling.

5. Conclusion

This paper further develops an intelligent and systematic approach to product innovation design by exploring how to obtain information related to product design from the big data generated from the product life cycle and analyzing it in depth using techniques such as genetic algorithm neural network model based on multilayer perceptron, and the main research work is as follows. This paper analyzes the advantages and disadvantages of each multilayer perceptron neural network as well as genetic algorithm, and by combining genetic algorithm with multilayer perceptron neural network model, a set of multilayer perceptron genetic algorithm neural network models is formed, and product design domain knowledge is incorporated into it, and the method can automatically identify, extract, and reconstruct

the content and color features of images and migrate them to the product shape in the content map. Real-time generation of new product images is achieved. Among them, the training of the multilayer perceptron neural network migration model is an unsupervised training based on image data, and the trained model is used to automatically migrate the stylistic features of stylistic images; the genetic algorithm model is a supervised training, and the trained model is used to predict the product semantics in the content graph and guide the selection of the stylistic graph. The method alleviates the problems of poor image quality, uncontrollable content, and lack of theoretical guidance in the product design domain of the generated solution. The subjective imagery of users is ambiguous, and there is a "black box" problem between their subjective evaluation value and the elements of product form and shape. It is also not easy to improve the competitive advantage of the product. This paper also integrates product design domain knowledge into textual big data techniques to propose a data-driven perceptual engineering approach for online reviews. In terms of perceptual word collection, online reviews are used as a source of perceptual words; in terms of perceptual word acquisition, a GA-MLP-NN perceptual word extraction method combining three dimensions of word frequency and EPA is proposed; in terms of perceptual evaluation, a perceptual evaluation value calculation method combining degree adverbs with word clustering for online reviews is proposed, and the basic idea is to obtain users' emotional tendency towards the product by mining the emotional tendency of perceptual words. In terms of mapping model construction, a multilayer perceptron genetic algorithm neural network is used to construct a relationship model between users' difficult-to-quantify perceptual needs and product design elements, while the models constructed by multiple linear regression methods are compared to verify the effectiveness and feasibility of the proposed method.

In recent years, the development of prefabricated building (PB) mode in China has gradually attracted the attention of stakeholders. It is of great significance to explore the adoption behavior of PB mode by Chinese construction enterprises. Using the method of combining evolutionary game theory with system dynamics and considering the multiagent interaction of the government, construction enterprises, and consumers, as well as the influence of multiple factors, this paper constructs a model of construction enterprises' adoption behavior of PB mode. The purpose is to clarify the mechanism of Chinese construction enterprises' adoption behavior of PB mode and the evolution law of market share. The research results show the following. Firstly, government subsidy plays an important role in promoting the maturity of PB market, but it plays a relatively small role in the more mature and stable market. Secondly, the higher the initial acceptance probability of the construction enterprise, the greater the peak of the PB market share and the greater the volatility, but it has no differential impact on the balance of the PB market in the later stage. Thirdly, price factors and quality factors, respectively, have an important impact on the increase of the PB market share in the early and late stages of the formation of the PB market, but the delivery waiting time factor has no significant impact on the PB market share.

1. Introduction

The construction industry occupies a pivotal position in the national economy of all countries in the world, but it is also one of the industries with a high degree of energy intensiveness [1, 2]. It has always had problems such as high carbon emission and serious energy consumption. For example, the annual carbon dioxide generated by global construction accounts for more than 40% of the world's total carbon dioxide emission, and the annual energy consumed accounts for more than 30% of the world's total energy consumption [3–5].

The traditional construction mode has the problems of high pollution and high energy consumption during the construction period, which is not in line with the modern development concepts such as energy conservation and emission reduction and green and sustainable development [6]. In order to promote the green and sustainable development of the construction industry, the prefabricated building (PB) mode has been gradually introduced into China. PB mode not only has the advantages of improving production efficiency, reducing construction cost, and increasing construction safety but also has the functions of reducing carbon emission, reducing energy consumption, and reducing construction waste [7, 8]. Therefore, the Chinese government pays more and more attention to the transformation from traditional construction mode to PB mode and tries to promote the development of PB by means of encouraging technological innovation and policy incentives such as subsidies [5]. The Chinese government stipulates that by 2020, 15% of new buildings nationwide (according to the floor area) will be constructed using the PB mode each year, and this proportion will increase to 30% by 2025 [9]. However, the current application and promotion of the PB mode is not ideal.

In fact, the application and promotion of PB mode in China faces many obstacles. For example, in terms of the government, there is a lack of detailed government policy formulation and effective incentives [10]. In terms of the industry, there is a lack of specific construction specifications and construction standards for prefabricated buildings [11]. In terms of market demand, there are obstacles such as insufficient consumer awareness of PB and insufficient market demand [12, 13]. Therefore, considering the significance of promoting PB mode in China and many obstacles it faces in the development process, it is necessary to model and analyze the adoption behavior of the PB mode by construction enterprises in the context of multiagent interaction.

Modeling and analyzing the behavior of construction enterprises adopting PB mode and then understanding the mechanism of the adoption of PB mode play an inestimable role in the development of the whole industry. Some scholars have conducted relevant research on the factors affecting the adoption and promotion of the PB mode. For example, Li et al. [14] believe that the prefabricated component subsidies implemented by the government have a positive impact on the use of prefabricated components and the improvement of construction performance. Multiple policy measures are mutually complementary, and the combined effect of these policy measures is greater than the sum of the effects of individual policy measures. Wei et al. [15] believe that the promotion of government policies and the leadership of construction enterprises are the main driving factors to promote the development of PB. Research by Gan et al. [7] showed that strengthening policies and regulations has a strong stimulating effect on the promotion of PB and has a significant effect on solving organizational and environmental problems in the promotion process, but the effect on solving technical problems is not ideal. However, Xiahou et al. [16] found that in order to promote PB mode, China needs not only the promotion of the government and the pull of the market environment but also the self-driving of the PB industry. It is pointed out that the main way to promote the development of China's PB is to transform and upgrade the traditional construction industry and solve the development difficulties.

Some scholars believe that the government plays an important role in the process of whether the PB mode is adopted by the construction enterprise [5]. Government policy incentives have a positive effect on the promotion of PB mode, and reasonable policy incentives can help reduce opportunistic behavior [17, 18]. However, policy documents tend to favor the environment and supply and lack policy measures for other areas [7]. Currently, government subsidies are the main way to promote the development of PB mode, but in the long run, continuous government subsidies are not a long-term solution to maintain the steady development of the industry. At the same time, the government's publicity and guidance work is also gradually starting. For example, Xi'an, China, has begun to encourage consumers to purchase prefabricated commercial residential buildings and promote the development of prefabricated buildings from the consumer level.

Secondly, the construction enterprise is also one of the most influential stakeholders in the PB industry [19]. As the investor of a construction project, the construction enterprise's behavioral willingness and adoption behavior are highly correlated [20]. Therefore, whether the construction enterprise adopts the behavior and decision making of PB mode is very important for the development of the PB industry. The construction enterprise will make reasonable decisions on its own construction mode based on the economic benefits, environmental performance, maintenance cost, and other factors of the construction project [21, 22]. However, the high initial cost of adopting PB mode is one of the main factors that hinder the construction enterprise from adopting PB mode [7, 23]. The poor overall efficiency of PB industry also leads to the lack of motivation for some construction enterprises to adopt PB mode [13].

In addition, whether the PB mode is adopted is closely related to market demand [24]. The purchase motivation of consumers will have an important impact on the development of the PB market. Due to the lack of Chinese consumers' understanding of PB [12], Lee and Kim [25] believe that it is necessary to increase the correct publicity and guidance to change consumers' attitudes towards PB. Some scholars have studied consumers' attention to PB and the evolution trend of their attention content. For example, Wang et al. [26] pointed out that although consumers' attention to PB fluctuates greatly, it shows an overall upward trend, and the introduction of relevant government policies will significantly affect consumers' attention. Hu et al. [27] found that the content of PB that consumers are most concerned about mainly involves high-quality building performance.

In summary, the behavior and decision making of the construction enterprise adopting the PB mode are affected by multiple stakeholders. Existing research studies have identified the stakeholders who influence the adoption of the PB mode and analyzed the influencing factors and their effects. However, it rarely involves the influence of consumer group decision making on the adoption of the PB mode. In addition, less consideration is given to the complex interaction between a large number of factors and their nonlinear effects on the adoption behavior of PB mode.

In fact, first of all, consumers' cognition of PB and purchasing decisions are of great significance to the adoption of the PB mode. Consumers' purchase decision making is a more complex process, which considers many factors, such as price, quality, delivery waiting time, and so on. Previous studies generally regarded consumer demand as an exogenous variable to analyze its linear relationship with the adoption behavior of PB mode. This paper constructs a more realistic consumer decision-making model, which plays a vital role in revealing deeply the adoption behavior of PB and the evolution of market competition in the context of multiagent interaction. Secondly, the adoption behavior of PB mode by construction enterprises is also affected by many subjects and factors. They will comprehensively consider government policies, the status quo of the industry, market demand, and competitive pressure and adopt a suitable construction mode in the

pursuit of maximizing their own economic benefits. Therefore, there are relatively complex dynamic interactions between construction enterprises and between construction enterprises, government, and consumers. In the process of studying the adoption behavior and mechanism of PB mode, this dynamic and complex interaction and game relationship cannot be ignored [9].

To sum up, on the basis of considering more realistic consumer purchase decisions and more complex interaction among multiple subjects, this paper will focus on the analysis of the adoption behavior and mechanism of the construction enterprise to PB mode under the scenarios of government subsidies to the construction enterprise, government publicity and guidance to the market, PB products with different prices, qualities, and delivery waiting times, and different adoption intentions of the construction enterprise. This paper attempts to provide a theoretical basis for improving the market competitiveness of PB products and formulating reasonable policies and measures for the government. This is of great significance for the Chinese construction industry to achieve energy saving and emission reduction targets and to practice the concept of green and sustainable development.

This research considers the complex interactions among stakeholders (government, construction enterprises, and consumers) that influence the adoption of PB mode and the bounded rational behavior of decision-making. This research also considers many obstacles in the process of adopting PB mode, as well as the complex interaction and nonlinear feedback relationship between these factors. This research will use the method of system dynamics to model and analyze related problems. System dynamics are more suitable for analyzing complex systems. This method can be used to understand the behavior of the system over time and the relationship between the system structure and decision rules [28]. Also, in the process of Chinese construction enterprises adopting PB mode, the bounded rational game between them and industry competitors is continuous. Therefore, the behavior of both parties must be discussed from a dynamic perspective [9]. Evolutionary game theory has been widely used in the study of bounded rational behavior, such as the study of stakeholders in the construction industry [29]. Therefore, this paper will use the research method of combining evolutionary game and system dynamics to model and analyze the behavior and mechanism of PB mode adopted by construction enterprises in China. It hopes to provide a theoretical basis for the rapid and sustainable development of PB mode in China.

This paper attempts to solve the following three problems:

(1) What impact will government subsidies and government propaganda and guidance have on the adoption behavior of PB mode by construction enterprises?

(2) What impact will the initial willingness of Chinese construction enterprises to adopt PB mode have on the diffusion and evolution of the follow-up market of PB mode?

(3) What kind of evolutionary trend will the market proliferation of PB products under different prices, qualities, and delivery waiting times be?

2. Model

This paper combines evolutionary game theory with system dynamics to model and analyze the relationship and behavior of the three subjects involved in the adoption of PB mode: government, construction enterprises, and consumers.

2.1. Evolutionary Game Model. The construction enterprise will make decisions on the specific construction mode of the project. One is the adoption of traditional cast in situ buildings (TB) (hereinafter referred to as "D_N"). The second is the adoption of PB (hereinafter referred to as "D_Y"), including the selection of qualified and capable design institutions for modular design of drawings, the production of prefabricated components by prefabricated component manufacturers, and the assembly construction by construction organizations.

Whether the construction enterprise adopts PB mode will be mainly affected by government subsidies, competition from the same industry, consumer demand, and other factors. The interaction relationship and decision-making mechanism between agents are shown in Figure 1.

In order to clarify the competition mechanism among construction enterprises and then construct a system dynamics model with multiagent and multifactor comprehensive influence, this paper first uses the evolutionary game method to construct the behavior rules for construction enterprises to adopt PB mode. The construction enterprises are divided into two groups: initial adoption (Type Y construction enterprises) and initial nonadoption (Type N construction enterprises) of PB mode.

In the given situation, the two groups will take different strategies to play the game. This paper makes the following assumptions for model construction:

Hypothesis 1: assume that the overall number of construction enterprises remains unchanged. The construction enterprise will select a strategy that suits itself based on certain rules in each time unit.

Hypothesis 2: "D_Y" will increase the construction cost of the project. Use x_Y to represent the probability of the "D_Y" strategy and x_N to represent the probability of the "D_N" strategy, where $x_N = 1 - x_Y$, and x_Y and x_N are all functions of time t.

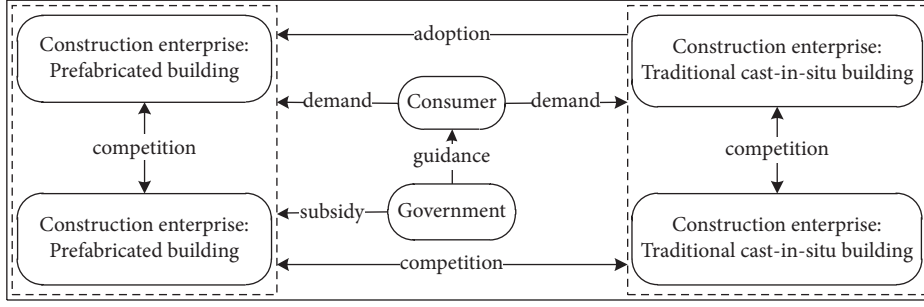
Hypothesis 3: the construction enterprise will choose its strategy according to its own profit level. The construction enterprise will compare its payoff with that of its competitors, so as to choose a strategy to make its expected payoff higher. Type Y construction enterprises and Type N construction enterprises will calculate their respective payoff differences. Taking Type Y construction enterprises as an example, if their payoff difference is greater than or equal to 0, Type Y


FIGURE 1: System analysis of construction mode selection of construction enterprise.

construction enterprises will maintain their existing strategy. When the payoff difference is less than 0, it will change its strategy with a certain probability [30]. The probability $\Phi(U_Y^D - U_N^D)$ of changing the strategy is shown in the following formula:

$$\Phi\left(U_Y^D - U_N^D\right) = \begin{cases} \dfrac{\left(U_Y^D - U_N^D\right)}{U_Y^D}, & U_Y^D < U_N^D, \\[3mm] 0, & U_Y^D \geq U_N^D. \end{cases} \tag{1}$$

Hypothesis 4: the expected average payoff of the construction enterprise that chooses the "D_Y" strategy is U_Y^{DA}, and the expected average payoff of the construction enterprise that chooses the "D_N" strategy is U_N^{DA}. Due to the different qualifications and capabilities of each construction enterprise, their real payoff will also be differentiated. Assume that the payoff of Type Y construction enterprise is $U_Y^D = \lambda_Y * U_Y^{DA}$, and the payoff of Type N construction enterprise is $U_N^D = \lambda_N * U_N^{DA}$. λ_Y, λ_N are the influence coefficients of expected average payoff.

Hypothesis 5: hypothesis p is the probability of the construction enterprise adopting PB mode. Using $\overline{x}$ to represent the derivative, the replication dynamic equation of the basic dynamic change rate at which the construction enterprise may choose to "D_Y" the strategy can be expressed as

$$\overline{x}_Y = x_Y * x_N \left[\Phi\left(U_Y^D - U_N^D\right) - \Phi\left(U_N^D - U_Y^D\right) \right] p. \tag{2}$$

2.2. System Dynamics Model Based on Evolutionary Game

2.2.1. Main Modules and Equations.
The system dynamics model based on evolutionary game is constructed by Vensim PLE. The model consists of three main modules: the construction enterprise decision-making module, the construction enterprise payoff module, and the consumer decision-making module. As shown in Figure 2, the construction enterprise decision-making module and the construction enterprise payoff module have an interactive relationship with each other, and the consumer decision-making module has an impact on the construction enterprise payoff module. Among them, the construction

FIGURE 2: Interaction between modules.

enterprise decision-making module is constructed according to the assumption rules and logical relations of the evolutionary game part.

(1) The Construction Enterprise Decision-Making Module. In this module, each construction enterprise has different qualifications and abilities and will change its own decisions according to the development of the industry, so the time of their "D_Y" may be inconsistent. Each construction enterprise will go through a certain period of observation and then choose a strategy that suits itself. According to the plan of the Chinese government, the construction target of PB in the next stage is 2025. Therefore, the longest observation and consideration time of the construction enterprise is 5 years, and the average observation and consideration time is 1.5 years. Based on the above data, the dynamic change rate after D_Y (R_T) is set.

This model will use the relevant data of PB development planning in Jiangsu Province, China. According to statistics from the National Bureau of Statistics of China, the number of real estate construction enterprises in Jiangsu Province in 2018 was 6,723, of which 39 were state-owned real estate construction enterprises [31]. Since PB mode has been implemented in China for a short time, the priority to adopt PB mode is mainly state-owned real estate construction enterprises. Therefore, suppose that the number of construction enterprises that initially adopted PB mode is 39. This module includes two level variables, namely, the construction enterprise adopting PB mode (D_Y) and the construction enterprise not adopting PB mode (D_N). One

rate variable is the adoption rate of PB mode (D_R) obtained according to the replication dynamic equation R_B of evolutionary game. The model is shown in Figure 3, and the meaning of the symbols is shown in Table 1.

The main equations of this module are as follows:

$$D_R = D_T * R_T,$$
$$R_T = \text{Delay Fixed}\,(R_B, \text{Random Normal}\,(0, 5, 1.5, 0.1, 0), R_B),$$
$$R_B = \overline{x_Y}$$
$$D_Y = 0.039 + \int D_R,$$
$$D_N = 6.684 - \int D_R,$$
$$p = \text{Random Normal}\,(0, 1, 0.4, 0.3, 0).$$

$$(3)$$

(2) The Construction Enterprise Payoff Module. The construction enterprise payoff module mainly involves the payoff of the construction enterprise that selects the "D_Y" strategy (U_Y^D) and the "D_N" strategy (U_N^D). The payoff of the construction enterprise mainly includes construction payoff and government subsidies. Construction payoffs are realized through consumers' choice to purchase, and government subsidies are realized through government subsidies for construction projects that adopt PB mode. According to the current market conditions, government subsidies to construction enterprises are affected by factors such as subsidy factors, prefabrication ratio, and construction area of unit buildings. The model types of the payoff module of the construction enterprise that selects the "D_Y" strategy (U_Y^D) and the "D_N" strategy (U_N^D) are similar. Therefore, this module takes the module that the construction enterprise selects the "D_Y" strategy (U_Y^D) as an example. The model is shown in Figure 4, and the meaning of the symbols is shown in Table 1.

The main equations of this module are as follows:

$$U_Y^{DA} = \frac{\left[(P_1 - C_1) * A_R * C_1^C\right]}{D_Y} + S,$$

$$S = \begin{cases} A_C * s * f * 100, & Z \geq 0.5, \quad A_C * s * f * 100 \leq 1800, \\ 1800, & Z \geq 0.5, \quad A_C * s * f * 100 > 1800, \end{cases}$$

$$f = \begin{cases} (D_Y - \text{Delay1}\,(D_Y, \text{Time Step})), & (D_Y - \text{Delay1}\,(D_Y, \text{Time Step})) \geq 0, \\ 0, & (D_Y - \text{Delay1}\,(D_Y, \text{Time Step})) < 0. \end{cases}$$

$$U_Y^D = U_Y^{DA} * \lambda_Y,$$

$$\lambda_Y = \text{Random Normal}\,(0.9, 1.3, 1, 0.2, 0).$$

$$(4)$$

(3) The Consumer Decision-Making Module. The consumer decision-making module mainly characterizes the consumer's purchase decision for TB or PB, and its purchase decision mainly considers the price, construction quality, and delivery waiting time of construction products. Assuming that there are N types of developed construction products on the market, consumers will give priority to the construction products that can generate the greatest purchase motivation [32]. The consumer's purchase motivation function can be expressed by the following formula:

$$M_i = P_i * PS_i + Q_i * QS_i + W_i * WS_i + l_i. \quad (5)$$

The price sensitivity distribution model shows that the lower the price of a product is, the less price sensitivity the product produces, that is, the smaller the obstacle to consumers' purchasing motivation [33]. The consumer's price sensitivity is an exponential function of the difference between the actual product price P_i and the expected price P_e. Due to the different socioeconomic attributes k of different consumers, their expected price P_e is different. Therefore, the formula is as follows:

$$PS_i = -\alpha^{P_i - (P_e + k)},$$
$$k = \text{Random Uniform}\,(-0.2, 0.1, 0). \quad (6)$$

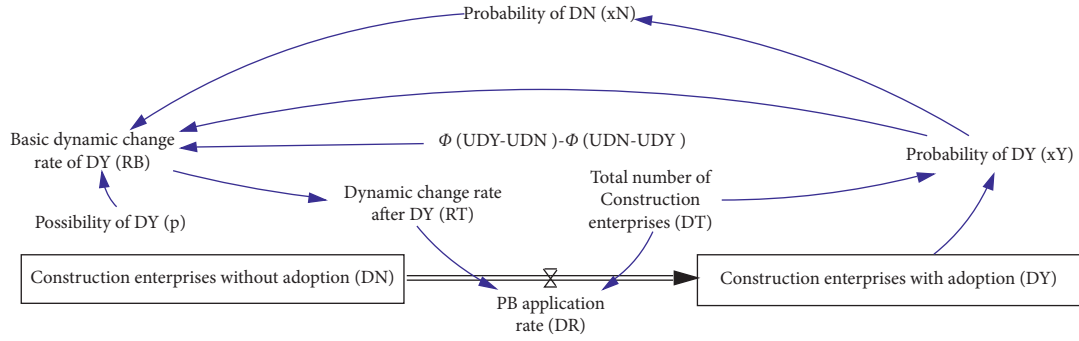
The quality sensitivity distribution model is used to measure the extent to which the quality of TB products and PB products affect consumers' motivation to purchase the products [34]. According to Taguchi quality theory and related research [35], consumers' perception of construction product quality mainly involves two aspects, including construction management level and information technology


FIGURE 3: System diagram of the decision-making module of the construction enterprise.

TABLE 1: The symbolic meaning of the main equations.

Symbol	Implication
D_R	PB application rate
D_T	Total number of construction enterprises
R_T	Dynamic change rate after D_Y
R_B	Basic dynamic change rate of D_Y
p	Initial probability of D_Y
U_Y^{DA}	Average expected payoff of D_Y
C_i	Cost for per square meter of $i (i = 1$ is PB; $i = 2$ is TB)
P_i	Price for per square meter of i
S	Subsidies for D_Y
A_R	Average building area of per suite
A_C	Building area of unit building
C_i^C	Consumers of choosing i
Z	Prefabrication ratio
U_Y^D	Expected payoff of D_Y
s	Subsidy per square meter of D_Y
f	The amount of change of per unit time of D_Y
M_i	Consumers' motivation to purchase i
PS_i	Consumers' price sensitivity parameters for i
Q_i	Quality of i
QS_i	Consumers' quality sensitivity parameters for i
W_i	Delivery waiting time for i
WS_i	Consumers' delivery waiting time sensitivity parameters for i
l_i	The degree of external influence of consumers purchasing i
P_e	Consumer expected price for per square meter of building
k	Consumers' socio-economic attributes of price factors
μ_i	The quality to cost ratio of i
m_i	Management level in i construction
t_i	Information technology level in i construction
Q_e	Consumer expected quality for building
a, b, d	Constant
W_e	Expected delivery wait time for consumers
w	Consumers' socio-economic attributes of delivery waiting time factors
C_i^{CC}	Probability of consumers choosing i

level. Therefore, comprehensive consumers' perception of different quality factors will get consumers' overall quality evaluation of construction products. The overall quality evaluation formulas of different building modes are expressed as follows:

$$\mu_i = aQ_i^2 + bQ_i + d,$$
$$Q_i = m_i t_i, \qquad (7)$$
$$QS_i = \beta^{|Q_i - Q_e|}.$$

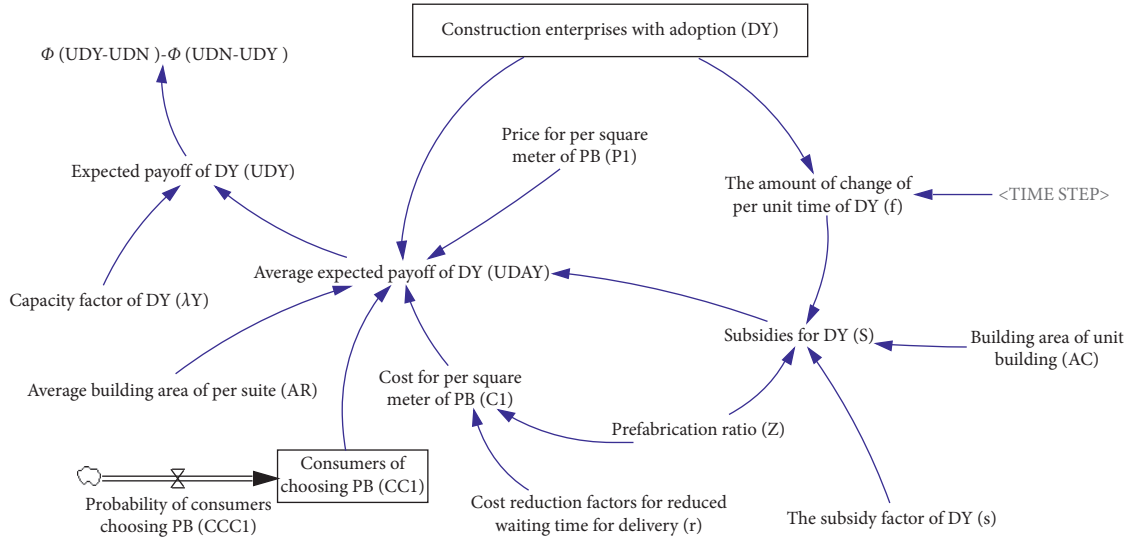
The delivery waiting time sensitivity distribution model is used to measure the extent to which the delivery time of different building modes affects consumers' motivation to purchase the product. WS_i is an exponential function of the difference between the actual delivery waiting time W_i and the expected delivery waiting time W_e of the building. Due to the different socioeconomic attributes w of different consumers, the expected delivery waiting time W_e is different. Therefore, the formula is as follows:


FIGURE 4: System diagram of the payoff module of the construction enterprise.

$$WS_i = \eta^{W_i - (W_e + w)}, \tag{8}$$
$$w = \text{Random Uniform}\,(-0.5, 0.5, 0).$$

The conditions for consumers to choose PB based on purchasing motivation are

$$C_1^{CC} = \begin{cases} 1, & M_1 \geq M_2, \\ 0, & M_1 < M_2. \end{cases} \tag{9}$$

Under this condition, the number of consumers purchasing PB is

$$C_1^C = 50 + \int C_1^{CC}. \tag{10}$$

The conditions for consumers to choose TB are

$$C_2^{CC} = \begin{cases} 1, & M_1 \geq M_2, \\ 0, & M_1 < M_2. \end{cases} \tag{11}$$

The number of consumers purchasing TB is

$$C_2^C = 100 + \int C_2^{CC}. \tag{12}$$

The model is shown in Figure 5, and the meaning of the symbols is shown in Table 1.

2.2.2. System Dynamics Model.
Based on the above three modules, the system dynamics model of PB mode adopted by Chinese construction enterprises is established. As shown in Figure 6, this model includes 4 level variables, 3 rate variables, 33 auxiliary variables, and 21 constants.

3. Model Simulation

3.1. Initial Value Setting and Simulation.
This paper sets the initial value based on the current data of PB in Jiangsu Province, China. According to the "Thirteenth Five-Year Development Plan for the Modernization of Construction Industry in Jiangsu Province," PB construction can apply for affordable housing projects, and for affordable housing projects built with PB, you can apply for a reward of no more than 300 yuan/m^2. When the prefabrication ratio of reinforced concrete structures is not less than 40%, the project will be subsidized, and the maximum subsidy for a single project will not exceed 18 million yuan per unit. Since China has determined that the minimum prefabrication ratio of PB is 50%, this paper sets the minimum prefabrication ratio as 50%. The prefabrication ratio set in the model has a linear relationship with the construction cost, in which the linear scale coefficient is 0.56 [36]. Based on the literature [37], when the prefabrication ratio of PB is greater than or equal to 50%, the cost of each additional 1% increase in the prefabrication ratio is about 29 yuan. This paper assumes that the construction area of the initial new construction project is 30000 m^2. According to the data query of China National Bureau of statistics in 2018, the average sales price of residential commercial housing is 10773.5 yuan/m^2. This paper uses Vensim PLE software to set TIME STEP to 0.0078125, and the initial value setting is shown in Table 2.

According to the setting of the initial value, the result of the adoption of PB mode in the construction enterprise is shown in Figure 7. The simulation results show that the adoption of PB mode by construction enterprises will reach a peak of 3.566 in the fourth year, that is, 3566 construction enterprises will adopt PB mode in engineering projects. However, after reaching the peak, the construction enterprises that adopted PB mode fluctuated in the form of shocks and eventually decreased gradually at a lower rate.

3.2. Analysis of Different Influencing Factors

3.2.1. Influencing Factors at the Government Level

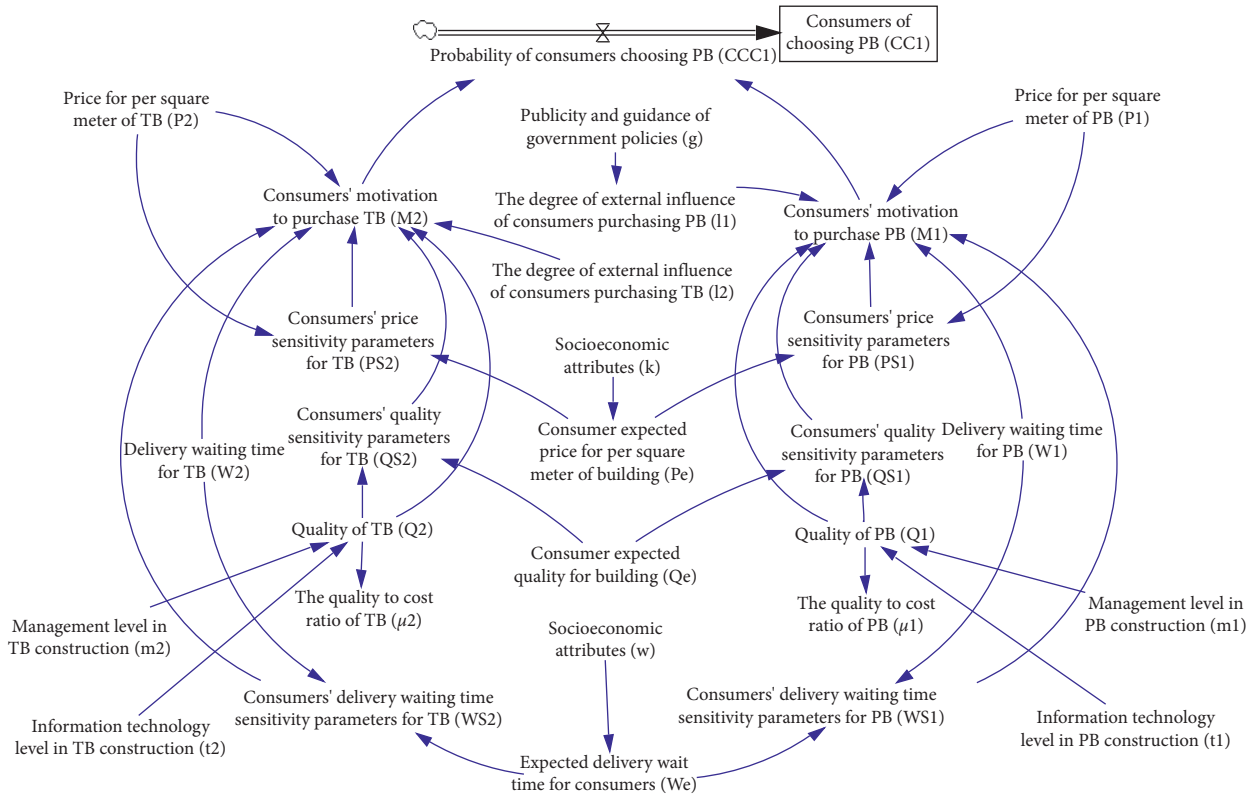
(1) The Impact of Government Subsidies. In this experiment, we changed the value of the D_Y subsidy factor and set the


FIGURE 5: System diagram of consumer decision-making module.

value to 0, 0.01, and 0.02, respectively, that is, the subsidy of 0, 100, and 200 yuan per square meter for the PB project. The simulation results are shown in Figure 8. The higher the amount of subsidy, the higher the peak value of D_Y and the faster the growth rate.

The simulation results show that government subsidies play a relatively important role in promoting the maturity of PB market, but for an already mature stable market, the role of government subsidies is relatively small.

(2) The Impact of the Publicity and Guidance of Government Policies. In this experiment, we will analyze the impact of government policy propaganda and guidance on the adoption of PB mode by construction enterprises. We set the value of g to 0.1, 0.2, and 0.3, respectively, that is, the government has promoted consumers' favorability of PB mode by 10%, 20%, and 30% through publicity and guidance. The simulation results are shown in Figure 9. The government's publicity and guidance strength can play a positive role in promoting the results of the previous PB adoption, and the effects of different publicity and guidance strengths are not very different. However, in the later stages of the market, different publicity and guidance efforts will show differentiated promotion effects. The greater the strength is, the better the market will adopt PB.

Therefore, in the early stage of PB being introduced into the market, the government should adopt the way of subsidy to increase the market share of PB, while in the later stage of the market, the government should adopt the way of publicity and guidance to further promote the development of PB mode.

3.2.2. Influencing Factors at the Construction Enterprise Level

(1) The Impact of the Initial "D_Y" Probability of the Construction Enterprise. In this experiment, firstly, we set the probability of initial adoption of PB by the construction enterprise to 20%, 30%, 40%, and 50%, respectively. The simulation result is shown in Figure 10. At the initial stage of the formation of PB market, it is very important to improve the probability of the construction enterprise's initial adoption of PB mode to quickly improve the market share of PB, and the higher the initial adoption probability, the greater the peak value and fluctuation of the market share. However, the market share of PB will gradually reach a balanced and stable state. The probability that the construction enterprise initially adopts PB mode has no differential impact on the later market equilibrium. Therefore, the probability that the construction enterprise initially adopts PB mode does not have a first-mover advantage for the final market share of PB mode.

(2) The Impact of the Information Technology Level. In the scenario where m_1 in the quality factor is set to 1, we set the value of t_1 in the quality factor to 1, 1.5, and 2, respectively, which means that the information technology level in the PB product quality factor is increased by 0%, 50%, and 100%, respectively. The simulation result is shown in Figure 11.

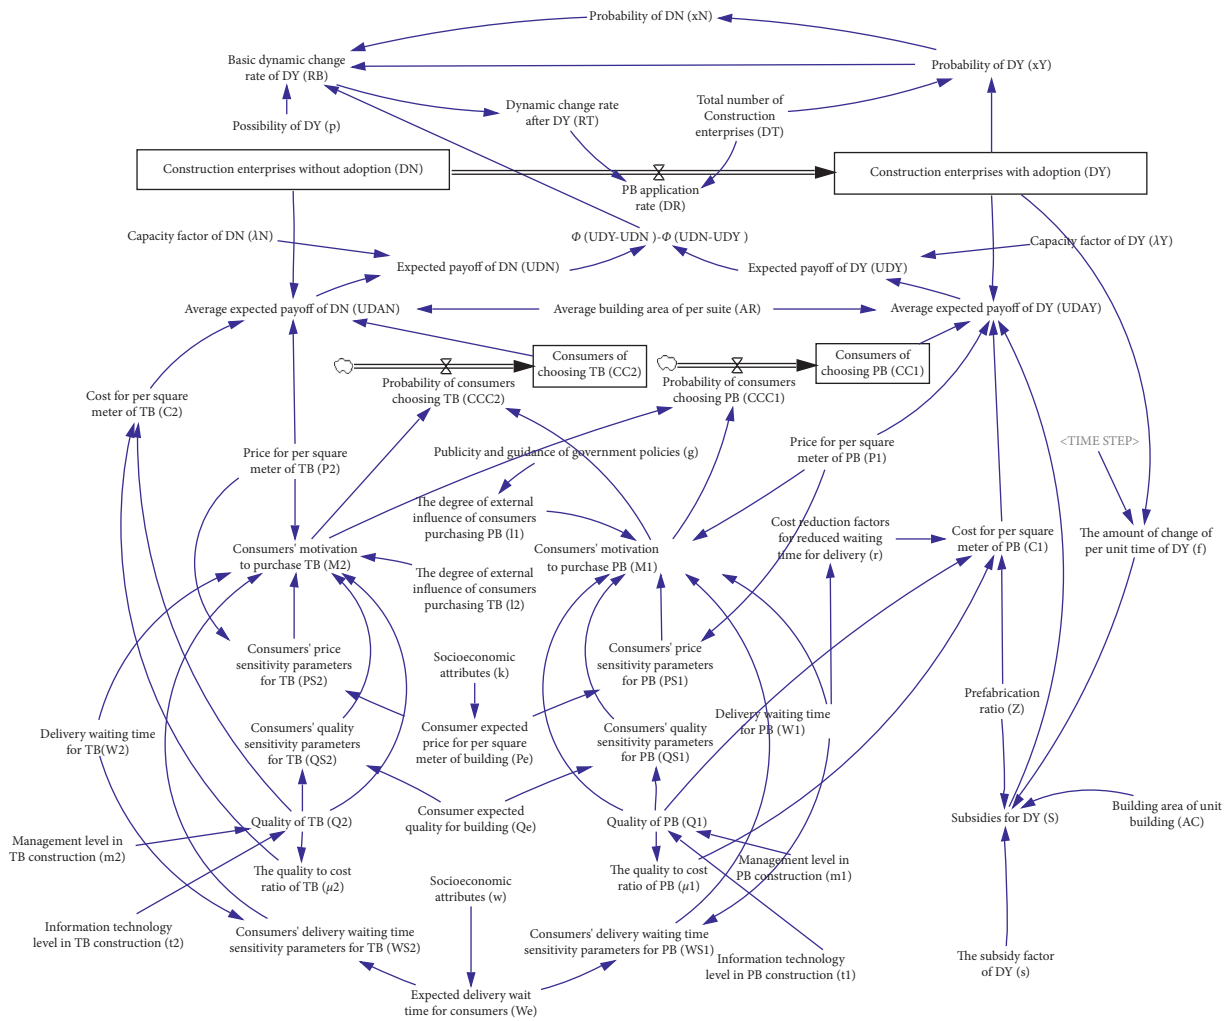
The results show that in the early process of the adoption of PB mode, different information technology levels have little impact on the market share of PB. However, in the later stages of the market, different information technology levels


FIGURE 6: The system dynamics model of adoption behavior of PB mode by Chinese construction enterprises.

have had a different effect on the adoption of PB. When t_1 increases from 0% to 50%, the growth rate of PB market share is greater than that when t_1 increases from 50% to 100%. It can be seen that the construction enterprise should follow the principle of moderation when deciding on the information technology level, and that too high information technology level has a limited effect on advancing the PB market share.

(3) The Impact of Quality Factors. In this part, we will analyze the comprehensive influence of construction management level and information technology level on the adoption of PB mode. First, we set the value of m_1 to 1.5 (the initial value of m_1 is 1). On this basis, we set the value of t_1 to 1, 1.5, and 2, respectively. The simulation result is shown in Figure 12.

As can be seen from the figure, the market share of PB mode shows a rapid rise and then a decline and a slow rise. Compared with Figure 10, when the value of m_1 is set to 1.5, the overall D_Y number is further improved. In the scenario where the value of m_1 increases, a higher t_1 will bring a larger PB market share. When t_1 increases from 0% to 50%, the increase in PB market share is greater than the increase when

t_1 increases from 50% to 100%. It can be seen that increasing m_1 and t_1 will play a superimposed role in promoting the growth of PB market share.

(4) The Impact of Price Factors. In this experiment, we change the value of P_1 to $P_1 - 0.1$ and $P_1 + 0.1$, that is, the price of PB products per square meter is reduced by 1,000 yuan or increased by 1,000 yuan. The simulation results are shown in Figure 13, and the market share of PB mode shows an evolutionary trend of rapid rise and then slow decline.

Reducing the value of P_1 can quickly increase the market share of PB in a short period of time and enable it to reach a higher share. However, after reaching the peak, the market share of PB has shown a slow downward trend. It can be seen that adopting a low-price strategy will help PB mode to quickly penetrate the market, but for the later stage of the market, the ability of price to further enhance the market share of PB is limited.

(5) The Impact of Delivery Waiting Time Factors. We set the value of W_1 to 0.75, 1, and 1.25, respectively, that is, the delivery waiting time of PB is set to 0.75, 1, and 1.25 years.

TABLE 2: Setting of initial simulation value.

| Variable	Category	Initial value	Unit
Initial value of D_Y	Level	0.039	Thousand
Initial value of D_N	Level	6.684	Thousand
D_T	Constant	6.723	Thousand
λ_Y	Constant	1	1
λ_N	Constant	1	1
P_1	Constant	1.07735	Ten thousand yuan
P_2	Constant	1.07735	Ten thousand yuan
P_e	Constant	0.8	Ten thousand yuan
W_1	Constant	1.5	year
W_2	Constant	2	year
W_e	Constant	1	year
t_1	Constant	1	1
t_2	Constant	1	1
m_1	Constant	1	1
m_2	Constant	1	1
Q_e	Constant	3	1
A_C	Constant	30000	m^2
A_R	Constant	100	m^2
Z	Constant	0.5	1
s	Constant	0.03	Ten thousand yuan
g	Constant	0	1
FIGURE 7: Initial simulation results.

The simulation result is shown in Figure 14. It can be seen from the figure that under the condition that consumers set in this paper have the same sensitivity to product price, quality, and delivery waiting time, different delivery waiting times have little difference on the market share of PB. However, in the early stage of the market, the delivery waiting time has a certain impact on the peak of the PB market share, but this differential impact is not very obvious.

4. Discussion

In the above simulation results and analysis, it can be found that the changes of different factors will have a different impact on the adoption strategy of the construction enterprise. It is necessary to analyze the most favorable aspects of different factors affecting the construction enterprise's adoption of PB mode from different angles. This paper will analyze the influencing factors from the following perspectives.

4.1. Influencing Factors at the Government Level. From the perspective of changing government subsidies, government subsidies play a positive role in promoting construction enterprises to adopt PB mode, especially in the initial stage of adopting PB mode by construction enterprises, which confirms Li et al.'s research results [14]. Also, the higher the government subsidy is, the higher the peak value of construction enterprises adopting PB mode is and the longer it will continue to grow. However, for the PB market that has gradually stabilized, government subsidies have no obvious promoting effect. Timely reduction or termination of government subsidies can effectively reduce fiscal expenditures and achieve good market effects.

From the perspective of improving the publicity and guidance of government policies, the government's positive guidance for PB mode has improved consumers' favorability of PB mode, which in turn promoted the long-term and steady development of the PB market, which is consistent with Wang et al.'s research results [26]. This effect is not obvious in the initial stage of the PB market but gradually widened the gap in the later stage. Positive publicity and guidance have a subtle effect on the development of the PB market, and the longer the time, the more obvious the effect.

In summary, in the early stage of PB mode entering the market, the government should use subsidies to increase the market share of PB. Although the publicity and guidance of government policies are more obvious in the later stage of the PB market, the government should still adopt positive publicity and guidance methods in the early stage of the PB market to further promote the development of PB mode.

4.2. Influencing Factors at the Construction Enterprise Level. From the perspective of changing the initial acceptance probability of the construction enterprise, higher initial acceptance probability of the construction enterprise is of great significance to the formation of the initial PB market, which is conducive to the rapid improvement of the maturity of the PB market. However, excessive pursuit of the probability of construction enterprises initially adopting PB mode is not conducive to the stable development of the PB market. In the long run, the adoption intention of the construction enterprise should follow a step-by-step process and maintain a relatively stable growth trend.

From the perspective of changing the level of information technology, the improvement of the level of PB construction information technology has significantly accelerated the rate at which construction enterprises adopt PB mode. However, the degree of improvement in the level of PB construction information technology is not linearly related to the rate at which construction enterprises adopt PB mode. When the PB construction information technology level is raised to a higher level, the impact of the increase in the PB construction information technology level on the increase in the rate of the construction enterprise
Figure 8: Simulation results of changes in government subsidies.

Figure 9: Simulation results of changes in government policy publicity and guidance.

adopting PB mode will show a decreasing trend under the same proportion each time. Therefore, it is necessary to uphold the principle of moderation for the improvement of the information technology level, and blindly pursuing the unilateral improvement of the information technology level may not achieve the expected results.

From the perspective of changing quality factors, when the level of PB construction management improves, the corresponding improvement in the level of construction information technology will have a significant impact on accelerating the increase in the rate at which construction enterprises adopt PB mode. While maintaining the

FIGURE 10: The simulation result of the initial "D_Y" probability change.

FIGURE 11: Simulation results of changes in the information technology level.

improvement of the construction management level, the improvement of the same proportion of the information technology level will sharply reduce the increase in the rate of construction enterprises adopting PB mode. It can be seen that the improvement of the construction management level has a positive effect on the adoption of PB mode by the construction enterprise, and the improvement of the construction management level and the information technology

level at the same time will facilitate the rapid development of PB mode and maintain the PB market share for a long time.

From the perspective of changing price factors, compared with increasing the price of PB per square meter, the price reduction has shown an advantage in the early stage of the PB market. The price lower than the market price has been supported by more consumers, which has affected the construction enterprise's adoption of PB mode. Therefore,
Figure 12: Simulation results of quality factors.

Figure 13: Simulation results of changes in price factors.

the price factor has a more direct impact on the PB market, and the lower price indirectly stimulates the construction enterprises to improve the adoption of PB mode.

From the perspective of changing the delivery waiting time factor, the reduction in PB delivery waiting time does not significantly affect the rate at which construction enterprises adopt PB mode. This also shows to a certain extent

that when the delivery waiting time of the building is within the consumer's tolerance range, it will not cause strong rejection due to the long delivery waiting time. Therefore, the impact of the delivery waiting time factor on the construction enterprise's adoption of PB mode is not significant.

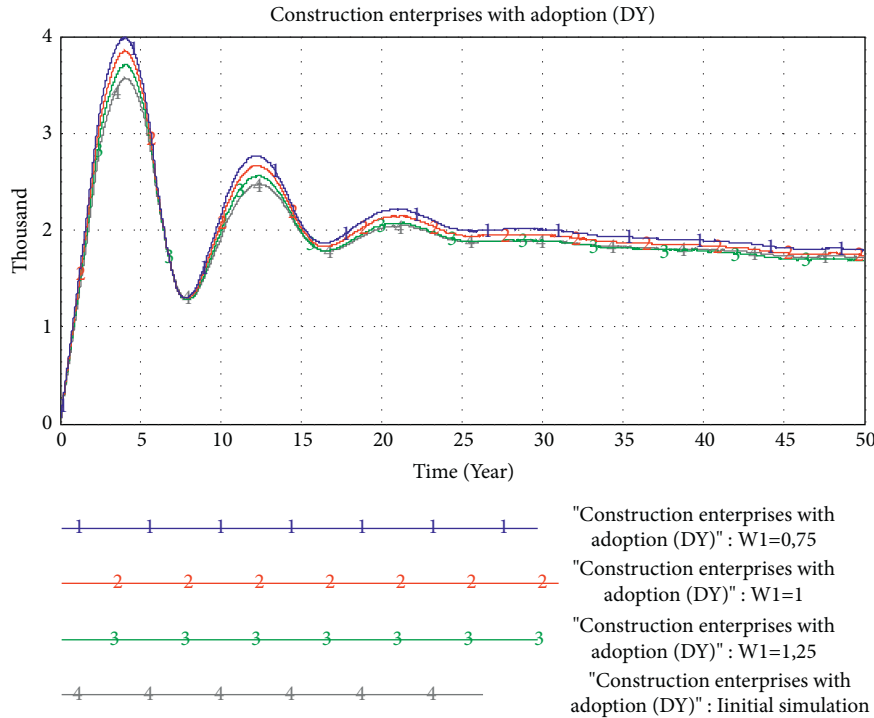
To sum up, we can draw the following conclusions. Firstly, the initial adoption intention of the construction


FIGURE 14: The simulation result of the change of the delivery waiting time factor.

enterprise should adopt the strategy of gradual improvement. Secondly, the construction management level and the information technology level in the quality factor of PB have complementary effects. At the same time, their improvement can not only quickly increase the PB market share but also maintain the stable and good development of the PB industry. Thirdly, the reduction of the price factor is conducive to the rapid increase of the PB market share in the short term. Fourthly, the delivery waiting time factor will not have a major impact on the construction enterprise's adoption of PB mode.

5. Conclusions and Recommendations

PB has developed earlier in some developed countries, such as the United Kingdom and the United States, and already has a certain market scale [38]. However, PB mode is still in the ascendant in China, but based on the needs of China's energy saving, emission reduction, and green development, PB mode has attracted the attention of many scholars in recent years.

Combined with evolutionary game theory, this study establishes a system dynamics model of Chinese construction enterprises' adoption behavior of PB mode under the scenario of multiagent interaction and uses the data of Jiangsu Province in China for simulation analysis. The purpose is to clarify the behavior mechanism of Chinese construction enterprises' adoption of PB mode and the evolution law of PB market share, so as to provide a certain theoretical basis for the vigorous development of PB mode in China. The corresponding conclusions and recommendations are as follows:

(1) Government subsidies play an important role in promoting the maturity of the PB market. Maintaining certain government subsidies can ensure a longer and more stable market share of PB mode. However, for the already more mature market, the role of government subsidies is relatively small. Therefore, government subsidies can be gradually reduced or cancelled after promoting the development of PB mode to achieve a good market effect. At the same time, the publicity and guidance of government policies have gradually produced the effect of promoting the market share of PB, which requires the accumulation of preliminary work. Therefore, in the early stage of the introduction of PB mode to the market, the government should simultaneously provide subsidies to construction enterprises and publicize and guide consumers to increase the market share of PB and further promote the development of PB mode.

(2) The initial acceptance probability of the construction enterprise should not be excessively pursued. The higher the initial probability of adoption, the greater the peak of the PB market share and the greater the volatility, which is not conducive to the stable development of the PB industry. Also, the probability that the construction enterprise initially adopts PB mode has no differential impact on the later market equilibrium state. Different initial acceptance probabilities of the construction enterprise will make the market share of PB reach a gradually balanced and stable state. Therefore, the probability that the construction enterprise initially adopts PB mode

does not have a first-mover advantage for the final market share of PB mode.

(3) The reduction of the price factor can quickly increase the market share of PB mode in a relatively short period of time. However, in the later stages of the market, lowering the price factor has limited ability to further increase PB's market share. The reduction of price factors cannot maintain the lasting and stable development of the PB market. The simultaneous improvement of the construction management level and the information technology level in the quality factors has an important impact on the market share of the later stage of PB mode and can maintain the steady growth of the PB market. Compared with price factors and quality factors, the delivery waiting time factor has no significant impact on the market share of PB mode. Therefore, the delivery waiting time factor does not need to be considered more by the construction enterprise in the decision to adopt PB mode. In summary, the PB industry still needs to promote the development of PB with the promotion of quality improvement as the main direction. Under the premise of small price fluctuations and stable quality improvement, the reduction in delivery waiting time should be gradually reduced, so that the PB industry can go more stable and go further.

This paper also has some limitations. For example, the model does not consider the specific components of construction cost, the relationship and behavior of other stakeholders, etc. In addition, this paper mainly studies the adoption behavior of PB mode by Chinese construction enterprises and comes to the conclusion that the universality and reference significance of management conclusions need to be strengthened. In the future, we can consider the relationships and behaviors between more stakeholders, add more abundant influencing factors, and promote the steady development of PB.

A new analysis method for the environmental stability of uranium tailing ponds is established in this paper, and the stability intervals and environmental stability rates of indicators are defined in precise mathematical language and analyzed with examples. The results show that the overall environmental stability of this uranium tailings pond is still in a poor state after the first phase of decommissioning treatment, and special decommissioning treatment should be carried out for factors such as pH and radionuclides Po and Pb. Using the powerful nonlinear mapping function of the artificial neural network, a radial basis function neural network algorithm was constructed to predict the environmental stability of the uranium tailing pond. It provides a new feasible method for the comprehensive evaluation technology of uranium tailings ponds. *Accuracy in DOA Estimation.* The research work in this paper mainly analyzed the environmental stabilization process and stability of decommissioned uranium tailings ponds, proposed a new concept of environmental stability with ecological and environmental protection concepts and gave it a new connotation, established an environmental stability evaluation index system for decommissioned uranium tailings ponds through index screening by using rough set theory, comprehensively considered the influence of environmental factors such as external wastewater and exhaust gas, and realized the multifactor. The system of evaluation indexes for the stability of decommissioned uranium tailings ponds was established by combining multiple factors, and the long-term monitoring and modeling of the environmental stabilization process of decommissioned uranium tailings ponds was carried out by using mathematical methods. The results show that the RBFNN-GA algorithm can reduce the training error of the random radial basis function neural network, improve the generalization ability of the network, and make it capable of handling large data sets.

1. Introduction

The goal for the governance and management of uranium metallurgical tailings is that the decommissioning environment must be restored to an acceptable level that allows for the protection of present and future personnel and the environment, with considerations for future generations that include potential radiation exposure, economic consequences, and requirements for monitoring and maintenance, and that do not place an undue burden on future generations. However, the current concept of stabilization of tailings ponds in China only considers their mechanical properties and uses only the mechanical stability of tailings dams as a criterion for judging the safety or otherwise of uranium tailings ponds, which obviously can no longer meet the needs of ecological and environmental

protection and sustainable development of uranium tailings pond decommissioning management [1]. From the perspective of protecting the ecological environment and safeguarding the safety of public life and property, it is of great significance to analyze and study the stabilization process and stable state of decommissioned uranium tailings ponds [2]. Therefore, it can better reflect the objective existence of ambiguity. For uranium tailings ponds, due to the complex environmental factors, how to define the stability of various environmental monitoring indicators and the overall stability of the environment is itself a difficult problem to determine. However, the current analysis and evaluation of the stability of uranium tailing ponds only consider the mechanical stability of tailings dams, and only the mechanical stability index of tailing pond dams as the evaluation index of the safety of decommissioned uranium tailing ponds obviously cannot meet the needs of ecological environmental protection and sustainable development of decommissioned uranium tailing ponds. In this paper, based on the systematic examination of the factors influencing the environmental stability of uranium tailings ponds, the analysis of the change pattern of environmental monitoring items of uranium tailings ponds over time, the analysis of the environmental stabilization process characterization of uranium tailings ponds, a new concept and connotation of the environmental stability of uranium tailings ponds in a comprehensive and systematic way, the establishment of the environmental stability evaluation index system of decommissioned uranium tailings ponds were proposed [3]. The analysis method of environmental stability of tailings was constructed, and the quantitative calculation of environmental stability rate was carried out, and the environmental stability grade of each month was divided, on this basis, the environmental stability of existing decommissioned uranium tailings ponds was evaluated and predicted, and a new method of environmental stability analysis and prediction of decommissioned uranium tailings ponds was systematically established, which further enriched and improved the comprehensive evaluation technology of decommissioned uranium tailings ponds, and has a positive impact. It has positive significance and impact on the decommissioning management and environmental protection of uranium tailings ponds [4].

It is generally believed that uranium mining and metallurgical tailings ponds do not cause great impact on the environment after decommissioning and treatment according to the design, but with the passage of time, influenced by external factors (including earthquakes, rainfall and human damage, etc.), the possibility and infiltration of radionuclides from uranium mine tailings ponds into the reservoir area and mine groundwater through the bottom and dam of the reservoir increases greatly with the growth of its age and the infiltration of radionuclides from the groundwater in the reservoir, causing pollution of the reservoir area and mine water environment, which then spreads to various organisms in the biosphere and causes serious ecological hazards, and this hazard has the characteristics of long-lasting, hidden, large degree of harm and difficult to repair; based on the above problems of

decommissioned uranium tailings ponds, the effect of treatment in the end needs to be scientifically assessed [5]. With time, some uranium metallurgical tailings ponds are inadequately monitored for safety and ineffective after decommissioning treatment. The leakage of toxic pollutants from uranium tailings dams in the nuclear industry can cause serious accidents, will have a significant impact on the natural environment, and negatively affect the safety of the living environment, and with the migration of radioactive elements, the impact will be further expanded and is difficult to recover. Therefore, strengthening the safety supervision of uranium tailings dams, the treatment of pollutants in uranium tailings dams, and the scientific assessment of the treatment effect are of great practical importance to help people understand the current situation of uranium tailings dams and the treatment effect and to inform people about the safety of nuclear production and social and environmental safety.

At present, there is no clear regulation and management for the effect of management of uranium mine tailings ponds after decommissioning in China, which leads to the lack of clarity of environmental protection departments at all levels on the issue of the effect of management of uranium mine tailings ponds after decommissioning, and the management of uranium mine tailings ponds after decommissioning is a comprehensive work, involving safety supervision, environmental protection, and many other departments. Only a scientific assessment of the effectiveness of the current situation of the tailing's ponds can improve their shortcomings and defects, improve the effectiveness of governance, and ensure the stability of the environmental impact of the uranium mine tailings ponds after decommissioning, which is of great significance to ensure the safety of people's lives and health. The environmental management of uranium tailings ponds is only based on whether the monitoring values of each item meet the standards; i.e., it is usually considered safe to be lower than the emission standards and unsafe to be higher than the emission standards; however, due to the special nature of uranium tailings ponds themselves, their surroundings are easily affected by various factors such as rainfall, earthquakes, dam structure, and human intervention, and the data obtained from monitoring at different moments often vary greatly. We perform 30 trials on each training set and test set and then take the median as the result to reduce the impact of random errors. The stabilization process of each environmental indicator needs to be considered comprehensively to make an objective and effective analysis and evaluation of the environmental stability state of uranium tailings ponds.

2. Status of Research

Uranium tailings ponds, as a major hazard source and a long-term potential source of huge radioactive pollution, are ranked 18th in the international ranking of disaster accidents, in which radionuclides, heavy metals, and other toxic and hazardous substances have caused serious pollution to the ecological environment around the tailings ponds through diffusion and migration, posing a serious threat to

the safety of downstream residents and facilities, and the quality of their environment is increasingly becoming a concern [6]. Because of the current research status of uranium tailings ponds and related problems of stability research, the author summarized the current research status of environmental stability analysis of uranium tailings ponds at home and abroad by reading a large amount of relevant literature on safety, environment, and stability of uranium tailings ponds at home and abroad [7]. It is important to focus on the three aspects of tailings dam seepage stability analysis, stability analysis of tailings dam deformation and mechanical characteristics, and comprehensive evaluation of uranium tailings pond environment [8]. The analysis methods for tailings dam stability mainly include numerical analysis method and limit equilibrium analysis method, the numerical analysis method is only applied to theoretical discussion and analysis, while the limit equilibrium method is more used in engineering practice; the comprehensive evaluation of the environment mainly applies fuzzy comprehensive evaluation, artificial neural network evaluation, and grey comprehensive evaluation methods [9]. Since radioactive waste is both radiation hazardous and chemically toxic, the treatment of uranium tailings should provide an acceptable level of environmental protection and must provide an acceptable level of human health protection, ensuring that it is within the limits set by the state and predicting that the impact of uranium mining and metallurgical facilities and radioactive waste treatment on the health of future generations is below the dose level of the relevant standards [10]. The residual uranium, needles, radium, etc. and decay substrates in uranium tailings have half-lives of several years, decades, centuries, or even tens of thousands of years and will have a long period of radioactive and chemical hazards to the surrounding atmosphere, water bodies, soil, vegetation, and other apparent environments, groundwater, and organisms, etc. Therefore, the decommissioning treatment of uranium tailings should adopt advanced technologies and methods, appropriate safety, and control measures as far as possible, to ensure that the treatment of uranium tailings the measures should be sufficiently stable and safe for a long period [11].

The environmental performance assessment method is now mainly applied to enterprise environmental performance, which mainly refers to the main achievements and effects achieved by enterprises in their business activities, due to environmental protection and management of environmental pollution; generally speaking, enterprise performance refers to the economic benefits of enterprises, comprehensive hierarchical analysis, and principal component analysis to build an index system to systematically assess the economic performance or environmental performance [12]. An assessment method in the systematic assessment and theoretical assessment results are more objective; the system construction is also more flexible; the disadvantage is that the implementation of a certain degree of difficulty requires a certain theoretical basis and scientific research capabilities to build the index system and determine the assessment scheme. In the stability study of tailings dam deformation and mechanical characteristics, the stability

analysis is mainly carried out using the limit equilibrium method [13]. Taking the tailings pond in Hunan Province as an example, the influence of tailings and its medium parameters on the stability and dynamic response of the tailings pond was analyzed by a combination of numerical simulation and model test, and the characteristics and laws of the seismic dynamic response of the tailings pond were summarized systematically by static analysis and dynamic calculation [14]. Baghaee et al. introduced the reliability theory into the stability of tailings dams based on the limit equilibrium theory and the traditional safety factor method. The feasibility and effectiveness of this method were verified [15]. The stability of tailings dams was analyzed based on the finite element method using ANSYS software, which verified the significant advantages of the numerical method in the stability calculation of tailings dams and effectively reflected the stability of tailings dam, providing a certain basis for the safety management of tailings ponds. The stability of the tailings pond accumulation dam was analyzed by using the circular arc bar division method, and the safety coefficient of the dam was calculated by the mechanical geometric model, which effectively reflects the current situation of the tailings dam stability. A three-dimensional numerical simulation study of the tailings dam was carried out using FLAC3D software, and the stress distribution laws of the tailings dam deformation were derived.

Based on the environmental monitoring data of uranium tailing ponds, the dynamic change pattern of environmental indicators over time was systematically analyzed, and the decommissioning management situation and stabilization trend of each environmental monitoring item were initially analyzed. The environmental stability evaluation index system of decommissioned uranium tailing ponds was constructed by considering three aspects, namely, external seepage water, atmospheric environment, and radioactive pollution, and the core index system of comprehensive environmental stability evaluation was finally determined by applying the method of rough set attribute simplification for index screening; the weights of each evaluation index were determined by using the GO method to construct a judgment matrix, and the stability grade of uranium tailing ponds was determined according to the weighted average principle. The environmental stability prediction model based on the BP neural network was established to predict the environmental stability rate and stability grade of a decommissioned uranium tailing pond by using its powerful nonlinear mapping function, and the prediction results were in good agreement with the actual situation.

3. Analysis of Radial Basis Function Neural Network Algorithm with Genetic Algorithm for Environmental Restoration and Treatment Effectiveness Evaluation of Decommissioned Uranium Tailings Ponds

3.1. Radial Basis Function Neural Network Algorithm Design for Genetic Algorithm. Most of the existing neural networks are improved in structural design and parameter

training; the more complex the structure, the more parameters are often required and the more demanding the correction algorithm. The radial basis (RBF) neural network has been chosen and widely used by most scholars because of its simple structure and its ability to approximate arbitrary nonlinear functions. RBF neural network is a novel and effective feedforward neural network with the best approximation and global optimum performance. RBF neural network is proposed based on the feature that neuronal cells in the human brain have a local response, which simulates the local tuning in the human brain. The generalization situation is also very good, and the generalization results are basically consistent with the test set data. It shows that the results of the random radial basis function neural network in the classification task are also satisfactory. The RBF neural network is a local approximation neural network structure with local tuning and mutual coverage of the receptive domain. The activation function is a radial basis function with multivariate interpolation, and the training method is fast and easy, without the problem of local optimality, which makes RBF neural networks have a wide range of applications in many fields, such as function approximation, classification, pattern recognition, regression problems, and prediction and signal processing. Structurally, RBF neural network has a simple topology and a simple and clear learning and training process [16]. It uses the radial basis function as the activation function, and the nodes in the hidden layer produce a larger output only when the input signal is near the center of the radial basis function. The RBF neural network consists of three layers: the input layer, the hidden layer, and the output layer. There is no weight connection between the input layer to the hidden layer, and the input vector is mapped directly to the hidden layer. The mapping from the input layer to the hidden layer is nonlinear; i.e., the transformation function of the hidden layer is nonlinear. There are connection weights between the implicit layer and the output layer, and the mapping from the implicit layer to the output layer is linear; i.e., the output of the entire network is a linear weighted sum of the outputs of the implicit layer. The topology diagram with structural RBF neural network is shown in Figure 1.

This layer is mainly to pass the input samples to the hidden layer. Before that, data normalization, such as normalization, needs to be done on the input samples so that the input values of each node are in the same order of magnitude to avoid the effect of magnitude. The second layer is the hidden layer, the number of neurons in the hidden layer J varies with the application to be solved, and the activation function of each hidden node uses a radial basis function. The radial basis function is a nonnegative nonlinear function that is symmetric about the centroid and decays radially, which has a local response function. The implicit layer performs a nonlinear transformation of the input vector to map the low-dimensional input vector into the high-dimensional space, where it solves problems that would otherwise be unsolvable in the low-dimensional space.

$$h_j(X) = \varphi\left(\frac{\|X - c_i\|}{\sigma_j}\right),$$

$$y_k = \sum_{j=1}^{J} w_{ik} h_j(X). \tag{1}$$

The main difference between RBF neural networks and other feedforward neural networks is the hidden layer. The "base" of the implicit layer space is a radial basis function so that once the center of the radial basis function of each implicit layer node is determined, the input vector can be mapped to the implicit layer space without the need to connect through weights. The diversity of neural networks is reflected not only in the network model determined by the number of nodes in the hidden layer but also in the radial basis functions selected. The radial basis function of the RBF network is nonlinear, and there are many parameters to be set in the process of building the RBF neural network model, including the center and width of the radial basis function and the connection weights of the connection layer. Moreover, solving the outer weight of the random radial basis function neural network by the least square method is a linear operation, and it is very fast in the calculation. Compared with solving the center and smoothing factor of the neural network through supervised learning, this method can effectively improve the learning efficiency of the network. The choice of the center and width of the radial basis function seriously affects the performance of the RBF neural network [17]. At the early stage of the development of RBF, many scholars have incorporated many optimization algorithms for the parameter optimization of RBF neural networks. It was found that once the center and width of RBF were determined, the RBF neural network became a linear system of equations about the connection weights from the input to the output, at which time the connection weights of the output layer could be obtained by solving with the least-squares method or by training with gradient algorithms such as the gradient descent method. How to select the center and what training weight method to use became the research direction of many scholars on RBF network learning.

$$p_K(f, f_{wn}) = \sqrt{\int_K [f(x) - f_{wn}(x)]^2 dx},$$

$$h_x(y, \theta) = g\{\theta \cdot [x + y] \cdot (x - y)\} \prod_{i=1}^{m} \sqrt{\theta_j}. \tag{2}$$

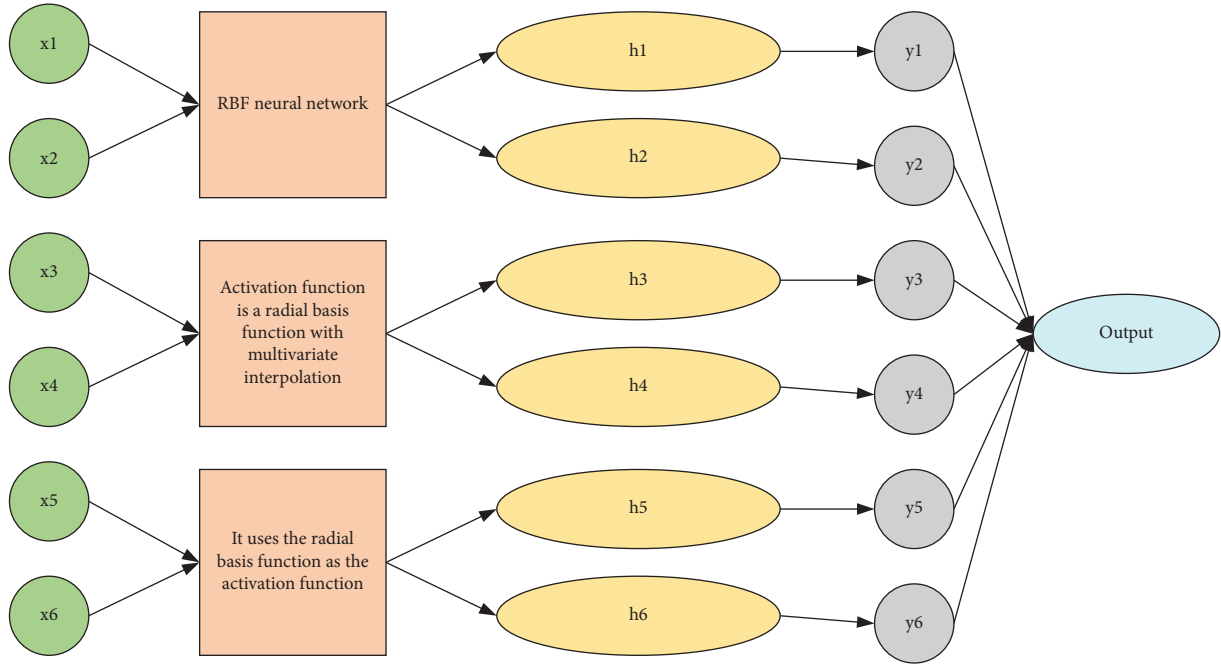
To explore the function approximation ability of the random radial basis function neural network, the thought method of convergence proof of random weighted feedforward neural network is applied to prove that the random radial basis function neural network can approximate any continuous function. The convergence error between the stochastic radial basis function neural network and the approximated function can be known from the analysis process. As the number of neuron nodes n increases, the convergence error gradually decreases tending to 0. It is easy to reach the error range that one can accept, so the neural


FIGURE 1: RBF neural network topology.

network is an efficient function approximator. The work has shown theoretically that the stochastic radial basis function neural network is capable of approximating arbitrary continuous functions and is also an efficient function approximator. To verify the above theoretical results, we give algorithms on how to solve for the weights of the output layer of the stochastic radial basis function neural network.

$$t_j = \sum_i^m \beta_i g\left(\frac{\|X_i + y_j\|}{\varsigma_i^2}\right),$$

$$H = \begin{bmatrix} g\left(\frac{\|X_i + y_j\|^1}{\varsigma_i^2}\right) & \cdots & g\left(\frac{\|X_i + y_j\|^3}{\varsigma_i^2}\right) \\ \cdots & \cdots & \cdots \\ g\left(\frac{\|X_i + y_j\|^2}{\varsigma_i^2}\right) & \cdots & g\left(\frac{\|X_i + y_j\|^5}{\varsigma_i^2}\right) \end{bmatrix}. \quad (3)$$

This idea has been used in several studies, such as the introduction of kernel methods for data classification in over-the-limit learning machines and stacked kernel networks (SKNs). However, a neural network model of the class of overdetermined learning machines, which essentially solves for a stochastic suboptimal solution of the network, is difficult to achieve the same results in large data. Stacked kernel networks, on the other hand, successfully apply kernel methods to classification tasks but also point out that the use of kernel methods can easily lead to overparameterization and overfit the network. Therefore, the introduction of kernel methods into deep learning models requires further exploration (Figure 2).

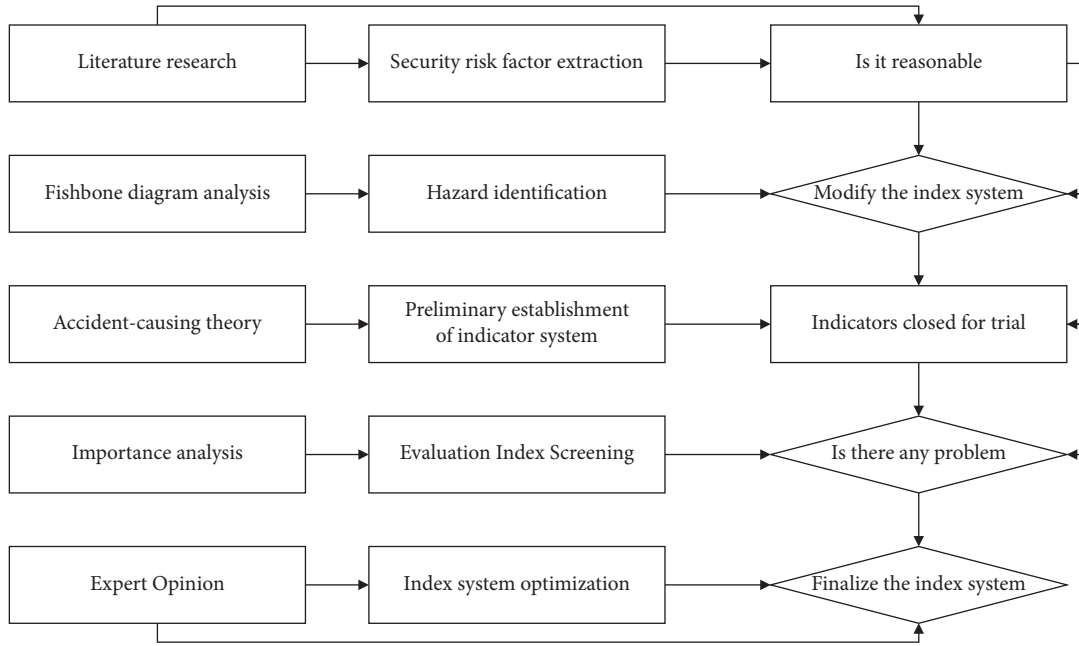
Therefore, instead of using these two ways of introducing kernel functions, this topic uses the ordinary radial base layer. Although this weakens the role of the kernel method, this cuts down the number of parameters in the model and makes it easier to avoid the problem of model overfitting due to overparameterization. In addition to the background related to the kernel method, the Gaussian function's properties are also of interest. In this way, the order of things based on the comparison feature is determined by the comparison result of a certain feature, and the order obtained from this comparison is used to judge the general situation of the membership function of these things for the specific feature, and then, the membership function is further constructed. To solve, the binary comparison ranking method is different according to the contrast measure. For example, the local approximation property, where the parameters associated with a local target space are only a small fraction of the total parameters, also fits some mechanisms of the organism. In terms of the mathematical nature of the function, the target of activation is not the data itself but the distance of the data from a particular central vector, and the fact that Gaussian functions have infinite order derivatives is also an advantage [18]. As a result, this topic proposes a radial basis self-encoder model, which consists of an input layer, a radial basis kernel function layer, and a self-coding layer, which is an improvement of the self-classical self-encoder model. Mathematically, in essence, the process of solving the model parameters is to solve the optimization problem shown in equation (4), which is often nonconvex, so it is important to choose a suitable solution. In this topic, we will combine the properties of Gaussian functions and use a gradient-based optimization algorithm for the parameter solution.


Figure 2: Flow of constructing safety risk assessment index system for tailing ponds.

$$\theta^* = \arg\max L\left(\theta^2, x_1, g^2\left(f\left(\phi\left(X\right)\right)\right)\right). \tag{4}$$

Like the classical self-encoder model, the training of the radial-based self-encoder model proposed in this paper also employs a back-propagation algorithm and uses a gradient-based training method. The data first go through a forward propagation process to get the output under the current model parameters, then, some loss function is used to measure the deviation of the current output from the true value, and then, the current model parameters are corrected and the next calculation is performed through a backward propagation process, and such an iterative process continues until a specific condition is satisfied and terminated. In this topic, the Gaussian function is chosen as the activation function for the radial basis function layer, and since the Gaussian function contains two hyperparameters center vector and variance, which can be selected in various ways, this section will discuss the methods for selecting these two hyperparameters as well as the overall network optimization methods (including loss function selection, activation function selection for the classical layer, and gradient-based methods for overall network parameter optimization).

3.2. Experimental Design for the Evaluation of Environmental Restoration and Treatment Effects of Decommissioned Uranium Tailings Ponds. ISO 14001 is the number of environmental management systems certified by the International Organization for Standardization. It is a standard developed in response to the global environmental damage and environmental pollution that is becoming more and more serious, global warming, destruction of the ozone layer, reduction of biodiversity, and other major ecological and environmental problems that threaten the future survival and sustainable development of mankind, to comply

with the development of international environmental protection, to take the road to sustainable development, and following the needs of international economic and trade development. ISO 14001 states that environmental performance is the measurable effectiveness of an organization's environmental management system based on environmental policies, objectives, and targets to control its environmental factors. The "organization" is the actor, which can be either a company or a government (department). The source of environmental performance varies from subject to subject [19]. Depending on the source of environmental performance, environmental performance is divided into organizational environmental performance and regional environmental performance.

Some scholars define environmental performance as an evaluation indicator of production efficiency that takes environmental issues into account and is used to analyze some of the problems of economic development in harmony with the environment, with its meaning being mainly the ratio of the economic value of products and services that meet human needs to the environmental load, i.e., the corresponding economic benefit per unit of environmental impact. The definition states that to improve environmental performance, people must take the initiative to control environmental pollution and protect the environment while carrying out development. Through the scientific and reasonable evaluation of the environmental efficiency of enterprises, individuals, or related organizations in the work of environmental management assessment, we can find out some necessary links between the situation of environmental protection and economic growth and some key problems of mutual constraints and influences between the two, to further provide new reference basis for managers or plan makers and then on a certain basis to revise. Obviously, it has been unable to meet the needs of ecological environment

protection and sustainable development for the decommissioning of uranium tailings ponds. Whether it is from the perspective of protecting the ecological environment or protecting the safety of public life and property, the analysis and research on the stabilization process and stability status of decommissioned uranium tailings ponds are of great research significance. Therefore, environmental performance assessment is a rather important way and assessment tool for individuals, enterprises, institutions, and projects, as shown in Figure 3.

As a systematic process for assessing and measuring environmental performance in all aspects of an organization's internal economy, environmental performance assessment provides a reliable and optimal guide for program design and implementation of economic investments, etc. within an organization. The process includes the selection of parameters, data collection and statistical analysis, information evaluation based on environmental performance guidelines, evaluation reports, and academic communication, and targeted periodic review and improvement of the evaluation process. As an internal implementation process and management tool, the purpose of environmental performance assessment is to provide managers with reliable and verifiable external environmental information of varying relevance to assess the gaps and shortcomings between an organization's environmental performance and the standards set by the organization's managers and to make further improvements and optimizations [20]. In the whole process of collecting and evaluating information, environmental performance assessment has a clear continuous (including past, present, and future) character compared to other methods. The purpose of environmental performance assessment is to provide a detailed description of the strengths and weaknesses of environmental conditions, to reveal the overall situation of environmental policies and environmental changes, to significantly improve the environmental awareness of all sectors of society, and to scientifically measure the level of management of organizations and their environmental managers. A sound environmental performance assessment is a prerequisite for the objective and effective management of organizations and projects.

The concept of stabilization of uranium tailings ponds only considers their mechanical properties, and only the mechanical stability index of tailings ponds as the evaluation index of the safety of decommissioned uranium tailings ponds can no longer meet the needs of ecological environmental protection and sustainable development of decommissioned uranium tailings ponds. The concept and connotation of environmental stabilization of decommissioned uranium tailings ponds proposed in this paper objectively reflect the necessity of evaluating the environmental stability of decommissioned uranium tailings ponds, which requires comprehensive consideration of environmental radiation, effluents, and other factors, to establish a reasonable evaluation index system, which is also the key to the evaluation of the stability of decommissioned uranium tailings ponds. The evaluation index system should be based on a system perspective, on the one hand, to grasp the key factors, and on the other hand to consider all other factors,

FIGURE 3: Statistics on environmental indicators.

so that the evaluation index system can reflect the actual situation of the evaluated object comprehensively and objectively. For the uranium tailings pond system, the index system should comprehensively include seepage water environmental indicators, atmospheric environmental indicators, and radiation environmental indicators (Figure 4).

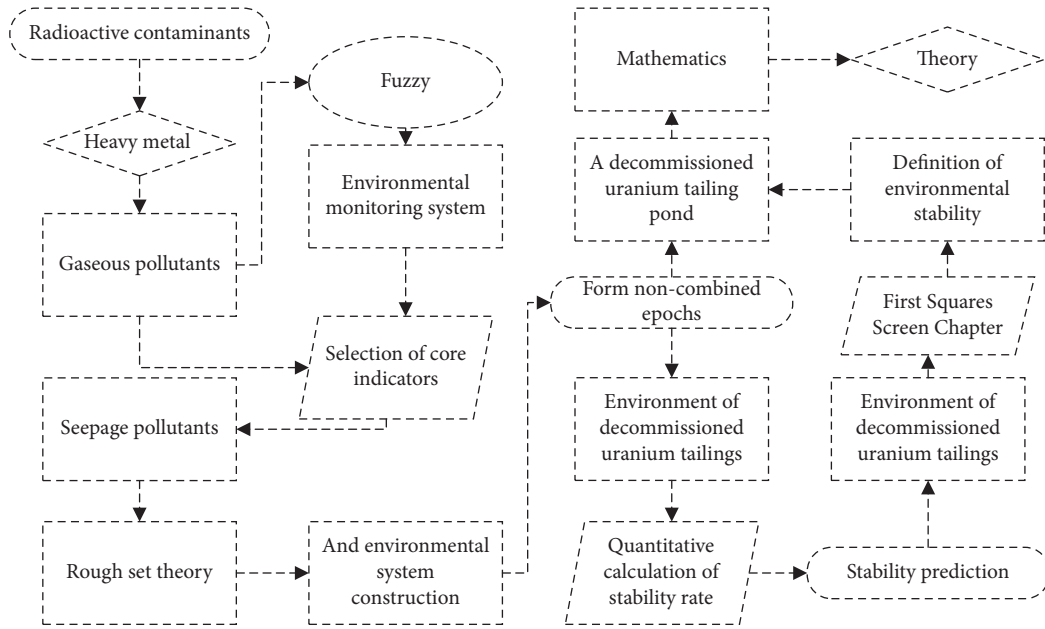
The number of indicators in the indicator system should be reduced as much as possible, and the core impact indicators should be highlighted, so as not to make the evaluation indicator system too large and affect the accuracy of the evaluation results, and to avoid the interrelationship between indicators so that the selection of indicators is both adequate and necessary. For uranium tailing ponds, on the premise of including the main environmental monitoring indicators and the indicators with greater impact on the environment of uranium tailing ponds, irrelevant or harmless environmental indicators should be reduced as much as possible. The indicator system is used to describe social phenomena, and science is the premise and basis for the existence of the indicator system. Therefore, it is necessary to start from the actual situation, and the constructed indicator system should be able to objectively reflect the actual situation, while the indicators included should be in line with the scientific and theoretical basis. The uranium tailings pond is a complex system, and the indicator system should be able to analyze and compare with existing theories and methods, while the indicators with inclusive relationships should be deleted appropriately, and cross-over information should be avoided between each layer of indicators [21]. The process of constructing the indicator system is essentially the process of decomposing the top target layer by layer, so the evaluation indicator system is also a multilayer and multi-indicator system, analyzing the complex evaluation problems layer by layer, considering them comprehensively, grasping the key points, and considering both qualitative and quantitative indicators. Through the analysis of the change law of the environmental monitoring project of uranium tailings pond over time, the


FIGURE 4: Technical roadmap for environmental stability analysis and prediction of decommissioned uranium tailings ponds.

characterization of the environmental stabilization process of the uranium tailing pond is analyzed, and the new concept and connotation of the environmental stability of the uranium tailing pond are comprehensively and systematically put forward. There is an environmental stability evaluation index system for decommissioned uranium tailings ponds. According to the actual situation of uranium tailings ponds, the environmental indicator system can usually be decomposed into three levels, and the decomposition process is from coarse to fine, from macro and micro, and from general to specific.

Fuzzy mathematics takes uncertainty as its research object; it uses precise mathematical language to describe fuzzy phenomena, so it can better reflect the objective fuzzy phenomena. For uranium tailings ponds, because of the complex environmental factors, how to define the stability of each environmental monitoring index and the comprehensive stability of the environment is itself a difficult problem to determine, and the use of fuzzy mathematical theory can make up for the shortcomings of exact mathematics and stochastic mathematics by making the fuzzy objects exact. In fuzzy mathematics, there are many branches such as fuzzy topology, fuzzy group theory, fuzzy graph theory, fuzzy probability theory, fuzzy linguistics, and fuzzy logic. After decades of development, they have been widely used in many neighborhoods. This thesis is theoretically feasible to use fuzzy mathematical theory to analyze the environmental stability of uranium tailing ponds.

4. Results and Analysis

4.1. Performance Results of Radial Basis Function Neural Network Algorithm with Genetic Algorithm. For these three datasets, we simplify the centroids of the hidden layer neurons in the random radial basis function neural network, and the smoothing factors uniformly distributed between

$[−1, 1]$ and $[0, 1]$, respectively. Thirty trials were conducted for each training and test set, and then, the median was taken as the result to reduce the effect due to random errors. The results of the performance test of the random radial basis function neural network are shown in Figure 5. During the task of fitting the cos (z) function of the random radial basis function neural network, the training error becomes smaller and smaller as the number of neuron nodes in the hidden layer gradually increases, and the fitting results become better and better. Observing Figure 5, it can be found that when the number of neuron nodes is small, the fit is inadequate, and as the number of neuron nodes increases, the fitting result of the random radial basis function neural network is gradually able to match the cos (a) function. It should be noted that the fitting results are not the same for each training here because of the random selection of some parameters in the network, and we have selected one of the cases for the graph.

To be able to better represent the performance of the stochastic radial basis function neural network, the Spectra dataset was selected to test its fit. Unlike the dataset with one-dimensional cos (z) functions for both input and output, the Spectra dataset has a higher dimensionality than the actual data. Figure 5 directly illustrates how the training error gradually decreases as the number of hidden layer neuron nodes increases during the fitting of the random radial basis function neural network to the Spectra training set.

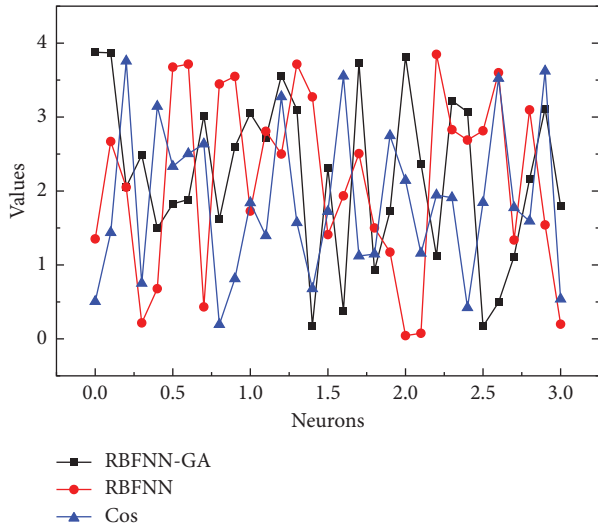
The generalization of the random radial basis function neural network on this Spectra test set is also very good, and the generalization results can match the test set data. It illustrates the equally satisfactory results of the random radial basis function neural network in the classification task. In the classification dataset, the recognition rate in its training set can reach almost 100% with the increase of neuron nodes in the hidden layer of the network, and the highest


FIGURE 5: Results of the function training set fitting.

FIGURE 6: Training error and recognition rate of Spectra dataset under RBFNN algorithm.

recognition rate in the test set is close to 90%. Observation of the recognition rate in the test set reveals that the curve has a first increase and then decrease, which is because, with the increase of the number of hidden layer nodes, the weights of the output layer of the random radial basis function neural network derived by the simple RBFNN algorithm can easily lead to the overfitting phenomenon of the neural network. From Figure 6, the training time of the random radial basis function neural network is very short in the training tasks of both the Spectra dataset and Iris dataset, reflecting its fast-learning ability. According to the two curves toward the situation, the training time of the neural network increases gradually with the number of neuron nodes. The input dimension of Spectra is 401 dimensions and the output dimension of Iris is 4 dimensions. But the difference in training time between the two is only in the microsecond level, which is enough to show that the random radial basis function neural network has great potential to handle large data set tasks.

The random selection of some parameters in the radial basis function neural network is an important complement to the existing how to determine the radial basis function neural network center and smoothing factor. Improving its shortcomings and deficiencies, improving the governance effect, and ensuring the stability of the environmental impact after the decommissioning of the uranium mining and metallurgical tailings pond are of great significance to ensure the people's life, health, and safety. Unlike traditional BP neural networks, this random setting of radial basis function centers and smoothing factors makes it possible to calculate only one parameter, the output layer weight, in a radial basis function neural network with a three-layer network structure, which drastically reduces the number of parameters to be solved in the network. And solving the stochastic radial basis function neural network outer weights by least squares is a linear operation, which is very fast in computation. Compared to solving the center and smoothing factors of a neural network through supervised learning, taking this approach can effectively improve the learning efficiency of
the network, making it a great potential for handling big data tasks. In this paper, we use the properties of generalized functions to construct a limit integral expression for the approximated function; secondly, we use Monte Carlo methods to compute the integrals in this expression and theoretically prove that this random radial basis functions neural network is not only capable of approximating arbitrary continuous functions but also an efficient function approximator. And the random radial basis function neural network is tested by fitting and classifying simulation by selecting different data sets. The results show that the stochastic radial basis function neural network does exhibit good performance.

4.2. Results of the Evaluation of the Environmental Rehabilitation and Treatment Effects of Decommissioned Uranium Tailings Ponds. Benchmarking, also known as benchmarking, is a method of environmental performance assessment in which an organization sets itself an example and a goal to strive for in its development process, with the basic idea of systematic optimization, continuous improvement, and continuous improvement. Benchmarking is unique in its assessment method, which is achieved through comparison. The first step in the benchmarking method is to identify a benchmark, usually a leading organization in the field, as a goal for the organization to strive for. At the end of each implementation phase, the results are compared with the identified benchmark, and a phase summary assessment is conducted to adjust the next phase of the approach until finally the benchmark level is reached and a higher benchmark is identified, as shown in Figure 7.

The binary comparison ordering method is more practical in the method of determining the affiliation function, which is implemented by making a reasonable two-by-two comparison of certain specific features between multiple things, to determine the order of things
Figure 7: Classification of environmental performance benchmarking levels.

Figure 8: Changes in monitoring values.

based on this comparison feature with the comparison result of certain features, and the order obtained from this comparison is used to judge the approximate situation of these things for the affiliation function under this specific feature and further then construct the affiliation function for solving; the binary comparison ranking method can be divided into relative comparison method, comparison average method, priority relationship ordering method, and similar priority comparison method according to different comparison measures, as shown in Figure 8. The RBF neural network was proposed based on the characteristics of the human brain's neuronal cells that have a local response. It simulates the local approximation neural network structure of the human brain that is locally adjusted and covers the receptive domains.

As a result, a large amount of acidic wastewater is generated, which flows through a special pipeline to the wastewater treatment plant, where it is degraded and precipitated so that the heavy metals in it are precipitated and neutralized using lime, and then, the treated wastewater is discharged to the tailings pond. The wastewater migrates from the outfall to each section of the tailings reservoir, and the distance from each dam section to the outfall varies, resulting in different degrees of contamination. Dam B is located at the southwest end of the tailings dam, and due to the distance, the wastewater needs to flow for some time to reach this dam section, so the change in the pH of the water body is relatively flat, and because the wastewater contains more free state ammonia ions. The larger the concentration of ammonia ions, the more $H+$ produced by hydrolysis, and the more severe the acidification of the water body. The variation of pH values with time was plotted based on the monitored raw data. A new method for environmental stability analysis of uranium tailings ponds is proposed, and the stability intervals of indicators and environmental stability rates are defined in precise mathematical language, which is of positive significance for further
enriching and improving the comprehensive evaluation techniques of decommissioned uranium tailings ponds.

5. Conclusion

The research work in this paper mainly analyzes the environmental stabilization process and stability of decommissioned uranium tailing ponds, proposes a new concept of environmental stability with ecological and environmental protection concept and gives it a new connotation, establishes an evaluation index system of environmental stability of decommissioned uranium tailing ponds through index screening using rough set theory, integrates the influence of environmental factors such as external wastewater and exhaust gas, and realizes the multifactor. The system of evaluation indexes for the stability of decommissioned uranium tailing ponds was established by combining multiple factors; the long-term monitoring and model verification of the environmental stabilization process of decommissioned uranium tailing ponds were carried out by using mathematical methods, and the change law of the stability of environmental parameters over time was studied; the connotation of environmental stability was further deepened and supplemented; uncertainty theories such as statistical theory and fuzzy mathematics were applied to construct a comprehensive evaluation model for the stability of decommissioned uranium. There are an input layer, hidden layer, and output layer. There is no need for a weight connection between the input layer and the hidden layer, and the input vector is directly mapped to the hidden layer.

A comprehensive evaluation model of the stability of a decommissioned uranium tailings pond was constructed by applying statistical theory, fuzzy mathematics, and other uncertainty theories, and a prediction model of the environmental stability was established by using BP neural network. The average error rate of the predicted environmental stability rate was only 6.27%. Based on the principle of maximum affiliation, the predicted stability level was the same as the expected stability level of the sample, and the overall prediction results were consistent with the actual situation, which further verified the applicability and feasibility of the method. The degree of influence of environmental indicators on the environmental stability of uranium tailings ponds was also analyzed using the univariate method, which provides a new method and technique for the comprehensive evaluation and decommissioning management of uranium tailings ponds.

Based on the BP neural network and the ARIMA model, this paper predicts the nonlinear residual of GDP and adds the predicted values of the two models to obtain the final predicted value of the model. First, the focus is on the ARMA model in the univariate time series. However, in real life, forecasts are often affected by many factors, so the following introduces the ARIMAX model in the multivariate time series. In the prediction process, the network structure and various parameters of the neural network are not given in a systematic way, so the operation of the neural network is affected by many factors. Each forecasting method has its scope of application and also has its own weaknesses caused by the characteristics of its own model. Secondly, this paper proposes an effective combination method according to the GDP characteristics and builds an improved algorithm BP neural network price prediction model, the research on the combination of GDP prediction model is currently mostly focused on the weighted form, and this article proposes another combination, namely, error correction. According to the price characteristics, we determine the appropriate number of hidden layer nodes and build a BP neural network price prediction model based on the improved algorithm. Validation of examples shows that the error-corrected GDP forecast model is also better than the weighted GDP forecast model, which shows that error correction is also a better combination of forecasting methods. The forecast results of BP neural network have lower errors and monthly prices. The relative error of prediction is about 2.5%. Through comparison with the prediction results of the ARIMA model, in the daily price prediction, the relative error of the BP neural network prediction is 1.5%, which is lower than the relative error of the ARIMA model of 2%.

1. Introduction

GDP refers to the market value of all products and services produced by a country or region in a certain period of time using production factors. GDP not only is the accuracy of demand forecasting, but also provides a reference and basis for countries and regions in the deployment of strategic guidelines and the formulation of macroeconomic policies [1]. In addition, the statistics of GDP are more accurate and the calculation repeatability is small, so statistics are relatively easy [2]. GDP and economic growth rate, inflation rate, and unemployment rate are the main macroeconomic operation indicators that are closely related and are the most basic indicators [3]. In order to meet the requirements of social development and meet the needs of more accurate predictions, some prediction problems have introduced

computer technology, mathematical methods, and logical reasoning. The gradual development and maturity of these systems have led many countries in the world to establish various predictions. Research departments provide decision-making references for economic development, provide strength support for strategic research, and guide enterprises and the country's current and future social activities to maximize utility [4–6].

In GDP forecasting, a single model is used for forecasting. When generating forecast results, we often discard the forecast errors. We think that the useful information has been extracted. In fact, the error contains a small part of the information, and it is still desirable [7–9]. Therefore, some scholars integrate existing prediction methods and use the promotion and complementation of different information to improve the prediction accuracy of the model. Many

scholars have added error correction models when making GDP predictions [10]; the results show that the addition of the error correction model can significantly improve the accuracy of GDP prediction. Gao [11] et al. used a combination of ARIMA model and neural network in the forecast of tourism demand. Qin [12] et al. used SARIMABP to construct seasonal error correction time prediction model. In their article on carbon emissions prediction, they divided the data into linear and nonlinear parts, making full use of the good advantages of time series linear forecasting to make preliminary predictions, and then through the neural network implements error correction, the results show that the participation of the neural network is much better than the prediction effect of ARIMA alone. Yang [13] first used the adaptive filtering method to complete the preliminary prediction on the prediction data and then used Markov chain to correct the residuals generated after the preliminary prediction, and the result shows the feasibility of the method. Wang [14] further discussed the variable weight GDP forecast model and gave corresponding theoretical proofs and practical applications. Wang [15] proposed a generalized recursive reciprocal variance GDP prediction method on the basis of recursive equal weight GDP prediction and recursive reciprocal variance GDP prediction and deduced the iterative formula, starting from the GDP prediction accuracy. A combination model with the objective function as the predictive effectiveness index is established, and the optimal approximate solution of the weights is obtained. Some scholars comprehensively consider the mathematical expectation and standard deviation of GDP forecast accuracy, establish a multiobjective optimization GDP forecast model, derive its mathematical programming solution, and introduce entropy theory, and according to the degree of variation of the error sequence of the single forecast model, we obtain the weighting coefficient of each single model [16–19].

This paper studies and analyzes the artificial neural network model, especially the operating mechanism of BP neural network, compares its advantages with traditional forecasting methods, constructs a GDP forecast model, and discusses the setting rules of various parameters in the model. Experiments analyze the feasibility and superiority of artificial neural network in the field of GDP prediction and compare the prediction accuracy of BP neural network and traditional time series forecasting method. In the selection of prediction methods, the comparison is based on the superiority of the algorithm's BP neural network and the prediction accuracy of the BP neural network and the ARIMA prediction model. In order to reduce the prediction error and improve the accuracy of the model, this paper proposes a combination prediction model and a combination coefficient method to find a suitable model based on the information characteristics of the sequence value itself. From the final fitting results, it can be seen that the predicted value and the true value are very consistent; the true value falls within the 95% confidence interval, which fully shows that the model combination effect is good and the prediction accuracy is high. This empirical study shows that the ARIMA model and the ARIMAX model can be applied in actual work to make short-term macroforecasts.

2. Construction of the GDP Prediction Model Based on the BP Neural Network and ARIMA Model

2.1. BP Neural Network Spatial Sequence. The BP neural network is a computer-based processing system created by imitating the human brain. It is trained to understand the operating rules of the real system [20]. Figure 1 shows the spatial architecture of the BP neural network. Its outstanding ability is reflected in the prediction of nonlinear time series. It has strong predictive ability for exponentially increasing trend models, high accuracy, and strong fault tolerance, and fast information processing speed and can process quantitative and qualitative information at the same time, without the need to consider the system for problem of decoupling. The disadvantage is that the learning speed is very slow, the network training is very likely to fail, and it is more difficult to find the global minimum [21–24].

The establishment of the dynamic regression model is based on the assumption that there is a long-term equilibrium relationship between the response sequence and the independent variable sequence; that is to say, not all sequences can establish a dynamic regression model, only those sequences that have a long-term equilibrium relationship. It is suitable for establishing dynamic regression model [25, 26].

$$f(x \mid n) = \{x(1), x(2), \ldots, x(n) \mid n \in R\}, \tag{1}$$

$$Y(x) = \sum_{x=1, y=1}^{n} p(y \mid x) \times f(y \mid x). \tag{2}$$

According to the introduction of the one-time exponential smoothing model, it is suitable for stationary series without changing trend. In order to apply to the time series with obvious upward or downward trend, a double exponential smoothing model is proposed. The double exponential smoothing model uses the first exponential smoothing model to process the data after the first exponential smoothing model for the second time [27, 28].

$$|x(1) - f(x)| + |x(2) - f(x)| + \cdots + |x(n) \\ - f(x)| = n \times f(x), \tag{3}$$

$$\frac{g(x) - \sum_{i,j=1}^{n} [s(1, i) + s(2, i) + \cdots + s(j, i)]}{s(i, j)} = 0. \tag{4}$$

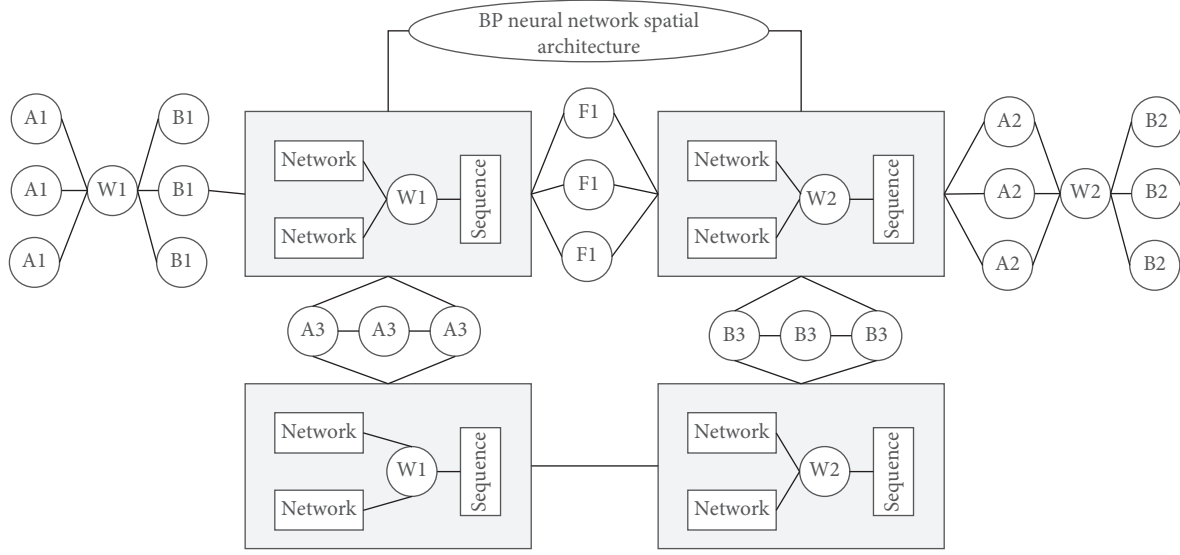
Since random fluctuations are not actually measurable, when we actually make a model, we usually set the value of the unobserved value to 0 and then perform the least squares. This estimation is called because of the addition of the preconditions. When we are building a model, it is impossible to try all models. The first thing we have to do is to determine the selected model form and then determine the order of the model. Generally for this step, we usually call it the model order. It can be determined based on the ACF diagram and the PACF diagram.


FIGURE 1: BP neural network spatial architecture.

$$\sigma(x, y) = \frac{1}{E} \times (\varepsilon(x, x) - t(\varepsilon(y, y))), \tag{5}$$

$$\{\sigma(x, x), \sigma(y, y), \sigma(z, z)\} \longrightarrow \{\varepsilon(x, y), \varepsilon(y, z), \varepsilon(z, x)\}. \tag{6}$$

With the observation sequence, we have to study the properties of these sequences, but the properties of random sequences cannot be obtained intuitively. In this way, we indirectly study the properties of his observation sequence and then infer randomness through the properties of the observations. When a group of data containing gray information is obtained, this group of data is usually irregular, but there is always some kind of generation to process the data to make it regular.

$$U = \frac{1}{2} \times \int_{\Omega} \sigma(z, x) \sigma(x, y) \sigma(y, z) d\Omega. \tag{7}$$

Based on this feature, we can process the data to build an equation generation model to achieve the fundamental mode of predicting the future. In general, the model constructed by the gray model is similar to a differential equation.

2.2. ARIMA Algorithm Structure Distribution. The Auto Regressive Integrated Moving Average model is abbreviated as the ARIMA (p, d, q) model, where p, d, and q represent the order of the autoregressive model, the order of the difference, and the order of the moving average model, respectively; ARIMA(p, d, q) model is essentially a combination of difference operation and autoregressive moving average. First, the sequence is subjected to d difference processing, transforms it into a stationary time series, determines the values of p and q according to the obtained stationary time series, and then uses the ARMA(p, q) model to predict and analyze the stationary time series. The aforementioned AR(p) model, MA(q) model, and ARMA(p, q) model are all stationary series. For nonstationary series, it is usually processed by difference processing several times first to convert them into stationary series. AR(p), MA(q), and ARMA(p, q) models are all established on the assumption that the time series are stationary. Table 1 shows the composition of the time series factors.

There are a large number of nonstationary series in practical problems, so it is necessary to use a time series model suitable for nonstationary series. That is, the nonstationary sequence becomes a stationary sequence after d-order difference processing; then it is called the d-order single integer sequence. If a sequence can be transformed into a stationary sequence after several difference operations, then the sequence is called a homogeneous nonstationary sequence, and the number of previous differencing operations is called the homogeneous order. In the actual economic situation, the time series we get are usually nonstationary. In real life, most time series are nonstationary, showing trend or periodic characteristics, such as economic development data, electricity consumption, and passenger travel volume. The characteristic of ARIMA is that when dealing with nonstationary time series, it is first differentiated into a stationary time series, and then AR, MA, and ARMA model theories are used for modeling and analysis. Figure 2 shows the structure topology of the ARIMA algorithm.

When predicting a stationary time series, the longer the prediction time is, the more the unknown information is represented. So a modified prediction is proposed; that is, as time develops, we can gradually get a real value, put this true value together with the previously known sequence value, refit the model, and then predict the value after again, and when the true value is obtained again, refit the model again, until the required predicted value until. If we use some methods to simplify the complex, convert the nonstationary

TABLE 1: Time series factor composition.

| Factor index	Network sequence	Coefficient	Significance level
1	AR	1.71	0.58
2	MA	2.43	0.43
3	AR (D)	1.63	0.39
4	MA (Q)	1.56	0.54

FIGURE 2: ARIMA algorithm structure topology.

to the stationary, and then use the ARMA model for fitting, we can solve the above problems. In the exponential smoothing model, the parameter smoothing coefficient can not only reflect the speed of response to changes in the time series, but also affect the ability to correct random errors. The magnitude of a determines the degree of influence of the new and old data on the forecast results.

2.3. GDP Forecast and Evaluation Method. According to the differences in GDP forecast goals and characteristics, people divide GDP forecasts into qualitative forecasts and quantitative forecasts. Qualitative forecasting is a subjective forecasting method, which is mainly used in the absence of historical data. In the event of statistical data, it is suitable for short, medium, and long-term forecasting. Quantitative forecasting is mainly based on a large amount of data through a mathematical model to explore the law between the data. The fitting and prediction of the sequence are the ultimate goal of analyzing the time series. After the model has passed the significance test, the sequence can be fitted. Combining several methods with an appropriate weight, combining geometric empirical mode decomposition and support vector regression method, the prediction index has good fit and accuracy. If the fitting effect is good, the model can be predicted; that is, according to the experience summarized in the forecasting work, when the data series

shows a stable trend and no obvious fluctuations, it is more appropriate to choose between 0.1 and 0.3; when the data series shows a stable trend but there are obvious fluctuations, it should be between 0.3 and 0.5; when the data series has a clear trend and fluctuates, it is more reasonable to choose between 0.5 and 0.8. Figure 3 shows the prediction error ladder diagram of the BP neural network sequence.

Since the prediction method changes with time, place, and environment, the predicted value will be different with the change of the prediction method, and there will be unavoidable errors between the actual value and the predicted value, so it needs to be formulated. A certain standard evaluates the feasibility and rationality of the prediction method as a basis for measuring the pros and cons of the model. When the fitted model passes the above two significance tests, it can only show that the model is at this level of significance, but it cannot be said that this model is optimal. There are generally two criteria for model optimization, AIC criteria and SBC criteria. Using a certain prediction method to predict it, and the resulting sequence of prediction results, the prediction error can be expressed as T. If there is a correlation between the time series values, it should test whether there is a stationary correlation between the series. This test is called the stationarity test of the series. Commonly used testing techniques include time series graph testing, autocorrelation function graph testing, and unit root testing to plot the time series data in a rectangular coordinate
Figure 3: Prediction error ladder diagram of the BP neural network sequence.

system and observe whether the broken line has periodicity and trend. If it is a stable time series, then the graph should fluctuate randomly around a certain value with a small amplitude. By observing the autocorrelation function graph of the sequence, if the autocorrelation coefficient shows a rapid decay state as the order k increases, then it can be determined that the sequence is stationary; conversely, if the decay is very slow, then the sequence is nonstationary.

2.4. Model Weight Factor Analysis. The key to GDP forecasting is what criteria are used to obtain the weight coefficients, so that the GDP forecast has a higher forecast accuracy, but no matter how the guidelines are formulated, the measurement standards are considered from the perspective of error, and the forecast error is inversely proportional to the weight distribution. The weight coefficient is determined by the principle. The nonoptimal positive weight combination is to use the above theory to solve the weight coefficient with a simple principle. It is obviously inferior to the objective function of the optimal positive weight combination in terms of calculation difficulty, but some nonoptimal positive weights are currently better and the calculation is simple. Sort the variance sums of the prediction errors of each single model, and assign smaller weight coefficients to the single model corresponding to the error variance and too large or too small, and the single-term model in the middle is assigned a larger weight coefficient. Figure 4 shows the needle chart of the deviation of the individual weight coefficients of the BP neural network. The pros and cons of the prediction method can be reflected by the absolute value of the error. The maximum absolute value of the error is to be minimized based on the forecaster's needs, and the maximum absolute value of the GDP forecast error is minimized as much as possible, thereby improving the prediction accuracy.

For an observation time series, it is necessary to select the model that is most consistent with the actual development process from a variety of models, this is, the model identification process. That is to say, when predicting new

unknown values, this model is not used to predict forever, but after predicting the first new value, the first value that is the furthest in time in the sequence is removed, and then the predicted value is added to the sequence, a new model is reconstructed, and so on, so as to improve the whitening degree of the gray space. Based on the tailing and truncation of the calculated autocorrelation function and partial correlation function, combined with the identification rules of the model, we preliminarily determine the model type. In terms of time series, for annual data, we use a data for modeling, and b data mainly is to compare forecasts. In addition, c data is predicted. For quarterly data, because the data is relatively small, d data is used to fit the model, and e data is used to determine whether the model is good or bad. It can be summarized as follows: when the autocorrelation function is truncated at step q and the partial correlation function is tailing, then the MA(q) model should be selected; when the partial correlation function is truncated at step p, and the autocorrelation function is tailing, then the AR(p) model is selected; if both the autocorrelation function and the partial correlation function show tailing, then the ARMA model is selected. Therefore, the combination coefficient method combining the least square method and the MAE weight coefficient method is proposed in the selection method of the combination model weight, and the difference in nature between different combination methods is compared. The best criterion function method uses a criterion function, which can not only examine the degree of fit to the original sequence, but also consider the number of unknown parameters in the model. If the minimum value is obtained under the established criterion function, the order of the model can be determined.

3. Results and Analysis

3.1. Empirical Analysis of the BP Neural Network. This article has elaborated on the relevant theories of time series and now constructs the GDP time series forecast model, using EViews software to establish the ARIMA model and the exponential smoothing model, respectively. This paper uses the Box-Jenkings model identification method to conduct preliminary identification of the model. The main idea of this method is to visually judge the truncation and tailing of the sequence by observing the autocorrelation function graph and partial correlation function graph of the sample and screening series five suitable model types. Before applying the dynamic regression model, it is necessary to test the stationarity of each series to avoid the appearance of false regression. The stationarity of the sequence can be observed through the sequence diagram of the sequence, but it has a strong subjective impression. In order to improve the accuracy of the test, we usually perform a unit root test on the sequence, which is the most widely used statistical test method. First, the correlation analysis of the variables was carried out using the Pearson correlation coefficient. According to the results obtained, it was found that the selected variables all showed a high degree of positive correlation with GDP, and the variables also showed a strong correlation.
FIGURE 4: BP neural network individual weight coefficient deviation needle chart.

Figure 5 shows the distribution of each significance level curve of the BP neural network. From the figure, we can see that the GDP series has an obvious time trend, which is an exponential growth trend with time. It can be preliminarily judged that this is a nonstationary series. According to the ADF test, the test t statistic value is 1.493627, which is greater than the critical value at each significance level; that is, the null hypothesis cannot be rejected at the 1%, 5%, and 10% levels. Therefore, it can be judged that the original series is a nonstationary series. Since there are 6 independent variables in total, the input layer node is selected to be 6, the number of output layer nodes is 1, and the activation function is selected as a sigmoid type function. This is because it has good nonlinear mapping capabilities, and the hidden layer is selected as tan-sigmoid function; the output layer selects the linear purelin function. In order to eliminate the trend of the series and reduce the fluctuation of the series, we now take the logarithmic first difference of the original GDP series to get its series. According to the ADF test, the test t statistic value is -4.705133, which is less than the critical value under each significance level, that is, rejecting the null hypothesis, and it can be judged that the series is a stationary series at this time. Combining it can be seen that the sequence after the first difference of the logarithm of the original sequence is a stationary sequence, that is, $d = 1$. At this time, each parameter has a significant effect on the model, and the significance test of the parameter is passed. Then drawing the residual correlation diagram, it can be seen that there is no autocorrelation and heteroscedasticity in the residual, and it is normally distributed, and the model passes the test. Therefore, the established ARIMA(4, 1, 0) model meets the requirements.

3.2. Realization of GDP Prediction Model Simulation.

In this paper, statistical software SAS9.2 is used for ARIMA modeling of GDP total forecast; using the form of rolling window, the number of rolling windows is the number of forecast periods, and the data in the window is used to construct the ARIMA model. Sample 1 contains 18 windows
FIGURE 5: Distribution of saliency level curves of the BP neural network.

for building models, and sample 2 contains 20 windows for building models. Due to space limitations, sample 1 and sample 2 only describe the modeling process of the first window in detail. The error fluctuation range of ARIMA prediction alone is large, and the error of BP prediction alone is relatively small. However, the combined prediction error is the smallest, and the obtained prediction data is closest to the actual value. The ARIMA model has certain adaptability to nonstationary demand. Compared with the ARIMA model, the BP neural network based on genetic algorithm has a greater improvement in the prediction accuracy. This is mainly due to the fact that the generation of data is random and uncertain, and most of the data contains white noise. For stationary non-white noise sequences, the stationarity can be predicted. Stationary non-white noise sequence refers to the correlation between the sequences; that is, there are rules to follow in the sequence. The ARIMA model is a linear model, which has shortcomings and defects in the analysis and prediction of this nonlinear behavior of change. According to the results of the simulation analysis of

the calculation example, the combined model of the two methods can prove a great improvement compared with the single model. Figure 6 shows the histogram of the average absolute relative error of the GDP forecast model.

According to the GDP sequence diagram, it can be roughly judged that GDP is growing in a weak exponential form. If the double exponential smoothing method is used to predict GDP, then the original sequence can be processed by logarithm, and then the sequence can be fitted with double exponential smoothing. After the model is calculated, it is transformed into an exponential curve trend form, and the predicted value of the GDP series can be obtained. In general, low-order numbers are selected when building the model, so let $p = 1$ and $q = 1$. From a long-term perspective, the autocorrelation graph shows two 4th-order truncation, and the partial autocorrelation graph shows tailing. That is, $P = 1$, $Q = 1$ or 2, and because the first-order 4-step difference is started, $d = 1$, $D = 1$, and $S = 4$. Note that this article uses EViews software to build an exponential smoothing model. The initial smoothing value is the system default value. The Alpha and Beta values let EViews automatically choose to minimize the error.

Figure 7 shows the matchstick chart of the relative error of the ARIMA model fitting prediction. It can be seen from the autocorrelation graph of the quadratic difference sequence that the autocorrelation coefficients fall within 2 times the standard deviation after a delay of 3 orders, and the speed of attenuation to zero is faster, and after a delay of 9 orders, it fluctuates around the zero value. Based on the above two judgment methods, it can be considered that the sequence after the second-order difference is stationary. After the fitted model is determined, the model needs to be tested in two aspects, one is the adaptability test of the model, and the other is the significance test of the parameters. Each neuron on the hidden layer and the output layer corresponds to an activation function and threshold. The neurons on each layer are connected to the neurons on the adjacent layer through weights. For a nonstationary time series, the nonstationarity is usually eliminated by difference operation and relevant information is extracted. But you cannot blindly use the difference operation multiple times, because every time a difference operation is performed, the time series will lose part of the information. When multiple differences of the time series result in too much information loss, the estimated model parameters are unreliable, which will reduce the value of the model. This phenomenon is called overdifferential. In order to avoid excessive differences, when a low-order difference operation can be used to obtain a stationary sequence, there is no need to use high-order differences. It can be seen from the above results that if only one year's data is predicted, according to the time series method, the forecast error of quarterly data is smaller than that of annual data. Therefore, if the data is sufficient, if the ARIMA model is used to fit the forecast data, the number predicted by the quarterly data is better than the data predicted by the annual data, because the quarterly data is more seasonal than the annual data. The adaptability test of the model is mainly to determine whether the model is valid by checking whether the residual sequence is a white noise

sequence. The significance test of a parameter is to test whether the unknown parameter is significant to zero. If the independent variable corresponding to the parameter does not have a significant effect on the model, the variable should be considered to be eliminated.

3.3. Analysis of Experimental Results.

3.3. Analysis of Experimental Results. The nonlinear component of the total GDP sequence is added to construct an ARIMA-BP mixed model. The nonlinear component in the input layer is the residual of the ARIMA model's first-order delay. The ARIMA-BP hybrid model will simultaneously model the linear component and the nonlinear component in the GDP total sequence. The structure of the BP neural network in the sample 1 construction of the ARIMA-BP mixed model is $5 \times 6 \times 1$, and the structure in the sample 2 construction of the ARIMA-BP mixed model is $5 \times 11 \times 1$. The model is trained to predict the daily closing price of the total GDP. The actual values and predicted values of BP neural network and ARIMA-BP mixed model can be found in the article. First, the data input_train and data output_train are used as the data of the training learning sample, and the data input_test and data output_test are used as the input and output data of the test sample, respectively. According to the parameter-related setting theory and multiple tests of the model, the appropriate model is selected according to the prediction effect. The model parameters are set as follows: the normalization function of the data is mapminmax; the number of hidden layers is set to 8; the number of iterations is net.trainParam.epochs = 1000; learning rate net.trainParam.lr = 0.1; training target net.trainParam.goal = 0.00001; other parameters are the system default settings.

Figure 8 shows the BP neural network feasibility test deviation line chart. It is found from the result that when using all the data to test the feasibility of the model, the partial grade ratio does not fall within the tolerance interval, the data does not pass the feasibility test, and the gray model cannot be fitted. Cross-validation can evaluate the regression performance of LSSVM. It divides the data in the sample into multiple groups randomly. The training set trains LSSVM, and the validation set is used to test the prediction performance of LSSVM. After verification, a model that performs well in the sample can be used for out-of-sample predictions. RMSE measures the absolute error, and MAPE measures the relative error. RMSE and MAPE measure the accuracy of prediction from two different perspectives, and the two do not have similarities. For example, the RMSE index of the prediction effect of the A model is smaller than that of the B model, but the MAPE index of the prediction effect of the A model may be greater than that of the B model. Therefore, it is feasible to choose RMSE and MAPE to evaluate the predictive effects of different models in this paper. The smaller the two indicators, the closer the actual value to the predicted value, and the higher the prediction accuracy. When the level ratio test fails, one solution is to add a constant to the original sequence until the new sequence passes the level ratio test. The amount of change in the weight and threshold is equal to the amount of change in

FIGURE 6: Histogram of the average absolute relative error of the GDP forecast model.
FIGURE 7: The matchstick chart of the relative error of the ARIMA model fitting prediction.

the previous moment. By increasing the momentum term, the network not only has a faster convergence speed, but also can effectively avoid the occurrence of local minimum problems in network training. Experiments show that if all the sequences are tested, only the constant is increased to 65000 or even more. The test can only be passed when it is large, and the predicted sequence, as shown in the text, can only roughly reflect a rising trend of GDP year by year, but the actual effect of predicting the future is very poor.

Table 2 shows the sequence-level comparison test of the neural network. It can be found that the process of ACF and

PACF attenuation to zero presents a tailing feature. The tailing order is the first order and the fourth order, which fits the ARMA(4, 1) model. Taking into account the process of first-order difference, the ARIMA(4, 1, 1) model was finally constructed on the basis of logarithms. The equation passed the significance test, but some coefficients failed the significance test. The reason is considered and compared, and the sparse coefficient model ARIMA((1, 3), 1, 1) is finally constructed, and the R language operation result is obtained. The prediction interval is trumpet-shaped, indicating that the prediction error is increasing with the growth of the

FIGURE 8: BP neural network feasibility test deviation line chart.

TABLE 2: Sequence-level comparison test of the neural network.

Level number	Correlation coefficient	Weight	Error rate/%
1	0.97	0.32	9.17
2	0.86	0.34	5.43
3	0.88	0.21	6.77
4	0.91	0.13	3.54

prediction period. In addition to the significance test of the parameters, the adequacy of the model must also be verified; that is, the significance of the model is tested. If a model is significantly effective, it has extracted sufficient information from the time series, and the fitted residual series are no longer relevant. If the residual sequence is white noise, it indicates that the model is significantly effective; on the contrary, when the residual sequence is correlated, it indicates that the model does not sufficiently extract the correlation relationship in the time sequence. The logarithm operation was performed during the stationarity test of the original sequence at the beginning. Therefore, the predicted value obtained through the program on the basis of the logarithm needs to be exponentially operated to return to the actual required value. According to the formula for determining the weight of the correlation coefficient at the k time, the improved correlation coefficient matrix is obtained.

4. Conclusion

GDP forecast mainly includes two important aspects, one is the choice of a single model, and the other is the combination of models. In the choice of a one-way model, this article chooses the differential autoregressive moving average model (referred to as the ARIMA model), and BP neural network model and exponential curve model are studied. In terms of combination methods, this article combines weighted combination and error correction combination on the single model. After processing the sequence and identification, we use time series analysis theory 67ARIMA (p, d, q) model to predict GDP, and finally the graph is intuitively fitted well, and compared with the real

value of the GDP prediction result, the relative error is small, and the result is more reasonable. The predicted value of the time series is fitted to the GDP forecast, and the results are compared and analyzed with the ARMA model. First, an ARIMA model and an exponential curve regression model are established, and then MAPE and least squares are finally used to predict the GDP using a comprehensive weighted GDP prediction model based on MAPE and least squares. The simulation results show that the comprehensive weight is compared with a single weight. It is found that the forecasting effect of the combined model is better than that of a single model, and the combined weight coefficient method proposed in this paper is better than the combined model composed of other weight coefficient methods in the prediction error. In terms of the accuracy of GDP forecasting, the accuracy of GDP forecasting can be improved; in terms of error correction combination, this paper establishes gray adaptive filtering and ARIMA-BP according to the principle of complementary advantages and commonality of the model and establishes two error correction GDP forecasting models, which are verified by examples. The results show that the neural network has strong nonlinear mapping ability and good robustness, can identify and distinguish noisy samples, and is also a better GDP prediction model.

This paper aims to systematically analyze the reasons for the differences in the relationship between transformational leadership (TL) and project success and apply meta-analysis to summarize which dimensions of TL are the main driving forces for project success. Adopting the meta-analysis approach, we investigated 31 independent studies ($N = 6475$) and studied the theoretical moderators of this relationship from the perspectives of mediating variables, cultural background, and document type to test whether the moderating effects can explain the inconsistent research results. The results reveal that TL positively affects project success and leadership charm is the primary driver of TL. Also, the existence of a mediating mechanism has a more significant impact on the success of the leading project. Meanwhile, compared with project construction under the Western cultural background, countries with Eastern culture are more inclined to use a people-oriented philosophy for project management to promote project success. This research provides an empirical perspective to help project leaders select management talents, regulate leaders' words and deeds, and cultivate technical and soft leadership skills. Besides, this paper proposes a unique and nuanced view of the relationship between TL and project success, enhancing people's understanding of the TL's role in influencing project success.

1. Introduction

"Construction Industry 4.0," as a part of "Industry 4.0," is a specific application under the subdivision of the construction industry. It mainly contains two themes: "smart factory" and "smart production." With the emergence of the intelligent construction concept, a plenty of new-generation information technologies, such as 5G, construction robots, and BIM, have been applied in construction projects [1–3]. The integration of technologies has led to a gradual shift in project management from mechanization and digitalization to informatization and intelligence. However, many studies have shown that even with the increasing level of technology and management associated with project construction, the level of project success has not improved significantly due to the increasing complexity and uncertainty of the construction environment. For construction companies and project organizations,

changes in production models require far-reaching strategic decisions at all levels of the construction industry. Therefore, it is necessary to change the project organization to achieve a higher level of sustainable project success. It is well known that leaders play a dominant role in project organization reform, which is essential to increase organizational resilience and agility and develop high-reliability organizations [4]. Particularly in the last decade, an increasing number of project operations have developed under the project manager responsibility system. The project manager undertakes the leadership responsibility for the entire process of project implementation and overall management. This change will inevitably affect the leadership behavior of project managers and put forward higher requirements for their ability and comprehensive quality. Compared with other leadership styles, transformational leadership (TL) has advantages in enhancing project success. For example, it attaches great

importance to the leaders' standards of behavior and concerns for the needs of followers. Meanwhile, many reasons suggest that TL is indispensable in project organizational change [5–7]. Bass [8] argued that today's construction environment requires subordinates to perform beyond ordinary expectations, and TL can deliver. Therefore, both subordinates and superiors of the project believe that leaders with a transformational style are more productive and suitable for project managers [9].

In recent years, many scholars have conducted many empirical studies to explore the role of TL in project success [10, 11]. On the one hand, most researchers have shown that TL can promote project success. Zhang et al. [12] summarized the recent research results of some scholars and believed that TL plays a vital role in project success or failure. Appropriate TL is necessary for individuals or groups to carry out innovative behaviors [13]. Odusami et al. [14] conducted research to suggest a remarkable correlation between project managers' professional level, leadership style, team composition, and project success. Berssaneti et al. [15] pointed out that project success depends on many factors, including leadership ability, leadership style, and leadership skills of the project manager. However, on the other hand, some studies are reckoning that the project's successful realization will be hindered by TL [16–18]. Zhang [19] found an inhibitory relationship between the project manager's emotional intelligence and leadership style. Iqbal et al. [20] conducted surveys and interviews with engineering organizations in Malaysia. They believed that project leaders' high degree of psychological empowerment negatively impacted project performance due to their leadership style. Besides, Chen et al. [21] proposed an inverted U-shaped relationship between TL and project success, which suggests that it is most conducive to improving the project success rate when TL is at a medium level.

According to the discussion above, there are apparent conflicts in the strength, direction, and statistical significance of the relationship in most studies, which creates confusion in theory and practice. The scholars have not yet formed a consistent perspective on the relationship between TL and project success. Furthermore, the existing research lacks a more systematic and comprehensive integration of TL that contributes to project success, as well as fails to analyze and explain the differences in findings. Simultaneously, the impact of different dimensions of TL on the project's success has not yet been explored by scholars from the perspective of meta-analysis. Therefore, this paper intends to adopt a meta-analysis method through the comprehensive reanalysis of different individual research results to examine the overall effect of TL and other dimensions of TL on project success. Based on the literature collation results, this study explores mediating variables, cultural factors, and publication type factors as the moderating variables, focusing on identifying the reasons for the divergence between different research variables. The research conclusions are expected to comprehensively evaluate TL's theoretical and practical value in construction projects and inspire the sustainable development of project management practices in construction enterprises.

The remainder of the paper is structured as follows: Section 2 sums up the theoretical literature. Section 3 describes the methodology and the process of data collection. Section 4 analyses the results of the meta-analysis. A detailed discussion, implication, and limitation are provided in Section 5. Finally, Section 6 concludes this paper and points out the future research direction.

2. Literature Review and Hypotheses Development

2.1. Transformational Leadership. Burns proposed TL in 1978, and then Bass defined and quantified it in 1985 [8]. According to Bass, TL means that the leaders use words and actions to make subordinates realize the meaning and value of their work [22]. In this process, leaders also create a working atmosphere of trust and cooperation to inspire subordinates' enthusiasm for success and self-realization. In this way, the project manager can encourage them to surpass their interests for the organization's benefit to work more and improve their personal and organizational interests as well as the society's common well-being.

At present, most of the research on TL has been influenced by Bass. Although the multidimensionality of the transformational leader structure has been controversial [23, 24], with the gradual intensification of the discussion on TL, experts and scholars have extended the research from qualitative to quantitative and gradually presented different measurement dimensions of TL. Bass [22] initially proposed that the dimensions of TL have charm, intellectual stimulation, and individualized consideration. After that, Bommer [23] developed the integration, high-performance implementation, and personalized support. Also, Bass and Avolio [24] thought it includes charm, charisma, intellectual stimulation, and individualized consideration. Eventually, Li [25] proposed that TL can be divided into four dimensions: idealized influence, intellectual stimulation, leader charism, and individualized consideration, and they are widely accepted and used. Based on the discussion above, TL is embodied in four dimensions in this paper: (1) idealized influence, which draws a future blueprint for team members, and strengthens team beliefs; (2) intellectual stimulation, which clarifies team goals and encourages members to continue to cooperate in their work, practice, and innovation; (3) leadership charisma, which enhances the self-confidence, self-esteem, and autonomy of members; (4) individualized consideration, which can improve employee identification, loyalty, and enthusiasm.

2.2. Project Success. Nowadays, project management has become ubiquitous in the construction industry, capacity building, and social projects [26]. Project success was introduced in the research field of project management in the 1960s and was initially applied for project management performance. Many scholars have defined project success with deepening the research, but they have not yet come to a consistent conclusion. This article summarizes the opinions of essential project management scholars and practitioners

on the definition of project success based on the published literature (Table 1).

However, as project functions and the number of stakeholders has ascended, project success has a broader concept, which must be a multidimensional structure [34, 35]. Therefore, the Project Management Institute (PMI) defines project success to balance the competing demands for project quality, scope, time, and cost, as well as meet project stakeholders' changing concerns and expectations (PMI, 2008). Specifically, it includes the organization's benefits, user satisfaction, the benefits to project personnel, sustainability, and business success. Specific to the engineering project, the stakeholders have not formed a unified opinion on the project's success. The main reason is that many stakeholders involved in the project have inconsistent standards about project success and an extended project success evaluation period.

At the same time, scholars now no longer only focus on complex indicators such as quality, schedule, and cost for measuring project success but start to explore soft indicators, such as whether the partnership is enhanced, whether the company's capabilities have improved, and whether there is a willingness to cooperate next time, etc.

2.3. Transformational Leadership and Project Success.
Many scholars, such as Nam [36], Khawaja et al. [37], and Wang et al. [38], have supported leadership as a critical factor in promoting project success. Empirical evidence generally recognises the positive impact of TL on follower attitudes, effort, and performance. According to Bass and Avolio [39], TL motivates their subordinates to do things that not only exceed what they are simply asked to do, but also the effects often exceed their expectations. Simultaneously, in addition to directly affecting the performance of cross-level followers, TL can also indirectly affect project performance through direct subordinate leaders who contact cross-level followers [40]. Singh [41] postulated that the intellectual stimulation dimension of TL enhances exploratory thinking and communicates a clear vision of the project, motivating project members to generate new ideas.

Moreover, the leaders who demonstrate TL can gain their immediate followers [9] and are increasingly confident in trying new methods to complete projects with the support of their managers. Dulaimi [41] found that the leader's charisma and innovation support behavior are the main reasons for the investigated project's success in Singapore. Also, literature reviews show that project managers' individualized care and idealized influence play a vital role in achieving tremendous project success [42, 43]. Therefore, according to the findings above, this research proposes the following hypotheses:

H1: TL positively affects project success

H2a: leader charisma positively affects project success

H2b: idealized influence positively affects project success

H2c: intellectual stimulation positively affects project success

H2d: individualized care positively affects project success

2.4. Moderating Relationships.
Due to independent research's heterogeneity, certain potential control variables may affect the relationship between TL and project success. This paper summarizes the literature in this article and finds that the literature has differences in mediating variables, cultural background, and publication types.

2.4.1. The Existence of Mediating Variables.
Many studies have used mediating variables when discussing the relationship between TL and project success. Chou [44] used cognitive trust and collective effectiveness as intermediary variables to reveal the interrelationship between TL and team performance. Furthermore, García-Morales et al. [45] analyzed the impact of TL on organizational performance through organizational learning and innovation's dynamic capabilities. Aga and Vallejo [46] adopted a field survey with a sample of 200 development project managers in Ethiopian nongovernmental organization (NGO) departments. It adopted the structural equation model to find that team building plays a mediating role between TL and project success. Hassan et al. [47] saw that leaders apply their skills and abilities to contribute to the success of construction projects in Pakistan in project management. Thus, based on the existing literature, this study proposed the following hypothesis:

H3: the existence of mediating variables moderates the relationship between TL and project success

2.4.2. Document Type.
As the relationship between TL and project success varies across studies, the meta-analysis literature includes both published journal articles and unpublished papers. Therefore, the type of literature publication may be a source of variation. Furthermore, the earlier the published research, the more likely it will report significant training effects [48]. Meanwhile, the uncertainty and controversy gradually become clear through the indepth analysis. Compared to unpublished literature such as thesis, the journal papers are more inclined to describe significant results and distort the natural effect to avoid becoming drawer files [49]. Therefore, this paper proposes the following hypothesis:

H4: the document type moderates the relationship between TL and project success

2.4.3. Cultural Background.
Culture is a consciousness system gradually formed by human beings through coping with problems and adapting to the social development. It shapes not only humans' behavior but also influences humans' psychological needs. The leaders' attitudes, behaviors, and motivations towards their subordinates will vary depending on their culture [50].

These cultural differences will also impact the effectiveness of leadership behavior [51]. Western culture is mainly

TABLE 1: Definitions of project success.

Author	Definition
Edward [27]	Project success covers quality, time, cost.
Bryde and Robinson [28]	Project success includes pre-success, successful completion, and successful operation.
Kim and Reinschmidt [29]	The leading indicators of project success are customer satisfaction, quality, duration, cost, and other complex indicators.
Gabriella Cserháti [30]	There are five criteria for project success: efficiency, impact on a customer, impact on the team, business and immediate success, and preparation for the future.
Joslin and Müller [31]	Project success measurements include the iron triangle "time-cost-quality" and customer satisfaction.
Wang et al. [32]	Project success includes project efficiency, organizational benefits, project impact, stakeholder satisfaction, and future potential.
Luo et al. [33]	Project success includes time, cost, quality, health and safety, environmental performance, participants' satisfaction, user satisfaction, sustainability, and commercial value.

influenced by European and American cultures, which actively encourages people to express their visions and tendencies in organizations and promotes individualism. However, Eastern culture is more affected by Confucian patriarchal culture, and it advocates collectivism more than Western civilization, especially during the construction of large-scale projects [3]. The project teams can collaborate and cooperate based on task interdependence to promote the efficient integration of heterogeneous innovation resources. On the other hand, the samples used in different studies usually come from different countries. The differences in the countries' economic level and cultural environment where the models belong have a particular impact on the project's successful realization [52, 53]. Therefore, the following hypothesis is formulated:

> H5: cultural background moderates the relationship between TL and project success, and TL in developed countries has a more significant impact on project success

According to the above assumptions, this study proposed a theoretical research model, shown in Figure 1.

3. Method and Data

In recent years, meta-analysis has contributed prominently to the literature review as a new method of combining empirical research with research hypotheses. Specifically, meta-analysis can reanalyze multiple empirical research results with the same research purpose to obtain the fundamental relationship between variables. The advantage of meta-analysis is that it can systematically analyze many documents and evaluate the inconsistency of different research results [54]. This method can discover and explain the differences between various research results, systematically integrate the existing empirical research results, and further improve its reliability and validity. Therefore, this paper mainly uses Hunter and Schmidt's primary effect test as well as moderating effect test method. It adopts CMA 2.0 software to assist with the version bias heterogeneity test.

3.1. Literature Sources and Collection.
According to the following three steps, this research points to the literature collection to ensure the systematic literature collection.

Firstly, this study shows computerized keyword searches in the databases Web of Science, Google Scholar, Science Direct, Elsevier, and Springer before October 2020. The papers are searched by the following keywords: "transformational leadership," "project success," "project manager," and "Construction project success." Secondly, to avoid the omission of essential documents since some related studies on TL and project success are not included in the above databases, this research combines the collected records with the references of these documents, especially compared to the review literature one by one. Finally, the study manually searches the most essential and relevant journals, such as "*Journal of Cleaner Production*," "*The Leadership Quarterly*," and "*International Journal of Project Management*."

The process and results are shown in Figure 2.

3.2. Literature Inclusion Criteria.
The searched documents are filtered according to the following criteria: (1) It must be a survey or experimental empirical research, excluding pure theoretical and literature review articles. (2) It uses both the TL measurement scale and the project success measurement scale, and at least reports the correlation coefficient (r) between the dimension or total score of one scale and the dimension or total score of another scale. Or it can be converted into the F-value, t-value, or X^2 value of r. (3) The selected research is not only limited to journal papers, but also includes thesis, book chapters, etc. (4) If the data is published repeatedly, the published journal articles shall be taken. (5) Document effect value encodes an effect value based on each independent sample.

3.3. Document Coding Content and Results.
The subsamples included in the meta-analysis are also ordered as follows: firstly, the necessary information of the research (author name and publication time), sample size, and whether there are intermediate variables in the empirical research (divided into yes and no), the cultural background of the study (divided into Eastern culture, Western culture, and others) and the type of article (journal papers, thesis).

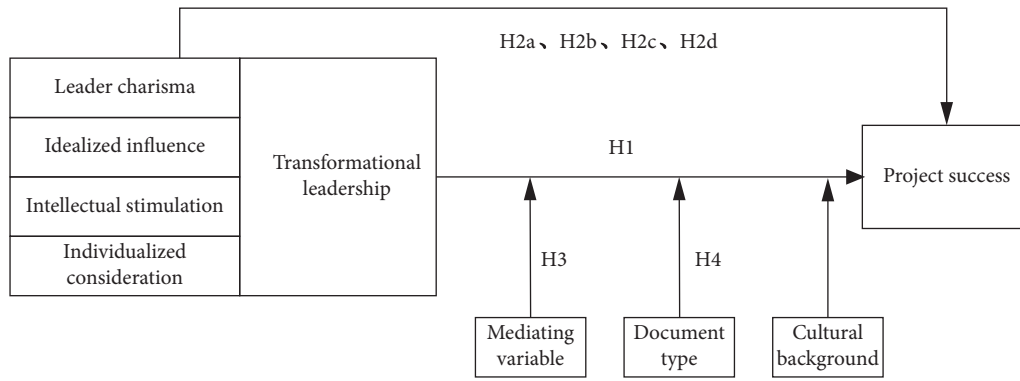
Secondly, the research should primarily discuss the total effect of TL on project success. This paper adopts the


FIGURE 1: The theoretical research model.

FIGURE 2: The flowchart of study selection.

weighted average method for the influence coefficients of different dimensions of TL mentioned in the literature on project success. If they encounter the literature that discusses the disparate dimensions of TL on project success, the final effect value would be obtained by taking the average layer by layer. The necessary coding information of the main effects analysis is shown in Table 2.

4. Results

4.1. Test for Publication Bias. Funnel plots are the most commonly used approach to determine the presence of publication bias. Figure 3 shows the distribution of the effect value. It can be seen that most of the samples concentrate at the top of the funnel chart, and the scattered points distribute near the effect value [55]. Therefore, the possibility of publication bias in this study is relatively slight. Besides, this paper introduces a "file drawer" analysis according to Rosenthal [56] to estimate the severity of publication bias. The larger the coefficient, the greater the number of studies required to reverse this result, the more reliable the

conclusions of the meta-analysis, and the smaller the relative impact of bias. After calculation, when $P = 0.05$, Nfs = 10223, and $P = 0.01$, Nfs = 7945, the fail-safe coefficient of this study indicate that the conclusion is more reliable.

This paper adopts Fail-safe, Egger's test (regression intercept method), and rank correlation test for further testing to test the publication deviation more accurately. The results are shown in Table 3. The fail-safe factor is $N = 11495$, indicating that if people want to overturn the TL effect, 11,495 documents are needed to get the opposite result. Egger's test results show that the P value is 0.88, which is not significant, and there is no publication bias. The level correlation test results, Tau values being -0.09 ($P = 0.58$), suggest that there is no publication bias in the effect size.

4.2. Test of Heterogeneity. This study tests data for heterogeneity, which is a key step in synthesizing the global effect value from the practical value of a single study. The Q test results reflect the degree of heterogeneity of each

TABLE 2: Descriptive characteristics of the studies.

TABLE 3: Publication bias test.

| Leadership style | NFS | Egger's test | Tau | Trim and fill | | |
				Observations	Adjusted value	Change value
TL	11495	1.01 ($P = 0.88$)	0.09 ($P = 0.58$)	0.589	0.301	0.288

effect size. If each effect size is heterogeneous, it indicates that the true error causes the difference of each effect size in the meta-analysis. Since the combination of variables can lead to sampling errors, the random-effects model should be applied. The test results are shown in Table 4. It can be learnt that Q (19) = 1713.0, $P < 0.001$, and $I^2 = 98.89\%$, indicating that the effect size of each study is heterogeneous. Among them, I^2 greater than 75% means that the observed variation above 75% is caused by the true difference in effect size, reaching a high level of heterogeneity [56]. The values of Tau^2 are 0.317, which means that 31.7% of the inter-study variation can be used to calculate the weight.

The heterogeneity test results show that the correlation between TL and project success is heterogeneous in the selected studies. Therefore, the random effect model is used in this study since it is more accurate for meta-analysis.

4.3. Theoretical Model and Test of Direct Relations

4.3.1. Total Effect Size Test Result. According to the heterogeneity test results, the random-effects model was selected to test the main effects of the relationship between TL and project success (see Table 5). From the drawing, we can see that the overall test of the relationship between TL and project success, a total of 31 effect sizes ($N = 6475$), the overall correlation coefficient of TL and project success is 0.589 ($P < 0.001$), in 95% of the confidence interval is significant. When $|r| \leq 0.1$, it is low correlation, $0.1 < |r| < 0.4$ is medium correlation, and $|r| \geq 0.4$ is high correlation. Based on this judgment, TL is positively correlated with project success. Therefore, hypothesis 1 is supported.

4.3.2. Subdimension Effect Size Test Results. It can be seen from Table 6 that the Q test results of the heterogeneity of the relationship between each dimension of TL and project

TABLE 4: Results of the heterogeneity test.

TABLE 6: Dimensional meta-analysis results.

| H | Heterogeneity test | | | K | N | 95% CI | | | Two-tailed test | | NFS |
	Q	df	P			Point estimate	Lower	Upper	Z	P	
H2a	1589.59	10	<0.001	20	3243	0.731	0.612	0.817	8.366	<0.001	6376
H2b	824.79	10	<0.001	12	2948	0. 673	0.487	0.811	5.638	<0.001	5178
H2c	484.94	8	<0.001	8	2149	0.619	0.482	0.785	5.842	<0.001	3154
H2d	1093.4	9	<0.001	10	2543	0.721	0.576	0. 822	7.051	<0.001	6602

Note. K = number of studies; N = sample size; r = effect size; and 95% CI = confidence interval around r.

success are significant, indicating that each effect size is heterogeneous, and the random-effects model can be used. N's loss of safety factor is more powerful than 500, showing no publication bias in each dimension's effect value.

From the dimensional meta-analysis results, the four dimensions of TL have some differences in their effect size; in detail, leadership charm is the largest (0.731) while intellectual stimulation is the most minor (0.619). According to Cohen's scale for social science research, correlations with values close to 0.2, 0.5, and 0.8 correspond to weak, moderate, and decisive effect sizes. Thus, leadership charisma reasonably correlates with project success, while vision motivation has a fragile relationship. As a result, hypothesis 2a–d is accepted.

4.3.3. Moderation Analysis. As can be seen from the above, there is significant heterogeneity in the effect sizes for the meta-analysis in this paper. To further analyze the heterogeneity source, random-effects models are also adopted to test whether mediating variables, cultural background (Eastern culture, Western culture, and others), and literature publication types (journal papers, thesis).

The results in Table 7 show that whether to participate in the intermediary variables has a significant moderating effect on the relationship between TL and project success ($Q = 336.669$, $P < 0.001$). In the presence of intermediary variables, TL ($r = 0.649$, $P < 0.001$) and the correlation coefficients of project success were significantly higher than those of Western cultural background ($r = 0.452$, $P < 0.001$). Hence, hypothesis H3 is supported.

The cultural background also significantly moderates the relationship between TL and project success ($Q = 55.641$, $P < 0.001$). The empirical results indicate that TL in Eastern cultural backgrounds can play a more critical role in influencing project success. Thus, hypothesis H4 is supported.

Similarly, the literature publication has a significant moderating effect on the relationship between TL ($Q = 214.251$, $P < 0.001$) and project success. Under the dissertation type, the correlation coefficient between TL ($r = 0.765$, $P < 0.001$) and project success was significantly lower than that of the journal paper type ($r = 0.513$, $P < 0.001$). Therefore, it assumes that H5 is accepted.

5. Discussion and Implications

5.1. Discussion. This paper conducts an in-depth analysis of the empirical research on the relationship between TL and project success based on the meta-analysis method. It mainly focuses on the relationship between the various dimensions of TL and project success and the moderating role of the mediator variables, cultural background, and document type. Therefore, the following conclusions are drawn:

Firstly, the results suggest that TL can positively influence project success, in line with previous studies. The significant challenges of modern society and the increasingly different business environment require people to re-examine leadership research and change the traditional concepts and ways of thinking about leadership in the construction industry. A study by scholar Kissi [57] confirmed the necessity of project organizations to cultivate TL behavior to improve performance. By summarizing traditional team-building practices, Do [58] found that transformational leaders are more likely to enhance team members' understanding of project goals, roles, and responsibilities, interpersonal communication, and problem-solving skills, which will also help affect project success.

Secondly, this article's four dimensions of TL can improve project success in a cooperative-friendly way. To be

Moderating variable	Leadership style	Heterogeneity test			Sort	K	N	95% CI			Two-tailed test	
		Q	df	P				Point estimate	Lower	Upper	Z	P
Mediating variable	Transformational leadership	336.669	2	<0.001	Y	23	1254	0.573	0.622	0.817	8.546	<0.001
					N	8	1583	0.469	0.608	0.795	7.128	<0.001
Cultural background	Transformational leadership	55.641	2	<0.001	E	10	2319	0. 893	0.587	0.831	5.748	<0.001
					W	17	1826	0.759	0.452	0.776	5.682	<0.001
					O	4	1382	0.723	0.632	0.797	8.426	<0.001
Document type	Transformational leadership	214.251	2	<0.001	J	3	781	0. 611	0.467	0.834	5.678	<0.001
					T	28	2825	0.677	0.512	0.792	5.7843	<0.001

Note. Y: the existence of mediating variables; N: the absence of mediating variables; W: Western culture; E: Eastern culture; O: other; J: journal; T: thesis; K = number of studies; N = sample size; r = effect size; 95% CI = confidence interval around r.

specific, correlation strength is leadership charm, individualized consideration, idealized influence, and intellectual stimulation. Perhaps most empirical research on TL focuses on business operations, and the number of research samples in the construction context is relatively tiny. Stanislas [59] analyzed the indicators that affect sustainable construction and found that the personal charm of the project manager is one of the crucial indicators that can improve leadership effectiveness. Zia [60] reckoned that the emotional intelligence of project managers could improve partnerships and promote effective communication between project members. Maqbool [61] pointed out project managers with high emotional intelligence who bear the desired competencies and exhibit transformational leadership behavior are influential leaders and ensure higher success in projects than their counterparts. Also, Shafi [7] also indicated that idealized influence, intellectual stimulation, and inspirational motivation greatly influence organizational innovation. Many studies support this article's results [62, 63]. Therefore, the results of this article will help construction companies choose the right project manager for the project. At the same time, TL should pay attention to the rational use of the complementarity and dependence between various dimensions in the management process to promote project success.

Thirdly, mediating variables, cultural background, and document types are all sources of heterogeneity. Through a systematic review of meta-literature, this article finds one or more intermediary variables in most existing empirical models, such as knowledge learning, psychological capital, interorganizational relationships, and innovation atmosphere. Scholar Qaisar introduced psychological capital as an intermediary variable to construct a model and found that it negatively affected the relationship between the two. The existence of positive mediating variables will positively impact the relationship between project leadership style and performance, and vice versa. Under the East and the West's different cultural backgrounds, the influence of TL on project success is significantly different and regular. Under the environment of Eastern culture, the impact of TL on project success is higher than that of Western civilization. In particular, influenced by traditional Confucian culture [3, 64], high power distance, and collectivism, low-level project members in Chinese construction organizations are more likely to follow or accept organizational tasks assigned to leaders. However, the project members under a Western

cultural background are more inclined to individualism, reflecting their ability and value [65]. Therefore, the construction project members under different cultural backgrounds will have other internalized explanations when facing the same leadership style, resulting in differences. Under the experience of Eastern culture, TL has a more noticeable impact on project members than in Western countries, resulting in a higher project success rate. In journal papers, more studies have been found to study the relationship between the two, and a large number of research scholars tend to establish empirical models to explore the boundaries of the two through different variables, which is also the direction of future research.

5.2. Theoretical Implications. On the one hand, this research enriches and extends the development of TL and project success theory. Through a meta-analysis, the reasons for the inconsistent conclusions on the relationship between TL and project success in past studies have been identified, and a focused comparison of the impact of different dimensions of TL and project success is conducted. The research results show that TL has a positive and significant relationship with project success, which provides a new research perspective for improving project success. TL and its impact on the success of the project have been reviewed in previous studies, mainly from the perspective of the overall impact of TL on the success of the project; this is far from enough. Therefore, this article analyzes and explains the differences in previous research results as a whole and helps to clarify the indistinguishability of the project success relationship caused by the mixed use of TL concepts. It can provide more accurate estimates of TL performance in different dimensions and dig deeper. The essence of TL's influence on project success is analyzed, and the impact of TL's dimensions on project success is sorted.

On the other hand, this article enriches and refines the boundary conditions and scope of application that influence the success of the TL project. Based on the empirical data analysis of the former National People's Congress, by further refining the moderating effects of the existence of mediating variables, document type, and cultural background, on the relationship between the two, a detailed discussion of the mechanism of TL and project success can be realized. The research results reveal the precise path of transformational

leadership influencing project success, enriching and perfecting the existing project success model research. This article helps to understand TL-style project managers' internal laws of successful project operation and consolidates academic support for project management success in construction projects.

5.3. Practical Implications. This study provides several practical implications for construction companies and leaders. First of all, it helps construction companies preferentially select project managers. The results show that TL's leaders enhance team cohesion and mutual understanding, create a harmonious working atmosphere, promote the open exchange of ideas and analyses between project teams, and emphasize developing followers' self-management or self-leadership skills. In particular, selecting talents with strong leadership charm and abilities is more conducive to establishing a highly reliable organization for the project to cope with today's complex and changing international environment.

Then, the project managers should focus on their words and deeds on project members. Each project member can understand their mission and goal direction through vision incentives, translating into personal work goals. Inspiring leadership behavior through intelligence can create a challenging organizational atmosphere. This can make the project members more innovative and encourage them to express their ideas. The project manager actively cares about the organization's tasks and the needs of the project members, recognises the uniqueness and diversity of the beliefs and values of the project members, and provides corresponding support. Project managers should improve their own leadership charisma to enhance the self-confidence of members. At the same time, when making decisions, project leaders must have individualized considerations and seek more opinions from members to improve the identity and loyalty of project members. For example, in the Hong Kong-Zhuhai-Macao Bridge [66], well-trained professional subcontractors need better treatment, stable commitment, professional training, improved working conditions, genuine care, and on-site management for workers on-site. Therefore, it helps the Hong Kong-Zhuhai-Macao Bridge to achieve great success.

Finally, the construction project managers require to be trained in technical and soft leadership skills. The former ensures that project managers clearly understand and apply project management methods. The latter helps to adapt these methods to the specific social and cultural environment of the construction project. Thus, TL's leaders must make full use of the new generation of information technology, such as 5G, BIM, robots, etc. In the whole life cycle of project construction, they should lead the project members to achieve project success [67]. Also, they need to learn to use knowledge management and scenario deduction to make decisions, create a working environment that is most suitable for project members, and avoid limiting leaders' behaviors to a certain level. Meanwhile, as a survey concluded, different leadership styles are ideal for various projects [68].

So, it is necessary to adopt a diverse leadership style that adapts to the organizational environment to balance administrative tasks and meet the requirements of project members.

6. Limitation and Future Research Directions

There are several limitations that are worth mentioning. Firstly, the meta-analysis method only includes the analysis of the Pearson correlation coefficient when selecting samples, which will lead to the loss of some models. The removal of samples due to the inability to obtain effective effect sizes may affect the relationship in this article. Secondly, there is a limitation of potential moderating variable analysis. This study examines the potential moderating effects of situational features, design features, and measurement features, but different research samples will be affected by other factors. Future research can further explore other mediating factors, such as stakeholder relationships, psychological empowerment, individual values of project members, etc., to understand why certain construction activities can succeed while others fail.

7. Conclusions

There is a growing amount of research on the relationship between TL and project success, but the findings lack consensus. This meta-analysis provides more statistically valuable and accurate results for the general relationship between TL and project success by overcoming a single study's sampling error and sample size limitations. In addition, the moderating effects can be further tested to explore the influence of the existence of mediating variables, cultural background, and document types on the relationship of TL and project success and the inconsistent results of extant studies. In this way, a comprehensive theoretical framework is constructed for this study. The findings of this paper can provide better insights for choosing the right development strategy and improve leadership effectiveness to promote the project's sustainable development under the Industry 4. 0 era.
