Construction workers' unsafe behaviors are closely related to construction safety performance. Most existing studies on construction workers' personality traits and safety behaviors have ignored the flexibility of worker mix at construction sites, the dynamics of workers' behaviors, and the complexity of environmental risks at construction sites. Based on the cognitive process of construction workers' safety behaviors and from the perspective of personality traits, this research establishes an agent-based model of steelworkers' mutual assistance behavior. The AnyLogic platform is adopted to show emerging phenomena in complex problems. Through simulation experiments, the optimized configuration of construction team members under different risk environments can be obtained. This research is conducive to project managers to understand the influence of construction workers' mutual assistance on team safety, assess workers' potential for safe work before recruitment, and carry out active safety management from the source instead of looking for the cause of the accident afterward, making safety management theory more realistic and dynamic.

1. Introduction

According to statistics, the construction industry employs approximately 6%–10% of the labor force but accounts for 20%–40% of occupational fatal accidents [1]. The frequent occurrence of accidents makes the safety problem of building construction very serious. Researchers [2–4] analyzed the relevant data on accidents and found that the unsafe behavior of the construction personnel was the fuse for the accident. Even in the same situation, construction workers will have different behaviors. This is because, besides being affected by environmental factors, workers' behavior is also affected by personal characteristics. Many studies [5, 6] have identified personality as one factor that significantly affects workers' safety performance. Personality can also be used to explain and predict human behavior and job performance [7]. Florez and Cortissoz [8, 9] show that workgroups with similar personalities can speed up project progress. Also, personality has been proven to be related to

risk perception [10], risk propensity [10], risk preference [11], unsafe behavior [11], and social behavior [12]. Although researchers have explored the relationship between workers' unsafe behaviors and personality traits, existing studies hardly consider the dynamic effects of personality traits on worker behavior and interactions between workers and the external environment.

Complex construction tasks exist on the construction site. Some traditional research methods, such as the field observation method [13] and qualitative analysis method [14], can only analyze the static state of the project but cannot capture the processes of on-site dynamic changes. Therefore, it is necessary to investigate methods that can capture the nature of dynamic site changes as well as the impacts of different personality traits.

Computer simulation technology provides a good way to solve complex systemic problems [15]. By reproducing relevant scenarios in the real world and setting parameter ranges in simulation experiments to observe changes at the

macro level, the shortcomings of traditional analysis methods such as limited data, excessive interference factors, and difficulty in controlling variables [16] can be effectively avoided. Agent-based modeling (ABM) is a classic research method to explore changes in macroscopic results caused by microinteractions [17]. Aiming at the workers in the construction team and considering the mutual assistance of on-site workers and workers and the interactions with the external environment, an agent model is established in this study based on the cognitive process of behavior.

2. Literature Review

2.1. Big Five Personality Traits and Behaviors.
In the construction industry, many researchers studied the factors that influence individual unsafe behaviors from the perspective of psychology. Neal and Griffin [18] proposed that personality traits affect safety behaviors and can affect safety results. Lingard and Rowlinson [19] found that there are almost no workplaces where personality does not affect work-related behaviors. Since accidents are caused by a series of events and the agents of these events are a person. Therefore, it is vital to understand the relationship between the personality characteristics of people and the high incidence of human error accidents on construction sites [20]. The Big Five personality traits, proposed by McCrae and Costa [21], are the version accepted by most psychologists, including five dimensions of extraversion, agreeableness, conscientiousness, neuroticism, and openness. In interviews, self-descriptions and observations, as well as a wide range of participants of different ages and different cultures, showed consistency [22].

Many researchers have studied the correlation between Big Five personality traits and the unsafe behavior of construction workers. Geller [23] took construction workers as the research object and explored the correlation between the five characteristics of the Big Five personality traits and unsafe behaviors through a questionnaire survey. Similarly, Clarke [24] also found that workers' accident tendency is closely related to their personality traits. Although an individual's personality traits do not directly determine whether unsafe behaviors occur, they can have an important impact on the main actions in the process of unsafe cognition. As far as risk perception is concerned, different individuals have different perceptions of risks. Different individuals have different cognitions and understandings of the origin of different risks, the composition of risks, and the severity of risks [25].

Chauvin et al. [26] found that the environment faced by construction workers is complex and changeable when performing work tasks. When making risk decisions, they are often affected by personality factors. Myers et al. [27] found that the perception of risk is closely related to individual differences based on research. The risk assessment also involves the individual's risk tolerance. Risk tolerance is related to the number of risks, the qualitative characteristics of the hazards, the perceived benefits of risks, and personal acceptability. Faced with the same risk situation, everyone's risk tolerance is different. Risk tolerance is affected by factors such as personal characteristics, expected consequences, and safety culture [28]. Thanki [29] found a correlation between personality traits and risk tolerance. Bye and Lamvik [30] also proposed that personality traits are related to risk tolerance.

2.2. The Cognitive Process of Safe Behavior.
Many researchers found that the unsafe behaviors of construction workers mainly caused accidents. For the unsafe behavior of construction workers, the mechanism of unsafe behavior is the sorting out of the influencing factors of unsafe behavior and the construction of interrelationship to clarify the position and role of each influencing factor in the chain of unsafe behavior, which is a further deepening based on the analysis of influencing factors. With the in-depth study of psychology and social cognitive processes, Fang et al. [31] began to explain the mechanism of unsafe behavior from the perspective of safety cognition. Goh et al. [32] borrowed from the theory of planned behavior [33] to analyze and believes that unsafe behavior is the result of rational decision-making by construction workers. Chi et al. [34] pointed out that workers' unsafe behaviors are misjudgments or wrong decisions made in the cognitive process. From a physiological point of view, construction workers' cognitive status can also be assessed by valence, arousal, and dominance index in the valence-arousal-dominance (VAD) model [35], which can be measured by electroencephalography (EEG) [36]. By analyzing the three broadly influential cognitive models: Rasmussen's step-ladder model [37], Wickens et al.'s model of human information processing [38], and the IDAC model [39], Fang et al. [31] summarized the cognitive process of construction workers' unsafe behaviors into five stages: discovering information, understanding information, thinking and responding, choosing a response, and implementing the response. Among them, the failure of the choice response is the most important cause of unsafe behavior. Ye et al. [40] sorted out the influencing factors in the cognitive process and discussed the impact of the failure of the cognitive process on construction workers' unsafe behavior from the individual and the environment. The research summarizes the cognitive process into four stages: obtaining information, understanding information, choosing response, and taking action. Although there are differences in the details involved, these models all emphasize risk perception, risk assessment, and decision-making.

2.3. Workers' Mutual Assistance and Construction Safety.
With the continuous improvement and progress of various mechanisms in human society, the emotions and instincts of cooperation and mutual assistance between individuals have become increasingly mature [41]. The behavior of mutual assistance is very important to the work and life of the individual. Herman [42] believes that mutual assistance behavior is when others have certain needs, the behavior for satisfying the real needs of others. Anderson and Williams [43] believe that helping others deal with the problems encountered in work and life, that is, the behavior of colleagues in favor of others is a mutual assistance behavior.

In the construction and production activities, the team is not only closely related to the equipment, machinery, tools, and materials required in the construction and production activities but also the most basic organization that implements the various rules and regulations, construction technology, and on-site management activities in the construction enterprise. In the construction team, most of the construction workers come from the same place. They are not only the relationship of colleagues at work but also the relationship of friends in life. No matter in life or work, construction workers will care about their workers, help and cooperate, and strengthen emotional exchanges in daily activities. Mutual help behavior not only helps team members better establish interpersonal relationships and better adapt to the surrounding environment but also has important significance in completing construction tasks safely and improving the overall performance of the team.

In the field of construction safety, many researchers have researched the mutual assistance behavior of construction workers. Liang et al. [44] believe that workers often surpass team leaders and managers and have a more social influence on workers. Some researchers [45–47] regard worker mutual assistance as a dimension to evaluate the safety atmosphere of construction and verify the relationship between the safety mutual assistance of workers and workers and the safety atmosphere of the organization. Burt et al. [46] have further realized that workers who care about the safety of their colleagues play an important role in improving safety performance. The active care of workers may overcome (or supplement) the need for management to continuously monitor safety-related behaviors. Workers help ensure the safety of their colleagues by taking on this responsibility. Suppose the dominant attitude of each worker is to care about each other, and each worker actively identifies hazards and reminds workers. In that case, the safety performance of the team will be improved. Osama Jannadi et al.'s [48] research also shows that mutual safety assistance between colleagues positively impacts safety performance.

Safety mutual help between workers is mostly in the form of communication, such as reminding workers to abide by safety rules, sharing hazard information with workers, and discussing past accidents and safety improvement measures [45, 49]. These exchanges and mutual help will not only bring about the flow of information and knowledge and other organizational resources but also positively impact the members of the organization. Knowledge and experience sharing among colleagues can better promote performance [50]. Through safe and mutual help exchanges with workers, construction workers not only make it easier for construction workers to master the operating methods of the tools and machinery used but also avoid unsafe behaviors to the greatest extent.

3. Research Gap

Existing studies have explored the correlation between personality traits and the work behavior of construction workers through questionnaires, focusing on the psychological factors of the agents of construction activities. However, each worker's behavior is not the direct result of a factor but rather a combination of personal characteristics, mutual assistance with others, and interaction with the external environment. In a site environment with complex construction tasks, the variability of behavior caused by different personality traits, the interactivity caused by mutual assistance and cooperation with workers, and the dynamism caused by real-time adjustment of their behavior according to site changes make the interactive behavior of individual construction personnel at the individual level lead to changes at the project level.

Thus, traditional research methods, such as the field observation method and qualitative analysis, are only possible to analyze the project situation in a static state but not to capture the dynamic changing processes. In addition, although these studies can find universal rules and provide certain guiding significance, they ignore the composition of workers' personality traits, the interactions between workers and the external environment, and the influence of construction workers' mutual assistance on team safety. Furthermore, those studies do not consider the degree of environmental risk on the construction site.

4. Research Methodology

4.1. Overview. Due to the complexity of the construction tasks, characteristics of the individuals, and the changing environment, it is more difficult to use traditional methods to study the behavior changes of construction workers and their dynamic effects [51]. Using computer simulation technology to study the behavioral activities of interaction in building construction can actively change the parameters for control, avoid the interference of unrelated external factors on the experimental results, and achieve real experimental and control effects. It can also create a new research space for construction safety-related behaviors of construction workers from the perspective of technical methods [16].

In this study, firstly, based on the findings of existing literature, the relationship between the five personality traits in the Big Five personality theory and the key parameters (risk perception, risk tolerance) in the cognitive process of unsafe behavior of construction workers was synthesized. Then, based on the workers' key parameter attributes and their external environment, whether they perform unsafe behaviors or not is determined. Finally, while the cognitive process of workers' unsafe behaviors occurs, the possibility of cooperation and mutual assistance between workers and their surrounding colleagues is considered to explore the impact of individual behaviors on the overall team safety.

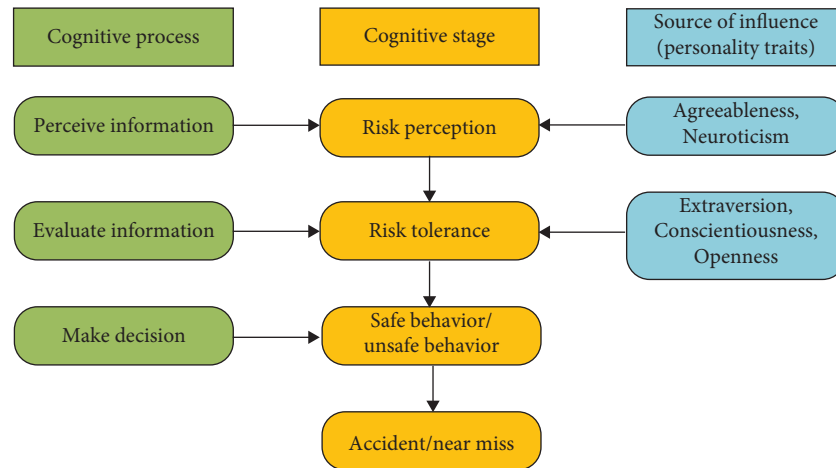
This study adopts an ABM approach to solve the problem of inconvenient control of variables such as external environmental factors and an individual's actual situation when personality trait factors are involved. A variety of combinations of workers with different personality traits are realized by dynamically adjusting the relevant parameters in order to explore the different combinations of workers' mutual assistance on the overall unsafe team behavior. This study simulates the impacts of safety and mutual assistance of workers with different personality traits on team safety and provides an optimized combination plan for team workers.


FIGURE 1: Framework of decision-making in the cognitive process of unsafe behavior of construction workers.

4.2. Model Framework. In recent years, research on theoretical models of cognition has matured and improved, providing a strong foundation for the scientific study and explanation of individual cognitive processes in many fields. The cognitive process of construction workers' unsafe behavior can be divided into three stages: perceiving information, evaluating information, and making decisions [52]. In the stage of perceiving information, workers perceive the risks from external information. This means the subjective judgment and assessment of the current danger when the individual is in an environment where danger may occur [53]. The risk level perceived by an individual is not only related to the true risk level [54], but risk perception is also affected by personal beliefs, attitudes, judgments, and feelings [55]. In studies on the Big Five personality traits and individual perceived risk, perceived risk is influenced by agreeableness [54] and neuroticism [26]. According to Sjöberg [54] and Chauvin et al. [26], the more neurotic and agreeableness of an individual, the more risks they feel. Individuals with high agreeableness scores may prefer safer solutions or alternatives to reduce their discomfort [56]. During the evaluation information phase, construction workers consider the level of acceptance of risk to assess the level of injury and benefit from the behavior. The risk evaluation process can be determined by comparing the perceived risk with the risk tolerance the individual can bear. Hunter [57] defines risk tolerance as "The amount of risk that an individual is willing to accept when pursuing a certain goal." According to this definition, it can be found that risk tolerance includes two aspects: subjectivity (the degree that an individual can tolerate) and goal (total risk). Wang et al. [58] verified that the psychological characteristics of construction workers significantly impact risk tolerance through questionnaires and structural equation models. Individuals' acceptance of risk is related to their extroversion [30], openness [29], and due conscientiousness [28]. In the decision-making phase, workers make judgments based on a combination of information from the first two phases as well as physiological and skill factors. The first two cognitive stages, perceived and evaluated information, are important for the safety of construction workers. Therefore, risk perception and risk tolerance in the two stages will be selected as key parameters in the model, and the influence of personality traits on these two parameters will be investigated. The framework of decision-making in the cognitive process of unsafe behavior of construction workers is shown in Figure 1.

4.3. Agent-Based Model Development. Establish an agent-based model according to the cognitive process of safe behavior, which is composed of (1) a description of the environment and the agent (2) defining the mutual assistance rules between the agent and the interaction rules between the agent and the external environment (3) model validation [59]. Each of these model components is explained in detail below.

4.3.1. Defining Environment and Agent. In the agent-based model, the virtual construction site environment is set according to the grid form proposed by Lu et al. [60]. The area is set to $40 * 40$ (each grid represents $1\,m^2$ of space); the task volume is included in the site (range 0–20); and the risk level (range 0–1) has two parameters. Different grids have different tasks and risk levels as shown in Figure 2. Among them, parameters 1–9 are the initial parameters of the environment (1–2) and the agents (3–9) that need to be set when the model is constructed and are mainly set according to existing studies [44, 61]. Parameters 10–21 are process parameters calculated when the model is running, and the calculation method is executed according to the define interaction rules.

Because steelworkers have the highest occupational disease and injury rate [62], the workers in the model are set as steelworkers. Considering that the death rate of tower crane-related accidents is relatively serious and the location is relatively fixed, more importantly, the tower crane is easy to be noticed by colleagues' safety warnings and avoid accidents [63]. So the hazard source is set as a tower crane and placed in the center of the site.

TABLE 1: Model parameter setting.

No.	Parameter name	Parameter meaning	Initialization value
1	riskLevel	Construction site environmental risks	Triangular (0, 0.5, 1)
2	workload	Construction site tasks	Triangular (0, 10, 20)
3	workerNum	Number of workers	20
4	id	Worker's ID	—
5	extroversion (E)	Worker's extroversion	N (0.5, 0.13)
6	agreeableness (A)	Worker's agreeableness	N (0.5, 0.13)
7	conscientiousness (C)	Worker's conscientiousness	N (0.5, 0.13)
8	neuroticism (N)	Worker's neuroticism	N (0.5, 0.13)
9	openness (O)	Worker's openness	N (0.5, 0.13)
10	riskPerception (RP)	Risk perception of worker	—
11	riskTolerance (RT)	Risk tolerance of worker	—
12	unsafeBehavior (UB)	Unsafe behavior of worker	—
13	safeHelpBehavior (SHB)	Mutual assistance of workers	—
14	numberOfUnsafeBehaviors	Number of worker's unsafe behaviors	—
15	numberOfSafeBehaviors	Number of worker's safe behaviors	—
16	unsafeBehaviorRate	Unsafe behavior rate	—
17	numberOfAccidents	Number of accidents	—
18	numberOfNear-missingAccidents	Number of near-missing	—
19	ratioOfAccidentsToNearMisses	Ratio of accidents to near-missing	—
20	unsafeBehaviorReductionRate	Unsafe behavior reduction rate	—
21	accidentRate	Accident rate	—

Steelworkers are the main agents of the model, and each worker has the following state variables: ID number, Big Five personality traits (extraversion, conscientiousness, agreeableness, neuroticism, and openness), risk perception, risk tolerance, and unsafe behavior. Based on the size of the construction team, the number of workers on site is set to 20. Before each simulation model runs, the grid unit's risk value and task amount are assigned different values to simulate different construction situations. The five personality traits of construction workers are assigned different values, representing their heterogeneous attributes. Among them, different personality traits will affect the behavior and decision-making in performing tasks. Based on the statistical research of Schmitt et al. [61], the distribution of personality traits in each dimension follows the normal distribution, and the model sets its range from 0 to 1. To exclude extreme traits, the worker's traits range from 0.1 to 0.9, which is set to obey the normal distribution of N (0.5, 0.13) through analysis. The on-site environmental risks and on-site tasks are set to a medium level that obeys

the triangular distribution [44]. Table 1 shows the parameter settings for the construction of the benchmark model (the model that has set the relevant initial parameters of the agent).

4.3.2. Defining Interaction Rules. This research assumes that construction workers have two states: task-Searching and task-Executing. In task-Searching, the grid unit where the worker is currently located has no tasks, and at this time, the agent needs to move to the grid with tasks, and its state also changes from task-Searching to task-Executing. Since injuries or accidents usually occur in the task execution process rather than the task search process, this research mainly focuses on the cognitive process of safety behavior during the task execution process.

(1) The Decision-Making Rules of the Cognitive Process. According to the conclusion of the cognitive model, workers mainly experience three stages: perception information,
FIGURE 3: Modeling logic of workers' construction safety behavior based on the cognitive model.

evaluation information, and decision-making response, in the process of cognition of unsafe behaviors, corresponding to the three states of risk perception, risk tolerance, and safe behavior or unsafe behavior. The modeling logic is shown in Figure 3.

In the stage of perceiving information, workers will make subjective judgments and assessments of hazards. Risk perception can be affected by actual risk levels [54] and individual factors [55].

Chauvin et al. [26] found that construction workers face complex and changeable environments when performing work tasks, and they are often affected by personality factors when making risky decisions. Even facing the same environmental risk, the risk perceived by one worker may be different from that of another colleague. Therefore, the risk perception in the model is determined by the actual risk value of the current environment and the personality traits of the worker. Individuals with a high level of agreeableness tend to view risk as a higher risk factor [26]. In contrast, people with high neuroticism scores are prone to anxiety and tend to be conservative in the face of risks [64]. According to Sjöberg [54] and Chauvin et al. [26], the more neurotic and agreeableness of an individual, the more risks they feel. An individual with high agreeableness scores may prefer safer solutions or alternatives to reduce their discomfort [56]. Therefore, risk perception can be determined by agreeableness and neuroticism from the perspective of personality traits. To ensure the balance of contribution, the proportion is set to 0.5. Based on the above analysis, the model can express risk perception by the following formula:

$$\mathrm{RP}_i^t = \mathrm{ER}_i^t * \left(0.5 * \frac{a_i}{A} + 0.5 * \frac{n_i}{N} \right), \tag{1}$$

where RP_i^t: worker i's risk perception at time t, ER_i^t: the actual risk value of worker i's environment at time t, a_i: the agreeableness score of workers i, A: the maximum value in the value range of agreeableness, n_i: the neuroticism score of workers i, and N: the maximum value in the value range of neuroticism.

When workers perceive risk, they will conduct an informal assessment based on their situation, that is, assess the degree of risk that can be tolerated. Williams and Noyes [65] believe that risk tolerance is a personal assessment of risk and the corresponding comfort or discomfort to the risk. It depends on the level of confidence that controls the uncertainty of the situation. Studies have found a correlation between risk tolerance and personality traits [28–30]. Oehler and Wedlich [66] found that people with high extraversion have a higher risk tolerance, and openness positively correlates with risk-taking behavior [67]. The results of the study by Pak and Mahmood [68] show a significant negative correlation between conscientiousness and risk tolerance. Therefore, the risk tolerance set in the model is determined by the extraversion, openness, and conscientiousness of the personality traits. To ensure the balance of the distribution of traits and avoid the influence caused by a relatively high proportion of a certain trait, the proportional coefficients of the three traits are set to be 1/3 in the model. In addition to being related to their personality traits, they will also be affected by the organizational climate so that workers will adjust their behavior to conform to group norms. Moreover,

the behavioral role models of coworkers can have a significant impact on individual workers and can provide individual workers with relevant information on acceptable behaviors on site [69]. Therefore, each worker will know the risk tolerance of other colleagues as a result of being affected by the safety climate of the construction team. And, due to the existence of the memory utility, the worker's risk tolerance is also determined by the average value of the risk tolerance of other workers on site in the previous time unit determined. The proposed model in this research assumes that the worker's personality traits and the influence of external colleagues have the same contribution to risk tolerance, both at 50%. Based on the above analysis, this model sets the following formula:

$$\mathrm{RT}_i^t = 50\% * \left(\frac{1}{3} * \frac{e_i}{E} + \frac{1}{3} * \frac{o_i}{O} - \frac{1}{3} * \frac{c_i}{C} \right) + 50\% * \frac{1}{m} \sum_{j=1}^{m} RT_j^{t-1}.$$

(2)

Here, RT_i^t: the risk tolerance of worker i at time t, e_i: extraversion score of worker i, E: the maximum value in the value range of extraversion, o_i: worker i's openness score, O: the maximum value in the value range of openness, c_i: worker i's conscientiousness score, C: the maximum value in the value range of conscientiousness, m: the number of other workers on site, and RT_j^{t-1}: the risk tolerance of worker j at $t-1$.

In the decision-making stage, workers make risky behavior decisions based on perceived risks and their risk tolerance. The theory of risk steady-state points out that risk perception and risk tolerance are the two main aspects that determine risk behavior [70]. Workers will compensate for the behavior if the perceived risk exceeds the internal threshold (i.e., the current risk tolerance). In the proposed model, if the perceived risk exceeds the worker's current risk tolerance, then the worker will perform safe behavior to prevent accidents. Conversely, if the perceived risk does not exceed the worker's current risk tolerance, then the worker will take unsafe behavior. Based on the above analysis, this research proposes the following formula:

$$\mathrm{UB}_i^t = \begin{cases} 1, \mathrm{RP}_i^t < \mathrm{RT}_i^t, \\ 0, \mathrm{RP}_i^t > \mathrm{RT}_i^t. \end{cases}$$

(3)

Here, UB_i^t: worker i's unsafe behavior state at time t, 1: take unsafe behavior, and 0: take safe actions.

Since there is no danger when taking unsafe behaviors, it may be safe and sound, which is only a near-missing event [71]. Therefore, the model assumes that when workers take unsafe behaviors, if the environment happens to be in an unsafe state, then an accident will occur; otherwise, no danger will occur, and only a near-missing accident will occur. Based on the above analysis, this model sets the following formula:

$$D_i^t = \begin{cases} 1, & \mathrm{UB}_i^t = 1, \mathrm{ER}_i^t > \mathrm{random.uniform}\,(0, 1), \\ 0, & others. \end{cases}$$

(4)

Here, D_i^t: the dangerous state of worker i at time t, ER_i^t: the actual risk value of worker i's environment at time t, and

random.uniform (0, 1): generate a uniformly distributed floating-point number between [0, 1].

After experiencing a dangerous state, the worker's risk tolerance will change. If unsafe behaviors are taken, but no danger occurs, workers' tolerance for risks will increase and become riskier [72]. If accidents occur after unsafe behaviors, workers' risk tolerance will be weakened. That is, risk tolerance will decrease. Among them, the degree of reduction of risk tolerance is greater than the degree of increase. The purpose of the research is not to accurately measure the change value of the risk tolerance of workers after mutual assistance but to reflect the changes of different combinations of workers under different environmental risks. Therefore, after multiple simulations to observe the value range of risk tolerance, setting the reduction coefficient and the increase coefficient to 0.1 and 0.5, respectively, indicates that the change range is different. Because workers with different personality traits have different sensitivity to danger, their risk tolerance changes after the dangerous state are not the same. Therefore, after the dangerous state, the worker's risk tolerance change value is set in the model as follows:

$$\mathrm{RT}_i^{t+1} = \begin{cases} \mathrm{RT}_i^t, \mathrm{UB}_i^t = 0, \\[2mm] \mathrm{RT}_i^t - 0.1 * \left(\frac{1}{3} * \frac{e_i}{E} + \frac{1}{3} * \frac{o_i}{O} - \frac{1}{3} * \frac{c_i}{C} \right), \mathrm{UB}_i^t = 1, D_i^t = 1, \\[2mm] \mathrm{RT}_i^t + 0.05 * \left(\frac{1}{3} * \frac{e_i}{E} + \frac{1}{3} * \frac{o_i}{O} - \frac{1}{3} * \frac{c_i}{C} \right), \mathrm{UB}_i^t = 1, D_i^t = 0. \end{cases}$$

(5)

Here, RT_i^{t+1}: the risk tolerance of worker i at $t+1$.

(2) Decision-Making Rules for Mutual Assistance Behavior. When construction workers are task-Executing, they will randomly engage in safe mutual assistance behaviors with surrounding workers. In the five dimensions of the Big Five personality traits, agreeableness reflects the orientation of interpersonal relationships such as trust, understanding, sympathy, and altruism [73]. Agreeableness people are good at cooperating, like to help others, and have strong empathy. Therefore, this model sets an agreeableness value as a switch for triggering safety mutual assistance behavior. According to Table 1, the agreeableness follows a normal distribution with a mean of 0.5. Therefore, it is assumed in the model that when the agreeableness of workers is higher than the average, there is an altruistic tendency and mutual assistance with other workers. Based on this, this model sets formula (6). To more accurately simulate the limitations of human perception and behavior in the actual construction environment, the range of safe mutual assistance behavior is set to workers within a radius of three meters from the workers [74].

$$\mathrm{SHB} = \begin{cases} 1, & a_i > 0.5, \\ 0, & others. \end{cases}$$

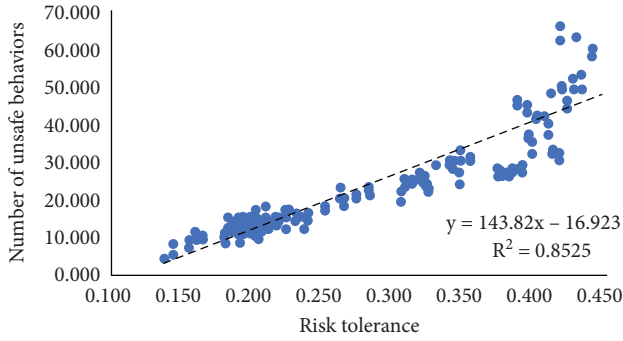
(6)


FIGURE 4: The relationship between the average risk tolerance of construction workers and the number of unsafe behaviors.

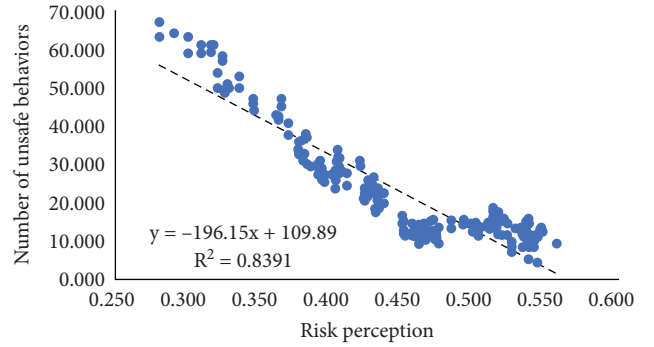
FIGURE 5: The relationship between the average risk perception level of construction workers and the number of unsafe behaviors.

Here, SHB: safe mutual assistance behavior and a_i: the agreeableness score of worker i.

Learning behavior is closely related to the process of mutual assistance. Mutual assistance from others can help individuals clarify concepts, improve problem-solving skills, and increase retention. Mutual assistance is one of the prerequisites for external learning [75]. Interaction can bring about information exchange, knowledge acquisition [76], and obvious behavior changes [77]. Mutual assistance behavior is one of the important manifestations of the interactive process. After workers undergo safe mutual assistance during construction, both participants will have new cognition and understanding of construction safety, so the feedback to the individuals of both participants is a positive behavior change rather than a negative impact. So set in the model; the two participants have a certain improvement in risk perception after mutual assistance behavior and are also more risk-conscious. Run the model multiple times to observe the value range of risk perception and set the increased value to 0.01. Based on the above analysis, this model proposes the following formula:

$$RP_i^{t+1} = RP_i^t + 0.01. \tag{7}$$

4.3.3. Model Verification. The purpose of model verification is to ensure that the simulation model can reasonably express the logic of the real world to solve the problem to be studied [78]. Zeigler et al. [79] divided the verification method into replicative validity (i.e., "the model matches data obtained from the real world"), predictive validity (i.e., "the model matches data before being acquired from the real world"), and construct validity (i.e., "the model truly reflects how the real world operates"). At the same time, Sargent [80] proposed that an appropriate verification method should be selected according to the purpose of the model. This paper aims to explore the role of construction workers with different personality traits on safety-related behaviors based on the cognitive mechanism of safety behaviors, rather than to make accurate predictions of safety behaviors. Therefore, the verification of this model will focus on replicative validity and construct validity.

First, a qualitative consistency test of replicative validity was carried out for the model. It can be seen from Figure 4


that the overall risk tolerance level of construction workers in the benchmark model is directly proportional to the number of unsafe behaviors (the total number of unsafe behaviors taken by workers in the team from the beginning of the task to the current model time; $R^2 = 0.852$, $p < 0.001$). That is, the higher the level of construction workers who can tolerate risks, the more unsafe behaviors may occur during the execution of the task. This result is supported by existing literature in many fields. Ji et al. [81] interviewed pilots and used questionnaires to analyze the relationship between pilots' behavioral decision-making and risk tolerance. The results showed that the higher the risk tolerance, the fewer safe behaviors. Davidson [82] found that the higher the coal miners' tolerance to risk, the greater the risk of their decision-making plans by studying the process of coal miners' final behavior selection. In construction, Ma [83] established a construct equation model, conducted empirical analysis, and found that the risk tolerance of construction workers was significantly negatively correlated with safety behavior.

The simulation results are consistent with existing studies on the relationship between risk perception and unsafe behavior. As shown in Figure 5, the unsafe behavior of construction workers will be inhibited by their risk perception level ($R^2 = 0.839$, $p < 0.001$). Under the same level of risk environment, the more risks construction workers can perceive and the more comprehensive, the higher the probability of taking safe actions. Existing studies also support this result. The research of Xia et al. [84] found that the more risks construction workers perceive, the more they can recognize the potential dangers in the current state and thus can choose safe behaviors to prevent themselves from accidents. Huang et al. [85] found that risk perception and unsafe behavior have a significant negative correlation through a survey of front-line workers in Chinese construction projects. Xia et al. [86] found that improving the risk perception of construction workers can play a positive role in safe behavior.

To ensure the quantitative consistency of replicative validity, this study implemented the benchmark model 50 times, calculated the mean value of important indicators, and compared the results with the empirical data of previous studies. Among them, the unsafe behavior rate (formula (8)) is 0.35 (standard deviation = 0.006), which is consistent with

the research results of Sa et al. [87] and Fang and Wu [88]. Both studies have found that one-third of workers are unsafe at the construction site. Also, according to Heinrich's [89] triangle rule, every major accident will cause 29 serious accidents and 300 near-missing accidents. That is, the ratio of accidents to near-missing accidents (formula (9)) is roughly 1:10. Execute the benchmark model 50 times and calculate that the ratio of accidents to near-missing events is 1:8.6, which is near the value of the triangle rule. Finally, the average accident rate is calculated and compared with the relevant accident statistics. The benchmark model is executed 50 times, and the accident rate (formula (10)) is calculated to be 3.3, which is the same as the 2016 Occupational Injury and Disease Incident Rate (3.0) published by the U.S. Bureau of Labor Statistics [90] very close. Therefore,

TABLE 2: Big Five personality parameter settings in the experiment (extraversion as an example).

	Group A	Group B
E	0.3	0.3
	0.3	0.7
	0.7	0.7
A	$N(0.5, 0.16)$	$N(0.5, 0.16)$
C	$N(0.5, 0.16)$	$N(0.5, 0.16)$
N	$N(0.5, 0.16)$	$N(0.5, 0.16)$
O	$N(0.5, 0.16)$	$N(0.5, 0.16)$

the quantitative consistency between the simulation results and the empirical data is proved.

$$\text{unsafe behavior rate} = \frac{\text{number of unsafe behaviors}}{\text{number of un safe behaviors} + \text{number of safe behaviors}}, \tag{8}$$

$$\text{ratio of accidents to near misses} = \frac{\text{number of accidents}}{\text{number of nearmissing accidents}}, \tag{9}$$

$$\text{accident rate} = \frac{\text{number of accidents}}{\text{number of unsafe behaviors} + \text{number of safe behaviors}}. \tag{10}$$

In terms of construct validity, this study uses three methods to enhance the construct validity of the model. First, the agent's behavioral rules and interaction rules are based on theories that have been established and verified in the social science literature (such as cognitive science theory, risk homeostasis theory, and Big Five personality traits). Secondly, the influencing factors of parameters (such as risk perception and risk tolerance) are derived from the research results of the existing literature. Finally, the initialization of model parameters refers to the common principles in existing empirical research and related construction simulation literature [52, 60].

5. Experiments and Results

5.1. Experimental Design. Based on the parameters set by the benchmark model, this study changed the risk level of the construction environment. The model kept running until the changes in each variable have stabilized (elapse of 80 model time units).

In the experiment, the construction workers in the construction team were divided into two groups (A and B), and each group has ten workers. The five dimensions of the personality traits of the construction workers have two levels, high and low. For example, extraversion is divided into high-level extraversion (i.e., extroversion, denoted by 0.7) and low-level extroversion (i.e., introversion, denoted by 0.3). The variable traits of the two groups of workers will take a combination of high and low levels. The personality traits of other dimensions all obey the normal distribution. In the benchmark model, all traits are set to follow a normal

distribution. Take the extraversion as an example. The experiment sets the parameters as shown in Table 2 to explore the relevant effects of different combinations of extraversion. Different levels of environmental risk are set by changing the mode value of the triangular distribution, as shown in Figure 6.

5.2. Simulation Results. Figures 7–11, respectively, show the combination of construction workers with different personality traits in high-, medium-, and low-risk environments. After the cognitive process of unsafe behavior and the process of mutual assistance, they reflect the change in the rate of unsafe behavior reduction on the overall level of the construction team (i.e., the ratio of the difference between the number of unsafe behaviors before and after the safe mutual assistance behavior and the number of unsafe behaviors before mutual assistance). It should be pointed out that the average unsafe behavior rate of construction workers within the construction team in the baseline model was reduced by 53% in the medium-risk environment.

It can be seen from Figure 7 that with the increase of environmental risks, the average unsafe behavior reduction rate of the three types of extraverted combination forms of team workers is getting lower. This is because the high-risk environment is relatively more dangerous and prone to accidents. The resulting warning effect will prompt workers to pay more attention to construction safety. As far as the combination is concerned, regardless of the high or low environmental risk, the team with the same number of high- and low-extroverted workers has the largest reduction rate of unsafe behavior, and the overall safety performance of the
FIGURE 6: Different environmental risk levels (indicated by triangular distribution function): (a) medium risk triangular (0, 1, 0.5), (b) low risk triangular (0, 1, 0.3), and (c) high risk triangular (0, 1, 0.8).
FIGURE 7: The reduction rate of unsafe behaviors of construction workers with different levels of extroversion (E) under different risk environments.

team has the best improvement effect. The team with more highly extroverted workers has the lowest reduction rate of unsafe behavior, which is caused by the characteristics of highly extroverted individuals who like to take risks and pursue excitement.

In Figure 8, as far as the combination is concerned, regardless of the high or low environmental risk, teams with the same number of agreeableness workers have the greatest reduction in unsafe behaviors. At this time, the overall safety behavior of the team has the best improvement, especially in the medium- and high-risk environments by about 90%. This may be because workers with different levels of agreeableness are more efficient in learning safety in mutual assistance behaviors, thereby reducing the occurrence of unsafe behaviors.

Figure 9 shows that with the increase in environmental risk levels, the average incidence of unsafe behaviors of the

three types of conscientious combination of team workers is getting lower. This is because the environmental risk becomes higher, the greater the impact of conscientiousness; workers will carefully assess the safety situation before performing tasks and act more cautiously so that there are fewer unsafe behaviors. Especially in a high-risk environment, in teams with more highly conscientious workers or teams with the same number of high- and low-conscientious workers, the unsafe behavior of construction workers after mutual assistance is reduced by about 90%.

It can be found in Figure 10 that in terms of the combination form, regardless of the level of environmental risk, team workers with the same number of high- and low-neurotic workers have the greatest reduction in unsafe behavior, and the improvement of team safety behavior is the best, especially in the high-risk environment; it is reduced to 85%. Teams with more highly neurotic or less
FIGURE 8: The reduction rate of unsafe behaviors of construction workers with different levels of agreeableness (A) under different risk environments.
FIGURE 9: The reduction rate of unsafe behaviors of construction workers with different conscientiousness (C) levels under different risk environments.

neurotic workers are more effective in reducing unsafe behaviors in medium to high risks but are less effective in low-risk environments. This may be due to workers' safety mentality being more relaxed and emotionally stable and will not always worry about accidents in low-risk environments.

Figure 11 shows that in a low-risk environment, the reduction rates of unsafe behaviors of workers in a combination of the three types of openness levels after mutual assistance

are very small, all of which are around 50%. In a medium-risk environment, when the overall openness of the team is at the mid-to-high level, mutual assistance has the best effect on safety. While in a high-risk environment, the overall openness and consistency of the team are more important. The overall reduction rate of unsafe behaviors in teams with high or low overall openness after mutual assistance is nearly 80%, which can effectively improve team performance.
FIGURE 10: The reduction rate of unsafe behaviors of construction workers with different neuroticism (N) levels under different risk environments.
FIGURE 11: The reduction rate of unsafe behaviors of construction workers with different openness (O) levels under different risk environments.

Based on the results of the above experiments, according to the idea that the higher the rate of unsafe behavior reduction after the mutual assistance of the construction workers of the team is, the better the improvement of safety performance. It can analyze the best combination of different personality traits to improve the overall safety level of the team under various levels of environmental risks as shown in Table 3.

In a low-risk environment, when the number of high and low levels of extravert, agreeable, and neurotic workers in the team is similar, and there are more low-conscientious and low-neurotic workers, the effect of improving team safety is best. In a medium-risk environment, the team has the best potential for safety performance when the team has much the same as the workers with high and low levels of each trait. In a high-risk environment, when the number of high and

TABLE 3: The best combination of workers' personality traits under various levels of environmental risks to improve safety performance.

Environmental risk level	Low		Medium		High	
Group	Group A	Group B	Group A	Group B	Group A	Group B
Extroversion	High	Low	High	Low	Low	Low
Agreeableness	High	Low	High	Low	High	Low
Conscientiousness	Low	Low	High	Low	High	Low
Neuroticism	High	Low	High	Low	High	Low
Openness	Low	Low	High	Low	Low	Low

low levels of agreeable, conscientious, and neurotic workers in the team is almost identical and there are more low-extraversion and low-openness workers, the team's safety behavior improvement effect is best after worker safety mutual assistance. It can be found that when the number of workers with high and low levels of extraversion, agreeableness, and neuroticism is nearly equal, regardless of the level of environmental risk, mutual assistance improves the overall safety of the construction team.

6. Discussion and Conclusion

This paper mainly explores the change difference in the overall unsafe behavior of the workers after the safety mutual assistance of workers with different personality traits. First, based on the occurrence mechanism of unsafe behaviors of construction workers, the critical processes in the cognitive process of unsafe behaviors are extracted: risk perception, risk tolerance, and decision-making. Existing studies indicate that the Big Five personality traits affect the risk perception and risk tolerance in the process of individual unsafe behaviors and indirectly determine whether unsafe behaviors of construction workers occur.

Agent-based modeling (ABM) is used in this paper as a bottom-up and micro-to-macro classical modeling approach. At the same time, the research analyzes the relationship between construction workers and workers and the relationship between construction workers and the external construction environment to establish individual behavior rules and interaction rules that are consistent with the actual construction context. The individual worker's personality trait, an inherent attribute that cannot be easily changed later in life, determines each worker's unique outwardly expressive behavior and decision-making style. By setting up worker agents possessing different traits in the agent-based model and arranging various combinations of workers in the team, it is possible to maximize the simulation of the behavioral differences of workers with different personality traits in the real environment and measure the impact of such differences on overall team safety performance. This paper explores the optimal combination of workers with varying traits of personality in various risk environments from the perspective of psychology, providing a new way to improve the safety performance of teams in different situations and ultimately deepen the understanding of the complex system in construction.

By introducing the Big Five personality traits theory into the research of the construction industry, combined with the agent-based modeling method in the complex system theory, this paper is conducive to understanding the cognitive process of construction workers' unsafe behavior and the differences in the results of unsafe behavior from the perspective of psychology. According to the conclusions of the simulation analysis, this research proposes corresponding management measures to improve construction safety from the perspective of enterprise human resources and personnel arrangements based on personality traits and actively manages from the source to improve the level of construction safety performance.

The construction industry is a labor-intensive industry in China. In recent years, as people's living standards have risen, so have their requirements for the functionality, appearance, and comfort of buildings. The amount of information attached to construction projects is also increasing, especially for some modern large-scale construction projects. Due to the long construction period and a large amount of information in the construction process, the difficulty of project engineering management has also increased significantly. At the same time, with the gradual development and improvement of China's market economy system, the prices of labor and materials in the construction industry continue to rise, and the huge consumption of energy and resources no longer meets the strategic requirements of sustainable development. Therefore, construction project cost management is facing a huge impact, the actual effect of construction project cost management work is not good, and the phenomenon of uncontrolled construction project investment commonly occurs. The use of BIM software to build a building information model can integrate information from all stages of the project and facilitate the participation and cooperation of all project entities. Cost management is carried out before the actual construction of the project, thus realizing the whole process of cost management and effectively avoiding the occurrence of actual costs exceeding the budget after the project is completed. The study analyses the suitability of applying BIM technology to the whole process of construction project cost management with computational intelligence and explains the value and advantages of BIM in the whole process of construction project cost management. On this basis, this research provides a specific analysis of the application of BIM technology in the process of cost management at various stages of the whole process of construction projects and thus puts forward suggestions that can solve the obstacles that may be encountered in the whole process of cost management of construction projects in China.

1. Introduction

As one of the oldest industries in the world, the construction industry has always played a very important role in the history of human development. The construction industry has an irreplaceable position in China's national economic growth and social and economic development and has become an important pillar industry of the national economy [1]. In recent years, influenced by the national macrocontrol policies, the development of China's construction industry has gradually slowed down, but the construction industry output value in China's national economy still occupies a large proportion, and the proportion is increasing year by year trend. For a long time, the construction industry has been a labor-intensive industry in China, and the phenomenon of low efficiency and high construction costs is more common [2]. As living standards improve, people are demanding more and more information about the function, appearance, and comfort of buildings, and the amount of information attached to construction projects is increasing [3]. In the course of the actual construction of a project, changes are often made due to design failures or communication problems between the parties involved, especially for modern large-scale construction projects with large

investment scales. Due to the large number of construction units involved and the long construction cycle, the difficulty of project management is greatly increased, and the problem of cost management is particularly acute [4]. However, because of the lack of overall planning for the whole life cycle of China's construction industry management, the attention of project participants is still only on a certain stage of the life cycle and a certain partial business. For instance, the traditional cost management model is unable to achieve information sharing throughout the construction life cycle [5]. Therefore, in order to ensure the effectiveness of engineering projects and reduce the waste of resources, it is necessary to improve the engineering management model, especially cost management which plays an important role in engineering management [6]. The effective use of information technology in the processing of various relevant information to achieve the whole process of project cost management can fundamentally reduce engineering changes and delays, thus reducing costs and maximizing the benefits of the project.

The three main objectives of construction project management are cost [7], quality [8], and duration [9]. With the continuous development of modern construction material technology, quality and duration are no longer universal issues in the construction industry. In the competitive environment of economic globalization, construction cost has become the focus of attention in the construction industry [10]. The most direct effect of the serious waste and low productivity caused by the lagging application of information technology in the construction industry is reflected in the cost [11]. Thus, how to use modern science and technology to reasonably control the cost of construction has become an urgent task for the construction industry. For a long time, experts and scholars at home and abroad have been committed to research the whole process of cost management of construction projects. They hope that, through the continuous management and control of the whole process of construction project cost, the organic link between each stage can be established, so as to realize the whole process and all-round project cost management [12–14]. However, at present, there is still a clear division of labor between design and construction in China's construction industry, and the vast majority of construction project management models adopt the DBB (Design, Bid, and Build) model. This model can hinder the transmission of information between the various stages of engineering construction and poor communication between the parties involved, making it difficult to implement whole process cost management for construction projects [15]. In this context, people began to explore a large number of new technologies and management models, such as three-dimensional mapping [16], lean construction management model [17], integrated project delivery management model [18], BIM model [19], system dynamic model [20], and electroencephalogram model [21], the purpose of which is to build bridges between the various stages of the project and the various parties involved, so as to reduce information communication obstacles, so that the whole process of construction project cost management can be implemented.

Currently, 3D graphics technology has been implemented in the budgeting software, allowing users to quickly implement 3D graphics modeling in the budgeting software, and the system will automatically calculate and summarize the quantity information and establish a link with the cost estimation database to generate cost estimates. The system will automatically calculate the summary quantity information and establish a link with the cost estimate database to generate cost estimates [22]. This model supports the construction of geometric operations and spatial topology relationships, which not only improves the accuracy of cost estimates but also improves intelligence and automation [23]. However, there are several problems with this technology. For instance, there is not yet a good interface between cost forecasting and design, which prevents the direct use of design information and affects the efficiency of cost forecasting and control. Furthermore, there is no intuitive link between building components and cost information, and when design changes or changes in cost parameters occur, they need to be adjusted item by item in each system, which is less efficient.

With the rapid development of information technology today, information resources have become one of the three strategic resources in the new century. Along with the continuous development of Internet technology and the data industry, the capacity and performance of computer hardware have also been upgraded, which has made it possible for the development of information technology in all industries [24]. In China, the level of informatization in the electronics and manufacturing industries is already at a high level, and the models generated by information technology have significantly improved the productivity of these industries, but the informatization of the construction industry is still in its infancy. Informatization in the construction industry refers to the use of information technology, such as computer technology, communication technology, control technology, and information security technology, to transform and upgrade the technical means and production organization of the construction industry, thereby improving the management level and core competitiveness of construction enterprises. In developed countries such as Europe and the USA, where information technology in the construction industry started earlier, the application of information technology in construction enterprises has become more common, mainly in the extensive use of BIM [25]. BIM is a new concept that has emerged in the construction industry in recent years. Its introduction and development have placed higher demands on decision-makers and participants in engineering and construction projects in terms of collaborative work and application management for information sharing. In terms of modeling, BIM is based on three-dimensional digital technology, with the database formed by the three-dimensional model as the core [26]. The whole modeling process not only contains the professional design concepts of designers from various disciplines but also contains information on the whole process from design to construction and even completion and final demolition. From the application point of view, the model is based on the

parametric design and is an object-oriented, parametric, and intelligent digital representation of the building, supporting various operations in construction projects and containing engineering information that is all interrelated [27]. Based on the parametric, visual, collaborative, and information-sharing advantages of BIM models, BIM can facilitate the early involvement of all parties involved in construction projects. In addition, the application of BIM can help constructors make the most effective decisions and use BIM to participate in construction project management during the construction process, thereby reducing project duration, controlling project risks, and promoting the smooth implementation of the whole process cost management.

The understanding of what BIM means varies due to the different levels of understanding of BIM. The most straightforward understanding of BIM is that it is a production tool that is used as a platform on which all information related to a construction project is placed to create a building model that simulates the real situation of the building [28]. BIM is also a new management concept, as the building model created through BIM can accommodate information from all stages of the building construction process and can be updated at any time to facilitate the participation and cooperation of all parties involved in the project, thus achieving whole life cycle management from design to construction, operation, and even demolition. With the support of BIM technology, all parties involved in the project can visualize the results of the design through BIM software. With the help of BIM, communication between the various project participants is made easier. Through construction simulations, they can identify any design irregularities in advance, thus reducing the need for rework due to changes and optimizing the design [29]. Cost management before the actual construction of the project can prevent the actual cost of the project from exceeding the budget after completion. As a result, the emergence and application of BIM technology provide a reference for the realization of whole process cost management [30]. However, there are still a few cases of BIM being used in construction projects in China, but research on BIM has already started. Some universities have set up BIM research groups to research BIM theory, BIM software, and BIM applications [31]. The research and development of BIM and the use of BIM technology to build an information platform to facilitate the efficient implementation of the whole process of construction project cost management will be a key focus of future research and development in the field of construction project costing in China.

In this context, this paper investigates the whole process of cost management of project construction based on BIM technology, focusing on the whole process of cost control of engineering construction projects from conceptual design to construction and completion and handover. In addition, this research focuses on the application of BIM technology in the whole process cost management of construction projects as an example and proposes a proven solution for BIM technology in the whole process cost management of construction projects.

2. Construction Cost Management

The construction cost refers to the construction price of an item of engineering construction. In a broad sense, construction cost covers construction cost, installation cost, municipal cost, power cost, water cost, and communication cost. The meaning of construction cost can be understood in two different ways from the perspective of the owner and the contractor, respectively. From the owner's point of view, the construction cost is the total one-off cost of the planned reproduction of fixed assets, the formation of corresponding intangible assets, and the laying down of working capital, i.e., the investment in the fixed assets of the construction project. On the other hand, from the contractor's point of view, the construction cost is the price of the construction and installation work and the total price of the construction work expected or formed in the land market, the technical labor market, and the equipment market, and other trading activities.

2.1. Current Status of Construction Cost Management in China. At the present stage, China's construction cost management mode is a whole process construction cost management mode in which fixed-price pricing and bill-of-contract pricing coexist. The whole process of cost management refers to reasonable determination and effective control of project costs throughout the entire process from the decision-making stage to the completion and acceptance of the project. To facilitate the establishment of economic relations between the parties in the process of construction and to meet the requirements of construction management, budget estimates are required for each stage of construction. Each construction stage and its corresponding budget estimates are shown in Figure 1.

In recent years, with the improvement of the bidding system and the continuous development of the quota standard, the cost management level of China's construction industry has been significantly improved, and cost consultancy has become a relatively mature profession. However, the level of cost management of construction projects in China still has a large gap with that of developed countries, and the current situation of cost management of construction projects in China is not optimistic. From the perspective of project cost management, each stage of cost management can reflect common features. The relationship between the various stages of a construction project also inevitably requires that the cost management of each stage is also coherent with each other. The entire construction project cost management should form an organic whole, so that all parties involved in the construction project can be the first to know the occurrence and changes in construction investment and cost. Therefore, the whole process of cost management of construction projects is the most advantageous management mode at present. At the same time, the current situation of cost management in China's construction projects and many problems that have been revealed have made whole process cost management an inevitable trend.
FIGURE 1: Construction stage and its corresponding budget estimates.

FIGURE 2: Framework of BLM.

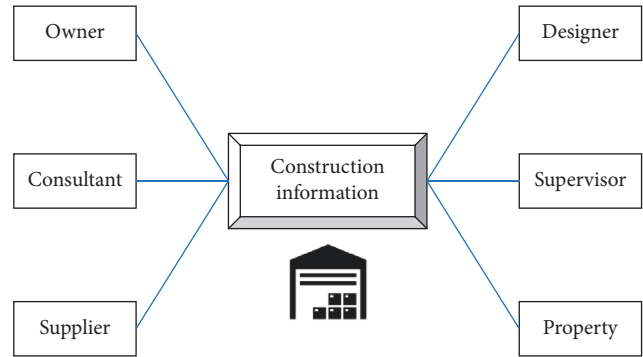
2.2. Building Lifecycle Management.

Building lifecycle management (BLM) is a digital approach to creating, managing, and sharing information about the capital assets of a project throughout its construction. The core idea is to integrate the design, construction, and management processes through information integration and collaborative working. BLM covers all aspects of the full project lifecycle, including component design, document management, cost forecasting, construction management, project management, and visualization in the decision phase, implementation phase, and operational phase. The construction information is characterized by the large volume, diversity, and frequent changes, and the difficulty of managing project information is exacerbated by the large number of parties involved. The starting point of BLM is to solve the challenges of project information management, including information creation, management, and sharing. The process of creating information involves the selection of solutions and the integration of relevant information to ensure the accuracy of the information, including project solutions, spatial geometric properties, bills of materials, product structures, and cost information. An important way to achieve the creation of information is through the use of BIM technology.

The realization of the concept needs to rely on the support of relevant technical software. As shown in Figure 2, BIM technology completes the collection and creation of basic building information data, and each participant extracts and uses project information through their respective data interfaces to realize the value-added final realization of the project concept.

The core purpose of BLM technology is to solve the problem of information creation, information management, and information sharing in the whole life cycle of a construction project, and the process of its realization can be expressed in Figure 3.

2.3. Building Information Modeling.

Building information modeling (BIM) is the process of creating and managing building information. It is a technique for modeling the


entire construction project through one or more building information databases and is a parametric model containing a variety of information. Through technology-based design software, designers can input parametric information directly into the database in a graphical environment, without the need to expend more effort on abstract two-dimensional drawings, to obtain objects with a range of characteristics to represent the basic properties of a building. In recent years, with the widespread application of modern computer technology in the construction industry, BIM technology has slowly been realized. The application and promotion of BIM technology is not only a technical upgrade to the construction industry but also a revolution to the traditional concept of construction engineering.

With the support of BIM technology, designers can carry out a comparative analysis of multiple solutions, thus minimizing the impact of design changes or professional conflicts on construction projects and providing security for project decisions. Designers can directly create parametric 3D building models through BIM-related software, putting more effort into the design rather than wasting a lot of time on 2D output drawings. Figure 4 reflects the difference between the design process based on BIM and the traditional design process.

The key to BIM applications is how to solve the problem of information expression, information transfer, and information exchange. For a long time, it has been difficult to exchange information between different software due to the large differences in data formats between them. To solve this problem, the most effective way is to develop a data file standard that all software can support so that all software can exchange information with each other through this data file standard. For this reason, a number of standards have been implemented internationally to regulate the representation and exchange of different data, and three of the more popular ones are industry foundation class (IFC), information delivery manual (IDM), and international framework for dictionaries (IFD). As shown in Figure 5, IFC, IDM, and IFD form the basis for information exchange on the BIM platform, ensuring the smooth transfer and sharing of information on construction projects and thus maximizing the value of the BIM technology platform. IDM is the process of defining the types of information that need to be exchanged between different phases and objects and the methods of
FIGURE 3: Realization process of BLM.
FIGURE 4: Difference between design process based on BIM and traditional design process.

exchange and ensuring that these information exchange processes are properly understood and used. The relationship between FC and IDM can be understood as the IFC is like a pharmacy with all the medicines, while the IDM is a prescription for a particular disease or a particular patient. That is, the IFC supports all business requirements between all projects and all phases, while the IDM supports one business requirement for one project and one phase, and it is the IDM that decides which IFC information is needed for this business.

3. BIM-Based Construction Cost Management

The first step in cost budgeting is quantity surveying. The biggest advantage of building information model quantity surveying over traditional drawing surveying is that it minimizes the need for manual surveying.

3.1. Investment Decision Stage. The investment decision stage is the most crucial step in the construction of a project, where different investment options are economically and technically justified, and the best option is selected after comparison. A mistake in decision-making can often bring irreparable losses to the enterprise and even plunge it into an economic crisis, so the investment decision stage of the project needs to be given high priority. The content of the investment decision stage is the basis for determining the cost of the project, and a correct investment decision requires an accurate grasp of the costs of each option. Therefore, on the premise of technical feasibility, it is essential to make investment estimates for each option. The use of Excel archives has been a further development, but for many reasons, the amount of data that can be accumulated is small. Historical data are less structured, less calculable, and more cumbersome to accumulate. The BIM model has construction data, technical data, quantity data, cost data, schedule data, and application data that can be restored when comparing and selecting investment options and can be displayed in a three-dimensional mode. As shown in Figure 6, the model of a project with a similar history can be changed and innovated according to the program characteristics of the new project, so that the cost and total amount
FIGURE 5: Information exchange among IFC, IDM, and IFD.
FIGURE 6: Program choice based on BIM.

of work can be calculated for several costs programs. Based on this procedure, the selection of the overall solution is made easier, making it much more efficient and helping to design future solutions.

3.2. Design Stage. The preparation of estimates at the design stage depends on the depth of the design, the degree of completeness of the information, and the requirements for the accuracy of the estimates. When design information is insufficient, budgets for similar projects can be selected as a basis for preparation after analysis and adjustment of co-efficients. If the information on similar projects is not available, the budget estimates will be prepared using in-dicators. When the design has reached a certain depth and a detailed list of equipment, a sketch of the pipeline alignment, building and structure type, and technical requirements for construction can be provided, and the estimate is prepared on the basis of quotas and cost indicators.

It is now generally accepted that cost management at the design stage should focus on limit design, i.e., the initial

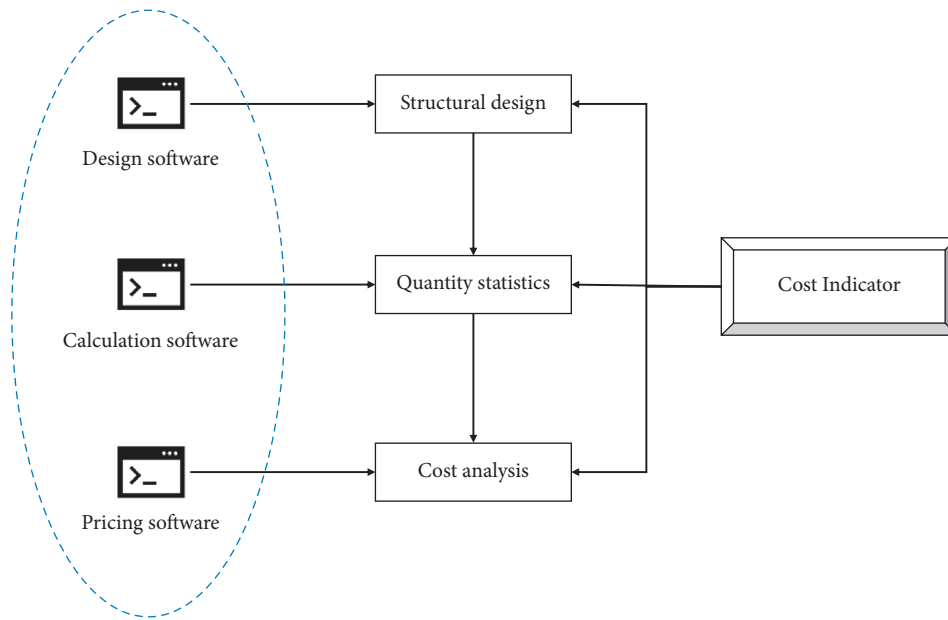
scheme design should be based on investment estimates. Nowadays, it is not easy to achieve a reasonable limit design based on traditional manual algorithms and engineering budgeting methods. Firstly, the varying technical levels of the designers and the lack of cost control thinking mean that the tasks of the different disciplines are separate, and co-ordination and control have to be carried out regularly. Furthermore, the lack of adequate cost information in the design drawings due to the current design approach means that cost consultancy work and design work cannot be synchronized, and design proposals cannot be revised in a timely manner due to the constraints of cost indicators. As shown in Figure 7, with the introduction of BIM technology, the designer can extract some of the relevant design indi-cators from the model database for a more rapid limit de-sign, thus achieving the goal of an economical and reasonable design. Along with this objective, construction information and the corresponding quantity information can be obtained by the cost engineer and compared with the information in the database, so that the estimated price can be derived more quickly. The reasonableness of the design


FIGURE 7: Construction limit design process.
FIGURE 8: Interface relationship between design and calculation software.

indicators is then verified, and the value engineering approach is combined with the control of construction and use costs based on the whole project cycle, thus optimizing the design solution. The BIM model's real-time modeling and accounting of costs can be used as a basis for designers and cost engineers to carry out real-time and simultaneous calculations and analyses of the cost of the units designed, so that the information obtained can be used to optimize every detail of the design scheme, thus enabling limit design to be achieved.

The establishment of a great BIM model is highly valued by engineering cost practitioners, different professions have different BIM models, and the quality of the BIM model has a direct impact on the outcome of the project. Figure 8 illustrates the interface relationship between design and calculation software. Many domestic costing-related software companies are doing their best to develop relevant model data interfaces to implement the model design. Their efforts have been tested in several engineering cases, and some results have gradually been achieved. With the promulgation of national standards for the interface from design to measurement, this technology is gradually being accepted by engineers.

4. Conclusion

In the current construction industry, there are many participants and a huge amount of information. Traditional construction cost management methods and information communication mechanisms have been unable to meet the

requirements of modern construction project cost management work and must be committed to exploring new ways of working and information transmission channels to realize the whole process of construction project cost management. Only in this way can China's current construction project cost management be optimized, the overall cost control level of the industry be improved, and the waste of energy and resources be reduced, so that we can ultimately stand out in the fierce international competitive environment. In order to realize the whole process of cost management of construction projects, this study applies BIM technology to it. BIM is suitable for the whole process of cost management in construction projects. It can be used to effectively improve the efficiency of cost management at all stages and control the total cost of construction projects. BIM establishes an information-sharing platform to share information and improve the efficiency of cost management at each stage. In addition, BIM technology can achieve coordination and cooperation in cost management between all stages and all parties involved, thus realizing BIM-based cost management for the whole construction process, which is the key to solving the current problems of cost management for the whole construction process in China.

However, this paper is only a theoretical study and discussion of how to achieve BIM-based construction cost management, and there are still the following problems to be solved. Firstly, further research should be carried out on the creation of a computer-literate API interface to BIM software data and a database of BIM correspondence with lists and quotations. In addition, it is necessary to explore how to establish working methods and communication mechanisms between the various stages of the project and between the various parties involved in specific business operations based on BIM.

Equipment health state assessment is of great significance to improve the efficiency of industrial equipment maintenance support and realize accurate support. Using the method driven by the fusion of digital twin model and intelligent algorithm can make the equipment health state assessment more suitable for the "accuracy" requirement of equipment support. Taking the neural network algorithm as an example, this paper studies the method of unit level health state assessment of equipment driven by the fusion of digital twin model and intelligent algorithm. The principle and opportunity of equipment health state assessment based on digital twin model are analyzed, the equipment health state grade is redefined from the data-driven perspective, the selection principles of assessment parameters are established, and the unit level health state assessment model of equipment based on digital twin model and neural network algorithm is established. The proposed method is implemented by programming with Python, and the effectiveness of the method is verified by a case study. It provides support for further research of equipment-level health state assessment and the decision-making of equipment maintenance and provides reference for the study of the combination of digital twin model and other intelligent algorithms for health state assessment.

1. Introduction

The introduction should be succinct, with no subheadings. Limited figures may be included only if they are truly introductory and contain no new results.

Industrial equipment is the foundation of production-oriented enterprises, and its health state directly affects the production efficiency of enterprises. In order to improve its core competitiveness, enterprises must try to improve the healthy operation time of equipment and reduce the investment in equipment maintenance support as much as possible, so as to save costs and increase profits. Therefore, production-oriented enterprises urgently need to realize accurate equipment maintenance support.

Facing the characteristics of industrial equipment, such as complex structure and function, various degradation conditions, and various failure modes, studying its performance degradation rules and health state assessment method, and timely assessing the health state of equipment can guide enterprises to make optimal support decisions, which is of great significance for enterprises to carry out accurate support [1–3].

Based on the methods of fuzzy comprehensive assessment [4], combined weighting model [5], neural network model [6], and Bayesian network model [7], research works have studied the equipment health state assessment from the qualitative perspective or probability of failure perspective. However, most of the existing research results on the assessment of equipment health state give the level of failure probability, which cannot solve the problem of when the equipment fails and when to carry out maintenance to achieve the best efficiency. The assessment is vague and cannot meet the requirements of accurate equipment support.

The fusion application of digital twin technology and intelligent algorithm provides a way to solve this problem.

After continuous exploration, the digital twin modeling technology of industrial equipment has matured. Using the established digital twin model for data analysis and algorithm implementation has become a new research focus of the practical application of digital twin technology. The combination of digital twin technology and intelligent algorithm can give full play to the advantages of digital twin model in mastering a large amount of equipment historical data, real-time data, and empirical knowledge and give full play to the advantages of intelligent algorithm in finding rules through machine learning, so as to obtain high-precision results. Taking the combination of digital twin technology and neural network algorithm as an example, this paper studies the equipment health state assessment method driven by the fusion of digital twin model and intelligent algorithm.

2. Analysis of Equipment Health State Assessment Based on Digital Twin Model

2.1. Basic Concepts. Equipment health state assessment is the assessment of the ability of equipment and its components to perform its design functions [8, 9]. Health assessment of equipment can effectively ensure the healthy and safe operation of equipment and provide technical support for equipment maintenance and repair decision-making [10].

Equipment health state assessment based on digital twin model is to assess the health state of equipment by using a large amount of data mastered by digital twin model and intelligent algorithm on the basis of digital twin model.

Equipment is composed of replaceable units that perform different functions. Equipment health state assessment can be divided into equipment level assessment and unit level assessment. The equipment level assessment is to assess the overall health state of the equipment. The unit level assessment is used to assess the health state of the replaceable unit of the equipment. The overall health state of equipment is affected by the health state of each unit. This paper mainly studies the method of unit level health state assessment of equipment in use stage based on digital twin model and neural network algorithm, so as to provide basis for equipment use units to research the equipment level health state assessment and make equipment support decisions.

2.2. Principle of Assessment. With the increase of equipment operation time, the health state of each component of equipment deteriorates according to different rules, and the health degree decreases continuously. The degradation curve of equipment health state is shown in Figure 1 [10].

It can be seen from the figure that the equipment generally does not fail instantaneously but has state degradation after operation for a period of time, and the degradation process is gradually accelerated under the action of various stresses until it is degraded enough to affect the realization of equipment functions, resulting in failure [11]. The degradation curve of equipment health state is an irregular decreasing curve, which cannot be described by analytical method. However, as long as the relevant

parameters representing equipment health state are found, the degradation rules of equipment health state can be found.

The purpose of health state assessment is to identify and monitor in a timely manner the relevant parameters that represent the health state of the equipment, to find the best maintenance time between the state degradation point and the functional failure point, to repair the equipment before it is close to failure, and to reduce excessive maintenance and save equipment support cost before ensuring normal operation of the equipment. At the same time, the maintenance equipment is prepared in advance to reduce the waiting time of the equipment [12].

2.3. Opportunity of Assessment. Equipment health state assessment based on digital twin model can realize real-time state assessment and master the health state of equipment at any time. In practical work, the combination of centralized assessment and assessment can be adopted at any time. In general, the assessment of the affiliated equipment shall be performed once a day and arranged in the idle time of the equipment at night, so as to avoid affecting the operation of the equipment and the accuracy of the assessment. Under special circumstances, when major changes or emergencies occur to the equipment, it can be assessed at any time. Through the assessment, the health state of the equipment can be mastered in time, and the corresponding countermeasures can be prompted, such as failure early warning, spare parts allocation demand, and equipment maintenance demand.

3. Digital Twin Technology and Neural Network Algorithm

Combining digital twin technology with neural network algorithm and giving full play to their respective advantages, we can obtain a high-precision assessment model.

3.1. Equipment Support Model Based on Digital Twin. Digital twin is a technology that creates virtual models of physical entities in a digital way. It simulates the behavior of physical entities in the real environment with the help of data and adds or expands new capabilities for physical entities through virtual and real interactive feedback, data fusion analysis, decision iterative optimization, and other means [13]. Based on a large number of advanced technologies such as sensor technology and big data technology, digital twin technology realizes the functions of automatic measurement, automatic recording, active uploading, active analysis, active early warning, auxiliary decision-making, and so forth with high data consistency and reliability; it is favored by research in various fields of production and life, such as engineering manufacturing, aerospace, smart city, smart grid, and system operation and maintenance.

The research of digital twin technology originates from the life cycle management of equipment. It has great matching and many advantages in the application of equipment maintenance support, which can greatly improve
FIGURE 1: Degradation curve of equipment health state.

the initiative and accuracy of equipment maintenance support. NASA combines the physical system with its equivalent virtual system, studies the failure prediction and elimination method of complex systems based on digital twins, and applies it to the health management of plane, aircraft, launch vehicles, and other flight systems [14]. By combining the ultrahigh fidelity aircraft virtual model with the structural deviation and temperature calculation model affecting flight, the structural science center of the US Air Force Research Laboratory has carried out the life prediction of aircraft structure based on digital twins and summarized the technical advantages of digital twins [15]. Reference [16] introduced the digital twin five-dimensional model into prognostics and health management (PHM) and proposed a method of PHM based on digital twin.

At present, the digital twin modeling technology of industrial equipment has matured; [17] has studied and given the equipment support model based on digital twin, as shown in Figure 2.

The equipment support model based on digital twin is divided into four parts: physical layer, twin layer, application layer, and connection layer. In the process of operation, the physical layer transmits the real-time data to the twin layer. The twin layer provides data support to the application layer through data collection and processing and uses the processing results to guide the operation of entities in the physical layer. The application layer uses the data given by the twin layer to provide application services to equipment managers, assist equipment maintenance support decision-making, and act on the physical layer. The connection layer plays the role of internal and external communication of the model, transfers data between various layers within the model, and establishes communication with other relevant digital twin models.

Through the operation of digital twin model, the physical system and the cyber model can be synchronized, making it possible to analyze data online [18, 19]. Using the equipment support model based on digital twin, we can realize the real mapping of virtual equipment model to physical equipment entities, accurately reflect the actual situation of physical equipment, provide support for accurate equipment health state assessment, failure prediction, and spare parts demand prediction, better realize the timely maintenance support of equipment, and reduce the overall support cost [20].

3.2. Basic Principle of Neural Network. Artificial neural network system refers to a technical system that uses engineering technology to simulate the structure and function of the human brain neural network. It is a large-scale parallel nonlinear complex network system and is called neural network for short [21]. The neural network has good self-learning ability, nonlinear mapping, and fault tolerance [22] and has been widely used in classification, pattern recognition, prediction, signal processing, expert system, and other fields [23]. As long as there are enough hidden layers and hidden nodes, the neural network can approach any nonlinear mapping relationship, and its learning algorithm belongs to the global approximation method, so it has good generalization ability [24].

The typical neural network structure consists of three layers of neurons, namely, input layer, hidden layer, and output layer, as shown in Figure 3. Each layer is composed of several neurons, which are fully connected, and bias nodes (represented by (b) are added in the input layer and hidden layer. Through the continuous correction of the connection weights of each layer, the error convergence is realized, and finally a reliable neural network model is obtained to realize the required functions.

Due to the large difference in the probability of different results, the training dataset of neural network is usually imbalanced, which requires the use of algorithms such as granular computing and random forest to identify the optimal granularity and refine the imbalanced dataset [25, 26].

Programming with Python or other languages can realize the processing of training dataset, as well as the establishment and training of neural network model, and the neural network model that meets the training requirements can be used to realize the functions of data fitting, classification, clustering, and so on.

4. Equipment Health State Grade under Data Drive

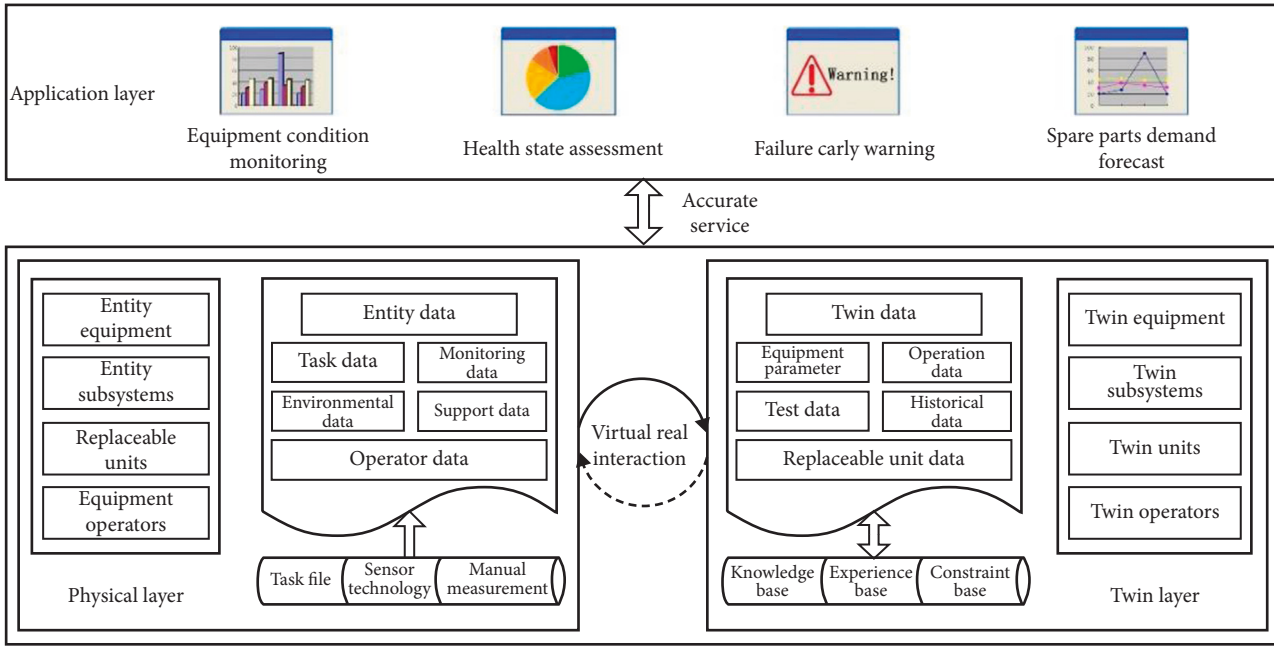
The health state of equipment is described by health state grade. At present, the research on health state grade is mostly described by qualitative description or failure probability, which cannot adapt to the data-driven health state assessment method. To adapt to the data-driven health state assessment and provide support for the assessment, it is


Figure 2: Equipment support model based on digital twin.
Figure 3: Typical neural network structure.

necessary to redefine the health state grade from the data-driven perspective.

According to the degradation curve of equipment health state and the support cycle of equipment maintenance equipment, the health state of equipment replaceable units is divided into five grades: health, subhealth, attention, danger, and failure, which are defined from the perspective of digital drive, as shown in Figure 4 and Table 1.

Health. The equipment is healthy and has good performance, and all indicators are in good condition, which is suitable for long-term operation. For such equipment, only daily maintenance is required.

Subhealth. The equipment performance degrades to a certain extent, but it does not affect the normal operation of the equipment. The failure is almost impossible to occur in the next 30 days. For such equipment, while doing well in daily maintenance, it is necessary to strengthen condition monitoring.

Attention. The equipment performance degradation is serious and can be detected obviously. Failure may occur in the next 30 days. For such equipment, it is necessary to strengthen condition monitoring, prepare for repair, and query the inventory of spare parts. If the inventory is insufficient, spare parts shall be allocated in time.

Danger. The equipment performance degradation is very serious, which has affected the operation quality of equipment. Failure may occur in the next 7 days. For such equipment, it needs to be repaired immediately during the scheduled downtime.

Failure. The equipment failure has occurred and the function of the equipment has been affected. Such equipment can only be shut down for repair.

5. Assessment Method of Equipment Health State

In the process of equipment health state assessment driven by the fusion of digital twin model and intelligent algorithm, the physical layer of digital twin model is responsible for connecting with the physical equipment through various sensors to obtain the most real original data and provide the data to the twin layer. The twin layer is responsible for preliminary statistical analysis of the obtained data, obtaining the analyzed twin data and transmitting it to the application layer for use. The application layer is responsible for using the obtained twin data to complete the task of health state assessment through intelligent algorithm. The information transmission between each layer is uniformly scheduled and transmitted through the connection layer. The data flow diagram of equipment health state assessment
FIGURE 4: Equipment health state grade.

TABLE 1: Detailed table of equipment health state grade.

Health state grade	Grade identification	State performance	Definition under digital drive	Maintenance measures
Health	1	Good performance, all indicators are in good condition, suitable for long-term operation.	All indicators are in good condition.	Carry out the daily maintenance.
Subhealth	2	The performance degrades to a certain extent, but it does not affect the normal operation of the equipment.	The failure is almost impossible to occur in the next 30 days.	Carry out the daily maintenance and strengthen condition monitoring.
Attention	3	The performance degradation is serious and can be clearly detected.	Failure may occur in the next 30 days.	Strengthen condition monitoring, prepare for repair, and allocate spare parts in time.
Danger	4	The performance degradation is very serious, which has affected the operation quality of equipment.	Failure may occur in the next 7 days.	Repair at the right time.
Failure	5	A failure has occurred and the function of the equipment has been affected.	Failure has occurred.	Shutdown for repair.

driven by the fusion of digital twin model and intelligent algorithm is shown in Figure 5.

A large number of papers have been studied on the establishment of digital twin model, as well as the application of sensor and preliminary statistical analysis of data, which will not be repeated in this paper. This paper mainly studies the process of health state assessment in the application layer of digital twin model, combined with intelligent algorithm.

The basic idea of equipment health state assessment driven by the fusion of digital twin model and intelligent algorithm is as follows:

(1) Select assessment parameters.

(2) Obtain parameter data from the digital twin model.

(3) Assess health state through an intelligent algorithm.

(4) Give assessment conclusions and suggestions.

Taking the neural network algorithm as an example, the specific process of equipment health state assessment driven by the fusion of digital twin model and intelligent algorithm is shown in Figure 6.

5.1. Select Assessment Parameters. The health state of equipment can be characterized by a series of state parameters. As long as the parameters are selected comprehensively and reasonably, the health state of equipment can be characterized [27]. The state parameters commonly used in equipment mainly include temperature, vibration, pressure, speed, and acceleration, such as water temperature, oil temperature, oil pressure, amplitude, and frequency. At the same time, the analysis data of relevant parameters after preliminary analysis are also the characterization of the health state of the equipment, such as water temperature at startup, oil pressure at startup, maximum water temperature, minimum oil pressure, temperature rise speed, temperature 10 minutes after startup, steady-state temperature, and abnormal vibration characteristics.

When selecting assessment parameters, attention should be paid to the following aspects:

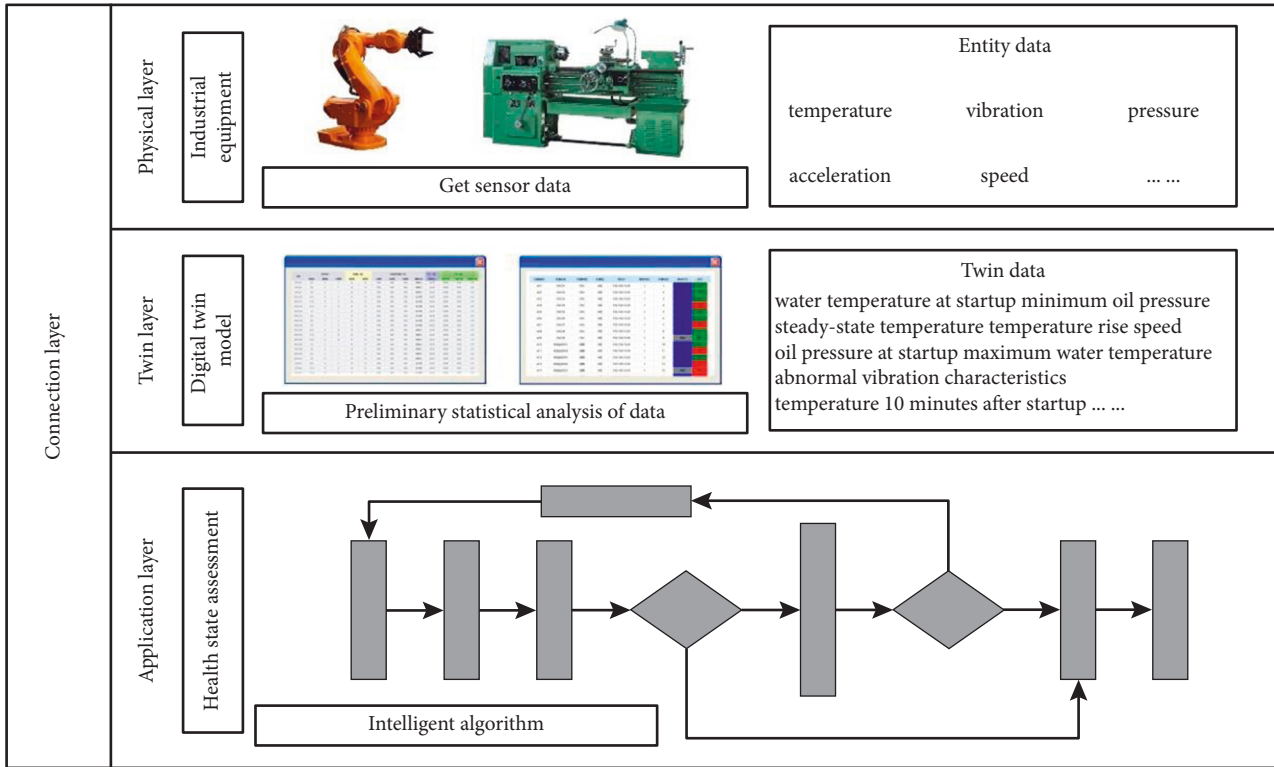
(1) The assessment parameters are not limited to the determinants of equipment health state and can also be related factors of health state, that is, the factors that will change due to the change of health state. As long as it can reflect some or several changes in the health state of equipment, it can be used as the selection object. When selecting assessment parameters, the most closely related state parameters should be selected as much as possible from the perspective of failure inducing mechanism.


FIGURE 5: Schematic diagram of the data flow.

(2) When selecting assessment parameters, we should take into account the principles of correlation and measurability, should comprehensively analyze and optimize measurable state parameters from the perspective of existing measurement technology, and should not put forward too high requirements for the measurability of parameters. If too many sensors are added, not only will the cost be greatly increased, but also the normal operation of the equipment may be affected. The analysis of equipment state data can be strengthened, and the analysis of relevant data can be used to solve the problem that some data cannot be measured.

(3) The selected parameters should not be too many or too few. On the premise of reflecting the changes of equipment health state from the perspective of intelligent assessment, the assessment parameters should be selected as few as possible.

If it is found that the training result is not good enough in the process of training the neural network model, it shows that the correlation between the selected parameters and the equipment health state is not strong; that is, the parameter selection is not reasonable. At this time, it is necessary to reselect the state parameters with strong correlation with the equipment health state as the assessment parameters of the equipment health state.

5.2. Query Parameter Data from Digital Twin Model. Using sensor technology, digital twin model can obtain a large amount of state data efficiently, establish the real mapping between the virtual model and the physical entity,

and truly reflect the real-time state of equipment. At the same time, the digital twin model has sufficient historical and empirical data, which can be used as the support of data analysis.

Querying parameter data from digital twin model is to query and collect relevant data of assessment parameters in digital twin model, including current data, historical data, and empirical data, as the basis for further analysis. If no relevant data is queried from the digital twin model, the digital twin model needs to be adjusted.

5.3. Adjust Digital Twin Model. When establishing the digital twin model, the common parameters of equipment are mainly considered. If some selected parameters are not collected in the digital twin model and it is necessary to collect these parameters for health state assessment, it is necessary to adjust the digital twin model, add corresponding sensors, collect these parameters, and collect relevant historical and empirical data.

5.4. Preprocess Data. To meet the needs of neural network algorithm, the input data need to be preprocessed in two aspects: state data normalization and grade data formatting.

(1) State data normalization. The state data of the input data of the neural network model should be normalized according to a certain method to avoid the influence of different data value range on the results. There are many normalization algorithms, and appropriate methods can be selected according to the characteristics of data. Here, a simple method of
FIGURE 6: Assessment process.

maximum linear conversion is introduced as an example. The conversion equation is

$$x' = \frac{(x - x_{\min})}{(x_{\max} - x_{\min})},\qquad(1)$$

where x' is the value after normalization, x is the value before normalization, $x_{\min}$ is the minimum value of the sample, and $x_{\max}$ is the maximum value of the sample.

(2) Grade data formatting. The grade data of the input data of the neural network model shall be marked by a one-dimensional array in the format of 0-1. For example, if the health state of the equipment is divided into five grades, the grade data of the five grades shall be represented by a one-dimensional array [1,0,0,0,0], [0,1,0,0,0], [0,0,1,0,0], [0,0,0,1,0], and [0,0,0,0,1], as shown in Table 2.

TABLE 2: Grade data format.

Health state grade	Grade identification	Grade data format
Health	1	[1,0,0,0,0]
Subhealth	2	[0,1,0,0,0]
Attention	3	[0,0,1,0,0]
Danger	4	[0,0,0,1,0]
Failure	5	[0,0,0,0,1]

5.5. Establish and Train the Neural Network Model. In the stage of state assessment through the neural network model, if the assessed unit has established and trained the corresponding neural network model in the early stage, it can directly use this model for health state assessment. Otherwise, it should use the data obtained from digital twin model to establish and train the neural network model and assess the training result of the model. The established neural network model should also be retrained once a year.

5.5.1. Design the Model. The number of nodes in the input layer is represented by n, which is equal to the number of selected assessment parameters. The more assessment parameters, the more nodes.

The number of nodes in the output layer is represented by m, which is the number of required classifications. For example, if the equipment health state is divided into 5 grades, the number of nodes in the output layer is $m = 5$.

The hidden layer is designed as one hidden layer, and the number of nodes is represented by n_1. It is calculated according to (2), and the number of nodes with the best training result is set after many tests within the value range.

$$n_1 = \sqrt{n + m} + a, \tag{2}$$

where n_1 is the number of hidden layer nodes, m is the number of output layer nodes, n is the number of input layer nodes, and a is a constant between 1 and 10.

After adding bias nodes in the input layer and hidden layer, respectively, the neural network design is shown in Figure 7.

5.5.2. Train the Model. Distinguish the input data, so that 75% of the data is used for model training and 25% of the data is used for model testing. Write the neural network algorithm program in Python; we can train the neural network model. By continuously correcting the connection weights of each node in each layer, the error convergence can be realized and a reliable neural network model can be obtained.

5.5.3. Assess the Training Result. After the training of neural network model is completed, the training result of the model can be assessed and the accuracy of the model can be given through the model error and the classification effect of the model on the training data and test data. If the training effect meets the needs of assessment, the model can be used for health state assessment. If the training effect is not good enough, it indicates that the selected assessment parameters are not strongly correlated with the equipment health state. The assessment parameters should be adjusted according to the selection principle of assessment parameters, and the neural network model should be reestablished.

5.5.4. Retrain the Model. The established neural network model should be retrained regularly, and the newly collected actual operation data should be substituted into the model as input data, so as to increase the amount of data and improve the accuracy of the model. Since one year is generally a cycle of equipment operation and support and relatively complete operation and support data can be obtained at the end of the year, the retraining is generally conducted once a year and arranged at the end of each year.

5.6. Conduct Health State Assessment. After obtaining the data from the digital twin model and establishing and training the neural network model, we can use the state data
FIGURE 7: Neural network design.

and neural network model to assess the health state of equipment. After preprocessing the parameter data reflecting the current state of the equipment according to the same method as the input data and inputting them into the trained neural network model, the current health state grade of the equipment can be obtained, which directly reflects the health state of the equipment.

5.7. Give Assessment Conclusions and Suggestions. According to the health state assessment result, combined with the knowledge base and expert system of digital twin model, we can give the health state assessment conclusion, describe the current health state of the equipment, and present equipment maintenance suggestions, so as to help equipment managers better carry out equipment support and give full play to the maximum efficiency of the equipment.

6. Case Study

We take the engine fuel system of a certain equipment as an example to assess its health state. The engine fuel system is a replaceable unit of the equipment.

6.1. Select Assessment Parameters. According to the characteristics of engine fuel system, the pressure of high-pressure oil pipe is selected as the measurement basis, and six parameters are selected as the assessment parameters of the health state of the engine fuel system, as shown in Table 3.

6.2. Obtain and Preprocess Data. 3000 groups of historical data can be obtained from the built engine digital twin model as the input data of the neural network model, and the data are preprocessed. Part of the preprocessed data is shown in Table 4.

6.3. Establish and Train the Neural Network Model. We can write a program in Python to establish and train the neural network model.

The number of input layer nodes $n = 6$ and the number of output layer nodes $m = 5$ of the neural network model can be determined by 6 state parameters and 5 health state grades. According to (2), the number of hidden layer nodes n_1 can

be selected from 4 to 13. Through many experiments, when the number of hidden layer nodes $n_1 = 13$, the model training effect is the best. Thus, the neural network model can be established.

The neural network model is trained by using the preprocessed input data. After many times of training, the satisfactory training result is obtained, as shown in Figure 8. It can be seen that the error of the neural network model decreases gradually through training. In the final neural network model, the correct rate of training data is 92.93%, the correct rate of test data is 91.87%, and the correct rate of all input data is 92.67%. The correct rate of the test data is close to that of the training data, and the error results only appear in the adjacent state of the actual results, indicating that the model does not overfit, and its correct rate is high, which can meet the requirements of the assessment model.

6.4. Conduct Health State Assessment. After extracting the current state information of the engine fuel system from the digital twin model and preprocessing, the state data can be obtained, as shown in Table 5.

After running the neural network model and entering the state data into the model, the assessment result can be obtained, as shown in Figure 9.

It can be seen that the assessment result of the current state is [0.0000, 0.1573, 0.5573, 0.1907, 0.000], suggesting that the engine fuel system is in the "Attention" state at this time. The assessment result is consistent with the actual situation.

6.5. Give Assessment Conclusions and Suggestions. Through the assessment, the engine fuel system is in the state of "Attention" at this time. Combined with the grading principle and referring to the knowledge base and experience base in the digital twin model, the assessment conclusion is that the performance degradation of the engine fuel system is serious and failure may occur in the next 30 days. The assessment suggestions are as follows: strengthen condition monitoring, prepare for repair, and allocate spare parts in time.

The above case shows that using the fusion driven method of digital twin model and neural network algorithm

can effectively realize the assessment of equipment health state and obtain intuitive and accurate assessment results.

7. Discussion

The above method defines a data-driven health state grade and uses the fusion drive of digital twin model and neural network algorithm to assess the health state of equipment and achieves the expected results.

This problem can also be solved by SOTA methods such as fuzzy comprehensive assessment, combined weighting model, and Bayesian network model, but because these methods are mostly assessed from the qualitative perspective or probability perspective, the assessment results are relatively fuzzy, which cannot meet the requirements of equipment support accuracy.

Compared with these methods, this method has the following characteristics:

(1) Faster. Using this method, real-time health state assessment can be realized. Because the digital twin model is established in advance and the way to obtain data is established, the data acquisition is faster. Because the training of neural network model is completed in advance and the training results can be used for many times, the assessment process is also faster.

(2) More accurate. In this method, the intelligent algorithm is used to make full use of the advantages of big data and find the failure rules suitable for each equipment. It avoids the process of determining the weight through expert scoring in some traditional methods and eliminates the interference of human factors, and the result is more accurate and objective. It meets the needs for accurate support.

(3) Better adapt to new requirements. The data-driven state grade is redefined to define the state with data, which meets the needs of big data-driven mode. The complex calculation process of some traditional methods is avoided, and the model can be used many times after training, which reduces the amount of calculation of state assessment and meets the needs of big data processing.

(4) More practical. The traditional health state assessment can only be used to count the state of batch equipment and master the overall state of equipment. This method can be used to assess the equipment group, single equipment, and a part of equipment. The assessment results can be used to reliably judge the health state of equipment, guide the support decision-making, and improve the active of equipment support.

(5) More automated. From data collection to processing to assessment, the whole process of assessment is automated, which saves labor, improves work efficiency, and greatly reduces the error rate.

(6) Portable. For new equipment that lacks a large amount of data support, the parameter data in the assessment model of similar equipment can be transplanted as empirical data to become the initial data of new equipment to bring the initial support data of new equipment closer to reality and provide support for the support decision of new equipment.

8. Conclusions

Equipment health state assessment is of great significance to realize equipment accurate support. Taking the neural network algorithm as an example, this paper studies the method of unit level health state assessment of equipment driven by the fusion of digital twin model and intelligent algorithm. The equipment health state grade is redefined from the data-driven perspective, and the unit level health state assessment model of equipment based on digital twin

model and neural network algorithm is established. The effectiveness of the method is verified by case study. Support is provided for further research of equipment-level health state assessment and the decision-making of equipment maintenance.

This paper mainly studies the method of health state assessment based on the combination of neural network algorithm and digital twin model. In fact, there are many intelligent algorithms that can be combined with digital twin model for equipment health state assessment. Different equipment or different replaceable units may need to use different algorithms according to their characteristics, but the method of combination with digital twin model is the same. The combination of digital twin model and other algorithms for health state assessment can be further studied in the future.

Data Availability

The raw data used to support the findings of the study can be obtained from the corresponding author upon request.

Knowledge tracing (KT) is the task of modelling students' knowledge state based on their historical interactions on intelligent tutoring systems. Existing KT models ignore the relevance among the multiple knowledge concepts of a question and characteristics of online tutoring systems. This paper proposes a neural Turing machine-based skill-aware knowledge tracing (NSKT) for conjunctive skills, which can capture the relevance among the knowledge concepts of a question to model students' knowledge state more accurately and to discover more latent relevance among knowledge concepts effectively. We analyze the characteristics of the three real-world KT datasets in depth. Experiments on real-world datasets show that NSKT outperforms the state-of-the-art deep KT models on the AUC of prediction. This paper explores details of the prediction process of NSKT in modelling students' knowledge state, as well as the relevance of knowledge concepts and conditional influences between exercises.

1. Introduction

With the development of intelligent tutoring systems (ITSs) and the emergence of massive open online courses (MOOCs) [1, 2], knowledge tracing plays an important role in improving the efficiency of personalized learning platforms. Knowledge tracing is the task of modelling students' knowledge state based on their historical interactions to predict students' mastery of knowledge concepts (KCs), where a KC can be an exercise, a skill, or a concept [3, 4].

In order to better model students' knowledge state, various knowledge-tracing models have been proposed. In previous studies, Bayesian knowledge tracing (BKT) is a powerful knowledge-tracing model. BKT models students' knowledge concept state by using a hidden Markov model (HMM) for each KC [5].

As deep learning develops, a lot of deep learning models have been applied in KT. Chris Piech applies the recurrent neural network (RNN) to model the student learning process for the first time and proposes deep knowledge tracing (DKT) [6–9]. The dynamic key-value memory network (DKVMN) uses a static memory called key and a dynamic memory called value to discover latent relations between exercises and knowledge concepts [10, 11]. Self-attentive

knowledge tracing (SAKT) proposes a self-attention-based KT model to model the students' knowledge state, with exercises as attention queries and students' past interactions as attention keys/values [3, 12–15].

However, the aforementioned works only focus on students' exercise interactions and ignore the relations between questions and skills. It cannot model students' knowledge state accurately by merely focusing on students' interactions. Knowledge tracing models begin to pay attention to the structure of the knowledge concepts [16–18].

Deep hierarchical knowledge tracing models students' knowledge state by capturing the hierarchical structure of questions and knowledge concepts [16]. Neil Heffernan's latest work considers the question information to which the knowledge concept belongs [17]. Graph-based knowledge tracing considers the influence among neighboring knowledge concepts [19–22]. The bipartite graph is an effective structural model to capture latent relations between questions and skills [18]. This method is effective, but the amount of calculation is huge because it needs to extract questions and skills, respectively. Thus, it is difficult to be regarded as a streamlined and effective knowledge-tracing model.

None of the above KT models make full use of the multiknowledge concept information of the questions.

Existing knowledge tracing models cannot capture latent relations between questions and concepts concisely and effectively. We know that questions are generally composed of multiple knowledge concepts, which are actually closely related. In order to better model the students' learning process, our model is constructed by using neural Turing machines (NTMs), which are an instance of memory-augmented neural networks (MANNs) that have a large external memory capacity [23–25]. Therefore, on the basis of above deep knowledge tracing models, we propose an NTM-based skill-aware knowledge-tracing model. The highlight of our work is to utilize the knowledge concept composition information of questions to model the students' knowledge state more accurately and to discover more latent relevance among knowledge concepts effectively. The contributions of this paper are concluded as follows:

(i) We process the real-world KT datasets in detail and discover new characteristics of online tutoring systems and knowledge tracing datasets.

(ii) We design a question-skill dictionary algorithm to obtain the conjunctive skills of questions. The input encoding contains both students' answering interaction information and the related knowledge concept information.

(iii) We apply neural Turing machines into knowledge tracing innovatively to enhance the memory capacity of our model and to predict students' mastery of knowledge concepts accurately and discover knowledge concept substructure effectively.

(iv) We propose a novel NTM-based skill-aware knowledge-tracing model for conjunctive skills and apply a novel loss optimization function to deep knowledge tracing to enhance the model's ability of skill awareness. Our model considers the conjunctive knowledge concept information contained in a question in the process of modelling the students' knowledge state; thus, our model outperforms existing KT models.

The rest of this paper is organized as follows: Section 2 presents a brief overview of related work in the field of knowledge tracing. In Section 3, we formulate the process for NSKT to perform the knowledge-tracing task. Then, Section 4 introduces the characteristics and classifications of online tutoring systems. The details of the NSKT model are provided in Section 5. The experimental results and the comparison of models' performance in the real-world datasets are given in Section 6. In Section 7, we discuss in detail the process of NSKT in modelling the students' knowledge state. Section 8 presents the conclusions and future studies of this work.

2. Related Work

In this section, we present a brief overview of the models and methods of related work in the field of knowledge tracing, which can be classified into two main categories, as shown in Table 1.

TABLE 1: Related work.

Models	Methods	Categories
IRT	Logistic model	Statistical model
BKT	Bayesian model	
DKT	Long short-term memory network	Deep learning models
DHKT	Long short-term memory network	
DKVMN	Memory-augmented neural network	
SAKT	Self-attention	

2.1. Item Response Theory. Item response theory is the most commonly used cognitive model to predict students' mastery of knowledge concepts before knowledge tracing was proposed in 1995 [26, 27]. On the basis of IRT, the students' knowledge state cognitive model based on factor analysis was later proposed: LFA [28] and PFA [29]. These logistic regression models predict students' mastery of knowledge concepts by analyzing the relationship among factors that have an impact on students' answering accuracy [30, 31].

2.2. Knowledge Tracing. Bayesian knowledge tracing (BKT) models the students' knowledge state by using the hidden Markov model (HMM) for a single knowledge concept, which is represented as a set of binary latent variables [5].

With the rise of deep learning, deep knowledge tracing (DKT) was proposed in [6], which regards students' historical interactions as time sequences and models the students' knowledge state by the recurrent neural network (RNN). The experimental results show that DKT has the powerful ability of modelling the students' knowledge state. After DKT, a lot of deep KT models have been proposed to improve the AUC of the prediction of students' mastery of knowledge concepts. However, most of these deep knowledge-tracing models only focus on students' interactions on knowledge concepts and ignore the structural relationship between questions and knowledge concepts.

2.3. Question-KC Relation in Knowledge Tracing. Cen et al. proposed the two IRT models (additive factor model (AFM) and conjunctive factor model (CFM)) to model the conjunctive skills in the student datasets [32]. Both the AFM and CFM consider the conjunctive skills information contained in an item to predict the probability of students answering the item correctly.

Deep hierarchical knowledge tracing begins (DHKT) to focus on the hierarchical relationship between knowledge concepts and questions to predict the performance of students [16]. DHKT trains a question embedding by the average embeddings of the skills belonging to the question. The model using the bipartite graphs can capture relationships between knowledge concepts and questions effectively and systematically to pretrain question embeddings for each question [18]. Neil Heffernan's latest work begins to focus on the architecture of knowledge concepts and questions too [17].

TABLE 2: Notations.

Notations	Description
p	Problem/question
q	KC (skill/concept)
a	Answer correctness to the knowledge concept (KC) q
c	Answer correctness to related knowledge concept (RKC)
M	Number of unique KCs in the KT dataset
P	Probability
S	The RKCs
H	Interaction sequence of a student: $\{h_1, \ldots, h_{|H|}\}$
D	Dataset
E	Encoding
KC	Knowledge concept
RKC	Related knowledge concept
Dic	Dictionary

3. Problem Formulation

Generally, KT can be formulated as a supervised sequence learning problem: the student's interaction tuple at the timestamp t, $h_t = (q_t, a_t)$ that represents the combination of which skill (exercise) was answered and if the skill was answered correctly, so $a_t \in \{0, 1\}$, $q_t \in \{q_i\}_{i=1}^M$, where M is the number of unique exercises in datasets. Given the student's past exercise interactions, $H_t = \{h_0, \ldots, h_t\}$, the goal of KT is to predict the probability that the student will answer question q_{t+1} correctly at the next timestamp $t + 1$, $P(a_{t+1} = 1/q_{t+1}, H_t)$ [3, 6, 10].

It can be seen that existing KT models only focus on students' exercise interactions, so they are difficult to predict students' mastery of skills effectively. The notations used in this paper are shown in Table 2.

Definition 1. Related knowledge concepts (RKCs): the related knowledge concepts (RKCs) refer the other knowledge concepts S that compose the question p with a knowledge concept q, where S and q are mutual conjunctive knowledge concepts (skills).

The Algorithm 1 processes the skills and the questions of the dataset to obtain a dictionary Dic with the question number as the key and conjunctive skills of the question as the value, while conjunctive skills are the skills that make up the same question. The time complexity of Algorithm 1 is $\mathcal{O}(n^2)$. In this paper, we use KC shown in Table 2 to represent skill. Let S be the RKCs related to KC q of the answering question p, where $S = \{x/x \in \text{Dic}_p, x \neq q\}$ is illustrated in Figure 1(a).

The skill-aware knowledge tracing model can be formulated as follows: the student's interaction at the timestamp t, $h_t' = (p_t, q_t, a_t, S_t, c_t)$, where a_t is the correctness to the question p_t on skill q_t, S_t are the of RKCs of KC q_t, c_t is the correctness to RKCs S_t. Given the student's past interactions, $H_t' = (h_0', \ldots, h_t')$, we can predict the probability that the student will answer next KC q_{t+1} correctly at the timestamp $t + 1$, $P(q_{t+1}) = P(a_{t+1} = 1/q_{t+1}, H_t')$ or predict students' mastery of holistic knowledge concepts, $\{P(q_i)\}_{i=1}^M$.

4. Online Tutoring Systems

The online tutoring systems can be classified into two categories:

4.1. Question-Level Online Tutoring Systems. In question-level online tutoring systems, students answer the question directly. If the question is answered correctly or incorrectly, all KCs (skills) of the question are answered correctly or incorrectly too. So if a student has answered q_t correctly or incorrectly, then they must answer the RKCs S_t correctly or incorrectly too, which is illustrated in Figure 1(b). Because q_t and S_t are from the same question, so in question-level online tutoring systems, for a student's interaction at the timestamp t: $(p_t, q_t, a_t, S_t, c_t)$,

$$c_t = a_t. \tag{1}$$

4.2. Skill-Level Online Tutoring Systems. The question-answering situation in skill-level online tutoring systems is much more complicated than that of the question-level online tutoring system. Students can individually answer one of the skills in the question and can answer this skill once or multiple times. So if a student answers KC_1 correctly, it does not mean that the student must answer KC_2 correctly, which is shown in Figure 1(c).

Superficially, there is no obvious answering correctness relationship between skill q_t and the related skill set S_t. However, there are a large number of students answering examples shown in Table 3 in skill-level online tutoring systems, indicating that if a student answers q_t incorrectly many times, even if he finally answers q_t correctly, which demonstrates that his mastery of skill q_t is very poor, and similarly, he has poor mastery of S_t. It is very likely that he will answer q_t's-related skills S_t incorrectly. So the student's mastery of q_t, $P(q_t)$ and the student's mastery of S_t, $P(S_t)$ are close:

$$P(q_t) \approx P(S_t). \tag{2}$$

This finding is strongly supported by the actual responses of students in skill-level online tutoring systems. So in skill-level online tutoring systems, according to formula (2), we can assume.

$$c_t \approx a_t, \tag{3}$$

as shown in Table 4.

5. Method

In this section, we will give a detailed introduction of our NSKT framework, of which, the overview architecture is given in Figure 2.

5.1. Model. The model consists of an encoding layer and a neural network layer. In order to better model the students' knowledge state, the model is constructed with

Input: question list L^p; skill list L^q; dictionary Dic; dataset $D = \{(q_i, p_i)\}_{i=0}^{|D|-1}$ composed of skills and questions.
Output: Dic
(1) Dic **initialization**
(2) L^p **initialization**
(3) $\mu \leftarrow 0$

ALGORITHM 1: Question-skill dictionary algorithm.

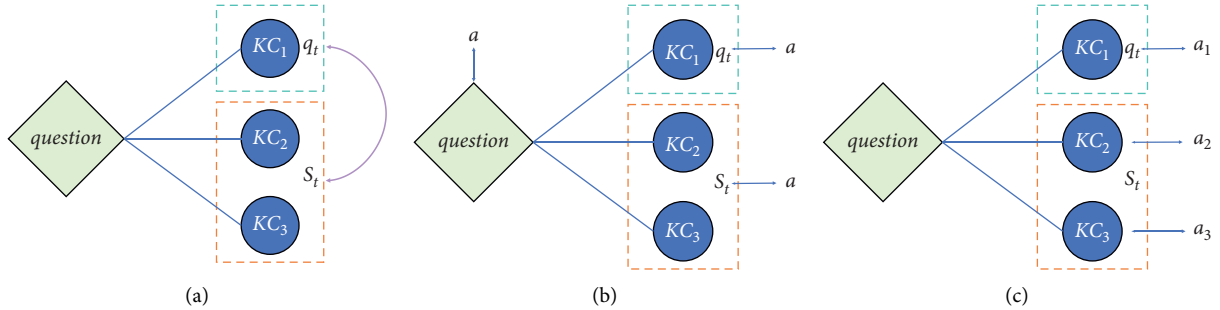
(a)   (b)   (c)


FIGURE 1: Illustrations. (a) Illustration of RKC S related to KC q, where S and q are mutual conjunctive skills. (b) Illustration of the question-level online tutoring system, where a denotes answer correctness to a question. (c) Illustration of the skill-level online tutoring system, a_1 denotes answer correctness to KC1, a_2 denotes answer correctness to KC_2, and so on a_3.

TABLE 3: Example of a student answering question 33 in skill-level online tutoring systems. Question 33 is composed of skill $s11$ and $s21$. The student answers $s11$ incorrectly three times $t_1 - t_3$ in succession. Even if he answers $s11$ correctly at the timestamp t_4, his mastery of $s11$ is very poor and his mastery of $s11$'s-related skill $s21$ is not good too, so it is very likely to answer $s21$ incorrectly, in fact, he answers $s21$ incorrectly at the timestamp t_5.

Timestamp	Skill	Correctness
t_1	$s11$	0
t_2	$s11$	0
t_3	$s11$	0
t_4	$s11$	1
t_5	$s21$	0

the neural Turing machine, which is an instance of memory-augmented neural networks (MANNs) that offer the ability to quickly encode and retrieve new information [23].

TABLE 4: The relationship between a_t and c_t in skill-level online tutoring systems.

timestamp	q_t	a_t	S_t	c_t
t_1	$s11$	0	$s21$	0
t_2	$s11$	0	$s21$	0
t_3	$s11$	0	$s21$	0
t_4	$s11$	1	$s21$	1
t_5	$s21$	0	$s11$	0

5.2. Input Features

5.2.1. Answer Information Encoding. Let E^q be the encoding of the student's interaction tuple (q, a), thus $E^q = [e_i^q] \in \{0, 1\}^{2M}$:

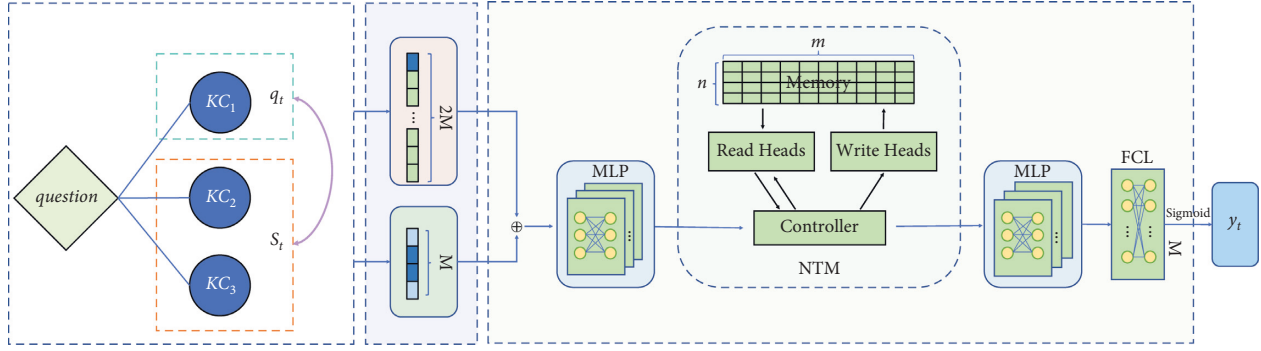
$$e_i^q = \begin{cases} 1, & \text{if } i = q + a \times M, \\ 0, & \text{otherwise} \end{cases} \tag{4}$$


FIGURE 2: The NSKT framework overview.

5.2.2. RKC Information Encoding.

The information of the set S of RKCs related to KC q is encoded E^s with a length of M: $E^s = [e_i^s] \in \{0, 1\}^M$:

$$e_i^s = \begin{cases} 0 & i \notin S, \\ 1 & i \in S. \end{cases} \tag{5}$$

5.3. Neural Turing Machines.

Neural Turing machines are an instance of memory-augmented neural networks (MANNs) that extend the capabilities of neural networks by coupling them to external memory resources. Experiments show that neural Turing machines have stronger memory capabilities than the LSTM [23], which is very suitable for modeling the students' knowledge state [33–35]. Figure 3 shows a high-level diagram of the neural Turing machine architecture.

As can be seen from Figure 3, the NTM is composed of 4 modules: controller, read heads, write heads, and memory. The controller can be a feed-forward neural network or a recurrent neural network [23, 34] and has read and write heads that access the external memory matrix.

5.4. Reading.

Let $\mathbf{M}_t$ be the external memory content which is a $n \times m$ memory matrix at the timestamp t, where n is the number of memory locations and m is the vector dimension at each memory location. The n elements $w_t(i)$ of $\mathbf{w}_t$, which is a vector of weightings over the n locations emitted by a read head at the timestamp t, obey the following constraints:

$$\sum_i w_t(i) = 1, 0 \le w_t(i) \le 1, \forall i. \tag{6}$$

Let $\mathbf{r}_t$ be the read vector of a length m returned by the head at the timestamp t:

$$\mathbf{r}_t \leftarrow \sum_i w_t(i) \mathbf{M}_t(i). \tag{7}$$

5.5. Writing.

The memory matrix $\mathbf{M}_t$ at the timestamp t is modified by the erase vector $\mathbf{e}_t$ and the add vector $\mathbf{a}_t$:

$$\begin{aligned} \widetilde{\mathbf{M}}_t(i) &\leftarrow \mathbf{M}_{t-1}(i)\left[1 - w_t(i)\mathbf{e}_t\right] \\ \mathbf{M}_t(i) &\leftarrow \widetilde{\mathbf{M}}_t(i) + w_t(i)\mathbf{a}_t. \end{aligned} \tag{8}$$
FIGURE 3: Neural Turing machine architecture.

5.6. Addressing Mechanisms

5.6.1. Focusing on Content.

Each head produces a length m key vector $\mathbf{k}_t$ that is used to compute the normalised weighting w_t^c as follows:

$$w_t^c(i) \leftarrow \frac{\exp\left(\beta_t K\left[\mathbf{k}_t, \mathbf{M}_t(i)\right]\right)}{\sum_j \exp\left(\beta_t K\left[\mathbf{k}_t, \mathbf{M}_t(j)\right]\right)}, \tag{9}$$

where β_t is a positive key strength generated by the controller and the similarity measure K is cosine similarity:

$$K[\mathbf{u}, \mathbf{v}] = \frac{\mathbf{u} \cdot \mathbf{v}}{\|\mathbf{u}\| \times \|\mathbf{v}\|}. \tag{10}$$

5.6.2. Focusing on Location.

The location-based addressing mechanism is designed to facilitate both simple iterations across the locations of the memory and random-access jumps. It does so by implementing a rotational shift of a weighting as follows [23].

Firstly, the interpolation gate g_t is used to blend between the weighting $\mathbf{w}_{t-1}$ and the weighting $\mathbf{w}_t^c$:

$$\mathbf{w}_t^g \leftarrow g_t \mathbf{w}_t^c + (1 - g_t)\mathbf{w}_{t-1}. \tag{11}$$

Furthermore, the model uses a one-dimensional convolution shift kernel to convolve the current weighting w_t^g:

$$\widetilde{w}_t(i) \leftarrow \sum_{j=0}^{n-1} w_t^g(j) s_t(i - j), \tag{12}$$

where $\mathbf{s}_t$ is the shift weighting generated by the controller.

To correct the blur that occurs due to the convolution operation, each head emits one further scalar $\gamma_t \geq 1$ whose effect is to sharpen the final weighting as follows:

$$w_t(i) \leftarrow \frac{\widetilde{w}_t(i)^{\gamma_t}}{\sum_j \widetilde{w}_t(j)^{\gamma_t}}. \tag{13}$$

5.7. Controller. The NTM controller in our model is the long short-term memory network [36], which can be formulated by the formulas as follows:

$$
\begin{aligned}
\mathbf{f}_t &= \sigma\big(\mathbf{w}_f[\mathbf{h}_{t-1}, \mathbf{x}_t] + \mathbf{b}_f\big), \\
\mathbf{i}_t &= \sigma\big(\mathbf{w}_i[\mathbf{h}_{t-1}, \mathbf{x}_t] + \mathbf{b}_i\big), \\
\mathbf{o}_t &= \sigma\big(\mathbf{w}_o[\mathbf{h}_{t-1}, \mathbf{x}_t] + \mathbf{b}_o\big), \\
\mathbf{c}_t &= \mathbf{f}_t \odot \mathbf{c}_{t-1} + \mathbf{i}_t \odot \tanh\big(\mathbf{w}_c[\mathbf{h}_{t-1}, \mathbf{x}_t] + \mathbf{b}_c\big), \\
\mathbf{h}_t &= \mathbf{o}_t \odot \tanh(\mathbf{c}_t).
\end{aligned}
\tag{14}
$$

$\mathbf{i}, \mathbf{f}, \mathbf{o}, \mathbf{c}, \mathbf{h}$ are the activation matrices of the input gate, the forget gate, the output gate, the memory cell, and the hidden state matrix, respectively. $\mathbf{w}$ and $\mathbf{b}$ are the weight matrix and the bias vector of the corresponding gate, respectively. $\odot$ denotes the Hadamard product. σ and tanh denote the sigmoid and hyperbolic tangent function, respectively:

$$\sigma(x) = \frac{1}{1 + \exp(-x)}, \tag{15}$$

let logits $\in \mathbb{R}^M$ be the output of the last neural network of the NSKT model, the student's mastery of knowledge concepts predicted by the model at the timestamp t is

$$\mathbf{y}_t = \sigma(\text{logits}), \tag{16}$$

where $\mathbf{y}_t \in \mathbb{R}^M$.

5.8. Optimization. The loss function of the model consists of two parts, namely, the answering interaction loss $\mathscr{L}_1$ and the related knowledge concept information loss $\mathscr{L}_2$. Let ℓ be the binary cross entropy loss:

$$\ell(p, a) = -(a \log p + (1 - a)\log(1 - p)). \tag{17}$$

We optimize the average cross entropy loss of the student's interactions as follows:

$$\mathscr{L}_1 = \frac{\sum_t \ell\big(\mathbf{y}_t^{\mathbf{T}} \delta(q_{t+1}), a_{t+1}\big)}{|H| - 1}, \tag{18}$$

where $\delta(q_{t+1})$ is the one-hot encoding of KC q_{t+1} at the timestamp $t + 1$, $|H|$ is the total number of the student's interactions, and $\mathbf{T}$ denotes transpose operation.

The average cross-entropy loss of the related knowledge concept information is

$$\mathscr{L}_2 = \frac{\sum_t \sum_{i=1}^{|S_{t+1}|} \ell\big(\mathbf{y}_t^{\mathbf{T}} \delta(q_i), c_i\big)}{\sum_t |S_{t+1}|}, \tag{19}$$

where $q_i \in S_{t+1}$, c_i is the correctness to skill q_i.

The loss for a single student is represented by $\mathscr{L}$, which is as follows:

$$
\begin{aligned}
\mathscr{L} &= \lambda \mathscr{L}_1 + (1 - \lambda)\mathscr{L}_2 \\
&= \lambda \frac{\sum_t \ell\big(y_t^T \delta(q_{t+1}), a_{t+1}\big)}{|H| - 1} + (1 - \lambda)\frac{\sum_t \sum_{i=1}^{|S_{t+1}|} \ell\big(y_t^T \delta(q_i), c_i\big)}{\sum_t |S_{t+1}|} \\
&= \sum_t \left(\lambda \frac{\ell\big(y_t^T \delta(q_{t+1}), a_{t+1}\big)}{|H| - 1} + (1 - \lambda)\frac{\sum_{i=1}^{|S_{t+1}|} \ell\big(y_t^T \delta(q_i), c_i\big)}{\sum_t |S_{t+1}|} \right),
\end{aligned}
\tag{20}
$$

where the hyperparameter λ is the coefficient that determines the proportion of the answering information loss and the related information loss. We use an optimizer to optimize our model. Let Θ be the minimum of $\mathscr{L}$, thus, the training objective of NSKT is as follows:

$$\Theta \leftarrow \text{optimizer}(\mathscr{L}). \tag{21}$$

5.9. Skill Awareness. The student's past interactions in online tutoring systems: $H_t' = \{h_0', \dots, h_t'\}$, where $h' = (q_t, a_t, S_t, c_t)$ denotes that the student interaction tuple at the timestamp t. The set of knowledge concepts Set_q that students have answered actually so far is represented as follows:

$$\text{Set}_t^q = \{q_i\}_{i=1}^t. \tag{22}$$

The set of knowledge concepts (skills) Set^S answered by NSKT so far is represented as follows:

$$\text{Set}_t^S = S_1 \cup \dots \cup S_t. \tag{23}$$

As shown in Figure 4, when the student answers the next skill q_{t+1} at the next timestamp $t + 1$, even if the student has not answered questions related to skill q_{t+1} before, $q_{t+1} \notin \text{Set}_t^q$, but if NSKT has awareness of skill q_{t+1} so far, $q_{t+1} \in \text{Set}_t^S$, NSKT can predict the student's mastery of skill q_{t+1} accurately.

6. Experiments

In this section, we give a detailed explanation of datasets and experiments conducted to evaluate the performance of the NSKT model and other KT models in three real-world open-source knowledge tracing datasets.

6.1. Datasets. To evaluate KT models' performance, we use three datasets collected from online learning platforms. These three datasets are widely used real-world datasets in KT.

(i) ASSISTments2009 (https://sites.google.com/site/assistmentsdata/home/2009-2010-assistment-data) (ASSIST09) is provided by the ASSISTment online tutoring platform and is the most widely used dataset in knowledge tracing.

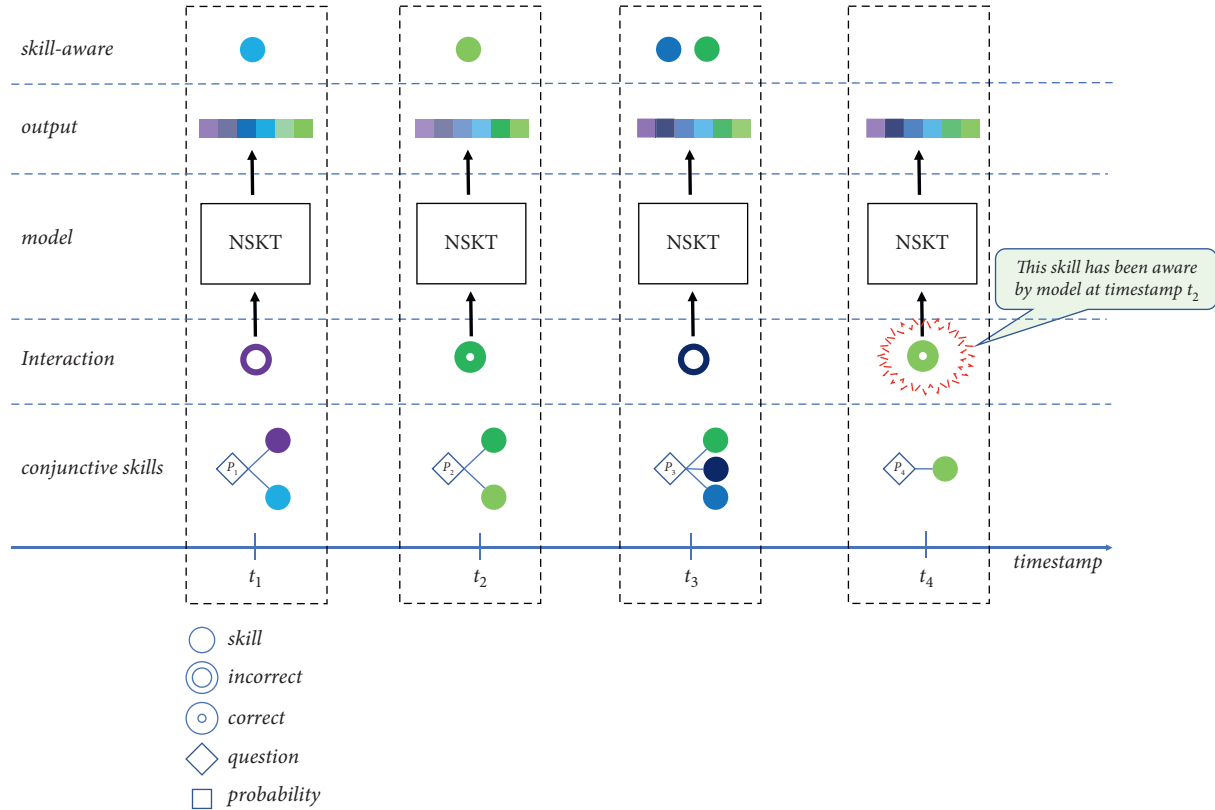
(ii) ASSISTments2017 (https://sites.google.com/view/assistmentsdatamining/dataset/) (ASSIST17) is


FIGURE 4: The process of skill awareness in NSKT. Different skills are indicated by different colors.

TABLE 5: The statistics of the three datasets.

	Students	Skills	Questions	Interactions (K)	MIN[a]	MAX[b]	AVG[c]
ASSIST09	4,162	124	26,688	526[d]	0	3	0.316
ASSIST17	1,709	102	3,162	942	0	2	0.472
EdNet	784,309	189	13,169	962	0	6	1.388

The symbol [a] indicates the minimum value of $|S|$, where 0 means that the question is a single KC (skill) question. The symbol [b] indicates the maximum value of $|S|$. The symbol [c] indicates the average value of $|S|$. The symbol [d]K stands for a thousand.

provided by the 2017 ASSISTments data mining competition and is the latest ASSISTments dataset with the most student responses.

(iii) EdNet (https://github.com/riiid/ednet) is the dataset of all student-system interactions collected over 2 years by Santa, a multiplatform AI tutoring service with more than 780 K users in Korea available through Android, iOS, and Web [37]. We conducted our experiments on EdNet-KT1 which consists of students' question-solving logs and is the record of Santa collected since April 2017 by following the question-response sequence format.

The complete statistical information for the three datasets is shown in Table 5.

The details about the columns in datasets are shown as follows:

ASSISTments:

(i) user_id: the ID of the student

(ii) problem_id: the ID of the problem

(iii) skill_id: the ID of the skill associated with the problem

(iv) 1: Correct on the first attempt
0: Incorrect on the first attempt,

EdNet:

(i) user_id: the ID of the student.

(ii) question_id: the ID of the question.

(iii) tags: the expert-annotated tags for each question.

(iv) correct_answer: the correct answer of each question recorded as a character between a and d inclusively.

(v) user_answer: the answer that the student submitted was recorded as a character between a and d inclusively.

6.2. Dataset Characteristics

(i) ASSIST09 and EdNet: For multiple skill questions, the records of students' interactions will be repeated with different skill taggings and each record

represents the student response to a skill of the question [38].

(ii) ASSIST17: similar to the ASSIST09 dataset, each record in ASSIST17 represents the student response to a skill of the question. However, we noticed the special features of this dataset. A large number of users in the ASSIST17 dataset only answered one skill of multiple skill questions and answered this skill one or more times. The number of multiple skill questions in this situation accounted for 44.88% of the total number of questions answered by students. That is, the student answers one or more skills of multiple skill questions, and the number of responses to a skill may be given once or multiple times.

6.3. Compared Models and Implementation Details.
To show the performance of our model and demonstrate the improvement of our model to existing KT models, we compare NSKT against the state-of-the-art KT models. We give the reference GitHub repositories of some KT models.

(i) BKT [5]: Bayesian knowledge tracing uses the hidden Markov model (HMM) to model the students' latent knowledge state as a set of binary variables. We use pyBKT (https://github.com/CAHLR/pyBKT) to implement BKT and set the model parameters: seed = 42, num_fits = 1.

(ii) DKT-LSTM [6]: the DKT-LSTM is the standard deep knowledge-tracing mode. We implemented DKT (https://github.com/chrispiech/DeepKnowledgeTracing) with the LSTM with tanh activation.

(iii) DKT-NTM: DKT is implemented by using the neural Turing machine (https://github.com/MarkPKCollier/NeuralTuringMachine).

(iv) DKVMN [10]: the DKVMN (https://github.com/jennyzhang0215/DKVMN) is a variation of MANNs, which uses a static memory called key and a dynamic memory called value to model the students' knowledge state.

(v) SAKT [3]: SAKT (https://github.com/shalini1194/SAKT) is the KT model based on the self-attention architecture with exercises as attention queries and students' past interactions as attention keys/values.

(vi) DSKT: the skill-aware deep knowledge-tracing model is implemented with the LSTM and tanh activation. We dynamically set the value of the coefficient λ to explore the best performance of DSKT.

(vii) NSKT: NSKT is an NTM-based skill-aware knowledge tracing. We test the performance of NSKT with different values of the coefficient λs to optimize the model's performance.

For all models, we use the Adam optimizer with learning_rate = 0.001, beta1 = 0.9, beta2 = 0.999, and

epsilon = $1e - 8$ to optimize. The minibatch size and the maximum length of the sequence for all datasets are set to 32 and 100, respectively. We perform standard five-fold cross-validation to evaluate all the KT models in this paper. We conduct experiments on the server with an 8-core 2.50 GHz Intel(R) Xeon(R) Platinum 8163 CPU and 64 GB memory.

6.4. Experimental Results

6.4.1. Models' Performance.
We use the area under the receiver operating characteristic curve (AUC) as an evaluation metric to compare prediction performance among the KT models mentioned in Section 6.3. A higher AUC indicates better performance. The test AUC results in the three real-world datasets for all KT models are shown in Table 6. From the experiment results, we can find the following observations:

(i) NSKT performs better than the other competing KT models in all datasets and achieves the average test AUC of 85.38%, 82.35%, and 80.81% in ASSIST09, ASSIST17, and EdNet, respectively.

(ii) DSKT performs better than the DKT-LSTM, achieves the average test AUC of 84.88%, 81.27%, and 79.71% in datasets ASSIST09, ASSIST17, and EdNet, respectively, gaining an average performance improvement of 0.82% (DKT-LSTM achieves the AUC of 84.45%, 80.04%, and 78.91%). NSKT performs better than the DKT-NTM, gaining an average performance improvement of 1.33% (DKT-NTM achieves the AUC of 84.53%, 80.51%, and 79.49%).

(iii) The DKT-NTM model has a better performance than the standard DKT-LSTM in knowledge tracing. The DKT-NTM achieves the average test AUC of 84.53%, 80.51%, and 79.49% in the three datasets, respectively, while the standard DKT-LSTM achieves the average test AUC of 84.45%, 80.04%, and 78.91% in the three datasets, respectively.

(iv) The performance of NSKT is better in dataset ASSIST17, which has more complex data features than those of ASSIST09 and EdNet. NSKT gains an average performance improvement of 2.31% in ASSIST17 compared to the standard DKT-LSTM while improving AUC by 0.93% and 0.90% in ASSIST09 and EdNet, respectively. It proves that NSKT is better in mining hidden information from complex educational data features to improve the accuracy of prediction.

Figure 5 shows the training process of KT models in the three KT datasets. It shows that the DKVMN and SAKT can learn faster than other KT models. The training speed of the DKT-LSTM, DKT-NTM, DSKT, and NSKT is close, but the test AUC of NSKT is the best.

We set the probability to KC q_t predicted by KT models: $P(q_t)$, and assume that students will answer KC q_t correctly if $P(q_t) > = 0.5$ and if $P(q_t) < 0.5$, the student will answer q_t incorrectly:

TABLE 6: Test AUC results for all datasets (%).

	BKT	DKT-LSTM	DKT-NTM	DKVMN	SAKT	DSKT	NSKT
ASSIST09	72.06	84.45	84.53	84.37	84.70	84.88	**85.38**
ASSIST17	65.25	80.04	80.51	80.55	81.25	81.27	**82.35**
EdNet	66.28	78.91	79.49	79.72	79.83	79.71	**80.81**

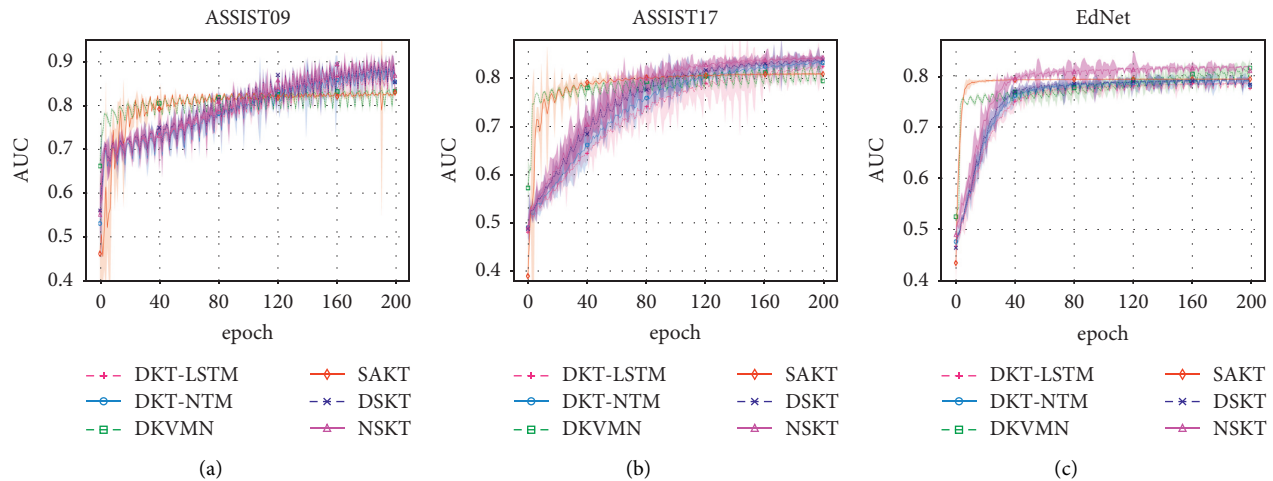
Bold values indicate the best performance.


FIGURE 5: The dynamics for training models in the KT datasets with the best hyperparameter selection for each model and each dataset individually. Each line plots the mean over multiple runs, while the corresponding root mean square error (RMSE) is shown as the shaded area around the mean. (a) ASSIST09. (b) ASSIST17. (c) EdNet.

$$a'_t = \begin{cases} 0 & P(q_t) < 0.5, \\ 1 & P(q_t) > = 0.5. \end{cases} \tag{24}$$

If $a'_t = a_t$, it means that models can predict correctly. Thus, the accuracy of prediction for KT models in the datasets is shown in Figure 6.

Figure 7 shows the performance of DSKT and NSKT under different λ values and the value of λ when models achieve the best performance. From Figure 7, we can draw the following conclusions: the test AUC of DSKT and NSKT is not ideal with a small λ value. However, as the value of λ increases, the test results of DSKT and NSKT get better and better; thus, we recommend $\lambda \geq 0.9$.

6.5. Friedman-Aligned Rank Test.
We perform the Friedman-aligned rank test [39] on the AUC test results of the KT models shown in Table 6 by the following formula:

$$X^2 = \frac{12}{nk(k+1)} \sum R_i^2 - 3n(k+1), \tag{25}$$

where R_i is the sum of the ranks of the i-th sample, k is the number of groups of samples, and n is the number of samples in each group. The probability distribution of X^2 can be approximated by that of the chi-squared distribution with $k - 1$ degrees of freedom χ^2_{k-1}. Now, we test the null hypothesis, which is as follows:

H$_0$: there is no significant difference in the performance of the KT models.

The P value P of the Friedman-aligned rank test on test AUC results is

$$P(\chi^2_{k-1} \geq X^2) = 0.013 < 0.05. \tag{26}$$

Then, we reject the null hypothesis H$_0$, which indicates a significant difference in the performance of the KT models.

6.6. Execution Time.
We compared the execution time of KT models per 200 batches in each dataset shown in Figure 8. As shown in Figure 8, the BKT model requires the least execution time to train the same size of data. This is because the BKT is not a deep learning knowledge tracing model, and it needs to train fewer parameters. For deep learning knowledge tracing models, the execution times of the DKT-LSTM, DKVMN, and SAKT are close and the execution times of the DKT-NTM and DSKT are close. The execution time of the DKT-NTM is more than that of the DKT-LSTM. The reason can be that the NTM takes more time to access its own external memory matrix. NSKT considers the conjunctive skills of the questions during the training process and needs to access the NTM's external memory matrix to enhance the memory ability of the model. Hence, NSKT has the most execution time, but this is also the reason why NSKT performs better in modelling the students' knowledge state.

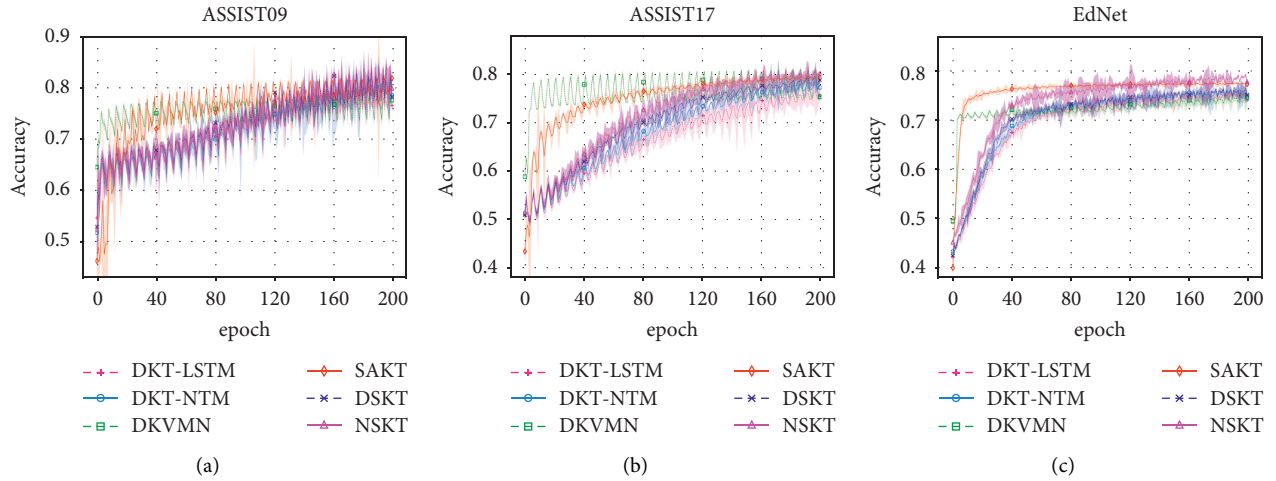
The experimental results show that the NTM-based skill-aware knowledge-tracing model has a strong ability to capture the relevance among knowledge concepts and can enhance the model's ability of skill awareness for conjunctive skills and improve the accuracy of prediction in modelling


Figure 6: The accuracy of prediction for training models in the KT datasets with the best hyperparameter selection for each model and each dataset individually. Figure 8: The comparison of the KT models' execution time per 200 batches in each dataset.

the students' knowledge state. Experiments demonstrate that NSKT is effective.

7. Discussion

In this section, we discuss the details of the prediction process of the KT model in modelling the students' knowledge state, as well as the relevance of knowledge concepts and conditional influence between exercises.

7.1. Prediction Process. In our opinion, an excellent KT model not only can predict the probability that students will answer questions correctly at the next timestamp accurately but also can perform well in modelling the students' holistic knowledge concept state.

Analyzing the prediction process of KT models can show the performance of NSKT. We randomly select a student sample U_1 from the ASSIST09 dataset, and the detailed process of DKT and NSKT modelling U_1's knowledge state is shown in Figure 9.

It can be seen from Figure 9(a) that although DKT performs fairly well in prediction, DKT only focuses on the knowledge concepts to be predicted at the next timestamp and does not care about the U_1's mastery of other knowledge concepts. Therefore, after U_1 answers $s32$ correctly $(s32, 1)$ at the timestamp t_3, the model's predicted probability of $s32$ decreases rapidly, indicating that U_1's mastery of $s32$ is getting worse and worse, which should not be consistent with the U_1's real knowledge state shown in Table 7. Because of lacking related knowledge concept (RKC) information, DKT's prediction accuracy and prediction breadth are not ideal.

As shown in Figure 9(b), we use two heatmap subfigures to show the process of modelling the U_1's knowledge state on NSKT. The x-axis of the lower subfigure is the sequence of U_1's interactions (q_t, a_t) and the y-axis is the skill index. The x-axis of the upper subfigure is the RKC S_t and the y-axis is the index of the RKCs S_i.

Because U_1 answers skill 32 (abbreviated as $s32$) correctly $(s33, 1)$ in the first three timestamps $t_1 - t_3$, the predicted probability of $s32$ gets higher and higher and the color of $s32$ in the y-axis of the lower subfigure gets brighter and brighter. As shown in the x-axis of the upper subfigure, $s33$ is the related knowledge concept of $s32$ in the first three timestamps $t_1 - t_3$; thus, the predicted probability of $s33$ gets higher and higher and the color of the $s33$ in the y-axis of the upper subfigure gets brighter and brighter too.

In the next three timestamps $t_4 - t_6$, U_1 answers s33 correctly $(s33, 1)$ in succession, the predicted probability of $s33$ gets higher and higher and the color of $s33$ in the y-axis of the lower subfigure gets brighter and brighter. $s32$ is the related knowledge concept of $s33$, so the predicted probability of $s32$ continues to increase, and the color of $s32$ in the y-axis of the upper subfigure gets brighter and brighter too and remains at a relatively high value.

In the next three timestamps $t_7 - t_9$, U_1 continues to answer $s33$ correctly $(s33, 1)$; however, this $s33$ is a single skill without related knowledge concepts, so only the

predicted probability of $s33$ gets higher and higher and the color of $s33$ in the y-axis of the lower subfigure gets brighter and brighter.

At the last timestamp t_{10}, U_1 answer $s37$ correctly $(s37, 1)$, so the predicted probability of $s37$ gets higher and higher and the color of $s32$ in the y-axis of the lower subfigure gets brighter and brighter. Because $s55$ is the related knowledge concept of $s37$, so the predicted probability of $s55$ gets higher and higher and the color of $s55$ in the y-axis of the upper subfigure gets brighter and brighter too.

In contrast, we randomly select a student sample U_2 with a low answering accuracy shown in Table 8.

The process of DKT and NSKT modelling the U_2's knowledge state is shown in Figure 10. It can be seen from Figure 10(a) that DKT models the U_2's knowledge state almost accurately, but the prediction breadth is not enough.

As shown in Figure 10(b), NSKT, like DKT, models the U_2's knowledge state accurately and performs better in prediction breadth. At the timestamp t_4, U_2 answers $s95$ incorrectly many times, the predicted probability of $s95$ gets lower and lower and the color of $s95$ in the y-axis of the lower subfigure gets darker and darker. As shown in the x-axis of the upper subfigure, $s2$ is the related knowledge concept of $s95$; thus, the predicted probability of $s2$ gets lower and lower and the color of $s33$ in the y-axis of the upper subfigure gets darker and darker too.

It can be concluded from Figures 9 and 10 that NSKT performs better in prediction accuracy and prediction breadth and can better model the students' knowledge state. NSKT not only focuses on students' mastery of the knowledge concept to be predicted at the next timestamp but also focuses on the students' mastery of the related knowledge concepts. This is where NSKT is superior to other existing KT models, and NSKT performs better in modelling the students' knowledge state than DKT [4].

7.2. Pearson Correlation Coefficient. In this paper, we use the Pearson correlation coefficient as the metric to measure the correlation among skills. By estimating the covariance and standard deviation of the sample, we can get the sample Pearson coefficient r:

$$r_{(X,Y)} = \frac{\sum_{i=1}^{n} (X_i - \overline{X})(Y_i - \overline{Y})}{\sqrt{\sum_{i=1}^{n} (X_i - \overline{X})^2} \sqrt{\sum_{i=1}^{n} (Y_i - \overline{Y})^2}}. \quad (27)$$

Figures 11 and 12 show the comparison of skill Pearson correlations of U_1's interactions and U_2's interactions on DKT and NSKT, respectively. Figures 11(a) and 12(a) show the skill Pearson correlation on DKT, and Figures 11(b) and 12(b) show the skill Pearson correlation on NSKT. It can be seen from the figures that DKT can only mine the correlation among the skills that have been answered in the past, indicating that DKT cannot effectively discover the relevance among knowledge concepts. As shown in Figures 11(b) and 12(b), NSKT can discover the correlation among four skills, while DKT can only discover among three. For example, it can be seen from Figure 11(b) that the Pearson correlation between $s32$ and $s55$ on NSKT of U_1's interactions is

(a)

(b)
Figure 9: Comparison of the prediction process of U_1 on DKT and NSKT. The color of the heatmap indicates the predicted probability that U_1's mastery of skills after interaction (q_t, a_t) at the timestamp t. The yellower the color, the higher the probability. (a) Heatmap for the prediction process of DKT. The x-axis is the sequence of U_1's interactions $(q_t; a_t)$ and the y-axis is the skill index. (b) Heatmap for the prediction process of NSKT. The x-axis of the lower subfigure is the sequence of U_1's interactions $(q_t; a_t)$ and the y-axis is the skill index. The x-axis of the upper subfigure is the RKC S_t and the y-axis is the skill index of the RKCs S_t.

Table 7: Skill maps of ASSIST09 and U_1's interaction accuracy.

Skill index	Skill name	Accuracy (%)
32	Ordering positive decimals	100
33	Ordering fractions	100
37	Addition whole numbers	100
55	Absolute value	100

Table 8: Skill maps of ASSIST17 and U_2's interaction accuracy.

Skill index	Skill name	Accuracy (%)
2	Point plotting	30
4	Reading graph	100
34	Equation solving	50
95	Divisibility	30
FIGURE 10: Comparison of the prediction process of U_2 on DKT and NSKT. The color of the heatmap indicates the predicted probability that U_2's mastery of skills after interaction (q_t, a_t) at the timestamp t. The yellower the color, the higher the probability. (a) Heatmap for the prediction process of DKT. The x-axis is the sequence of U_2's interactions $(q_t; a_t)$ and the y-axis is the skill index. (b) Heatmap for the prediction process of NSKT. The x-axis of the lower subfigure is the sequence of U_2's interactions $(q_t; a_t)$ and the y-axis is the skill index. The x-axis of the upper subfigure is the RKC S_t and the y-axis is the skill index of the RKCs S_t.

$r_{(s32,s55)} = 0.31$, which means there is a weak positive correlation between $s32$ and $s55$.

The Pearson correlation between $s33$ and $s55$ on NSKT of U_1's interactions is $r_{(s33,s55)} = 0.92$, which means there is a strong positive correlation between $s33$ and $s55$. Through the above examples, we can conclude that NSKT performs better in the ability of discovering latent relevance among knowledge concepts than existing KT models.

7.3. Knowledge Concepts' Discovery. NSKT can learn latent knowledge concept substructure among skills without expert annotations and can cluster related skills into a cluster, which denotes a knowledge concept (KC) class [6].

Figure 13 shows the visualization of using k-means to cluster the skill representation vectors, which have been performed by the t-SNE method [40, 41]. All skills are clustered into eight clusters, and each cluster can represent a knowledge concept class. Skills in the same cluster are labeled with the same color, and those skills have strong relevance and similarity. For example, $s32$ and $s33$ do have a strong relevance and similarity because they are very close in Figure 13, which further proves that NSKT has a stronger ability of discovering skill latent relevance information than existing KT models.

We have explored latent conditional influence between exercises by

$$J_{i \longrightarrow j} = \frac{y(j/i)}{\sum_k y(j/k)},$$ (28)

where $y(j/i)$ is the correctness probability assigned by NSKT to exercise j when exercise i is answered correctly in the first
FIGURE 11: Comparison of U_1's interaction skill Pearson correlations on DKT and NSKT ((a) DKT and (b) NSKT). Both the x-axis and the y-axis are the skills in U_1's interactions.
FIGURE 12: Comparison of U_2's interaction skill Pearson correlations on DKT and NSKT ((a) DKT and (b) NSKT). Both the x-axis and the y-axis are the skills in U_2's interactions.

time step [6]. We have shown a latent conditional influence relationship among the exercises corresponding to Figure 9(b) interactions. We have marked them with arrow symbols in Figure 13. The line width indicates connection strength, and nodes may be connected in both directions. We only show edges with an influence threshold greater than 0.08. Attached ASSIST09 skill maps are shown in Figure 13 (we only show 110 skills with the skill name).

8. Conclusion

In this work, we proposed a novel NTM-based skill-aware knowledge-tracing model for conjunctive skills, which can capture the relevance among the multiple knowledge concepts of questions to predict students' mastery of knowledge concepts (KCs) more accurately and to discover more latent relevance among knowledge concepts effectively. In order to better model the students' knowledge state, we adopt the neural Turing machines, which use the external memory matrix to augment memory ability. Furthermore, NSKT relates knowledge concepts (KCs) to related knowledge concepts (RKCs) as a whole to enhance the model's ability of skill awareness and improve prediction accuracy and prediction breadth. Experiments in the real-world KT datasets demonstrate that the NTM-based knowledge concept skill-aware knowledge-tracing model (NSKT) outperforms existing state-of-the-art KT models in modelling the students' knowledge state and discovering latent relevance among knowledge concepts.

For future studies, we will focus on mining hidden associations among knowledge concepts and building students' personalized answering paths in intelligent tutoring systems. Furthermore, we will construct the holistic structure of knowledge concepts to enhance students' understanding of how the overall knowledge affects each other.

China has been the world's largest market for industrial robots since 2013. Industrial robots improve accuracy, safety, and efficiency in industrial production but have a substantial impact on the labor market. This investigation uses the task-based model to explore the relationship between industrial robots and employment across industries. This study uses industrial robot data from the International Federation of Robotics and employment data from the China Statistical Yearbook from 2010 to 2019 to examine robot applications' influencing mechanisms on labor demand in different industries in China. The results show a significant positive correlation between robots' exposure and labor demand for IT, health and social services, science research and technical services, and management of water conservancy and environmental industries. Based on the results, the use of robots promotes high-skilled talent employment and some third-sector employment, like education, food and beverages, utilities, household appliances, and transport. However, multiple regression analysis reveals that the use of robots has reduced employment in traditional industries such as agriculture and mining.

1. Introduction

The issue of the potential impact of robots on the labor market has received considerable attention. The popularity of artificial intelligence and new robot designs has significantly influenced both the economy and society. At the beginning of the 20th century, the famous economist, John Maynard Keynes, predicted that humankind would have a new employment challenge, that is, "technological unemployment" [1]. Rapid progress in the fields of artificial intelligence and robotics has begun to solve major problems in terms of productivity and the acceleration of the replacement of labor by robots. This introduces tremendous challenges having to do with the human workforce [2]. According to application, robots can be classified as repetitive-tasks robots, medical robots, guarding robots, domestic-purpose robots, astronomical robots, entertainment robots, mining robots, defense and military robots, agriculture robots, and remote-areas robots [3]. A recent study by the McKinsey Global Institute

(MGI) pointed out that robots will replace 400 to 800 million people in the world by 2030. In the rapid development of automation, up to 31% of working hours in China will be automated [4]. To what extent will robots replace human workers in the future? Is the rapid development of artificial intelligence and robotics responsible for introducing positive opportunities or challenges? This set of questions has become a global issue that cannot be ignored.

Since 2015, artificial intelligence has seen explosive growth in China, attracting significant attention from all social sectors. In September 2017, the government released a document entitled, "New Generation Artificial Intelligence Development Plan." This plan urges China to seize the global command of artificial intelligence by the year 2030 and incubate 10 trillion Yuan in industrial output. As an essential component of artificial intelligence, robot applications have become a critical fulcrum for transforming China from manufacturing to higher-quality economic development. More robots are utilized from the IFR (IFR, 2019) data than

ever before. The operational stock of robots measures the number of robots currently deployed. The working stock of robots in the world rose from 1.02 million in 2009 to 2.73 million units in 2019 with a steady upward trend. China, Japan, the United States, South Korea, and Germany constitute the five major industrial robot markets. They account for about 70% of the global import and export in trade in robots and their installation. The data from the past ten years show that robot operations in China are in a state of continuous growth. At the same time, the United States, Germany, Japan, and South Korea have experienced zero or even negative growth in the rate of robot ownership in the past ten years. China has been the world's largest market for industrial robots since 2013. The number of robot installation was about 550 units in 1990. After ten years of slow augmentation, robot installations increased from 5525 units in 2009 to 156,000 units in 2017. In 2017 and 2018, China's total industrial robot installations accounted for 38% of the global total. In 2019, a total of 140,000 units were installed which is 9% less than that in 2018 but still higher than the total robots installed in Europe and the United States. With the acceleration of artificial intelligence development, robots have had a greater impact on labor force employment. Against this backdrop, it is necessary to systematically study the technical progress of robots and their effect on the labor market from the perspective of economic method and theory.

Both the government and private enterprise in China have expended a tremendous amount of money to promote and support technological innovation in terms of artificial intelligence and robots' development. The rise of human-machine collaborations has affected all areas of the modern world, from work to everyday life and beyond. However, it is difficult to answer the question of whether robots are responsible for creating or eliminating employment opportunities. More than 100,000 new industrial robots were installed in the United States industry (IFR, 2019), mainly in the automotive industry where the employment increased by 230,000 jobs from 2010 to 2015 [5]. Although, certain occupations may disappear in local communities, the total number of jobs may increase globally. In addition to changing the jobs quantity, the nature and characteristics of employment and labour are likely to change fundamentally. As one of the largest developing countries with a transitional economy, the rapid popularization of robotic technology will undoubtedly have a profound dual effect on human resource management in the market. Previous studies about the impact of robots on the labor market, however, are inconsistent. Most studies of these studies have only been conducted in developed countries [6–9]. Although a few studies have investigated the development of robotics and artificial intelligence and the corresponding economic impact on China [10–12], most studies have focused on the theoretical dimension or country, provincial, and firm levels [13–15]. A wide gap also exists between China's robotic development and its impact. Systematic empirical studies are lacking on the relationship between industrial robots and China's employment in different industries and skills. This investigation aims to explore the relationship between industrial robots and employment across industries. This study

uses the International Federation of Robotics (IFR)'s industrial robot data and employment data from the China Statistical Yearbook to construct a penetration index for industrial robots in China. Thus, we examine the influence of robot deployment on labor demand in China. We also analyze the potential impact of robots on economic outcomes, which may provide the Chinese government with guidance for economic growth and employment in the future.

The paper organization is as follows: the next section reviews the existing theoretical and empirical literature on industrial robots' impact on economic and labor markets. Section 3 describes research methods, with a particular focus on the theoretical framework, data description, and the empirical model. The last section represents a summary of the research.

2. Literature Review

With the rapid development of artificial intelligence technology, a new era of technological revolution and industrial transformation is gradually taking shape. It is an era in which robots are changing manufacturing processes and life patterns [16]. The rapid development of the international robot market has become an important phenomenon that cannot be ignored in terms of its consequences for economic life. This section reviews the existing theoretical and empirical literature on the impact of industrial robots on the economy and labor market.

Some scholars believe that technological innovation leads to social progress and reduces the importance of human resources in the production sector, which increases the unemployment rate [2, 17, 18]. In examining this proposition, Susskind developed a task-based model. He argues that using intelligent machines can reduce relative wages and the income share of the labor force, while leading to a high unemployment rate [17]. Frey and Osborne developed a model based on the Gaussian process to classify more than 700 detailed occupations in the United States according to their susceptibility to automation based on data from the United States Department of Labor's Occupational Classification Database. The results of this line of investigation show that about half of jobs in the United States will be challenged by automation in the next decades [2]. Acemoglu and Restrepo [18] examine the competition between human labor and robots in terms of different production tasks. They conclude that the use of robots will reduce employment and lower the laborers' salaries. Their analysis is based on the usage of industrial machines, employment, and wage changes to return in the United States (IFR). According to the results of each additional robot in every thousand workers, the employed population ratio decreases by 0.18%~0.34%, and the wage decreases by 0.25%~0.5%. This negative effect Indicates that the application of robots has a significant negative impact on the employment and wage in the commuting field [18].

Many scholars also support the view that innovation positively affects employment [19–21]. Bloom et al. estimate that, due to the extensive integration of artificial intelligence

technology into daily life, between 2010 and 2030, the world will develop 734 million new jobs [19]. Acemoglu and Restrepo [20] argue that, from the standpoint of the development history of science and technology, in the long run, technological progress will lead to the development of new employment opportunities. In this respect, the compensation effect produced by new jobs can offset the substitution effect caused by automation [20]. Similarly, Gregory et al. [21] examined data from 27 European countries from 1999 to 2010. They found that conventional forms of technological change led capital to replace labor in the production process, reducing employment by about 9.6 million jobs. In comparison, the spillover effect on product demand brought about by technological progress led to an increase of nearly 21 million jobs. On the whole, technological progress has had a net positive impact on employment in the European labor force [21].

A series of empirical studies have shown that unskilled labor and capital are substitutes, while skilled labor and capital are complementary [22–25]. For example, when machine prices fall, firms reduce the use of unskilled labor. In contrast, when the prices of machinery fall, manufacturers increase the use of equipment, and the demand for skilled labor increases because equipment operation requires skilled labor. According to the study, a 10% decrease in equipment prices leads to a 5% decrease in the use of unskilled labor and a 5% increase in the use of skilled labor [26]. This finding is widely known as the capital–skill complementary hypothesis, which has several important policy implications. For example, the hypothesis suggests that technological advances, such as the rapid drop in the cost of computing in recent decades, may significantly influence income inequality. This effect exists because technological progress causes an increase in demand for skilled labor and a decrease in demand for unskilled labor.

The impact of technological progress on the employment of laborers with different skills shows that highly skilled laborers can quickly master and adapt to new technologies; and, in this sense, skilled labor has a complementary relationship with new technologies. However, unskilled labor is limited by its level of human capital since unskilled laborer are unable to master new technologies quickly. For this reason, its risks are replaced by new technologies. As with the progress of traditional technology, artificial intelligence will increase the demand for and employment opportunities for skilled labor. This will create a substitution effect for unskilled labor [27–29]. In this respect, Acemoglu and Restrepo [20] point out that artificial intelligence and robot learning have enabled robots to make breakthroughs in analysis, problem-solving, and the performance of complex and unconventional tasks. It is also possible that robots can do the work of highly skilled workers instantly. By constructing a theoretical model, they found that the skilled labor force replaced by a high-skilled labor force might compete with low-skilled workers and be competent for other jobs. The employment creation effect of artificial intelligence on the labor force is thus concentrated in high- and low-skill positions, and the substitution effect is centered on medium-skill positions. This labor force has

comparative advantages in terms of communication, service, innovation, and research and development (R&D) [20]. Artificial intelligence is complementary to the labor force in these sectors and can, in fact, create jobs.

The substitution and creation effects on labor caused by intelligent robots produce changes in labor supply and demand, and they can ultimately lead to changes in wage equilibrium. Previous studies have also explored the impact of robots on labor compensation from various perspectives. Some researchers conclude that intelligent robots can quickly replace workers in certain jobs and thereby reduce wages. The two-phase overlapping generations model proposed by Benzell et al. illustrates the idea that the operation of intelligent robots will cause labor's share of national income to decrease in the long run [30]. Similarly, DeCanio [31] uses the Houthakker model [32] to briefly evaluate the influence of intelligent robots on labor compensation in the United States [31]. Cabrales et al. demonstrated that the threat of robot replacement does not affect the efforts of workers [33]. According to DeCanio's results, if the job substitution elasticity of humans and robots exceeds 1.9, then the expansion of robots will induce salary reductions.

Several studies have examined the impact of robot adoption on the labor market in China [12–15]. Fan et al. examined the impact of rising labor costs on the adoption of industrial robots by Chinese companies. A 10% increase in the minimum wage between 2008 and 2012 increased the probability of a company adopting a robot by 0.11% points. Higher minimum wages have a significant impact on the adoption of robots for firms that are more productive, located in coastal areas, private, and skilled labor-intensive [13]. Tang et al. found that the adoption of robots and highly skilled workers are complementary. After adopting robots, companies hire more highly skilled and educated workers. Therefore, the adoption of robots has resulted in an employment skill bias among Chinese enterprises [12]. Du and Lin systematically investigated the impact of adopting industrial robots on total factor productivity in different regions according to the panel data of Chinese provinces from 2006 to 2019. The results showed a U-shaped relationship between the adoption of industrial robots and total factor productivity [14]. Fu et al. studied the labor markets of 74 economies using international panel datasets from 2004 to 2016. The study found that the adoption of industrial robots is associated with a significant increase in labor productivity and total employment in developed economies, whereas the impact is not significant in developing countries, where increased robot adoption is associated with a significant decline in the labor share of GDP. In both developed and developing countries, increased robot adoption is associated with a substantial increase in income inequality [15].

3. Research Methods

3.1. Theoretical Framework. For investigating the effect of industrial robots on employment, our research uses the task-based model with automation technology [7]. Firstly, we introduce the basic model, and then, in the second part, we replace the automated capital with robots to analyze the

impact of robots on the labor market. In this way, we obtain the labor quantity under equilibrium conditions.

(I). Basic model: task-based model with automation technology

Assume that the economy produces only one good Y, accomplished by a series of tasks $y(i)$, and the production function is as follows:

$$Y = \left(\int_{N-1}^{N} y(i)^{\sigma - 1/\sigma} di \right)^{\sigma/\sigma - 1}, \tag{1}$$

where σ is elasticity of substitution. An increase in N implies that a new complex task appears. An increase in $N - 1$ also means that the old task disappears.

Labor can produce any task. Capital is unable to produce complex new tasks. Assume that $I \in [N-1, N]$, when tasks $i < I$, it is feasible to produce with capital. If $i > I$, tasks I must be produced by labor. When $i < I$, the production function of task i is as follows:

$$y(i) = k(i) + \gamma(i) \cdot l(i), \tag{2}$$

where $\gamma(i)$ is labor productivity, $l(i)$ is labor, and $k(i)$ is capital.

When $i \geq I$, the production function of task i is as follows:

$$y(i) = \gamma(i) \cdot l(i). \tag{3}$$

The cost of each task is as follows:

$$p(i) = \begin{cases} \min\left\{ r, \dfrac{W}{\gamma(i)} \right\}, & i \leq I, \\[3mm] \dfrac{W}{\gamma(i)}, & i > I. \end{cases} \tag{4}$$

Where r is capital rent and W is wage. From equations (2)–(4), we can get the following equation:

$$y(i) = Y \cdot p(i)^{-\sigma},$$

$$y(i) = \begin{cases} Y \cdot \left[\min r, \dfrac{W}{\gamma(i)} \right]^{-\sigma}, & i \leq I, \\[4mm] Y \left[\dfrac{W}{\gamma(i)} \right]^{-\sigma}, & i > I. \end{cases} \tag{5}$$

We use robots only when the cost of using the robot is less than that of labor. There exists a unique $\tilde{I}$ such that $r = W/\gamma(\tilde{I})$. For task $\tilde{I}$, the production cost is equal for labor and capital. Let $I^* = \min\{I, \tilde{I}\}$. All tasks are produced with capital if $i \leq I^*$, while all tasks are produced with labor if $i > I^*$.

So, the demand for capital and labor is as follows:

$$k(i) = \begin{cases} Y r^{-\sigma}, & i \leq I^*, \\ 0, & i > I^*, \end{cases} \quad \text{and}$$

$$l(i) = \begin{cases} 0, & i \leq I^*, \\[3mm] Y \left(\dfrac{W}{\gamma(i)} \right)^{-\sigma}, & i > I^*. \end{cases} \tag{6}$$

When the capital and labor market clear, the following equations hold:

$$(I^* - N + 1) Y \cdot r^{-\sigma} = K,$$

$$Y \cdot \int_{I^*}^{N} \left(\frac{W}{\gamma(i)} \right)^{-\sigma} di = L^s, \tag{7}$$

$$(I^* - N + 1) \cdot p^{1-\sigma} + \int_{I^*}^{N} \left(\frac{W}{\gamma(i)} \right)^{1-\sigma} di = 1.$$

(II). Task-based model for robots and employment

Suppose that there are C regions in the economy, and each region has I industries. The output of each region is Y_C, and the output of each industry in the region is Y_{ci}, $c \in C$. Consumption of the region is X_C, and the consumption of the region for each industry is X_{ci}. Suppose that there is no trade, then we get the following equation:

$$\begin{aligned} Y_C &= X_C, \\ Y_{ci} &= X_{ci}, \\ Y_C &= \left(\sum_{i \in I} v_i^{1/\sigma} \cdot Y_{ci}^{\sigma - 1/\sigma} \right)^{\sigma/\sigma - 1}, \end{aligned} \tag{8}$$

where v_i is the share of industry i, σ is substitution elasticity, and $\sum_{i \in I} v_i = 1$, the price is p_{ci}^X for industry i's output. Output is produced by combining capital K with continuous tasks $s \in [0, 1]$. A task can be produced by robots or labor. $x_{ci}(s)$ shows the quantity of task s.

$$X_{Ci} = A_{Ci} \left[\min_{s \in [0,1]} \{ x_{Ci}(s) \} \right]^{\alpha} \cdot K_{Ci}^{1-\alpha}. \tag{9}$$

According to the basic model in I, there is a boundary θ_i when tasks $s \leq \theta_i$. Tasks can be performed using labor or robots while they must be performed using labor if tasks $s > \theta_i$.

$$X_{Ci} = \begin{cases} \gamma_M \cdot M_{Ci}(s) + \gamma_L L_{Ci}(s), & s \leq \theta_i, \\ \gamma_i \cdot L_{Ci}(s), & s > \theta_i, \end{cases} \tag{10}$$

where γ_M and γ_L are productivity of robot and labor, respectively. $M_{Ci}(s)$ and $L_{Ci}(s)$ are numbers of robots and labors in task s, respectively.

Robots are produced using investment I_C with $M_C = D \cdot (1 + \eta) I_C^{1/1+\eta}$. So $Y_C = C_C + I_C$. C_C is the consumption of household. Let L_C is the labor supply and W_C is

wage. The rental price of robot is R_C^M and nonrobot capital is fixed at K_C with price R_C^k.

We use robot only when its cost is less than that of using labor (i.e., $R_C^M/V_M < W_C/\gamma_L$). Let $\pi_C = 1 - R_C^M/\gamma_M/W_C/\gamma_L$. We use robot when $\pi_C > 0$. Now, we look at the impact of robots on employment. We get the following equations:

$$M_C = D \cdot (1 + \eta) \cdot I_C^{1/1+\eta},$$
$$I_C = D^{-1-\eta} \cdot (1 + \eta)^{-1-\eta} \cdot M_C^{1+\eta}, \qquad (11)$$
$$C_C = Y_C - I_C = Y_C - D^{-1-\eta} \cdot (1 + \eta)^{-1-\eta} \cdot M_C^{1+\eta}.$$

In region c, the following equations define the first-order condition for the representative household:

$$W_C = B C_C^{\psi} \cdot L_C^{\varepsilon}$$
$$= B \cdot \left[Y_C - D^{-1-\eta} \cdot (1 + \eta)^{-1-\eta} \cdot M_C^{1+\eta} \right] \cdot L_C^{\varepsilon}. \qquad (12)$$

For robots, we obtain the following equation:

$$R_C^M = \frac{dI_C}{dM_C},$$
$$R_C^M = D^{-1-\eta} \cdot (1 + \eta)^{-1-\eta} \cdot (1 + \eta) \cdot M_C^{\eta+1-1}, \qquad (13)$$
$$R_C^M = D^{-1-\eta} \cdot (1 + \eta)^{-\eta} \cdot M_C^{\eta}.$$

Price of industry i is marginal cost, so we get the following equation:

$$p_{Ci}^X = \frac{1}{A_{Ci}} \cdot \left[\theta_i \frac{R_C^M}{\gamma_M} + (1 - \theta_i) \frac{W_C}{\gamma_L} \right]^{\alpha} \cdot \left(R_C^k \right)^{1-\alpha}. \qquad (14)$$

The share of labor in tasks is as follows:

$$S_{Ci}^L = \frac{W_C L_{Ci}}{\partial p_{Ci}^X X_{Ci}}$$
$$= \frac{(1 - \theta_i)(W_C/\gamma_L)}{\theta_i \left(R_C^M/\gamma_M \right) + (1 - \theta_i)(W_s/\gamma_L)}, \qquad (15)$$

αS_{Ci}^L is the share of labor in the value added of industry i. $1 - \alpha$ of total cost are paid to capital.

$$\sum_{i \in I} v_i \left(p_{Ci}^X \right)^{1-\sigma} = 1. \qquad (16)$$

From (15), we get the wage in the region c: $W_C \cdot L_{Ci} = \alpha S_{Ci}^L \cdot p_{Ci}^X \cdot X_{Ci}$

$$W_C L_C = \sum_{i \in I} \alpha S_{Ci}^L v_i p_{Ci}^{X/1-\sigma} \cdot Y_C. \qquad (17)$$

Similarly, the demand for robot and capital can be represented as follows:

$$R_C^M \cdot M_C = \sum_{i \in I} \alpha \left(1 - S_{Ci}^L \right) v_i \cdot p_{Ci}^{X\,1-\sigma} \cdot Y_C, \qquad (18)$$
$$R_C K_C = (1 - \alpha) \cdot Y_C.$$

Because the added-value of industry i is $v_i \cdot p_{Ci}^{X,1-\sigma} \cdot Y_C$ and labor share is $S_{Ci}^L \alpha$, using (14) and (15) we get the following equation:

$$\sum_{i \in I} vi \left(p_{ci}^x \right)^{1-\sigma} = 1. \qquad (19)$$

Then,

$$L_{Ci} = (1 - \theta_i) \left(\frac{\alpha(1 - \alpha)(1 - \alpha/\alpha) v_i}{\gamma_L A_{Ci}^{1/\alpha}} \right) p_{Ci}^{X1-\sigma-(1/\alpha)} Y_C^{1/\alpha} K_C^{\alpha-1/\alpha}. \qquad (20)$$

Taking the log form as follows:

$$\ln L_{Ci} = \ln (1 - \theta_i) + \ln \frac{\alpha(1 - \alpha)^{1-\alpha/\alpha} v_i}{\gamma_L A_i^{1/\alpha}} - \left(\sigma + \frac{1}{\alpha} - 1 \right) \ln p_{Ci}^X$$
$$+ \frac{1}{\alpha} \ln Y_C + \frac{\alpha - 1}{\alpha} \ln K_C. \qquad (21)$$

Differentiating both sides, we obtain the following equation:

$$d \ln L_{Ci} = -\frac{1}{1 - \theta_i} d\theta_i + \frac{1}{\alpha} d \ln Y_C - \left(\sigma + \frac{1}{\alpha} - 1 \right) d \ln p_{Ci}^X. \qquad (22)$$

There are three different forces of robots that affect labor demand, as shown in (22). The first part is the displacement effect. When θ_i increases, it means that more robots are involved in replacing labor and this effect always reduces the labor force. The second part is a positive productivity effect. Automation reduces costs and increases productivity and labor demand among industries. Finally, workers can be transferred from the automated tasks to the nonautomated tasks, and thus they can specialize in the performance of new tasks.

3.2. Data Description

3.2.1. Exposure to Robots. Robotics data for industries comes from the IFR (IFR, 2019). The IFR compiled annual robot use data for 50 countries from 1993 to 2019. The use of the IFR data for studying changes in employment and robot adoption has been widely reported in the literature. Using the robot data, Acemoglu and Restrepo [7], Graetz and Michaels [6], Dauth et al. [9], Carbonero et al. [34], and Chiacchio et al. [8] have explored the impact of robot adoption on employment in the United States, Germany, and different EU countries [7–9, 34]. We use data from the period between 2010 and 2019 since robots in China have been growing rapidly since the early 2000s. Table 1 lists 13 industries for which we collected robot data. Similar to Du and Lin [14], we compare these industries with those in the Chinese national standard (GB/T 4754–2017). In this industry classification standard, there are 13 industries, as shown in column 3 of Table 1. The first column of Table 1 represents the industries with robot data. The second column is the industry label, such as information technology (IT) and scientific research and technical (R&T) services. More robots are utilizing the IFR (IFR, 2019) data than ever. The number of robots

TABLE 1: List of all industries based on the China National Standard (GB/T 4754-2017).

Included in robotics data	Label	Code description
√	Agriculture	Agriculture, forestry, animal husbandry and fishery
√	Mining	Mining
√	Manufacturing	Manufacturing
√	Utilities	Production and supply of electricity, heat, gas and water
√	Construction	Construction
√	Transport	Transport, storage and post
√	IT	Information transmission, software and information technology
√	Food and beverages	Hotels and catering services
√	Science R&T	Scientific research and technical services
√	Chemical	Management of water conservancy, environment
√	Household appliances	Services to households, repair and other services
√	Education	Education
√	Pharmaceuticals	Health and social service

Notes. Table 1 lists 13 industries for which we collected robot data from IFR. We compared these with the industries in the Chinese national standard (GB/T 4754-2017) as shown in column 3 of Table 1. The first column of Table 1 represents the industries with robot data. The second column is the industry label, such as information technology (IT) and scientific research and technical (R&T) services.

currently utilized was measured by the operational stock of robots.

China's use of industrial robots began in the early 1970s but developed slowly thanks to abundant labor resources and backward technology. The popularity of robots began to increase in the mid-1980s during the period of reform and opening up. Robots were listed as the key national scientific research program in the seventh five-year plan. When the National High Technology Research and Development Program ("863" Program) of China was launched, the theme of intelligent robots was created, and robotics was listed as a crucial field in the "Made in China 2025" document.

From the robot operation data for the most recent ten years, it is evident that the robot operations in China have been in a state of continuous growth. At the same time, the United States, Germany, Japan, and South Korea have experienced zero growth or even negative change in the rate of robot ownership in the past ten years. Since 2013, China has been the world's largest industrial robot market. Figure 1 shows robot installations in China between 1999 and 2019 measured as the number of units. The number of robot installations was about 550 units in 1990. After ten years of slow growth, robot installations increased from 5525 units in 2009 to 156,000 in 2017. In 2017 and 2018, China's industrial robot installations accounted for 38% of the world's total. In 2019, a total of 140,000 units were installed, which is 9% less than that in 2018 but still greater than the total number of robots installed in Europe and the United States.

3.2.2. Labor Market Data. The China Statistical Yearbook compiled by the National Bureau of Statistics of China covers the employment numbers for each industry from 2010 to 2019. Figure 2 displays the industrial data to identify the trend of the change in the number of people employed from 2010 to 2019.

We divide industries into four categories based on sectors and employment trends. The first group (A) is the industries where employment has tended to rise, including IT, pharmaceuticals, science R&T, and chemicals. The second group (B) includes agriculture and mining. Their employment has followed a downward trend for the last ten years. The third group (C) is the rest of the tertiary sector, including education, food and beverages, utilities, household appliances, and transportation. In these industries, employment has remained unchanged over the decade of the study period. The fourth group (D) is the industries in the secondary sector, including construction and manufacturing, with a growing trend of employment until 2013 but decline since 2014. The first is the industries where employment is rising, including IT, pharmaceuticals, science R&T, and chemicals. Based on Table 2, these four industries require a relatively high level of education and about 70% of employees have a college degree or above. For example, the proportion of college, university, and graduate and higher level attainment of urban employed persons in the IT industry in 2019 was 27.5, 39.4, and 4.7, respectively.

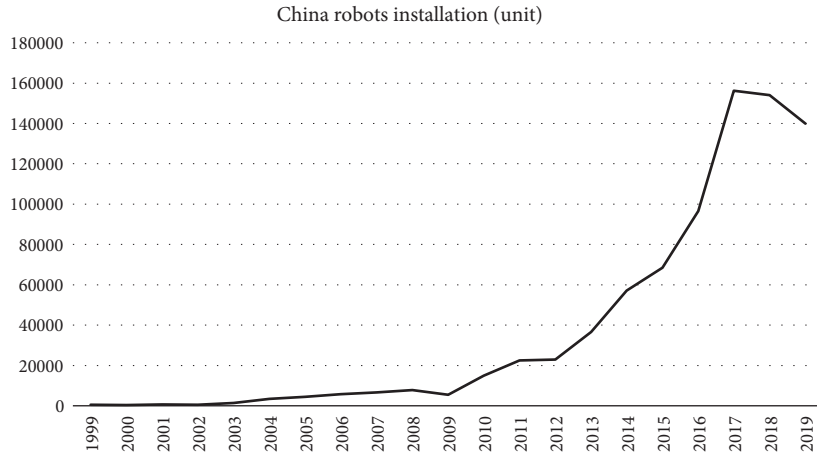
3.2.3. Control Variables. Different theories exist in the literature regarding the effect of technological progress on employment, among them classical theory, Marxist theory, neoclassical theory, new growth theory, Schumpeter's innovation theory, and business cycle theory. Up to now, several studies have revealed a correlation between technological progress and employment [19–21, 35–38]. Brouwer et al. [35] conducted two innovative studies in the Netherlands to estimate the effects of technological progress on employment. They found a positive effect caused by product-related R&D activities but an adverse effect in relation to overall R&D investments [35]. Greenan and Guellec [39] used market research in France from 1991 to analyze employment growth from 1986 to 1990. They found positive effects for both process and product innovation, with more muted effects for process innovations [39]. Bloom et al. estimated that, thanks to progress in artificial intelligence, more than 700 million new jobs will be created between 2010 and 2030 globally [19]. Acemoglu and Restrepo believe that, from the perspective of the history of science and technology, while rendering certain jobs obsolete,


FIGURE 1: China's robots installations from 1999 to 2019. (Source: IFR, 2019).
FIGURE 2: Employed persons by industry from 2000 to 2019. Notes: The results were graphed using Stata 15. This figure displays the industrial data to identify the trend of the change in the number of people employed from 2010 to 2019.

technological innovation will create many more new jobs in the long-run. The compensation effect produced by the new positions can offset the substitution effect [20]. Gregory et al. studied data from 27 European countries during the period from 1999 to 2010. They found that conventional substitution resulting from technological change led capital to replace labor in production, thereby eliminating about 9.6 million jobs. In comparison, the spillover effect from product demand brought about by technological progress led to an increase of nearly 21 million jobs. On the whole, technological progress has had a positive impact on employment levels for the European labor force [21].

Table 2: Educational attainment of urban employed persons by industry in 2019.

Industries	Total	Junior secondary school and below	Senior secondary school	Medium vocational education	High vocational education	College	University	Graduate and higher level

Expenditure on R&D, contractual value deals in domestic technical markets (CVD), foreign direct investment (FDI), imports of capital goods, technology purchases, patent citations, and the index of industrial robots are some of the most commonly used indicators of technological change. Interestingly, all of these indicators catch different dimensions of technology. This study uses expenditure on R&D activities and FDI to model technological progress. The amounts of FDI and R&D for each industry were obtained from 2010 to 2019 from the China Statistical Yearbook.

Since the new millennium, China's R&D expenditure has increased at an average annual rate of about 20%. R&D expenditure has expanded from 89.6 to 2443 billion Yuan in 2000 and 2020, respectively, accounting for 0.89% to 2.40% of GDP. Especially eight years ago, China became the world's second-largest consumer, which is a major phenomenon in terms of its global economic status and deserves attention. From 2000 to 2016, China's contribution to the worldwide R&D economic expansion was 27.4%, close to the 29.5% growth of the United States.

3.3. The Empirical Model.
According to our discussion in the theoretical framework, there are three forces about the power of robots affecting employment, including displacement, productivity, and composition effects [7]. To explore the total impact of robots on employment in different industries, we can posit the following formula:

$$\ln L_{it} = \alpha_0 + \alpha_1 \ln \text{RobotExposure}_{it} + x_{it}^L + \varepsilon_{it}, \quad (23)$$

where L_{it} is the level of employment; robot exposure refers to the penetration of industrial robots in industry i in year t, which is equal to the stock of industrial robots in Chinese industry i in t years divided by the employment level of i industry in China in year t; and x_{it}^L represents other factors affecting labor demand. In our empirical model, we use R&D

Notes. This table reports the impact of industrial robots on employment of the four groups. The dependent variable is employment at the industrial level. All other variables are defined in Section 3.2. OLS is the pooled regression and FE, RE are the fixed and random effect model, respectively. t statistics are reported in parentheses. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

and FDI as control variables. To standardize the data, we took log form for all the variables.

The correlation between robot exposure and employment was tested using panel data, which provides richer models and estimation methods than cross-sectional data. An extreme strategy for estimating panel data is pooled regression as cross-section data, requiring each individual in the sample to have exactly the same regression equation. The disadvantage of pooled regression is that it ignores the heterogeneity of individuals, which may relate to explanatory variables and lead to inconsistent estimates.

In practice, a compromise estimation strategy is often adopted; it is assumed that individual regression equations have the same slopes but different intercepts to capture heterogeneity. This model is called the individual-specific effects model and is formulated as below.

$$y_{it} = x'_{it}\beta + z'_i\delta + u_i + \varepsilon_{it} \ (i = 1, \ldots, n; t = 1, \ldots, T),$$
$$L^D = F(W, Q^D, T), \tag{24}$$

where z_i is a time-invariant individual characteristic. x_{it} can vary with individuals and over time. The disturbance term consists of $u_i + \varepsilon_{it}$, called composite error term. Among them, the unobserved random variable u_i is the intercept term representing individual heterogeneity, namely individual effects. ε_{it} is a disturbance term that varies with individual and time, known as idiosyncratic error.

If u_i relates to an explanatory variable, it signals the fixed effects (FE) model. If u_i is not correlated with all explanatory variables (x_{it}, z_i), it implies the random effects (RE) model. Hence, this research use the Hausman check if this model follows FE or RE model.

4. Results

4.1. The Empirical Results. Table 3 shows the descriptive statistics of the relevant variables used in this paper. These statistics are the mean, maximum, minimum, standard deviation, and number of observations. For example, the minimum, maximum, mean, and standard deviation of the log form of employment in group A are 2.28, 3.30, 2.80, and

0.30, respectively. T is years, n represents four industries in the first group, and the number of observations is 40. Table 4 shows the statistical results for the above groups. There is a significant positive correlation between robots' exposure and labor demand for Group A. These results show that the use of robots promotes high-skilled employment. A 10% increase in robot density leads to a 1.1% rise in high-tech jobs. The Hausman test statistics reject the null hypothesis of the RE model and accept the FE model at a 5% statistically significant level. Also, the resulted F statistics reject the pool regression and accept the FE model.

Group B shows a significant negative correlation between robots' exposure and labor demand. According to the Hausman test and F test, the FE model is superior to the RE and pooled regression model. Another finding was that R&D promotes employment in traditional industries according to the FE model, which explains the fact that various technological transformations or upgrades have a corresponding effect on workers. China is predominantly agricultural and very populous. According to the National Bureau of Statistics, employment in primary industries, mainly agriculture, accounted for 50% of the total workforce in 2001, 37% in 2010, and only 24% in 2020.

The proportion of the population employed in primary industry has declined year by year. Of the country's more than 600 million farmers, very few are engaged in the agricultural sector. More people have chosen to enter secondary and tertiary industries to go elsewhere for work or to start a small business. With the rapid development and industrialization of China, the R&D of agricultural robots has been gradually expanding. Agricultural robots can be engaged in planting, spraying pesticides, harvesting, and other field operations, and they can play an essential role in animal husbandry. This not only saves human resource costs but also improves quality control ability and enhances resilience. For the mining industry, there are many problems with underground production operations in coal mines: high accident rates, harsh operating conditions, serious environmental pollution, and high disaster risk. Faced with high-risk underground operations, robots have become an essential means of achieve the safe and efficient production

Notes. This table reports the results of the robustness test in Section 4.2. FE_Robust is FE using clustering robust standard and LSDV is least-squares dummy variables regression. The dependent variable is employment at the industrial level. All other variables are defined in Section 3.2. t statistics are reported in parentheses. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

goals in coal mines. To achieve safety of coal miners, it is a general trend for robots to replace miners in underground operations. Coal mine production will therefore develop toward the use of unmanned, autonomous, intelligent, and highly efficient robots in the future. Artificial intelligence technology can play an irreplaceable role in that and diversified artificial intelligence technology can be applied to coal mine robots. Although the current application of artificial intelligence in the field of industrial coal mining is still in a period of exploration, with the increasing application of artificial intelligence technology in the field of coal mining, it is imperative to build unmanned mines.

For Group C, after the Hausman test and F test, the FE model is superior to the RE model and pooled regression. Table 4 indicates that the use of robots has a positive effect on the third employment sector. Robots have been used in the service industry for decades. Helpmate, a service robot created in the 1980s by Joseph F·Engelberger, the so-called "father of robotics," delivers meals, medicine, and supplies to hospital patients [16]. Helpmate, of course, is a square box, impersonal and rudimentary. Service robots are growing fast in Japan in another direction: entertainment robots. In recent years, robots have been increasingly used in the service industry. As Engelberger predicted, robots are more likely to be used in the service industries, including maintenance, repair, transportation, cleaning, security, rescue, and domestic tasks and nursing [16]. In recent years, modern information technologies have developed rapidly including cloud computing, the "Internet of Things," artificial intelligence, and "big data." A series of proactive policies continued to develop, including the transformation of the real economy, cross-border e-commerce, and support for rural e-commerce. Also, new forms of online retail and orders have risen, creating a large number of new jobs in wholesale and retail trade, hotels, and restaurant industries.

In Group D, the results of the Hausman and LR tests in MLE support the RE model against the FE and pooled regression models. Nonetheless, the LM test results suggest a pooled regression against the RE model. In this group, there is no significant correlation between robot density and employment in the secondary sector. Secondary industries

involve many industries, such as steel manufacturing, automobile production, and wired and wireless communication. Some companies have tried to liberate front-line workers by using industrial robots in recent years. Foxconn, the largest mobile phone manufacturer, uses industrial robots to perform the tasks previously performed by workers on production lines. Now, some domestic manufacturing enterprises have begun to replace front-line operators with industrial robots, improving their efficiency.

4.2. Robustness Check. Table 5 shows the results of different estimated regression methods on the employment of robots. The regression results of FE using clustering robust standards in Table 5 show that robots have a positive relationship with the employment of the first and third groups, and a negative relationship with the employment of the second group. Both of them are significantly valid at 0.05, which indicates that the use of industrial robots increases employment in tertiary sectors and high-tech industries, but is ineffective in employment in agriculture and mining industries. Table 5 shows that the results obtained by different regression estimation methods (i.e., FE_Robust and LSDV) are the same, which verifies the validity and robustness of the basic FE regression and the empirical results.

In addition to using different regression methods, we add a lagged core explanatory variable for endogeneity problems. In this paper, the lag variable L.lnRobot of explanatory variable lnRobot is used as a substitute variable to conduct regression tests. Table 6 shows the results. The coefficients of lag variable L.lnRobot on the employment of the three groups are 0.096, -0.202, and 0.033, respectively, and significant at the 1% level, indicating that the regression results are still robust after considering endogeneity.

Following [40], the equation of demand for labor is as follows:

$$L^D = F(W, Q^D, T), \tag{25}$$

where L^D is labor demand or the desired level of employment, W is the wage rate, Q^D is the output or product

TABLE 6: Adding lagged core explanatory variables to deal with endogeneity.

Notes. This table reports the results of the robustness test in Section 4.2. The dependent variable is employment at the industrial level. We add wage and value-added (VA) in our model as control variables. All other variables are defined in Section 3.2. t statistics are reported in parentheses. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

demand, and T is the technology. We add wage and value-added (VA) in our model, and the robot, R&D, and FDI represent technology. Table 7 displays that industrial robot still has a significant impact on employment under the model of increasing control variables, indicating that the regression results are still robust after the intervention of increasing control variables.

4.3. Discussion of the Results.

According to the capital–skill complementarity hypothesis discussed in the literature review, technological progress leads to an increase in demand for skilled labor and a decrease in demand for unskilled labor. An initial objective of this study was to identify the relationship between industrial robot adoption and China's employment in different industries and skills. Our results suggested that an association existed between robot adoption and employment across industries. There is a significant positive correlation between robots' exposure and labor demand for high-skilled employment and third sector employment. A 10% increase in robot density leads to a 1.1% rise in high-tech jobs. However, multiple regression analysis reveals that robots have reduced employment in traditional industries such as agriculture and mining. This study supports evidence from previous observations [11, 12, 41, 42] that industrial robots are a skilled-biased technology change.

Using data about Germany, Dauth et al. found that industrial robots reduce manufacturing employment, but the reduced employment is offset by increased employment in the tertiary industry [9]. The industry-based estimates in this study are inconsistent with those of Acemoglu and Restrepo [7], which are based on data about the United States. Their findings showed that the negative effects of robot adoption on employment are mainly felt in highly mechanized industries, such as automobile manufacturing, chemical, pharmaceutical, and food manufacturing. Robotic applications will promote labor employment in industries such as finance, the public sector, and nonrobotized

manufacturing [7]. These results are inconsistent for two reasons. First, compared with developed countries such as the United States, China's robot adoption is still in its early stages. The first adopters of robotic production technology can use this competitive advantage to expand their market share, thereby increasing the demand for labor. This role is particularly prominent in the capital- or technology-intensive industries, such as information transmission, software and information technology, communication equipment, and computer and other electronic equipment manufacturing. Second, with the rise in labor costs in China, labor-intensive industries such as construction, manufacturing, and mining face more prominent cost pressures, indicating that such industries have more substantial economic incentives to replace labor with robots.

5. Conclusion

Our study aims to assess how robots contribute to the employment of different industries and skills. The results of this investigation show a significant positive correlation between robots' exposure and labor demand for the third sector of employment. The results show that the use of robots promotes high-skilled talent employment. However, multiple regression analysis reveals that the use of robots has reduced employment in traditional industries such as agriculture and mining. This study represents the first comprehensive assessment of how industrial robots contribute to the employment of different industries and skills of China. A limitation of this study is that the robot data is only from 2010, because the use of robots in China has started late but has increased rapidly since the 2000s. The use of robots affects not only employment but also other aspects of the labor market and the economy as a whole. There is still uncertainty

about whether robot technical progress impacts wage inequality. Further work needs to be done to establish whether the application of robots is conducive to improving the labor share of national income. Much uncertainty still exists about the relationship between the industry robots, total factor productivity, and added-value of China. Further research needs to examine more closely the links between industrial robots and productivity.

The robot industry will be the main engine of economic growth in the next few years. The progress of robotics is inevitable. There will be unprecedented significant development and improvement in the field of robotics. We must accept this trend and seize this opportunity to leap into economic development. Obviously, under the state's leadership, robot technology as a whole is helping to promote positive economic growth, and it has become an opportunity for people to find jobs again. The findings of this study have a number of important implications for future practice. Studying the impact of robots on economic outcomes may provide guidelines for governments about China's economic growth and employment in the future.

This study showed that the employment promotion effect of robot adoption mainly lay in the middle- and high-skilled labor groups, indicating that intelligent manufacturing provided by robots needs a large medium- and high-skilled labor force to match it. The average skill level in China's current labor force was low, and the low-skill labor force accounted for a large proportion of the total labor force. Therefore, China should further strengthen the guidance and expenditure on vocational skill education and training, provide abundant labor resources for intelligent manufacturing, and reduce frictional unemployment caused by technological change.

We also found the employment substitution effect of robot adoption in traditional industries, such as agriculture and mining. The government should provide more guidance and support for unemployment insurance, job-transfer training, and especially new skills learning. The government should also alleviate the employment impact of new technology adoption on traditional industries and ensure a fuller and higher employment quality.

We provide three recommendations for the education system. First, higher vocational education should be developed. The state can establish and improve the majors of artificial intelligence and robotics, train high-skilled professors, and establish practice bases to cultivate intelligent, automated, and information-based technical workers. Second, re-employment training should be strengthened. In addition to the existing higher vocational colleges, the government should support the establishment of more re-employment training centers. Subsidies should be increased for the return of low-skilled young people to advance their studies and for the unemployed to undergo re-employment training; this would reduce re-education costs for both groups and enable them to acquire competent skills in intelligent, automated, and information-based production positions. Finally, relevant preferential policies should be introduced to guide the flow and transfer of labor among various industries of the national economy in an orderly manner so that citizens do not need to bear more costs for acquiring new labor skills and positions.

Data Availability

To effectively diagnose and monitor the vertical collusion in construction project bidding, this paper developed a comprehensive evaluation model with deep neural network and transfer learning. By this model, the collusion characteristics of bidders, tenderers, and bid evaluation experts were mined from limited data set hidden and collusion tendency was evaluated. Firstly, 18 evaluation indicators were established from literature review, court file summarization, typical case analysis, and expert consultation. Then, a comprehensive evaluation model was developed with the deep neural network and transfer learning. Finally, the model was trained and tested with the collected data set. The test results showed that the developed model achieved 87.3% identification accuracy in collusion tendency evaluation of different subjects.

1. Introduction

There are many problems in the process of project construction, especially the collusion phenomenon in the bidding stage [1, 2]. In addition, the collusion in bidding has become more and more prominent due to factors such as information asymmetry, inadequate supervision, imperfect system, and unscientific management [3], and the concealment and non-detectability of the bidding collusion in construction projects are gradually increasing [4].

For the problem of vertical collusion in bidding for construction projects, a lot of research has been conducted by scholars, mainly including: in terms of the motivation of collusion behavior, Aoyagi [5] deduced the equilibrium conditions of collusion between bidders and tenderers and analyzed the distribution of benefits after collusion; Zarkada-Fraser and Skitmore [6] studied the factors influencing bidder collusion based on their psychology, attitude, and behavior when colluding; Pesendorfer [7] stated that the two main ways of tenderer-bidder collusion were compensation and subcontracting; Lugovskyy et al. [8] stated that cooperation experience, reputation, and initiative were the main

factors that lead to collusion between regulators and bidders; Dotoli et al. [9] showed that inadequate government oversight of bidding collusion and low penalty costs led to invalid oversight and occurred collusion; Friedman [10] found that the high rate of return (financial interest) was the underlying motive for collusion by analyzing the causes of collusion. Scholars also found that the psychology of the participants had some influence on collusive bidding [11]; cost asymmetry and unreasonable offers were the "triggers" for collusion [12, 13]. In terms of collusion prevention, Zhang [14] analyzed the possibility of collusion based on the project properties, market environment, collusion costs, and collusion benefits, and also constructed a three-party game model, which showed that reducing regulatory costs, improving regulatory tools, increasing penalties, and benefits for participants can strongly curb collusion; Cavill and Cavill [15] pointed out that strengthening the accountability of the stakeholders involved in bidding, improving their respective responsibilities, and efficiently fulfilling their obligations have important effects on preventing the collusion; Rahman et al. [16] emphasized the importance of maintaining information symmetry, guaranteeing information security,

TABLE 1: Cases of bid conspiracy crimes in China judgements online (partial).

No.	Release date	Case	Case no.	Court name
1	July.7 2020	Tenderers used the convenience of their jobs to illegally accept property from bidders for their benefit.	(2020) No.2 Yue crime	Guangdong high People's court
2	Oct.2 2020	Bidders borrowed the qualifications of other enterprises to obtain qualifications.	(2020) No.53 11E crime	Huanggang intermediate people's court, Hubei province
3	Aug.31 2020	Bidders borrowed qualifications, agreed on bid prices, and participated in bidding.	(2020) No.67 05 Zhe crime	Zhejiang Huzhou intermediate people's court
4	June.28 2019	Tenderers and bidders negotiated on bid prices, programs, and other contents before bidding	(2019) No.2181 supreme court civil	Supreme people's court of the people's republic of China
5	Nov.6 2019	Bidders bribed tenderers in return for bid information before bid publicity.	(2019) No.1507 01 Yue crime	Guangzhou intermediate people's court, Guangdong province
6	Dec.31 2019	Being a member and leader of the bid evaluation committee, the bidder participated in whole process of the evaluation.	(2019) No.5242 supreme court civil	Supreme People's court of the people's republic of China
7	Sep.21 2018	Bid evaluation experts made use of their job convenience to make profit for bidders for illegal properties against bid evaluation regulation.	(2018) No.7 0921 chuan crime	Pengxi county people's court
8	Dec.6 2018	Bidders undertook projects in the form of bidding after obtaining information about bidding in advance from the tenderers.	(2018) No.1055 0103 Hei crime	Harbin Nangang district people's court

and preserving data privacy in the process of against collusion, and proposed the signing of privacy bid agreement as a governance measure; Boone and Mulherin [17] and Ishiguro [18] indicated that the fundamental way to eliminate the occurrence of collusion in bidding was to establish a bidding supervisory body and gave full play to the regulatory role of the acting government, and handled timely for supervision efficiency; Howlader et al. [19] detected vertical collusion in bidding by constructing an SNA network model of individuals, organizations, communities and other participants and achieved good results; Van Den Heuvel [20] deterred bidding stakeholders' willingness to collude by feature analysis of vertical collusion in bidding and trace to the master and follower of bidding combined with genetic algorithm. Scholars also considered the psychology of participants [21] and the probability density function of auction price [22], etc. on collusion prevention.

To sum up, most of the studies on collusion in bidding of construction projects are focused on the analysis of collusion subjects and influencing factors, while the studies on evaluating and determining collusion tendency are relatively rare. In view of the constant change of vertical collusion in bidding for construction projects, more difficulty in collusion detection, unavailability of the evaluating data, deficiency in sample, and complex correlation among indicators, a comprehensive evaluation model of the tendency of vertical collusion in bidding for construction projects was developed based on deep neural network (DNN). Firstly, through literature research, file summarization, case analysis, and expert consultation, 18 evaluation indicators were determined for the tendency of bidders, tenderers, and bid evaluation experts to collude; secondly, a comprehensive evaluation model based on deep neural network was developed, and 130 cases were collected as the training set and test set of DNN model input data; at last, the stable DNN model could effectively evaluate the tendency of vertical collusion in bidding, which can help to prevent vertical collusion targetedly.

2. Methodology

2.1. Data Collection

(1) Literature review: In China National Knowledge Infrastructure (CNKI) and Web of Science (WOS), the keywords "collusion", "bidding collusion", and "bidding corruption" were searched. In order to avoid potential influence from age-old literature, 847 papers in the past 5 years (from 2015 to 2020) were chosen as data samples, including 291 from the general journal, 187 from master or doctor thesis, and 369 from the core and above journals.

(2) Summarization of court files: In the study of bid collusion, court files give sufficient resources of real cases, so it is necessary to make full use of this data source. For its case abundance and authenticity, bid conspiracy registered in China Judgements Online from 2015 to 2020 were researched and summarized in this paper. Table 1 shows some cases of crimes.

(3) Typical case analysis: The typical cases of bidding were searched and summarized from the Chinese government procurement network, Chongqing public resources trading network, and other websites. Table 2 shows some typical examples of collusion on the website.

2.2. Expert Consultation.
By qualitatively analyzing and summarizing the collected collusive data, five experts in the field of bidding in China were consulted on the vertical collusion among the tenderers, bidders, and bid evaluation experts. Table 3 shows the profile of the expert panel. Three specific questions were included. Generalized indicators were extracted by recording and analyzing the original expert responses.

TABLE 2: Bidding collusion cases (partial).

No.	Publishing platform	Collusive practice	Company name
1	https://www.ccgp.gov.cn/	Provide false materials to win bid	XX Co., Ltd.
2	https://ggzyjyjgj.cq.gov.cn/	Bid evaluation experts were inclined to the intended bidders.	XX Co., Ltd.
3	https://www.ccgp.gov.cn/	Bidders provided false materials to meet the tender requirements.	XX Greening Co., Ltd.
4	https://jycg.hubei.gov.cn/	Tenderers used their positions or power to unintentionally or intentionally authorize bid evaluation experts to give high scores to specific bidders.	XX environmental construction Co., Ltd.
5	Other sites	Tenderers broke the rules to facilitate intended bidders	XX consulting Co.

TABLE 3: Profile of the expert panel.

Employer	Position	Years of experience	Largest project ever managed/consulted
Contractor	Project manager	19	RMB ¥ 1.1 billion
Consultant	Deputy manager	16	RMB ¥ 3.5 billion
Academia	Professor	20	RMB ¥ 64 million

Question 1: What do you think are the general manifestations or behaviors of tenderers when they are involved in collusion?

Question 2: Based on the bidders' behavior provided by us, what do you think will the bidders do when they are involved in collusion?

Question 3: In your opinion, what are the main bias practices of bid evaluation experts in bidding activities?

2.3. Deep Neural Network.

The main shallow machine learning models are Support Vector Machines (SVM) [23], boosting models [24], and maximum entropy models [25], etc. The emergence of BP algorithms has effectively promoted the development of deep neural network represented by Multi-Layer Perceptron (MLP) [26]. Compared with shallow machine learning models, deep neural network models are characterized by deep network layers, large number of network model parameters, and strong learning ability, which has triggered a wave of scholars' research in this field. For example, Zhu and Shan [27] established a high-dimensional neural network model to comprehensively evaluate the probability of public engineering project investment risk. Langkvist et al. [28] pointed out that the deep neural network has three advantages: breaking through data limitations, considering complex interactions, and avoiding overfitting problems. Takeuchi and Lee and Ding et al. [29, 30] both used deep neural network to explore the trend of stock price fluctuations, and verified the model through empirical research. Dixon et al. [31] have proven through a large number of cases that deep neural network has the advantages of fusion and analysis of multiple information, thus forming a more effective information set for follow-up research. Pei et al. [32] applied the white box testing framework to the deep neural network system to further improve the performance of the deep learning system. Ma et al. [33] transplanted the mature combined testing technology from traditional software testing to the deep neural network system, during the test, the technology of using combined test coverage to guide the generation of test cases was proposed and achieved good results. Sun et al. [34] proposed a set of relatively complete and systematic test standards based on the characteristics and applicability of deep neural network, which provided strong support for follow-up research, etc. DNN is a neural network model with several hidden layers added, also known as MLP. Among several common structures of deep learning, DNN is superior in strong feature extraction ability, simple model structure, low training difficulty, and fast convergence speed, etc. Considering the problems that the data of the indicators for comprehensive evaluation of vertical collusion in bidding of construction projects are not easy to obtain, insufficient sample size and complex interrelationship, as well as the characteristics and requirements of comprehensive evaluation of tendency of vertical collusion, this study used DNN model to conduct the comprehensive evaluation.

2.3.1. Structure of DNN.

Deep neural network generally consists of an input layer, a number of hidden layers, and an output layer (as shown in Figure 1), and the layers are fully connected to each other, i.e., any neuron in layer i must be connected to any neuron in layer $i + 1$. In terms of the small local model, the data in DNN, same as perceptron's, is transferred among different neurons by linear function $z = \sum w_i x_i + b$ and function $\sigma(z)$, where xi represents the input from the ith neuron, w_i is the connection weight of the ith neuron, and b represents the offset, and the learning process of the neural network is essential to continuously adjust the connection weights and neuron offsets between the neurons to get closer to the output of the training samples.

2.3.2. Application of DNN.

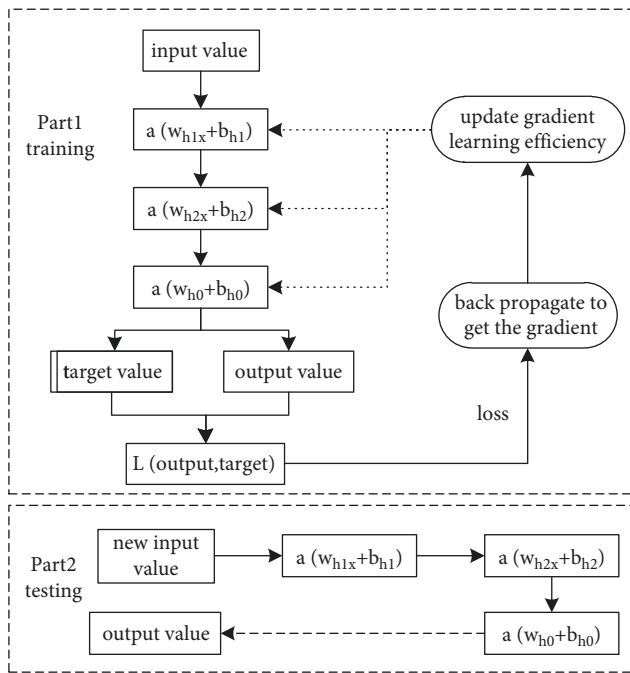
The training and testing process of deep neural network includes training, determining parameters, testing, and checking network accuracy (as in Figure 2).
FIGURE 1: DNN basic structure.


FIGURE 2: DNN basic implementation process.

FIGURE 3: Research flow.

2.4. Research Flow. Specific to small data set, this paper developed the model by employing DNN method and transfer learning algorithm, in which the obtained tendency evaluation value of tenderers, bidders, and bid evaluation experts were as input. Transfer learning can apply the knowledge learned in a domain or a task to another domain or task. Given a source domain Ds and a learning task Ts in the source domain, a target domain Dt and the corresponding learning task Tt, the goal of transfer learning is to use the knowledge in Ds and Ts to complete the task Tt in Dt. This method can be used when there is insufficient data. Combining the transfer learning with deep neural network can reduce the sample size requirement of DNN model, so as to adapt to the small dataset of vertical collusion in bidding in order to obtain a high comprehensive evaluation accuracy. The flow of the developed evaluation model is shown in Figure 3.
3. Results

Based on the keywords in literature, collusion in typical cases, and the causes in the court files, the frequency of collusion of bidders and tenderers is plotted as shown in Figure 4.
Figure 4: Indicator frequency of tenderers and bidders' collusion.

Based on the collected keywords of collusive practices of bidders and tenderers, the three questions were interviewed to experts and their original judgment was recorded. Grounded on the collated expert consultation results, indicators and explanations were reached for evaluating actors in construction projects bids, shown in Table 4. The range of model input values for all indicators was [1, 10].

4. Development of the DNN Model

4.1. Data input. In this study, a total of 130 cases were collected (due to the large number of participants, only the data of the top 5 bidders were obtained for each case), and divided into two parts: training samples and testing samples. In terms of the ratio of training and test sample settings, Zhang and Zhao [35] set 90% as the training set and 10% as the test set when building a neural network model of user Q&A-related variables and monthly sales of clothing; Wen et al. [36] randomly divided the data into 80% of the training set and 20% of the test set when building a neural network with effective wave height inversion set; Ding et al. [37] used the improved lion swarm algorithm to optimize the neural network model for the housing price prediction problem by using the first 70% of the data samples as training samples and the last 30% as test samples, etc. In view of the concealment of vertical collusion in bidding, the correlation among monitoring indicators and the difficulty in obtaining indicator data, this study took about 60% training samples and about 40% test samples, i.e., 75 training samples (former 60 collusive cases and latter 15 non-collusive cases) and 55 test samples (former 40 collusive cases and rest 15 normal cases) (see Table 5).

4.2. Transfer Learning. A parameter-based transfer learning approach was used in this study, on the premise that some parameters or prior distributions were shared between the source and target tasks model. The algorithm achieved knowledge transfer by finding these shared parameters or prior distributions and processing them. The unique advantages of transfer learning have caused widespread application by scholars: Liao et al. and Liu et al. [38, 39] used the transfer learning algorithm to complete the text detection task and the edge detection task on the basis of the visual geometric group network structure; Wu et al. [40] used the transfer learning algorithm to control the ship name

identification, and considerable test results were obtained. Considering the concealment of vertical collusion in bidding and the complex relationship between indicators, the study improved the model with the help of parameter transfer algorithm, aiming to improve the accuracy of vertical collusion evaluation.

In the tendency evaluation analysis, Hu [41] studied electricity consumption characteristics and constructed a tracking monitoring model for electricity theft users with the help of improved BP neural network to conduct deep monitoring of electricity users. The main reasons for using this model as a transfer learning source were: (1) the similarity of electricity consumption characteristics and vertical collusion evaluation indicators as source domains; (2) the outputs of the two models are basically the same, one is the theft suspicion coefficient, and the other is the tendency of vertical collusion; (3) the indicator data is readily available from inner system of an electric power company, where the electricity consumption data is abundant and easily accessible; hereafter, the specific process of the comprehensive evaluation model based on transfer learning algorithm in this study, see Figure 5.

Among them, the fine-tuning method of the model was as follows: the relevant parameters of the source model were transferred to the target model; the weights of some layers were fixed to adjust the weights of other layers, and the process was repeated until the error between the output value of the model and the actual value meets the requirements; at this time, the optimal weights between layers were obtained. Suppose there were P samples to train, where X_{pi} = the ith input value of p, n, q, m = the respective number of nodes in each layer, V_{ki} = the weight from node i in the input layer to node k in the hidden layer, w_{jk} = the weight from node k in the hidden layer to node j in the output layer, and the activation function was the sigmoid function. The forward input process of this model network is as follows.

The output from input layer to the hidden layer is

$$Z_{pk} = g(\text{net}_{pk}),$$
$$= g\left(\sum_{i=0}^{n} v_{ki} - x_{ki} + \theta_k\right), \quad k = 0, 1, 2, \ldots, q. \tag{1}$$

The output from the hidden layer to the output layer is

TABLE 4: Comprehensive evaluation indicator system.

Subjects	Indicators	Indicator description
Tenderer	Valid bid ratio X_{11}	The ratio of valid bids to total bids. The range of value is 0–100%. The tenderer, on purpose of boosting cooperative bidder's success rate, may reduce the valid bid rate in some way to let the activity less competitive.
	Selection of tendering method X_{12}	Dismemberment (unreasonable) or normal bidding activities (reasonable). One is to split project to evade due tender procedure, and the other is to set specific conditions to change the public tender to invited tender, awarding "benefits" to collusive bidders.
	Tenderers convey tendentious information X_{13}	Yes or no. The tenderers pass project-related information to collusive bidders or persuade other bid evaluation experts privately to make the related enterprise win the bid.
	Release timeliness of bidding information X_{14}	Some tenderers may change the tender release time for collusive bidders' consideration, resulting in information not accessible simultaneously to advance winning rate.
	Setting reasonability of technical parameter X_{15}	Some unreasonable arrangements, for instance, changing range value to specific value, may be done towards to bidders by tenderers.
	Tendency of tender requirements X_{16}	Tenderers may require previous business contacts such as construction performance or similar project experience as tender premise to preclude other participants.
	Extra credit bias X_{17}	Tenderers may set unreasonable qualification conditions such as the size of registered capital, geography, years of operation, and employees in bid preparation as a way to increase the evaluation score of collusive bidders.
	Rationality of evaluation setting X_{18}	Normally evaluation in bid documents should be made in regard to actual project situation, past experience, and relevant regulations, practically the tenderers may set inclined standard and unscientific weight to favor collusive bidders.
Bidder	Bid winning rate X_{21}	The residual difference indicator is examined. When the residual difference between the actual and predicted winning bids falls outside a certain interval, it indicates that the bidder has a tendency to collude with the tenderers partly.
	Special requirements compliance X_{22}	The conformity of unreasonable conditions such as the scale of registered capital, geographical area, years of operation, and employees in tender.
	Reassessment rate X_{23}	The value range is 0–100%. When the supervisory authority finds that the bidder's conditions are consistent with the evaluation factors listed in the agreements or that the bidder has unreasonable practices, it will ask the experts to re-evaluate.
	Authenticity of bidding materials X_{24}	Yes or no. During the review of the bidders' materials, the tenderers may know the materials have problems but keep silent, and then tacit collusion of both sides occurs.
	Similarity of technical bid parameters X_{25}	The value range is 0–100%. The technical content similarity between tender party and bidder party, expressed as the overlapping content accounting for the total technical content.
	Fitness to business documents X_{26}	The value range is 0–100%. The degree of business conformity (such as project performance, and enterprise qualification) specified in tender documents, expressed as similar content accounting for total content of the business bid.
	Type of bidder risk appetite X_{27}	Aggressive, positive, balanced, robust, and conservative. Risk appetite has a significant positive effect on the tendency of collusion, and aggressive risk appetite further stimulates the occurrence of collusive practices.
	Degree of mastery of key project information X_{28}	The tenderers may deliberately conceal key information about the project and only let collusive bidders know the information to ensure their dominance in the bid evaluation process.
Bid evaluation expert	Deviation of expert score X_{31}	The deviation range is examined. There are horizontal deviation and vertical deviation. The experts may be suspicious of collusion when two deviations exceed the range ($\pm 10\% \sim \pm 20\%$).
	Reward strength of bid evaluation X_{32}	The strength of rewards for bid evaluation experts largely reflects whether experts adopt collusive practice, and the greater the strength of rewards based on previous good evaluations, the less likelihood experts' collusion will occur.
	Rigor of bid evaluation process X_{33}	In the bid evaluation process, the experts select the team leader randomly; the experts are guided by the tenderer's comments and actions and do not question the bid evaluation methods or the experts make targeted remarks.
	Expert type X_{34}	Randomly selective experts are tested on personality and psychological scales, and then define according to results as 4 types: Capricious, ambitious without knowledge, independent, and opinion leader, with sequence of decrease in collusion.

TABLE 5: Data set classification.

Sample type	Quantity (abnormal & normal)
Training sample	75 (60 + 15)
Test sample	55 (40 + 15)
Total	130

$$Y_{pk} = g(\text{net}_{pj}),$$
$$= g\left(\sum_{k=0}^{q} w_{jk} z_{pk} + \theta_j\right), \quad k = 0, 1, 2, \ldots, m. \tag{2}$$

The total model error is

$$E = \sum_{p=1}^{P} E_p,$$
$$= \frac{1}{2} \sum_{p=1}^{P} \sum_{j=1}^{m} (t_{pj} - y_{pj})^2. \tag{3}$$

where E_p = the sample error, t_{pj} = the expected output, and y_{pj} = the model output.

The inverse process uses the gradient descent method to adjust the weight values, and the calculation process is as follows.

The weights between layers are updated as follows:

$$\Delta w_{jk} = -\eta \frac{\partial E}{\partial w_{jk}},$$
$$= \eta \sum_{p=1}^{P} \left(-\frac{\partial E_p}{\partial w_{jk}}\right), \tag{4}$$
$$= \eta \sum_{p=1}^{P} \left(-\frac{\partial E_p}{\partial \text{net}_{pj}} \cdot \frac{\partial \text{net}_{pj}}{\partial w_{jk}}\right).$$

where η = the learning rate.

The output layer error is

$$\delta_{pj} = -\frac{\partial E_p}{\partial \text{net}_{pj}},$$
$$= -\frac{\partial E_p}{\partial y_{pj}} \cdot \frac{\partial E_{pj}}{\partial \text{net}_{pj}}. \tag{5}$$

The hidden layer node weights are updated as:

$$\Delta v_{ki} = -\eta \frac{\partial E}{\partial v_{ki}},$$
$$= \eta \sum_{p=1}^{P} \left(-\frac{\partial E}{\partial v_{ki}}\right), \tag{6}$$
$$= \eta \sum_{p=1}^{P} \left(-\frac{\partial E_p}{\partial \text{net}_{pk}} \cdot \frac{\partial \text{net}_{pk}}{\partial w_{ki}}\right).$$

The hidden layer error is

$$\delta = -\frac{\partial E_p}{\partial \text{net}_{pk}},$$
$$= -\frac{\partial E_p}{\partial z_{pk}} \cdot \frac{\partial z_{pk}}{\partial z_{pk}}. \tag{7}$$

4.3. Training and Testing of Network

4.3.1. Transfer of the Benchmark Network Structure. In this study, the configuration 10-6-1(number of inputs-number of hidden layer neurons-number of output) of DNN model for tracking and monitoring electricity theft users was used as the benchmark network structure based on the transfer learning algorithm to develop a DNN model for comprehensive evaluation [41], and the benchmark network parameters are shown in Table 6.

4.3.2. Optimization and Training. For the characteristics of the evaluation of bidding vertical collusion tendency, the transferred benchmark network was debugged in this study, specifically: considering the small sample size of the evaluation indicators of the participants in the vertical collusion and the data correlation is more complicated, increased network dimensions, and adjusted the number of neurons. The compact network structure is conducive to get the optimal conclusion through less training data. Due to the difference in collusion evaluation indicators among bidders, tenderers, and bid evaluation experts, two different network structures were designed to match the comprehensive evaluation; the configuration of tenderer & bidder network. The training parameters of DNN-based comprehensive evaluation model for bidders, tenderers, and bid evaluation experts are finally determined in Table 7.

Specifically, the mean squared error MSE was generally chosen as loss function for the training of DNN models, as shown in the following equation.

$$\text{MSE} = \frac{1}{mp} \sum_{r=1}^{p} \sum_{j=1}^{m} (\hat{y}_{rj} - y_{rj})^2, \tag{8}$$

where m = the number of output nodes, $\hat{y}_{rj}$ = the expected output value of the network, p = the number of training samples, and y_{rj} = the actual output of the network. Sigmoid, the activation function of hidden layer and output layer, also functioned as threshold function of neural network, mapped its variables to interval from 0 to 1 with input interval whole real number and output internal [0, 1], satisfying the designed need for comprehensive vertical collusive evaluation. The expression of the sigmoid function is shown in the following equation.

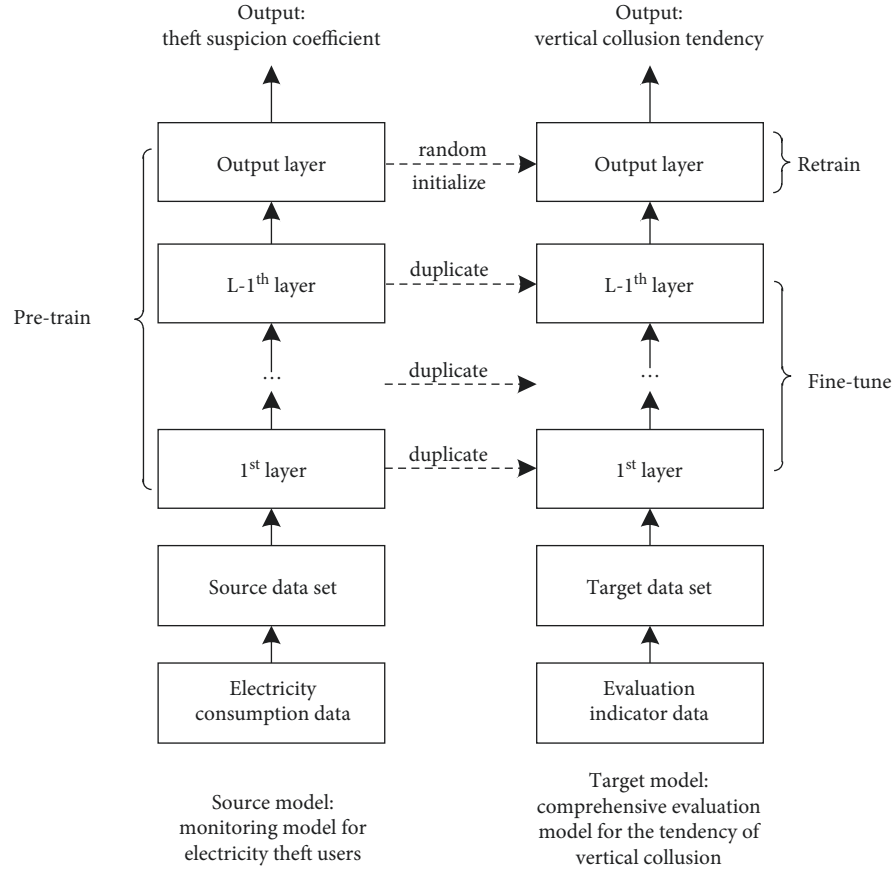
$$f(x) = \frac{1}{1 + e^{-x}}. \tag{9}$$


FIGURE 5: Parameter transfer process.

TABLE 6: Training parameters of the Benchmark network.

Parameter	Value
Configuration	[10, 6, 1]
Number of layer (n)	3
Activation function of hidden layer	Sigmoid
Learning rate	0.02
Loss function	Mean squared error (MSE)
Iteration	2000
Output layer activation function	Sigmoid

TABLE 7: Training parameters of the developed DNN model.

Parameter	Value	
Configuration	Tenderer&Bidder	[8, 4, 2, 1]
	Expert	[4, 2, 1]
Number of layer (n)	Tenderer&Bidder	4
	Expert	3
Activation function of hidden layer	Sigmoid	
Learning rate	0.5	
Loss function	MSE	
Iteration	2000	
Output layer activation function	Sigmoid	

According to the training results, the configuration of the developed model is obtained as shown in Figure 6.

In this study, the Python 3.9 code was implemented for model training, and the output target value of collusion case was set as any value in [0.3, 1] and the output target value of normal case was set as any value in [0, 0.3] during training [42].

In the tenderer and bidder network structure, the input layer was the value of the vertical collusion indicator of tenderer and bidder, value range [1, 10], input randomly based on actual situation; the hidden layer, the optimal number determined by constant adjustment, was 2 layers with 4 and 2 neurons, respectively; the output layer was any value in tenderer and bidder collusion tendency interval (0, 1). In addition, in movement of twice dimension reduction in achievement of higher accuracy for tendency evaluation, the weight distribution matrices were matrix 8×4 and 4×2, respectively. In the 3rd dimension degradation, the weight distribution matrix from $L3$ to $L4$ was matrix 2×1 with [0.169, −0.317] in tender network and matrix 2×1 with [0.404, 0.827] in bidder network.

Since there were only 4 indicators for evaluating the collusion behavior of bid evaluation experts, this paper adjusted the dimensions of the comprehensive evaluation DNN network towards experts referring to the DNN network for tenderers and bidders. In the bid evaluation expert network structure, the input layer was the value of the bid evaluation expert vertical collusion indicators, value range [1, 10], input randomly based on actual situation; the hidden layer, the optimal number determined by constant adjustment, was 1 layer with 2 neurons; the output layer was any value in bid expert collusion tendency interval (0, 1). In
FIGURE 6: Configuration of the developed model.

reach of high accuracy for comprehensive tendency evaluation model in bid evaluation expert's party, the weight distribution matrix in first dimension reduction was matrix 4×2, the second dimension, namely, from $L2$ to $L3$, was matrix 2×1 with [0.044, 0.075].

4.3.3. Gradient Descent of the Error.

Since the loss function used in the model was the minimized loss function, the model output error could be solved by gradient descent algorithm. In this study, the number of iterations was set to 2000 when training the developed model, and it was found that the mean square error of training samples was close to 0 (see Figure 7). Thus, the final determined network parameters and weight distribution matrix could reflect that the developed model was regarded as reliable. In this study, in order to alleviate or avoid the problem of overtraining, an early termination algorithm was carried to mitigate overfitting, i.e., the training was terminated as soon as the overfitting trend of the model was detected.

4.3.4. Testing.

The test was conducted using the aforementioned 55 test samples, and the results are shown in Table 8. The experimental results showed that the developed model predicted 48 correct and 7 incorrect, with a comprehensive accuracy of 87.3%, which was high, further
FIGURE 7: Training effect.

TABLE 8: Accuracy of model test results.

Case collusion type	Total	Incorrect number	Correct rate (%)
Tenderer & bidder & expert	11	2	81.82
Tenderer & bidder	21	2	90.48
Bidder & expert	8	0	100
Normal	15	3	80

TABLE 9: Collusion evaluation level.

Participate	Evaluation levels and collusion tendency intervals

indicating that the model could be regarded as reliable and accurate.

5. Model Application and Discussion

5.1. Background. In bid evaluation of a provincial highway mainline site construction project, the expert panel finally locked 4 candidates, in the order of $A1$, $A2$, $A3$, and $A4$. The project department determined the first and the second winning candidates according to the number of labor teams to be recruited and the recommended order of winning candidates.

Combined with the obtained evaluating indicators of the tenderers, bidders, and bid evaluation experts, the following improper practices were found in the bidding activity after repeated review and continuous retroactive tracking of the indicators by the government supervisory department: (1) in the process of preparing bidding documents, the tenderers added "special technology", and "enterprise qualification", and the scoring criteria and scoring indicators in bid evaluation part were unreasonable; (2) in the bidding process of $A1$, the tenderer leaked relevant bidding information to the enterprise before bidding announcement, what was more, the tenderer used his position to inform the enterprise of important information about the required materials; (3) during the bidding process of $A2$, the tenderer set "limited number system" pre-qualification conditions for him; selected the bid evaluation experts at his will, and finally designated his next bid evaluation experts by the enterprise; (4) $A3$ and $A4$ participated in the bidding in accordance with normal procedures, and no abnormalities were found in the indicators; (5) during bid evaluation, the bid evaluation team deliberately gave $A2$ high score at tenderer's instruction, and made obvious tendentious remarks.

5.2. Comprehensive Evaluation of the Tendency of Vertical Collusion. Wu [42] established a model for measuring the strength of the tendency of bidders and tenderers to collude based on evidence-based reasoning approach, and concluded

that the strength level could be divided into weaker (0–0.3), weak (0.3–0.5), strong (0.5–0.8), and stronger (0.8–1), and the strong level reflect the existence of collusion between the two parties. Through comparative analysis, in this case, the collusion evaluation level is as shown in Table 9, which provides some theoretical reference significance for the comprehensive evaluating level of the tendency of collusion of the model output value.

The input values of the model are shown in Table 10, each caught by three regulatory experts' investigating and tracking indicators of the tenderer, 4 bidders, and bid evaluation experts.

The above three sets of values were applied to the developed model and run in Python 3.9, respectively, and the results are shown in Table 11.

Based on the output results, we could get that there was a high probability of collusion in the bidding activity, and the colluding subjects were the tenderers, $A1$ bidder, $A2$ bidder, and bid evaluation experts.

5.3. Discussion. Based on the tendency indicators of vertical collusion in bidding and the comprehensive tendency model of vertical collusion, four types of prevention suggestions for vertical collusion in bidding can be put forward, namely, routine prevention, early warning prevention, moderate prevention, and severe prevention.

(1) Routine prevention faces the situation that the actors are labeled weaker with the developed model. Preventive measures are mainly routine check, irregular check, special check, and emphasized check to materials and practices of the body of tenderer, bidder, and bid evaluation expert in the implementation process.

(2) Early warning prevention suits for monitoring the weak assessed by the developed model, and the preventive measures are mainly to monitor the whole process of bidding activities dynamically, compare bidding data at multiple levels, and review

TABLE 11: Output values of the model (3 regulatory experts).

Output	Tenderer	Bidder $A1$	Bidder $A2$	Bidder $A3$	Bidder $A4$	Bid evaluation expert
Expert 1	0.8559	0.8083	0.7053	0.2019	0.2456	0.7997
Expert 2	0.8553	0.8089	0.7055	0.2023	0.2458	0.8001
Expert 3	0.8562	0.8091	0.7049	0.2020	0.2451	0.7998

bidding problems in all aspects with the help of intelligent technologies such as 5 G communication network, Internet of Things, and cloud computing. At the same time, the blockchain multi-point storage technology for data confidentiality management, identification system to strengthen expert management and other intelligent technologies can combine to guarantee the whole process, multi-level and all-around strict review of bids, judges, evaluation, and management of bidding activities in construction projects.

(3) Moderate prevention applies to those scored strong doers evaluated by the developed model, and the preventive measures mainly include the implementation of commitment system, joint and several penalty system and heavy fine system. In addition, giving full play to the advantages of trading platform facilities and resources and real-time interaction of network information, it is suggested that the relevant supervisory department and government legal department should reasonably reorganize the business process to effectively prevent collusion in construction bidding.

(4) Severe prevention adapts to the stronger participants marked by the developed model, and the preventive measures mainly include introducing social credit code system and weaving a detailed and sound credit record system for those bidding-related parties. With this system, any relevant activities are always observed, recorded, and exposed on the designated platform haunting psychology of daring not collusion. Moreover, expending supervision role of public service and third party, constantly innovating supervisory ideas, improving supervisory methods, and maintaining supervisory concepts, all are organically bonded to a systematic supervision mechanism to monitor the whole stage of bidding.

6. Conclusions

This study developed a deep neural network model for comprehensive evaluation of the tendency of vertical collusion with the help of transfer learning, subdivided to 4-layer model (8-4-2-1) for tenders, 4-layer model (8-4-2-1) for bidders, and 3-layer model (4-2-1) for bid evaluation experts. The collected 130 cases were trained and tested to the established DNN model, and the result of 87.3% accuracy said the model was reliable. Depending on comprehensive evaluation results of the model, four types of collusion prevention suggestions are proposed: routine, early warning, moderate, and severe. The specific measures for routine

prevention include routine check, irregular check, special check, and emphasized check; early warning prevention include strengthening the audit strength of participating parties, improving the transparency of bidding activities, and popularizing intelligent technology; the moderate prevention are mainly implementing the commitment system, strengthening the public reporting channels, and improving electronic bidding; the severe prevention falls on temporary inclusion in blacklist, encouraging joint departmental supervision, and establishing a new regulatory mechanism bridging the whole bidding process. The comprehensive evaluation model of tendency of vertical collusion behavior developed in this study has some reference value for the standardization of bidding market in China and other countries.

Since the comprehensive evaluation executed in this study needs to fully consider various factors, the study needs to be further explored and improved, mainly in the following two aspects: on one hand, the differences in corporate culture and local customs have not been taken into account when obtaining the comprehensive evaluation indicators, which need to be considered in future research; on the other hand, there is some subjectivity in data collection by using expert consultation as input value, thus subsequent collection means of evaluation data waits for deep exploration to be close to actual situation.

The factors affecting urban rail tunnel construction projects are very complex and are influenced by many factors such as the social environment, the construction process, and the way construction is managed. These influencing factors interact with each other, leading to the complexity of the development risks of this type of project. However, at present, the research on engineering construction risk is mainly focused on the field of housing construction, and there are few researches on the risk of urban tunnel construction. At the same time, with the continuous development of urbanization, the coverage of urban underground rail transport is increasing, so it is of great theoretical and practical significance to study the construction process of urban underground tunnels. This paper uses the literature collection method and the LDA model to initially identify the impact factors, and on this basis, the final set of evaluation impact factors is determined by means of expert interviews. Based on the set of influencing factors, the Dematel-ISM model was used to obtain a comprehensive analysis of the factors affecting urban rail tunnel construction projects by comparing topological maps and obtaining a Dematel-ISM model diagram with a cause-effect reachable hierarchy. Finally, the results obtained are applied to the actual development to verify the validity of the model. The results of the study show that construction operation, sequence arrangement, and procedure selection are the key influencing factors for safety risks in urban rail tunnel construction projects.

1. Introduction

Transport infrastructure refers to transport engineering facilities that provide public services for social production and residents' lives and is a public service system used to ensure the normal conduct of social and economic activities in a country or region, mainly including railway, highway, aviation, water transport, road and bridge, tunnel, port, and other construction contents. With the continuous development of China's economy, the construction of China's transport infrastructure has made significant developments since 1978. Transport facilities have achieved the transformation from constraining economic development to basically adapting to the level of economic development. By the end of 2020, China's total road mileage reached 5,198,100 kilometers, and railway operating mileage reached 146,300 kilometers, with highways and high-speed railways reaching 161,000 kilometers and 39,800 kilometers, respectively. Both

have achieved leapfrog development, and China has also made greater development in shipping. Urban railways, as an important part of the transport infrastructure, have been developed rapidly in recent years. However, urban rail transit inevitably encounters many problems in the construction process, especially in the construction process, as the location of the construction is mostly the city center, and the requirements for construction technology are more stringent. Therefore, this paper will study the risk of tunnel construction in the process of urban rail transit construction, which is of great practical significance.

At present, there are few studies on unsafe behavior and unsafe factors in the construction of urban rail tunnels, and the research content is usually biased towards the purely technical level. Fewer studies have been conducted on the relationship between the risk factors from a management perspective. Therefore, this paper adopts a Dematel-ISM linkage approach to gradually construct an explanatory

structural model to understand the key factors and structures affecting the safety of the construction process of urban rail tunnels and to provide suggestions for the control of unsafe behavior in urban rail tunnel construction. Based on the clarification of the key factors and structures affecting the safety of urban rail tunnel construction, ideas and strategies are proposed for the impact of risk-cause pairs.

The Dematel method was developed in the 1970s by Prof. Gabus and Fontela of the Geneva Research Centre and is commonly used to address the relationships between factors in the analysis of complex systems [1]. The method uses mathematical theory to analyze the relationship between the criteria and the strength of their effects by observing the degree of interaction between them and to model the structure of the indicators. In recent years, due to its wide applicability and introduction has received much attention and has been applied in a large number of applications and with the continuous optimization by many scholars, the method has made great progress in the fields of systems engineering, management science, project management, and safety management. In the Dematel method, there are three main expert information expressions as follows: point estimation judgment information, fuzzy number estimation judgment information, and grey number estimation information. Dytczak and Ginda pointed out through experimental analysis that there is a big controversy on how to use the Dematel algorithm and further made suggestions on how to carry out optimization [2]. Bai and Sarkis put forward grey-based Dematel and fused successful key factors for a business project in practical [3]. Lee et al. resolved the infeasibility of Dematel [4]. However, the comprehensive influence matrix (TIM) in Dematel can provide more information than the reachable matrix, so the combination of Dematel and ISM methods can achieve the complementary advantages and integration of the two methods; at the same time, there are also many studies combining Dematel method with ANP, AHP, and VIKOR methods [5–10]. These methods replace the evaluation matrix of the above methods with the constructed TIM matrix, but some scholars point out that the mismatch between the use of Dematel and ANP scales can have some impact on the rationality of the combination of methods [11].

The explanatory structure model (ISM) was proposed by Warfield in 1973, and the method is mainly used to analyze the constituent elements and interdependencies of complex systems. The ISM method forms a top-down arranged hierarchical diagram by decomposing the constituent elements of a complex system and transporting them through the system topology.

This paper further explores the risk influencing factors for sustainable transport infrastructure development in China and analyzes the project using the Dematel method and the ISM method, making the role of the relationship between the fuzzy, entangled risk influencing factors in the development process clear and providing a topological model for the continuous development of transport infrastructure development.

The innovation of this paper is mainly reflected in the following two points:

(i) This study analyzes the impact of safety factors on urban rail tunnel construction projects based on Dematel-ISM and identifies key impact indicators, which are important for controlling the process of urban rail tunnel construction and ensuring construction safety.

(ii) In this study, the LDA model was used to extract risk factors from the safety factors of previous urban rail tunnel construction projects, which is more scientific and reasonable than traditional methods.

2. Influencing Factors and Index System Construction

In order to construct an evaluation index system for transport infrastructure development, the first step of the thesis selects the LDA topic model to carry out topic semantic identification of the 500 highly cited papers collected and selects high-frequency words for risk factor extraction at the best topic count, and the second step is to use the Delphi method to screen the main influencing factors from the preliminary collated risk influencing factors for sustainable development of transport infrastructure.

2.1. A Determination of Impact Factor Evaluation Indicators for Sustainable Development of Transport Infrastructure Based on LDA Theme Model

2.1.1. Extraction of Risk Theme Words Based on LDA Model. The thesis selected the LDA topic model for data mining of selected research texts; data mining is also known as knowledge discovery in databases. By processing a large amount of random data, information containing patterns or values in the text is extracted. Text mining processes textual information and can be used to analyze and refine the themes implied behind the text through technology. Text mining has been used extensively in processing large amounts of irregular text. The thesis chooses latent Dirichlet allocation (LDA) topic model to process selected text data. The LDA model is a commonly used topic model that automatically extracts potential topics from large-scale texts. LDA does not require manual processing of relevant preliminaries during recognition and is an unsupervised machine learning algorithm that can be more efficient in the large-scale text processed. The LDA topic model is artificial in that individual documents are made up of implied topics, and the words in the documents make up the implied topics. The logical structure of the LDA model is shown in Figure 1.

The thesis uses the Gensim and Numpy libraries to construct an LDA topic model after setting up a specialized thesaurus and deactivating words. The LDA topic model is based on a Bayesian model. By counting the input text, the number of words in each of the M documents is recorded. The distribution of topics and the distribution of words in each topic are found for each document. The LDA topic model is currently used in information management and user comment analysis.

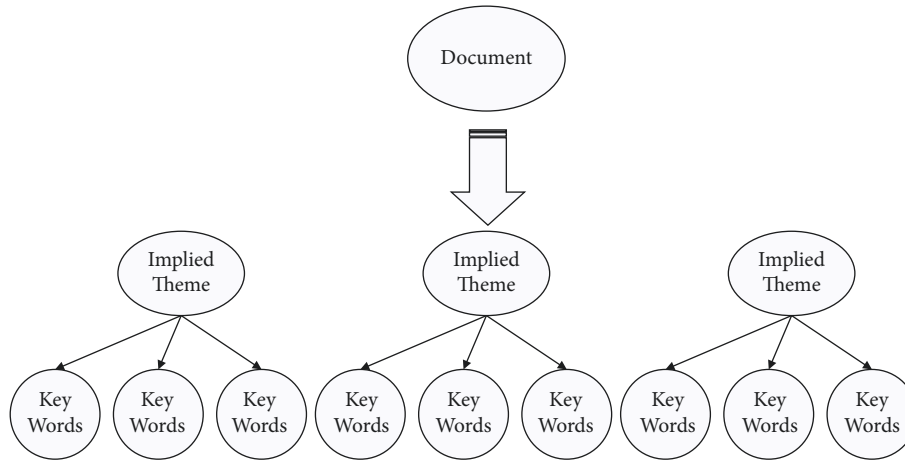
As the thesis focuses on Chinese issues, it was searched on CNKI using the keywords "tunnel," "construction," and


FIGURE 1: LDA model of the banking theme topology.

"risk," and 81 core papers and 16 incident reports with high relevance from 2000 to 2021 were selected as the initial source data. The 81 core papers and 16 incident reports with high relevance from 2000 to 2021 were selected as the initial source data for analysis. After downloading, 55 texts were retained after the initial manual screening. The model perplexity of the analyzed texts is shown in Figure 2.

Through Figure 2, it can be found that the article has the least confusion when the topic is selected as 8. The paper selects topic = 7, 8, 9; analyzes the obtained data; and finds that the best results are obtained when the topic is selected as 8. The results of the analysis of high-frequency topic words in the LDA model part are shown in Table 1.

2.2. Preliminary Risk Influencing Factors Determination.

Since the thesis addresses the risk of sustainable development of transportation infrastructure, the probability of generation of relevant factors has a small impact on the study. After referring to the subject terms, each subject term is statistically organized and the collated preliminary impact indicators for key risks are shown in Table 2.

The paper identifies the initial risk factors after the subject terms are advanced through the LDA subject matter model. The final evaluation metrics will be determined through the Delphi method. The Delphi method is a commonly used expert scoring method, which was proposed by RAND in 1946. The method collects expert opinions and eventually achieves a unified opinion among the investigators.

Steps of the paper to determine the final evaluation indicators are as follows:

(i) Clarify the survey objectives, survey purposes, and survey methods and create questionnaires as needed. The method and precautions for filling out the survey questionnaire are explained. The thesis selects the Likert seven-level scale to make the questionnaire. The relative importance among the indicators is judged by means of an expert interview survey. Duplicate indicators and those with less influence were screened out.

FIGURE 2: Topic perplexity of LDA model.

(ii) Expert panel members were identified. Ten experts related to theory and practice were selected for this study. Through interviews with experts and questionnaire filling, evaluation indicators are determined based on Table 2. The surveyed experts included government staff, university teachers, relevant researchers, and related practitioners. For the information on survey personnel (see Table 3).

(iii) A questionnaire (see Table 4) was sent to the selected experts by face-to-face communication or letter. And each expert's opinion on the indicators was sought.

(iv) The returned questionnaire results were statistically analyzed, and after collecting the questionnaire data, the questionnaire data were processed using SPSS AU software, and after determining that the data reliability validity met the requirements, the indicators were censored according to the factor loadings. And the final results were returned to each expert.

After the experts discussed the 29 influencing factors, 24 influencing factors with greater practical significance were finally summarized (see Table 5).

3. Dematel-ISM Modeling of Safety Influencing Factors in Urban Rail Tunnel Construction Projects

The core idea of this paper is to combine the Dematel method with ISM to reflect the impact of each safety influence factor on the project in the process of urban rail tunnel construction more clearly and reasonably. Compared with text and symbols, the Dematel-ISM method expresses the results more intuitively and clearly and reduces the inverse influence of experts' personal subjective factors on the results on the basis of clear and accurate reflection of the cause-effect relationships seen in each element. In this method, the influencing factors are considered as nodes, and the nodes with causal relationships are linked using directed line segments. In the obtained directed topology diagram, if an element is active, it is called an activity element, and the system containing an Activity element is called extension variable system. In a directed topology diagram, elements are said to form a loop if they are reachable to each other. A reasonable ISM-directed topology diagram requires the presence of a nonloop system. The intercept is set reasonably through the expert interview guided to determine the correlation and hierarchy among the influencing factors and to determine the influence relationship between the factors. The basic process of constructing a model based on the model is as follows (see Figure 3).

3.1. Total Impact Matrix Establishment and Specification.

Twenty-four influencing indicators of construction safety of urban rail tunnel are quantified by the Dematel method for factor analysis, and on the basis of the quantitative analysis, a direct influence matrix O was formed. The direct impact matrix O should be normalized. The formula is as follows:

$$N = \frac{O}{\max \sum_{j=1}^{n}} = O_{ij} = \left(X_{ij} \right)_{n*n}. \tag{1}$$

The normative direct relation matrix N is aggregated by accumulating all direct and indirect relationships, and the sum of all direct and indirect relationships of each factor should be identified to obtain the total impact matrix T as follows:

$$T = N(I - N)^{-1}, \tag{2}$$

where I is the unit matrix.

The direct impact O matrix of construction safety indicators of the urban rail tunnel is shown in Table 6, and the total impact T matrix is shown in Table 7.

3.2. The Dematel Factors Analysis.

The cause degree and centrality of each factor of construction safety in the urban rail tunnel should be calculated to obtain the level and weight of each factor. The main steps are as follows:

(i) Set D represents the comprehensive influence of each factor on all other factors. Set C represents the comprehensive affected degree of all other factors on each factor.

(ii) Set $D + C(M)$ represents the correlation degree of this factor in the system, which is called centrality. Set D-C (R) denotes the cause degree of this factor in the system, which is called reasonability. The sets D, C, M, and R of construction safety indicators of the urban rail tunnel are shown in Table 8, and the (M, R) scatter diagram is shown in Figure 4.

$D + C$ means the significance of the factor centrality in the system; the greater the value, the more important the

factor; $D - C$ means the influence of a certain factor on other factors. The factor whose value is greater than 0 means more influence on other factors and is denoted as the reason factor. The factor whose value is less than 0 means more influence by others and is denoted as result factor. Each factor should be normalized to obtain weight according to its $D + C(M)$ value.

From the factors analysis of construction safety in the urban rail tunnel, R_{11} (stratigraphic conditions), R_{12} (complex hydrological situation), R_{23} (complex surrounding building conditions), and R_{31} (accuracy of survey data) have the highest reasonability, which means the greatest impact on other factors. R_{48} (construction operation), R_{47} (sequence arrangement), and R_{42} (procedure selection) have the highest centrality, which means the fundamental impact on the construction safety of the urban rail tunnel.

3.3. ISM Factor Analysis and Reachable Matrix Establishment.

Since the Dematel factors analysis on themselves belongs to each factor interaction correspondence, the unit matrix I is used to indicate the influence value of factors on themselves. The comprehensive influence relationship of factors in the whole system can be replaced by multiplication matrix B.

$$B = T + I. \tag{3}$$

In matrix B, if $b_{ij} = 0$, it shows that factor b_i has no effect on b_j; otherwise, b_i has an effect on b_j. The matrix B obtained in Dematel factors includes not only the existence of factor relationships but also the degree of scope of factors interaction. Therefore, the matrix B calculated by Dematel can be simplified to reachable matrix R, which shows the reachable

hierarchical structure of the urban rail tunnel safety index system.

The reachable matrix R is used to reflect a directed topological hierarchy graph that can link each influencing safety factor of an urban rail tunnel through a certain path. The threshold value $\lambda = 0.016$ is determined according to the actual situation and the influence strength, which the purpose of threshold setting is to discard the less influential relationship and simplify the factor relationship, so as to clearly express the main system structure level. The matrix R is simplified according to the following formula. The matrix R of the urban rail tunnel safety index system is shown in Table 9.

$$R = (r_{ij}) = \begin{cases} 0, r_{ij} < \lambda, \\ 1, r_{ij} \geq \lambda. \end{cases} \tag{4}$$

3.4. Topological Hierarchy Diagram Establishment.

There is a reachable set R, a prior set Q, and a common set A from the matrix R, where $T = R \cap Q$ to further get the relationship levels of interaction among factors. All the factors of each row correspond to a path value of 1 are called reachable sets $R(i)$. All the factors of each corresponding column value of 1 are called the prior set $Q(i)$. The common set of the reachable set $R(i) \cap Q(i)$ and the prior set is called $T(i)$. The topological hierarchy extraction process of the urban rail tunnel safety index system can be seen in Table 10.

By comparing directed topological diagrams, the influencing factors of construction safety in the urban rail tunnel are analyzed comprehensively to determine the correlation and hierarchy among the influencing factors and determine

the influencing relationship among factors. The basic process of constructing the model according to this is shown in Table 11.

From the topological hierarchy extraction process, the levels can be shown in Table 11.

According to the relationship between the confrontation hierarchy extracted process and levels, the directed topological hierarchy diagram can be drawn as shown in Figure 5.

As shown in Figure 5, the root cause factors set of R_{24} (climatic conditions), R_{11} (stratigraphic conditions), R_{12} (complex hydrological situation), R_{23} (complex surrounding building conditions), and R_{31} (accuracy of survey data), which are at the bottom of the system and are not affected by other factors, can directly or indirectly affect other factors within the system. The features of factors up to down are from superficial to essential, which means dominant levels are from level 4 to level 7. As shown in figures, factors of R_{23} (complex surrounding building conditions), R_{31} (accuracy of survey data), R_{32} (design reasonableness), R_{48} (construction operation), R_{47} (sequence arrangement), and R_{42} (procedure selection) are the dominant function factors of great importance, which means their fundamental impact on

construction safety of urban rail. It can be found that geological conditions, planning and design, and construction technology are more important indicator categories in the safety of urban railway tunnel construction, which should be paid more attention. It also can be noted that by combining the weight analysis of factors in Table 9, R_{48} (construction operation), R_{47} (sequence arrangement), and R_{42} (procedure selection) have the greatest centrality and

importance for the construction safety of urban rail, which means that the choice of technology and the effectiveness of its implementation during construction have a dominant influence on construction safety in urban railways.

4. Conclusions

This paper studies the risk of tunnel construction in the process of urban rail transit construction. It adopts a Dematel-ISM linkage approach to gradually construct an explanatory structural model to understand the key factors and structures affecting the safety of the construction process of urban rail tunnels. This paper uses the literature collection method and the LDA model to initially identify the impact factors, and on this basis, the final set of evaluation impact factors is determined by means of expert interviews. Based on the research 6 clarification of the 24 key factors affecting the safety of urban rail tunnel construction can be obtained, then the Dematel-ISM model was used to obtain a comprehensive analysis of the factors affecting urban rail tunnel construction projects by comparing topological maps and obtaining a Dematel-ISM model diagram with a cause-effect reachable hierarchy. Finally, the results obtained are applied to the actual development to verify the validity of the model.

From the research, it can be found that the root cause factors set of R_{24} (climatic conditions), R_{11} (stratigraphic conditions), R_{12} (complex hydrological situation), R_{23} (complex surrounding building conditions), and R_{31} (accuracy of survey data), which are at the bottom of the system and are not affected by other factors, can directly or indirectly affect other factors and result within the system, which should be paid more attention. It can be found especially during the prior period that the most direct safety impact factors come from geological conditions, climatic conditions, and complex surrounding conditions. Therefore, on the basis of fully collecting and possessing accurate information, professional experts should be invited to improve the accuracy and rationality of conditions research in this phrase. During the prior period, the possible changes in the conditions of the project shall be fully considered, and the disposal plan shall be made for relevant changes to reduce the possible impact of unpredictable changes in conditions.

It also notes reachable hierarchy diagram that R_{31} (accuracy of survey data), R_{32} (design reasonableness), R_{48} (construction operation), R_{47} (sequence arrangement), and R_{42} (procedure selection) are the dominant function factors of great importance, which means their fundamental impact on construction safety of urban rail. It can be found that planning and design and construction technology are more important indicator categories in the safety of urban railway tunnel construction, which should be paid more attention. Design and construction periods are also important for the safety of the urban railway tunnel. Combing the weight analysis of factors, R_{48} (construction team arrangement), R_{47} (sequence arrangement), and R_{42} (procedure selection) have the greatest centrality for construction safety of urban rail, and the calculations imply that the choice of technology and the effectiveness of its implementation have a dominant

influence on construction safety in urban railways during construction, which means we should pay full attention to the construction standards, reasonable construction arrangement, and team arrangement. This paper puts forward the important influencing factors that may have a great impact on the safety of urban railway tunnel construction, which can provide some reference for the construction of relevant projects and improve the investment efficiency. At present, further research is needed on the relationship of factors contained in the study and the impact degree on the project caused by the relationship between them. Therefore, it is necessary to conduct in-depth research on the practical cases of urban railway tunnel construction.

In this study, the risk factors were extracted using the LDA model, and based on this, the relationship between the influencing factors was investigated using the Dematel-ISM method. However, the process of determining the relationships between the factors relies heavily on expert scoring, which is highly subjective, and does not take into account the impact of information technology and industrial clustering on tunnel construction risks.

Dust pollution in construction sites is an invisible hazard that is often ignored as a nuisance. Regulatory and engineering control methods are predominantly used for its mitigation. To control dust, dust-generating activities and their magnitudes need to be established. While researchers have comprehensively studied dust emissions of construction work, prediction of dust concentrations based on work phases and climatic conditions is still lacking. To overcome the above knowledge gap, this article selected two construction stages of a project to monitor dust generation using the HXF-35 dust sampler. Based on the collected data, dust emission characteristics of these two stages are studied, and dust emission characteristics under multiple pollution sources are analyzed. Based on the results, a BP neural network model is built to perform simulations of dust emission concentrations in different work areas and predict construction dust concentrations under different conditions. Except few, the majority of the work areas monitored have exceeded the allowable upper limit of TSP concentration stipulated by relevant standards. In addition, dust emission differences of work areas are pronounced. The results verified that the BP neural network dust concentration prediction model is feasible to be used to predict dust concentration changes in different work faces under different climate conditions and to provide a scientific base for pollution control. This study provides several practical solutions where the prediction of dust concentrations at designated work areas will allow construction companies early warning to implement mitigation measures before it becomes a serious health hazard. In addition, it provides an opportunity to re-evaluate those hazardous work in the light of these revelations. The outcome of this study is both original and useful for both construction companies and regulatory agencies. It can better predict the concentration of construction dust in different operating areas and different weather conditions and provide a guide for the prevention and control of construction dust.

1. Introduction

With the rapid economic development, China's construction industry has been ushered into a period of large-scale construction and infrastructure development. The increasing scale of construction activities, including building construction, building demolition, equipment installation, and so on, has aggravated particle pollution. The majority of construction activities are in-situ and organized in the open air. In addition, material transportation, loading and unloading, and stockpiles of earthwork cause large-scale unavoidable emissions. The large particles of these emissions tend to settle down near the construction site after being raised. However, small particles tend to flow with the wind

and enter the atmosphere to form suspended solids that are commonly known as construction dust [1]. According to past research, construction dust has been considered to be an important source of particle pollution [2–4].

The formation of construction dust has been widely studied by scholars for years, which included dust monitoring technologies [5], dust emission factors [6, 7], dust diffusion rules [8–10], dust pollution characteristics [11, 12], health hazard evaluation [13–15], and dust prevention and control measures [16]. So far, instrument sampling has been the most commonly used method to monitor construction dust particle concentration. Gao [17] measured the TSP (total suspended particulate) concentration using the HXF-35 dust sampler and the TSP as a monitoring index of

construction dust. In response to the complexity and uniqueness of construction sites, Ma [18] adopted unmanned aerial vehicles and image recognition technologies to design an automatic monitoring system of construction dust pollution sources and analyzed construction dust from three aspects: tests for construction dust pollution sources, identification of construction dust polluted areas, and characteristic comparison of construction dust pollution sources.

In order to quantify dust data acquired from monitoring, researchers have employed construction dust emission factors and emissions via three commonly used research methods [19]: exposure profiling method, four-dimensional Flux model, and Flux-FDM method. Tian [20] built a mathematical model, a four-dimensional flux model, which is similar to the exposure profiling method proposed by the U.S. Environmental Protection Agency, and a set of construction dust emission monitoring plan matched with this model. The model also combined the actually measured data of more than 40 construction sites for a quantitative assessment of emissions and emission factors of construction dust. After analyzing relevant data of a Tianjin building construction site, Zhao [21] set up the Flux-FDM model, which is used for the estimation of PM10 emissions of construction, and combined the dust emission factors and construction dust influencing factors obtained through the nonlinear fitting. They found wind velocity and the superficial dust water content are key factors that affect dust emissions. However, construction dust emission is not only subjected to the influence of climate factors, but also to the monitoring height, construction intensity, and other factors.

In the studies of emission characteristics of construction dust particles, Tian [22] studied the vertical and horizontal diffusion laws of construction dust at the boundary of the construction site by monitoring the change of the dust fall concentration near the construction site. They found construction dust fall concentration is inversely proportional to the square of height on the same plane of the construction site boundary. The same correlation was also observed between the dust concentration and the square of the distance from the monitoring point to the center on the same height. Li [23] chose typical residential construction projects in Beijing and set up dust concentration collection points in major work areas during three different periods, namely earthworks, frame, and partitions and interior decoration. They conducted on-site monitoring with TSP as the monitoring index. By comparing the dust pollution status of different construction activities, Li [24] analyzed dust emission characteristics and major distribution principles, and the results suggested that dust emissions of different construction activities significantly differed from each other in terms of their concentration, which, to be specific, showed that the dust concentration during the construction of frame is lower than that of the earthworks. The emission intensity of the former is more stable, and the overall dust concentration of the partitioning and interior decoration stage was high but stable. Hou [25] selected the construction sites in Mentougou District and Daxing District of Beijing as the monitoring objects and used the light scattering method and

the gravimetric method to measure the dust at different points of the construction site. The results suggested that the dust concentration distribution characteristics are different in different areas of the earthwork construction site. The dust concentration of the foundation pit is much higher than that of the main entrance and downwind area, and the construction site with poor dust prevention level is more likely to produce high-concentration dust pollution.

To sum up, researchers have comprehensively studied dust emissions characteristics of construction work, but most researches have focused on the analysis of the overall dust emission levels and characteristics of the entire construction site. Nevertheless, research into dust emissions characteristics of different work phases of construction is still lacking. The construction process is not homogenous and hence different work phases generate different dust concentrations, dust types, and hazards. A building's construction process goes through three distinctly unique stages: foundation, frame, and internal partitions/finishes. Different from the first two stages, the third mainly happens indoor. Therefore, dust generated during the third stage would not influence the external environment, and the dust characteristics are significantly different from those of the other two stages. Meanwhile, researchers have also done a lot of work in the prediction of construction dust particles. In the establishment of construction dust prediction models, researchers mostly use traditional multiple linear regression models [26, 27], but they have great limitations and cannot capture the relationship between the concentration of dust emission particles and dust monitoring factors, resulting in predictions are not accurate. While a back propagation (BP) neural network can overcome this limitation very well, it can build a very complex nonlinear model, which can well reflect the nonlinear relationship between particle concentration and dust monitoring factors [28].

Hence, in order to accurately portray the dust emission concentration of outdoor construction, this article mainly focuses on the first two stages, namely foundation and construction of the frame of a building. Based on the field data monitoring, dust emission characteristics of these two stages are studied, and dust emission characteristics under multiple pollution sources are analyzed. Meanwhile, a BP neural network model is built using the monitored data. This model is employed to perform simulation analysis of dust emission concentrations in different work areas and predict construction dust concentrations under different conditions.

2. Division of Work Areas and Layout of Monitoring Points

The foundation and construction of frames are the main stages of a building construction, whose activities are quite different. Foundation work mainly includes preparation of site, excavation, slope support, filling disposal, rebar processing, concreting, etc. Among them, excavation, slope support, and filling would form part of the foundation excavation. Therefore, the foundation excavation area is chosen as a monitoring point. Activities in the rebar processing area and concreting area differ from each other

TABLE 1: Profile of dust monitoring points.

Construction stage	Monitoring points	Construction dust types	Major activities
Foundation	Foundation excavation area	Silicious dust	Soil excavation, slope support, earthwork compaction
	Rebar processing area	Silicious dust	Rebar transportation, processing, and storage
	Concrete mixing area	Cement dust	Concrete mixing and transportation
	Road area	Silicious dust	Earthworks and construction material transportation
Structural frame	Floor area	Silicious dust	Rebar binding, erection of formwork, scaffolding work, and demolition
	Concrete mixing area	Cement dust	Concrete mixing and transportation
	Rebar processing area	Silicious dust	Rebar transportation, processing, and storage
	Timber formwork area	Timber dust	Timber formwork and other timber processing
	Road area	Silicious dust	Transportation of premixed concrete and other construction materials

significantly; therefore, they should be two separate monitoring points. The construction of the frame mainly covers formwork, bar bending, rebar processing, concrete mixing, concrete pouring, and timberwork. Additionally, activities such as formwork demolition and setup, floor rebar binding, concrete pouring, and scaffolding are all done on the construction floor or nearby. Since these work areas are close to each other and have a similar construction environment, the floor work area is set up as a monitoring point. Meanwhile, the rebar processing area, concrete mixing area, and timberwork area are set up as other monitoring points. Moreover, vehicles transporting construction materials during these two stages can easily raise road dust. Therefore, the road area where the vehicles travel in and out of the site was set up as a monitoring point. The profile of all monitoring points in this research is presented in Table 1.

As shown in Table 1, there are 9 monitoring points set up for the two construction stages. The type of dust in different work areas varies different, which primarily includes silicious dust, cement dust, and timber dust. As the most commonly seen dust type, silicious dust generally comes from the soil, which is diffused into the air through natural wind and by vehicles. Cement dust is generally caused by the dust settlement during the loading and unloading of cement bags, transportation process, and dust diffusion during the feeding process, which is common in the concrete mixing area. Timber dust refers to the dust generated during the erection of timber formwork [29].

3. Construction Dust Monitoring

3.1. Monitoring Index, Equipment, and Methods. At present, there are four main monitoring indicators to measure construction dust, namely dust fall, TSP, PM10, and PM2.5. The total suspended particle (TSP) is defined as the suspended particle whose aerodynamic diameter is smaller than $100\,\mu$m, and from a particle size perspective, TSP includes particulate matter 10 (PM10) [30]. The increasing mass concentration of TSP in the air can increase the morbidity of chronic obstructive pulmonary diseases, cardiovascular diseases, cerebrovascular diseases, and acute respiratory tract infections [31, 32]. Compared with direct monitoring of PM10 concentrations, monitoring TSP concentrations is less expensive and simpler to operate and can increase the

density of monitoring sites and enable larger data collections [33]. Therefore, considering the scientificity and operability of monitoring indicators, combined with the consideration of construction site conditions and dust monitoring costs, the TSP concentration in the air is chosen as the construction dust monitoring indicator. In this research, the TSP concentration is monitored using the dust sampler HXF-35. Measurement results of this instrument can accurately reflect the position and occurrence time of dust pollution and realize multipoint simultaneous monitoring to acquire mass data.

This research refers to the Chinese national standard, "Determination of Dust in the Air of Workplace–Part 1: Total Dust Concentration" and uses the filter membrane increment method for measurement. Before sampling, the filter membrane is weighed. During the process of sampling, the dust sampler HXF-35 is installed on an A-frame holder. Under the obligation of not influencing the construction operations, the sampling point can be kept as close to the operator as practically possible, and the sampling flow rate is set to be 20 L/min. After the end of sampling, all samples are taken back to the lab for weighing and data recording. The TSP concentration can be given by the following equation:

$$c = \frac{m_2 - m_1}{V * t} * 1000, \tag{1}$$

where c denotes the total dust concentration (mg/m^3), m_2 denotes the membrane quality after sampling (mg), m_1 denotes the membrane quality before sampling (mg), V denotes the sampling flow (mg), and t denotes the sampling time (min).

Because of sharp differences in dust concentration at different monitoring points, the monitoring points should be selected according to the practical situations. If there is no serious dust within the vicinity, the sampling time should be above 60 min. If the monitoring point is severely affected by pollution, the sampling time should be controlled within 30 min. The dust concentration of every monitoring point should be monitored for at least four different periods of a day to ensure the completeness and accuracy of dust data. In addition to dust monitoring of different work areas, meteorological data should be recorded, including, temperature, wind velocity, and humidity.

(d)

Figure 1: Location of the project.

3.2. Overview of the Project Monitored. This research chose a residential construction project in the Donghu District of Nanchang, as shown in Figure 1. Nanchang is located at $115°27'$ $-116°35'$ E and $28°10'$ $-$ $29°11'$ S, which is characterized by a moist monsoon climate of the mid-subtropical region with a pleasant temperature and ample sunlight. The average annual temperature of Nanchang is between $17°C$ and $18°C$, and its average annual precipitation is around 1,600 mm. The meteorological conditions in Nanchang are characterized by a high frequency of calm wind, a high frequency of atmospheric stability, and a high frequency of near-earth inversion layers. The frequencies of calm winds in the four seasons are 25.9%, 24.8%, 21.4%, and 26.6%, respectively. During the calm wind period, the wind speed is small, about grades 1-2, and the temperature inversion phenomenon lasts for a long time, which inhibits the diffusion and dilution of atmospheric pollutants in Nanchang. According to relevant researches, calm wind and temperature inversion are the most important meteorological conditions that cause serious air pollution [34].

TABLE 2: Concentrations of dust at different monitoring points of work areas.

Construction periods	Dust monitoring points	Dust types	Average concentration (mg/m³)	Scope of excess multiple	Measurement point yield (%)	Variance
Foundation	Foundation excavation area	Silicious dust a	0.988	0.000–0.320	72.000	0.042
	Rebar processing area	Silicious dust a	1.103	0.000–0.590	70.000	0.082
	Concrete mixing area	Cement dust b	7.392	0.000–3.440	37.000	10.017
	Road area	Silicious dust a	4.287	0.000–5.650	13.000	3.391
Structural frame	Floor area	Siliciousdust a	1.148	0.000–0.600	60.000	0.066
	Concrete mixing area	Cement dust b	2.093	—	100.000	0.791
	Rebar processing area	Silicious dust a	1.374	0.000–0.740	38.000	0.127
	Timber formwork area	Timber dust c	8.697	0.000–3.740	12.000	4.855
	Road area	Silicious dust a	2.124	0.000–2.200	30.000	0.860

Note. The concentration of silicious dust, cement dust, and timber dust is a, PC-PWA = 1 mg/m³, b, PC-PWA = 4 mg/m³, and c, PC-PWA = 3 mg/m³ [35], respectively.

4. Dust Concentration Emission Characteristics

4.1. Dust Concentration Monitoring Result.
According to the "Occupational Exposure Limit for Hazardous Agents in the Work-place," it can be seen that the standard limit of dust concentrations is related to dust types. In order to compare the dust emission concentration of different work areas, this article chose the standard limit for different types of dust concentration to calculate the average concentration, excess multiple, measurement point yield, and other indices, as shown in Table 2.

As shown in Table 2, the average construction dust concentration of the foundation during excavation is 0.988, which is the lowest of value and falls within the allowable limit of the silicious dust. There are two reasons for this. Firstly, the soil water content in the construction area is high, which retards the formation of dust. Secondly, earthwork is mainly carried out by large machinery, whose tracks can help consolidate the soil beneath, preventing the generation of dust. The dust emissions of the road area and the concrete mixing area are severe. The average dust concentration, dust concentration peak, and sample variance of the concrete mixing area are 7.392, 17.760, and 10.017, respectively, which are considerably higher than those of other work areas. The average dust concentration of the road area is 4.287, which is around four times the average dust concentration of the foundation area and rebar processing area. This suggests that concrete processing and vehicular traffic are the main sources of dust during the foundation work.

During the construction of the frame, the average dust concentration of timber formwork area is 8.697, which is around eight times the average of the floor area and exceeds the average of the concrete mixing area and the road area by four-folds. The measurement point yield of the work area is just 12%, meaning that the dust emissions are severe in the timber formwork area and also constitute the main dust source of this stage. This is mainly caused by a tight workspace, which slows down dust diffusion. Emissions from the road area are the second largest for this stage, whose average dust concentration, measurement point yield, and sample variance are all below those of the timber formwork area. The average dust concentration of the concrete mixing area is below that of the floor work area and the rebar processing area. The dust concentration of the concrete mixing area is within the allowable standard, its exceeding multiple is 0, and its measurement point yield is 100%. All these data suggest that dust emissions of the concrete mixing area are slightly lower than those of the floor area and the rebar processing area. Compared with the floor work area, the rebar processing area has a higher average concentration, exceeding multiple, and measurement point yield, implying that dust emissions of the latter are more severe than those of the former; because the dust pollution in the vertical direction of the spread is limited, the dust concentration of the floor area decreases constantly with the increase of floors.

4.2. Comparison of Construction Dust in the Same Work Area but at Different Stages.
Table 3 summarizes the average construction dust concentration, average exceeding multiple, and variation of the indices during earthwork and structural frame stages. Overall, with the exception of the rebar processing area, a decrease in the average construction dust concentration and average exceeding multiple could be observed, when construction activities move from the foundation to the structural frame.

Based on average concentration, emissions in the rebar processing area are on an upward trend, because of the heavy demand placed on rebar for the structural frame. Though road area is the major dust source during foundation, it decreases by more than 50% when construction moves to the

TABLE 3: Comparison of construction dust in the same work area at different stages of construction.

Monitoring point	Average concentration (mg/m^3)			Average exceeding multiple		
	Foundation	Structural frame	Variation	Foundation	Structuralframe	Variation
Rebar processing area	0.988	1.374	39.070	0.590	0.740	25.420
Concrete mixing area	7.392	2.089	−71.730	3.440	0.000	−100.000
Road area	4.287	2.124	−50.450	5.650	2.200	−61.060

structural frame. There are two main reasons for the decline. Firstly, there is more bare soil during the earthwork as most pavements have not been hardened. However, by the time construction moves over to the structural frame, most of these road surfaces are hardened, reducing dust raised by vehicles. Secondly, during the structural frame, there are fewer vehicles transporting soil from and to the site. The dust concentration of concrete mixing during earthworks is three times higher than that of structural frame. This is mainly because concrete is transported using a pump for pouring into the formwork, whereas for foundation, a pump is not used. The cement, before entering the compression pump, has full contact and reaction with water and aggregates, thus evading the generation of cement dust.

From the average exceeding multiple perspective, vehicle movements cause severe dust during both foundation and structural frame stages. As to dust emissions of the rebar processing area and the road area, their average exceeding multiple varies significantly and drops by a large margin. In particular, the average exceeding multiple of the concrete mixing area during the structural frame has dropped to zero.

4.3. Comparison of Work Areas with Major Construction Dust Emissions. Table 4 summarizes work areas with severe construction dust emissions in the two stages. During foundation work, road area, concrete mixing area, and rebar processing area are the main dust-generating areas. However, during the construction of structural frame, timber formwork area, road area, and rebar processing areas have emerged as major dust-generating areas.

A comparison of average dust concentration and average exceeding multiple of the three work areas is shown in Figure 2. The highest average excess multiple is found for the road area, which is five times as high as that of the other two. Hence, these three work areas should be the key areas for construction dust prevention and control during construction.

5. Establishment of Dust Concentration Prediction Model Based on the BP Neural Network

Considering the complexity of building construction process, multiple work phases, high emission randomness, and difficulty of quantifying dust pollution, it is very important to model dust concentrations at different work phases. Therefore, this research conducts a simulation prediction of dust particle concentration at different work areas in an attempt to build a construction dust particle concentration prediction model using the BP neural network.

TABLE 4: Comparison of work areas with severe dust emissions.

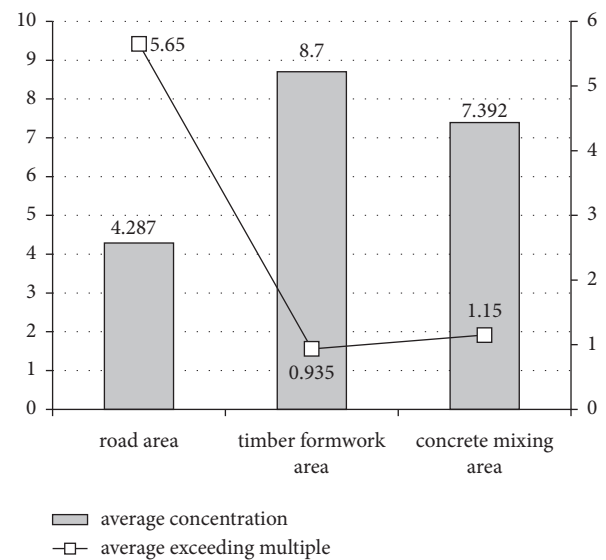
Serial number	Foundation	Structural frame
1	Road area	Timber formwork area
2	Concrete mixing area	Road area
3	Rebar processing area	Rebar processing area


FIGURE 2: Comparison of dust concentration and excess multiple in work areas with severe emissions.
FIGURE 3: BP neural network structure.

5.1. Overview of the BP Neural Network. As one of the most widely used models, the BP neural network has found applications in many fields [36–38]. The BP neural network is defined as a feedforward neural network or backpropagation
FIGURE 4: Comparison between the predicted values and the measured values of dust particle concentration during the foundation stage: (a) foundation excavation area, (b) rebar processing area, (c) concrete mixing area, and (d) Road area.

neural network, which is characterized by the forward propagation of signals and backward propagation of errors. Generally speaking, the BP neural network consists of the input layer, hidden layer, and output layer [39], and its structure is presented in Figure 3. The optimization capacity of the BP neural network has a close bearing on its structure—a structure characterized by variability, nonlinearity, error tolerance, self-adaption, and autonomous learning.

5.2. Dust Concentration Prediction Model. The neural network model adopted in this research to build the construction dust concentration prediction model features a three-layer network structure, in which there are three neurons in the input layer, namely the temperature, moisture, and wind velocity [40]. The initial hidden layer has 20 neurons, and the output layer has one neuron that is dust concentration. In other words, it is a model with a 3-20-1 three-layer network structure. Meanwhile, MATLAB2016a is adopted as the numerical computing platform. Before prediction, the BP neural network should first receive network model training to get equipped with the ability of memorization and prediction. To the end, the "Rand" function is used to acquire 60 samples from every monitoring point, and the first 50 samples are adopted as the training set, while the other 10 as the test set. The iteration items are set as 100, and the learning rate is taken as 0.01.

TABLE 5: Dust particle concentration of different work areas.

Construction periods	Work areas	$R2$
Foundation	Foundation excavation area	0.9807
	Rebar processing area	0.9872
	Concrete mixing area	0.9677
	Road area	0.9726
Structural frame	Floor area	0.9749
	Concrete mixing area	0.9097
	Rebar processing area	0.9556
	Timber formwork area	0.9608
	Road area	0.9988

TABLE 6: Regression analysis results of the predicted output and the target data of different work areas.

Construction stage	Work areas	Training	Validation	Test	All
Foundation	Foundation excavation area	0.9937	0.9459	0.9833	0.9859
	Rebar processing area	0.9968	0.9135	0.9583	0.9746
	Concrete mixing area	0.9821	0.869	0.9098	0.9586
	Both sides of road	0.9986	0.9913	0.9966	0.9973
Structural frame	Floor area	0.9917	0.9777	0.9908	0.9837
	Concrete mixing area	0.9986	0.9894	0.9988	0.9962
	Rebar processing area	0.9962	0.9956	0.9721	0.9921
	Timber formwork area	0.9968	0.7586	0.9442	0.9885
	Both sides of road	0.9996	0.9949	0.9953	0.9978

5.3. Dust Concentration Simulation of Different Work Areas. The model with a 3-20-1 network structure thus built is used to conduct simulated prediction of various work areas. Figure 4 shows the actually measured values and predicted values of the dust emission concentration of different work areas of the foundation stage. Table 5 shows the correlation coefficient of simulation prediction of different work areas during the foundation and structural frame stages. Hence, R2 below denotes the decision coefficient of regression analysis, which is 0.9807, 0.98724, 0.9677, and 0.97255 in the foundation area, rebar processing area, concrete rebar area, and road area of the foundation stage, respectively. The prediction results and the actually measured value show a high degree of fitting, indicating favorable simulation prediction effects as shown in Figure 4. From Table 5, it can be seen that R2 of the floor work area, concrete mixing area, rebar processing area, timber formwork area, and road area are 0.9749, 0.9097, 0.9556, 0.9608, and 0.9988, respectively. Combining the results of Table 4 with the results of Figure 4, the neural network training results of different work areas in the structural frame stage are favorable.

Table 6 shows the regression results of the predicted output and the target data of different work areas during the two stages. Figure 5 shows the regression analysis results of the predicted output and the target data of the road area during the structural frame stage, where training, validation, test, and all represent the regression coefficient R of the training samples, verification samples, test samples, and integrated samples, respectively. The regression coefficients are above 90% as shown in Table 6 and are generally close to 1. By combining the results demonstrated in Figure 5, it is concluded that the model generates favorable simulation prediction results. It also shows the feasibility of developing a construction dust emission

concentration prediction model based on the BP neural network.

6. Discussion

Research results suggest that, during the construction period, dust emissions of different work areas differ from each other significantly, which aligns with the previous research findings [41]. However, numerical simulations of construction dust at present are mostly based on the gas-solid two-phase flow theory to simulate the diffusion based on rules of the wind velocity, height of the generation source, and dust concentration [42, 43]. It is not based on the characteristics of on-site construction activities and their influences on dust emissions. This is a major gap in the extant literature, and hence some of the highly polluting areas are neglected in auditing and monitoring schemes. In order to fill the above gap in the knowledge, this research chose the wind velocity, temperature, and moisture as input factors to build a construction dust simulation prediction model for different work areas of a construction site, focusing primarily on two work stages that happen in the open air. Hence, the model considers not only the influence of the meteorological conditions, but also the influence of construction activities on dust emissions. The regression coefficients show that the predicted values and the measured values demonstrate good agreement. Therefore, the established model should be capable of well-predicting construction dust concentration changes in different work areas and under different weather conditions and providing a scientific base for its control, diffusion, and pollution.

In order to verify the validity of the construction dust prediction model, ten test samples are randomly chosen
Figure 5: Regression analysis results of the road area during the structural frame stage: (a) training: $R = 0.99957$, (b) validation: $R = 0.99492$, (c) test: $R = 0.99533$, and (d) all: $R = 0.99783$.

from the road area during the construction of the structural frame for prediction as shown in Table 7. The relative error between the predicted values and the actual values of the ten samples are all around 0.01, meaning that the construction dust prediction model proposed by this article can obtain favorable results. In addition, the neural network construction dust prediction model is easy to use and well demonstrate the prediction results in the form of curves. The prediction of dust concentrations in different work areas of a construction site has several positive implications. It allows the construction company to monitor dust levels at different stages of work and plan strategic interventions before it is

TABLE 7: Predicted results of the road area during the structural frame.

Index	1	2	3	4	5	6	7	8	9	10
Measured value	2.65	2.58	2.98	0.87	2.98	3.18	0.95	3.20	3.15	2.65
Predicted value	2.64	2.62	3.04	0.93	3.01	3.19	0.99	3.15	3.15	2.64
Relative error (%)	0.32	1.91	1.88	4.27	1.11	0.53	3.99	1.44	0.06	0.32

too late. It could prevent dust-related long-term illnesses among workers who are routinely involved in such tasks.

For example, an investigation by the Australian Broadcasting Cooperation (ABC, 2019) revealed that the workers who are involved in installing stone kitchen bench-tops have reported silicosis due to exposure to silica dust (http://www.aap.com.au/,2019). The report states "doctors are worried Australia is facing the worst occupational lung disease crisis since the peak of the asbestos disaster" as number of stonemasons in New South Wales, Victoria, Australian Capital Territory, and Queensland have been reported to the hospital with accelerated silicosis of alarming levels. However, the builders involved in residential construction in Australia have never been on the spotlight for any violation of WHS laws related to dust pollution. The reason is, construction dust is considered as "nuisance dust" because most auditing and monitoring (if all happens) is based on the overall measurement results rather than on designated areas. Based on these overall measurements, the site does not exceed the regulatory thresholds set by the Environmental Project Agency (EPA) of Australia. However, if measurements were taken at different work areas, some areas could be well above those limits. Therefore, the prediction of dust concentrations at designated work areas should be a high priority for construction companies. Furthermore, regulatory agencies should avoid blanket rulings on construction sites as different activities have varying dust generation potential, some of which could be very harmful to workers and the neighboring community.

7. Conclusion

Due to the complexity, continuity, and time-varying characteristics of construction dust emissions, traditional regression prediction models cannot accurately predict the concentration of the dust emissions. Therefore, in order to simulate construction dust under multiple pollution sources, this article monitored dust emissions during two important stages of a residential construction project, namely foundation and structural frame. The study identified training and learning samples for the neural network, compiled the learning and training algorithm, and built the neural network model reflecting dust emission concentrations in different work areas. Based on the results of simulation prediction, the output data of the BP neural network model demonstrate a favorable and ideal correlation, and compared with the traditional regression model, the dust concentration prediction model established by the BP neural network is feasible to be used to predict dust concentration changes in different work areas and under different climate conditions, which can provide a scientific base for pollution control.

The majority of work areas have exceeded the allowable upper limit of TSP concentration stipulated by relevant standards. This means that most work areas are suffering from the serious concentration of dust pollution under multiple pollution sources. The dust emission differences of work areas are pronounced. To be specific, the areas with serious dust emission concentrations during foundation include the road area, concrete mixing area, and rebar processing area. The areas with serious dust emission concentrations during the construction of structural frame include the timber formwork area, road area, and rebar processing area. While the road area in foundation construction, concrete mixing area, and wood formwork area in structure construction are the key areas of dust emission in construction period.

The prediction of dust concentrations in designated work areas will provide construction companies with an early warning to implement mitigation measures before it becomes a serious health hazard. In addition, it provides an opportunity to re-evaluate those hazardous work in the light of these revelations. Although this study showed that the BP neural network could develop such early warning, the study only used two stages of a long and laborious construction process as a demonstration. Further research is needed in other stages and activities to evaluate the true potential of BP neural network simulations and to demonstrate their suitability. Further research into other stages of construction could reveal activities that are prone to severe dust emissions which at present are not considered as hazardous by builders or regulatory bodies.

Community amateur sports training equipment is necessary to ensure the development of national fitness activities. It is found that the design concept of community public sports space in China is not perfect, the structural layout is not reasonable, the stock space is not optimized, and the resource allocation is not balanced. In particular, there is a lack of indoor fitness facilities and sports venues in the community, and the people's "fitness where to go" is still a difficult problem. In the smart city construction, the resource integration and optimization of community amateur sports training facilities have also been further developed. Considering various influencing factors, this paper establishes a location model of community amateur sports training facilities with the least total cost and convenience. Aiming at the practical optimization problem with high complexity, an improved adaptive weight multiobjective particle swarm optimization (PSO) model is proposed. These parameters in the algorithm were adjusted dynamically, which balanced the overall search ability and partial improvement ability of the PSO algorithm and completed the optimal scheduling of community amateur sports training equipment configuration while ensuring the optimal global solution. Experimental results show that the algorithm's efficiency and searching ability have been further promoted. It also has an excellent performance in solving the complex location problem of community amateur sports training facilities.

1. Introduction

In January 2019, the CPC Central Committee clearly proposed to take people's yearning for a better life as the starting point and focus of spatial planning [1]. Improve the quality of the living environment [2]. Improve the quality of people's life [3]. Community amateur sports facilities are an important carrier for public fitness activities [4]. It is a necessary condition to ensure the development of national fitness activities. For improving national physical quality. Achieve high quality of life. The cause of national fitness continued to develop. The supply and service level of community amateur sports facilities continued to improve. The "six sides" project of national fitness has been preliminarily constructed as the main content. A relatively sound public service system for national fitness covering urban and rural areas [5]. According to the report on the development

of Chinese mass sports (2014) issued by the State Administration of sports in 2014. The number of sports parks in China is 1662, according to the statistical survey data of national sports venues in 2019. In 2019, there will be 823500 national fitness paths in China. 76800 fitness trails, according to the statistical bulletin of national economic and social development in 2020 [6]. By the end of 2020, there were 3.713 million sports venues in China.

However, the effective supply of community amateur sports facilities in China is insufficient. The utilization rate of existing facilities is low. Popular and convenient amateur sports facilities are still seriously insufficient [7]. These have formed a serious contradiction between supply and demand with the growing fitness demand of the public [8]. "Land grabbing," "noise disturbing residents," "elderly occupying the stadium," and other events occur frequently [9]. People's "fitness where to go" has become the focus of social

attention. Hindering the development process of the national fitness project [10]. Under the tight situation of land resources, reasonable optimization of the existing community amateur sports facilities is occurred [11]. "Make the best use of everything" so that community amateur sports facilities can meet and guide people's sports and fitness needs.

Focus on the convenience and benefit of the people. China has implemented policies and measures such as the "six sided project" of mass sports. Increase the effective supply of community amateur sports facilities [12]. Community amateur sports facilities around the masses are also stepping up the layout and construction. However, the layout method of "sticking to the seams" is usually adopted according to the actual situation in the specific implementation process. There is still a lack of echo with the surrounding environment and necessary humanistic care [13]. "Basketball and fitness dance conflict case" and "fitness dance disturbing residents" were once pushed to the commanding height of public opinion. The lack of sports fitness venues and facilities and the disturbing fitness activities have fully exposed the defects and deficiencies in community amateur sports facilities [14]. The official website of the Sichuan Provincial People's government once listed "unscientific setting of square dance venues, nonstandard management and noise disturbing residents" as one of the "ten things that the masses are most dissatisfied with." To some extent, this also reflects the unsatisfactory layout planning of community amateur sports facilities in China. The accessibility of community amateur sports facilities was not fully considered in the planning and site selection [15]. It is not enough to meet the time and space needs of different people and the needs of fitness activities with multilevel and diversified configuration [16]. Especially in the context of rapid aging, community amateur sports facilities show some problems, such as insufficient scale, unreasonable function allocation, and poor accessibility. It has seriously affected the demand for outdoor activities of the elderly [17]. It is of great significance to pay attention to improving the accessibility and convenience of community amateur sports facilities in geographical space and the safety, fitness, and entertainment of content space [18].

Health is the premise of a happy life. Health is the foundation of a country to create a better future. Health is the strength of national prosperity. National fitness is the foundation of building a sports power [19]. Achieve national health through national fitness, and then achieve the goal of a well-off society in an all-around way. It is also the internal requirement of accelerating the construction of a sports power [20].

The supply of community amateur sports facilities is insufficient and unbalanced. Insufficient supply is mainly reflected in the single supply type of venues around the masses [21]. In particular, there is a lack of indoor fitness facilities and sports health service platforms in the community. People's "fitness where to go" is still a difficult problem.

With the rapid development of China's economy and people's increasing concern for health, community amateur

sports facilities, as an infrastructure for national service, are developing rapidly across the country [22]. It has had a major impact on people's lives and health. Community amateur sports facilities are the core configuration of public sports space. To a large extent, it determines the development of national fitness. Community amateur sports facilities' spatial distribution and location must be reasonable and scientific [23]. Its location optimization has always been an important planning problem in most cities. It is also an issue of concern and concern to scholars. Because of its nonlinearity, high complexity, and many constraints, the traditional mathematical model can not obtain the global optimal solution [24]. The particle swarm optimization algorithm has a strong global optimization ability [25]. The group parallel search method is used to calculate and solve, with high efficiency and fast convergence speed [26]. In this paper, the improved adaptive weight multiobjective PSO is used to solving model, which is applied to the location problem of community amateur sports facilities with constraints, and good results are obtained.

2. Methodology

2.1. User Satisfaction Model. In order to improve users' satisfaction and fitness experience during the construction of community amateur sports facilities, users' satisfaction is judged by the distance of community amateur sports facilities. According to the questionnaire survey, the satisfaction is shown in Table 1.

Therefore, if you want to improve user satisfaction, you need to ask for the time period of going to the fitness place $[S_g, F_g]$. The longer the journey time, it will directly reduce user satisfaction. There is a negative correlation between user satisfaction and journey time; that is, the longer the journey time, the worse the user satisfaction will be. The satisfaction function is shown in the following formula:

$$S_g = 1 - \frac{S_g^d - S_g^r}{F_g - S_g}, \tag{1}$$

where S_g^d is the ideal travel time and S_g^r is the actual travel time. At the same time, the AHP is used to determine the key degree of amateur sports facilities in each community to users. The weight of facility g is recorded as M_g, and the total user satisfaction of all facilities is recorded as shown in the following formula:

$$S = \sum_{g \in G} S_g \cdot M_g. \tag{2}$$

In order to let users experience the practicability and economy of the community amateur sports facilities optimization model, the total satisfaction acceptable to users is recorded as A, combined with the lowest cost model.

$$\sum_{g \in G} S \cdot M_g > A. \tag{3}$$

2.2. User Demand Fluctuation Model. Compared with users, the main purpose of optimal configuration is to realize the

Table 1: Satisfaction survey.

Distance (m)	Time spent (min)	Satisfaction
[0, 500]	[0, 8]	Very satisfied
[500, 1000]	[8, 15]	Satisfied
[1000, 1500]	[15, 23]	Basically satisfied
[1500, 2000]	[23, 30]	Dissatisfied

use demand of fitness equipment. In this topic, the use frequency of equipment is selected as the fluctuation degree of user demand. Therefore, if the fluctuation degree of user demand is smaller, the use frequency of fitness equipment is more stable. Divide the day into 48 time periods, each of which is 30 minutes. The optimization objective function is shown in the following formula:

$$d = \max_{1 \leqslant n \leqslant N} \sum_{g=1}^{G} e_g^h - \min_{1 \leqslant n \leqslant N} \sum_{g=1}^{G} e_g^h, \tag{4}$$

where e_g^h is the usage frequency of facility g in period h. G is the total number of facilities. $g = 1$ indicates the first facility. The smaller the final result, the smaller the fluctuation of user demand.

2.3. Multiobjective Processing. The multiobjective optimization is processed by the method of square sum weighting, and the optimal value f_x of each objective function is obtained, respectively. Since it is impossible to achieve the optimal situation of each objective at the same time and try to ensure that it approaches the ideal situation, the weighted evaluation function is constructed as follows:

$$F(I) = \sum_{x=3}^{t} M_x \left[\frac{f_x(I) - f_x}{f_x} \right]^2. \tag{5}$$

The optimal solution of multiobjective optimization is obtained through (5). M is the weight coefficient, which can reflect the importance of each objective in the optimization process. Based on this, the unified function of the multi-objective optimization problem in this paper can be constructed.

$$F(I) = M_C \left(\frac{C_{\min}}{C_{\min}\Delta} - 1 \right) + M_S \left(\frac{S_{\max}}{S_{\max}\Delta} - 1 \right) + M_d \left(\frac{d_{\min}}{d_{\min}\Delta} - 1 \right), \tag{6}$$

where $C_{\min}\Delta$, $S_{\max}\Delta$, and $d_{\min}\Delta$ represent the optimal value of facility cost, user satisfaction, and fluctuation degree of user demand, respectively.

2.4. Standard PSO Algorithm. PSO is a classical intelligent algorithm based on mutual cooperation to find the most appropriate solution [27]. Compared with other algorithms, it does not have too many complex parameters and is easier to implement. In this text, a multiobjective PSO algorithm (IAW-MOPSO) with an improved weight strategy is proposed to consider the fitness of the whole particle. It can not only solve multiple objective optimization problems but also optimize faster. At the same time, in the search principle of

the optimal solution, it combines the idea of nonsupported sorting and the method of Pareto optimal appropriate allocation and uses the cooperative relationship between particles to constantly update the optimal solution of particles, so as to solve the problem. Finally, the particle set with the best fitness is selected.

The core of the PSO algorithm is to determine the overall best value and local best value of the particle by changing the next movement through its own experience and the better in the population [28]. The update process is shown in the following formula:

$$\begin{cases} q_{x+1} = mq_{x+1} + c_1 \cdot \text{rand} \cdot \left(U_{\text{best}_x} - I_x \right) + c_2 \cdot \text{rand} \cdot \left(a_{\text{best}_x} - I_x \right), \\ I_{x+1} = I_x + q_{x+1}, \end{cases} \tag{7}$$

where q_x is the velocity of particles. I_x is the position of particles. U_{best_x} is the best position found so far for each particle. a_{best_x} is the best position in all groups. Rand() is a random function between 0 and 1. q_{x+1} is the $x + 1$ particle velocity. I_{x+1} is the position of the $x + 1$ particle. c_1 and c_2 are learning factors. m is the dynamic weight value of particle swarm. Update inertia weights with nonlinear variations as follows:

$$m_v = \frac{m_{\max} - [v(m_{\max} - m_{\min})]}{n_{\max}}, \tag{8}$$

where v is the current iteration number. m_v is the weight value updated in the v iteration. $m_{\max}$ and $m_{\min}$ are the maximum and minimum values of m set artificially. $n_{\max}$ is the maximum iteration number.

2.5. Improvement of PSO Algorithm. Compared with other intelligent algorithms, the PSO algorithm is simpler to set parameters in the process of solving problems, and simpler to understand compared with other bionic algorithms. The difference is that the PSO algorithm does not need coding, so it does not have the solving accuracy limitation brought by coding in other bionic algorithms. However, it still has the problem that the universal intelligent algorithm is better for single objective optimization and easy to fall into some of the most optimal when carrying out multiobjective optimization. To solve this problem, this paper promotes the standard PSO. It not only dynamically adjusts the inertia weight and learning factor but also introduces dynamic time-varying control factors to restrict the position update amplitude of particles, because the nonlinear time-varying adjustment of parameters can obtain better algorithm performance than linear adjustment. These parameters are adjusted by nonlinear dynamic adaptive time-varying adjustment strategy. The inertial weight m is the most important parameter in the multiobjective PSO. With the increase of m, the overall search ability of the algorithm will be promoted, and with the decrease of m, the part search ability of the algorithm will be promoted.

The improved PSO algorithm optimizes the configuration of community amateur sports training equipment, and the management unit can adjust the community amateur

sports training facilities on this basis. The improvement process of this algorithm is as follows:

(1) Calculate the current fitness value of all particles

(2) Update and iterate the new generation of particles and count the particles whose fitness value is more than and less than the average value in the population

(3) Using nonlinear dynamic inertial weights to update m, the global and local searching ability of PSO is improved

$$
m = \begin{cases} m_{\min} - \dfrac{(f_{\mathrm{mean}} - f_{\min})\Delta m}{(f_q - f_{\min})}, & f_{\mathrm{mean}} \leq f_q, \\[3mm] m_{\max}, & f_{\mathrm{mean}} > f_q, \end{cases} \tag{9}
$$

where $m_{\max}$ and $m_{\min}$ show the maximum and minimum values of m, respectively, $\Delta m = (m_{\max} - m_{\min})$. F_{mean} show the current particle fitness value. F_q show the current particles average fitness value. $f_{\min}$ show the current particles minimum fitness value. m changes with the fitness value of particles.

When the f_{mean} of the particles tends to be uniform, or vice versa. The particle whose f_{mean} is better than f_q and its corresponding m is smaller, which protects the particle. For the particle below f_q, its corresponding m is larger, so that the particle will move towards a better search area.

2.6. Dynamic Parameter Update Strategy.

In particle swarm optimization, inertia weight ω function of is to keep the particle in the motion state of the previous moment, and its value has an important influence on the convergence of the algorithm. The basic PSO algorithm sets the inertia weight as a fixed value, and its search result is very poor. The main function of the learning factor is to adjust the proportion of individual optimal position and overall optimal position in speed update to balance the overall search ability and part search ability of the algorithm. In order to make the algorithm more flexible and reliable, this paper adopts the parameter dynamic adjustment strategy. The following formula conveys all the details:

$$
\omega = \omega_{\max} - \frac{(\omega_{\max} - \omega_{\min})n}{N_{\max}},
$$

$$
c_1 = c_{\max} - \frac{(c_{\max} - c_{\min})n}{N_{\max}}, \tag{10}
$$

$$
c_2 = c_{\min} + \frac{(c_{\max} - c_{\min})n}{N_{\max}},
$$

where $\omega_{\max}$ show the maximum value of inertia weight, respectively. $\omega_{\min}$ show the minimum value of inertia weight, respectively. $N_{\max}$ show the maximum number of iterations. $C_{\max}$ show the maximum value of learning factor, respectively. $C_{\max}$ show the minimum value of learning

factor, respectively. At the initial stage of the algorithm iteration, the inertia weight value is large, the initial speed of particles changes rapidly, the algorithm has a fairly strong overall search ability, the learning factor c_1 value is large, and the c_2 value is small, so the algorithm has a fairly strong individual cognitive ability. With the iteration of the algorithm, the inertia weight decreases, the change of particle velocity slows down, the value of learning factor c_1 decreases and the value of c_2 increases. The algorithm has a strong global cognitive ability.

The variation curve of each parameter is shown in Figures 1–3.

2.7. Model Solving Process.

Aiming at the optimal allocation strategy of amateur sports training equipment in the smart city community, this paper studies the improved adaptive weight multi-objective PSO algorithm.

When solving the multiobjective problem, the optimal individual can be selected through the Pareto hierarchical sorting principle, and finally, the Pareto optimal solution set can be obtained. The specific multiobjective scheduling operation process is as follows:

Step 1: coding strategy. The coding strategy adopts binary coding, and each particle represents a feasible solution of the multiobjective problem. All particles are designed as "gh" dimension 0–1 matrix $I = (i_{xy})_{gh}$, where i_{xy} represents the x flexible load, and the y period is selected as the working period, $\sum_{y=1}^{g} i_{xy} = 1, \quad x = 1, 2, \ldots, h$ which means that each equipment selects a period for operation. The particle velocity is expressed by $q = (q_{xy})_{gh}$.

Step 2: system and algorithm initialization. Determine the load model to be dispatched, and inputting the operation time, power, model, and other basic parameters of each load. Setting the particle swarm size as U_{size}, the maximum number of iterations, $n_{\max}$ and other algorithm parameters, initialize the particle swarm and the external file set at the same time, and each particle is randomly distributed in the feasible solution space and given an initial velocity within a given range.

Step 3: determining extremal value. The fitness value of each particle was calculated. The historical optimal position was recorded as the individual extreme value. The global optimal solution was found in the external archive set. The best solution was selected as the global extreme value by comparison with the individual optimal solution.

Step 4: update the velocity and displacement of particles according to equation (7).

Step 5: update the weight according to equation (9).

Step 6: update location. According to the fitness updating historical best U_{best} and overall best a_{best}, the current particle fitness value is compared with the previously determined optimal solution. If the current optimal solution is better, the extreme value is replaced.
FIGURE 1: Inertia weight value change curve.
FIGURE 2: C_1 learning factor value change curve.

FIGURE 3: C_2 learning factor value change curve.

TABLE 2: Community location coordinates and fitness demand.

Community serial number	Coordinate	Demand (person-time)
1	(200, 1500)	125
2	(600, 800)	132
3	(1500, 300)	128
4	(2000, 1500)	112
5	(600, 2000)	116
6	(1000, 2500)	119
7	(3000, 1500)	111
8	(1500, 200)	135

Step 7: update the external file set. Retaining the currently found optimal solution set, then merge the solution set found in the latest iteration with the current optimal, and selecting the nondominated optimal again.

Step 8: judge whether the termination conditions are met. If the conditions are met, the algorithm terminates the iteration and outputs the optimal solution set, the optimized community amateur sports training equipment and facilities. Conversely, return to step 4 to continue optimization as shown in Figure 4.

3. Result Analysis and Discussion

To prove the algorithm's effectiveness in solving complex and multiconstraint problems in reality, it is applied to solve the location of community amateur sports training facilities. The location coordinates of 8 communities are collected. The coordinates of each community and the total amount of fitness needs are shown in Table 2.

It is planned to build amateur sports training facilities within the range of $200 \leq x$ and $y \leq 3000$ to minimize the initial construction cost and the total cost of users. To meet the timeliness requirements of users' fitness, it is agreed that the maximum distance between sports training facilities and the community shall not be greater than 2000 m. The use loss cost is set as 2 yuan/person time. The construction cost is different in different subregions: within the coordinate range of $200 \leq x$, $y \leq 1500$, the construction cost is 30000 yuan. Within $1500 < x$, $y \leq 3000$ coordinates, the construction cost is 35000 yuan; within the coordinate range of $200 \leq x \leq 1500$, $1500 < y \leq 3000$, the construction cost is 40000 yuan. Within the coordinate range of $1500 < x \leq 3000$, $200 \leq y \leq 1500$, the construction cost is 25000 yuan. According to the given constraints, the optimal location coordinates of community amateur sports training facilities are determined by using the proposed improved PSO optimization model to minimize the total operation cost. The distribution of construction costs is shown in Table 3. The total operating cost analysis is shown in Table 4.

The proposed algorithm is compared with the standard PSO algorithm ($c1$ and $c2$ are constant, and inertia weight decreases linearly). The dynamic adaptive PSO algorithm runs the corresponding program. The change of fitness function value is shown in Figure 5. A comparison of the operation time of different algorithms is shown in Figure 6. The location results of community amateur sports training facilities are shown in Figure 7.

The improved PSO algorithm based on the dual mechanism proposed in the paper is used to solve the

location problem of community amateur sports training facilities, which has good convergence. The number of iterations to obtain the optimal solution is about 40 times, the best distribution center coordinates (513.77, 599.99), and the minimum total cost of construction and later distribution is 1228 million yuan. The standard PSO algorithm and the dynamic adaptive PSO algorithm can not converge to the global optimum, although the solution results are close to
Figure 5: Comparison diagram of changes in fitness function values.

the solution results of the former. This paper constructs the mathematical model of community amateur sports training facility location and solves the optimal community amateur sports training facility location scheme through the improved PSO algorithm. The obtained scheme can significantly reduce the total cost to the minimum. Therefore, the PSO algorithm based on a dual mechanism has achieved the desired results in solving the location problem of community amateur sports training facilities, which has a very positive significance.

4. Conclusion

The traditional PSO is dynamically self-adjusted and optimized from inertial weight and acceleration factors, and dynamically changing control factors are added to improve the efficiency. Results show that the performance of PSO is improved significantly by the dynamic adaptive adjustment of multiple parameters, and the overall optimization ability of the improved is enhanced. The improved PSO can be used to solve nonlinear and complex problems such as path planning and automatic control. Through the application of the sports training facility location model, which proved the accuracy of the location selection model and adaptive weighting based on improved multiobjective PSO to solve complex optimization problems the effectiveness of the adaptive weighting based on improved multiobjective PSO to improve the easy to fall into part optimum, the disadvantage of poor robustness, the model is applied to sports training facility location problem solving, it has good dynamic observation and convergence. In the next step, we will continue to optimize the algorithm and apply the model to solve other problems, such as commercial location and constantly optimize and improve it.

In order to accelerate the transformation of offline retailers and improve sales by using big data technology, this paper proposes a data-driven customer profile modeling method based on the collected historical purchase records of offline consumers. This method is mainly divided into three aspects: (1) an incremental RFM model is designed to classify the value of historical consumers and support the dynamic update of the model, which is more efficient than the traditional RFM model; (2) the commodity preference of different types of customers is analyzed by the TGI model, so as to guide the retail terminal to optimize the marketing strategy; (3) a commodity purchase behavior prediction model based on LSTM is proposed, which can predict the commodity that each customer may purchase in the future, so as to optimize the retail strategy. According to extensive experiments based on a true tobacco dataset, the incremental RFM model can save 80% more time than the traditional method, and our proposed prediction model can achieve 59.32% accuracy, which is better than other baselines.

1. Introduction

In recent years, with the transformation and upgrading of offline retail stores, smart point-of-sale terminals have become popular, enabling offline retail stores to collect consumers' historical purchase records. By analyzing these consumer data, offline retailers can optimize their resource allocation and increase consumer stickiness, which is helpful to attract consumers and improve their sales.

However, how to form an accurate and knowledge of consumers' consumption motivation, consumption ability, consumption preference, consumption habits, and consumption trends through the analysis of consumers' purchase behavior records is the main challenge at present. Therefore, this paper proposes a data-driven customer profile modeling method, which mainly includes coarse-grained value classification and preference analysis of customers, as well as fine-grained purchase behavior prediction.

Based on the consumers' purchase behavior collected by the POS terminals, we firstly use the RFM model [1] to evaluate the customers' value according to their consumption recency, consumption frequency, and consumption monetary. This paper also proposes an incremental optimization on the RFM model.

With the continuous generation of new consumer purchase behavior data, an efficient update strategy is designed to avoid the repeated reading of historical data and unnecessary redundant calculation, so as to speed up the update efficiency of the RFM model. At the same time, this paper introduces TGI (target group index) model [2], analyzes consumers' consumption habits according to their consumption records, and describes consumers' preferences according to their groups, which is conducive to recommending their preferred products according to people.

In addition, in order to help retail terminals achieve fine-grained precision marketing, this paper designs a

purchase prediction model based on LSTM (long short term memory) [3], which is used to predict the commodity that the consumer is most likely to buy in the future based on his/her historical purchase behavior. To eliminate the preference biases between customers, the model takes the historical commodities purchased by a consumer in the last five times and the commodity most frequently in history as the model input and finally predicts the commodity that the consumer is most likely to buy in the future. Because the historical purchase behavior has a chronological relationship, this paper uses the LSTM model to model it. In addition, the model also uses the embedding layer [4] of the neural network to embed commodities and maps the original independent commodities into low-dimensional vectors, which can improve the prediction accuracy of the model.

The main contributions of this paper are as follows:

(1) An incremental RFM model updating method is proposed, which can quickly update the old RFM model with the continuous accumulation of data.

(2) We propose to use the TGI model to analyze the preference of customer groups rather than individuals, which is useful to alleviate individual bias.

(3) A commodity purchase prediction model based on LSTM is proposed; it outperforms other baselines by 1.31% accuracy.

The organization of this paper is as follows: Section 2 mainly introduces the incremental RFM model; Section 3 mainly introduces the TGI model; Section 4 mainly introduces the commodity purchase prediction model based on LSTM; Section 5 carries out extensive experiments to verify the effectiveness of the proposed methods; related work is introduced in Section 6; finally, Section 7 summarizes the work of this paper.

2. Customer Classification Based on Incremental RFM Model

In this section, we will first introduce the relevant knowledge of the traditional RFM model, then propose our incremental RFM model update method, and finally help understand with a simple example.

2.1. Introduction of Traditional RFM Model. RFM model is usually used to evaluate customer churn tendency, loyalty, and customer value. This model depicts the customer dynamically through three indexes, recency, frequency, and monetary consumption. Recency means the time interval since the last transaction; frequency means the number of transactions in the last n months; monetary means the total cost in the last months.

The RFM model calculates the overall average value of the three indicators, records them as r_{avg}, f_{avg}, and m_{avg}, r_{avg}, and then marks the corresponding indicators as 0 or 1 according to the relationship between each customer's own RFM indicators and the average value, that is,

$$sr_i = \begin{cases} 1, & r_i < r_{avg}, \\ 0, & r_i \geq r_{avg}, \end{cases}$$
$$sf_i = \begin{cases} 1, & f_i > f_{avg}, \\ 0, & f_i \leq f_{avg}, \end{cases} \qquad (1)$$
$$sm_i = \begin{cases} 1, & m_i > m_{avg}, \\ 0, & m_i \leq m_{avg}. \end{cases}$$

Based on the above formula, each customer can be marked with three 0/1 marks and finally can be classified into 8 types of consumers as shown in Table 1.

2.2. Incremental RFM. The three indicators of the RFM model are real-time; that is, the recency, frequency, and monetary of consumption will change with the passage of time and the generation of orders. At the same time, consumers' consumption habits and consumption demand are not invariable. It may change at any time due to consumers' new attempts, age growth, and other factors. The grab and prediction of consumers' consumption habits should be based on the "current situation." Therefore, in order to obtain the latest RFM model, it is necessary to consider the newly generated consumption data based on historical consumption data. However, if we use the traditional calculation method to recalculate the RFM model for historical data and newly generated data, it will be very time-consuming, especially when the scale of historical data is very large. Therefore, in this section, we propose an incremental RFM calculation method to efficiently update the RFM model by counting relevant indicators of newly generated consumption data based on the historical RFM model.

For historical data, the RFM index of each consumer i is recorded as R_i^{old}, F_i^{old}, M_i^{old}. For the newly added data, the RFM index of consumer j is recorded as R_j^{new}, F_j^{new}, M_j^{new}. In order to update the old RFM model, we need to consider the new data. At this time, the following three situations will occur:

Case 1: the consumer u has purchase records in both historical data and new data:

$$R_u = R_u^{new},$$
$$F_u = F_u^{old} + F_u^{new}, \qquad (2)$$
$$M_u = M_u^{old} + M_u^{new}.$$

Case 2: the consumer u only has purchase record in the historical data, and there is no purchase record in the new data:

$$R_u = R_u^{old} + I,$$
$$F_u = F_u^{old}, \qquad (3)$$
$$M_u = M_u^{old},$$

where I indicates the time interval of new data. If we update the RFM model every month, then $I = 30$.

Table 1: Consumer classification of RFM model.

Consumer classification	Type	Recency	Frequency	Monetary
Important value consumers	1	1	1	1
Important development consumers	2	1	0	1
Important maintain consumers	3	0	1	1
Important retain consumers	4	0	0	1
General value consumers	5	1	1	0
General development consumers	6	1	0	0
General maintain consumers	7	0	1	0
General retain consumers	8	0	0	0

Case 3: the consumer u only has a purchase record in the new data, but there is no purchase record in the historical data:

$$
\begin{aligned}
R_u &= R_u^{\text{new}}, \\
F_u &= F_u^{\text{new}}, \\
M_u &= M_u^{\text{new}}.
\end{aligned}
\tag{4}
$$

After the RFM indicators of each consumer are updated, the average value of each indicator needs to be calculated before consumers can be classified. Suppose that the consumer set in the historical data is recorded as U^{old}, including N^{old} consumers, and the average RFM values of the historical data are $R_{\text{avg}}^{\text{old}}$, $F_{\text{avg}}^{\text{old}}$, $M_{\text{avg}}^{\text{old}}$. Suppose that the consumers in the new data are recorded as a combination of consumers U^{new}, including N^{new} consumers who have purchase behavior in the historical data, and N_2^{new} consumers who have no purchase behavior in the historical data, and then they meet $N_1^{\text{new}} + N_2^{\text{new}} = N^{\text{new}}$. The average value of each index of the updated RFM model can be calculated by the following formula:

$$
\begin{aligned}
F_{\text{avg}} &= \frac{\left(F_{\text{avg}}^{\text{old}} \times N^{\text{old}} + \sum_{j \in U^{\text{new}}} F_j^{\text{new}}\right)}{\left(N^{\text{old}} + N_2^{\text{new}}\right)}, \\
M_{\text{avg}} &= \frac{\left(M_{\text{avg}}^{\text{old}} \times N^{\text{old}} + \sum_{j \in U^{\text{new}}} M_j^{\text{new}}\right)}{\left(N^{\text{old}} + N_2^{\text{new}}\right)}, \\
R_{\text{avg}} &= \frac{\left(\sum_{i \in U'} \left(R_i^{\text{old}} + 30\right) + \sum_{j=1}^{N^{\text{new}}} R_j^{\text{new}}\right)}{\left(N^{\text{old}} + N_2^{\text{new}}\right)},
\end{aligned}
\tag{5}
$$

where $U' = U^{\text{old}} - (U^{\text{old}} \cap U^{\text{new}})$ represents the consumer set with purchase records only in the historical data.

3. Examples

Assume that we have obtained RFM results for four consumers based on the historical data, as shown in Table 2:

Table 2: Consumer RFM table based on historical data statistics.

Consumer	Recency	Frequency	Monetary
$u1$	33	3	28
$u2$	34	1	27
$u3$	36	3	26
$u4$	37	1	59

The average value of each indicator can be calculated:

$$
\begin{aligned}
r_{\text{avg}} &= \frac{1}{4}\left(33 + 34 + 36 + 37\right) = 35, \\
f_{\text{avg}} &= \frac{1}{4}\left(3 + 1 + 3 + 1\right) = 2, \\
m_{\text{avg}} &= \frac{1}{4}\left(28 + 27 + 26 + 59\right) = 35.
\end{aligned}
\tag{6}
$$

Then, according to the relationship between the RFM data of each consumer and the average value, calculate the scoring of each consumer in the three indicators, and $u1$ is used as an example:

$$
\begin{aligned}
r_1 &= 33 < r_{\text{avg}} = 35 \Rightarrow sr_1 = 0, \\
f_1 &= 3 > f_{\text{avg}} = 2 \Rightarrow sf_1 = 1, \\
m_1 &= 28 > f_{\text{avg}} = 35 \Rightarrow sm_1 = 0.
\end{aligned}
\tag{7}
$$

Similarly, the scoring matrix of all consumers can be obtained, as shown in Table 3:

According to Table 1, the consumer classification results of the four consumers are shown in Table 4:

It is assumed that another month has passed on the basis of Table 2, and the data volume of one month has been increased, and the RFM statistics of this month are shown in Table 5:

A new consumer $U5$ is added, which has not appeared in Table 2 before. In addition, $U2$ and $U4$ are not recorded in Table 5 because they have not bought goods within this month.

According to Tables 2 and 5, it can be calculated that $N^{\text{old}} = 4$, $N_2^{\text{new}} = 1$, $F_{\text{avg}}^{\text{old}} = 2$, $M_{\text{avg}}^{\text{old}} = 35$, $U' = \{u2, u4\}$, so according to the formula in Section 2.2,

$$
\begin{aligned}
F_{\text{avg}}^{\text{new}} &= \frac{2 * 4 + 2 + 1 + 2}{4 + 1} = 2.6, \\
M_{\text{avg}}^{\text{new}} &= \frac{35 * 4 + 18 + 15 + 18}{4 + 1} = 38.2, \\
R_{\text{avg}}^{\text{new}} &= \frac{(34 + 30 + 37 + 30 + 10 + 2 + 5)}{4 + 1} = 29.6.
\end{aligned}
\tag{8}
$$

It can be seen that the incremental method does not need to traverse the historical data to obtain the historical RFM value, which saves much time.

3.1. Product Preference Analysis Based on TGI Index. Target group index (TGI), also known as the target group index, can reflect the strength or weakness of the target

Table 3: Consumer RFM scoring table based on historical data statistics.

Consumer	Recency	Frequency	Monetary
u1	0	1	0
u2	0	0	0
u3	1	0	0
u4	1	1	1

Table 4: RFM results based on historical data statistics.

Consumer	Classification
u1	General maintain
u2	General retain
u3	General develop
u4	Important value

Consumer	Recency	Frequency	Monetary
u1	10	2	18
u3	2	1	15
u5	5	2	18

group within a specific research scope. In short, it is the preference of the target group for an object or feature

$$\text{TGI} = \frac{\text{Proportion of certain characteristics in the target group}}{\text{Proportion of groups with the same characteristics in the population}} * 100\%. \tag{9}$$

TGI index represents the difference of different groups on the same problem. TGI index equal to 100 indicates the average level, and an index higher than 100% indicates that such consumers pay more attention to a certain problem than the overall level. For example, assume that there are 35% of people smoke in China, and 50% of Chinese men smoke. Therefore, we can calculate that $\text{TGI} = 50/35 * 100\% = 142\%$, indicating that Chinese men prefer smoking than women.

Based on the classification results of the RFM model in Section 2, we will use the TGI model to analyze the preference of different categories of customers for various goods. The general flow of analysis is shown in the Figure 1.

Firstly, we will use the RFM model to classify customers (red arrow part), then select the four goods with the highest sales volume from the historical data for analysis, and calculate the TGI index of eight types of consumers (blue arrow part). Through the TGI index, we can analyze the preferences of different types of customers, so as to provide suggestions for the replenishment of retail terminals in the future.

4. The Commodity Purchase Prediction Model Based on LSTM

Consumers' purchase behavior can be regarded as sequential data, and traditional machine learning can be used. However, the ability of traditional machine learning methods to

compared with all members. The TGI index can be calculated by the following formula:

capture time-series correlation characteristics is weak, while the recursive neural network (RNN) [5] in deep learning can handle time-series correlation data well. Therefore, in this section, we will use the framework of the recursive neural network to predict commodity purchase behavior.

4.1. Introduction of the LSTM Model. The traditional RNN model structure is shown in Figure 2. The data of each time step is composed of the input data of the current time and the data of the previous time step. Each edge of the input and output has weights, which are W, U and V respectively. RNN network mainly includes two important processes, forward propagation of data and backward propagation of gradients. The parameters of the model are adjusted through forward and backward propagation to optimize the network. However, the traditional RNN model will have the problem of vanishing gradient or exploding gradient [6] with the increase of time step, so someone later optimized the RNN model and proposed the long and short memory neural network (LSTM) [3].

On the basis of RNN, LSTM adds input gate, output gate, and forget gate to make the model selectively remember important data and forget unimportant data and further optimize the prediction method of RNN. The input gate determines the update of information, and the output gate
Figure 1: TGI analysis process.
Figure 2: RNN model.

Figure 3: LSTM model.

determines the information output of the cell state. Through the gate structure, important information is saved, and unnecessary information is forgotten to improve the memory of long-term sequences. The calculation of each gate of LSTM is shown in equations (10)–(15). The structure of LSTM is shown in Figure 3.

$$f_t = \sigma\left(W.\left[h_{t-1}, x_t\right] + b_i\right), \quad (10)$$

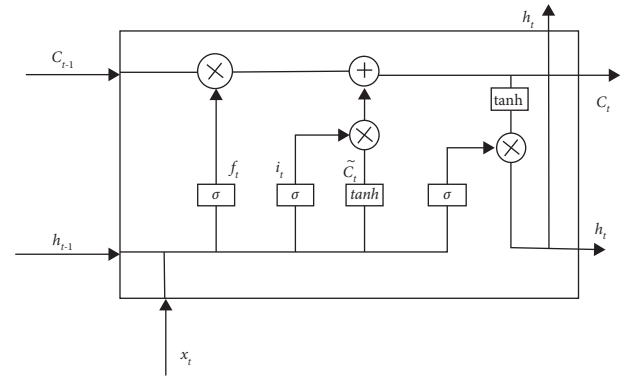
$$\widetilde{C}_t = \tanh\left(W_C.\left[h_{t-1}, x_t\right] + b_i\right), \quad (11)$$

$$i_t = \sigma\left(W_i.\left[h_{t-1}, x_t\right] + b_c\right), \quad (12)$$

$$C_t = f_t * C_{t-1} + i_t * \widetilde{C}_t, \quad (13)$$

$$o_t = \sigma\left(W_o\left[h_{t-1}, x_t\right] + b_o\right), \quad (14)$$

$$h_t = o_t * \tanh\left(C_t\right). \quad (15)$$

4.2. The Prediction Model Based on LSTM. In this section, we design a commodity purchase prediction model based on LSTM, as shown in Figure 4. Firstly, it takes the commodities purchased by the consumer for the first five times as the time-series feature, which is recorded as $X1$, $X2$, $X3$, $X4$, and $X5$. It also takes the most frequently purchased commodity in history as the additional feature, which is recorded as $TzX6$. The model inputs them into the embedding layer [7] and maps each commodity into a low-dimensional vector


representation. The vector representation of each commodity implies the correlation between commodities and their respective characteristics, which can help the prediction model better analyze the historical behavior of consumers.

After embedding, $X1$ to $X5$ are fed into LSTM neural network and output the final hidden layer result P. The hidden layer result P integrates the characteristics of the consumer's previous five purchase behaviors and then maps to a deeper feature space through a layer of full connection, which is recorded as P_C.

As an additional feature, the most frequently purchased commodity in the consumer's history has no sequential relationship with the commodities that are purchased in the last five times, so it is not processed by LSTM neural network. We input the embedding representation of $TzX6$ into a fully connected layer and map it to P_A, whose dimensions are the same dimension as P_C, written as TZ_C. Then, we concatenate P_C and TZ_C and fed them into two fully connected layers to produce the final prediction result $Y\_predict$.

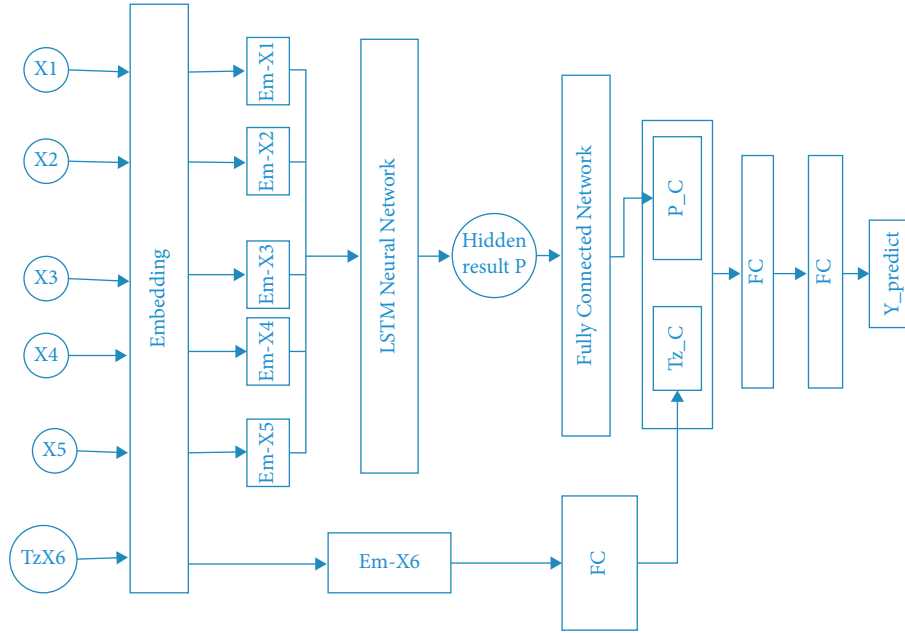
Because there are many commodities that can be predicted, the prediction task actually is a multiclassification problem. Therefore, the final model output $Y\_predict$ is a multidimensional vector, and the corresponding number of each dimension in the vector represents the probability that the consumer purchases the corresponding commodity. We


FIGURE 4: The architecture of the prediction model.

can take the commodity represented by the one dimension with the greatest probability as the final prediction result.

Therefore, we adopt the cross-entropy loss [8] as the loss function of the model. Then, we adopt the Adam [9] gradient optimization algorithm to optimize model parameters according to the error between prediction and ground truth.

5. Experiments

In this section, we will use the real consumer consumption records collected by cigarette sales terminals in a prefecture level city of Hubei Province from June 9, 2019, to March 9, 2021, for experimental verification. Our experimental data is from the real purchase records generated by customers in commodity enterprises. On this basis, we preprocessed and annotated the data. Each record of data contains the customer's last five purchases, the most frequently purchased commodity and labels. Through data cleaning and preprocessing, the final data includes 371089 consumers and 51095 purchase records, including 1655 cigarette brands.

Firstly, we conduct efficiency experiments on the incremental RFM model to study the time cost in updating the RFM model in different ways and verify the effects of the incremental calculation method proposed in this paper. Secondly, we display the TGI results of the top-4 cigarette brands based on classified consumers by the RFM model. Finally, we test the accuracy of the prediction model based on LSTM and compare its accuracy with different classification models, so as to verify the prediction effect of the proposed model. At the same time, we also conducted some ablation experiments to analyze the performance differences of the model under different conditions.

In the purchase prediction experiment, we conducted a 10-fold cross validation and then calculated the average and standard deviation of the experimental results as the final performance of models.

5.1. RFM Efficiency Experiments.
In order to compare the update efficiency of the incremental RFM model before and after optimization, based on the data of one and a half years (2019/6/9–2020/2/9), we compared the calculation time after adding new data of different D days, in which D takes 7, 14, 21, 28, 35, and 42. In order to avoid accidental errors, we run the program several times to calculate the average running time (see Figure 5).

As can be seen from Figure 5, with the increase of new data, the incremental RFM model can save about 5 seconds than the tradition RFM model, which means that our proposed method can greatly improve the efficiency of update the model (the updating model).

5.2. TGI Results.
According to statistics, the four kinds of cigarettes with the highest sales volume in history are yellow crane tower (soft blue), Liqun (new version), Yellow Crane Tower (hard wonder), and Red Golden Dragon (soft boutique). Figure 6 shows the TGI index of eight categories of customers.

Taking Yellow Crane Tower (soft blue) as an example, the TGI index of important value consumers is 929.925%, which is much higher than the measurement standard of 100%, which shows that important value consumers have a high preference for Yellow Crane Tower (soft blue) compared with other consumers; the TGI index of important retained consumers is only 48.125%, far lower than 100%. In proportion, few important retained consumers buy Yellow Crane Tower (soft blue).

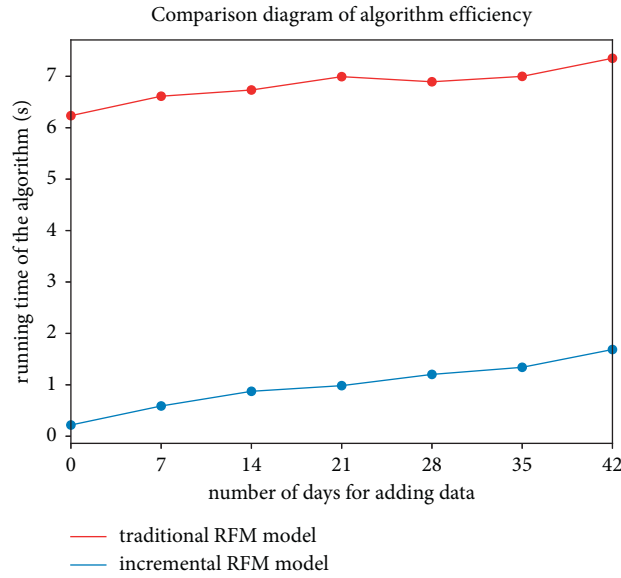
If the four products with the highest sales volume are compared horizontally, it is not difficult to find that these


FIGURE 5: Comparison of RFM model efficiency.
FIGURE 6: TGI index of TOP-4 well-sell cigarettes by different categories of customers. (a) Yellow crane tower (soft blue). (b) Liqun (new version). (c) Yellow crane tower (hard wonder). (d) Red golden dragon (soft boutique).

four products are more popular with the four types of consumers: general maintenance consumers, important maintenance consumers, general value consumers, and important value consumers, especially the important maintenance consumers and important value consumers, while the Yellow Crane Tower (hard wonder) and Red Golden Dragon (soft Boutique) are also popular with important development consumers. In contrast, important value consumers prefer Liqun (new version), important maintenance consumers and important development consumers prefer Hongjinlong (soft boutique), and important retention consumers prefer yellow crane tower (hard spectacle).

5.3. Accuracy Evaluation of the Prediction Model Based on LSTM. In this section, we will compare the accuracy of the cigarette purchase prediction model based on LSTM proposed in this paper with other machine learning algorithms, including support vector machine (SVM) [10], random forest (RF) [11], decision tree (DT) [12], and XGBoost [13]. The parameters of each model are determined according to the prediction results after careful grid search.

Figure 7 shows the accuracy comparison results of the five methods, where the blue bar represents the average accuracy and the green bar represents the standard deviation of accuracy. It can be seen from the figure that the method proposed in this paper achieves the highest accuracy, reaching 59.32%. It is 1.31% better than the second-place method (XGBoost). And the standard deviation of the method proposed in this paper is lower, which shows that our method has better robustness and can better deal with data anomalies.

Secondly, in the comparison methods, we can see that the prediction algorithm based on the tree is better than SVM, probably because the prediction model based on tree can potentially describe the temporal relationship of purchase behavior according to the splitting order of tree nodes.

5.4. Ablation Study. In this section, we will compare the impact on the LSTM cigarette purchase prediction model by 3 key factors, which are the embedding layer in the model, and the characteristics of the most frequently purchased cigarettes in the data, and the characteristics of the previous *K* purchases.

5.5. Influence on Prediction Effect of the Embedding Layer. In this section, we study the impact of the embedding layer by comparing the prediction accuracy of models with and without an embedding layer (see Figure 8).

In Figure 8, the blue bar graph represents the mean value of accuracy and the green bar represents the standard deviation of accuracy. When there is an embedded layer in the model, the average accuracy rate reaches 59.32%, which is 16.77% higher than that without this layer. It can be found that the average accuracy rate is greatly improved. In addition, the standard deviation of accuracy is also reduced by 1.86% compared with that without the embedding layer, indicating that the prediction effect of the model is more stable when this layer is added. Therefore, the embedding layer is useful to improve the prediction accuracy of the model.

5.6. Effects of the Most Frequently Purchased Commodity. In this section, we study the impact of the most frequently purchased good by comparing the prediction accuracy of models with and without this feature, and the results are shown in Figure 9.

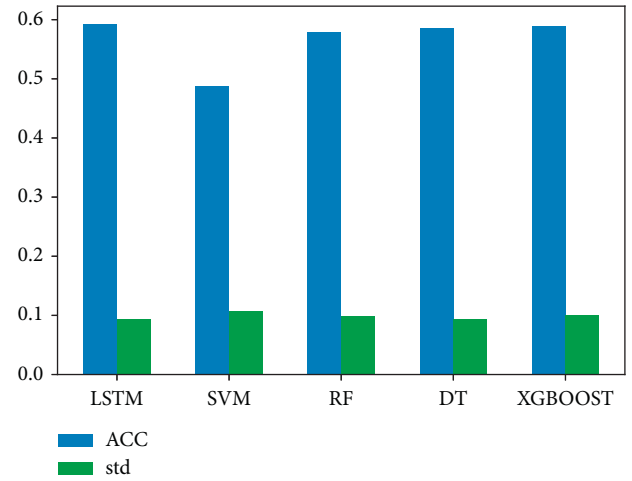
In Figure 9, the blue bar represents the average value of accuracy and the green bar represents the standard deviation of accuracy. It can be seen from the figure that the accuracy with *TzX6* in the feature reaches 59.32%, which is 7.62%


FIGURE 7: Comparison of model evaluation results.
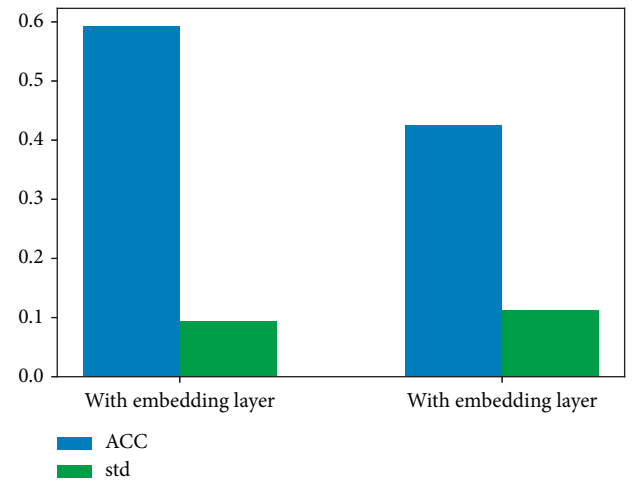

FIGURE 8: Comparison of effect with and without embedding layer.
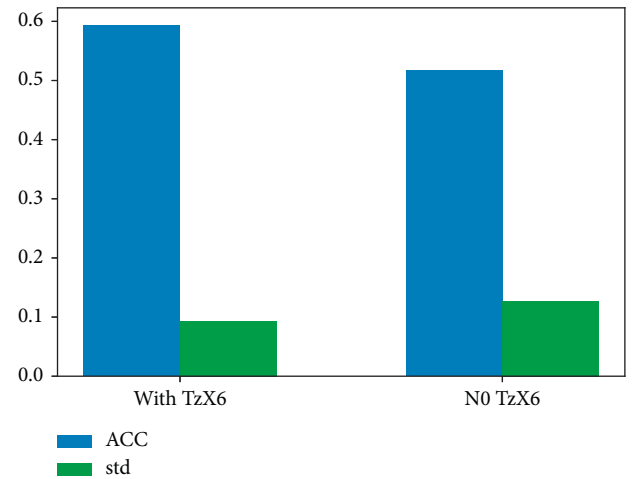

FIGURE 9: Comparison of effect with and without *TzX6* feature.

higher than that without *TzX6*. In addition, the standard deviation is reduced by 3.4%, which makes the prediction effect of the model more accurate and more stable.

5.7. Effects of Previous K Purchase Records. In this section, we compare the impact on the prediction effect of consumers' recent K different purchase behaviors.

Figure 10(a) compares the average accuracy of five different K consumption records. It can be seen from the figure that the prediction accuracy first decreases and then increases with the increase of the K value. When K is 5, the accuracy of the model is more than 0.92% higher than the average accuracy when K is 2, 3, and 4. It is interesting that when we only consider the latest purchase record, the model achieves the best performance. It indicates that the consumer's purchase behavior is most related to his/her latest purchase behavior and his/her long-term behavior.

In Figure 10(b), it compares the standard deviation of accurate values of five different K values. It can be seen that, among the last four K values, the standard deviation of five consumption records is the smallest, reaching 9.32%, indicating that the prediction effect is the best and most stable when $K = 5$. Similarly, when $K = 1$, although the standard deviation is relatively small, the randomness of the customer's latest record is relatively large, which cannot explain the customer's long-term consumption preference and consumption habits. Therefore, considering the prediction effect and significance of each K value, five is a better choice than one.

6. Related Work

The main work of this paper is to carry out customer profiling work, so we first investigate the work related to the customer profiling. Besides, we improve the traditional RFM model and classify customers by the incremental RFM model. And we solve the commodity purchase predictions problem. Therefore, we further investigate the related work into the RFM model and commodity purchase predictions.

Customer profiling: In the trend of a big data environment, customer profiling is used more and more in online shopping and offline retail. In 2016, Li et al. [14] used the K-means algorithm to divide different cigarette attributes and customer attributes and proposed the retailer with the format of the grocery store, the market type of city, the regional type of school district, and the business scale of medium scale. Customers recommend flue-cured cigarettes. In the product recommendation problem in 2019, Zhou et al. [15] proposed a multimodel stacking ensemble (MMSE) algorithm for the personalized product recommendation problem, which is mainly divided into data analysis and model construction. In the data analysis section, Zhou et al. proposed a feature model containing six feature clusters. They designed a sampling algorithm to balance the ratio of positive and negative samples through k-means clustering and undersampling. In the construction of customer profile in the new retail environment proposed by Wang [16], the author takes the customer of offline stores and online stores on the "Tesco on Campus" platform as the research object, based on the essential attribute characteristics of customers, consumer behavior characteristics. There are three dimensions of time and space features, and the data is analyzed by clustering, and the RFM model is constructed using the time and space feature dimensions. Different from the above work, the incremental RFM model is first proposed, and then it used to classify customers. And we solve the commodity purchase predictions problem. This approach helps us construct customer profiling from multiple perspectives.

RFM model: Different researchers have improved the traditional RFM model to varying degrees. For example, Ye [9] designed the online consumer value RFM from three dimensions. Wei [17] proposed adding customer demographic characteristics to the RFP model by combining qualitative and quantitative analysis, breaking the traditional collaborative filtering algorithm based on the RFM model. Anitha and Patil [18] combined the RFM model and K-means clustering method to classify customers. Khajvand et al. [19] extended the RFM model and introduced a new counting parameter to classify customers. You et al. [20] used the RFM and decision-making models for precision marketing. Different from the above work, starting from the update efficiency of the RFM model, this paper proposes an incremental RFM calculation method. Based on historical RFM model, it counts relevant indicators of newly generated consumption data and quickly updates the RFM model.

Commodity purchase predictions: Commodity purchase predictions mostly use machine learning and deep learning methods in purchase behavior prediction. With the gradual deepening of research, some multistage hybrid models have been derived from the single initial model. Ge et al. [21] established an overall customer behavior feature model by constructing customer behavior feature engineering and designed a customer purchase behavior prediction method based on deep forest, which achieved an efficient behavior prediction training effect. XGBoost algorithm is based on Bagging strategy in commodity purchase prediction proposed by Dongqing and Chengji [22]. After that, researchers gradually realized that commodity purchase prediction is essentially a time-series prediction problem. Therefore, some e-commerce commodity prediction problems use related single models or multistage hybrid models based on deep learning and neural network models. For example, Xuyang and Fengjing [23] proposed a prediction model based on the combination of LSTM and random forest. In commodity purchase predictions, Yin et al. [24] designed a customer profiling based on TF-IDF customer cigarette preference prediction algorithm model based on a tobacco company, combining customer portraits and customer preference prediction. The character data author uses TF-IDF to analyze and predict the customer's emotional tendency towards commodity. The text-based data predicts the customer's preference value for cigarettes by calculating
FIGURE 10: Comparison of different K consumption records. (a) Average accuracy. (b) Average standard deviation.

the similarity of the data. Due to the lack of mature customer preference and commodity purchase predictions models in cigarette companies, the TF-IDF prediction model only considers the purchase frequency of customers and does not consider the time-series nature of commodity purchase predictions. Different from the above work, based on the LSTM model, this paper uses six fine-grained features to make predictions, and the fine-grained data include the last five purchases of consumers and the most frequently purchased goods. Commodity purchase predictions consider the customer's commodity purchase frequency and the timing of the customer's purchase behavior and can make dynamic and accurate predictions based on changes in customer behavior in recent times.

7. Conclusions

This paper proposes a consumer profiling method from three aspects by using the historical purchase records of consumers collected by retail terminals. Firstly, an incremental RFM model is designed to classify customers' value and judge whether customers are valuable and loyal. The incremental RFM model can achieve model update in a shorter time than the traditional method. Then, the TGI model is used to analyze the preference of classified customers. Although we only analyze the top four well-sell cigarette brands in experiments, it can be easily extended to other goods of interest. Finally, we propose a commodity purchase prediction model based on LSTM to predict which commodity will be bought by each customer in the future. We take the customer's last five purchase records and the most frequently purchased commodity in history as the input features and adopt semantic embedding and LSTM model to predict the final results. Through experiments on real cigarette purchase data, it is verified that the model can achieve the best prediction accuracy, reaching 59.32%.

In future work, we will continue to optimize the commodity prediction model, hoping to mine the patterns of consumer interest changes and improve the prediction accuracy of the model.

Data Availability

The dataset used were collected from the tobacco monopoly bureau and are not publicly accessible.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

As countries around the world pay more and more attention to the sustainable development of the construction industry, the prefabricated building model has become the best construction type to achieve energy conservation and emission reduction. However, the prefabricated building entails higher technical requirements, and the workers involved in the construction must be trained to reduce the risks. For China, where the demographic dividend is gradually disappearing, how to quickly promote the industrializing workers process has become an urgent issue. This research focuses on the training and management of industrializing workers in prefabricated building. First, the facial images of the participants were collected from the actual test data, and the changes of participants' facial expressions were analyzed through multitask convolutional neural network-Lighten Facial Expression Recognition (MTCNN-LFER). The results of the analysis were plugged into the facial expression recognition and evaluation model for industrializing workers training in this research to calculate the weights, and then all the weights were clustered through the improved SWEM-SAM method. The results show the following: (1) the values of objective data were used to judge the participating workers' mastery of each knowledge and to evaluate whether they are qualified. (2) The evaluation results were used to analyze the risk events that may be caused by participating workers.

1. Introduction

With the development of global economy and engineering technology, the urbanization and industrialization of each country are also advancing [1], and the advancement of electronic intelligence technology has enabled the world industrial level to move into a New Era of Industry 4.0. In today's world of advocating resource conservation and sustainable development, the traditional construction model consumes a large amount of resources [2, 3] and produces a huge amount of construction waste that causes great damage to the environment. Therefore, the Chinese government has proposed the 14th Five-Year Plan and the long-range goals

for 2035 [4], in which prefabricated building model was promoted widely to drive sustainable development of the world environment. Since the prefabricated building model is not yet mature in China, there is a high technical requirement for workers. Besides, as China's population distribution changes, China is gradually entering an ageing society and the demographic dividend is rapidly declining. The Chinese government has proposed to accelerate the process of industrialized workers to ensure sufficient numbers of professionals and high-quality technologies in the construction industry.

According to data released by the Ministry of Housing and Urban-Rural Development of the PRC, this study

investigated safety accidents in the construction industry between 2009 and 2020 [5]. 96.17% of accidents with casualties were caused by workers' unsafe behaviours. 284 safety accidents in prefabricated buildings were reported in 2020 alone, with an average casualty rate of 1.63 people per accident [6]. Besides, 72.64% of the economic and legal problems leading to project delays stemmed from the failure of relevant practitioners to fulfil their obligations in accordance with contracts and laws and regulations. Therefore, a strict control of the training and management system for industrialized workers in prefabricated building is of greater significance in origin-tracing of accidents in such projects and can promote the stable and standardized development of the construction industry as a whole [7].

At present, the construction of prefabricated buildings worldwide is through the combination of prefabricated components and cast-in-place technology, the design concept of which is similar to the structural strength of cast-in-place buildings. The main design method is to connect the prefabricated elements to the cast-in-place structure by solid longitudinal reinforcement connections and then technical processes are implemented to the joints of the whole building structure in order to achieve safety and durability that match the architectural design level [8]. As finished products, prefabricated components have high requirements on humidity, storage space, and maintenance methods in terms of production, transportation, and storage. Considering construction, the longitudinal reinforcement connection technology of prefabricated buildings is quite complex with a large number of joints and splicing gaps, and the waterproofing and insulation of walls are technically challenging [9]. Therefore, prefabricated buildings require workers with higher technical skills.

The traditional worker training system is only a two-phase process from training to employment, and the workers are rural migrant workers with a mobile work nature. As these workers are poorly educated generally, they usually rely on "experience" and tend to ignore the correct mechanical operation steps or the standardized and safe construction sequence, which has posed great engineering hidden dangers to the whole project. In recent years, with the advancement of industrialized workers, the relevant training system has incorporated the concept of assessment. But the practice of determining whether the training standards are met only based on the workers' test scores leads to neglect of workers' mastery of knowledge in different situations. It results in redundant training or muddling through the test, which will cause economic losses to the company and even failure to detect safety hazards in time.

In summary, based on the development background of China's construction industry, how to establish a training system with sound risk control for industrialized workers to ensure the quality of the advancement of the industrializing workers and to reduce the incidence of various risks in the construction industry is an urgent problem to be solved at present. This research uses human behaviour modelling as the grassroots theory, adopts a combination of artificial intelligence and machine vision to recognize and analyze the facial expressions of workers undergoing industrializing

worker training tests, and decomposes the test results of workers in different emotional contexts, so as to establish a facial expression recognition and evaluation model for industrializing worker training. Then the calculation results were clustered through the improved SWEM-SAM method to evaluate the effects of the worker training and to uncover the hidden risks and hazards in this worker group.

The rest of the research is organized as follows. In Section 2, literature research on basic theory involved in this paper is conducted to find theoretical support. Section 3 introduces the methods adopted in this research and improvement points. In Section 4, a facial expression recognition and evaluation model for industrializing worker training is established and four different scenarios are analyzed. In Section 5, the actual test data are plugged into the model for analysis. Section 6 discusses the analysis results, the correctness of the model, and the trends of the interpretation results and concludes the research to provide theoretical directions for further research.

2. Literature Review

2.1. Human Behaviour Modelling. Human behaviour modelling is an interdisciplinary mathematical modelling method that evaluates what is happening and predicts what will happen through the external behaviour of humans. It has been successfully applied in a number of disciplines. Human behaviour is modelled based on rationality to find optimal solutions [10, 11], but, in practice, much human behaviour is found to deviate from rationality.

Steyn investigated contingency reserves in engineering projects and modelled workers' behaviour at construction sites, so as to use the model to predict contingency reserves and prevent economic overruns of the project and possible shortening of construction period [12]. Meel et al. investigated personnel management in chemical plants and analyzed the management relationship between plant risk calculations and human behaviour patterns to study the correlation between unsafe human behaviour and training the workers received [13, 14]. Zhang et al. analyzed risk factors of man-made accidents in underground engineering by modelling human behaviour from three aspects of safety cognition, behaviour, and physiological states of humans and proposed how to control man-made risk causes [15]. Ronchi modelled dynamic evacuation behaviour of the crowd in fire scenarios by starting with big data analysis. He put forward a theory of management and prevention of disasters caused by crowd gathering by the fitting analysis of large bulk of data of movement patterns of each individual in the crowd and their state performance [16]. Asilian-Mahabadi et al. surveyed a large number of relevant practitioners by studying the prerequisites for unsafe behaviour of front-line workers and managers in civil engineering and discussed the ability of human behaviour models to accurately expose the risk causes of unsafe worker behaviour [17]. van der Kleij and Leukfeldt analyzed the status quo of unsafe behaviour in cyberspace and proposed a new network resilience framework that integrates resilience engineering and human behaviour models. A pilot study of more than 60

small- and medium-sized enterprises in the Netherlands was conducted, the results of which could provide solid recommendations for organizations to better address cyberthreats [18]. Bai and Qian conducted a study on the validity and reliability of the human behaviour cognition factor and found that higher ratings of the people involved in such models had a greater contribution to quality assurance and safety behaviour in construction projects [19].

There are many similar studies that can reflect the existence of a management relationship between human behaviour modelling and accident risk, which means trends of human behaviour can be used to predict the likelihood of risk occurrence. This study aims to identify hidden risks in engineering by analyzing the distribution of workers' test scores.

2.2. Emotional Expressions in Facial Expressions.

Human facial expressions vary significantly under different emotions and the changes in facial expressions caused by each emotion are basically the same regardless of the country to which the person belongs. Therefore, studies related to emotion communication through facial expressions are mostly associated with human behaviour. Words can sometimes deceive, but a momentary change in facial expressions is difficult to hide.

Suhr et al. started with the rising crime rate of automated bank teller machines. As the machine's sensing system could not accurately determine sabotage, the offenders' facial expressions captured by the camera were identified, especially during the sabotage period, to build a model of facial expressions of emotion, and finally a correlation between facial expressions and insecure behaviour was identified [20]. Pantano collected data on the facial expressions of a large group of consumers when they were engaged in consumer behaviour to build a machine learning model and employed facial expression recognition system to evaluate consumer behaviour and activities, allowing salespeople to guide consumers according to their emotional activities [21]. Israel and Schonbrodt measured the physiological phenomena generated by changes in facial expressions (including facial electromyography, heart rate changes, and brain electrical changes) to create a benchmark test emotion evaluation system based on machine learning algorithms and found that human emotional changes could affect human behaviour [22]. Liu et al. proposed a multilabel and distributed learning approach to analyze students' facial expressions in the classroom and assessed teaching quality by observing respondents' facial expressions. Corresponding improvement suggestions on teaching models were proposed to educational administrators [23]. Monaro et al. used machine learning methods to identify facial microexpressions with the study subject of criminals in interrogation and introduced the concept of speaker cognitive load to determine whether criminals lied to conceal the truth during questioning with the help of machine vision. Given the same control group experiment, judgment by facial expressions was correct 78% of the time, compared to the 57% of human judges [24]. In the healthcare industry,

Altameem and Altameem developed a multimodal visualization analysis method by detecting facial expressions on patients to provide emergency treatment for patients through facial expression changes caused by adverse emotions [25]. De la Torre-Luque et al. found that emotion recognition is a key process of social cognition which reflects a person's maximal social adaptability. By comparing the facial expressions of a great number of normal people with those of psychopaths, a theoretical model for emotional decoding of human behaviour and facial expressions was developed [26]. Riquelme et al. collected a large amount of facial expression data of drivers and extracted feature codes to develop a driver fatigue monitoring system, which detects the driver's mouth aspect ratio, blinking frequency, and head tilt angle to determine whether the driver is in fatigue and alerts control staff in time, so as to avoid traffic accidents [27]. In a study on classroom teaching, Schneider et al. found that facial expressions are expressions of mental activity and that different facial expressions have a greater impact on learning efficiency. The analysis of the emotional state of facial expressions provides effective suggestions for educational administrators to improve students' learning efficiency [28].

Through the above scholars' research, it is found that changes in facial expressions can convey the inner activities of human beings, which is a great aid to judging the mental state of the test subjects.

2.3. Industrializing Worker Training.

"Industrializing workers" refers to, in China where the demographic dividend is gradually disappearing, the process by which construction worker teams, mainly migrant workers, are reeducated, assessed, and qualified to engage in industrial production with long-term work effectiveness. With 200 million mobile migrant workers in China, migrant workers need to receive instruction and education in industrial production ideas, science and technology, the use of wearable devices, and efficient and safe workforce regulations to become industrializing workers.

He's study found that vocational education occupies a greater proportion of worker industrialization, suggesting a connection model that combines higher vocational education and industrializing worker training in conjunction with the talent cultivation models in construction vocational colleges [29]. Wang and Ji conducted a research on the demand for construction workers in different development stages of construction industrialization, analyzed the differences between construction workers in developed countries and in China in various aspects, and pointed out the significance of safety education for industrializing workers and implementation of labor security system on promoting industrializing workers [30]. In a study on the risk cognition of Spanish workers, Rodriguez-Garzon et al. found that the industrial transformation efficiency of workers was related to working population mobility. By aggregation and clustering analysis, it was found that the worker groups who received multiple trainings had stronger risk perception ability [31]. In the industrial transformation

of workers in the construction of a laboratory at the Graz University of Technology, Karre et al. found that the key to transformation lied in supervision system and technical training should be strengthened [32]. Ke analyzed the complexity of the evolution from migrant workers to industrializing workers in the construction industry in China on the basis of CAS theory and made recommendations based on an agent-based modelling [33]. Hatami and Kakavand deemed that behaviour modification plays an indispensable part in worker industrialization and proposed the PRECEDE-PROCEED approach to evaluate the educational intervention effectiveness of occupational safety training on industrializing workers. As a result, the programme greatly reduced unsafe behaviour [34]. Radhakrishnan et al. combined the industrializing worker training system with artificial intelligence by using IVR technology to simulate accidents in a virtual environment and transmit the perception data of the trainers [35]. Cao et al. adopted a CHAID decision tree and chi-square analysis from the aspect of construction safety to explore the primary and secondary influencing factors and unrelated factors in education and training for industrializing workers. A five-factor method for training effectiveness was proposed [36].

Most of the previous studies have applied methods of traditional education industry to industrializing worker training, exploring the potential correlation between worker training effects and the reduction of accident probability. Combined with previous findings, this research focuses on the management relationship between training effect and risk factors occurrence in engineering.

In the previous studies, the calculation of risk and effect assessment was often based on the experts' criteria and ignored the influence of subjective wills. For example, it is difficult to know whether an expert is sensitive to a certain influencing factor and therefore the objective rules of development are ignored in the scoring. Moreover, the common mathematical model evaluation methods do not take into account the randomness and ambiguity of the evaluated objects, so the evaluation results sometimes differ greatly from the real situation. With the reduction of China's demographic dividend, the policy of industrializing workers has become an excellent strategy for China to address the coming huge labor shortage. There is still a large research gap on how to ensure the quality of training and education for industrializing workers. To fill this gap and make a combination to the prospect of highly intelligent industrial development in the context of Industry 4.0, this paper combines AI machine vision with an evaluation system as a theoretical basis. The industrial worker training evaluation system is improved by considering the combined effect of workers' personal influence and experts' subjective will, so that the industrial worker training evaluation results can make timely and effective rectification of hidden engineering problems in the existing project management process of prefabricated buildings construction projects.

3. Methods

3.1. Face and LFER Facial Expression Recognition Based on Multitask Convolutional Neural Network. A large number of algorithms for image segmentation and artificial intelligence

recognition already exist, and each algorithm is designed for different areas. For the background of this research, the MTCNN face recognition algorithm is selected for individual objects, and, because of the need for real-time evaluation of facial expressions, the Lighten Facial Expression Recognition (LFER) is chosen and improved as human facial expression recognition algorithm, and the FER2013 dataset is used for expression classification and recognition training.

3.1.1. MTCNN Human Face Recognition Method. The high accuracy of the MTCNN face recognition algorithm comes from the organic combination of face detection and facial landmark detection. In the face classification and bounding-box regression stage, the main framework of MTCNN is similar to that of the Cascade algorithm and can be decomposed into a three-layer network structure. Before detection, the images are transformed to different sizes and image pyramids are constructed to accommodate face images of different pixels.

The MTCNN implementation process mainly adopts the method of candidate box plus classifier to realize fast and efficient face detection. The three cascade networks are P-Net for fast candidate box, R-Net for candidate box filtering selection, and O-Net for generating face landmarks and face boundaries [37].

The training data for the MTCNN algorithm was sourced from the Wider and CelebA databases. Wider gives the face detection data and marks the coordinate information of the bounding box, and CelebA provides the five landmark coordinate points [38].

(1) P-Net. The Proposal Network (P-Net) consists of a fully convolutional network. Rough feature extraction and boundary calibration of image pyramid are realized through fully convolutional networks (FCN), and the Nonmaximum Suppression (NMS) and bounding-box regression are used for border filtering and adjustment. The initial filtering transmits possible face region images determined by classifier to the next layer of the network.

In the screening process, each input sample should be represented by a cross-entropy loss function, which requires the use of positive and negative samples. The probability calculation formula for the face is shown in the following equation:

$$L_i^{\text{det}} = -\left(y_i^{\text{det}}\log(p_i) + \left(1 - y_i^{\text{det}}\right)\left(1 - \log(p_i)\right)\right). \tag{1}$$

(2) R-Net. The Refined Network consists of a convolutional neural network with an additional fully linked layer, which is more complex than the P-Net. The images transmitted from P-Net are further filtered and adjusted to achieve high-precision filtering and optimization of face image regions.

In the process of border regression, for each candidate box, the loss between the predicted offset and the true coordinate offset needs to be calculated. The formula for calculating the regression loss by Euclidean distance is shown in the following equation:

$$L_i^{\text{box}} = \left\| \widehat{y}_i^{\text{box}} - y_i^{\text{box}} \right\|_2^2. \tag{2}$$

(3) O-Net. The Output Network has one more layer of convolutional neural network than R-Net and regresses the facial feature points of the filtered face image. The image features are saved in bulk to optimize the model performance. Finally, the coordinates of the top left and bottom right corners are output for plotting bounding boxes and five face image feature points are output.

Feature coordinate point location is similar to that of candidate box regression, in which the Euclidean distance between the candidate feature coordinate offsets and the true coordinate offsets needs to be calculated to obtain the overall loss function. The formula for calculating the regression loss from the Euclidean distance in the landmark sample and the overall loss function are shown in the following equation:

$$L_i^{\text{landmark}} = \widehat{y}_i^{\text{landmark}} - y_{i2}^{\text{landmark2}},$$

$$\min \sum_{j=1}^{N} \sum_{j \in \{\text{det,box,landmark}\}} \alpha_j \beta_i^j L_i^j. \tag{3}$$

An image structure overlay and deconstructed diagram of the three-layer network structure are shown in Figure 1.

3.1.2. Lighten Facial Emotional Recognition Method. Human facial expression recognition relies on the classification of human face images collected by face recognition algorithms, equivalent to adding a classifier to the face recognition algorithm. LFER uses an annual deep convolutional network to fuse face expression feature extraction and classification into an end-to-end network. VGG-16/19 and ResNet-18/101/164 are employed in expression recognition and classification. Dropout is added before the full linked layer to increase the robustness of the algorithm model and prevent overfitting. An increase in robustness will improve the stability of the model and increase its recognition ability. Overfitting will lead to a lack of dispersion, thus increasing the probability of misjudgment. The seven categories of expressions were feeling disgusted, angry, sad, worried, neutral, happy, and surprised. The full linked layer in VGG and ResNet is removed, and the concept of loss function and cross-entropy is introduced. The calculation process of cross-entropy is shown in the following equation [39]:

$$J(\theta) = -\frac{1}{m} \sum_{i=1}^{m} \left[y^i \log\left(h_\theta\left(x^i\right)\right) + \left(1 - y^i\right) \log\left(1 - h_\theta\left(x^i\right)\right) \right]. \tag{4}$$

The LFER algorithm uses Network Slimming and binarization methods for model compression to speed up recognition and employs Batch Normalization (BN) to reduce computation amount. The images of low BN indicator will be removed. The BN calculation formula is shown as follows:

$$\widehat{z} = \frac{(z_{\text{in}} - \mu\beta)}{\sqrt{\sigma_\beta^2 + \varepsilon}; z_{\text{out}} = \gamma\widehat{z} + \beta}. \tag{5}$$

3.2. Structural Entropy Weight Method. In information theory, entropy represents the measure of uncertainty of a dataset. The absolute value of entropy becomes larger as the uncertainty of the information expressed in the dataset increases, and the value of entropy contains more information. Correspondingly, the smaller the value of entropy is, the poorer the information it contains and the more homogeneous the meaning of the representative indicator is.

Since SEWM has the function of both quantitative and qualitative analysis, it can be called an objective empowerment method in which the variation of values depends on the dispersion of the calculated dataset. The basic process of SEWM calculation is as follows: firstly, making a combination with Delphi method and fuzzy analysis method. The fuzzy analysis method is used to fuzzify the experts' scores and quantify the ranking according to the subjective will of the experts. After the quantification is completed, the normalization process is performed. Then, cognitive blindness degree analysis and entropy calculation are performed for the quantitative order of experts' judgments, and the possible bias due to the subjective opinions of experts is corrected. Finally, the weighting value is calculated [40]. The detailed calculation and formula are shown below.

3.2.1. Arranging the Quantization Order of the Datasets. According to the Delphi method, k experts in the relevant fields are selected to fill out the questionnaire. The basis of data acquisition in this paper is built on machine vision, so the sample data of answers from k relevant workers can be used as the data source. The questionnaire taken by the original Delphi method is replaced by a random fixed number of classified questions from the question bank.

The importance of the sample data is obtained by the positive and negative selection method considering facial expressions in this paper, where 1 is an important indicator and n unimportant. For the i samples and j indicators in the dataset, where $1 \leq i \leq k$ and $1 \leq j \leq n$, the representation performed by the a_{ij} array is shown as follows:

$$a_{ij} = \begin{bmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{k1} & \cdots & a_{kn} \end{bmatrix}. \tag{6}$$

3.2.2. Making Normalization of Indicators: Homogenization of Heterogeneous Indicators. Each indicator may have inconsistent measurement units in statistical decision-making, so it is necessary to standardize the sorted datasets and convert the relative values of indicators into absolute values to solve inconsistent measurement methods for different indicators. Since the normalization of the data group value is an absolute value, the greater the difference in the Hamming distance of each normalized data, the greater the dispersion.
FIGURE 1: The image structure overlay and deconstruction of the P-Net, R-Net, and O-Net network structures. (a) Image pyramid. (b) O-Net. (c) P-Net. (d) R-Net.

The normalization processing method is related to the calculation method, as shown in (7) and (8):

Positive indicators:

$$a'_{ij} = \frac{a_{ij} - \min\{a_{1j}, a_{2j}, \ldots, a_{nj}\}}{\max\{a_{1j}, a_{2j}, \ldots, a_{nj}\} - \min\{a_{1j}, a_{2j}, \ldots, a_{nj}\}}. \quad (7)$$

Negative indicators:

$$a'_{ij} = \frac{\max\{a_{1j}, a_{2j}, \ldots, a_{nj}\} - a_{ij}}{\max\{a_{1j}, a_{2j}, \ldots, a_{nj}\} - \min\{a_{1j}, a_{2j}, \ldots, a_{nj}\}}. \quad (8)$$

To simplify the formula, the normalized data a'_{ij} is still denoted by a_{ij}.

3.2.3. Weight Calculation for Qualitative Analysis and Quantitative Analysis.

Relying on the concept of entropy weight method, the quantitative analysis data is revised, where I is the order in the data group and m is the conversion parameter whose values are usually equal to $j + 2$ ($m = j + 2$) [40]. The quantitative analysis correction is shown as follows:

$$\mu(I) = -\frac{\ln(m - I)}{\ln(m - 1)}. \quad (9)$$

Substituting a_{ij} into the above formula, the quantitative analysis correction array b_{ij} is obtained. The expert cognitive blindness degree analysis parameter Q_j is introduced. The calculation formula of Q_j is shown as follows:

$$Q_j = \left| \frac{\left\{ \left[\max\{b_{1j}, b_{2j}, \ldots, b_{nj}\} - b_j \right] + \left[\min\{b_{1j}, b_{2j}, \ldots, b_{nj}\} - b_j \right] \right\}}{2} \right|. \quad (10)$$

The perception of the relevant respondents for the indicator is defined as x_j and the standardized weights are calculated. The calculation process is shown in the two following equations:

$$x_j = b_j(1 - Q_j). \quad (11)$$

$$\omega_j = \frac{x_j}{\sum_{j=1}^{n} x_j}. \quad (12)$$

3.3. Similarity Aggregation Method.

For the possibility of fuzzy numbers and uniform or normal distribution, the linguistic terms and sentiment labels of the relevant descriptions are expressible as affiliation functions of different values. In previous risk assessments, triangular and trapezoidal fuzzy numbers were mostly used. For qualitative and comparative analysis, converting collected data into fuzzy numbers is more adaptable than converting them into probability distributions [41]. In this study, it is necessary to use the improved SAM to convert the data into fuzzy numbers for aggregation and then to evaluate the effect through weight calculation.

This study proposes an improved SAM that introduces the concept of emotional expression when inputting data and changes the previous expert evaluation system to the facial expression recognition dataset of the surveyed person. The method quantifies the change in respondents' emotions during the test through human behaviour modelling, and the resulting fuzzy numbers are corrected based on multiple factors. In previous studies, some scholars selected experts' position, duration of practice, age, and education as rank divisions [42].

The improved SAM calculation processes are as follows:

(1) Suppose that there are E_i experts, where $1 \le i \le k$. Calculate the consistency $S(\widetilde{R_u}, \widetilde{R_v})$ of quantitative data for each expert (respondent), where R_u and R_v are the fuzzy numbers of S. The formula of quantitative data consistency is shown as follows:

$$S(\widetilde{R_u}, \widetilde{R_v}) = 1 - \frac{1}{5 \sum_{i=1}^{5} |a_i - b_i|}, \quad (13)$$

a_i and b_i represent the evaluation parameter values of different qualitative analysis. The larger the S value, the more unified the opinions of experts (respondents).

(2) Subsequently, the Delphi method was used for secondary quantitative analysis, combined with credibility to improve the reliability of aggregated analysis results. Finally, the consistency $WA(E_u)$ of weighted agreement (absolute value) is calculated, and the relative consistency $RA(E_u)$ and the consistency coefficient $RC(E_u)$ of the expert dataset are calculated according to the expert's $WA(E_u)$. In previous studies, some scholars introduced the concept of relaxation factor δ, $\delta \epsilon [0, 1]$. When the value of δ approaches 1, it means that the experts' judgment weight is the main basis; when the value of A tends to 0, it means that $RC(E_u)$ is an indicator of the relative value of experts' judgments. Finally, the summary results of experts' opinions are calculated to obtain the overall fuzzy number $\widetilde{R}$. The calculation formula of $\widetilde{R}$ is

$$\widetilde{R} = \sum_{u=1}^{M} \left[RC(E_u) \times \widetilde{R_u} \right]. \quad (14)$$

4. Data Survey and Model Establishment

4.1. Data Investigation and Collection. The data for this study, done with the assistance of Python 3.8 programming language, were obtained from the results of the responses to the questions drawn from the question bank, which were all multiple-choice questions about knowledge related to safety in assembled buildings, divided into five sections: Knowledge about Engineering Project Management (KPM), Cautions at Construction Site (CCS), Prefabricated Component Hoisting and Installation (PHI) Knowledge, Emergency Accident Handling Methods (EAM), and Laws and Regulations Related to Construction (LRC). As respondents took the training test, cameras were used to capture their facial expressions, recorded at 30 frames per second, with a 10-second response time for each question and a final 2-second answer checking phase. The footage is then split at 15-frame intervals. Twenty face images are collected for each question, and each respondent can provide 2000 face images for analysis. The pseudocode of collecting facial expression data for the industrializing worker training test is shown in Algorithm 1.

Subsequently, every 20 images were formed into a data group for expression analysis using the MTCNN-LFER model. Firstly, the acquired images are decomposed into image pyramids and then imported into the three-layer volume and network P/R/O-Net for expression analysis and recognition. The recognition process is shown in Figure 2. Then the probability of emotions is determined based on the relative coordinates of the expression features, and the output of the determination is shown in Figure 3.

4.2. Evaluation Model of Facial Expression Recognition for Industrializing Worker Training. Quantitative analysis of the collected data is required before the construction of the expression recognition evaluation model. The difference between the data collection phase of this study and the establishment of previous evaluation models is that previous evaluation models mostly use the mechanism of expert scoring, while that in this study is derived from the respondents' status while taking the answer test. This study uses the Likert's seven-level scale method to assign different categories of facial expression recognition (including disgusted, angry, sad, worried, neutral, happy, and surprised) from 1 to 7 points. The formula for preliminary scoring is shown in Equation (15). t is the moment, p_{emo} is the bias probability for each expression, and S_{l7} is the assigned score on the 7-point Likert scale. S_r is the parameter for correct or incorrect answers, and when the answer is correct, S_r is 1.2; otherwise, S_r is 0.8. The division of expression scores based on Likert's seven-level scale is shown in Figure 4 [43].

$$W_{emo} = \sum_{t=1}^{20} \sum_{p_{emo}=1}^{7} \left(\frac{p_{emo} \times S_{l7}}{n} \right) S_r. \quad (15)$$

However, the assignment of expressions is not the final "expert score," because the data comes from training tests, and the answers will be right or wrong. However, in the process of testing, workers may be unskilled in the operation of electronic equipment or emotionally resulting in deviations in the visual area. Furthermore, there is a possibility that when a worker encounters an uncertain option, he guesses the correct option by luck. Monaro et al. [24] defined the concept of error and hesitation degree in the research of facial expression detection deception. Through the survey, it was found that, due to differences in education, gender, age, and other influencing factors, different people will have abnormal facial expressions when they make judgment. According to the average conditions of Chinese workers, the range of the error degree τ is 0.6514 ± 0.1343, and that of hesitation degree v is 0.4875 ± 0.098 [24].

In view of the above situation, this article expresses the worker's facial expression changes and corresponding moments of each question with images and selects 4 curved surfaces and curves under abnormal mood fluctuations as special images for analysis. The four abnormal images are shown in Figure 5. According to the fluctuation trend of the four curves, it can be analyzed as the four following situations.

Situation 1. When the respondents first saw the topic, the expression was worried, indicating that the worker did not understand the randomly selected topic and felt worried. But, in the subsequent reading stage, workers who are skilled in training knowledge tend to be natural in their expressions. After finishing reading the questions, if the workers have a good memory of the correct answers, their facial expressions will turn into a happy state and will turn into a natural look during the answer verification stage.

(1) Import the video recorded by workers during the test into the program.
(2) if cap.grab ():
(3)   numframe + = 1
(4)   if numframe %15 = = 1: # Screenshot of dismantling the video.
(5)   flag, frame = cap.retrieve ()
(6)   end if
(7) Save the video split images to the specified path, and the naming rule is str(numframe/15).
(8) Import the image disassembled by video.
(9) $i = 0$; $m = 0$; $t = 0$
(10)   if≤100:
(11) $i + = 1$
(12)   if $t \leq 20$:
(13) $t + = 1$; $m + = 1$
(14)   Import the image numbered T for expression recognition, and input the recognition data into m rows.
(15)   end if
(16)   Arrange the positive and negative expression choice array by Eq. (3).
(17)   The array is normalized by Eq. (4) and (5).
(18)   The standardized weights are calculated by Eq. (6)–(9).
(19) end if

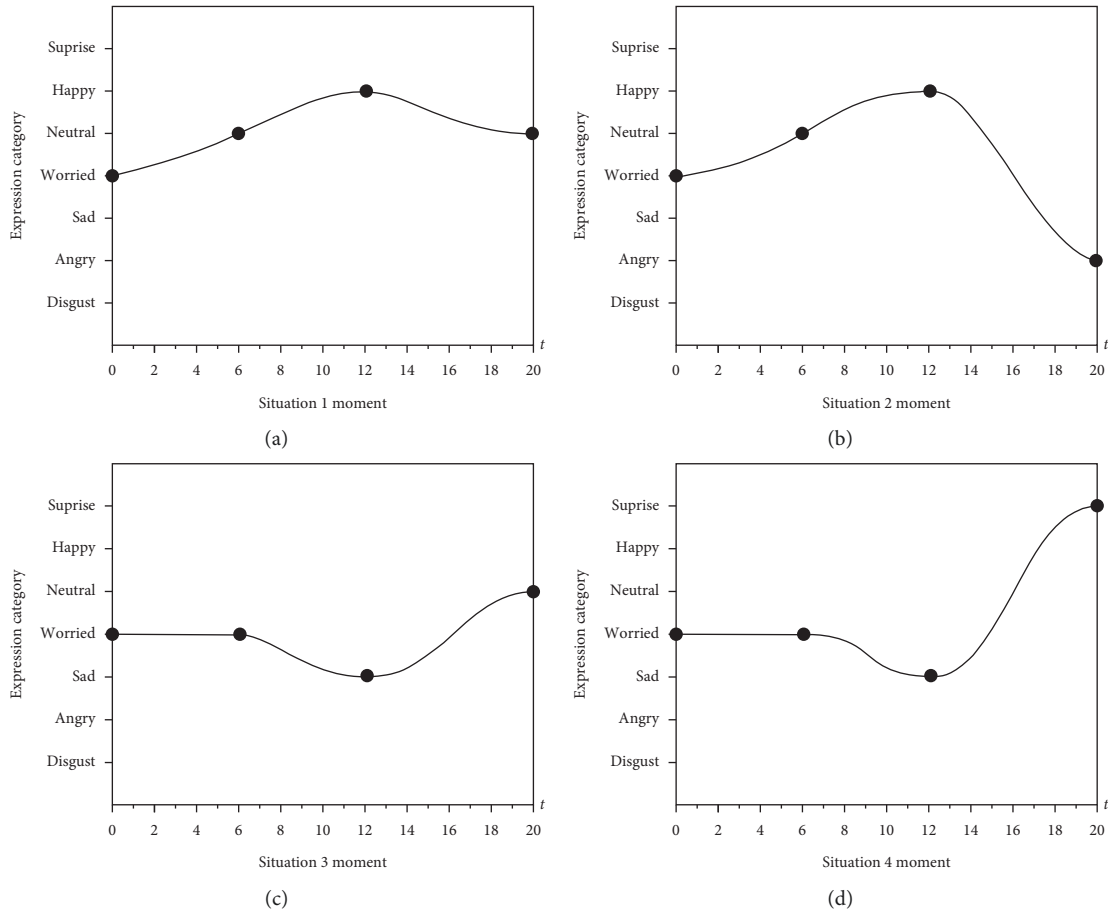
FIGURE 4: Expression score division based on Likert's seven-level scale.


FIGURE 5: Diagram of four abnormal mood fluctuations. (a) Situation 1. (b) Situation 2. (c) Situation 3. (d) Situation 4.

Situation 2. Before the answer verification, it is the same as situation 1. When checking the answers, if the worker is fully sure of the knowledge points involved in the question, but when making choices, it may be due to operational errors or incorrect memory, which may cause the worker to have a short period of frustration during the test. In order to eliminate the worker's wrong operation and memory error, the error degree τ ($\tau = 0.7$) is introduced for the first time to correct the evaluation score of the worker's answers.

Situation 3. When workers are not very familiar with randomly selected questions, they will maintain a worried look at the initial reading stage; then when thinking about the questions further, they will show sadness and regret expressions due to the vague memory. In the answer verification stage, as the

wrong answer is expected, the worker's expression will return to a sad look, worrying about the next question.

Situation 4. Before the answer verification stage, it is similar to situation 3. When checking the answers, they will feel surprised because of the unexpected correct answers. However, the workers' choices under this emotion are only done through luck and guessing, so this study introduces hesitation degree v ($v = 0.45$) to modify the evaluation score of the workers' answers [44].

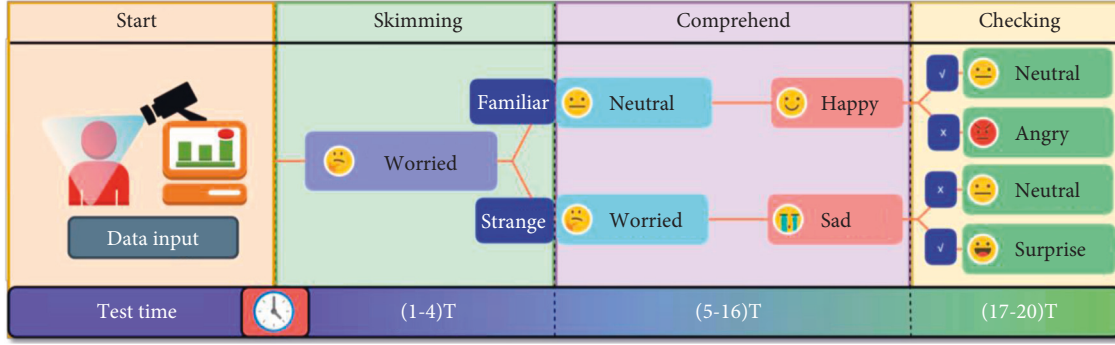
Based on the four situations of emotional changes in industrializing workers training test under normal conditions, this paper establishes an emotional analysis and evaluation process for industrializing workers training test. The process is shown in Figure 6.


FIGURE 6: Evaluation process of sentiment analysis of industrializing worker training test.

According to process analysis, (15) is improved with the introduction of the concepts of error and hesitancy degree. The improved expression score division weight calculation method is shown as follows:

$$W_{emo} = \left(\sum_{t=1}^{4} \sum_{p_{emo}=1}^{7} \left(\frac{p_{emo} \times S_{l7}}{n} \right) + \sum_{t=5}^{16} \sum_{p_{emo}=1}^{7} \left(\frac{p_{emo} \times S_{l7}}{n} \tau \right) + \sum_{t=17}^{20} \sum_{p_{emo}=1}^{7} \left(\frac{p_{emo} \times S_{l7}}{n} v \right) \right) S_r. \tag{16}$$

All data collected in this study were entered into the evaluation process, and the results were calculated with SEWM-SAM to derive the final weight ranking. The highest weight value is the most significant point of the model source data.

5. Result

This survey study relies on a prefabricated building project at Langfang Airport Free Trade Port, which is implementing a career path promotion for industrializing workers. After training and reeducation of the workers, a worker who had recently violated engineering regulations was selected and surveyed and analyzed by using the model developed in this paper. The testing system in this study draws 100 questions at a time from a pool of safety knowledge questions, with 20 questions in each of the five professional directions. Two thousand images and 14,000 cells of analysis data were collected for a single worker.

5.1. Facial Expression Recognition Score Based on MTCNN-LFER. Taking the multiple-choice questions in the construction site precautions test as an example, the collected images of respondents' expressions at that time were analyzed and imported into the facial expression recognition evaluation model for industrializing worker training in this study for score evaluation. According to the grading level of the education industry, 75% of the highest value is taken as the pass line. The process of image analysis and data extraction imported into the model is shown in Figure 7. The facial expression analysis data are shown in Table 1.

The data scores of 20 moments for each question were brought into the model of this paper and calculated by equation (16) to get W_{emo} value for each question. The values are shown in Table 2.

Find the average of W_{emon}, which is $\overline{W_{emon}}$ of the current question, indicating the average value of the standard scoring of this question in the evaluation system, which can be used as SWEM expert scoring data.

5.2. Numerical Solution of SEWM Weight. The test questions were graded into 5 first-level indicators and 20 second-level indicators by analyzing the collected image expression emotion data. The 5 first-level indicators are KPM, CCS, PHI, EAM, and LRC, and the 20 second-level indicators correspond to the questions under each first-level indicator. The expression scores of different moments represent the scoring values of experts. The weights of second-level indicators related to Section A are shown in Table 3.

After calculating the weights of the second-level indicators of the five sections, the values are used as the reference data for conducting the comparative solution. First, the extreme values of the second-level indicators' weights are transformed into fuzzy arrays, whose classifications are shown in Table 4. The weight of a single second-level indicator is multiplied by the corresponding grade score to find the average value, and the approximate integer solutions are the data of the first-level indicators. Then the data are substituted into equations (6)–(12) to get the weights of the first-level indicators. The weights of the first-level indicators are shown in Table 5.

From the first level and second level of indicator weight values, it can be analyzed that the expression data plays a decisive role in the evaluation of each question, and the change of the values can be divided into 3 segments, where the middle segment has the greatest influence, and when the good emotion overlaps with the correct option, the final comprehensive weight value will be larger.

5.3. Analysis of the Significance of SAM

5.3.1. Establishing Linguistic Fuzzy Sets.
In this study, five levels of fuzzy classification languages are used for expert inspiration. The fuzzy linguistic number set is determined by trapezoidal fuzzy numbers. The hazard impact assessment levels are shown in Table 6. In this study, 20 questions in each section are used to assess the understanding of surveyed workers on the 5 sections, and the total fuzzy number is derived from the formula to measure the implementation effect of industrializing worker training, where the relative weights of the sections are equal to the weights of the first-level indicators of each section.

The fuzzy language set of the expert evaluation classification is substituted into (13) as the parameters a_i and b_i,

and the evaluation data of each section are aggregated through SAM. Because the relaxation factor requires a large number of actual events to be tested, as a new method proposed for the training of industrializing workers, this study refers to relevant literature and takes the general value of the relaxation factor $\beta = 0.5$ as the test.

5.3.2. Acquiring Aggregation Fuzzy Numbers. A calculation of the consistency of the fuzzy language scale array to which each section belongs is made. The calculation process is as follows: $S(\widetilde{R}_1, \widetilde{R}_2) = 1 - [(0.4 - 0.2) + (0.4 - 0.3) + (0.5 - 0.4) + (0.6 - 0.4) + (0.6 - 0.5)]/5 = 0.86$. The results are substituted into the calculation of the weighted agreement degree WA(E_n) and the relative agreement degree RA(E_n). Then the relaxation factor is used to calculate the expert agreement coefficient, for example, CC$(E_1) = 0.5 \times 0.3706 + (1 - 0.5) \times$ RA(E_1). Substituting the expert weighted agreement degree, relative agreement degree, and agreement coefficient into (14), the overall fuzzy number R can be calculated. The calculation data of experts' opinions fuzzy aggregation indicators are shown in Table 7.

Through aggregation calculation, the aggregation total fuzzy number $\widetilde{R} = (0.3909, 0.5309, 0.5990, 0.4590, 0.6590)$ of expert opinion aggregation is obtained. The aggregated total fuzzy number and the second-level indicators are made into a cluster analysis, as shown in Figure 8. According to the images of the data group, it can be seen from the feedback from the training test of industrializing workers that the worker has the worst knowledge of relevant construction laws and regulations, which is in line with the fact that he has made mistakes in the project funds recently.

According to the statistics of the correct rate of the questions in the 5 sections, the correct rates of the questions in Section 2, 3, and 5 are all more than 75%, indicating that the worker has passed the test in these areas. However, with the score gap in Section 5 being too huge, it is necessary to verify whether it is personal reasons or a faulty training system that caused this result.
FIGURE 8: Cluster analysis of industrializing worker training management system.

5.4. Model Validation. This study relies on a prefabricated building project at Langfang Airport Free Trade Port and conducts surveys and statistics after the construction of the project. A total of 17 engineering hidden dangers and accidents were found in the acceptance stage. The 17 hidden dangers and accidents were classified according to the 5 first-level indicators in this study. The classified statistical graph of the number of hidden dangers and accidents in the Langfang Airport Free Trade Port prefabricated building projects is shown in Figure 9.

In this study, 10 workers who participated in the construction of prefabricated buildings in Langfang Airport Free Trade Port were randomly selected for training effect assessment, and the results were calculated. The aggregated total fuzzy number values are shown in Table 8.

The aggregated total fuzzy number of training assessment of 10 workers was compared with the number of engineering hidden dangers and accidents in the acceptance stage of Langfang Airport Free Trade Port. The association chart between industrializing workers' training assessment results and potential dangers and accidents in Langfang Free Trade Port project is shown in Figure 10.

From the comparison in the figure, it can be found that the aggregated total fuzzy number value of the worker's training assessment results is positively correlated with the probability of occurrence of such hidden dangers and accidents in the engineering projects that the worker is engaged in. As can be seen from Figure 10, the group of workers in the project at Langfang City Airport Free Trade Port was not well trained in CCS, PHI, and LRC, so the project has many hidden dangers and accidents in the
Figure 9: Statistical graph of the number of hidden dangers and accidents in the Langfang Airport Free Trade Port prefabricated building projects.

acceptance stage, with 4, 5, and 5 cases, respectively, which proves the correctness of the model proposed in this study.

6. Discussion and Conclusion

6.1. Discussion. In the process of building the model, MTCNN-LFER was used to analyze the respondents' facial expressions in real time in order to conform to objective facts, and four situations were analyzed according to the characteristics of expression changes under different mental activities. In previous evaluation system, respondents' feedback was only scored based on their performance results. For example, in Scenario 2, the respondents' misselection would be directly judged as a wrong situation according to the conventional evaluation system. However, their initial judgments are valid. Inaccurate evaluation results will lead to wrong final rating, thus affecting workers' training enthusiasm. For construction units, wrong evaluation leads to redundant training course arrangement, which affects the efficiency of workers' industrialization process and also wastes a lot of financial and material resources [33].

However, there is another situation, such as Situation 4, where the worker guesses the correct option. For this case, the traditional evaluation method does not consider whether the worker has a solid knowledge of the question but only recognizes that the worker's choices are correct and thus determines that the worker has a high level of mastery of such knowledge. According to the description of human behaviour, humans always make constant rather than consistent and repetitive guesses about the unknown. The worker will choose another answer when the correctly guessed question is retested in a short time. For workers, with the help of good luck to save time and effort, they do not need to master engineering-related knowledge. However, for construction units, workers who muddle through with this trick may cause greater property damage or even affect engineering safety and cause malignant casualty accidents. Therefore, it is necessary to introduce relevant parameters to modify the model to ensure that the model is suitable for the development rule of objective facts, so that the applicability of the evaluation system is stronger, which will have guiding significance for similar industries.

According to the final weight calculation and cluster analysis results, it was found that, in some knowledge sections, although a small number of them scored high and the final composite score was higher compared with other sections, there was a large dispersion, which proved that workers did not have a firm grasp of such knowledge and still many knowledge points needed to be checked and remedied. Therefore, even though the overall score is the highest, there is still a need for training and education. In engineering construction, muddling through is never an option, as workers with poor knowledge may have a great impact on the entire project. In Li et al.'s study, it was noted that unsafe behaviour in engineering is related not only to the workers' own behaviour but also to cognitive biases in different contexts. Poor worker handling can also contribute to engineering accidents; however, the correctness of the handling is related to the way the worker chooses to deal with the problem [45].

The weight solution of this study for each question can also give feedback on the proficiency of the question in the section to which it belongs; in particular, the test after training can reflect whether workers have evasive behaviour for a certain knowledge point. Chen has suggested in previous research that workers will often adopt unsafe behaviours to ensure that progress is efficient [46]. This type of problem can be explained by the pattern presented by the group industrial worker training test to explain the current engineering safety climate problem that exists in the group of industrial workers.

For example, a worker has insufficient knowledge about construction phase reports when answering questions, and most of the workers in the construction team have this situation; then it can be inferred that the construction is in poor quality. The root of this can be found to be a hidden line of conflict of interest between the worker, the construction unit, and the regulator [47]. The quality of training of the group can thus be screened to identify more hidden dangers that affect the economy and safety of engineering under the policy of industrializing worker training process.

According to the model validation, it can be seen from the calculation and analysis of the evaluation results of the training management of industrializing workers in this study that hidden dangers and accidents in engineering projects are closely related to the skills mastered by workers. In all construction stages of engineering projects, the management of industrializing worker training can be improved to eliminate possible hazards and stop accidents in time to ensure safe, economical, and stable construction and production of the engineering project.

6.2. Conclusion. This paper is based on the background that the Chinese government proposes to accelerate the process of industrializing workers in response to the rapid reduction of the domestic demographic dividend and the rapid weakening of the labor advantage in the era of Industry 4.0. The artificial intelligence machine vision and fuzzy mathematical evaluation system are combined to test the workers who receive industrializing training and record the information related to the change of facial expressions and the correct rate of assessment when the workers receive the test assessment. In addition, the evaluation model of facial expression recognition for industrializing worker training is used to conduct qualitative and quantitative analysis and finally arrive at the aggregated information results. The main conclusions of this study are as follows:

(1) The expert scoring mechanism in the evaluation model is improved by using machine vision to analyze the changes in workers' facial expressions during the test to determine their mental activities, effectively preventing the waste of money and time for subsequent training due to wrong operations. It also prevents workers from guessing the answers and ignoring the forgotten knowledge points, which reduces the possibility of more safety accidents and property damage to the project.

(2) The questions of each section are converted into primary and secondary indicators to conduct an aggregation consistency analysis, and the weight of each indicator and the significance of the aggregation analysis are used to indicate the degree of mastery of the tested workers on the knowledge of each section. According to the discrete degree of each question, we can check whether it is a common problem of the construction workers and can timely find out the safety, economic, or management hazards.

In this paper, although the necessity of objective facts is considered to the greatest extent when analyzing and mathematically modelling the changes in facial expressions of workers doing the test, there still exist the following deficiencies:

(1) There is no evaluation or research analysis of workers' psychological states. Actually, the differences in personalities and psychological states may affect the accuracy of emotions conveyed through facial expressions during the test.

(2) In analyzing the dispersion of each knowledge point, only the problems of the workers were considered, but, in fact, it is possible that some irregularities caused by "traditional experience" of the industry lead to workers not recognizing the standardized operation, or some people with management authority forbid workers to follow the standardized practice of construction or project handling.

These deficiencies can be refined in future research and solved by multiobjective optimization methods.

Portfolio optimization is one of the most complex problems in the financial field, and technical analysis is a popular tool to find an optimal solution that maximizes the yields. This paper establishes a portfolio optimization model consisting of a weighted unidirectional dual-layer LSTM model and an SMA-slope strategy. The weighted unidirectional dual-layer LSTM model is developed to predict the daily prices of gold/Bitcoin, which addresses the traditional problem of prediction lag. Based on the predicted prices and comparison of two representative investment strategies, simple moving average (SMA) and Bollinger bands (BB), this paper adopts a new investment strategy, SMA-slope strategy, which introduces the concept of k-slope to measure the daily ups and downs of gold/Bitcoin. As two typical financial products, gold and Bitcoin are opposite in terms of their characteristics, which may represent many existing financial products in investors' portfolios. With a principle of $1000, this paper conducts a five-year simulation of gold and Bitcoin trading from 11 September 2016 to 10 September 2021. To compensate for the SMA and BB that may miss buying and selling points, 4 different parameters' values in the k-slope are obtained through particle swarm optimization simulation. Also, the simulation results imply that the proposed portfolio optimization model contributes to helping investors make investment decisions with high profitability.

1. Introduction

Industry 4.0 was first introduced in 2013, defining "the transition from a time when people worked with computers to when computers work without humans." The world is witnessing the development of information technology and the widespread use of computers. The emergence of Industry 4.0 has impacted global financial markets and continues to drive technological iterations in the financial field [1]. Portfolio optimization has always been a popular topic in modern financial research, and investors with different capital levels have to face the problem of portfolio selection [2]. The optimal portfolio selection yields the highest expected return within an acceptable risk range [3], but high returns usually come with high risks [4]. Technical analysis uses historical long-term and

short-term stock trends to help investors make informed and profitable trading decisions [5]. Zhu and Zhou pointed out that technical analysis can add value to stocks when their returns are predictable. It contributes to identifying trading opportunities when there are uncertainties about stock returns [6]. Portfolio optimization in the real world is a very difficult and complex mathematical problem [7]. Based on the technical analysis, the portfolio optimization of gold and Bitcoin is divided into two subproblems, daily price prediction and decision algorithms of investment strategies.

1.1. Price Prediction. Intelligence in manufacturing is considered an essential hallmark of Industry 4.0, driven by the boom and maturity of new information and communication

technologies applied to industrial processes and products [8]. The growth of available information in industrial plants has contributed to the widespread use of machine learning in addressing specific industrial needs [9]. In the era of Industry 4.0, prediction is a hot topic, especially the ability to predict events related to industrial assets and production processes [10]. With the vigorous development of artificial intelligence (AI), many optimization techniques based on machine learning and deep learning have favored many investors, which are applied to predict the prices of financial products, especially stock price prediction. There are many optimal methods for stock price prediction, but no perfect solution has been developed yet. Stock prices are affected by multiple factors in the stock market, and the mechanisms of these factors are incredibly complex. Changes in investor sentiment are also a major cause for changes in stock prices, which are usually analyzed by sentiment analysis. With evaluation of the causal relationship between VIX and BTC, Chi concluded that Bitcoin is not a safe asset in a climate of fear, which contributes to obtaining the most risk returns [11]. Moreover, some external factors like the black swan event are difficult to predict but significantly impact stock prices. For example, the COVID-19 pandemic is a black swan event for financial markets [12].

Time-series forecasting is traditionally performed in econometrics using the autoregressive integrated moving average (ARIMA) model [13]. But some problems of the ARIMA model are gradually emerging as it is applied in different fields: (1) As a linear model, it is difficult for the ARIMA model to establish nonlinear relationships between variables. (2) Given that stock prices are usually noisy, volatile, and nonparametric, it should be a complex nonlinear problem. However, the error of the ARIMA model cannot have a constant standard deviation. Kane found that although the problem in the ARIMA model can be solved to a certain extent using the ARIMA-GARCH model, there are some problems of the optimization of parameters in the generalized autoregressive conditional heteroskedasticity (GARCH) model [14]. Sai optimized the kernel function of the support vector machine (SVM) and used the optimized model to predict and analyze the investment stock index, which performed significantly better than the ARIMA model [15]. With the development of neural networks and the superiority of long short-term memory (LSTM) in natural language processing tasks, LSTM has been applied to the same time-series stock price prediction problem. Ma compared the performances of three models in stock price prediction, the ARIMA model, the artificial neural network (ANN) model, and the LSTM model. Mahas found that the LSTM model performs better because of its improvement on the vanishing gradient problem [16]. Yurtsever noticed that LSTM performed the best by comparing three multivariate time-series models (LSTM, Bi-LSTM, and GRU), using six indicators of crude oil price, consumer price index, stock market index, effective exchange rate, interest rate, and gold price as model inputs [17]. Saifi proved that the LSTM-based prediction model is slightly better than other prediction models (GRU, DNN, and RNN) in Bitcoin price prediction (regression) [18]. Selvin et al. tested the performance of CNN, LSTM, and RNN on the same sliding window and concluded that CNN can capture short-term trend changes and achieve better results than LSTM and RNN because CNN does not rely on any previous information to make predictions. It only uses the current data window to make predictions [19]. Fleischer et al. used LSTM to evaluate predictions for cryptocurrencies such as Bitcoin and pointed out that the results seemed promising as the predicted values deviate very little from the true values. Still, upon closer inspection, it turned out that the prediction lags by a day since stock prices follow the random walk theory, which means that the nature of their movement follows a random walk; that is, changes in prices are not necessarily the result of previous changes [20].

1.2. Investment Strategy. Decision-making, a kind of human behavior aimed at achieving a specific goal, occurs in every activity of human society [21]. An investment strategy is a set of rules to guide investors in trading decisions. The right investment strategy is critical to an investor's success, which requires every investor to analyze as much of the available data as possible [22]. The simple moving average (SMA) and Bollinger bands (BB) are common investment strategies. SMA uses two moving averages, a long period and a short period moving average, which is straightforward to help investors make decisions [23]. Liu and Malik proposed a neural network-based framework to improve profit generation, where SMA effectively measures the volatility of stocks [24]. SMA has good stability, which is not influenced by temporary price fluctuations. BB consist of three lines, the upper, the middle, and the lower. BB can be used to recognize volatility and trends of the price, which allow investors to realize the breakouts. BB were applied to identify stocks with the highest profitability [25]. However, SMAs do not react promptly enough to rapid price changes at market reversal points, and BB overly reply to current market movements. The flaws of SMA and BB may cause investors to miss suitable and favorable buying and selling opportunities. In addition to providing the right time to buy and sell, the buy and sell ratio is also the focus of the investment strategy. Particle swarm optimization (PSO) was adopted to optimize the trading setups of Bitcoin [26]. Zhu et al. applied PSO to a metaheuristic approach to solving the intractability of portfolios [27]. Also, Butler and Kazakov pointed out that PSO can offer better trading results [28].

1.3. Contribution. This paper adopts the technical analysis to establish a portfolio optimization model based on the unidirectional dual-layer LSTM model and the SMA-slope strategy. The unidirectional dual-layer LSTM model is developed to predict gold and Bitcoin's daily average price data, which realizes one of the most important goals of Industry 4.0, intelligent prediction. It is a common approach to designing portfolios with an investment horizon greater than one year based on daily data [29]. Also, we propose a weighting method to address the traditional problem of prediction lags. The unidirectional dual-layer LSTM model is trained and tested on the two datasets, daily gold prices

(London Bullion Market Association, 9 November 2021) and daily Bitcoin prices (NASDAQ, 9 November 2021). Gold and Bitcoin are two diametrically opposed financial products due to their widely varying volatility trends and opposed characteristics, such as linearity and stability. Also, this paper introduces the SMA-slope strategy. The SMA-slope strategy uses PSO to determine the optimal buying and selling ratio. It also increases the buying and selling points using the concept of k-slope based on the SMA strategy, which solves the insensitivity of the SMA strategy to short-term price fluctuations. The introduction of the k-slope reflects a kind of human behavior, as investors do not tend to change their existing views until they are convinced of new plausible trends [30]. Simulation is a key technology in the era of Industry 4.0 [31]. With an initial principal of $1,000 and different trading commissions as a prerequisite, we compare the SMA-slope strategy to the SMA and BB strategies by simulating 5 years of actual trading from 2016 to 2021.

At present, most researches focus on the price prediction and investment strategies of stocks. Based on the technical analysis of stocks, this paper considers the portfolio optimization for gold and Bitcoin. Gold and Bitcoin are typical products of the financial market, which have opposite characteristics. The study of the portfolio optimization of these two financial products contributes to optimizing the portfolio of various products with different characteristics in the financial market. Also, more attention has been paid to regression evaluation indicators like RMSE and MAPE while predicting prices. Few studies have focused on the performance of times-series models on stocks and gold/Bitcoin in terms of prediction lags. The prediction lag is a traditional problem of time-series problem, and researches have shown that LSTM can solve it to some extent [32]. This paper focuses on the prediction lag and employs a lag metric (up and down accuracy) to assess the performance. A small sliding window is used to forecast, and predicted prices for the next few days obtained by the model are weighted. The specific weights are obtained from various tests, which improve the accuracy of the rise and fall. Moreover, few papers provide a comparative analysis of the SMA strategy and Bollinger band strategy, and the buying and selling points due to these two strategy measures are not addressed. In this paper, the SMA-slope strategy is proposed based on the concept of k-slope, which conduces improving the sensitivity to reasonable buying and selling points.

2. Methodology

2.1. Feature Selection. Based on the literature review [33, 34] and data availability, we select 18 features: simple moving average (SMA), relative change (RC), exponential moving average (EMA), moving average convergence/divergence (MACD), relative strength index (RSI), Bollinger bands, and so on. These features will be used as input vectors to the LSTM model for training. The LSTM model is used to predict the daily average prices of gold/Bitcoin.

The simple moving average (SMA) over the last k days is calculated by (1) as follows:

$$\text{SMA}_k = \frac{p_{n-k+1} + p_{n-k+2} + \cdots + p_n}{k} = \frac{1}{k} \sum_{i=n-k+1}^{n} p_i, \quad (1)$$

where p_i is the value of the gold/Bitcoin on the i-th day.

The relative change (RC) of the simple moving average is calculated by (2) as follows:

$$\text{RC} = \ln\left(\frac{\text{SMA}_1}{\text{SMA}_5}\right), \quad (2)$$

where SMA_1 is the simple moving average over the last 1 day and SMA_5 is the simple moving average over the last 5 days.

The exponential moving average (EMA) over the last n days is calculated by (3) as follows:

$$\text{EMA}_i = \begin{cases} p_1, & i = 1, \\ \left(\frac{n-1}{n+1}\right)\text{EMA}_{i-1} + \left(\frac{2}{n+1}\right)p_i, & i > 1, \end{cases} \quad (3)$$

where p_i is the value of the gold/Bitcoin on the i-th day.

The differential value (DIF) is calculated by (4) as follows:

$$\text{DIF}_i = \text{EMA}_i(12) - \text{EMA}_i(26), \quad (4)$$

where $\text{EMA}_i(12)$ is the exponential moving average over the last 12 days on the i-th day and $\text{EMA}_i(26)$ is the exponential moving average over the last 26 days on the i-th day.

The differential exponential average (DEA) is calculated by (5) as follows:

$$\text{DEA}_i = \begin{cases} 0, & i = 1, \\ (0.8)\text{DEA}_{i-1} + (0.2)\text{DIF}_i, & i > 1, \end{cases} \quad (5)$$

where DIF_i is the differential value of the gold/Bitcoin on the i-th day.

The moving average convergence/divergence (MACD) is calculated by (6) as follows:

$$\text{MACD}_i = 2\left(\text{DIF}_i - \text{DEA}_i\right), \quad (6)$$

where DIF_i is the differential value of the gold/Bitcoin on the i-th day and DEA_i is the differential exponential average of the gold/Bitcoin on the i-th day.

The growth periods over the last 14 days are characterized by the value of the gold/Bitcoin being higher than the value of the previous day; that is, $p_i > p_{i-1}$. The gross growth (GG) over the last 14 days is calculated by (7) as follows:

$$\text{GG} = \sum_{i=n-13}^{14} \left(p_i - p_{i-1}\right), \quad (7)$$

where p_i is the value of the gold/Bitcoin on the i-th day.

The decline periods over the last 14 days are characterized by the value of the gold/Bitcoin being not higher than the value of the previous day; that is, $p_i \leq p_{i-1}$. The gross decline (GD) over the last 14 days is calculated by (8) as follows:

$$GD = \sum_{i=n-13}^{14} (p_{i-1} - p_i). \tag{8}$$

The relative strength (RS) is calculated by (9) as follows:

$$RS = \frac{GG}{GD}, \tag{9}$$

where GS is the gross growth and GD is the gross decline.

The relative strength index (RSI) is calculated by (10) as follows:

$$RSI = 100 - \frac{100}{1 + RS}, \tag{10}$$

where RS is the relative strength.

The Bollinger bands refer to the upper Bollinger band, middle Bollinger band, and lower Bollinger band, which can reflect the value volatility of gold/Bitcoin over time. The middle Bollinger band (MBB) over the last 20 days is calculated by (11) as follows:

$$MBB = \frac{1}{20} \sum_{i=n-19}^{n} p_i, \tag{11}$$

where p_i is the value of the gold/Bitcoin on the i-th day.

The upper Bollinger band (UBB) over the last 20 days is calculated by (12) as follows:

$$UBB = MBB + 2\sigma, \tag{12}$$

where MBB is the middle Bollinger band and σ is the standard deviation of the value of the gold/Bitcoin over the last 20 days.

The lower Bollinger band (LBB) over the last 20 days is calculated by (13) as follows:

$$LBB = MBB - 2\sigma, \tag{13}$$

where MBB is the middle Bollinger band and σ is the standard deviation of the value of the gold/Bitcoin over the last 20 days.

2.2. Price Prediction with LSTM Model.

Recurrent neural network (RNN) can reflect the sequence-related characteristics of financial time-series data, but it has the problem of gradient disappearance or gradient explosion. Also, its mining of historical information for financial time-series data is very limited. LSTM is a special RNN that can well handle the long-term dependencies of time-series data [35]. Therefore, the LSTM model is an improved RNN model, to some extent. Figure 1 shows the network structure of the LSTM. The basic unit of the LSTM model is a memory block, which includes a memory cell and three gate structures that control the state of the memory cell, forget gate, input gate, and output gate. To be specific, the forget gate decides to forget the useless historical information from the memory cell state, the input gate decides the influence of the current input data on the memory cell state, and the output gate decides the output information.

Firstly, the information that needs to be eliminated from the cell is determined by the forget gate (f_t) of the (14) as follows:

$$f_t = \sigma(b_f + W_f x_t + U_f h_{t-1}), \tag{14}$$

where σ is the sigmoid activation function, which represents the amount of information retained, x_t is the current input vector, and h_t is the currently hidden layer vector. b_t, x_t, and x_t are the bias, the input weight, and the loop weight of the forget gate, respectively.

Next, the information state is updated in the cell. The external input gate (i_t) is controlled by a sigmoid activation function of the (15) as follows:

$$g_t = \sigma(b_g + W_g x_t + U_g h_{t-1}). \tag{15}$$

Meanwhile, the cell state (C_t) is updated on the basis of C_{t-1} by (16) as follows:

$$C_t = f_t * C_{t-1} + g_t * \tanh(b_c + W_c x_t + U_c h_{t-1}), \tag{16}$$

where C_t represents the state of the memory cell at time t.

Finally, the information output is controlled by the output gate (O_t) of the (18) as follows:

$$h_t = (O_t)\tanh(C_t), \tag{17}$$

$$O_t = \sigma(b_o + W_o x_t + U_o h_{t-1}). \tag{18}$$

We firstly build two models, unidirectional dual-layer LSTM model and bidirectional LSTM model, which aim to predict the average daily prices of Bitcoin after 1 day based on the prices in the previous 8 days. We compare the forecast results for different size time windows for the prices of gold/Bitcoin, respectively.

Furthermore, in order to address the problem of prediction lag, we adopt further optimizations to alleviate it and improve the accuracy of ups and downs. We expand the range of predictions, the average price 3 days after is based on the previous n-day prediction, and the up- and downtrend of prices (trend) is expressed in terms of yields over the next three days.

The up- and downtrend of prices (trend) is calculated by (19) as follows:

$$\text{trend} = \gamma_1 * \frac{\text{price}(n+1)}{\text{price}(n)} + \gamma_2 * \frac{\text{price}(n+2)}{\text{price}(n+1)}$$
$$+ \gamma_3 * \frac{\text{price}(n+3)}{\text{price}(n+2)}, \tag{19}$$

where $\gamma_i \cdot (i = 1, 2, 3)$ is the weight of the fluctuation rate for the next three days, price(n) is the price of yesterday for the n-th day, and price(i) $(i = n+1, n+2, n+3)$ is the predicted price for the next three days.

The final predicted result (Result) is calculated by (20) as follows:

$$\text{Result} = \text{trend} \times \text{price}(n). \tag{20}$$

We select 5 indicators as evaluation criteria for model performance: mean square error (MSE), root-mean-square deviation (RMSD), coefficient of determination (R^2), mean
FIGURE 1: LSTM network structure.

absolute percentage error (MAPE), and accuracy of ups and downs predictions (Accuracy).

The mean square error (MSE) is calculated by (21) as follows:

$$MSE = \frac{1}{n} \sum_{i=1}^{n} (y_i - \widehat{y}_i)^2, \quad (21)$$

where y_i is the true value and $\widehat{y}_i$ is the predicted value of y_i.

The root-mean-square error (RMSE) is calculated by (22) as follows:

$$RMSE = \sqrt{MSE} = \sqrt{\frac{\sum_{i=1}^{n} (\widehat{y}_i - y_i)^2}{n}}, \quad (22)$$

where MSE is the mean square error.

The coefficient of determination (R^2) is calculated by (23) as follows:

$$R^2 = 1 - \frac{SS_{res}}{SS_{tot}} = 1 - \frac{\sum_{i=1}^{n} (y_i - \overline{y})^2}{\sum_{i=1}^{n} (y_i - \widehat{y}_i)^2}, \quad (23)$$

where SS_{res} is the sum of squares of residuals, SS_{tot} is the total sum of squares, y_i is the true value, $\overline{y}$ is the mean of true values, and $\widehat{y}_i$ is the predicted value of y_i.

The mean absolute percentage error (MAPE) is calculated by (24) as follows:

$$Mape = \frac{100\%}{n} \sum_{i=1}^{n} \left| \frac{y_i - \widehat{y}_i}{y_i} \right|, \quad (24)$$

where y_i is the true value and $\widehat{y}_i$ is the predicted value of y_i.

2.3. Trading Strategies

2.3.1. Strategy Establishment. With an initial principle of $1000, we set the specified buy position ratio, sell position ratio, and buy position ratio for the first time/after clearance before starting the trading process. Figure 2 is the structure diagram of the strategy backtesting framework. Firstly, the daily price of gold/Bitcoin is predicted through the weighted unidirectional dual-layer LSTM model. Next, we determine whether today is a trading day and the appropriate time to buy or sell according to different strategies. In this way, we can derive nine different buy and sell combinations for gold and Bitcoin. Figure 3 shows the detailed trading strategy. For

the date of simultaneous buy or sell, we adopt the PSO to obtain the optimal buying and selling ratio of gold and Bitcoin, where the objective function is to maximize the profit. Finally, we summarize the state of the asset, including the total assets, the assets of gold, the assets of Bitcoin, and the empty asset. The experiment led by Schmidt and Traub showed that loss aversion is a common human behavior in most situations [36]. When the loss reaches 3% or 5% of the initial principle, all positions will be cleared so that the loss will be stopped in time.

2.3.2. Strategy Process

(1) Simple Moving Average Strategy. We choose two specific indicators, the long-term simple moving average (SMA) of 15 days average daily prices and the short-term SMA of 5 days. When the short-term SMA exceeds the long-term SMA, the asset has an upward trend, implying that it is suitable for buying. When the short-term SMA moves down and intersects with the long-term SMA, the asset has a downward trend, making it suitable for selling.

(2) Bollinger Bands Strategy. Bollinger bands (BB) indicate areas of support and resistance. A set of parameters can be adopted according to the length of time under various situations. We select 20 days and use 2 as the multiplicative parameter before standard deviation because the proposed combination is the most commonly employed standard and interests many investors [37]. When the average daily price of gold/Bitcoin exceeds the upper Bollinger lines, the price of the asset continues to rise, which implies that a sell operation should be considered conservatively. When the average daily price of gold/Bitcoin is lower than the lower Bollinger lines, the price of the asset continues to fall, which indicates that a buying operation should be considered conservatively.

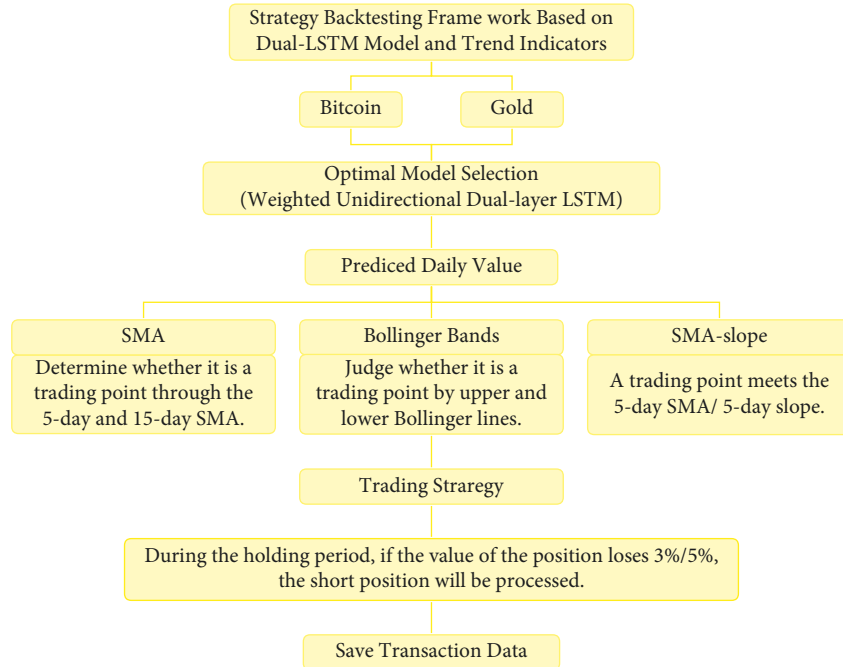
(3) SMA-Slope Strategy. We establish a new strategy called the SMA-slope strategy by introducing a new concept of k-slope based on SMA. The parameter k of the k-slope refers to the number of days where the slope is consecutively positive/negative. The k-slope is used to increase the buy and sell points, which promote the investment to generate more excellent interest rates.


FIGURE 2: Structure diagram of the strategy backtesting framework.
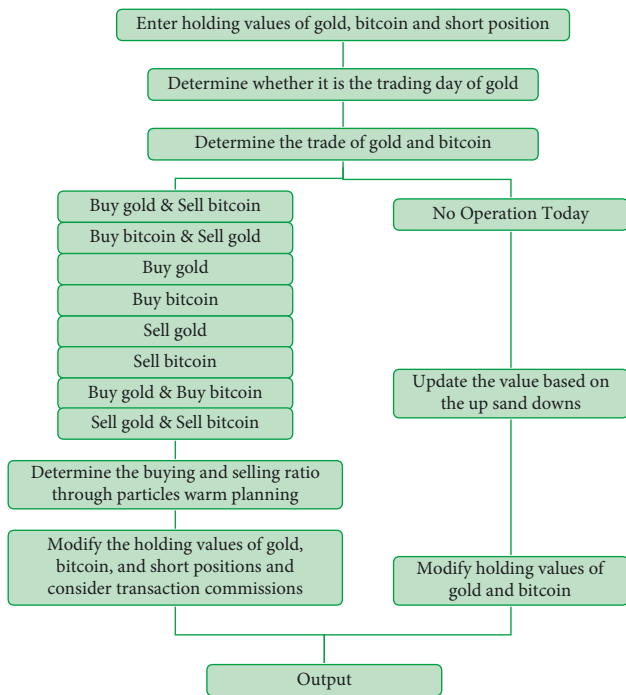

FIGURE 3: Flowchart of trading strategy.

We calculate the ratio of positive/negative slopes for gold/Bitcoin for k consecutive days (Table 1). It can be easily noticed that, by introducing the concept of k-slope, many k make the number of days that meet the trading conditions exceed the number of days to trade formed by SMA and BB strategies only. When $k > 10$, the number of days that meet the trading conditions is less. Therefore, we set traversals and search to range from k to [1, 12]. Considering that the SMA strategy has

outperformed the Bollinger band strategy, we incorporate the k-slope into the SMA strategy to form the SMA-slope strategy, which can create more trading days than the SMA strategy. Also, it makes gold and Bitcoin more likely to be traded simultaneously, so we expect better results by using PSO.

The k-slope of gold/Bitcoin represents how aggressively the price rises or falls, which can be used for trend identification to establish a trading bias. A positive slope dictates a bullish bias, while a negative slope dictates a bearish bias. However, the k-slope follows a trend or price point, which cannot predict a trend. In order to treat the problems of possible lags, we apply the predicted price of today and the actual data of yesterday to calculate today's slope.

The k-slope (s_i) is calculated by (25) as follows:

$$s_i = \frac{\widehat{y}_i - y_{i-1}}{1 \text{ day}}, \tag{25}$$

where y_{i-1} is the true value on the $(i-1)$-th day and $\widehat{y}_i$ is the predicted value of y_i.

When $k > 2$, if the slopes for consecutive k days are both positive and negative and the absolute value of the slope for the most recent day is less than the absolute value of the slope today, we will consider it as a possible buying/selling point. Directional movement is also important for analyzing the slope. When the k-slope continues to be positive and has a slowing trend, we decide that this is an appropriate selling point; when the k-slope continues to be negative and has a slowing trend, we decide that this is an appropriate buying point. To sum up, when $k > 1$, we consider $s_i > 0$ as a selling point and $s_i < 0$ as a buying point.

We set the number of consecutive days that Bitcoin has a positive slope as BITCOIN_k_positive, and the value that meets the requirements represents a suitable time to sell Bitcoin on that day. We set the number of consecutive days

TABLE 1: The ratio positive/negative slopes for gold/Bitcoin for k consecutive days.

k	Gold (1826 days)									Bitcoin (1826 days)								
	2	3	4	5	6	7	8	9	10	2	3	4	5	6	7	8	9	10
Positive (%)	38	32	28	26	24	22	21	20	19	42	36	32	30	27	25	24	23	23
Negative (%)	34	27	24	21	19	18	16	15	14	31	25	21	19	16	15	13	12	11

that Bitcoin has a negative slope as BITCOIN_k_negative, and the value that meets the requirements represents a suitable time to buy Bitcoin on that day. GOLD_k_positive and GOLD_k_negative are defined similarly. We perform a traversal search with the range from 1 to 12 for these four parameters to find the optimal value for k in the k-slope.

3. Results

3.1. Performance of LSTM Model Based on Feature Selection. Figures 4 and 5 represent correlation coefficients of all features with daily average price of gold/Bitcoin. The darker the colour, the smaller the influence of the feature on the value of gold/Bitcoin. Also, the lighter the colour, the greater the influence of the feature on the value of gold/Bitcoin. The value of gold has a large correlation coefficient with all features of SMA and Bollinger bands, implying a strong positive correlation. In particular, the correlation coefficients of 5-day SMA and 5-day EMA reach 1.0, which is a perfect positive correlation. Therefore, these characteristics can have a greater impact on the value of gold. The correlation coefficients of RC, RSI, and MACD were 0.05, 0.12, and 0.02, respectively, showing a positive weak correlation.

The value of Bitcoin has a strong correlation coefficient with all the characteristics of the simple moving average, exponential moving average, and Bollinger bands, even reaching 1.0 on the 5-day and 10-day SMA and EMA. Therefore, these characteristics can have a noticeable impact on the value of Bitcoin. The correlation coefficients of RC, RSI, and MACD are 0.02, 0.00, and 0.00, respectively, and there is almost no correlation. However, since only 18 indicators are selected in this paper, all indicators with weak correlations are reserved.

Table 2 represents the result of the performance comparison of LSTM models. It can be seen that the unidirectional dual-layer LSTM model is better than the bidirectional LSTM model in every index. As a result, we initially choose the unidirectional dual-layer LSTM as the basic model.

Δt and m in Table 2 refer to the average daily price data of consecutive trading Δt days as a time window to input the model training, which aims to predict the profit situation after m days. Therefore, it can use the predicted price data of m days to predict the short-term price trend.

Secondly, we compare different sizes of the time window (Δt), where 1, 5, and 8 are chosen.

Table 3 represents the performance of unidirectional dual-layer LSTM model with time windows of 1, 5, and 8. It is obvious that the 5 indicators are not particularly different. Given that we pay more attention to the accuracy of ups and downs predictions (Accuracy), we choose the unidirectional

dual-layer LSTM model with time windows of 5 to predict the average daily price of Bitcoin.

In the same way, a unidirectional dual-layer LSTM model with time windows of 8 is chosen to predict the average daily price of Bitcoin.

As shown in Figure 6, prediction lag is sometimes encountered, where the predicted average daily price of Bitcoin lags behind the change in the actual situation. It may lead to a decrease in the accuracy of ups and downs (Accuracy).

As shown in Tables 4 and 5, it can be inferred that, compared with $m = 1$, the accuracies of ups and downs (Accuracy) have more than 25% growth. Therefore, we can conclude that the model has been significantly improved. In addition, whether it is Bitcoin or gold, the result with a weight ratio of 0.4 : 0.5 : 0.1 performs better than the result with a weight ratio of 0.4 : 0.32 : 0.28. Hence, we choose a weight ratio of 0.4 : 0.5 : 0.1 to build the model.

According to the model we selected and improved, we predict the average daily prices of gold and Bitcoin, as shown in Figures 7 and 8. It can be clearly seen that the prediction lag with $m = 3$ has been alleviated. To sum up, with a time window of 5, the unidirectional dual-layer LSTM model predicting the next 3 days is the best for Bitcoin average daily price prediction. Also, with a time window of 8, the unidirectional dual-layer LSTM model predicting the next 3 days is the best one for gold average daily price prediction.

3.2. Financial Strategy Results. A 5-year trading simulation is conducted based on a $1000 principal. For the sake of concise and convenient representation, the symbols we will use frequently in the next two sections are explained in Table 6. The initial conditions of the simulation are as follows: the sell position ratio is 20%, the buy position ratio is 50%, the buy position ratio for the first time/after clearance is 70%, and the transaction commissions of Bitcoin and gold are 2% and 1%, respectively.

3.2.1. Performance of the SMA-Slope Strategy

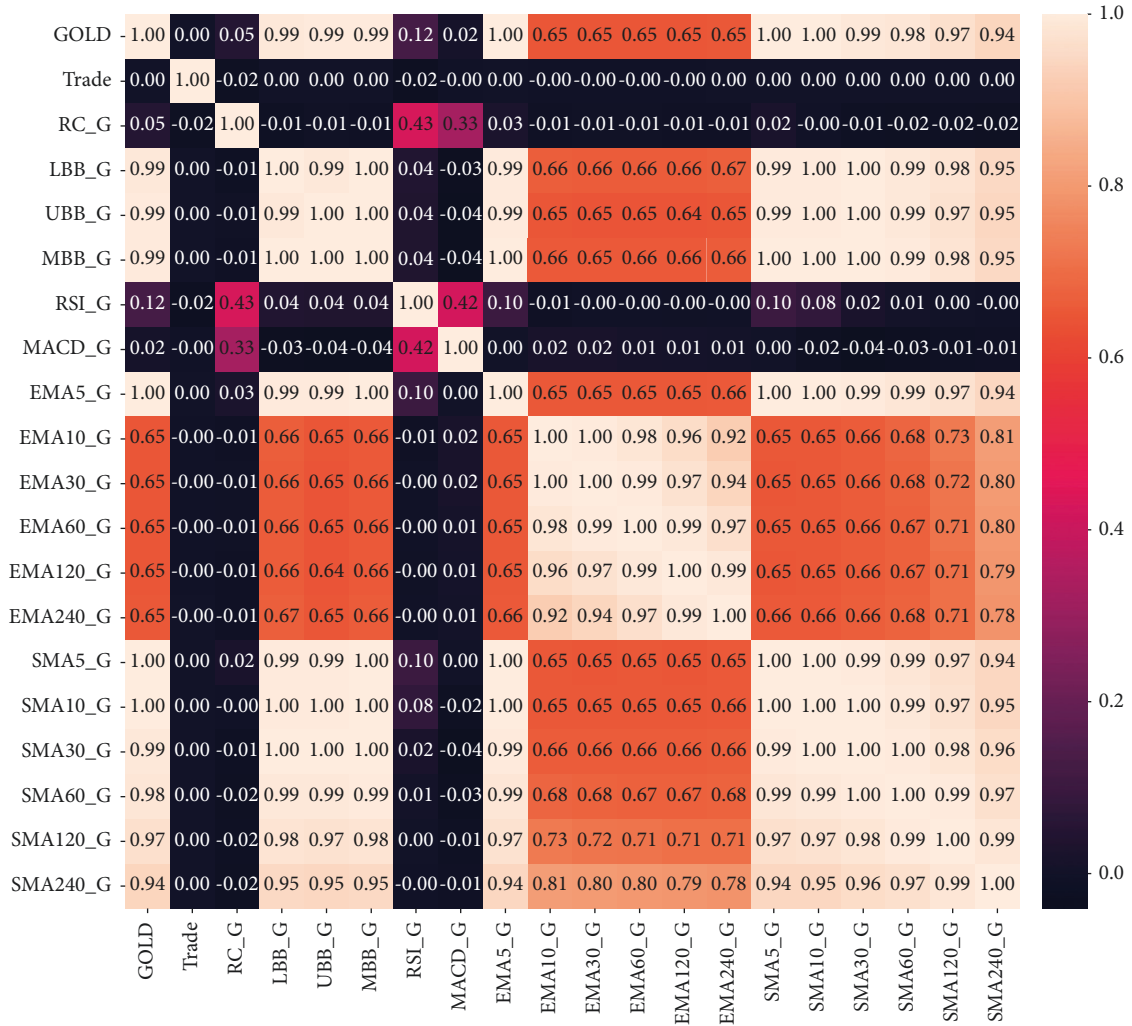
(1) Optimal Value of k in k-Slope for Gold. As the number of consecutive days with negative slopes for gold (GOLD_k_negative) increases, the number of buying points for gold decreases, but the upper limit of the gold asset increases. As the number of consecutive days with positive slopes for gold (GOLD_k_positive) increases, the number of selling points for gold decreases, but the upper limit of the gold asset increases. From Table 7, it can be concluded that long-term holding is more suitable for gold, while frequent reading operations are not appropriate. By analyzing gold assets under different settings of four parameters, we find that when


FIGURE 4: Correlation coefficients of all features with gold values.

GOLD_k_negative and GOLD_k_positive take 9 at the same time, the gold assets can reach the highest. Moreover, selling points have a more significant impact on gold assets because GOLD_k_positive can distinguish different gold assets while GOLD_k_negative cannot. When the buying and selling points are the same, the results of the SMA-slope strategy are better than those of the SMA strategy due to the influence of Bitcoin on gold. It increases the number of days to buy and sell both gold and Bitcoin at the same time, which contributes to better results of asset allocation.

(2) Optimal Value of k in k-Slope for Bitcoin. As the number of consecutive days with negative slopes for Bitcoin (BITCOIN_k_negative) decreases, the number of buying points for Bitcoin increases, and the upper limit of Bitcoin assets increases. As the number of consecutive days with positive slopes for Bitcoin (BITCOIN_k_positive) decreases, the number of selling points for Bitcoin increases, and the upper limit of Bitcoin assets increases. From Table 8, we can draw the conclusion that Bitcoin is more suitable for short-term holding. The buying point has a greater impact on Bitcoin because buying points can partition the Bitcoin asset,

while selling points cannot. When the selling points are the same, the SMA-slope strategy far outperforms the SMA results because the SMA-slope strategy increases the buying point for Bitcoin. With more days to buy and sell both gold and Bitcoin simultaneously, more proper asset allocation can be obtained.

(3) Optimal Values of k in k-Slope for the Portfolio. We perform a global search for four k-slope parameters, and the optimal solution set is shown in (26) as follows:

$$\begin{cases} \text{BITCOIN}\_k\_\text{negative} = 1, \\ \text{BITCOIN}\_k\_\text{positive} \geq 8, \\ \text{GOLD}\_k\_\text{negative} \geq 7, \\ \text{GOLD}\_k\_\text{positive} = 5, \end{cases} \quad (26)$$

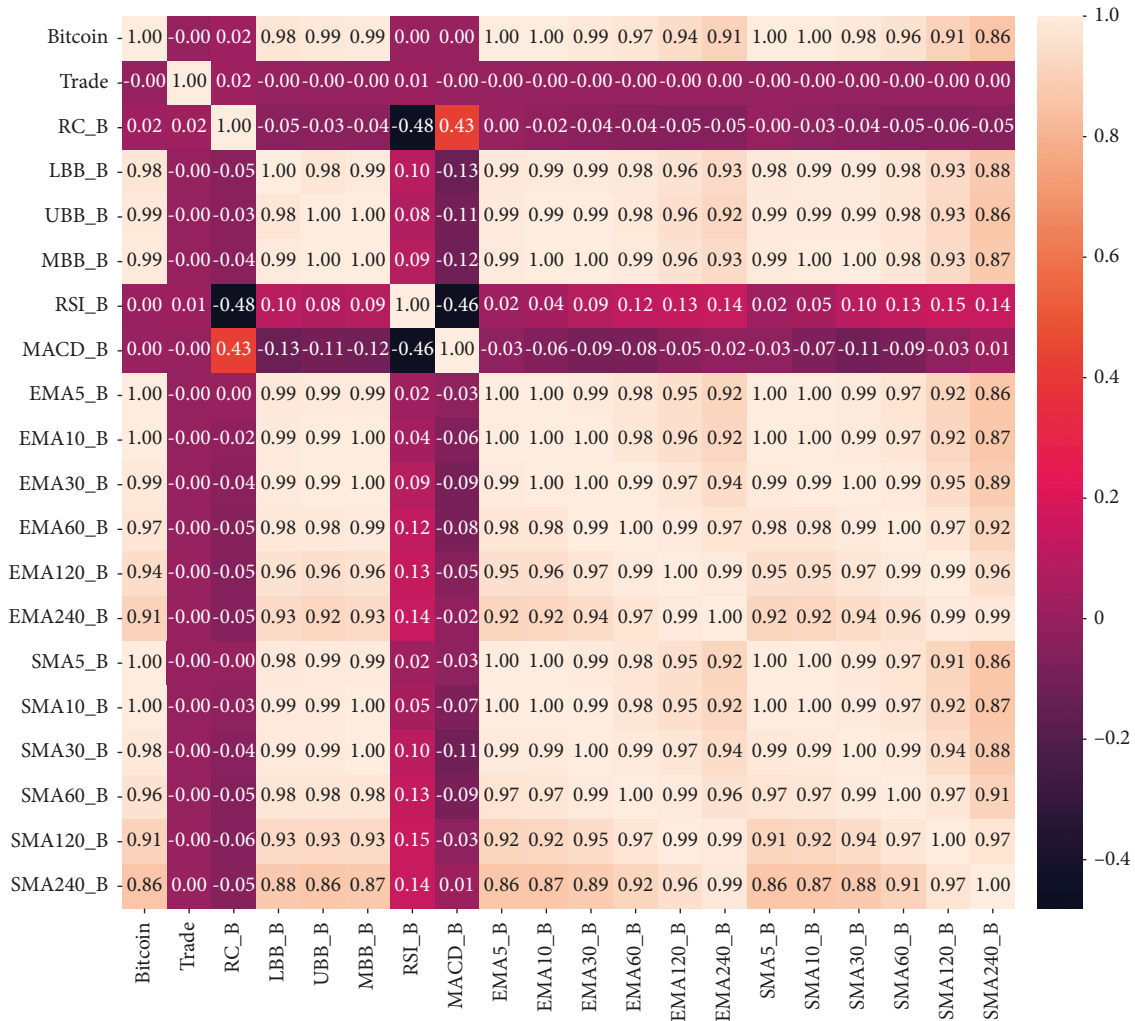
Bitcoin has 1567 buying points and 52 selling points, while gold has 31 buying points and 99 selling points. This optimal solution set confirms previous conclusions; that is, selling points play a decisive role in gold assets, and buying point is crucial for Bitcoin.


Figure 5: Correlation coefficients of all features with Bitcoin values.

Table 2: Performance comparison of LSTM models.

Model	Δt	m	MSE	RMSE	R^2	MAPE	Accuracy (%)
Unidirectional dual-layer LSTM	8	1	751150.9776	866.6897	0.9962	2.8881	46.9163
Bidirectional LSTM	8	1	752803.4835	867.6425	0.9962	2.8641	45.5044

Table 3: Performance comparison with different sizes of the time window of the LSTM model.

Model	Δt	m	MSE	RMSE	R^2	MAPE	Accuracy (%)
	1	1	731372.9356	855.2034	0.9963	2.9109	46.6410
Unidirectional dual-layer LSTM	5	1	739981.2836	860.2216	0.9962	2.8791	47.7974
	8	1	751150.9776	866.6897	0.9962	2.8881	46.9163

However, at this time, 99% or more of the total assets are composed of Bitcoin assets, and the holding ratio also exceeds 99% of the total positions. This is a very aggressive, risky behavior that does not conform to normal human behaviors. However, this set can be ignored by setting the empty, gold, and Bitcoin ratio not to be extreme. Table 9 shows the optimal asset results by global search.

Figure 9 presents the results of different BITCOIN_k_negative and GOLD_k_positive investment simulations. It

can be noticed that the best results are obtained when the value of BITCOIN_k_positive is 1. Similarly, Figure 10 presents the changes in gold assets at different BITCOIN_k_negative, and we can see that the more the proportion of Bitcoin, the smaller the proportion of gold and the more the total assets. Under different BITCOIN_k_negative, better results are obtained when the value of GOLD_k_positive is 7, but as the number of buying points for Bitcoin decreases, GOLD_k_positive moves to a smaller value to obtain the

Figure 8: Predicted values of Bitcoin by weighted unidirectional dual-layer LSTM model.

optimal solution. The portfolio has the tendency to decrease the proportion of gold and increase the proportion of Bitcoin in order to get a higher profit.

3.2.2. Comparison of SMA, BB, and SMA-Slope Strategies. From Table 10, as for the performance of the annual percentage rate (APR) of the portfolio consisting of gold and Bitcoin, the SMA-slope strategy is better than the SMA strategy, and the SMA strategy is better than the BB strategy. The empty, gold, and Bitcoin have unbalanced asset allocations with high risk when SMA-slope and BB

strategies perform best. It also confirms the possibility that investors may substitute Bitcoin for gold in a portfolio for higher risk-adjusted returns [38]. In the SMA-slope strategy, without pursuing the minimum value, we can get a set of slope values, which contributes to more balanced asset allocation, and the APR is higher than that of the SMA strategy. As shown in Table 11, the SMA-slope strategy dramatically increases the number of buying points of Bitcoin and changes the selling points of gold. It can be speculated that the SMA-slope strategy adjusts the number of trading times for gold and Bitcoin on the same day to get better results.

TABLE 6: Notations used in this section.

Symbol	Definition
Gold	Accumulated holding value of gold.
Bitcoin	Accumulated holding of Bitcoin.
Short	Cumulative remaining value of assets.
Total	Cumulative total value of assets.
Buy position ratio	The ratio of value of assets that are bought to the cumulative remaining value of assets.
Sell position ratio	The ratio of value of assets that are sold to the cumulative remaining value of assets.
Buy position ratio for the first time/after clearance	Buy position ratio for first purchase at the beginning and the first purchase after short position.

3.3. Analysis of Operational Factors Affecting Investment Results.

The proper asset allocation is key to achieving the goal of high return and risk tolerance. Rebalancing will be employed when the asset allocation is out of line, which will provide the best relative return on risk [39]. Therefore, we set the BITCOIN_k_negative as 5 and GOLD_k_positive as 5 to further analyze the SMA-slope strategy. Results with these settings avoid extreme imbalances in the ratio of gold and bitcoin.

3.3.1. Buy Position Ratio Analysis. Figures 11–13 are the analysis of buy position ratio under 3 strategies. For the SMA strategy, when we fix the gold/bitcoin sell position ratio of 20% each time and adjust the proportion of the short position each time we buy, it is evident that the APR is adjusted from 72.0% to 84.4%. The growth rate of the APR is proportional to the buy position ratio. The Bollinger band strategy shows that its annual interest rate has nothing to do with the buying position ratio, implying that the strategy is

highly conservative. Its proportion of gold and Bitcoin is highly unbalanced. For the SMA-slope strategy, it can be found that the annual interest rate shows a parabolic trend, and the total assets will fall back as the position increases to warn investors. When the buy position ratio is adjusted to 70%, the maximum APR is 83.0%. However, as the buy position ratio becomes closer to 100%, the APR shows a downward trend.

Moreover, the SMA-slope strategy obtains a better solution when the buy position ratio is within the interval [40%, 80%]. When the buy position ratio is adjusted to 40%, the difference between the APRs of the SMA and SMA-slope strategies is at most 8%. Considering risk factors, it is generally not recommended for investors to use all amounts of cash to buy assets at one time, especially for Bitcoin, which is highly volatile. Therefore, with careful consideration, the SMA-slope strategy performs better in response to adjusting the buy position ratio.

3.3.2. Sell Position Ratio Analysis. We try to explore the performance of the SMA strategy in extreme cases, that is, sell only a tiny percentage of gold/Bitcoin at one time. When we set the buy position ratio to 60% (Figure 14), it can be seen that the growth of the annual interest rate has a linear relationship with the sell position ratio. The higher the sell position ratio, the lower the annual interest rate. The position ratio between the holding value of Bitcoin and gold and the short position value is about 3 : 6:1, a stable ratio. We want to explore whether this ratio relationship is still satisfied in extreme cases (Figure 15). We figure out that when the sell position ratio is 1%, the final short position value is only 32.6, the value of Bitcoin holdings reaches 48436.5, and the total assets reach \$51711.0, where the Bitcoin share becomes 93.7%. It is dangerous behavior. Although the data shows that a lower sell position ratio can finally greatly promote the growth of total assets, it is still a dangerous behavior requiring alertness.

3.3.3. Buy Position Ratio for the First Time/after Clearance Analysis. We have conducted a detailed analysis of the purchases when the current gold/Bitcoin position value is 0 under different strategies; that is, we adjust the buy position ratio for the first time/after short positions to explore its impact on the annual interest rate. We set the sell position ratio as 20% and the buy position ratio as 50%, aiming to find the changes in annual interest rate under different buy position ratios for the first time/after short positions. It can be found that, under the SMA strategy (Figure 16), the annual interest rate and the buy position ratio for the first time/after short positions have a linearly increasing relationship. Moreover, the value of empty, Bitcoin, and gold has increased, and the proportion is relatively balanced. Under the Bollinger band strategy (Figure 17), the annual interest rate has no effect on buy position ratios for the first time/after short positions, and the total assets remain at \$4815.8. It confirms the conservative nature of the Bollinger band strategy again, avoiding short positions to the greatest extent.

TABLE 10: Comparison of the results of different strategies.

3.3.4. Different Transaction Commissions of Gold/Bitcoin.
As shown in Figures 18–21, the assets show a linear relationship with different transaction commissions of gold/Bitcoin for SMA and SMA-slope models. Also, with the increase of the transaction commission of gold/Bitcoin, the total asset decreases linearly.

Tables 12 and 13 show the effects on the two models when the transaction commission of gold/Bitcoin changes. The average sensitivity (average rate of change) of the SMA strategy to changes in Bitcoin transaction commission is 36%, and the average sensitivity of the SMA-slope strategy is 47. Additionally, SMA and SMA-slope strategies are

10	2	10890.9	30	14616	24

sensitive to gold transaction commission changes with an average sensitivity of 17%.

To sum up, due to the relatively gentle change of gold, the two models are less sensitive to changes in the transaction commission. However, because of the significant volatility and extensive fluctuation range of Bitcoin, the two models are more sensitive to it. Moreover, the sensitivity of the SMA-slope strategy is higher than that of the SMA strategy, and the highest rate of change is 75%.

4. Discussion

We have built a portfolio optimization model for gold and Bitcoin with high profitability to help investors make trading decisions. By sliding window and a weighted method for three days, we achieve a high accuracy of ups and downs for the unidirectional dual-layer LSTM model. Also, with the introduction of the k-slope and slight adjustments for the asset allocation, higher returns are realized by the SMA-slope strategy compared to common SMA and BB strategies. However, there are still some improvements that can be completed in the future work. Firstly, risk factors should be taken into more consideration. The current optimal set is a hazardous solution with highly unbalanced asset allocation. A fixed rule and some rebalancing methods can be conducted to avoid risks caused by inappropriate portions of different assets. Secondly, the relationship between gold and

Bitcoin can be explored while we currently train and test the LSTM model for prediction separately. The internal influence mechanism between gold and Bitcoin may play an essential role in predicting daily prices [40]. Thirdly, the window size can be dynamic as time goes by. Fix window size is used in the current model, limiting temporal modeling in deep learning neural networks because the data defined by the window size is only modeled and unsuitable for dealing with long-term dependencies in time-series data [41]. Also, the sliding window may be more suitable for Bitcoin than gold. Finally, in the context of Industry 4.0, AI technology can be applied more in the prediction model and the simulation for practical trading processes. Many alternatives for the LSTM model may contribute to higher accuracy for daily price prediction. AI can be described as a set of techniques for modeling and simulation environmental systems, such as artistic neural networks and reinforcement learning [42]. More use of AI technology may make trading simulations more realistic.

5. Conclusion

This paper establishes a portfolio optimization model for gold and Bitcoin, including a weighted unidirectional dual-layer LSTM model to predict the daily prices and the SMA-slope strategy for trading decision-making. We also carry out trading simulations for gold and Bitcoin with an initial

principal of \$1000 for further exploration. The weighted unidirectional dual-layer LSTM model is trained by daily prices of gold/Bitcoin and their related financial indicators. In order to make the simulation more in line with the actual, we adopt a sliding window for daily price prediction. For evaluation matrices, in addition to some common indicators like R^2 and RMSE, we pay more attention to the accuracy of ups and downs, which has a more direct relationship with trading decision-making. Changes in the financial market do not always obey the regular common rules or follow the same cycle. The predicted prices are obtained for the following 3 days, and a weighted method is used on them for higher accuracy of ups and downs, which reduces prediction lags to catch trends of prices better. In this paper, we compared three strategies, SMA strategy, BB strategy, and SMA-slope strategy. By analyzing results from various simulations, the SMA-slope strategy is considered the best choice for obtaining relatively high returns and avoiding extremely unbalanced asset allocation, where four parameters in the k-slope can be adjusted to achieve different outcomes. We focus on the operation derails involved in the investment processes and conclude that buy position ratios, sell position ratios, buy position ratios for the first time/after clearance, and transaction commissions of gold/Bitcoin all significantly impact the assets, which also have a more substantial effect on the performance of strategies.

Flood disaster is one of the critical threats to cities. With the intellectualization tendency of Industry 4.0, refined urban flood models can effectively reproduce flood inundation scenarios and support the decision-making on the response to the flood. However, the spatiotemporal variability of rainfall and the spatial heterogeneity of the surface greatly increase the uncertainties in urban flood simulations. Therefore, it is crucial to account for spatiotemporal variability of rainfall events and grids of the model as accurately as possible to avoid misleading simulation results. This study aims to investigate the effect of temporal resolutions of rainfall and spatial resolutions of the model on urban flood modeling in small urban catchments and to explore a proper combination of spatiotemporal schemes. The IFMS Urban (integrated flood modeling system, urban) is used to construct a one-dimension and two-dimension coupled urban flood model in the typical inundated area in Dongguan, China. Based on five temporal resolutions of rainfall input and four spatial resolutions, the compound effect of spatiotemporal resolutions on the accuracy of urban flood simulations is systematically analyzed, and the variation characteristics are investigated. The results show that the finer the temporal resolution is, the higher the simulation accuracy of the maximum inundated water depth. Considering the spatial resolution, as the spatial grid becomes smaller, the relative error of the maximum inundated water depth decreases, but it also shows some nonlinear characteristics. Therefore, the smaller grid does not always mean a better simulation. The spatial resolution has a greater impact on the flood simulation accuracy than the temporal resolution. The simulation performance reaches the best when the grid interval is 100 m and the rainfall input interval is 5 min, 10 min, or 15 min. Affected by other factors such as terrain slope, the simulation accuracies under different spatiotemporal resolutions present complex nonlinear characteristics. The mechanisms of the compound effect of the spatiotemporal resolutions on the model simulation and the effect of underlying surface and topography on model simulation will be the focus of in-depth exploration for the future urban flood model.

1. Introduction

With booming urbanization, the flood-inducing factors and hazard bearing bodies have experienced great changes in recent years. Many large and medium-sized cities around the world have suffered from frequent floods, which seriously threaten the safety of life and property of urban residents [1–3]. As an important basis for urban flood emergency control and risk management, the urban flood model is very important in real-time simulation, early warning, and risk assessment of floods. In recent years, under the background of Industry 4.0, the algorithms, calculation data, and computing power have greatly improved [4]. The spatio-temporal resolutions of urban flood models are becoming higher, and the decision-making is more intelligent. However, the fine-resolution simulation brings computational pressure and increases the uncertainties in the urban flood simulation. Due to the diverse underlying urban surface, the fast runoff process, and the short response time, its hydrological characteristics in urban regions show high spatiotemporal heterogeneity [5, 6]. Therefore, the urban flood model generally has strong resolution dependence, and the

simulation accuracy is constrained by the spatiotemporal resolutions [7–9]. To improve the simulation accuracy, we need to conduct in-depth and systematic research on the impact of spatiotemporal resolutions on the simulation accuracy of urban flood models.

Rainfall is one of the key driving factors of urban hydrological processes and is of high spatiotemporal variability [10, 11]. Variations of the rainfall spatiotemporal resolutions can affect the rainfall-runoff response time and water yield in the hydrological model [11]. Therefore, it is important to simulate the hydrological response with an appropriate spatiotemporal resolution of rainfall [12, 13]. A large number of studies have proved that for small urban catchments, urban flood simulation should use the rainfall data on at least 1–15 min time resolution and 100–1000 m spatial resolution [14–16]. Bruni et al. [17] analyzed the relationship between the urban catchment area and the required spatiotemporal resolutions of rainfall data and showed that for small urban catchments with less than 700 hectares, the urban hydrological simulation requires the rainfall data with at least a 5 min time resolution and a 1.7 km spatial resolution. In addition, the sensitivity of different hydrological models to the spatiotemporal resolutions of rainfall differs significantly, with the physical model being more sensitive than the conceptual model [18–20]. Aronica et al. [21] found that the Storm Water Management Model (SWMM) is more sensitive to rainfall temporal resolution than hydrological parameters. Meselhe et al. [22] compared the HMS (hydrologic modeling system) conceptual model with the physics-based hydrological model MIKE SHE. They found that the latter is more sensitive to rainfall temporal resolution. Gires et al. [23] found that the 1D/2D (one-dimension/two-dimension) coupled model, Multi-Hydro, is more sensitive to rainfall variability than the simpler 1D model. Many other studies also found that in small urban catchments, the time-scale variation of rainfall data has a greater impact on urban hydrodynamic models [24, 25]. To sum up, for a densely built and highly impermeable urban catchment, the output of the urban flood model is very sensitive to the rainfall spatiotemporal resolutions, and the bias of output increases obviously as the resolutions decrease.

Most urban flood models are distributed hydrological models based on grid data. The hydrological process is also sensitive to the spatial distribution of the underlying surface of the watershed [9]. The computational efficiency of the model and the accuracy of the simulations are often affected by the spatial resolution of the grid and the accuracy of input data [26, 27]. In the early 1960s, the importance of the spatial resolution of input data is recognized by scholars [28, 29]. Since then, many scholars have studied the spatial resolution of hydrological models. They found that the conclusions are different in different study areas. The model of high spatial resolution can lead to the systematic underestimation of peak flow [30, 31]. Ichiba et al. [27] found that increasing spatial resolution can reduce peak flow and total flow. The effect of spatial resolution of the grid on model performance is nonlinear, and higher mesh accuracy does not necessarily lead to better simulation. Zhang and Montgomery [32]

found that a spatial resolution of 10 m can greatly improve the simulations than 30 m and 90 m, while that of 2 m or 4 m only improves the model slightly. The above studies show that the difference in spatial resolutions will change the loss of underlying surface information and the complexity of the surface runoff between adjacent grids, which has a nonlinear impact on the simulations. Therefore, in the modeling process of the urban flood, the appropriate spatial resolution should be selected according to the comprehensive analysis of the calculation characteristics of the model, the characteristics of the underlying surface of the study area, and the accuracy of the input data.

To sum up, there have been extensive studies on evaluating the accuracy of urban flood simulation unilaterally from the temporal resolution of rainfall data or spatial resolution of the grids. These studies show that the effects of temporal resolution and spatial resolution on the simulation accuracy are obvious and nonlinear. So, the compound effects of grid spatial resolution and rainfall temporal resolution on the simulation accuracy should be more complicated. However, there are few studies on this aspect. To this end, we take the typical flooded area in Dongguan, China, as the study area (Section 2.1) and collect topographic and sewer network data (Section 2.2). The distributed urban flood model IFMS Urban (Section 3.1) is used to construct the coupling model of the 1D urban drainage network model and 2D surface hydrodynamic model in the study area, and the model is validated by using the high temporal resolution rainfall data and observed historical inundation events (Sections 2.2 and 3.3). Then, we explore the effects of rainfall temporal resolution and model spatial resolution on the maximum inundation water depth and the submerged water depth hydrograph based on five temporal resolutions of rainfall input and four spatial resolutions(Sections 4.1 and 4.2). Furthermore, we analyze the compound effects of different spatiotemporal resolutions on the accuracy of urban flood simulations (Section 4.3). Conclusions can be found in Section 5.

2. Study Domain and Data

2.1. Study Domain. The study site, Guancheng District of Dongguan City, is located on the south-central east coast of the Pearl River estuary, Guangdong Province, China (within E119°31′-114°15′, N22°39′-23°09′). It covers approximately 13.31 km^2 (Figure 1(a)). The study area represents a typical urban area with a density of human structures such as houses, commercial buildings, and roads. When the city is hit by heavy rainfall, the topographic characteristics of the study area make the flood converge to the middle from the sides south and north and finally discharge into the Dongyin Canal in the east.

2.2. Data Collection

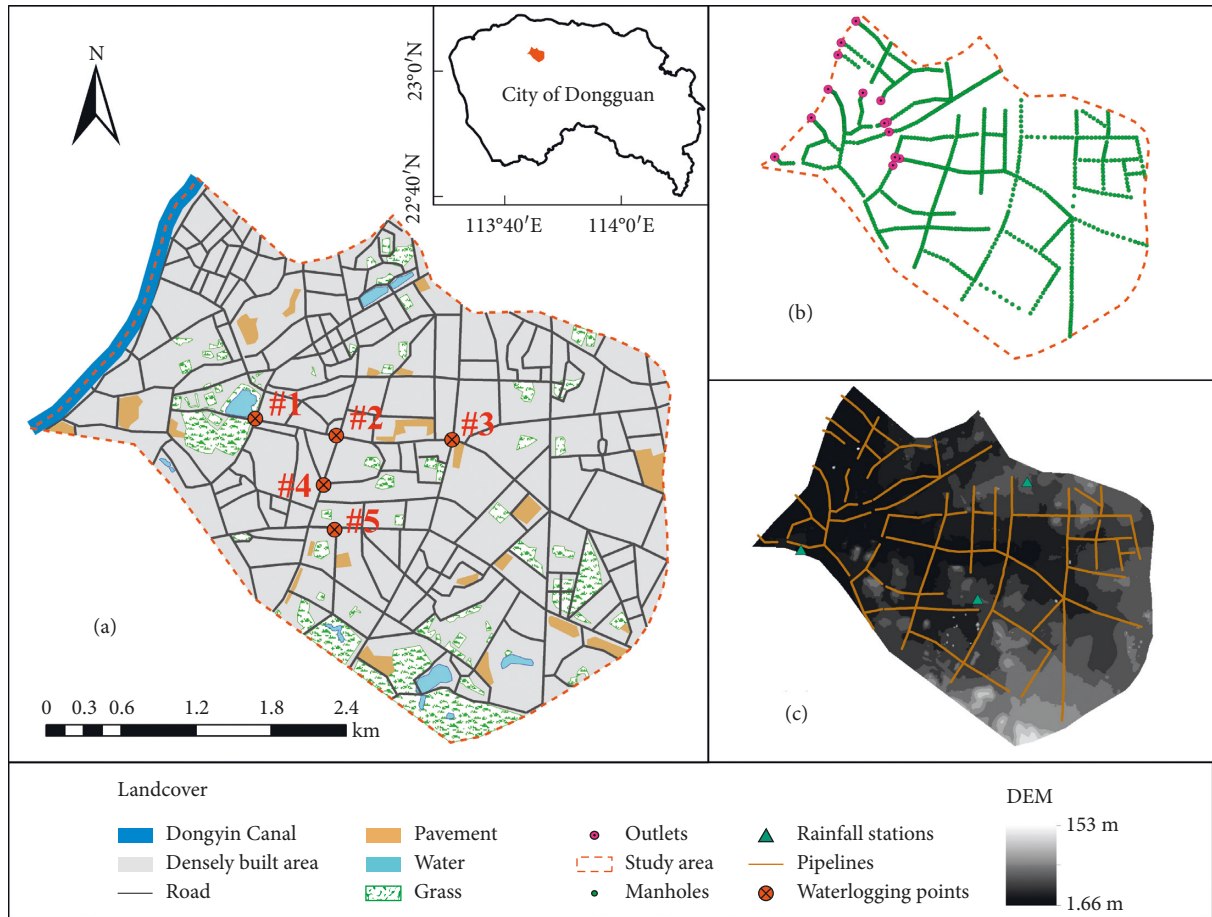
2.2.1. Topographic Data. The basic geographic data provided by the Urban Planning Bureau of Dongguan City (UPBDC) included a remote-sensing image and a digital elevation model (DEM). The resolution of the remote-sensing and


FIGURE 1: (a) Location and landcover conditions of the study area in which five numbers from #1 to #5 labeled with distribution of waterlogging points: #1 People's Park; #2 Dongzong Road; #3 Yinshan Street; #4 Dongcheng West Road; #5 Yonghuating. (b) shows the sewer network with manholes and outlets. (c) Top view of the DEM overlaid with the pipeline and rainfall station layer of the study area.

DEM are 5 m and 0.5 m, respectively. The former was used to distinguish the land use types of the underlying surface, and the latter was used to calculate the elevation and slope of the 2D grid.

2.2.2. Sewer Network Data. The sewer network data (Figures 1(b) and 1(c)) that were obtained from UPBDC is mainly based on the combined system. Most of the pipelines do not meet the design return period of one year, and most of the pipelines are less than 1000 mm in diameter, which is easy to cause waterlogging in the lower terrain.

2.2.3. Rainfall Data. In this research, two rainstorm events that occurred on August 30, 2018, and May 7, 2015, were used for model calibration and impact study of temporal and spatial scale, respectively. The maximum 24-hour cumulative rainfall of the two rainstorm events exceeded 50 mm, resulting in waterlogging in the study area. Three rainfall stations, which collect rainfall data at an interval of every 5 min, are located in and around the study area (Figure 1(c)). The rainfall of 10 min, 15 min, 30 min, and 1 h temporal scale was accumulated from the rainstorm of May 7, 2015.

Meteorological Bureau of Dongguan City provided the corresponding rainfall records.

2.2.4. Observed Historical Inundation Events. Generally, it is difficult to calibrate and validate the urban inundation model due to a lack of detailed observation of inundation events [2]. Therefore, in many cases, either a partial calibration/validation of the model or an indirect validation/verification based on testimonial reports is sought [33, 34]. In this research, the process of inundation depth in the inundation area in Yonghuating, Dongcheng Road West, and Dongzong Road on August 30, 2018, was observed for the calibration and verification of the urban flood model. The data on maximum inundation depth and distribution of inundation area on May 7, 2015, were collected and released by the Water Authority of Dongguan City.

3. Methodology

3.1. IFMS Urban. IFMS Urban couples the SWMM with a 2D surface hydrodynamic model that is conducted based on an adaptive grid and finite volume method, which can automatically identify the region with a large parameter

gradient and the boundary between dry and wet, adjust the grid size, accurately simulate the dynamic change of water flow propagation, and can be applied to the actual flood simulation [35]. The IFMS Urban efficiently calculates the urban flood process in the complex urban area with frequent waterlogging and achieves good calculation accuracy, which provides technical support for this paper.

3.1.1. 1D Urban Drainage Network Model.

The urban drainage system consists of water inlets, drainage pipes, drainage pumping stations, and river channels at the outlets of the pipe network. The 1D model can use three methods of dynamic wave method, kinematic wave method, and steady flow method to calculate the drainage pipeline confluence. The governing equation is specifically the following formulas:

$$\frac{\partial Q}{\partial x} + \frac{\partial A}{\partial t} = 0, \tag{1}$$

where Q is the discharge, A is the discharge section area, t represents the time, and x represents the distance.

$$gA\frac{\partial H}{\partial x} + \frac{\partial \left(Q^2/A\right)}{\partial x} + \frac{\partial Q}{\partial t} + gAS_f = 0, \tag{2}$$

where H represents the water depth, g represents the gravitational acceleration, and S_f is the slope gradient of friction resistance.

3.1.2. 2D Surface Hydrodynamic Model.

In order to establish a special well-balanced scheme technique for dealing with source term due to bottom topography constructed, this paper develops a well-balanced Godunov-type scheme of the second-order accuracy for 2D shallow water equation with mesh. As above, the MUSCL method is used to reconstruct the variable values on both sides of the unit interface $U_{i+1/2}^{L/R}$ and the Roe format is selected to solve interface flux in the evolutionary step. Regarding the discretization of the source term, the bed slope term is discretized by characteristic classification, and the resistance source term is discretized implicitly.

The 2D shallow water equation of depth-averaged can be abbreviated as follows:

$$\frac{\partial h}{\partial t} + \frac{\partial hu}{\partial x} + \frac{\partial hv}{\partial y} = 0,$$

$$\frac{\partial hu}{\partial t} + \frac{\partial}{\partial x}\left[hu^2 + \frac{1}{2}gh^2\right] + \frac{\partial huv}{\partial y} = S_x, \tag{3}$$

$$\frac{\partial hu}{\partial t} + \frac{\partial hvu}{\partial x} + \frac{\partial}{\partial y}\left[hv^2 + \frac{1}{2}gh^2\right] = S_y,$$

where h represents the water depth, u is the flow velocity of x-direction, v is the flow velocity of y-direction; S_x and S_y are the source terms.

3.1.3. Algorithm of Coupled Model.

The 1D urban drainage network model and 2D surface hydrodynamic model are coupled by calculating the exchange water volume, which is substituted into their respective model for calculation and update to the next step. The exchange water volume can be calculated through the following equation:

$$Q = M\left(H_{\text{node}} - H_{\text{surface}}\right)W_{\text{crest}}\sqrt{2g\left|H_{\text{node}} - H_{\text{surface}}\right|}$$
$$\cdot \frac{\left|H_{\text{node}} - H_{\text{surface}}\right|}{\left|\max\left(H_{\text{node}}, H_{\text{surface}}\right) - H_g\right|}, \tag{4}$$

where H_{Surface} is the head of land surface, H_{node} is the head of drainage pipeline, M is the discharge coefficient, W_{crest} is the width or perimeter of manhole, and H_g is the surface elevation.

3.2. Evaluation of Modeling Results.

The calibration process has been evaluated using error indicators including Nash-Sutcliffe efficiency coefficient (NSE), maximum inundation depth relative error (RE_P), and maximum inundation depth appearance time absolute error (AE_T) for the simulated and observed values. The error indicators are formulated as in the following equations:

$$\text{NSE} = 1 - \frac{\sum_{i=1}^{N}\left(q_i^{\text{obs}} - q_i^{\text{sim}}\right)^2}{\sum_{i=1}^{N}\left(q_i^{\text{obs}} - \overline{q}^{\text{obs}}\right)^2}, \tag{5}$$

where q_i^{obs} is the observed value of an event i, q_i^{sim} is the simulated value of an event i, N is the number of observed values, and $\overline{q}^{\text{obs}}$ is the average of observed values.

$$\text{RE}_P = \frac{\left|q_P^{\text{obs}} - q_i^{\text{sim}}\right|}{q_P^{\text{obs}}} \times 100\%, \tag{6}$$

where q_P^{obs} is the observed value of maximum inundation depth, q_P^{sim} is the simulated value of flood peak maximum inundation depth.

$$\text{AE}_T = T_P^{\text{obs}} - T_P^{\text{sim}}, \tag{7}$$

where T_P^{obs} is the observed value of maximum inundation depth appearance time, and T_P^{sim} is the simulated value of maximum inundation depth appearance time.

In order to compare the results from different rainfall temporal resolution and 2D grid scale and also to compare the effect of the composition of the rainfall temporal resolution and 2D grid scale, different measures were used. In addition to the common error indicators such as RE_P and AE_T, we also used the coefficient of determination (R^2) to compare the correlation of two inundation depth series. The closer R^2 to 1, the higher the correlation between the two inundation depth series. R^2 is specifically as follows:

$$R^2 = \frac{\sum\left(Y_A - \overline{Y_A}\right)^2 - \sum\left(Y_A - Y_B\right)^2}{\sum\left(Y_A - \overline{Y_A}\right)^2}, \tag{8}$$

where Y_A is the value of the inundation depth series A, $\overline{Y_A}$ is the mean value of the inundation depth series A, and Y_B is the value of the inundation depth series B.

3.3. Model Validation

3.3.1. Model Setup. The model is set up based on the drainage network. The study area is generalized into 999 pipes, 1011 manholes, and 12 outlets. The parameters for the model include the section size of the drainage network, the two-dimensional (2D) grid elevation, the subcatchment slope, and the 2D grid pervious surface ratio. The section parameters of the drainage network are obtained from the actual survey data. The 2D grid elevation and the subcatchment slope are determined based on the DEM data. The 2D grid pervious surface ratio is extracted from the remote sensing images over the study area. The empirical parameters of the model include the impervious area Manning's roughness, the depression storage for the pervious area, and the infiltration related parameters. The empirical parameters are calibrated according to the SWMM user manual and the hydrogeological characteristics of the study area, as shown in Table 1. The rainwater in the study area flows through the pipeline by gravity and is finally discharged into the Dongyin Canal. According to historical data, the water level of the Dongying Canal is low and does not affect the outflow of the pipeline. Therefore, the model boundary outflow condition is set to free outflow. The modeling time step is set to 20 s, and the total simulation time is 24 h. The setting can ensure that the pipeline network system has no inflow. The accumulated water in the pipeline has been emptied when the simulation ends under each input rainfall condition.

3.3.2. Model Validation. In this section, we validate the IFMS Urban model by using the rain and flood event on August 30, 2018, as an example. The rainfall poured heavily in the study area from 11:00 to 16:00, within which rainfall amount accounted for over 80% of the total in the day. Thus, a 5 h storm event spanning from 11:00 to 16:00 was used as model rainfall data.

A summary of the simulations performed is given in Figure 2 and Table 2. The model can well predict the flood occurring and receding at the typical waterlogging points of Yonghuating, Dongcheng West Road, and Dongzong Road. These results confirm that the simulation of flood processes is reasonably well, with NSE for all waterlogging points exceeding 0.75. The RE_P and AE_T ranged approximately from 11.11% to 17.50% and from 5 min to 12 min, respectively. All of them are within the allowable error range required by the Standard for Hydrological Information and Hydrological Forecasting of China. Furthermore, the results of Dongcheng West Road are better than other waterlogging points, with NSE, RE_P and AE_T being 0.86, 11.11%, and 5 min, respectively. In conclusion, the above results show that the parameters of the model are set reasonably, and the model has good applicability in the study area. The model is reliable and is suitable for the subsequent analysis.

Table 1: Values of empirical parameters.

Number	Parameter	Value
1	Manning's roughness for impervious area	0.013
2	Manning's roughness for pervious area	0.230
3	Depression storage on impervious area (mm)	2.500
4	Depression storage on pervious area (mm)	5.000
5	Roughness of pipe	0.014
6	Maximum infiltration rate (mm·h^{-1})	104.000
7	Minimum infiltration rate (mm·h^{-1})	12.000
8	Attenuation coefficient	8.500

Table 2: Simulation error statistics.

	Dongcheng west road	Yonghuating	Dongzong road
NSE	0.86	0.78	0.80
RE_P	11.11%	17.64%	17.50%
AE_T/min	5	8	12

4. Results and Discussion

4.1. Effect of Rainfall Temporal Resolution. Table 3 and Figure 3 show the maximum inundation water depth and RE_P at five typical waterlogging points under five temporal resolutions. With the increase of rainfall temporal resolution, the maximum inundation water depth gradually decreases and RE_P increases. However, the effect of the rainfall temporal resolution on the maximum inundation water depth is small on the whole. Increasing the time step of rainfall input from 5 min to 30 min, the variation range of the maximum inundation water depth at the five waterlogging points is within 5 cm, while the variation range of RE_P is less than 8%. RE_P at waterlogging points based on the 1 h temporal resolution is larger than the other four temporal resolutions, with that in Dongcheng West Road being the largest (13.73%). The errors of the maximum inundation

TABLE 3: Maximum inundation water depth at five typical waterlogging points under five temporal resolutions.

Waterlogging points	Maximum inundation water depth (cm)					
	Observation	5 min	10 min	15 min	30 min	1 h
Dongcheng west road	60	58.81	58.17	57.97	56.75	53.19
Dongzong road	25	23.65	23.61	23.34	23.21	22.19
Yonghuating	30	28.20	28.19	28.15	28.05	25.88
People's park	17	16.69	16.62	16.51	16.21	15.36
Yinshan street	22	21.17	21.11	20.90	20.84	20.12
FIGURE 3: Relative errors of maximum inundation water depth (RE_P) at five typical waterlogging points under five rainfall temporal resolutions.

water depth at the waterlogging points increase with the temporal interval of rainfall input, but the overall increase is not large.

The occurrence time of the maximum inundation water depth (referred to as the peak time of inundation water depth) at waterlogging points has a high correlation with the temporal resolution of rainfall input. As shown in Table 4, with the increase of the temporal resolution of rainfall input, the time between the peak time of inundation water depth at waterlogging points and the rainfall peak time (referred to as the lag time) also increases. The lag time of the 10 min and 15 min rainfall input intervals at the five waterlogging points is short (only 0–3 min). The lag time of the 30 min and 1 h rainfall input intervals changes a lot. Compared with the 5 min time interval, the lag time is, respectively, extended by 7–13 min and 23–36 min.

With the increase of rainfall input interval, the correlation between the submerged water depth and the rainfall at waterlogging points decreases. The deformation degree of the submerged water depth hydrograph at waterlogging points becomes larger. Taking the waterlogging point, Yonghuating, as an example (as shown in Figure 4), the rainfall peaks twice at about 1 h and 2 h. Correspondingly, there are two obvious waterlogging processes in 1-2 h and

TABLE 4: Lag time of maximum inundation depth to rainfall peak under five temporal resolutions.

Waterlogging points	Lag time (min)				
	5 min	10 min	15 min	30 min	1 h
Dongcheng west road	63	63	66	76	90
Dongzong road	80	83	83	93	116
Yonghuating	30	33	36	43	63
People's park	60	63	63	70	83
Yinshan street	63	63	66	70	86
FIGURE 4: The hydrographs of inundation under five rainfall temporal resolutions at Yonghuating.

3-4 h under the 5 min, 10 min, 15 min, and 30 min rainfall temporal resolutions at Yonghuating, and the results have a good correlation with the rainfall observation. The submerged water depth hydrograph under the 1 h rainfall temporal resolution has only one obvious waterlogging process. Compared with the waterlogging processes under other temporal resolutions, the maximum inundation depth is lower and the corresponding occurrence time is later. Using the coefficient of determination (R^2), this study further analyzes how well the shape of submerged water depth hydrographs under 10 min, 15 min, 30 min, and 1 h rainfall input resolutions at five typical waterlogging points match that of the hydrograph under the 5 min resolution (Figure 5). With the increase of temporal interval, the coefficient of determination decreases, and the difference between submerged water depth hydrographs increases. The
Figure 5: The coefficients of determination of inundation hydrograph between four rainfall temporal resolutions and the 5 min resolution.

shape for the 10 min and 15 min resolutions is in good agreement with the submerged water depth process under 5 min resolution, and R^2 are all higher than or equal to 0.97. However, there are certain differences of hydrographs between 1 h and 5 min resolutions, and the R^2 is only 0.69–0.81.

4.2. Effect of the 2D Spatial Resolution of Model Grids. The study area is used as the meshing area to generate four kinds of mixed 2D meshes of triangles and quadrilaterals with spatial scales of 50 m × 50 m, 100 m × 100 m, 150 m × 150 m and 200 m × 200 m. According to the remote sensing images, we analyze the land use type of the underlying surface and set the impervious area and roughness of the simulations under four spatial resolutions. The grid elevations for the four spatial resolutions are all obtained by inverse distance weighted interpolation based on a DEM with a resolution of 5 m.

As shown in Table 5 and Figure 6, the effect of grid spatial resolution on the model simulation is nonlinear. It means that the smaller spatial resolution does not correspond to the higher accuracy of model outputs. With the increase of grid spatial interval, the maximum inundation depth decreases and the absolute error (AE) of the maximum inundation depth increases on the whole. When the grid spatial resolution is increased from 50 m to 150 m, the maximum inundation depth decreases, and its variation range is small. All AE is within 4 cm and RE_P is less than or equal to 6%, while those of the 200 m grid are larger than the other resolution simulations. The maximum inundation depths with a spatial resolution of 50 m at the five typical waterlogging points are all overestimated. Except for Yinshan Street, RE_P of the 50 m grid is higher than that of the 100 m grid at other four waterlogging points.

There are significant correlations between the slope and the grid spatial resolution of the catchments of waterlogging points and the hydrological characteristics. As the spatial resolution becomes larger, the calculation accuracy of the waterlogging point with large slope of catchment area decreases obviously. The DEM and flow direction of main roads in the study area and around each waterlogging point are shown in Figure 7. On one hand, the three areas of Yinshan Street, Dongzong Road, and People's Park are located in the low-lying central of the study area, where the rain and floods in the eastern, northern, and southern parts of the study area are concentrated. But due to the flat terrain from the Yinshan Street to the People's Park, the converged rain and floodwater cannot be discharged in time, resulting in waterlogging in the three areas. When the grid resolution is increased from 50 m to 200 m, the simulation results at Yinshan Street, Dongzong Road, and People's Park are less affected by the grid size. All AE is less than 3 cm and RE_P is less than 13%. On the other hand, small-scale rain and floods are gathering in the mountainous southeast of the study area, mainly located in Yonghuating and Dongcheng West Road. The slope in the catchment areas is larger than that in other waterlogging areas. When the grid resolution is increased from 50 m to 150 m, AE and RE_P in Yonghuating and Dongcheng West Road have a small variation range, while AE and RE_P at the 200 m grid have increased obviously, reaching 7.07–27.26 cm and 23.6–45.43%, respectively. In the urban flood model, the spatial grid is the basic unit of the runoff calculation of the model. The slope and other properties of the underlying surface have a direct impact on the runoff calculation. In this study, most of the study area is continuous urban hard ground or green space. With the increase of the spatial grid interval, the generalization of the terrain and underlying surface information is greater, and variation details of the urban terrain and

TABLE 5: Maximum inundation depth and AE (cm) at typical waterlogging points under four spatial resolutions.

Waterlogging points	Observed value of maximum inundation depth	50 m × 50 m		100 m × 100 m		150 m × 150 m		200 m × 200 m	
		Maximum inundation depth	AE	Maximum inundation depth	AE	Maximum inundation depth	AE	Maximum inundation depth	AE
Dongcheng west road	60	61.39	−1.39	60.98	−0.98	58.81	1.19	34.13	27.26
Dongzong road	30	30.55	−0.55	29.55	0.45	28.20	2.35	23.48	7.07

People's park	22	22.45	−0.45	21.39	0.61	21.16	0.84	19.15	2.85
Yinshan street	17	18.20	−1.20	17.50	−0.50	16.69	0.31	15.25	1.75
FIGURE 6: Variations of RE_P at typical waterlogging points under four grid spatial resolutions.

underlying surface are covered up. Therefore, the simulations at Yonghuating and Dongcheng West Road where there is larger slope are more affected by the spatial resolution.

4.3. The Compound Effect of Rainfall Temporal Resolution and Grid Spatial Resolution.

In this study, four rainfall temporal resolutions of 5 min, 10 min, 15 min, and 30 min are selected to be matched with three grid spatial resolutions of 50 m × 50 m, 100 m × 100 m and 150 m × 150 m. Thus, 12 experiments with different spatial and temporal resolutions are conducted. The IFMS Urban model is used to simulate the 12 experiments, and the compound effects of spatiotemporal resolutions on flood simulations have been compared and analyzed.

As shown in Figure 8, the effect of spatial resolution at typical waterlogging points is greater than that of rainfall temporal resolution. For the grids with different resolutions, with the increase of rainfall temporal resolution from 5 min to 30 min, the maximum inundation depth at typical waterlogging points has a small variation range, and RE_P is less than 3%. The effects of the 5 min, 10 min, and 15 min temporal resolutions are very close. For different rainfall temporal resolutions, with the increase of grid spatial interval, RE_P at typical waterlogging points greatly changes with nonlinear characteristics. For the waterlogging points of Dongcheng West Road and Yonghuating with a large slope, large grids have a larger influence on the simulation results, while for the flat Dongzong Road and People's Park, small grids have a larger influence on the simulation results.

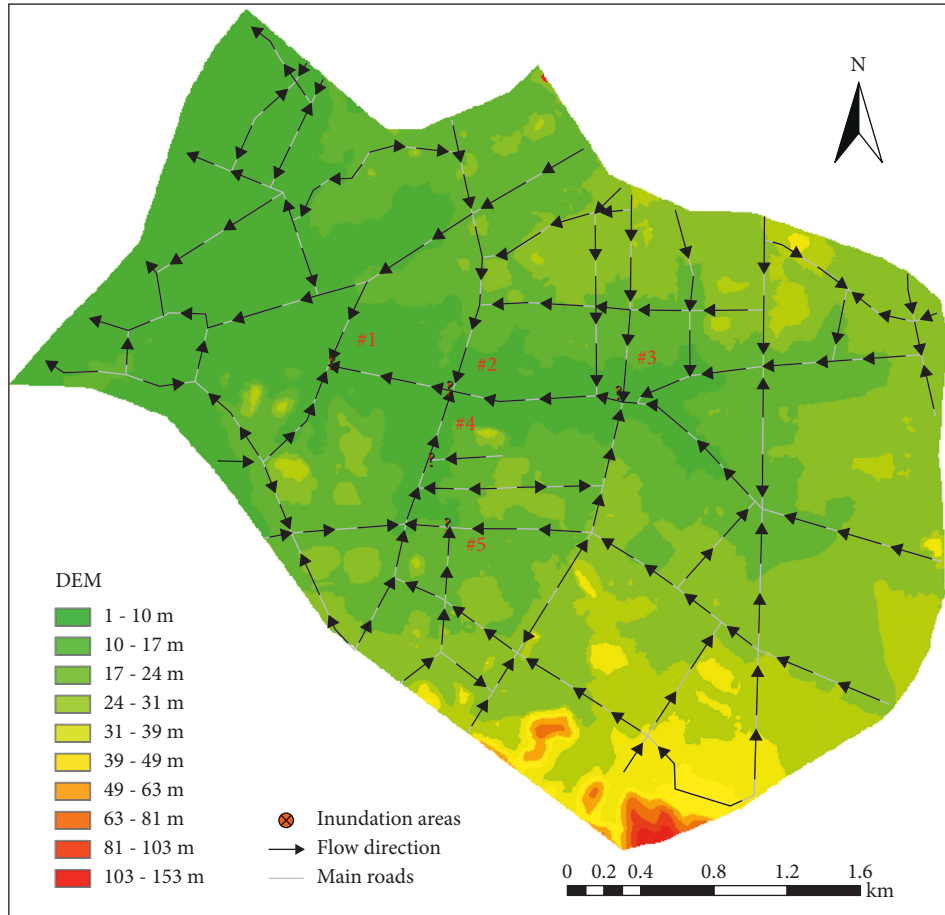
In urban flood simulation, the finer spatiotemporal resolution does not mean more accurate simulation results. For the 50 m grids, the maximum inundation depth is overestimated under different rainfall temporal resolutions. The finer the temporal resolution is, the greater the overestimation is. At the five typical waterlogging points, RE_P with the spatiotemporal resolutions of 5 min and 50 m is relatively large, ranging from 1.8% to 10%. In contrast, the water depth range that decreases with the increase of rainfall temporal resolution is small. It is not enough to compensate for the overestimated water depth range under the high-precision grid and RE_P is still larger than that of the 100 m grid. For the grid of 100 m, the overall simulations are better than those of 50 m and 150 m. The 5 min × 100 m, 10 min × 100 m, and 15 min × 100 m resolutions can achieve


FIGURE 7: Topography and flow direction of main roads in the study area (The five waterlogging points numbered #1 to #5 are People's Park, Dongzong Road, Yinshan Street, Dongcheng West Road, and Yonghuating).

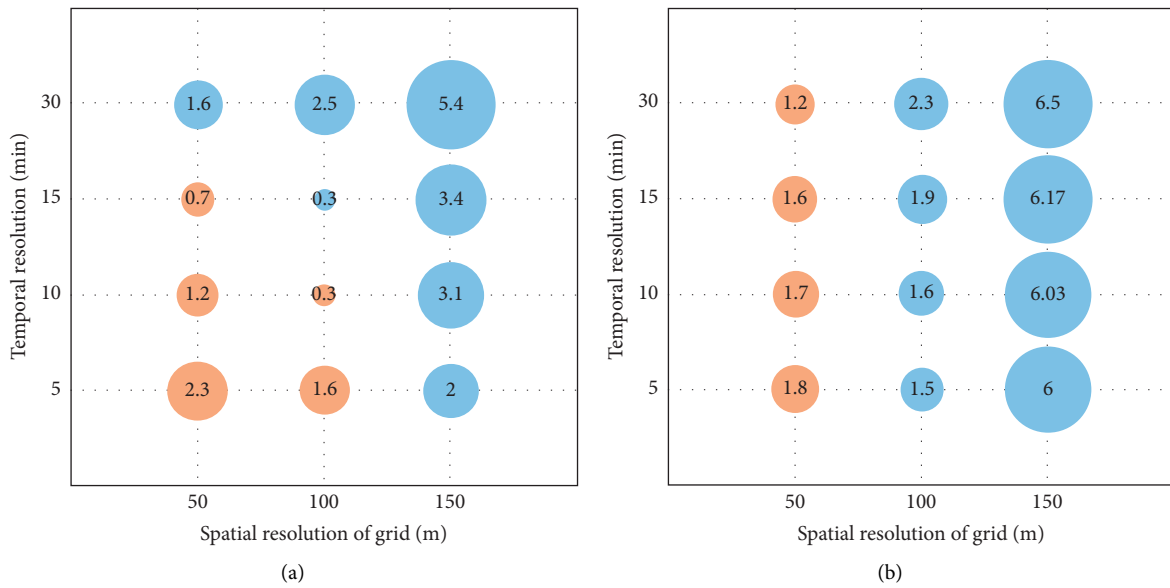

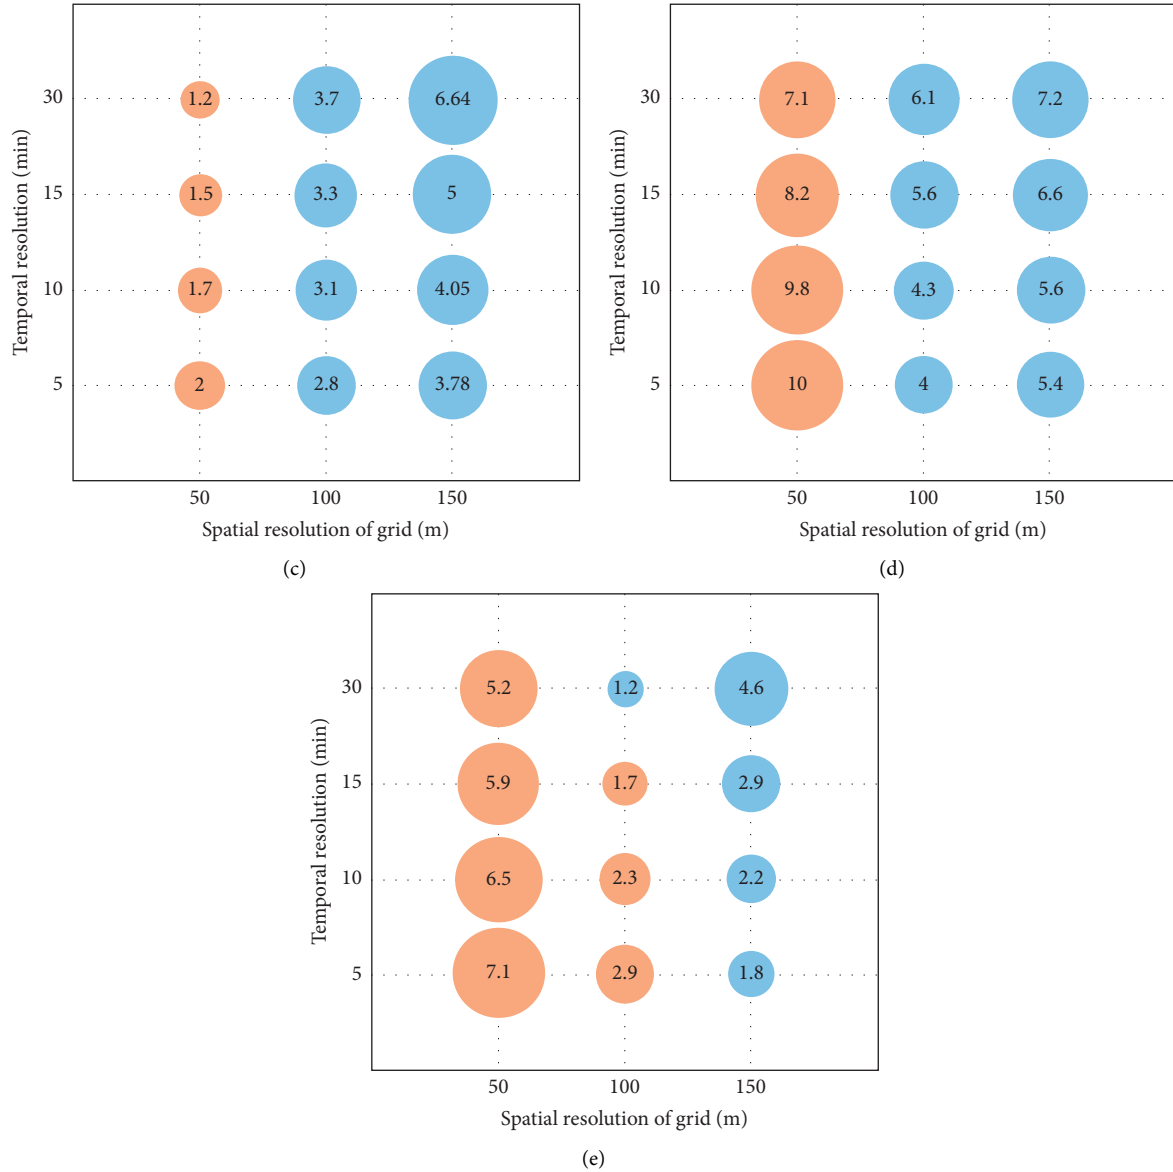

Figure 8: Bubble charts of the relative error of maximum inundation depth (RE_P) for 12 experiments with different rainfall temporal resolutions and grid spatial resolutions. The size of the bubble represents the range of RE_P. The yellow and blue colors represent that the simulated maximum inundation depth is higher and lower than the observation, respectively.

the best simulations at different typical waterlogging points, and their RE_P ranges from 0.3% to 6.1%. For the grid of 150 m, the maximum inundation depth of typical water-logging points is underestimated. With the increase of rainfall temporal resolution, the maximum inundation depth decreases and the RE_P increases. By judging the compound effect of rainfall temporal resolution and grid spatial resolution on the simulations, we find the simulation results are better with the 5 min, 10 min, or 15 min rainfall temporal resolution and the 100 m grid spatial resolution.

5. Conclusions

This study utilized the IFMS Urban model that couples SWMM and 2D hydrodynamic model to analyze the

response of the flood process of urban to different spatio-temporal resolutions. The typical waterlogged area, Guan-cheng District of Dongguan City, China, was selected as the study area. The variation characteristics of maximum in-undation water depth and inundation process were inves-tigated based on five rainfall temporal resolutions and four grid spatial resolutions. The main conclusions are as follows:

With the increase of rainfall temporal resolution, the accuracy of the simulated maximum inundation depth decreases, the time interval between the occurrence of the maximum inundation depth and the peak time of rainfall is prolonged, and the shape of the submerged water depth hydrograph changes greatly, which means the inundation process correlation with the rainfall process is decreased. Compared with the temporal resolution of 5 min, 10 min,

15 min, or 30 min, the 1 h temporal resolution has a greater influence on urban flood simulation.

For the effect of grid spatial resolution, the effect of grid resolution on urban flood simulation is nonlinear. With the increase of grid interval, the maximum inundation depth decreases and RE_P presents an overall increasing trend. For the fine 2D grids, the maximum inundation depth is overestimated, and the simulations at the waterlogging points with larger slopes are more affected by the spatial resolution.

In this study, the grid spatial resolution has a greater effect on the simulations at typical waterlogging points than the rainfall temporal resolution. It is not the case that the finer spatial and temporal resolutions are, the higher the accuracy of the simulation will be. The simulations perform better with the 5 min, 10 min, or 15 min rainfall temporal resolution and 100 m grid spatial resolution. For the area with the large slope in the catchment areas, using a 2D grid with a smaller grid spatial interval can obviously improve the computational accuracy of the model.

In this study, we have not considered the influence of terrain slope and vertical structure on the urban flood model. In the future, we will focus on the mechanisms of the compound effect of the spatiotemporal resolutions, and on how the model accuracy is affected by the type and slope of underlying surface.

Data Availability

The rainfall records are provided by the Meteorological Bureau of Dongguan City. The data of maximum inundation depth and distribution of inundation area on May 7, 2015, were collected and released by the Water Authority of Dongguan City. The basic geographic data provided by the Urban Planning Bureau of Dongguan City included a remote-sensing image and a digital elevation model. The sewer network data was provided by the Urban Planning Bureau of Dongguan City.

Conflicts of Interest

The authors declare that they have no conflicts of interest to report regarding the present study.

An enterprise's development and growth are inextricably linked to rational and efficient resource integration and optimization. This study focuses on the reorganization and integration of industrial elements inside the firm from the standpoint of resource integration. The ideal resource integration strategy is investigated by integrating the industrial parts of a certain enterprise in order to increase the efficiency of project completion and lower enterprise expenses. The enterprise's internal material and human resources are limited, but it is frequently necessary to execute numerous activities at the same time, and each activity must meet multiple goals. This research investigates how to properly integrate and schedule resources while attaining different goals. This research proposes using an enhanced particle swarm optimization technique (IPSO) to combine firms' internal resources. In order to address the issue of uneven particle dispersion caused by random population initialization, IPSO incorporates chaos theory into particle population initialization. The logistic mapping sequence generates a huge number of particles, and the particles with the highest quality are chosen for initialization. This can increase particle quality, allowing particles to be spread equally during setup. In the late stage, the classic particle swarm optimization algorithm (PSO) has a slow convergence rate, causing the algorithm to readily slip into a local optimal solution. This research proposes a dynamic inertia weight update approach based on fitness value. In the later stages of the algorithm, this strategy can improve the convergence speed and quality of the global optimal solution, allowing the particles to do a global search and eventually identify the population's ideal solution. Furthermore, IPSO creates a fitness function depending on task completion time. IPSO is used to test the performance of an enterprise's resource integration case. Experiments show that the method utilized can swiftly locate the ideal solution, complete the integration, and optimization of enterprise resources in the shortest job completion time, and for the least amount of money.

1. Introduction

Rapid advancements in science and technology have resulted in rapid economic growth. Economic development also poses difficulties for the management and operation of various businesses. To stand firm in today's rapidly changing society, businesses must not only have a long-term development plan on the outside but also a reasonable and efficient resource integration mechanism on the inside. The ability of an enterprise to screen, acquire, and combine various heterogeneous resources in the process of operation, including both the macrolevel that the enterprise obtains resources from the external environment where it is located, and the internal the microlevel of resource allocation. Some academics divide enterprise resource integration capabilities

into macrolevel categories based on this. The macrolevel enterprise resource integration capabilities include enterprises' ability to reconstruct operating rules and predict corporate strategies and risks in advance, whereas the microlevel enterprise resource integration capabilities include enterprises' ability to allocate, stimulate, and combine various existing resources. Existing research has examined the factors that may influence the development of enterprise resource integration capabilities in various contexts. According to the resource-based viewpoint, an enterprise is a collection of resources that can be obtained in a variety of ways. Resources are an important factor in an enterprise's long-term development. If a company wants to gain a competitive advantage and establish a market presence, it must invest in valuable resources and management skills.

Unrepeatable strategic management resources that can assist companies in successfully managing their businesses and obtaining additional compensation. At the moment, many scholars support the theory of resource-based view, and most studies are aimed at the impact of a specific type of enterprise's own resources on enterprise performance. Many of the results of the experimental analyses are consistent with resource-based theory. The uniqueness and nonreplicability of resources can play a role in the operation of businesses, forming competitive advantages and determining enterprise performance. Each enterprise's management resources are unique, and they have varying degrees of importance at each stage of the enterprise's operation. It can be defined as the various human, financial, and material resources that business managers manage in their daily operations. The good operation of the enterprise's resources can achieve the management goals of the enterprise.

Enterprise managers with varying management capabilities deal with their management resources in various ways. Reasonable resource allocation and utilization can result in satisfactory operational results. According to reference [1] the materials owned by the enterprise cannot directly create performance and obtain benefits for the enterprise. Professional resource integration talents, on the other hand, can integrate the enterprise's static resources and generate benefits for the enterprise. Differences in management resources will result in differences in resource allocation efficiency, resulting in differences in corporate performance. According to reference [2], each company has distinct management resources and management employees with different talents. As a result, each business will develop its own management style. This type of management disparity resulting from resource differences will have an impact on the company's performance. Firms with a wealth of management resources outperform their competitors. External mergers and acquisitions by businesses, according to reference [3], might boost a company's ability to manage resources swiftly. The outside offers fresh resources and management strategies to the company, which will boost the company's ability to adapt to changes in the external environment while also promoting its growth. Rich management resources, according to reference [4], can assist businesses optimize and alter their organizational structure to react to changing external market conditions. At the same time, businesses can create long-term plans and alter their management practices as needed. Reference [5] demonstrates that firms can strengthen their market position by fully utilizing management resources. To summarize, resources play an essential role in the development of enterprises, and management resources play a positive function in enhancing firm performance, according to resource-based theory. The better the managerial resources, the better the company's performance.

Enterprise resource management optimization's ultimate goal is to maximize the company's benefits. To optimize earnings, different companies have different criteria. It mostly entails optimizing earnings and reducing the time it takes to execute tasks. To do this, the enterprise's material and human resources must be integrated and dispatched in a

reasonable manner. Enterprise resource integration and scheduling are NP-complete problems [6, 7]. Particle swarm algorithms [8–10], ant colony algorithms [11–13], simulated annealing algorithms [14–16], and genetic algorithms [17–19] are currently available that can solve NP-complete problems. The PSO algorithm has the advantages of fast convergence speed, easy operation, and the algorithm is convenient for global optimization, but it also has disadvantages such as easy to fall into local optimum and low search accuracy. Aiming at these problems, this paper proposes an IPSO algorithm, and applies it to the instance of enterprise resource integration and scheduling. In order to verify the performance of the method used in this paper, the experimental results obtained through simulation experiments show that the IPSO algorithm has a good effect on solving the problem of enterprise resource integration.

2. Information Construction of Enterprise Resource Management

2.1. Enterprise Resource Management Platform. Business resources are not only the most significant aspect of an enterprise's internal environment, but they are also the prerequisites for enterprise resource integration. Enterprise management is now completely reliant on computers, and the advancement of information technology has expedited the reform of internal management and resource management in businesses. As a result, a series of information systems focused on the integration and deployment of enterprise resources have emerged. The system can help with resource integration and give a platform for all employees to quickly acquire tasks and resources. Figure 1 depicts the enterprise resource integration optimization platform's design structure.

Figure 1 depicts a three-tier architecture for an enterprise resource integration platform. The acquisition layer gathers the data that the system requires. The resource integration layer supports various resource release and interface negotiation models, as well as evaluating and classifying the released data before storing it in various databases. To achieve intelligent business resource integration, the resource application layer executes application processing on diverse enterprise information resources.

2.2. Optimization of Enterprise Resource Integration. Optimizing enterprise resource integration mainly starts from four aspects: resource creation, resource use, integration, and effect evaluation. The relationship and interaction of these four aspects are shown in Figure 2.

(1) Theory is an important basis for guiding actual production. Constructivist theory mainly emphasizes the initiative and situational nature of resource integration. Resource integration is not a stimulus to passively receive information, but to actively process external information according to the corporate background. When the resource content is related to the needs of the enterprise, the enterprise should propose appropriate resource integration and
FIGURE 1: Architecture of enterprise resource integration platform.
FIGURE 2: Optimization of enterprise resource integration.

allocation strategies to deal with various tasks. The resource integration dependence theory mainly emphasizes that the survival of the entire enterprise organization needs to absorb resources from the surrounding environment, and the interaction between the organization and the control resources in other environments is carried out.

(2) Resource creation. Resource creation should take enterprise managers as the main body and employees'

needs as the fundamental starting point, so as to encourage employees, managers, and leaders to work together. Build a resource environment dominated by service resources to ensure the reliability of resources, thereby providing guarantees for sustainable development of resources.

(3) Independent integration management includes user information maintenance, resource information maintenance, and integration strategy. User

information maintenance requires periodic updates and confidentiality of information. Enterprises need to set confidential information goals, formulate information integration plans, determine integration progress, and select integration resources to achieve self-maintenance. Resource information maintenance is to store and update resource information. Integrate and optimize resources based on integration strategies.

(4) Evaluation is the guarantee for resource integration. With the goal of resource integration and optimization, the design evaluation process is shown in Figure 3. Figure 3 shows that evaluation is an important indicator to measure the rational integration of resources and is the driving force behind the integration of resources and information within an enterprise. To evaluate based on the integration of platform resources, it is not only necessary to analyze each link but also to evaluate the effect of self-integration of employee information in a timely manner.

3. Enterprise Resource Integration and Optimization of IPSO Algorithm

3.1. Introduction to PSO. Suppose a population X is searched in a D-dimensional space, and each population consists of H particles. Each particle in the population can be represented as a solution to the problem. $X_i(t)$ to represent the position of the i-th particle in the t-th iteration of the population. $V_i(t)$ is the velocity of the particle at the t-th iteration in the population. S_i represents the self-optimal solution of the i-th particle, and S_{best} represents the optimal solution of the entire particle population. The mathematical expression formula of each variable is as follows:

$$
\begin{aligned}
X(t) &= \{X_1(t), X_2(t), \ldots, X_H(t)\}, \\
X_i(t) &= (x_{i1}(t), x_{i2}(t) \ldots, x_{iD}(t)), \\
V_i(t) &= (v_{i1}(t), v_{i2}(t) \ldots v_{iD}(t)), \\
S_i &= (S_{i1}, S_{i2}, \ldots, S_{iD}), \\
S_{best} &= (S_1, S_2, \ldots, S_D).
\end{aligned}
\tag{1}
$$

PSO updates the state of the particle through the particle's velocity and position; equation (2) is the velocity update expression, and equation (3) is the position update expression:

$$
v_i(t+1) = wv(t) + e_1 g_1 (S_i(t) - x_i(t)) + e_2 g_2 (S_{best} - x_i(t)),
\tag{2}
$$

$$
x_i(t+1) = x_i(t) + v_i(t+1),
\tag{3}
$$

where w is the inertia weight coefficient, which is used to determine how much velocity is retained after the last iteration; $e1$, $e2$ are the learning factors of the algorithm. Usually, both parameters are set to 2. $g1$, $g2$ are random numbers whose values are between [0, 1]; t is the number of
Figure 3: Enterprise resource integration assessment process.

iterations variable; and T is the maximum number of iterations. $[X_{min}, X_{max}]$ is the value range of position, and $[V_{min}, V_{max}]$ is the value range of velocity. The fitness value function f is used to judge the quality of particles. The size of the fitness function value indicates the pros and cons of the problem solution. After the particles are iterated, equation (4) is the update formula of the individual optimal value. When the maximum number of iterations is reached, the algorithm stops iterating:

$$
S_i = \begin{cases} X_i(t), & f(X_i(t)) > f(S_i), \\ S_i, & f(X_i(t)) \le f(S_i). \end{cases}
\tag{4}
$$

The flow of the PSO algorithm is shown in Figure 4. The specific implementation steps of PSO are as follows:

Step 1: Initialize the particle swarm. Given $t = 0$, bring the value of t into the particle velocity formula and position formula, and determine the initial position of the particle as $X_i(0)$ and the initial velocity as $V_i(0)$. Set all parameter values related to the algorithm, such as H, D, T, w, $e1$, $e2$, $g1$, $g2$.

Step 2: Calculate the fitness value of each particle.

Step 3: Set the fitness value of the current position of the particle as the optimal solution S_i of the particle itself. Set the optimal solution in the initial population as S_{best}.

Step 4: Update the particles.

① Update the position of the particle according to equation (3), and update the velocity of the particle according to equation (2).
② Judging the velocity and position of the current particle within a given range.
③ Calculate the fitness value of each particle, and then update S_i according to equation (4). Compare the fitness value of the individual optimal position and the group optimal position to update S_{best}.

Step 5: Judge whether the end condition is met, if the end condition is met, then step 6 is executed. Otherwise, the number of iterations is increased by 1, and step 4 is executed.

Step 6: Output S_{best}, and the algorithm ends.

Figure 4: PSO flow chart.

$$w = w_{\max} - \frac{w_{\max} - w_{\min}}{T} \times t, \tag{5}$$

where $w_{\max}$ represents the maximum inertia weight value, and $w_{\min}$ represents the minimum inertia weight value. In the early stage of the algorithm search, because the number of iterations is relatively small, the value of w will be large, which is convenient for particles to search globally. In the later stage of the algorithm search, as the value of t increases, the value of w will become smaller, which makes it easier for the particle to find the local optimal solution.

Inspired by the above strategies, this paper proposes a new method to update inertia weights. This method also dynamically updates the inertia weight based on the size of the fitness value. f_{avg} represents the average fitness value of the population. f_i represents the fitness value of the particle currently being iterated, $i = 1, 2, 3, \ldots H, H$ is the population size. The inertia weight value ranges from 0.4 to 0.9. The inertia weight expression used in this paper is as follows:

$$v_i(t + 1) = wv_i(t) + e_1 g_1 \left(S_{\text{best}} - x_i(t)\right),$$

$$s.Tw = \begin{cases} w_{\min} + \dfrac{f_{\text{avg}} - f_i}{f_{\text{avg}}}, & f_i \leq f_{\text{avg}}, \\[4mm] w_{\max} - \dfrac{f_i - f_{\text{avg}}}{f_{\text{avg}}}, & f_i \geq f_{\text{avg}}. \end{cases} \tag{6}$$

Chaos theory has different chaotic mapping methods, this paper adopts Logistic mapping. The principle of logistic mapping is the regression equation. Logistic maps are well ergodic and the particles are evenly distributed over their range. Its regression equation is as follows:

$$y_{k+1, j} = 4y_{k, j}\left(1 - y_{k, j}\right) y_{k, j} \in (0, 1), \tag{7}$$

where k is the number of iterations, and y_{kj} is the population sequence. This article will use chaos theory to initialize the population. PSO uses the chaotic sequence to produce a large number of particles during initialization and selects the particles with better quality as the initial particles of the population. This ensures that the particles are uniformly distributed in the solution space and the quality of the particles can be guaranteed.

(1) The steps to initialize using the chaotic sequence are as follows:

Step 1. Randomly generate a number $y_{0,0}$ in [0, 1].
Step 2. Bring $y_{0,0}$ into equation (8) for iteration to generate the sequence y_{kj}.
Step 3. Repeat step 2 until $k = 2^*H$;
Step 4. Map the generated sequence to the solution space of the population according to equation (8) so that 2^*H particles can be obtained.

$$x_{k, j} = a + y_{k, j}(b - a), \tag{8}$$

where $a = X_{\min}$, $b = X_{\max}$.
Step 5. Select the optimal H particles from the generated 2^*H particles as the initial population.

3.2. IPSO Algorithm. Due to the slow convergence speed of the traditional PSO late stage, this will result in the inability to perform global search in the particle late stage. Aiming at this problem, this paper improves the update method of inertia weight value, which can improve the convergence ability and search ability of the algorithm. In addition, since the population initialization of PSO is random, this will inevitably lead to a part of the particles far away from the optimal solution and affect the quality of the particles. Therefore, in this paper, chaos theory is added to the population initialization process to improve the particle quality and optimization ability.

Choosing an appropriate inertia weight w is the key to improving the convergence and optimization capabilities of PSO. The size of the inertia weight value determines the optimization ability of the algorithm. When the inertia weight value is small, the local optimization ability of the algorithm is better. When the inertia weight value is large, the global optimization ability of the algorithm is better. However, in the traditional PSO, the inertia weight value is set to a fixed value; so many studies have proposed various improvement strategies for the inertia weight to make the optimization ability of the algorithm the best. Among the many improvement strategies, the improvement ideas of the following strategies are very good. The strategy can update the inertia weight value according to the number of iterations. The ability of particle local optimization and global optimization is balanced by dynamically adjusting the w value. The mathematical expression for this strategy is as follows:

(2) The implementation steps of particle swarm optimization based on chaos theory are as follows:

Step 1. Population initialization based on chaos theory. Set the initial iteration number t to 0, and other parameters in the algorithm.

Step 2. Calculate the fitness value of the selected H particles with good quality.

Step 3. Set the fitness value of the current position of the particle as the optimal solution S_i of the particle itself. Set the optimal solution in the initial population as Sbest.

Step 4.Update the particle's position and velocity:

① Update the velocity and position of the particle according to the relevant update formula.

② Determine whether the current particle velocity and position are beyond the feasible range.

③ Update S_i and Sbest according to equation (4).

Step 5. Determine whether the end condition is reached. If the end condition is reached, execute step 6. If not, increase the number of iterations by 1, and execute step 4.

Step 6. Output S_{best}, and the algorithm ends.

4. Construction and Solution of Resource Integration Model Based on IPSO

4.1. Model Building. A single project has a clear project goal in the project planning stage and is divided into several tasks through work breakdown, and these tasks are all serving the project goal. Generally speaking, the scope of project objectives includes three dimensions: cost, time, and quality. In the multiproject management environment, the implementation of all projects of the enterprise serves the enterprise strategy. Project resource scheduling meets the project's time requirements for different resources as much as possible and strives to keep the completion time of all projects as short as possible. At the same time, such scheduling will inevitably involve organizational resources, so how to improve the utilization efficiency of organizational resources becomes a problem. In addition, the project leader will also pay attention to cost and quality issues. On the one hand, he hopes to reduce the project budget and improve the project income, and on the other hand, the quality should be as high as possible.

Under the premise of limited total resource supply, the multiproject resource scheduling problem can be regarded as the superposition of resource scheduling problems in multiple tiny time intervals. Therefore, it is possible to take a certain period of time during the execution of the project for analysis. Suppose the multiproject resource scheduling problem involves m mutually independent projects and n resource supply types. Within the time interval ΔT, there are e processes in progress in project i. Where the quantity of the kth resource required by the jth process is denoted as $z_{i,j,k}$, the quantity of the obtained resource is denoted as $n_{i,j,k}$, and the total supply of this type of resource is Z_k. Once the construction period delay in project i causes losses, the total cost of

delaying the project per unit time is recorded as s_i. Δt_i represents the engineering delay time of project i within the time interval ΔT. With the goal of minimizing project losses due to insufficient resource supply, the objective function is established, as follows:

$$Z = \min \sum_{i=1}^{q} \Delta t_i s_i, \tag{9}$$

where s_i is a known quantity, which can be known from the contract; Δt_i is an unknown quantity, which is determined by the quantity $z_{i,j,k}$ of resources obtained by the process j performed by the project i in the time period ΔT. Under the condition that the total supply of various resources is limited, $n_{i,j,k}$ should meet the restrictive conditions:

$$\sum_{i=1}^{q} \sum_{j=1}^{q} n_{ijk} \le Z_k, k = 1, 2, \ldots, w. \tag{10}$$

In the time period ΔT, the number of resources required by the critical path process in project i is z_{izk}, and the number of resources obtained is lick. Let t_{iz} denote the planned working time of the critical path, $t_{iz} = \Delta T$, and t'_{iz} denote its actual working time. From the principle that the total consumption of each resource in the same process remains unchanged, that is, $z_{izk}t_{iz} = n_{izk}t'_{iz}$, $t'_{iz} = z_{izk}t_{iz}/n_{izk}$, $k = 1, 2, \ldots, w$. Therefore, the delay time of the critical path of project i can be expressed and known as

$$\Delta t_i = \Delta t_{iz} = \frac{z_{izk} - n_{izk}}{n_{izk}}. \tag{11}$$

In the same way, for any process on the noncritical path in project i, mark the number of required resources as r_{isk}, and the number of obtained resources as n_{isk}, within the time period ΔT, the planned working time of this path is t_{if}, and the time difference is t_{is}. The delay time is expressed as follows:

$$\Delta t_{is} = \max \left\{ \frac{t_{is}(z_{\text{isk}} - n_{isk})}{n_{\text{isk}}} \right\}. \tag{12}$$

In order to ensure that the critical path of project i does not change, the difference between the delay time of the noncritical path and the time difference owned by the process should not exceed the delay time of the key process, namely,

$$\Delta t_{is} - T_{is} \le \Delta t_i. \tag{13}$$

In the actual project implementation, the construction of any process may require multiple resources at the same time, and a certain proportional relationship must be satisfied between different resources to coordinate and promote the process forward. In resource scheduling, under any circumstances, for the ongoing process j in project i, the supply quantity of resources and the demand quantity should satisfy the following proportional relationship:

$$n_{ijk} = \eta_{ij}z_{jk}, \quad k = 1, 2, \ldots, w, 0 < \eta_{ij} \le 1, \tag{14}$$

where η_{ij} represents the resource allocation coefficient related to each process j under construction within the time interval ΔT.

To sum up, substituting equations (7) and (11) into equations (9), (10) and (13) respectively, we get

$$Z = \min\left[\Delta T \sum_{i=1}^{q} s_i \left(\frac{1}{\eta_{iz}} - 1\right)\right], \tag{15}$$

$$\sum_{i=1}^{q} \sum_{j=1}^{q} \eta_{ij} z_{ijk} \le Z_k, \quad k = 1, 2, \ldots, w, \tag{16}$$

$$t_{is}\eta_{iz} \le \Delta T \eta_{is}. \tag{17}$$

Equations (15)–(17) constitute a mathematical model of enterprise resource scheduling in a multiproject environment with limited resources.

4.2. Model Solution.

The IPSO algorithm is proposed to be used for enterprise resource integration and scheduling. In order to verify the effectiveness of the proposed algorithm for enterprise resource integration scheduling, this paper introduces the method into a practical case. A company has a total of four projects to be completed within a certain period of time, and there are three types of resources needed and available. Each project has a different number of processes. Every project has strict delivery time requirements. The loss cost M_i ($i = $ P1,P2,P3,P4) of each item per delay unit time is 1000 for M_{P1}, $M_{P2} = 800$, $M_{P3} = 1500$, $M_{P4} = 1800$. Table 1 is a breakdown of the resource requirements of the enterprise to complete each project, where ΔT is set to 5.

Substitute the data shown in Table 1 into the resource integration model shown in equation (15), and the obtained formula is as follows:

$$\min z = 5 * 1000\left(\frac{1}{x_3} - 1\right) + 5 * 800\left(\frac{1}{x_5} - 1\right) + 5 * 1500\left(\frac{1}{x_6} - 1\right) + 5 * 1800\left(\frac{1}{x_{10}} - 1\right),$$

$$s.t. 18x_1 + 15x_2 + 10x_3 + 29x_4 + 17x_5 + 13x_6 + 21x_7 + 16x_8 + 23x_9 + 18x_{10} \le 150$$

$$25x_1 + 27x_2 + 16x_3 + 18x_4 + 23x_5 + 26x_6 + 10x_7 + 18x_8 + 15x_9 + 11x_{10} \le 190$$

$$9x_1 + 16x_2 + 35x_3 + 18x_4 + 12x_5 + 11x_6 + 14x_7 + 23x_8 + 14x_9 + 8x_{10} \le 150$$

$$4x_3 \le 5x_1$$

$$2x_3 \le 5x_2$$

$$3.5x_5 \le 5x_4 \tag{18}$$

$$4x_6 \le 5x_7$$

$$4.5x_{10} \le 5x_8$$

$$3x_{10} \le 5x_9$$

$$0 < x_i < 1,$$

where x_1, x_2, x_3 represents the resource allocation coefficient of process P11, P12, P13; x_4, x_5 represents the allocation coefficient of process P21, P22, x_6, x_7 represents the resource allocation coefficient of process P31, P32; x_8, x_9, x_{10} represents the resource allocation coefficient of process P41, P42, P43.

For the above mathematical programming model, the standard particle swarm optimization algorithm and the new PSO optimization algorithm proposed in this paper are used to solve the problem, respectively. The parameter settings of the algorithm are evolution times $T = 600$, population size $D = 300$, and parameter $e_1 = 1.532$, $e_2 = 1.541$, the error $\varepsilon = 0.0001$.

In addition, Figure 5 shows the simulation results of the two algorithms. It can be seen from the figure that the average value of the project loss cost obtained by the standard particle swarm optimization method is larger than the result obtained by the new particle swarm optimization algorithm. According to the discrete degree of the objective function, the simulation results of the new particle swarm optimization algorithm are more concentrated, while the simulation results of the standard PSO [20] are more scattered.

After the above comparison and analysis of the simulation results of the two algorithms, it is concluded that compared with the standard particle swarm optimization algorithm, the improved particle swarm optimization algorithm in this paper has higher stability and better convergence.

TABLE 1: Details of enterprise resource requirements.

Project	Process	Required time	Time difference	Resource R1	Resource R2	Resource R2
P1	P11	4	0	18	25	9
	P12	2	2	15	27	16
	P13	5	2.5	10	16	35
P2	P21	3.5	3	29	18	18
	P22	5	2	17	23	12
P3	P31	5	1.5	13	26	11
	P32	4	2	21	10	14
P4	P41	4.5	3	16	18	23
	P42	3	1	23	15	14
	P43	5	3	18	22	8
Resource requirements				**180**	**200**	**160**
Max supplies				150	190	150
FIGURE 5: Comparison of project loss costs obtained by different algorithms.

According to the resource allocation coefficients obtained by the PSO and IPSO algorithms, the allocation of each resource among different projects is calculated, and the resource allocation of the two algorithms is obtained as shown in Tables 2 and 3.

Observing the data in Table 2, it can be seen that the allocation of resource R1 based on PSO is 136.17, the allocation of resource R2 is 152.63, and the allocation of resource R3 is 121.07. There is a large gap between the calculated allocation and supply of each resource. This shows that the allocation of resources is not reasonable. The delay times for the three operations of project P1 are 1.489, 3.119, and 2.765, respectively. The planned time differences corresponding to these three processes are 0, 2, and 2.5, respectively. The delay time calculated based on PSO is larger than the planned time difference. This shows that resource integration based on PSO is not very effective. The delay times for the two processes of project P2 are 2.120 and 2.221 respectively. The planned time differences corresponding to these two processes are 3 and 2, respectively. It can be seen that the process P21 can be completed within the set time difference, but the process P22 cannot be completed within the set time difference. The delay times for the two processes of project P3 are 1.765 and 0.815

respectively. The planned time differences corresponding to these two processes are 1.5 and 2, respectively. It can be seen that the process P32 can be completed within the set time difference, but the process P31 cannot be completed within the set time difference. The delay times for the three operations of project P4 are 2.642, 0 and 2.812, respectively. The planned time differences corresponding to these three processes are 3, 1, and 3, respectively. From the comparison data, it can be seen that these three processes can be completed within the set time difference. To sum up, in the resource integration scheme based on the PSO algorithm, except for P4, which can be completed according to the set time difference, other projects cannot be completed within the set time difference.

Observing the data in Table 3, it can be seen that the allocation of resource R1 based on IPSO is 159.74, the allocation of resource R2 is 175.89, and the allocation of resource R3 is 137.41. The calculated allocation of each resource is very close to the available Supply amount. This shows that the allocation of resources is more reasonable. In the results calculated based on IPSO, the delay times for the three processes of project P1 are 1.622, 2.120 and 3.235, respectively. The planned time differences corresponding to these three processes are 0, 2, and 2.5, respectively. The delay time calculated based on IPSO is larger than the planned time difference. The delay times for the two processes of project P2 are 1.522 and 1.767, respectively. The planned time differences corresponding to these two processes are 3 and 2, respectively. It can be seen that both steps P21 and P22 can be completed within the set time difference. The delay time for the 2 processes of project P3 is 0.521,0 respectively. The planned time differences corresponding to these two processes are 1.5 and 2, respectively. It can be seen that both steps P31 and P32 can be completed within the set time difference. The delay times for the three processes of project P4 are 2.764, 1.656, and 2.701, respectively. The planned time differences corresponding to these three processes are 3, 1, and 3, respectively. From the comparison data, it can be seen that this process P41 and P43 can be completed within the set time difference, and P42 cannot be completed within the set time difference. To sum up, in the resource integration scheme based on the PSO algorithm, except for P2 and P3, which can be completed according to the set time difference,

TABLE 2: Details of the actual allocation of enterprise resources based on PSO.

Project	Process	Required time	Time difference	Resource R1	Resource R2	Resource R2	Partition coefficient	Delay value
	P11	4	0	13.33	18.51	6.66	0.7403	1.489
P1	P12	2	2	12.38	22.28	13.20	0.8251	3.119

other projects cannot be completed within the set time difference.

In order to compare the resource integration and allocation schemes obtained by the two methods more intuitively, screen out the optimal resource allocation scheme, and give a resource allocation comparison chart, as shown in Figure 6. In the figure, MaxSupply represents the amount of resources that the enterprise can supply. From the data in the figure, it can be seen that the allocation of the three resources based on IPSO is the closest to the maximum supply. However, there is still a big gap between the distribution scheme based on PSO and the maximum supply.

5. Conclusion

In the process of continuous operation and development of enterprises, there will definitely be some problems in the use and deployment of internal resources. In order to optimize the integration and allocation of enterprise resources, this paper proposes to use an optimization algorithm to allocate resources. Its purpose is to efficiently complete the delivery of each project within the contracted construction period. Based on the traditional PSO algorithm, this paper proposes

an IPSO algorithm. Firstly, to solve the problem of uneven particle distribution caused by random initialization of the population, the algorithm adds chaos theory to the initialization of particle population. It uses the Logistic mapping sequence to generate a large number of particles, and selects the particles with better quality for initialization, which improves the quality of the particles and enables the particles to be evenly distributed during initialization. Secondly, the late convergence speed of particle swarm optimization algorithm is slow, which makes it easy to fall into the local optimal solution. Aiming at this problem, a dynamic inertia weight update method based on fitness value is designed. This can improve the convergence speed in the later stage of the algorithm, improve the quality of the global optimal solution, and enable the particles to perform a global search and finally find the optimal solution of the population. Finally, a fitness function based on task completion time is designed, and the IPSO algorithm is applied to the integration and optimization of internal resources of the enterprise. Compared with the standard particle swarm optimization algorithm, the IPSO algorithm has higher stability and better convergence. In the experimental part, a set of optimal solutions are selected to solve the resource allocation of each project process in the experimental example. The results show that the IPSO algorithm can produce better results for this kind of resource allocation problem. It can not only allocate the limited enterprise resources reasonably, but also minimize the total project loss caused by the delay of the construction period. The optimization results show that the IPSO algorithm proposed in this paper can effectively integrate and schedule the internal resources of the enterprise and improve the operation efficiency of the enterprise.

In triangular mesh models, the repair of complex hole poses a difficult problem, which always causes serious repair defects. Therefore, it is needed to develop an intelligent identification and classification method of complex holes to reduce repair difficulties. First, the topological structure of the complex hole is studied and all the holes are divided into single holes and continuous holes depending on whether there are intersection points. Second, to tackle the nesting and connecting of complex continuous holes, a decomposition method of multiply connected domains based on intersection points is proposed to partition or reconstruct complex continuous holes into single holes. Based on the different geometric structures, single holes are classified into five common hole types and a corresponding identification method of single holes is presented. Finally, an experiment is carried out to verify the repair quality and efficiency of the proposed method. Compared with Geomagic software, the proposed method can automatically identify and partition complex holes with fewer defects and similar efficiency. It can reduce the difficulties of repairing complex holes and enable the repair of complex holes based on existing methods. It is shown that the method can be applied to complex hole repair of 3D printing models without the participation of technicians.

1. Introduction

As a rapidly developing manufacturing technology, 3D printing technology (also known as additive manufacturing technology or rapid prototyping technology) is gradually entering various fields and playing an important role [1, 2]. Compared with traditional manufacturing technology, 3D printing technology can better meet the modern green concept and presents a favourable trend in the green manufacturing industry. In 3D printing technology, triangle meshes are characterized by simplicity, straightforwardness, and expressiveness [3]. Thus, it becomes a widely used form of a geometric model and gradually proves to be an important basis of 3D printing technology. However, in the construction and acquisition of mesh models, holes are often generated, affecting the appearance and quality of 3D printed models. Therefore, the identification and repair of the holes in the triangle mesh model become the key to improving the quality of 3D printing.

At present, the identification and repair of triangle mesh holes are mostly carried out manually, with low efficiency and high requirements of operators' skills. Automatic hole identification and repair algorithms often regard all holes as single holes. Most research focuses on the repair method of single holes and disregards the processing and partitioning of complex holes, single hole geometry, and the topological relationship between relevant holes. This results in unsatisfactory model repair and new defects, such as self-intersecting surfaces, highly refracted edges, and degenerate triangles.

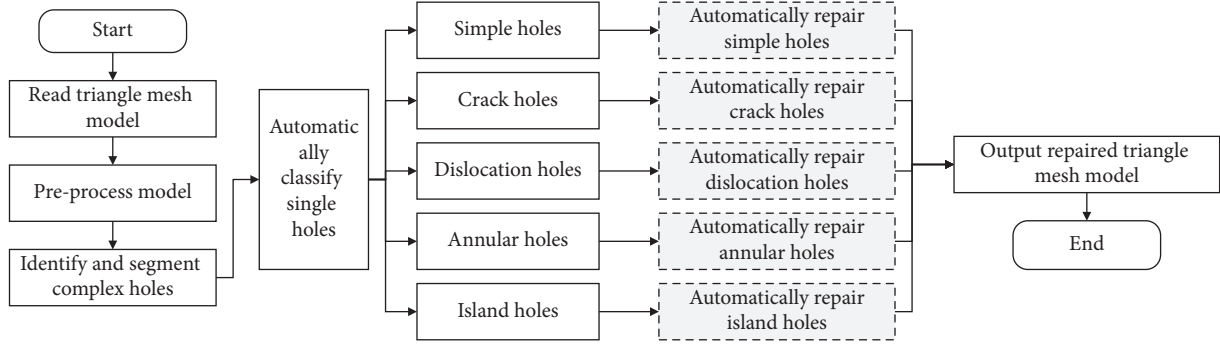
Therefore, to improve the quality of hole repair and to lower the reliance on specialized technicians, it is necessary to study the intelligent identification and partitioning method of complex holes in triangle meshes. The technical route of the paper is shown in Figure 1. First, the mesh model is checked and preprocessed. Second, the complex holes are identified and segmented and continuous holes are partitioned into single holes. Third, all the single holes are


Figure 1: Technical route.

automatically classified into specific single holes, such as the simple hole, crack hole, and annular hole. Finally, the appropriate hole repair methods are chosen and the ideal triangle mesh model is output. The results show that the proposed method can accurately identify, partition, and repair complex holes with intersection points. The main contributions are summarized as follows:

(1) A decomposition method of multiply connected domains based on intersection points is proposed to partition or reconstruct complex continuous holes into single holes. It can greatly improve the structure and size of the complex holes and can mostly avoid the intersection of various hole lines.

(2) An identification method of single holes is researched to divide single holes into five common hole types, which can reduce the difficulties of repairing complex holes and enable the repair of complex holes based on existing repair methods of single holes.

(3) The proposed repair process is completely automated, replacing the manual judgment and repair operation, reducing the dependence on professionals. At the same time, it can achieve high efficiency, similar to Geomagic.

2. Related Work

Hole identification and extraction is a critical preliminary process for hole repair. Given the considerable amount of data generated from the conversion from solid model to point cloud or grid, the data processing is time-consuming with low efficiency if holes are identified and extracted through repeated traversal. Therefore, the efficiency and accuracy of identification and extraction will directly affect the efficiency and quality of subsequent repair. The existing hole identification and extraction methods can be divided into two categories according to the data type: hole identification based on point cloud data and that based on grid [4, 5].

There are many methods for hole identification based on point cloud data [6–9]. Milroy et al. [10] identified the boundary of holes by calculating the extreme value of curvature. This method can generate good results in areas with small curvature changes and relatively smooth surfaces,

but less so when the model curvature changed dramatically. Orriols and Binefa [11] adopted the least squares method to identify and query holes, which was also not suitable for drastic curvature changes. Bendels et al. [12] used the minimum spanning tree to detect feature points of the point cloud boundary, but the complete extraction of the boundary still needed to be further improved. Liu [13] calculated the barycentre of sampling points and that of sampling points in the neighborhood to efficiently extract the hole boundary according to the distance ratio of various points. Alrashdan et al. [14] used the neural network method to automatically extract the boundary points, but the boundary points with small change of normal vector were easily to be missed, so that the extracted boundary might not be complete, and it was also time-consuming.

The grid-based hole identification method is also a focal point of research. In computer graphics, grid is a very basic representation method, and it can be obtained by point cloud data reconstruction or 3D model transformation. Triangular mesh is the most widely used form because of its simplicity, straightforwardness, and expressiveness. Zhan and Zhang [15] proposed the area expansion method to identify hole boundary and to form the Delaunay triangulation of point cloud data. Chen et al. [16] projected the object model onto a two-dimensional plane and used the interior angles of the projected polygon in the plane and related theories to automatically identify the holes. Li et al. [17] proposed a hole identification method based on the winged-edge data structure, in which all the holes of the model can be obtained through one traversal, greatly improving the efficiency of hole identification. However, in practical 3D printing application, the point cloud data obtained by traversal may be unevenly distributed, which may easily lead to a situation where multiple holes share a boundary vertex [18]. Therefore, the above algorithms cannot accurately identify such complex holes, and it will cause repair defects, such as self-intersecting surfaces and structure change.

Based on the above hole identification methods, many scholars have conducted in-depth studies on the hole-filling of triangle mesh models, among which the typical repair methods were as follows: the feature plane is calculated based on the point distribution of holes and the points of holes were projected onto the feature plane for partitioning. Then, implicit function [19], radial basis function [20, 21],

and the wave-front method [22] were used to map the points on the feature plane to the 3D model. The surface of the filled hole obtained by this method was often well shaped, but it was only applicable under extremely limited conditions. The method worked ideally for simple holes, but as for complex holes, mapping failure or errors may occur, leading to inferior hole filling. Therefore, a large number of scholars have proposed the classification and filling methods for complex holes.

Jun [23] proposed an algorithm of subdividing complex holes into simple holes before repairing them, providing a solution for the subdivision and repairing of holes with self-intersecting boundaries in the projection process. However, it was not conducive to dealing with other types of complex holes, especially with the challenge of self-intersecting boundaries in the nonprojection process. Inspired by this method, Li et al. [17] presented and created an algorithm based on edge expansion, which split the holes into flatter ones considering the spatial shape of holes. The method cannot deal with self-intersecting boundaries, and the complex holes were in fact just a simple hole with complex curvature changes. Lai et al. [24] mulled the processing of island holes and proposed a hole filling algorithm based on B-spline surfaces, fitting the vertices near holes to B-spline surfaces. This method focused on the topological accuracy and smoothness of the connection between new meshes and existing ones. Feng et al. [25] proposed a fast filling method for triangle meshes based on the hole size. The holes were classified into small holes, medium holes, and large holes according to their size, and different filling algorithms were used for different types of holes. However, the classification method only factored in the size of holes while ignoring the complex topological form of holes, thus leading to subpar filling results for complex holes. Wen et al. [26] proposed a method for automatic identification and repair of real defect holes, but it was only applicable in simply connected domains and ignored the topological form of the complex missing area. Therefore, the above studies lack the identification and segmentation of complex multiconnected domain holes, especially of the holes with self-intersecting boundaries.

To sum up, the repair methods for a specific type of holes, especially for simple holes, are relatively sophisticated, having delivered good repair results in previous research. However, the identification and partitioning of complex holes and the corresponding repair methods vary with each case. Adopting a uniform repair method will lead to self-intersecting surfaces in hole repair and unsatisfactory repair outcomes. At the same time, the human-computer interaction is often adopted in hole repair with ultralow identification and repair efficiency. In this case, the repair outcomes depend on the precision of the repair algorithm and the operator's skills. In order to solve this problem, based on the topological form of holes, ways must be found to intelligently identify and partition complex holes with multiconnected domains and self-intersecting boundaries. Thus, a method of automatically detecting, identifying, and partitioning of holes in triangle mesh models should be proposed, aiming at the nested and crossed characteristics of complex continuous holes. It can make up for the deficiency of various simple hole repair methods in complex holes.

3. Identification and Partitioning of Complex Holes

3.1. Features of Single Holes and Continuous Holes. Through compiling and analyzing the data of hole repair failure cases in the triangle mesh model, it is found that the failure often occurs when multiple holes are adjacent or nested to each other. It leads to mapping failure and thus unsatisfactory repair outcomes. In order to solve this problem, it is necessary to analyze the characteristics of such holes and differentiate them from single holes. Through analyzing many cases, it is found that the main difference is whether there are intersection points connecting multiple hole lines. On this basis, all the holes are classified into two types.

(1) Single holes: the points on the hole line can be connected in turn to form a closed loop with a unique solution. This is shown in Figure 2(a).

(2) Continuous holes: a continuous hole consists of multiple single holes, and there are one or more intersection points between the single holes. It offers multiple ways of representing each individual closed loop. As shown in Figure 2(b), four points A, B, C, and D of the continuous hole are the intersection points of multiple hole lines. When the counter-clockwise direction is defined positive, the continuous hole boundary can be identified as A-P1-A-B-P5-B-C-P6-P4-C-P3-D-P2-D-A.

3.2. Identification of Single Holes and Continuous Holes. Because of the large difference between repairing single holes and continuous holes in triangle meshes in terms of difficulties and methods, it is an essential step to classify and identify all holes and determine whether they are single holes or continuous holes before hole repair. Before identification, it is necessary to preprocess the input triangle mesh model and quickly establish the topological structure of the model's facets, edges, and vertices. According to the relationship between facets and edges of the triangle mesh model, all simply connected domains of the triangle mesh model are obtained, and each simply connected domain is regarded as a part. Free edges are found for each part, and all free edges are connected from end to end according to the connection between edges and points to obtain hole lines, so the basic information of all holes is obtained, including hole lines, hole directions, and the relationship between holes and parts. Among them, a free edge refers to an edge connected with only one facet. A hole line refers to the closed line formed by connecting the ends of free edges in each set, maintaining the topological relationship of the original triangle mesh model.

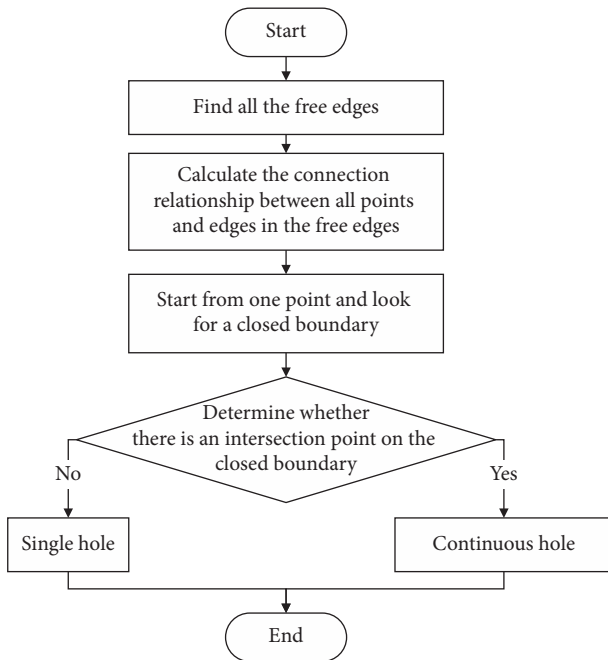
On this basis, an identification process of single holes and continuous holes is put forward, as shown in Figure 3. First, all the free edges of the hole lines are found by obtaining the basic information of the hole. The sets of free
FIGURE 2: Examples of (a) single hole and (b) continuous hole.


FIGURE 3: Identification process of single holes and continuous holes.

edges are discovered. Second, according to the topological structure relationship between each edge and each vertex, the connection between all points and edges in the free edges is calculated. Third, starting from any point, the closed boundaries are found according to the relation of connection. Then, it is judged whether there is an intersection point on the closed hole lines. If not, a single hole is output; if so, it is a continuous hole, and the corresponding boundary information is output to facilitate the subsequent partitioning of continuous holes.

3.3. Segmentation Method of Continuous Holes. In order to facilitate the repair of triangle mesh models, the complex continuous holes must be divided into single holes to improve the accuracy and repair quality of each single hole repair algorithm. The nesting and connection of the hole

lines in continuous holes are likely to cause errors in the partitioning of multiple holes. To solve this problem, a decomposition method of multiply connected domains based on intersection points is proposed to segment and reconstruct the hole lines of continuous holes. The specific steps are shown in Figure 4.

Step 1: detect the boundary of continuous holes.

Based on the information obtained during identification, the boundary of the continuous hole is detected, and the corresponding hole line is formed in the counterclockwise direction. For example, the continuous hole boundary in Figure 2(b) is A-P1-A-B-P5-B-C-P6-P4-C-P3-D-P2-D-A, and four intersection points A, B, C, and D are identified.

Step 2: divide the boundary line.

According to the intersection points of continuous holes, the inner area of continuous holes is divided into several separate holes. For example, the boundary of continuous holes in Figure 2(b) can be divided into five separate holes, namely, A-P1-A, B–P5–B, C–P6–P4–C, D-P2-D, and A-B-C-P3-D-A.

Step 3: distinguish the inner holes from outer ones.

The points on the hole line are projected onto the plane, and the positional relations of each hole are calculated according to the relative inner and outer relations between the points and the polygon. If the points of a hole L1 are all outside of another hole L2, it is assumed that L1 is outside of L2. If a hole line is not inside any of the holes, it is an outer hole, and if a hole line is inside one of the holes, it is an inner hole.

Step 4: judge whether it is an outer hole.

If the outer hole does not contain the inner hole, jump to Step 7; otherwise, continue with Step 5. It can be concluded that the outer holes in the continuous holes in Figure 2(b) are A-P1-A, B–P5–B, D-P2-D, and A-B-C-P3-D-A and the inner hole is C–P6–P4–C, which is included by the outer holes A-B-C-P3-D-A.

Step 5: identify and determine the new boundary point.

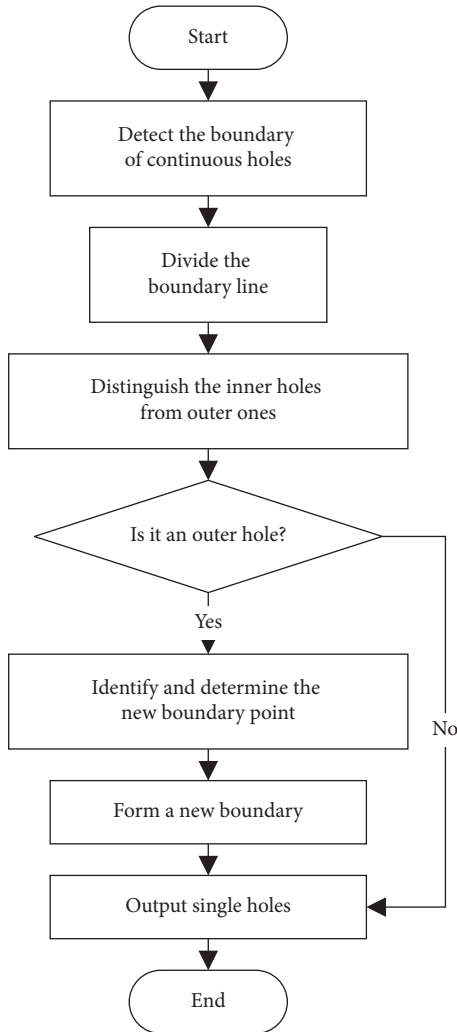
For an outer hole that contains an inner hole, the intersection point in its hole line must be found, and


FIGURE 4: Segmentation process of continuous holes.

FIGURE 5: Determination of the subsequent boundary point of an outer hole line.
FIGURE 6: Single hole identification and output.
FIGURE 7: Hole identification result of Geomagic.

there are three important edges connected to the intersection point, namely, the first edge connecting to the previous index point of the current outer hole line and the second and third edge connecting to two neighbouring index points in the inner hole line. Calculate the included angle between the first edge and the second and third edge. Select the neighbouring index point with the smallest included angle as the new boundary point. For example, Figure 5 shows that C1, C2, and C3 are the three important edges, and the included angle ∠1C2 is less than angle ∠1C3. Thus, the next boundary point is calculated to be in the direction of ray C2, that is, in the direction of P6, rather than P4.

Step 6: form a new boundary.

Starting from the new boundary point, all the points on the inner hole are inserted into the boundary of the outer hole in accordance with the connection order on the boundary, and the outer and inner edges of the hole are combined. In other words, in the example, the inner hole C–P6–P4–C is inserted into the outer hole A-B-C-P3-D-A and the new boundary line is A-B-C-P6-P4-C-P3-D-A.

Step 7: output single holes.

All the holes that meet the conditions are output as a single hole, with the boundary lines given. According to this method, the example outputs four single holes with the boundary lines A-P1-A, B–P5–B, D-P2-D, and A-B-C-P6-P4-C-P3-D-A. The filled area as shown in Figure 6 is four single holes surrounded by four boundary lines.

(a)   (b)
Figure 8: Crack hole. (a) Triangle mesh example. (b) Model example.

(a)   (b)
Figure 9: Dislocation hole. (a) Triangle mesh example. (b) Model example.

Step 8: end.

When the hole in this case is processed by traditional hole identification methods and software such as Geomagic, C–P6–P4–C can be easily identified and be output as a single hole. If filled based on this, the model obtained will not be desirable and a large number of self-intersecting surfaces will be created. As shown in Figure 7, both the green and red hole lines are identified as single holes, but the inner red hole line will intersect with the outer hole line during repair, obviously inconsistent with the actual hole.

4. Types of Single Holes and the Intelligent Identification Method

4.1. Types of Single Holes. After the complex continuous holes are divided into single holes, the geometry of each single hole still varies, posing challenges to the hole repair process. Therefore, by analyzing causes of self-intersecting surfaces based on the geometry of the hole and the current sophisticated hole repair methods, the single hole is further classified into five types: crack hole, dislocation hole, annular hole, simple hole, and island hole. Their respective characteristics are as follows:

(1) Crack hole: if the included angle and the cumulative included angle of any two sides forming the hole boundary are less than the set angle threshold, such a single hole is defined as a crack hole. Its shape resembles a straight line. The general rule of thumb is that the angle threshold is set between 5° and 10°, which is used to determine whether the hole resembles a straight line. The cumulative angle refers to the sum of angles between all boundary edges starting from the first edge. Crack holes, which occur in modelling or format conversion, are linear bad edges that are not sewn together at the surface joints. There are no triangles missing, but the adjacent triangles are not connected, as shown in Figure 8. Therefore, the crack holes are more suitable for repairing by stitching the boundary points and then optimizing the subdivision.

(2) Dislocation hole: if the distance between the points on the hole edge and on the nearest edge is very short (less than the set distance threshold), such holes are called dislocation holes, as shown in Figure 9(a). The distance threshold is also an empirical value and is generally set to about 0.1–0.5 mm. If it is less than this value, the hole is fixed by kneading the triangles together, generally without affecting the shape of the model; if it is above the set threshold, the hole is considered as a simple hole and can be repaired by adding triangle surfaces, which will not cause too many narrow and long triangles. As shown in Figure 9(b), both the red parts are dislocation holes.
FIGURE 10: Annular hole. (a) Triangle mesh example—coplanar annular hole. (b) Triangle mesh example—parallel annular hole. (c) Model example.
FIGURE 11: Simple hole. (a) Triangle mesh example. (b) Model example.

After judgment, the holes can be partitioned into simple holes and crack holes by merging the surfaces of dislocation holes.

(3) Annular hole: it refers to a hole composed of two boundary lines, nearly coplanar or parallel, with similar shapes and without intersection points, as indicated in Figure 10. There is an approximate coplanar or parallel relationship between the positions of the two annular closed curves, which is generally seen in the cross section or the profile of the model. The repair method of firstly stitching two hole boundaries and then optimizing the triangulation and fitting the surface is suitable.

(4) Simple hole: it refers to a single hole with no triangle surface data inside and only one closed boundary, as shown in Figure 11. It is the simplest type of single holes, and it is the type of hole that most repair methods are applicable to.

(5) Island hole: it refers to the existence of an independent grid area composed of triangle surfaces inside a hole, as shown in Figure 12. This individual grid area is called an island, and the number of islands can be one or more. According to the size of the islands, different repair methods can be selected,

such as the multidirectional advancing method [27] and variational implicit surfaces [4].

4.2. Intelligent Identification Method of Single Holes. After the identification and the segmentation of complex holes into single holes, the shapes of single holes are still different. To prevent various repair defects, different repair methods should be adopted according to hole types. Therefore, an intelligent identification method of single holes is researched to avoid human errors, which can judge the types of five holes in turn and realize the automatic and accurate identification of single holes. The specific judgment process is shown in Figure 13. It is described as follows.

Step 1: preprocess the model.

Traverse all the parts of the triangular model and output the basic information of every single hole, for instance, vertexes, free edges, and boundaries. This step provides a data basis for other steps.

Step 2: judge whether there is a crack hole.

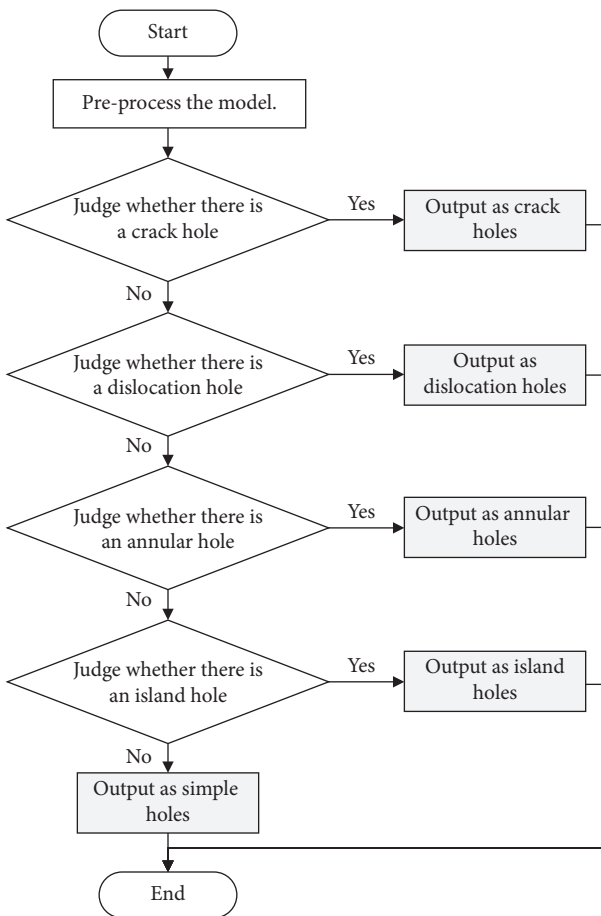
Calculate the included angle and the cumulative included angle of any two edges that constitute the single hole. If the value is less than the set threshold value, output the hole as a crack hole; if not, proceed to Step 3.
FIGURE 12: Island hole. (a) Triangle mesh example. (b) Model example.


FIGURE 13: Identification process of single holes.

Step 3: judge whether there is a dislocation hole.

Calculate the distance between points on the single hole and on their nearest edges. If it is less than the set distance, the current point is the dislocation point and output the hole as a dislocation hole; if not, continue with Step 4.

Step 4: judge whether there is an annular hole.

Determine whether there are two boundaries that are the closest and most similar to each other and whether

the gravity center of one boundary is within another boundary on the fitting plane. If so, output the hole as an annular hole; if not, proceed to Step 5.

Step 5: judge whether there is an island hole.

Determine whether there are one or more boundaries that are inside another boundary. If so, output it as an island hole; if not, output it as a simple hole.

Step 6: end.

5. Experimental Results and Discussion

As few studies have been conducted on the classification and identification method of the complex holes with intersection points in triangle mesh models, it is difficult to find a targeted algorithm for comparison. For this reason, the well-known commercial software Geomagic is selected to determine the identification and repair effect of the proposed method. All the developed algorithms are implemented in C++ by using Visual Studio 2013 and tested on a PC equipped with an Intel® Core i7-4790 processor and 8 GB of RAM on Windows 10. In the process of comparison, various proven methods in repairing different single holes can be chosen. Crack holes and dislocation holes are repaired through the suture or kneading of the corresponding points. Annular holes, simple holes, and island holes are repaired with the variational implicit surface algorithm [28–30].

Taking the backpack model in Figure 14 as an example, the model has a complex hole, including multiple single holes and complex continuous holes. All single holes and continuous holes can be identified by the proposed hole identification method. The red lines represent continuous holes, and the green lines represent single holes. Two sets of continuous holes are identified, that is, the area surrounded by dash-dotted lines. By means of the continuous hole segmentation method, the upper continuous hole can be merged into a complete single hole and the lower continuous hole can be divided into five simple holes. Therefore, it has been verified that this method can be applied to identify and to partition complex holes. It can provide effective preprocessing that facilitates subsequent hole repair.

FIGURE 18: Comparison of identification and repair results—complex holes of a hat model. (a) Original model with holes. (b) Repaired with the proposed method. (c) Repaired with Geomagic.

The repair result of the algorithm proposed in this paper is compared with Geomagic. In terms of the identification and repair of continuous holes, the proposed method can accurately complete the complex hole segmentation and repair, but the commercial software generates multiple spikes and a large number of highly refracted edges, as shown in Figure 15. In terms of the identification and repair of annular holes, the model is corrected after being repaired with the proposed method and many self-intersecting surfaces are produced with Geomagic, which destroy the original structure of the model, as shown in Figure 16.

In terms of the identification and repair of crack holes and dislocation holes, as shown in Figure 17, the repaired crack holes and dislocation holes are located in the yellow box. The model structure is normal after being repaired by the proposed method, and the repaired region does not produce self-intersecting and highly refractive edges. After the repair of Geomagic, a number of self-intersecting surfaces, highly refractive edges, and surrounding degenerate triangles, indicated by the red area, are generated. After the degenerate triangles are deleted, it has been found that there are obvious degenerate surfaces in the repaired model, which is not conducive to the subsequent editing and 3D printing of the model.

For the identification and repair of complex holes, the hat model and the ornament model are also chosen for

validation, as shown in Figures 18 and 19. In the hat model, eight crack holes and three simple holes were identified and partitioned. In the ornament model, one annular hole, two simple holes, and one island hole were identified. After using the identification and repair methods in this paper, the models are all better treated. By contrast, there is an obvious error in the repair of annular holes with Geomagic for the ornament model. The error is circled by a red line, as shown in Figure 19.

To accurately check the repair quality, the above two repaired models were scanned by a grid doctor. In terms of the six types of repair defects, including nonmanifold edges, self-intersections, highly-creased edges, spikes, small components, and small holes, Geomagic is found to generate more defects such as spikes, highly creased edges, and self-intersections, while the model repaired by the proposed method has fewer defects and a higher repair quality. The repair time of the proposed method is equivalent to Geomagic; thus, the repair efficiency is acceptable. Specific comparison information is shown in Table 1.

Through the above examples, it can be found that the complex continuous holes containing intersection points can be segmented and all kinds of holes can be accurately identified with the proposed method, as shown in Table 2. Subsequently, the existing mature methods can be used to repair corresponding holes and the repaired models have

fewer repair defects and a higher repair quality. However, some of these holes cannot be well segmented and identified with Geomagic without the participation of professionals. The proposed repair process is completely automated, replacing the manual judgment and repair operation, reducing the dependence on professionals.

6. Conclusion

In this work, an intelligent identification and classification method of complex holes is proposed. It can identify,

partition, and reconstruct complex holes into single holes based on the intersection points connecting multiple hole lines and classify all the single holes into five types, such as crack holes, dislocation holes, annular holes, simple holes, and island holes. Thus, proper hole repair algorithms can be selected according to the type of the single holes. Compared with Geomagic software, the proposed method can mostly avoid the intersection of various hole lines and reduce the defects of traditional hole repair methods, but it can achieve similar efficiency. The proposed method provides a new idea for the automatic hole repair of triangle meshes without the

participation of professionals and can be widely used in 3D printing model repair.

In future work, first, the identification method of boundary holes that do not have closed hole lines should be researched. Second, it is recommended to select and study more accurate repair algorithms for some single holes with large curvature variations to further improve the repair results.

In the field of natural language processing (NLP), machine translation algorithm based on Transformer is challenging to deploy on hardware due to a large number of parameters and low parametric sparsity of the network weights. Meanwhile, the accuracy of lightweight machine translation networks also needs to be improved. To solve this problem, we first design a new activation function, Sparse-ReLU, to improve the parametric sparsity of weights and feature maps, which facilitates hardware deployment. Secondly, we design a novel cooperative processing scheme with CNN and Transformer and use Sparse-ReLU to improve the accuracy of the translation algorithm. Experimental results show that our method, which combines Transformer and CNN with the Sparse-ReLU, achieves a 2.32% BLEU improvement in prediction accuracy and reduces the number of parameters of the model by 23%, and the sparsity of the inference model increases by more than 50%.

1. Introduction

Machine translation, an essential branch of computational linguistics, is a process of translating source language into the target language by computer. Translation has extremely high requirements for translators, and at the same time, there is a lack of professional translators, so machine translation has made significant progress in international exchanges [1]. In recent years, deep learning technology has developed rapidly. Researchers have introduced neural network into language model, which can better process the representation of common and rare words. For example, a recurrent neural network (RNN) can adapt to any sentence length and process the context recurrently to get the final result. Transformer applies the attention mechanism to machine translation and has better translation quality than traditional methods.

Compared with traditional statistical machine translation, which requires elaborate features, the flexibility of existing machine translation based on neural networks is greatly improved. Methods based on RNN and its derived models such as GRU and LSTM need to learn the long-distance dependencies of each input word vector. The principle is to use the embedding layer to map sentences to the embedding space and then use the hidden layer to compute the knowledge obtained in the previous step. As multiple hidden layers compute sequentially, calculations within a single hidden layer are executed sequentially and cannot be carried out in parallel. Different from the scheme of the RNN model that continuously accumulates input information, the Transformer network uses the Encoder-Decoder structure.

Because of its stacking self-attention layer and point-by-point full connection layer, the recursive structure in RNN is eliminated, and the network based on Transformer has the advantage of high parallelism. Transformer offers significant improvements to machine translation, but at the cost of a

large number of parameters. The number of BERT large parameters is 334M, the number of BERT base parameters is 109M, and the number of IB-BERT large parameters is 293M. Due to its large number of parameters and low sparsity of parameters, it is generally applied to the server side, and there is no suitable edge side Transformer algorithm. The existing RNN model must wait for all previous input processing to be completed before processing the next input, which is a bottleneck when processing long sequences. The number of operations required by the RNN model to correlate information from two arbitrary input or output positions increases as the position distance increases. This makes extracting complicated dependencies between far-away positions more difficult. Therefore, RNN is difficult to parallel, which is not conducive to hardware acceleration, and the translation effect is not ideal. On the other hand, the hardware-implementation-friendly CNN can not effectively process location information and is not effective in machine translation tasks when applied alone.

It is an effective method for hardware deployment of the neural network to reduce parameter storage and transmission amount and reduce the dependence on hardware data transmission bandwidth by using the compressed sparse matrix method. And it has little influence on algorithm accuracy. The premise of this scheme is that the sparsity of algorithm parameters is high enough. The weight parameters of the Transformer have not been optimized for sparsity, which is difficult to be applied to hardware accelerated by a compressed sparse matrix [2, 3]. The traditional ReLU activation function adopted by Transformer models such as [4] does not improve the sparsity of the neural network algorithm to the maximum extent. An appropriate activation function is an important measure to improve network performance and reduce the number of network parameters.

The hardware deployment machine translation algorithm must meet the requirements of lightweight and maintain high-precision translation results. At the same time, in order to further reduce the difficulty of deployment on edge devices, the algorithm optimization must improve the sparsity of weight parameters, so as to use the sparse matrix compression method for hardware deployment. To solve the above problems, this research proposes a new activation function that can improve the algorithm accuracy and parameter sparsity at the same time and designs a cooperative machine translation algorithm combining CNN to extract local features and Transformer to process sequence information. Our method combined with Sparse-ReLU improved the BLEU score of the algorithm to 35.24, increased the sparsity by more than 150%, and controlled the total number of parameters within 38M. Our main contributions are as follows:

(1) A new activation function, Sparse-ReLU, is proposed and applied to the machine translation model. The BLEU score of the IWSLT14 German-English translation task is enhanced from 34.29 to 35.16 by using the model whose parameter scale is 36.42 M. The number of parameters has been reduced, and more than 50% of sparsity has grown. Meanwhile, Sparse-ReLU can improve the translation effect.

(2) A Transformer structure with low number of parameters is proposed, which only uses three attention heads and a 7-layer encoder and decoder. The number of parameters of this structure is only 36.42 M, which solves the problem that Transformer is too large to be deployed on the hardware.

(3) A CNN structure for machine translation tasks is proposed and combined with a Transformer to optimize the network. The number of parameters of the overall algorithm is 37.99 M. The BLEU score is increased from 35.16 to 35.24.

1.1. Related Works.

The machine translation algorithm based on the neural network generally adopts the Encoder-Decoder model to deal with the machine translation task [5]. The encoder takes the source sentence as input and calculates a real expression value. The decoder inputs the real expression value and generates the target translation. CNN, RNN, and Transformer are the classical algorithms for constructing the Encoder-Decoder structure.

Machine translation jobs can be processed serially using an approach based on RNN and its derivatives LSTM [6, 7] and GRU [8]. It has the advantage of high extraction ability in processing series information. For example, the RNN-based algorithm [9, 10] generates dynamic context representation through its Encoder-Decoder architecture based on attention mechanism. Research [11] creates target phrases with fixed source statement representation. To make the RNN and its derivative networks deeper and better, [12] employs a residual strategy and skip connections to further the RNN development.

The Transformer based algorithm [4] and its variants [5, 13–16] achieve the most advanced results on multiple language pairs only based on the attention mechanism. Research [13] improves the effect by increasing the scale of model parameters. Still, increasing the number of parameters means that more extensive data sets are needed, and the training is more complicated. It is not suitable for hardware, especially edge devices. CNN-based algorithms [17, 18] are concerned because of their high parallelism. Among them, [17] proposes a CNN-based machine translation algorithm with higher parallelism and a shorter long-term dependency than RNN.

Machine translation projects employ a variety of Transformer structures to optimize the size of the model and precision, as well as the bandwidth required for hardware deployment. Research [2] proposes a pruning algorithm to increase model sparsity and deploy the model on GPU, and research [19] proposes a sparse matrix calculation method. Both of them reduced the bandwidth requirements of matrix calculation on hardware. One is to improve the activation functions such as the ReLU and SoftMax. Research [20] introduces a novel activation function WReLU for lightweight neural network design. Research [16] introduces a random calculation method to replace the traditional SoftMax calculation, which reduces the calculation complexity and improves the speed. Research [14] is a collaborative processing scheme that combines the advantages of
FIGURE 1: Overall structure of the algorithm.

multiple networks, and it combines BiLSTM and recurrent attention for machine translation tasks.

These works have effectively promoted the development of machine translation. However, most of the existing Transformer schemes dealing with machine translation tasks only use the attention mechanism and lack the research results combined with the CNN model. Most optimized networks are still too large, and there are defects in input sequence order when using the RNN model to process sequence information. The effect of processing sequence information using the CNN model is not ideal, making them challenging to deploy in edge devices. Based on these, the new activation function Sparse-ReLU, CNN submodel structure, Transformer submodel structure, and cooperation scheme proposed in this research achieve a better effect under a particular parameter scale condition.

1.2. Method. Unlike prior machine translation Transformer algorithms, this study proposes a Transformer model with few parameters, a CNN submodel, and a novel activation function Sparse-ReLU. CNN and Transformer submodels use Sparse-ReLU to optimize the effect. The three of them cooperate in dealing with machine translation tasks. CNN can process local information of word vectors and extract multiple features containing position-coding, and the attention mechanism can process local features extracted by CNN rather than input sentences. Figure 1 shows the process of our algorithm.

Figure 1 depicts the translation process. The input and output of the algorithm model are symbol sequences, and the word segmentation operation of the input symbol sequence uses the BPE word segmentation method. The position-coding operation embeds the position information into the symbol sequence obtained by word segmentation. The CNN submodel extracts the features of sentences containing location coding information. The Transformer submodel further extracts the output information of the CNN submodel. Both submodels use Sparse-ReLU.

2. Model Structure

2.1. Activation Function That Can Improve Sparsity and Accuracy. Most neural network algorithms currently

require activation functions to introduce nonlinear operations. However, activation functions such as sigmoid have the disadvantages of complex hardware implementation and high resource consumption in algorithm deployment. When implementing the algorithm in hardware, sparse matrix acceleration is a viable option, and sparse matrix acceleration necessitates high weights sparsity. The ordinary activation function can not maximize sparsity matrix compression technology. Based on this, this research proposes a new activation function Sparse-ReLU for hardware optimization. The activation function has the advantages of low hardware implementation cost and low computing time like the traditional ReLU function. It solves the disadvantages of limited representation ability and insufficient flexibility of the conventional ReLU function.

For machine translation and other applications in natural language processing, real-time computing requirements are high. Because of its low power consumption and small area, the edge devices cannot effectively deploy translation algorithms with huge parameters. In particular, the Transformer algorithm, although the translation effect is good, can only be deployed on the server-side. It is of great significance to realize the activation function with high flexibility and simple hardware implementation.

The activation function designed in this research can improve the sparsity and accuracy of neural networks. The expression is shown in formulas (1)–(4), in which the range of parameter a is $(0, 1)$, the content of b is $(0,1)$, which satisfies $a < b$ and $c < d$, and both a and b need to meet the relationships of $0.125x$, to complete the multiplication calculation only through the hardware shift operation. As shown in formula (1)–(3), the three subfunctions of Sparse-ReLU are y_0, y_1, and y_2.

$$y_0 = 0, \tag{1}$$

$$y_1 = a \times (x - c), \tag{2}$$

$$y_2 = b \times (x - d). \tag{3}$$

The function of the subfunction $y_0 = 0$ shown in Formula (1) is to set the activation value of the neural network to 0 and improve the sparsity of its activation value. The
Figure 2: Sparse-ReLU function.

traditional ReLU function sets the input of all negative numbers to 0 and the positive part to itself. The y_0 function in this research puts the output to 0 no matter what the input is. However, doing so will cause all information to be lost, so formulas (2) and (3) are required to retain the information. Taking the maximum value of the three subfunctions can obtain the formula of Sparse-ReLU.

$$\text{Sparse} - \text{ReLU} = f(x) = \max_{x \in (-\infty, +\infty)} (y_0, y_1, y_2). \quad (4)$$

When determining parameters a, b, c, and d, the functions with large c and d are preferred under the same translation effect, improving the sparsity of the weights and activations of neural network. When setting the parameters of Sparse-ReLU to $a = 0.25$, $b = 1$, $c = 0.2$, and $d = 0.4$ in Figure 2(a), the translation effect of the activation function is the best. According to the formula, the traditional ReLU function is a subset of the activation function designed in this research. Figure 2(b) is the image of setting parameters $a = 1$, $b = 1$, $c = 0.2$, $d = 0.2$ to make $Y1 = Y2$ in Sparse-ReLU. In this case, Sparse-ReLU degenerates into an offset traditional ReLU function. Furthermore, ReLU is a subset of Sparse-ReLU, and the characterization power of Sparse-ReLU is higher.

In this research, Sparse-ReLU replaces the traditional function to provide nonlinear characteristics for the network. It is applied between two fully connected layers or between the CNN layer and the fully connected layer in the network. Parameters a, b, c, and d in Sparse-ReLU are found through training, to make the effect of the network model better than that of the traditional ReLU activation function. According to the iterative experiment, the German-English translation task of IWSLT14 dataset performs best when the parameters are $a = 0.25$, $b = 1$, $c = 0.1$, and $d = 0.4$. After determining parameters in Sparse-ReLU, combined with the pruning operation, the sparsity of the network model is improved. Unlike other sparsity improvement methods, this activation function can enhance the sparsity of weight parameters and the sparsity of activation, which is convenient for further hardware acceleration using a sparse matrix.

Because it can efficiently use shift and addition operations to realize the activation function in hardware and complete the prediction task of the model based on Sparse-ReLU, Sparse-ReLU can obtain multiple zero values, in which the experimental statistics are more than 50% higher than the value close to zero in the ordinary ReLU activation

value. So, it can effectively improve the network sparsity. It has the characteristics of low resource consumption in hardware implementation and can enhance the sparsity of neural network parameters and the accuracy of the model prediction. Figure 3 shows the application of Sparse-ReLU in the model, as discussed in Section 1.2.

2.2. Transformer and CNN Submodels Combined with Sparse-ReLU.
Figure 1 shows the overall design, which is made up of a CNN and a Transformer submodel. We will introduce the Transformer structure used in this research in detail.

The Transformer structure has a high ability to extract sequence information. Figure 4 shows the Transformer structure in this research, composed of the residual layer, multihead attention layer, Sparse-ReLU layer, and layer normalization. As shown in Table 1, the parameters of each Transformer structure are listed. It has the characteristics of low parameter quantity. The Encoder combines Sparse-ReLU, which can improve prediction accuracy.

The CNN submodel needs to process the input sentences and extract the features without changing the size of the feature map. Convolution can improve the extraction ability of local features of the network. Figure 5 shows the CNN submodel. After the sentence is entered into the model, it needs to go through embedding and position-coding operation and then carry out layer normalization operation. Finally, utilizing two-dimensional CNN to process the sentence coding results containing position information. Figure 5 shows the CNN structure, where Len is the sentence length.

The input channel of CNN is 1, the output channel is the length of the word vector, that is, 512 channels, the size of convolution kernel is (5,512), the stride step is 1, and the size of padding is two zeros for rows and no padding for columns. The dimension of the feature map before CNN processing is (Len, 512), Len is the sentence length, and the dimension of the feature map after CNN is (512, Len). After dimension transformation and Sparse-ReLU, the fully connected layer maps the result to another dimension and makes the residual connection with the original input. Table 2 lists the detailed measurements of each structure of CNN.

CNN to extract local features, the combination of Transformer and CNN submodels can effectively improve the power of the algorithm to extract local features. There are a variety of cooperative processing strategies for multinetworks, including the concatenation operation method [21], result addition method [22], result point multiplication method [23], and matrix transformation after the concatenation operation. The model in research [21] adopted the method of submodules in series, effectively combined CNN and attention, and proposed an end-to-end ResNet structure model, which was used to extract local features, and summarized the local feature sequence through the attention

mechanism. This research discusses the impact of CNN and Transformer on machine translation tasks. Figure 6 shows the details of various collaborative processing schemes discussed in this research. The CNN submodel of Figure 6 is the structure in Figure 5. Encoder and decoder are also the forms discussed in Figure 4.

To make the size of the matrix output of the CNN submodel be the same as that of the attention submodel, we set the number of output channels of the convolution kernel to be 512, which is the same as the length of the word vector in the matrix output of attention submodel. Figure 6(a) shows the scheme that the attention submodel learns the
Figure 5: Structure of CNN submodel.

feature of input data, and the feed-forward module consisting of a CNN and a fully connected layer processes the result of attention computation, which is illustrated with the gray box. As shown in Figure 7, the output characteristic matrix of the feed-forward module is the result of the addition of a CNN and a fully connected layer. Figure 6(b) shows how to add a CNN submodel after the multihead attention layer of the encoder in the Transformer. Figure 6(c) uses the attention submodel to summarize the feature sequence from the original sentence, then uses a CNN submodel with a ResNet structure to extract local features from the features summarized by the attention submodel, and finally uses the decoder submodel to decode the target text.

Figure 6(d) shows that the CNN submodel first processes the input sentence and learns the local features of the sentence. The Transformer submodel extracts the sequence features processed by the CNN submodel. After the encoder operation in the Transformer, it is handed over to the decoder submodel for decoding operation again.

2.4. Algorithm Model. Figure 8 shows the details of the model in this research. According to the introduction of the previous three sections, the model in this research mainly includes the convolutional neural network feature extraction layer, encoder layer, and decoder layer. Table 3 shows the structural parameters of the algorithm.

3. Experiment and Result Analysis

3.1. Machine Translation Dataset and Word Segmentation Algorithm. This research selects the German-English translation task for the experiment, and the dataset is IWSLT14. The training set contains 160250 sentences, and the testing set uses 6750 independent sentences [24].

The input and output of the translation algorithm are symbol sequences. These symbols are the basic units of sentences. Because extensive vocabulary cannot be naturally decomposed into words, using words as the basic units

TABLE 5: Translation results of the model.

	Small model + Sparse-ReLU + CNN	35.24	37.99	Sparse-ReLU + small transformer + CNN

to form sentences will make it challenging to train the algorithm. An alternative is to use word segmentation algorithms such as [19, 25] to learn subwords from the dataset. This research uses the method of research [19] for word segmentation, which introduced the BPE algorithm variant for word segmentation, which can encode the available vocabulary with the vocabulary of variable length subword units. In this experiment, the size of the word table is 10000.

3.2. Evaluation Metric. Many automatic evaluation metrics have been proposed in the machine translation task to evaluate the quality of translation results. This research adopts the most popular BLEU [26] evaluation. It summarizes the overlapping words and phrases between machine translation and reference results. The translation results judged by the BLEU evaluation metric are highly consistent with those considered by human beings and have become a de facto translation evaluation standard after being proposed. This research does not use single testing set for BLEU score evaluation but combines multiple testing sets for score evaluation.

3.3. Experimental Environment and Model Training. This experiment uses 8 Titan XP graphics cards. PyTorch version is 1.4.0, and the CUDA version is 10.2. Table 4 lists the detailed configuration used in the experiment.

The algorithm uses a dropout operation to prevent training overfitting to ensure the training quality [27]. We use the dropout operation before the layer normalization of the CNN submodel, multihead attention submodel, encoder and decoder submodel output, and final output layer. Table 3 lists the network parameter configuration. The step of warmup is 8000. In the prediction process, a beam search algorithm is used instead of a greedy algorithm to obtain better prediction results, where the beam size is 5.

3.4. Result Analysis

3.4.1. BLEU Score Comparison. This model is being used to test German-English translation tasks. Table 5 lists the translation results of this algorithm and expected results.

Table 6 lists the comparison between the translation results of various types of machine translation algorithms and the algorithms in this research. The parameter size of the algorithm proposed in this research is 37.99 M, and the BLUE score reaches 35.24, which is 52.554% higher than other schemes such as research [17], 17.860% higher than research [29], and 2.442% higher than research [16]. The score of the algorithm model in this work is enhanced by 2.323% compared to the classic Transformer model [4], and the parameter size is decreased by 11.28 M, which is reduced by 23%. Compared with Dynamic CNN [30], the score of the proposed algorithm is 1.264% higher, and the parameter size is decreased by 247.01 M, which is reduced by 87%. Compared with the Transformer using the ReLU, the score of the Transformer using Sparse-ReLU is improved by 0.87 scores from 34.29 scores to 35.16 scores, an increase of 2.54%. The score of the optimization result using Sparse-ReLU and CNN is 35.24, an increase of 2.77%.

According to the four cooperation schemes between CNN and Transformer designed in Section 2.3, Table 7 lists the translation results obtained by the seven structures. The CNN structure of structure 2 is the one-dimensional CNN proposed in Figure 7, and the other CNN structures are the two-dimensional CNN submodel structure proposed in Figure 5. The input channel is 1, and the Transformer submodule is the structure proposed in Section 2.2. The input and output channels are word vector lengths, and the word vector dimension is the input channel of the convolution kernel. Using structure 7, when the convolution kernel size is 5×512, the BLEU score achieves the best result of 35.24 points.

TABLE 7: Comparison of translation results of different structures between CNN and Transformer (512 convolution output channels).

Structural details	Convolution type	Convolution kernel size	BLEU
Structure 1: Figure 6(a)	2d convolution	Same as structure 7	34.32
Structure 2: Figure 6(a)	1d convolution	in_ch = 512, kernel = (5, 1), stride = (1, 0), pad = 0	34.15
Structure 3: Figure 6(b)	2d convolution	in_ch = 1, kernel = (3, 512), stride = (1, 0), pad = (1, 0)	31.46
Structure 4: Figure 6(b)	2d convolution	Same as structure 7	33.61
Structure 5: Figure 6(c)	2d convolution	Same as structure 7	30.86
Structure 6: Figure 6(d)	2d convolution	in_ch = 1, kernel = (7, 512), stride = (1, 0), pad = (3, 0)	34.37
Structure 7: Figure 6(d) (This research adopts)	2d convolution	in_ch = 1, kernel = (5, 512), stride = (1, 0), pad = (2, 0)	35.24
FIGURE 9: Falling curve of loss value of each structure.

TABLE 8: Influence of Sparse-ReLU on model sparsity.

Sparse-ReLU parameters	Formula	Relative loss value	Relative sparsity
$a = 1$, $b = 1$, $c = 0$, $d = 0$	$Y = \max(0, x)$	100% (Baseline)	100% (Baseline)
$a = 1$, $b = 1$, $c = 0.2$, $d = 0.2$	$Y = \max(0, x\text{-}0.2)$	100.92%	127.09%
$a = 1$, $b = 1$, $c = 0.4$, $d = 0.4$	$Y = \max(0, x\text{-}0.4)$	114.68%	150.96%
$a = 0.25$, $b = 1$, $c = 0.2$, $d = 0.4$	$Y = \max(0, 1/4(x\text{-}0.2), x\text{-}0.4)$	57.80%	150.95%

Figure 9 shows the comparison results of the decline curves of loss during different structure training. The solid line in the figure is the loss decline curve of the benchmark model, and the dotted line is the loss decline curve of the Transformer model with CNN and Sparse-ReLU. Compared with the benchmark model, the loss reduction speed of the model with CNN and Sparse-ReLU is much higher than that of the benchmark model. Under the same 300 epochs, the loss value is reduced by 10.6%.

3.4.2. Sparsity Comparison. Table 8 lists the effects of Sparse-ReLU and ReLU on the sparsity of the algorithm. Compared with the conventional ReLU function, the Sparse-ReLU proposed in this research increases the sparsity of the relevant layer by 150.95% and reduces the loss value by 42.2%. Both indexes have an excellent optimization effect.

When the parameters of the new activation function are set to $a = 0.25$, $b = 1$, $c = 0.2$ and $d = 0.4$, the algorithm is pruned to improve the sparsity of the parameters. Table 9

lists the effects of traditional and new activation functions on the sparsity of the model when the model adopts different pruning algorithms. Table 9 shows that, compared with L1 norm pruning, the random unstructured pruning algorithm and Sparse-ReLU jointly improve the sparsity of the weight to 78.26% and the sparsity of the activation value of the tested layer to more than 120%.

The bar graph of key information in the above two tables is shown in Figure 10. Figure 10(a) shows that the Sparse-ReLU used in this paper significantly decreases the loss value and improves the sparsity when training the model compared with ReLU. According to Figure 10(b), when the model with Sparse-ReLU uses different pruning algorithms, it can further improve the sparsity with little accuracy loss.

4. Conclusion

This paper proposed a cooperative machine translation algorithm based on CNN and Transformer submodels combined with Sparse-ReLU, where the CNN is used to extract

TABLE 9: Experimental results of the combination of Sparse-ReLU and pruning algorithm.

Pruning algorithm	Set parameters	Relative activations sparsity	Relative loss value	Weights sparsity
No pruning + Sparse-ReLU	\	100% (Baseline)	100% (Baseline)	0.00% (Baseline)
L1Unstructured + Sparse-ReLU	0.3	121.22%	173.60%	22.58%
	0.5	122.97%	195.12%	68.47%
RandomUnstructured + Sparse-ReLU	0.3	120.18%	120.42%	65.99%

FIGURE 10: The influence of Sparse-ReLU on sparsity and accuracy.

local features of sentences containing location information, the Transformer is used to further extract sequence features, and the Sparse-ReLU can optimize the algorithm. Compared with the traditional counterpart, the count of parameters decreased by 23% with accuracy increased by 2.77%, and the sparsity increased by 50%. Consequently, Transformer and CNN parameters are only 36.42 M and 1.57 M, respectively. Test results show that the proposed scheme can effectively improve the accuracy of model translation and the sparsity of activation and weight value.

In future works, the author of this research will continue to study the collaborative scheme between CNN and Transformer and the parameter training method of Sparse-ReLU, hoping to achieve better results.

High-Performance Concrete Strength Prediction Based on Machine Learning

Yanning Liu [iD]

Shanxi Polytechnic College, Taiyuan 030006, China

Correspondence should be addressed to Yanning Liu; liuyanning960220@163.com

High-performance concrete is a new high-tech concrete, produced using conventional materials and processes, with all the mechanical properties required for concrete structures, with high durability, high workability, and high volume stability of the concrete. The compressive strength of high-performance concrete has exceeded 200 MPa. 28-d average strength between 100 to 120 MPa of high-performance concrete has been widely used in engineering. Compressive strength is one of the important parameters of concrete, and carrying out concrete compressive strength prediction is of high reference value for concrete design. Eight variables related to concrete strength are used as the input of the machine learning algorithm, and the compressive strength of HPC is used as the object of study. 60 samples are constructed as the dataset by concrete preparation, and the prediction of compressive strength of HPC is carried out by combining the XGBoost algorithm. In addition, SVR algorithm and RF algorithm are also performed on the same dataset. The results show that the XGBoost model has the highest prediction accuracy among the three machine learning models, and the XGBoost algorithm scores 0.9993 for $\mathbf{R}^2$ and 1.372 for RMSE on the test set. The XGBoost algorithm has high prediction accuracy in predicting the compressive strength of HPC, and the choice of model is important for improving the prediction accuracy.

1. Introduction

High-performance concrete (HPC) is a new type of high technology concrete, which is produced using conventional materials and processes [1]. The production process requires the incorporation of external admixtures that improve the properties of concrete, adding high durability, workability, and volumetric stability on top of improving the mechanical properties of concrete. The excellent performance of HPC makes it widely used in various fields of the construction industry. A lot of practical experience in engineering proves that controlling the quality of concrete is extremely important for the safety and durability of building structures. As a core element of concrete quality control and an important basis for structural design and construction, the 28-d compressive strength of concrete specimens after curing is a key parameter in the design of concrete structures and an important indicator of the engineering performance of HPC. It is a key parameter in the design of concrete structures and

an important indicator of the engineering performance of HPC. In engineering practice, whether the strength of HPC meets the design requirements is the primary issue, the ordinary orthogonal experimental method to determine the compressive strength of HPC is relatively time-consuming, and the procedure is cumbersome and costly. In order to meet the requirements of timely presumption and early control of concrete quality in construction, it is important to develop and improve the early concrete strength prediction technology adapted to the actual project and continuously improve the prediction accuracy to improve the construction quality and speed up the construction schedule. Therefore, it is of high economic value and practical guidance to predict the strength of HPC quickly and accurately [2].

As one of the most widely used and largest construction materials for modern engineering structures in the world today, concrete materials have played an important role in the process of economic development and social progress. With the development of capital construction and the

advancement of construction technology, the scale of engineering construction is becoming more ambitious, the structural forms are more replicated, and the requirements of the construction industry for concrete performance have increased. HPC is developed on the basis of high-strength concrete, and the definition of HPC varies from country to country. In general, HPC should have high permeability, high volumetric stability, appropriately high compressive strength, and good workability. It can be seen that the prediction of the strength of HPC not only is of theoretical value, but also has a high practical engineering value.

In recent years, with the rapid development of artificial intelligence technology, various industries are combining new artificial intelligence technologies for self-empowerment, and engineering-based research based on machine learning and deep learning has continued. Many machine learning theories have been applied to concrete-related research, mainly including artificial neural networks [3], support vector [4], and integration algorithms [5]. Erdal et al. [6] predicted the strength of HPC based on wavelet transform neural network model, and the prediction accuracy was good. Yuan et al. [7] proposed two hybrid neural networks, genetic optimization BP neural network, and ANFIS, to predict the strength of concrete, and compared the results with the ordinary BP neural network model, and the results showed that the prediction accuracy of the hybrid neural network model was greatly improved. Daneshvar and Behnood [8] used random forest algorithm to build a dynamic-elastic mode prediction model for asphalt concrete, and the prediction accuracy could reach 94.62%. Ren et al. [9] proposed a convolutional neural network for semantic segmentation of cracks based on computer vision technology, which provides a new method for health monitoring of tunnels. Cui et al. [10] introduced the attention mechanism into the semantic segmentation task of concrete cracks and proposed a convolutional neural network with AttUnet to achieve accurate semantic segmentation of cracks. Chun et al. [11] carried out the study of internal damage of reinforced concrete structures based on random forest algorithm and achieved accurate prediction results. Chou et al. [12] proposed an improved least squares support vector regression algorithm to improve the accuracy of high-performance concrete compressive strength prediction by parameter optimization. Behnood et al. [13] used M5P algorithm to study high-performance concrete compressive strength prediction by constructing model trees from high-latitude data. Zhou et al. [14] used 10 supervised learning algorithms for rock-burst prediction based on 246 sets of rock-burst cases and compared the prediction results of different algorithms.

Concrete-related research based on machine learning has been carried out and achieved some results. Farouk and Jinsong [15] explored machine learning in concrete strength prediction by using four machine learning algorithms, SVM, ANN, MLR, and SWR, to predict the strength of UHPC-NSC interface bond. Kim et al. [16] used CatBoost algorithm to predict FRP-concrete interface bond strength as an improved ensemble machine learning method with better performance metrics when compared with histogram gradient boosting algorithm and extreme gradient boosting

algorithm and random forest. Tran et al. [17] used six machine learning models such as GB algorithm, XGB algorithm, support vector regression, and hybrid models with particle swarm optimization, i.e., GB_PSO, XGB_PSO, and SVR_PSO, to predict the strength of recycled compressive strength of concrete. Researchers often compare multiple methods to select the optimal model for concrete strength prediction, but there is a lack of case studies on strength prediction of HPC. In this paper, three machine learning algorithms, RF, SVR, and XGBoost, are used to predict the compressive strength of HPC based on the quality characteristics of HPC. Also, cement dosage, age, water, coarse aggregate, fine aggregate, high-efficiency water reducing agent, fly ash, and mineral powder are used as multiple features and input to construct the machine learning model dataset. Training testing, along with comparing the accuracy of different models in applying to the prediction of compressive strength of HPC, and selecting the optimal model applicable to the prediction of compressive strength of concrete, can also be helpful in constructing the machine learning model dataset.

2. Concrete Preparation and Datasets

The concrete specimens were prepared using Southern P-O 42.5 grade cement, Guodian Shuang liao Class I fly ash, Huibei Mining crushed stone with continuous grading from 5 to 31.5 mm, Rong Shun quartz sand with fineness modulus of 2.29, and poly-carboxylic acid high-efficiency water reducing agent from Wuhan Harbor Research Institute Co. The powdered poly-carboxylic acid high-efficiency water reducing agent (water reduction rate of 23%) and alkyl-phenol ethylene oxide compound air-entraining agent were added during mixing, in which the high-efficiency water reducing agent accounted for 0.2%~0.8% of the cement mass and the air-entraining agent accounted for 0.8%~1.2% of the cement mass. The amount of HPC and air-entraining agent and the ratio of sand, cement, and water were adjusted experimentally according to the desired workability, including flowability, cohesiveness and water retention, and slump measured using a slump cone.

The HPC molding and mixing procedure include starting the mixer, putting in cement, fly ash, quartz sand, and other powders, dry mixing three minutes, adding water and water reducing agent, and mixing for three to five minutes. After the mixing is completed, the mix is poured into the steel mold, and after shaking and smoothing, the mold is covered with plastic film to prevent rapid moisture dissipation and left to stand at room temperature for 48 hours before demolding. The slump was measured to be 220 mm, with good fluidity, cohesion, and water retention. The test method was in accordance with GB/T 50081-2016 "test method for mechanical properties of ordinary concrete," and a total of 60 sets of data samples were produced.

A scientific and reasonable dataset is the key to achieve accurate prediction of concrete strength, which is mainly related to cement. Concrete strength is mainly related to variables such as cement dosage, age, water, coarse aggregate, fine aggregate, high-efficiency water reducing

agent, fly ash, and mineral powder. Therefore, the values of the above indicators need to be measured during the preparation of the specimens as the input to the machine learning model, and the output is the compressive strength value of the concrete.

3. Predictive Methods of HPCS

3.1. RF Algorithm. Bagging is the process of training multiple base classifiers on a dataset and then voting on the results obtained from the base classifiers as the final classification result. Random forest (RF) algorithm is an extended variant of bagging. Due to its excellent performance in data classification, it is often used in recent years for strength prediction of various types of concrete [18]. Based on the integration of the decision tree as the base classifier, RF further introduces random attribute selection in the training process of the decision tree. It selects the splitting feature by measuring the impurity of the feature division result and calculating the information gain. From the root node, according to the feature division condition and the principle of minimum purity of nodes, splitting downward until the rule is satisfied, the final prediction result is the weighted average of the results of each decision tree.

Information entropy is often used as a measure of the purity of a dataset. Let the proportion of the k-th class of data to all datasets X be p_k ($k = 1, 2, \ldots, n$); then, the information entropy of the dataset X is defined as equation (1) [19]. The smaller the value of $H(X)$, the less chaotic and purer the dataset X.

$$H(X) = -\sum_{k=1}^{n} p_k \log_2 p_k. \tag{1}$$

Assuming that the discrete feature α is used to classify the dataset X, I classification results are generated, where the I-th classification result contains all the data, denoted as X_I. The information entropy of X_I is calculated according to equation (1), and considering that different classification results contain different amounts of data, each classification result is given a weight of $|X_I|/|X|$, indicating that the more data the classification result has, the greater the role of the classification result, so the information gain obtained by using feature α to divide the dataset X is calculated in equation (2). Generally speaking, the larger the value of $\text{Gain}(D, \alpha)$ is, the more the complexity of the dataset is reduced after the feature a is used for splitting, and the more obvious the classification result is.

$$\text{Gain}(D, \alpha) = H(X) - \sum_{i=1}^{I} \frac{|X_I|}{|X|} H(X_I). \tag{2}$$

RF randomly selects m subsamples from the original dataset with put-back, and then randomly selects k features when training a single decision tree, and chooses the optimal features from these k features to split the nodes, which makes the random forest model not easily overlearn the features of the training set and reduces the variance of the model.

3.2. SVR Algorithm. The support vector regression algorithm is an application of SVM (support vector machine) to the regression problem, where the SVR creates a "spacing band" on both sides of the linear function with ε, also called the SVR creating a "spacing band" on both sides of the linear function with a spacing of ε, also known as tolerance bias, and does not calculate losses for all samples falling into the spacing band; i.e., only the support vector affects its functional model, and the optimized model is derived by minimizing the total losses and maximizing the spacing [20]. The basis consists of two main principles. One is that the model allows ε error between the predicted value $f(x)$ and the true value y. The second is that the loss function of the model is parameter updated only when the absolute value of the difference between $f(x)$ and y is greater than varepsilon. The SVR model constructs a band of model parameter nonupdating regions with $f(x)$ as the center and $\pm\varepsilon$ as the broadband.

Given the training data $D = \{(x_1, y_1), (x_2, y_2), \ldots, (x_m, y_m)\}$, the regression model $f(x) = w^T x + b$ is obtained by machine learning so that $f(x)$ is as close to y as possible. For the sample (x, y), traditional regression models usually calculate the loss directly based on the difference between the model output $f(x)$ and the true output y. The loss is 0 when and only when $f(x)$ is exactly equal to y. It follows that the SVR problem can be described by

$$L(w, y_i, f(x_i)) = \min_{w,b} \frac{1}{2}\|w\|^2 + C \sum_{i=1}^{m} l(f(x_i) - y_i), \tag{3}$$

where w is the normal vector, C is the regularization constant, L is the model optimization objective function, $f(x_i)$ is the predicted value of the model, and y_i is the true label value of the data.

The SVR algorithm uses a kernel function that allows mapping to a higher dimensional space and thus solves the classification of nonlinearities. The classification idea is simple, which is to maximize the interval between the sample and the decision surface. In addition, the SVR algorithm has better classification results. However, it is more difficult for processing large samples for large-scale data training, while the concrete strength prediction problem studied in this paper does not belong to large-scale data training and can achieve better prediction results using SVR algorithm.

3.3. XGBoost Algorithm. The idea of boosting algorithm is to integrate many weak classifiers together to form a strong classifier. XGBoost is also known as extreme gradient boosting. It is widely used in classification and regression fields because of its fast, efficient, and accurate operations and strong generalization ability [21]. Parameters such as the amount of cement used in concrete can affect its strength and durability, and XGBoost is often used to study the complex interrelationships between multiple influencing factors and their performance indicators [22]. XGBoost supports user-defined objective functions and evaluation functions, and for samples with missing values of features, it

can automatically learn its splitting direction. The core concept is to learn new features by adding trees, fitting the residuals of the final prediction, and then obtaining the sample scores, which can be summed up for each tree to obtain the final prediction score of the sample. For n labeled samples with m features, it uses G additive functions to predict scores, and the specific process is shown in

$$y_{\text{pre}} = \sum_{g=1}^{G} f_g(x_i), \quad f_g \in F;$$

$$F = \left\{ f(x) = w_{q(x)}\left(q: R^m \longrightarrow T, w \in R^T\right) \right\}, \tag{4}$$

where F represents the space of regression trees, $f(x)$ is one of the regression trees, and $w_{q(x)}$ represents the independent structure score of each T-leaf tree. The objective function of XGBoost is defined as

$$L = \sum_{i=1}^{n} l(y_i^*, y_i) + \sum_{g=1}^{G} \Omega(f_g);$$

$$\Omega(f_g) = \gamma T + \frac{1}{2} \mu w^2, \tag{5}$$

where l denotes the loss function of the model, Ω is the regularization term, T denotes the number of leaf nodes, w is the fraction of leaf nodes, while γ and μ represent the control coefficients to prevent overfitting. To speed up the optimization, a Taylor second-order expansion can be used, as shown in

$$L(t) = \sum_{i=1}^{n} \left[l\left(y_i, y_i^{*\,(t-1)}\right) + k_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i) \right] + \gamma T$$

$$+ \frac{1}{2} \mu \sum_{i=1}^{T} w_i^2. \tag{6}$$

By adding the loss function of the samples, the samples an be recombined. And finally using the vertex formula to find the optimal w and the objective function formula L as shown in equation.

$$w_i' = -\frac{K_i}{H_i + \mu};$$

$$L = -\frac{1}{2} \sum_{i=1}^{T} \frac{K_i^2}{H_i + \mu} + \gamma T, \tag{7}$$

where $K_i = \sum_{i \in I_j} k_i$ and $H_i = \sum_{i \in I_j} h_i$. XGBoost combines the traditional greedy algorithm with an approximation algorithm to find the best splitting point by enumerating several possible candidates based on the percentile method and then calculating the best splitting point according to equation (7). XGBoost uses various methods to avoid overfitting, such as introducing regularization, row sampling, and feature sampling, and also adds handling of sparse data. In addition, XGBoost has other advantages, such as the ability to perform parallel processing, which results in a significant speedup; a high degree of flexibility, with customizable optimization

goals and evaluation criteria; and built-in cross-validation, which allows cross-validation to be used in each boosting iteration. Combining the above advantages of XGBoost in classification algorithms, this paper selects XGBoost as one of the main alternative models for HPCS. The modeling steps of XGBoost are shown in Figure 1.

Firstly, we define the algorithm function and call the XGBoost function to build the network model; then, we set the initial parameters and input the training set to train the model, adjusting the weights every time until the training error is minimized or the required maximum training times are reached; after training, we store the current network file and input the validation set to compare the evaluation metrics to determine whether it is optimal or not, and so on until all parameters are optimal; then, we enter the testing phase and evaluate the model to obtain the corresponding metrics to complete the classification experiment of HPCS.

4. Experimental Results and Analysis

For the purpose of selecting the most suitable prediction model for HPCS, this paper uses the comparative experimental method. Specific concrete samples are prepared in the laboratory, and the data are preprocessed after understanding the characteristics of each data, so as to select the model with the best prediction performance based on machine learning theory. The overall technical route is shown in Figure 2.

In order to compare and analyze the performance of three machine learning methods, RF, SVR, and XGBoost, on the concrete compressive strength dataset, this paper selects R^2 and RMSE from the commonly used machine learning evaluation metrics. Where the root mean square error (RMSE) mainly measures the accuracy of the model, the smaller its value, the higher the prediction accuracy of the model. The correlation coefficient (R^2) characterizes the closeness between the predicted value of the model and the true value of the data, and the closer the R^2 is to 1, the higher the prediction accuracy of the model. The mathematical formula is shown in

$$R^2 = \frac{\sum_i \left(y_{\text{obs}} - y_{\text{pre}}\right)^2}{\sum_i \left(y_{\text{obs}} - \overline{y_{\text{obs}}}\right)^2};$$

$$\text{RMSE} = \sqrt{\frac{\sum_i \left(y_{\text{obs}} - y_{\text{pre}}\right)^2}{n}}. \tag{8}$$

4.1. Comparative Analysis of Model Results. Before comparing the prediction results of each model, the *GridSearch* method is used to optimize the parameters of various models for making the prediction results of each model more accurate. The results of the parameter optimization are shown in Table 1. Eight influencing factors such as cement use, age, water, coarse aggregate, fine aggregate, high-efficiency water reducer, fly ash, and mineral powder are selected as input variables, and 28-d compressive strength was taken as the prediction target to construct the initial index system of the
Figure 1: XGBoost modeling steps.
Figure 2: Technical route of HPCS prediction.

high-performance concrete compressive strength prediction model. The original dataset was randomly divided into 10 parts according to the ratio of 8 : 2, of which 80% was used as the training set and the rest as the test set. In this paper, there are 60 sets of data samples, 48 sets are divided into training set, and the remaining 12 sets are test sets. We perform statistical analysis on the prediction results of each model, and the comparison results in test sets are listed in Figure 3.

Analysis of Figure 3 shows that, overall, for the error measure RMSE, the XGBoost model has the lowest error prediction 1.372, followed by RF 2.347 and finally SVR 2.656. In terms of the correlation coefficient R^2, all three models get the desired value; that is, the concrete strength data in this paper are convincing. The correlation coefficient of the XGBoost model reaches 0.9993, reaching the maximum value of the three. The results of these two evaluation indexes fully illustrate the superiority of XGBoost algorithm in HPCS prediction, which can be used as a favorable reference for future prediction work.

4.2. Prediction Result Analysis of XGBoost.
XGBoost implements a general tree boosting algorithm. In view of the good performance of XGBoost algorithm in HPCS prediction, this

Table 1: Parameter configuration.

Algorithm	Parameter optimization
RF	n_estimators = 500, max_depth = 18, min_samples_split = 4
SVR	Kernel = "rbf," C = 1010, gamma = 0.56
XGBoost	n_estimators = 500, max_depth = 6, learning_rate = 0.01

paper analyzes the operation results of XGBoost in detail to better illustrate the adaptability of this method.

The statistical results of the comparison between the HPCS prediction results of the XGBoost model and the actual compressive strength are shown in Figures 4 and 5.

When training is performed, the XGBoost algorithm achieves good results, and the actual values are almost indistinguishable from the predicted values. Therefore, in order to visualize the prediction effect of the training set, Figure 4 shows the actual values as the horizontal coordinates and the predicted values as the vertical coordinates, and the distribution of each data point basically coincides with the line $y = x$. The composition of concrete strength data in the training set ranges from 20 MPa to 70 MPa, the RMSE is 0.341, and R^2 is 0.9989 after XGBoost training. This indicates that XGBoost has a very excellent prediction performance in the training phase.

FIGURE 3: Comparison of test set evaluation results.

FIGURE 5: XGBoost testing set result.

FIGURE 4: XGBoost training set result.

prediction model will greatly dominate the preparation of concrete. As a simple example, with the prediction model, it is possible to filter the dosage range of important indicators such as cement dosage according to the actual demand. This greatly reduces the number of pre-experiments conducted and the time to conduct them, which also saves experimental materials and speeds up the efficiency of experiments. Nowadays, there are still some problems in concrete prediction, such as lack of sample data, lack of representativeness, inability to reflect the sensitivity of input parameters, and narrow scope of application of the model. Concrete prediction, as a typical multivariate, nonlinear system, requires the incorporation of reasonable data processing methods such as machine learning to be performed. This paper uses comparisons to select a better quality method that can better serve HPC in practical engineering for problems such as proportioning optimization.

5. Conclusion

With the large-scale development of transportation infrastructure, how to use the available data to make accurate prediction of concrete strength, so as to feed back to optimize the concrete mix design, has become a hot topic of research in the academic and engineering circles nowadays. The strengths of the HPCs we prepared ranged from 20 MPa to 70 MPa. To better investigate the nonlinear relationship between HPCS and the eight influencing factors, machine learning approaches are used to solve this problem. In order to find the most suitable algorithm to strength prediction, three commonly used and effective methods, RF, SVR, and XGBoost, are selected using comparative analysis. Through data preprocessing and parameter optimization, all three methods achieve a nice prediction state, and the results of the study can provide some reference for machine learning in the field of concrete strength prediction research. The R^2 values of the three methods are all above 0.9, and the model fitting effect is good. By comparing the performance capability of RF, SVR, and XGBoost algorithms on the same dataset, it is found that XGBoost has the highest prediction

Figure 5 reveals that although XGBoost achieves good outcomes on the training set, there is no overfitting, and the performance on the training set is also outstanding. In general, for different strengths of high-performance concrete, the predictions of the XGBoost model are very close to the true values of the test set, and the dashed and solid lines are generally in the same direction. The RMSE on the training set is 1.372, while the R^2 is 0.993. The trend of the two lines in the figure shows that the strength prediction performance of concrete with strengths in the interval of 40–50 MPa is better than that of 50–70 MPa. Judging from the performance on the training set and validation set, the XGBoost prediction model has strong adaptability and superiority in HPCS prediction and can better guide the prediction of compressive strength of HPC.

The construction industry is pursuing higher and higher quality of construction, and the strength of concrete is often a key influencing factor of that. How to prepare high-performance concrete is an important topic in civil engineering materials science, and a high-performance concrete strength

accuracy and the lowest RMSE value of 1.372, which can be applied to HPCS prediction.

The prediction method in this paper has high precision; therefore, it will serve the experimental design of the laboratory. In addition, machine learning algorithms can also identify the most sensitive intensity influencers, which can also be used for future research.

This study investigates the mechanism of digital linguistic landscapes in enabling engineering education for smart construction according to the educational dimensions of A (ability), S (skill), and K (knowledge). A questionnaire survey was conducted based on the core concepts of the informative dimension and symbolic dimension in digital language landscape as well as the ability dimension, knowledge dimension, and skill dimension in engineering education. Structural equation modeling (SEM) was used as the test method. The results of the research demonstrate that the informative dimension and symbolic dimension are two main aspects of DLL in education of engineering students for smart construction. Additionally, DLL has a significant positive impact on the ability, knowledge, and skill education of engineering students for smart construction. The research has theoretical and practical significance, as it not only enriches research on the relationship between DLL and engineering education for smart construction but also expands the theoretical understanding of engineering education from the perspective of linguistics. Furthermore, the study explores the path of the practical application of digital language landscape to engineering education for smart construction.

1. Introduction

The construction industry faces a number of pressing challenges, including improving the level of productivity and responding to the high level of fragmentation and complexity as well as leveraging the emerging opportunities by digital transformation [1, 2]. Indeed, the construction industry has already started to adopt digital technologies to improve the operational performance of industrial activities, including virtual reality, Internet of Things, and machine learning [3]. Moreover, the requirement for smart buildings is rapidly becoming an inherent constituent of policies associated with the design and development of buildings for the future [4]. Therefore, smart construction has been

proposed as a new concept for the construction industry to adopt in order that the sector can fully capitalize on the opportunities afforded by digital transformation. Smart construction systems have huge potential to improve the efficiency of construction industry [5]. Specifically, they empower the engineering production system and promote the interconnection of engineering construction processes, including online and offline integration, resource, and element collaboration [6, 7]. In this context, the 21st century engineers and architects must be able to deal with the rapid pace of technological change and successfully navigate the highly interconnected world of industry [8]. Facing such profound changes in the construction industry triggered by digital technologies in the new era, there is an increasing

demand for engineering students who are suitable for engaging in smart construction. Such students need to meet the requirements for the future development of the construction industry and to adapt to the transformation and upgrading of the industry [1, 3]. This also requires changes at the educational level [9].

The current basis for the education of engineering students suitable for smart construction fails to adequately integrate with digital technologies. There is a need to make changes to the engineering education system from different perspectives, including the digital linguistic landscape as well as aspects of the new industrial technology, information, and humanistic literacy. Therefore, it is necessary to change the traditional mode of educating smart construction engineering students to adopt a new approach that is suited to the digital context of the construction industry. Consequently, this study focuses on addressing the following question: Does the digital linguistic landscape play a role in the development of smart construction-related abilities, skills, and knowledge as part of engineering education? What is the mechanism of action?

Educating engineering students who possess smart construction capabilities faces various challenges, which can be summarized in four main areas. Firstly, the educational mode for enhancing the innovation awareness and ability of students is comparatively singular in nature. On this matter and in the case of China, Chen and Ding [10] identified that there is still a large gap between the innovation level of the country's construction industry and that of the developed countries, and this gap is especially prominent in the field of smart construction. Besides, university-level engineering students in general do not have a good understanding of the importance of innovation awareness and possess the capacity for innovation [11]. In addition, their awareness of the need to learn innovation skills and knowledge is currently limited [12]. In developing countries, educational programs have often been using out-of-date teaching methodologies, whereby students listen to lectures delivered by academic faculty without any practical applications or hands-on experience. This provokes a decrease in students' attention span and motivation and makes them become bored with the learning process [13, 14].

Secondly, the path for cultivating internationalized engineering students in the construction industry in China is somewhat narrow. In the context of the globalization trend and the "Belt and Road" initiative, there is a growing need for internationalized engineering students [15]. Engineering universities often prefer to establish long-term and stable cooperation with world-class universities, research institutions, and enterprises [16]. This kind of cooperation could provide good opportunities for engineering students in academic exchanges, engineering practice, and visits [17, 18]. However, resources are limited, and the number of students is large, while the opportunity to go abroad for exchange is not enough, which makes engineering students at this stage disconnected from the international advanced engineering concepts and academic ideas and often results in a lack of international vision and global awareness in engineering practice [19].

Thirdly, the knowledge horizon of engineering students in many cases is too narrow. China's engineering knowledge system needs improvement, and while the knowledge obtained by students is comprehensive, there are still difficulties in responding to industrial development trends and other arising technological challenges [20]. The current professional settings of engineering education are bounded by the traditional engineering disciplines, which often pay too much attention to the systemic nature of the disciplines themselves and ignore the interconnection between the knowledge across disciplines [21].

Fourthly, the digital linguistic landscapes are insufficient in number. The quantity of digital linguistic landscapes in the education environment of engineering students is far from enough. This not only serves to weaken the influence of the language environment itself on the cultivation of engineering students' consciousness, thinking, and cultural heritage [7] but also installs certain obstacles to the cognitive ability of such students [22]. This affects their learning ability and also decreases the significance of the digital information platform on the education of students suitable for smart construction through difficulties adapting to the rapid changes in the era of digitalization and information technology.

In view of this, digitalization is a way of information processing and representation and a technical method to store, transmit, process, handle, and apply information carriers (i.e., text, pictures, images, and signals) in digitally encoded form (usually binary). Digitalization is developing fast and has become a powerful tool for digital planning, construction, and operations, for instance, in the case of digital twins [23]. Digitalization and digital transformation have become a major research trend. Kohtamaki et al. [24] researched the relationship between digitalization and servitization, Ferreira et al. [25] studied the benefits of digitalization, and Verhoef et al. [26] researched the strategies of digital transformation. Digital linguistic landscape refers to the linguistic landscape in digital space. Linguistic landscapes have multiple roles in the development of students, as they can be powerful tools for education, language learning, critical thinking, language activism, and so on [27, 28]. Therefore, as an information platform for displaying the linguistic landscape through digital technology, digital linguistic landscape is a tool to broaden the influence of linguistic landscapes. The information provided by the digital linguistic landscape is rich, diversified, and internationalized, and its presentation media are diverse. Language and symbolic information on digital websites, digital signage, digital media, and other media all belong to digital linguistic landscapes. Therefore, the application of the digital linguistic landscape concept to the education of engineering students suitable for smart construction provides rich, diversified, and multilingual knowledge information and thereby strengthens the humanities of smart construction engineering students while also promoting the digital capabilities of engineering students.

The study aims to explore and test the mechanism of digital linguistic landscape on the education of engineering students suitable for smart construction through the use of

the "ASK" (i.e., ability, skill, and knowledge) educational model based on the digital linguistic landscape platform. There is no relevant research on digital linguistic landscape for engineering talents cultivation at home and abroad, and this study has certain groundbreaking significance. This study has the following theoretical implications for the engineering education for smart construction: (1) defining the digital linguistic landscape; (2) expanding the theoretical scope of smart construction engineering education from the perspective of linguistics and providing the theoretical basis for the linguistic landscape atmosphere of the education; (3) exploring a new path to educate engineering students for smart construction and further enriching the research on the education path of smart construction-related engineering students.

2. Literature Review

2.1. Engineering Education for Smart Construction Students. According to the World Federation of Engineering Organization (WFOE), engineering capacity building, as a driver for sustainable socioeconomic development, has become a globally recognized priority [29]. Therefore, it is necessary to study the capacities of smart construction engineering students.

A search of the keywords "smart construction engineering students' qualities" and "abilities" in domestic and foreign mainstream databases showed that there was no relevant literature. In order to summarize the core qualities of engineering students suitable for smart construction more accurately, the core competence standards for graduates of the Washington Accord, Sydney Accord, and FEANI, as well as the domestic standards for the connotation of engineering students' qualities, were analyzed and extracted. This was carried out from the perspective of professional certification of engineering education at home and abroad, focusing on the keywords "smart construction," "engineering students," "qualities," "competence," and "abilities." After carefully screening the relevant literature, 10 of the core qualities were finally selected to analyze and summarize the core qualities of engineering students, as shown in Table 1.

From Table 1, it can be observed that, in the context of "New Engineering," the quality of engineering students mainly focuses on lifelong learning ability, engineering innovation ability, engineering thinking ability, interdisciplinary and integration ability, communication, and cooperation ability, as well as engineering knowledge and professional skills. On this basis and combined with the new requirements for professional students relevant to smart construction [1, 40–44], the core qualities of engineering students' in smart construction were summarized as follows:

(a) Engineering innovation ability: innovation is critical to economic and social prosperity [45]. Educating engineering students for smart construction who are innovative is the key to building a dynamic and successful economy [12]. The focus of cultivating the innovation ability of engineering students suitable for smart construction is to enhance their

engineering innovation abilities and knowledge and develop a greater understanding of the opportunities associated with adopting new technologies [39, 46, 47].

(b) International ability: internationalization is the process of integrating an international or intercultural dimension into the teaching, research, and service functions of a higher education institution [48, 49]. At present, there is no common definition of internationalized students in the academic field. Thus, this study summarized the international ability of students as intercultural communication ability, cooperation ability, international thinking, and vision, as well as global awareness of international competencies [35, 50, 51].

(c) Engineering thinking ability: engineering thinking is a form of "invisible" consciousness activity, which is a kind of nonlogical and comprehensive way of thinking adopted by engineering students based on the elements of engineering philosophy and engineering knowledge for the purpose of planning engineering entities [52–54]. The engineering thinking abilities of engineering students suitable for smart construction include interrogative and systematic thinking, critical thinking, and the ability to solve complex engineering problems [32, 39].

(d) Lifelong learning ability: lifelong learning ability is the prerequisite to ensuring the continuous development and improvement of smart construction engineering students. Engineering students must have the awareness and ability of lifelong learning in order to adapt to the development of industrial technology and meet the requirements of modern production systems [55]. Lifelong learning refers to having an awareness of independent and lifelong learning and the ability to continuously learn and adapt to development. The specific connotations are (1) the ability to recognize the necessity of independent and lifelong learning in the context of social development and (2) the ability to learn

independently, including the ability to understand technical problems and summarize and ask questions [39].

(e) Interdisciplinary ability: with the emergence of new industrial clusters, an education to develop an interdisciplinary ability for engineering students to meet the needs of economic development and smart construction is an emerging trend in the construction industry [56, 57]. It is the ability to integrate resources across disciplines while breaking through the limitations of individual knowledge boundaries [38, 58]. This includes the ability to think across disciplines and also integrate knowledge across disciplines [59, 60].

(f) Knowledge of engineering: engineering students suitable for smart construction need to master the basic theoretical knowledge necessary for the main engineering disciplinary area in a systematic manner [61]. The engineering knowledge necessary for smart construction students includes mathematics, natural science, engineering fundamentals, and expertise, which are useful for solving complex engineering problems [39, 62]. Smart construction education also needs to include the basic theory and knowledge of related disciplines, such as materials science, mechanical engineering, and digital skills and knowledge, so as to achieve the integration of information technology and engineering knowledge [1, 63].

(g) Engineering skill: professional skills of engineering students suitable for smart construction include both hard and soft skills. Hard skills refer to generic skills in specified engineering majors, such as design and development, application of modern tools, project management and financial analysis, research and study, and engineering analysis [31, 32, 64], while soft skills include exploring and management skills as well as communication skills [65–67].

2.2. Linguistic Landscape.

Landry and Bourhis [68] were the first to introduce and use the concept of "linguistic landscape" and defined it as "the language of public road signs, advertising billboards, street names, place names, commercial shop signs, and public signs on government buildings combines to form the linguistic landscape of a given territory, region, or urban agglomeration." The linguistic landscape has two main types of functions, namely, informative and symbolic. The informative function of language signs indicates the borders of the territory inhabited by a linguistic group and also the availability of a specific language to communicate in that territory. On the contrary, the symbolic function refers to the perception that members of a language group have of the value and status of their languages as compared to other languages [68].

Since the concept of linguistic landscapes was proposed, many researchers have conducted studies on the subject, which reached a climax in 2006. In 2015, John Benjamins, a well-known Dutch publishing group, launched "Landscapes: An International Journal," marking the maturation of the study of linguistic landscapes [69, 70].

The traditional topics on linguistic landscape include the spread of English, the phenomenon of multilingualism, the gap between language policy and concrete implementation, and the vitality of minority languages that continue to attract academia's attention [71], while new research areas have also emerged, including the linguistic landscape in virtual space and multimodal data-semiotic landscapes, such as [72–74].

Digital linguistic landscape is a new topic, and there is little relevant research on the matter, and this includes the virtual linguistic landscape. Virtual linguistic landscape or cyber linguistic landscape can be viewed as innovative subareas of the digital linguistic landscape. The development of virtual linguistic landscape research is still slow and mostly concentrates on exploring the presentation mode and linguistic forms of virtual linguistic landscape.

2.3. Digital Linguistic Landscape.

With the development of society and technology, eye tracking, virtual reality (VR), and other technologies have enabled people to extend their understanding of social space from "real space" to "virtual space" [75, 76]. The linguistic landscape with a multimodal combination of sound, picture, image, and color has become an emerging form of expression [77, 78]. In addition, with the growth of multilingual capabilities in digital communication, multilingual options in virtual spaces have become more popular, and linguistic landscapes can be defined not only in physical spaces but also in virtual spaces, such as electronic spaces, popular culture, and the Internet [79].

Digital linguistic landscape refers to the linguistic landscape in digital space. In a microsense, it is a controlled linguistic landscape space formed by combining traditional public road signs, billboards, and store signs with text, images, images, and 2D codes using various digital technologies. In a macrosense, it is the process, method, and technology of collecting, monitoring, analyzing, simulating, creating, and reproducing linguistic landscape information with the help of computer technology, multimedia technology, Internet technology, AI, VR, simulation and sensing technology, and other digital technologies. From a technical perspective, digital linguistic landscape is different from the traditional signage to express the linguistic landscape.

Digital linguistic landscape is an information platform for displaying linguistic landscapes through digital technology. Further, it is a tool for sharing language information. The information provided by digital linguistic landscapes is rich, diversified, and internationalized, and its media are diverse, such as digital websites, digital signage, digital media, and other media [80, 81]. Among them, digital signage refers to the multimedia professional audio-visual system that releases business, financial, and entertainment information through large-screen terminal displays in large shopping malls, supermarkets, hotel lobbies, restaurants, theaters, and other public places [82, 83].

Digital linguistic landscapes not only present linguistic information from around the world and are an important

gateway to knowledge, information, and skills but also are tools for people to understand the cultures of various countries and enrich their understanding of the world [73, 84]. Digital linguistic landscape is an extension of the physical linguistic landscape, which also has informative and symbolic functions. The informative function of the digital linguistic landscape includes information delivering function, information indicating function, and information mediation function. The information delivering function is manifested in the form of linguistic information at an intuitive level [85]; the information indicating function is manifested in the form of multimodal linguistic landscapes that serve as an aid to comprehension or emphasis [86]; and the information mediation function is manifested in the form of short, guiding messages that point to a broader pool of relevant information resources [74]. The symbolic function of digital linguistic landscape refers to its ability to reflect market trends and current social conditions [87, 88], as the information of digital linguistic landscape is shared, convenient, and expandable to facilitate the wide dissemination of social phenomena [89], and its information most directly reflects often the most cutting-edge social hotspots and trends. Besides, the information dissemination medium relies on the latest digital technology. Based on these features, digital linguistic landscape is a carrier that reflects current situations and market trends.

3. A Priori Model and Hypotheses

3.1. Theoretical Supporting Model: ASK. The supporting model "ASK" (also known as KSA) was applied to investigate the mechanism of the digital language landscape on the education of engineering students in smart construction. ASK, a benchmark of the American Council on Education, primarily aimed to assess the capabilities of a prospective job applicant [90]. In federal personnel guidance, KSAs are defined as the factors that identify higher qualified candidates from a group of individuals with varying levels of skills and knowledge [91, 92]. At present, the ASK model is mainly applied to the education of enterprise personnel and management, and it has also been explored in higher education and training of medical human resources. For example, at the level of personnel training, Stahl and Luczak [93] investigated personnel planning in concurrent engineering with KSA. From the perspective of higher education, Hu et al. [94] investigated the impact of the KSA competency enhancement framework on nonengineering students' competencies.

In the ability dimension of the model, this study examined innovation ability and international ability. The ASK model constructed in this study is shown in Figure 1.

3.2. Hypotheses. Based on the ASK education model for smart construction engineering, the hypotheses of the mechanism of digital linguistic landscape for smart construction education are proposed.

3.2.1. Digital Linguistic Landscape and the Smart Construction Ability of Engineering Students. With the advancement of China's new era of industrialization, an important mission of higher education institutions focused on engineering education is to cultivate innovative engineering students and provide support for the development of industrialization so as to meet the demand for continuous innovation. Innovation ability refers to the ability of people to discover new problems, propose new ideas, and new ways to solve problems through innovative thinking activities and produce new products, new technologies, or new methods through innovative and practical activities on the basis of rich knowledge and broad horizon [95]. Innovation ability is mainly a comprehensive ability formed by the interaction of such elements as knowledge horizon, innovation awareness, innovation thinking, and innovation skills [46]. Digital linguistic landscapes carry information that is diverse in presentation and rich in content, which helps to enrich knowledge and broaden horizons. It also has the potential to influence the acquisition and development of abilities at the consciousness level through the expansion of information and the diversification of information channels. Thus, the following research hypothesis was proposed regarding the digital linguistic landscape's role in the development of innovation ability for engineering students suitable for smart construction:

> H1: digital linguistic landscapes have a significant positive impact on the innovation ability of engineering students suitable for smart construction.

This study classifies intercultural communication ability, global awareness, and global vision as international abilities. Global vision requires students to be able to think and deal with problems from the perspective of global industrial development and seek opportunities for international development in a complex and changing international environment [96, 97]. Global awareness is a habit of mind that focuses on understanding and grasping the trends of the times [98]. Intercultural communication skills of smart engineering students cannot be developed without knowledge input and the practices of global engineering programs and immersive research experience abroad [99]. From the informative dimension of the digital linguistic landscape, it covers a wide range of information on humanities and history at home and abroad, as well as a wide range of languages, providing a global range of resources and a wide range of channels for inputting knowledge. From the symbolic dimension, the digital linguistic landscape provides a convenient medium to obtain information, a channel to understand the international market situation, and a facilitator to develop international thinking habits. Thus, the following research hypothesis was proposed regarding the digital linguistic landscape's role in the development of international ability of engineering students suitable for smart construction:

> H2: digital linguistic landscapes have a significant positive impact on the international ability of engineering students suitable for smart construction.
FIGURE 1: ASK education model for smart construction engineering.

3.2.2. Digital Language Landscape and Knowledge Acquisition by Engineering Students Suitable for Smart Construction. The education of engineering students in developed countries focuses on improving the professional knowledge and comprehensive quality of engineers and involves a wide range of courses covering multidisciplinary knowledge [100, 101]. The education mode of engineering students in the United States emphasizes liberal education in humanities, mathematics, and science. This involves a basic education in many disciplines with the goal of educating general engineering students, focusing on the integration of arts and science, enabling an adequate coverage of science and engineering, and supporting interdisciplinary [102, 103], whereas the education mode of engineering students in German universities mainly emphasizes the combination of basic education in humanities and social sciences and professional knowledge education and focuses on practical engineering education, with the goal of educating senior engineering students with a broad knowledge base [104–106].

A research report of the Chinese Academy of Engineering identified that engineering and technology students need to have more professional science and technology awareness and more solid engineering expertise as well as humanities and social knowledge [38]. Indeed, it can be seen that engineering students suitable for smart construction need not only to have the theoretical knowledge of their professions but also to learn the basic knowledge of multidisciplinary, humanities, and social sciences. Since the informative dimension of the digital linguistic landscape provides rich knowledge and information and basic knowledge of humanities and social sciences, as well as interdisciplinary knowledge, it is therefore able to play a key role in expanding the knowledge horizon of engineering students. In terms of the symbolic dimension, the digital linguistic landscape has the characteristics of information sharing, convenience, and expansion, which has the potential to impact the knowledge learning ability of students. Thus, the following research hypothesis was proposed regarding the digital linguistic landscape's role in the

education of knowledge acquisition of engineering students suitable for smart construction:

> H3: digital linguistic landscapes have a significant positive impact on the knowledge acquisition of engineering students suitable for smart construction.

3.2.3. Relationship between Digital Linguistic Landscape and Skills Training of Engineering Students. The overall scale and development level of China's construction industry continues to grow, but the construction industry still suffers from low skill quality of construction industry workers, imperfect skill education system, shortage of highly skilled personnel, and other problems, which seriously restricts the transformation of the construction industry. The provision of professional and systematic theoretical knowledge is an effective support to cultivate the skills of construction students [107, 108]. Indeed, China's Ministry of Education [39] proposed that, on the basis of the necessary basic theoretical knowledge and expertise, students should master the basic ability and basic skills to engage in the practical work in their professional fields. Therefore, in order to improve the skills mastery of smart construction engineering students, it is necessary to strengthen their professional theoretical knowledge base. As a platform for information provision and a medium for knowledge sharing, the digital language landscape plays a supporting role in the acquisition of skills and theories. Hence, the following research hypothesis was proposed regarding the digital linguistic landscape's role in the skill training of engineering students suitable for smart construction:

> H4: digital linguistic landscapes have a significant positive impact on the skills training of engineering students suitable for smart construction.

3.2.4. The Dimensions of Digital Language Landscape. Digital linguistic landscapes have informative and symbolic functions. The knowledge dimension in the ASK model derives from the informative function of the digital linguistic

landscape, which provides the source and support for the K in the ASK model. The symbolic function of the digital linguistic landscape can provide directions for the development of abilities and skills by reflecting current conditions and market trends. In view of this, the following research hypothesis was proposed on the role dimensions of digital linguistic landscape:

> H5: informative dimension and symbolic dimension are two main aspects of the DLL in the education of engineering students suitable for smart construction.

Based on the above hypotheses, the DLL-ASK model of the mechanism of digital language landscape on smart construction student educating was constructed, as shown in Figure 2.

4. Methods

4.1. Survey Design, Sample, and Procedure. A questionnaire was designed to survey the relations between DLL and engineering education. The questionnaire consists of two main parts, with four questions focusing on the background of participants and thirty-six statements to measure international ability, innovation ability, knowledge, skills, and informative and symbolic dimension of DLL (see Appendix). For the items in the second part, a 5-point Likert scale was used, with 1 indicating "strongly disagree" and 5 indicating "strongly agree."

The survey was designed and administered to collect data from September 28, 2021, to October 15, 2021, and was conducted in the form of online distribution on Sojump, a questionnaire platform. The survey was randomly sent to engineering college students, engineering professional teachers, and practitioners. In order to ensure the authenticity and objectivity of the survey data, the questionnaire was answered anonymously, and the purpose and the confidentiality of the study were informed in advance to reduce the privacy concerns of the survey respondents. A total of 193 responses were received.

As can be seen from Table 2, among the participants in the questionnaire survey, 1.05% of them are doctoral students and above, 10.47% are master's students, and 98.43% are bachelor's students and above, which reflects that the overall education level of the respondents in this survey is high. The statistics on the level of intercultural communication ability show that those who said they are not fluent in English account for the most (64.77%), while those who are fluent account for only 30.57%, and 4.66% said they could not communicate at all. This highlights that the overall intercultural communication level of college engineering students is low.

4.2. Data Analysis

4.2.1. Treatment of Data. In order to ensure the quality of data collected before commencing data analysis, all the completed questionnaires ($N = 193$) were checked against systematic response patterns and more than 5% missing items, as suggested by [109–111]. All questionnaires were completely answered. In view of the small proportion of engineering teachers and practitioners, their relevant data and questions (2nd question, years of working) were excluded, so 2 out of 193 completed questionnaires were dropped from the data set. To code responses for data analysis, the researchers identified each item as being favorable or unfavorable toward its factor to be measured, as suggested by Seo [109]. Items that score lower than 3 represent unfavorable; otherwise, they represent favorable.

4.2.2. Statistical Analysis. Data were analyzed with structural equation modeling (SEM) procedures, and MPLUS software was used to construct the SEM analysis of the DLL-ASK mechanism. This study used different types of indexes of overall fit for evaluating SEM models, including x^2/degrees of freedom ratio (x^2/df), Comparative Fit Index (CFI), Tucker-Lewis Index (TLI), and the root mean square error approximation (RMSEA).

(1) Absolute Fit Indexes. Absolute fit indexes typically evaluate "badness of fit." x^2/df and root mean square error of approximation (RMSEA) are two commonly used absolute fit indexes.

The model is regarded as acceptable, if the value of x^2/degrees of freedom ratio is less than two. MacCallum et al. [112] suggested that a value of 0.01, 0.05, and 0.08 of RMSEA indicates excellent, good, and mediocre fit, respectively.

(2) Incremental Fit Indexes. Incremental fit indexes typically evaluate "goodness of fit," as larger values indicate a better fit between hypothesized model and data. Commonly used incremental fit indexes include Bentler and Bonett's Normed Fit Index (NFI), Comparative Fit Index (CFI), Tucker-Lewis Index (TLI), and the Incremental Index of Fit (IFI), among which CFI and DFI were used in this study. A CFI value > 0.95 (ranging from 0.00 to 1.00) was considered representative of a well-fitting model. TLI value close to 0.95 represents indicative of a good fit [113].

5. Results

5.1. Descriptive Statistics. Correlations among all the dimensions are reported in Table 3, showing that all variables were significantly correlated ($p < 0.05$), and none of the correlation values exceeds the threshold value of 0.9, which suggests that the multicollinearity problem does not exist between the items [114].

5.2. Exploratory Factor Analysis. KMO and Bartlett's sphericity tests were conducted using SPSS software, and the results are shown in Table 4. The KMO value of the questionnaire sample was 0.864, and Bartlett's test value was less than 0.001, indicating that the sample is suitable for exploratory factor analysis (EFA) and the data information could be extracted effectively.

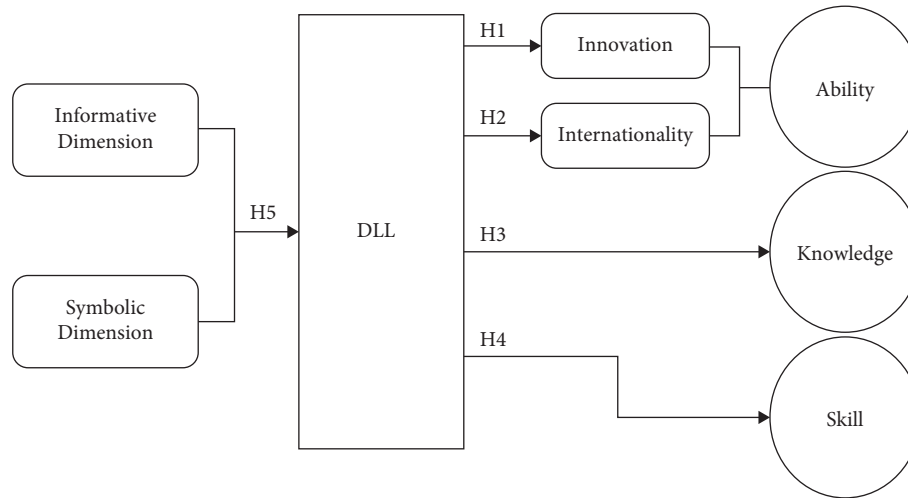
This study used SPSS24.0 software for the EFA to identify the dimensionality of the survey. After reducing the dimensionality of 36 factors, a total of 6 common factors were


Figure 2: DLL-ASK model.

Table 2: Sample information table.

Items	Options	%
Degree	Associate/bachelor	86.91
	Master	10.47
	Doctor and above	1.05
English level	Else	1.57
	Very fluent	1.55
	Fluent	29.02
	Not fluent	64.77
	Cannot speak at all	4.66

Table 3: Correlations among variables.

Dimensions	A-I	A-CX	K	S	DLL-Info	DLL-Sym
A-I	1					
A-CX	0.264**	1				
K	0.560**	0.151*	1			
S	0.225**	0.203**	0.255**	1

DLL-Sym	0.222**	0.187*	0.305**	0.412**	0.525**	1

**Correlation is significant at the 0.01 level. *Correlation is significant at the 0.05 level.

Table 4: KMO and Bartlett's test.

KMO and Bartlett's test		
KMO		0.864
Bartlett test of sphericity	Approx. Chi-square	9892.396
	df	1081
	Sig.	0.000

extracted, as shown in Table 5, and the cumulative variance explained by the extracted 6 factors was 70.614%, which proved that the extracted 6 factors could explain the original data of the questionnaire well.

Rotated component matrix result is shown in Table 6, and it can be seen that the classification of each question item corresponds exactly to the dimensional settings, indicating that the settings of each question item under the six dimensions are reasonable.

5.3. Testing the Measurement Model. The reliability of variables can be tested by Cronbach's alpha coefficient if $\alpha > 0.6$, indicating that the dimension is valid, and the larger it is, the better its reliability is. The results of the reliability test using SPSS software are shown in Table 7. It can be seen that the α values of variables are all greater than 0.7, and the CITC values of all measurement items are greater than 0.3, which shows that the data of each variable meet the requirements of reliability.

Then, the validity of factors was tested by confirmatory factor analysis (CFA). The CFA results are shown in Table 8. The results showed that the KMO values of these research variables are higher than 0.7, and Bartlett's test value is less than 0.001, representing statistically significant. Meanwhile, the factor loadings of items are all larger than 0.5, and the cumulative variance explained is above 50%. It represents each measurement item that belongs to the corresponding variable, and the dimension has good discriminant validity and convergent validity and meets the requirements needed for the study, so it can be tested by SEM.

5.4. Structural Model. The results of SEM analysis of the DLL-ASK mechanism are shown in Figure 3, and the specific coefficient results are shown in Table 9. The results of the SEM fit index are within the acceptable range, as x^2/df is 1.789 < 3, CFI is 0.950 > 0.90, TLI is 0.946 > 0.90, and RMSEA is 0.064 < 0.80. It can be seen that the DLL-ASK model constructed in this paper fits well.

According to the results of the SEM in Figure 3 and Table 9, it was found that the digital linguistic landscape contains an informative dimension and a symbolic dimension with factor loadings of 0.768 and 0.760, respectively. At the same time, the digital linguistic landscape variable consisting of these two dimensions has

TABLE 5: Common factors.

Component	Initial eigenvalues			Extraction sums of squared loadings			Rotation sums of squared loadings

a positive effect on international ability, with a path coefficient of 0.361 ($p < 0.001$), and also a positive effect on innovation ability, with a path coefficient of 0.229 ($p < 0.05$), assuming that path H1 and H2 are established. Among them, the digital linguistic landscape has more influence on the formation of international ability. In addition, there is a significant positive effect of digital linguistic landscape on knowledge, with a path coefficient of 0.397 ($p < 0.001$), and the same to skill, with a path coefficient of 0648 ($p < 0.001$), proving that the hypotheses paths H3 and H4 are tenable. Considering the effect of digital linguistic landscape on ability, this result shows that digital linguistic landscape has the most significant effect on skills training of engineering students suitable for smart construction.

The hypothesis H5 that the digital linguistic landscape contains both informative and symbolic dimensions holds true, and the digital linguistic landscape combines together the two dimensions to educate engineering students suitable for smart construction. Features 6 (providing rich linguistic information), 7 (providing domestic and foreign human history), and 8 (providing interdisciplinary knowledge) of the informative dimension play the most significant role, and features 4 (reflecting foreign market trends) and 5 (reflecting domestic market trends) of the symbolic dimension play the most obvious role.

6. Discussion

This study aims to test the mechanism of the digital linguistic landscape in engineering education for smart construction. The results underscore the importance of digital linguistic landscape in educating engineering students in smart construction. DLL plays a significant role in educating the international ability and innovation

ability of engineering students suitable for smart construction.

The findings have significant implications for the specification of the education objectives in regard to the ASK dimensions. The results identify the acting path of DLL on ability, knowledge, and skill education. To be specific, the path to enhance the international ability of engineering students for smart construction is mainly to improve the international competitiveness, cross-cultural communication ability, and broad international horizon. In addition, the path to enhance the innovation ability of the students is mainly to improve the innovation awareness, innovation thinking, and innovation skills, whereas the path to educate the underpinning knowledge of the students is mainly to enrich students' knowledge reserve, broaden their knowledge horizon, and enhance knowledge learning motivation. Furthermore, the improvement of the personal skill level of engineering students is of primary importance in skills training.

The innovation ability is an indispensable ability for engineering students suitable for smart construction [12, 95]. Digital linguistic landscape influences innovative thinking through feature 1 of the informative dimension (extensive information access) and features 2 and 3 of the symbolic dimension (reflecting market trends), innovative awareness through feature 5 of the informative dimension (diverse forms of information presentation), and innovative

skills through feature 1 (helping to understand digital technology) of the symbolic dimension. Digital linguistic landscape influences innovative skills through integrating the informative dimension and the symbolic dimension to cultivate the innovation ability of engineering students suitable for smart construction.

Digital linguistic landscape enhances cross-cultural communication ability through feature 6 (providing rich linguistic information) in the informative dimension and broadens international vision through feature 8 (rich interdisciplinary knowledge). Also, DLL improves international competitiveness through features 4 and 5 (reflecting domestic and international current conditions) in the symbolic dimension and integrates the informative dimension and symbolic dimension work together to cultivate the international ability of engineering students suitable for smart construction. Cultivation of the international ability of engineering students suitable for smart construction enables the students to become the leaders of the construction industry of the future [15].

Digital linguistic landscape educates the knowledge dimension of smart construction engineering students by enriching the professional and nonprofessional knowledge reserve of students through feature 4 (providing diversified foreign language information) and feature 6 (providing rich languages) of the informative dimension of digital linguistic landscape and broadens the knowledge horizon through feature 8 (rich interdisciplinary knowledge) of the informative dimension and features 2–5 of the symbolic dimension (reflecting market trends and current conditions). To broaden the knowledge horizons and enhance knowledge learning motivation through informative dimension feature 2 (easy access to information) and feature 5 (multimodal information presentation form) allow integration of two dimensions to cultivate the knowledge dimension of smart construction engineering students.

The specific path of the digital linguistic landscape for the skill education of engineering students suitable for smart construction is to train the skill of smart construction students through features 2 (easy access to

TABLE 10: Questionnaire statements.

Items	Specific statements
1	Understanding domestic and international current conditions can help people enhance one's international competitiveness
2	Understanding market trends helps people enhance international competitiveness
3	Access to information on foreign language knowledge can help enhance one's intercultural communication skills
4	Access to rich linguistic information can help enhance one's intercultural communication skills
5	Access to information on humanities and social sciences helps to develop one's international perspective
6	Access to multidisciplinary knowledge helps to broaden one's global vision
7	Understanding domestic and international current situation helps to enhance one's innovation awareness
8	Understanding market trends helps enhance one's innovative thinking
9	Understanding the latest digital technology helps enhance one's innovative skills
10	Diversified access to information helps enhance one's innovative thinking
11	Diversified forms of information presentation can help enhance one's innovative thinking
12	Access to more language information helps to strengthen one's professional knowledge base
13	Access to foreign language knowledge helps enhance one's nonspecialized knowledge base
14	Understanding multidisciplinary knowledge helps broaden one's knowledge horizon
15	Understanding domestic and international market trends helps broaden one's knowledge horizons
16	Easy access to language information helps to increase motivation to learn
17	Access to a wide range of language information helps to increase motivation to learn
18	Knowledge of the latest digital technologies helps to strengthen one's skills
19	Understanding more knowledgeable information helps to strengthen one's skills
20	Understanding domestic and international current conditions helps strengthen one's skills
21	Knowledge of domestic and international market trends helps strengthen one's skills
22	Knowledge of foreign language information helps strengthen one's skills
23	Easy access to information helps strengthen personal skills

TABLE 10: Continued.

Items	Specific statements
24	DLL can increase people's access tunnels to information
25	DLL makes it easier for people to access information
26	DLL allows people to share information resources
27	DLL multimodality increases people's interest in it
28	DLL provides various languages
29	DLL provides a wealth of linguistic information
30	DLL helps people understand the history of people at home and abroad
31	DLL can provide access to multidisciplinary knowledge
32	DLL provides access to the latest digital technologies
33	DLL provides access to domestic current situations
34	DLL provides access to foreign current situations
35	DLL helps people study foreign market trends
36	DLL helps people study domestic market trends

information), feature 4 (providing multiple foreign language information), and feature 6 (providing rich language information) of the informative dimension of digital linguistic landscape.

Educating the ability of engineering students in smart construction is the driver and support for the development of the smart construction industry [115]. Knowledge has been identified as a key driving force for innovation [95]. Thus, the development of the knowledge dimension also indirectly acts on the improvement of the innovation ability. By improving the skill level, smart construction students can improve their skill level and thereby be more able to adapt to society and meet its changing needs more quickly [99]. Therefore, it is necessary to strengthen the application of DLL in engineering education.

7. Conclusion

This research investigates the influence factors on the education of engineering students suitable for smart construction. The study divided the qualities of engineering students suitable for smart construction into the three dimensions of ability, knowledge, and skill based on the ASK model, and a DLL-ASK hypothesis model was subsequently constructed. Based on this approach, the DLL-ASK model was surveyed and tested using a questionnaire and SEM.

The results of the study identify the following: (1) The informative dimension and symbolic dimension are two main aspects of the DLL in engineering education for smart construction. (2) DLL has a significant positive impact on the ability, knowledge, and skills of engineering students suitable for smart construction. (3) DLL educates the ability, knowledge, and skills of engineering students for smart construction by transmitting rich language information and multilingual information as well as reflecting market trends at home and abroad. The research results are consistent with the DLL-ASK hypothesis model, and therefore, the DLL-ASK model is supported.

Based on the above results, the following suggestions are made on how to educate engineering students for smart construction from the informative dimension and symbolic dimension of the digital linguistic landscape:

(1) Increase the amount of digital linguistic landscapes in engineering education. It is highly important to enhance the use and edification of digital linguistic landscape in the real engineering student training environment or digital space learning environment. Through strengthening the edification and influence of digital linguistic landscape in smart construction training, it is more likely to gradually improve the ability and skills of students and broaden their knowledge horizon as well. Specific measures include increasing the amount of digital signage on campus, using digital media to support the education process, and establishing a digital linguistic landscape network platform for information sharing.

(2) Pay more attention to the content of digital language landscape information. Digital language information is most directly accessed and absorbed by students, so this feature can be harnessed to present the education contents to smart construction engineering students through the carrier of the digital language landscape. For example, for the cross-cultural communication ability of engineering students, the skills to enhance abilities or access to resources can be presented through multimodal presentation such as voice, image, and QR code.

(3) Make full use of digital language landscape technology guidance role. As the embodiment of digital technology, digital language landscape has a significant impact on the technical development of engineering students for smart construction. By learning the application of digital technology, smart construction students can better and faster integrate the trend of social development and meet the changing needs of the construction industry.

Therefore, it is necessary to periodically update the digital language landscape medium and use the latest technology-supported digital signage so as to connect digital technology with smart construction technology.

The limitation of this study is that although the participants appear to be representative of engineering students in China's higher education, there is nevertheless a lack of involvement of teachers and practitioners. Moreover, the participants were limited to Chinese engineering students, and there was a lack of involvement of international students. Therefore, future research should adopt a larger sample size with a wider range of participants to further examine the external validity of the study.

Appendix

Questionnaire

Linguistic landscape includes physical landscapes formed by language, such as language appearing on public signs such as public street signs, billboards, street names, place names, and store signboards. It also includes language information on virtual media such as digital signage, electronic billboards, and network video advertisements. Digital linguistic landscape is a platform for displaying linguistic landscape information through digital technology, a medium for carrying linguistic information in virtual space, such as QR codes, digital advertisements, and multimedia videos.

The survey is anonymous, and the data of this questionnaire is for academic research use only. Your honest, personal opinions are greatly appreciated and help us a lot. Thanks for your time!

(I) Demographic traits

(1). Your identity: ☐Engineering Practitioner ☐Engineering Teacher ☐Engineering Learner
(2). How long have you been working in this industry: _____
(3). Your major: _____
(4). Your education: ☐university or college ☐postgraduate ☐doctor ☐else

(II) Your evaluations of the following roles' degree

Five choices are listed below each question, from 1 indicating "strongly disagree" to 5 indicating "strongly agree" (Table 10).

Data Availability

The data used to support the findings of the study could be obtained from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interests or personal relationships that could have appeared to influence the work reported in this paper.

Authors' Contributions

Jingxiao Zhang contributed to the conception of the study, Lin Xu and Yin Yuan performed the experiment, Yin Yuan and Junwei Zheng contributed significantly to analysis and manuscript preparation, Yin Yuan and Jingxiao Zhang performed the data analyses and wrote the manuscript, P. Philbin and Brian H.W. Guo helped perform the analysis with constructive discussions, and Ruoyu Jin contributed to the revision and polishing of the paper.

In order to improve the performance of the urban building in urban design, this paper uses the mathematical method based on an improved fuzzy calculation to construct an intelligent building and urban design system. Moreover, this paper quantitatively studies the pedestrian wind environment of high-rise buildings and determines the optimal building aerodynamic shape and optimal building layout in the full wind direction. In addition, based on the results of the whole watershed analysis of CFD numerical simulation, this paper reveals the mechanism of building shape and layout in the pedestrian wind environment of high-rise buildings. Finally, this paper constructs an intelligent model to improve the effect of urban architectural design. Through the model research results, we can see that the urban design intelligent system proposed in this paper meets the needs of urban design in the environment of Industry 4.0.

1. Introduction

In the context of Industry 4.0, there are very few cases where the development of AI application science is supported by mainstream architects and urban designers. Early claims of artificial intelligence have raised concerns that the core jobs and competencies of architects and urban designers will be displaced. At the same time, when expectations fail to materialize, there is a loss of interest and funding for AI in building and urban design. However, interest in AI has picked up again since the second decade of the twenty-first century. Advances in technology, changing attitudes towards computer science in general, the emergence of big data and data analytics, the widespread use of civics, the rediscovery of civic design, the emergence of civic design science, and large-scale open online design approaches are working together to advance a more positive outlook for AI in building and urban design and may lead to compelling outcomes.

At present, the phenomenon of blindly copying foreign architectural creations is common in domestic building and urban design, which is obviously in mourning with the idea of a "harmonious society". In response to this phenomenon, we believe that we should not only actively absorb the good parts of the foreign building in architectural creation. What is more important is to absorb the excellent ideas in the development of foreign cities, such as the idea of focusing on the coordinated development of individual buildings and the city as a whole, to consider the issue of architectural creation in the context of macro urban society. Therefore, in order to realize a "harmonious society", it is necessary to emphasize the concept of coordination between people, buildings, and the environment in architectural creation.

The huge demand in the construction market and the relatively affluent social and economic conditions have led to the phenomenon of the one-sided pursuit of form and blind pursuit of novelty in the field of urban and architectural design. This "impetuous" design idea is reflected in the urban environment. First of all, various construction projects compete with each other to become the city's logo and image projects. It is conceivable that every building strives to highlight its individual image and play a leading role in the

city. The result is a cluttered urban landscape and weakens the overall appearance of the city. In addition, driven by the concept of the supremacy of form, urban architectural design is seriously plagiarized, applying some avant-garde and trendy fashion designs in the world, ignoring the specific base environment and cultural connotation; this leads to the disappearance of the environmental identity and cultural identity of urban areas. Many traditional urban areas and historical areas have been completely "renovated" after renovation, cutting off the social life network of the original residents, and the architectural form has become a false stage setting. The root cause of these problems lies in the neglect of the relationship between the part and the whole in creative activities and the lack of respect for the urban environment and regional culture. This self-centered view of creation will inevitably bring chaos to the overall urban environment, which is not conducive to the construction of a "harmonious society". Therefore, we should adhere to the people-oriented scientific development concept, deal with the relationship between architecture and the city from an overall perspective, and realize the harmonious development of people, buildings, and the environment.

From urban planning and design to architectural design, it is a "three-stage" relationship from the whole to the group and then to the individual [1]. If the individual building is taken out and analyzed again, the overall volume of the building, the volume transition relationship, and the detail processing will form a "three-stage" relationship [2]. In this way, when the building is enlarged into a system, the details of the near-human scale are at its most microscopic level. However, the building volume observed from the city's perspective becomes its macro scale, and it is observed from the perspective of the street, that is, urban design [3].

This paper combines the mathematical method of improving fuzzy calculation to construct the intelligent building and urban design system and improves the effect of urban architectural design through the intelligent model.

2. Related Work

The methods and capabilities of urban architectural planning and design continue to develop with the advancement of science and technology. In the early urban architectural planning, due to the use of traditional manual drawings for design, there were many problems due to the limitation of technology such as low labor efficiency, long design and design cycles of drawings, and error-prone architectural planning and design information. It is difficult to exchange and store design files and design results [4] and so on. The improvement of the economic level and the acceleration of the urbanization process affect the needs of urban architectural planning and design, and the traditional manual drawing method cannot handle a large number of design documents quickly and accurately. Information technology and CAD software have begun to be popularized on a large scale, various industries have also begun to enter the digital age, and the "electronic design" system of the urban architectural planning and design industry has emerged as the times require [5]. The electronic construction report design

system adopts CAD electronic drawings in a unified and standardized format, which can quickly extract and calculate and analyze the information to be designed for the building, complete the automatic quantitative accounting of design indicators, realize electronic filing, and dynamically store architectural project design plans. The precise data processing capability of CAD provides efficient and accurate design technology for architectural planning, and the specification standards and accounting indicators formulated by electronic design make the design results reasonable and serious [6]. With the increasingly complex development of urban architecture, urban planning and design need more comprehensive and objective analysis, and the CAD technology based on a two-dimensional plane is difficult to realize the image description of urban three-dimensional geospatial information [7].

At the beginning of the twenty-first century, the rapid development of 3D GIS technology made the concept of the digital city begin to be valued by people. The 3D visualization analysis of the architectural space environment in the digital city has become the development direction of architectural planning and design [8]. 3D GIS technology can be used for urban architectural planning and design. Comprehensive, intuitive, and scientific decision analyses are provided. In recent years, the fusion technology of BIM and GIS has attracted much attention in many industries, and its application in urban architectural planning and design has also entered the stage of research and exploration. BIM technology is widely used in some developed countries abroad [9]. Professional architectural engineering software based on BIM technology includes Revit and Infraworks series software products of Autodesk Company of the United States, ArchiCAD software of Graphisoft Company of Hungary, and MicroStation TriForma software of Bentley Company [10]. These large software developers provide comprehensive solutions for the needs of different stages of construction projects and the management goals of different professions. However, at present, most of these softwares are aimed at single building projects, which have poor support for terrain data and limited data capacity, which cannot meet the needs of urban planning and design in a three-dimensional environment. On the other hand, geographic information system (GIS) software is also moving closer to BIM. The processing of spatial data is a feature of GIS [11], and the storage, expression, and analysis of large-scale terrain spatial data are the strength of GIS, which just makes up for the shortcomings of traditional BIM software in infrastructure construction projects in a large-scale environment [12]. BIM and GIS are different in the geometric and semantic expressions of model objects. The key to their integrated application lies in the fusion of model data. With the in-depth research on the integration of BIM and GIS technology, although relevant personnel of various majors has completed the exchange of information and data through simple model conversion, similar methods only save part of the semantic information, resulting in obvious limitations in the application of BIM [13]. At present, the research on BIM and GIS integration mainly focuses on two aspects, one is the integration of basic data models, and the other is the
FIGURE 1: Basic model parameters. (a) Model size. (b) Average wind speed profile and turbulence intensity. (c) Distribution map of measuring points.

integration of existing data formats. The former analyzes the different expression types of BIM and GIS model objects and establishes a unified expression model for the two [14].

At this stage, most research directions are mainly focused on the latter, integrating model data in different formats, such as IFC Explorer developed by the Karlsruhe University of Technology in Germany, BIM Server developed by the Eindhoven University of Technology in the Netherlands, and Navisworks software developed by Autodesk [15]. Among them, IFCExplorer CityGML is committed to the seamless integration of the BIM standard model format IFC and the GIS standard model format CityGML, but it is difficult to achieve indiscriminate conversion between the two standard models, and it is still at the lower level of detail of the research model conversion [16]. BIMServer software supports the understanding and management of various BIM model structures, and at the same time, it can realize the simple conversion of BIM to GIS models. However, its functions are limited to data management and transformation and cannot achieve application analysis [17]. In addition, the conversion between its BIM and GIS models still has problems such as poor quality of the converted model and lack of semantics. Although Navisworks can realize the integrated analysis and application of BIM data sets, it is mainly based on a simple file system, so it is difficult to process large-scale data and the efficiency is low. And its support for GIS data can only be achieved through the conversion of third-party software, which will inevitably lose a lot of real information during the conversion process [18].

3. Architecture and Urban Design Based on Improved Fuzzy Computing

The structural model used in this paper is a single building with a square cross section. The scale ratio used in the numerical simulation is consistent with the experiment, which is $1 : 500$, and the size after the scale is $D_x \times D_y \times D_z = 0.1 \times 0.1 \times 0.8 m$ (Figure 1(a)), and Figure 1(b) shows the distribution of measuring points around the building. All the measuring points are located at the pedestrian

height, and a total of 280 measuring points are arranged. The distribution range of measuring points is $X \times Y = 0.792 \times 0.792$ m (the center point of the building is the origin of coordinates), which is about 8 times the cross-sectional area of the calculated model. The height H of the building is taken as the reference height, and $U_{\text{ref}} = 11.3$m/s, $I_u = 11.6\%$ at the reference height. Existing research conclusions show that, for the fitting of regions with lower heights, the logarithmic wind profile is better than the exponential wind profile. Since this paper studies the pedestrian wind environment at the pedestrian height (the height is 2 meters), in order to ensure the accuracy of the numerical simulation, the logarithmic wind profile is used for calculation. The distribution map of the measuring points is shown in Figure 1(c).

3.1. Calculation Domain and Boundary Condition Setting. In the CFD numerical simulation, the dimensions of all models are consistent with the wind tunnel test, and the size of the three-dimensional computational domain is set to $D_x \times D_y \times D_z = 15H \times 10H \times 6H$ (Figure 2). After calculation, the corresponding blocking rate is less than 3%, which meets the corresponding requirements.

The inlet of the computational domain is set to velocity inlet, the outlet is set to pressure outlet, and the boundary conditions on both sides and the top boundary are symmetric boundary conditions (symmetry).

The model is structured and meshed with ICEM CFD software. In meshing, because the Reynolds number of the fluid in the near-wall region is low during the flow process, in order to ensure the full development of turbulence, the mesh in the near-wall region must be refined. On the other hand, since different turbulence models have different requirements for mesh quality, it is necessary to divide meshes of different sizes according to the selected turbulence model.

In the CFD calculation, the size of the first layer grid of the model is often determined by calculating the size of the $y+$ value. The relevant calculation steps are as follows.

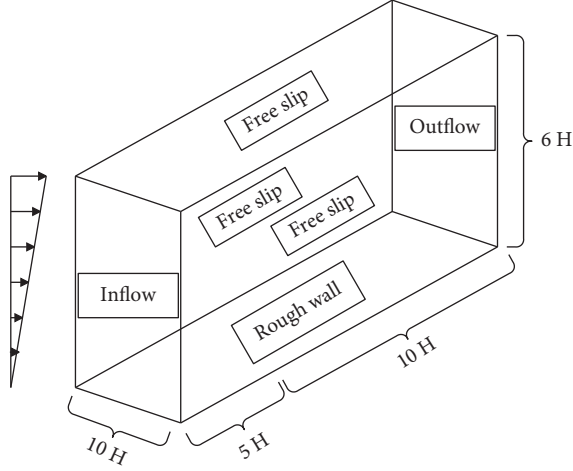
(1) It calculates the Reynolds number *Re*


FIGURE 2: Computational domain and boundary condition settings (square).

$$R_e = \frac{\rho U L}{\mu}. \tag{1}$$

(2) It calculates the wall friction coefficient C_f

$$C_f = \left(2 \log_{10} R_e - 0.65\right)^{-2.3} \left(R_e \leq 10^9\right). \tag{2}$$

(3) It calculates the wall shear stress τ_w

$$\tau_w = C_f \times \frac{1}{2} \rho U^2. \tag{3}$$

(4) It calculates the grid height of the first layer

$$u^* = \sqrt{\frac{\tau_w}{\rho}}, \qquad (4)$$
$$\Delta y = \frac{y^+ \mu}{\rho u^*}.$$

When meshing, it is often necessary to divide different meshes according to different calculation models. In order to facilitate the calculation, this paper uniformly selects $Y^+ = 15$ for mesh division, the corresponding first-layer mesh size is set to $\Delta y = 0.0005m$ after calculation, and the corresponding mesh schematic diagram and calculation conditions are set as shown in Figure 3.

In order to verify the influence of the mesh size on the calculation results, the working condition RANS-1 is used as the reference condition to verify the influence of different mesh sizes on the calculation results. Two sets of grids with different sizes were established on the basis of the working condition SCRS-1. The minimum grid size of the refined grid is 0.0005 m, the minimum grid size of the sparse grid is 0.002 m, and other related settings remain unchanged. The corresponding mesh numbers are as follows. The total number of refined meshes is about 9×10^7, and the number of sparse meshes is about 4×10^7. The comparison chart of different size grids is shown in Figure 4.

In the numerical simulation study in the pedestrian wind environment, the accuracy of the simulation calculation cannot be guaranteed due to the low height of pedestrians, which are easily affected by the ground roughness. Therefore, one of the key issues of CFD numerical simulation is to meet the requirement of wind speed self-sustainability in the empty flow domain, that is, to ensure that the flow characteristics of the flow field remain consistent in the horizontal direction when the fluid passes the ground surface.

In the CFD calculation, we first calculate an airflow field before starting the model calculation, from which we obtain the average wind profile at the entrance, exit, and three locations of the model. The wind profile without corresponding adjustment is shown in Figure 5, and it can be found that the unadjusted wind profile does not achieve good retention at lower altitudes. At this altitude, the wind speed profile is significantly affected, resulting in a change in wind speed. In order to keep the wind speed uniform at lower heights, the self-sustainability of the wind speed is achieved by modifying the wall function and roughness parameters in this paper.

It can be found that in the wind field after debugging, the wind speeds of the inlet and outlet surfaces are consistent, thus ensuring the accuracy of the numerical simulation in this paper.

When evaluating the pedestrian wind environment around a building, the wind speed ratio R_i is often used for analysis, and its related definition is as follows:

$$R_i = \frac{V_i}{V_0}, \tag{5}$$

where V_i is the wind speed at the pedestrian height at the measuring point around the building (this paper is 2 meters above the ground), and V_0 is the wind speed at the entrance pedestrian height when there is no building [19].

In order to find the turbulence model with the best match between the predicted results and the experimental results, the turbulence model is judged by three evaluation indicators. The corresponding parameters are as follows:

(1) The indicator q is

$$q = \frac{1}{M} \sum_{i=1}^{M} n_i,$$
$$n_i = \begin{cases} 1 & \left|\dfrac{R_{i\,\exp} - R_{iCFD}}{R_{i\,\exp}}\right| \leq 0.2 \text{ or } \left|R_{i\,\exp} - R_{iCFD}\right| \leq 0.2 \\ 0 \end{cases} \tag{6}$$

(2) The average error δ is

$$\delta = \frac{1}{M} \sum_{i=1}^{M} \left|R_{\text{iexp}} - R_{\text{iCFD}}\right|. \tag{7}$$

(3) The mean square error σ is

$$\sigma = \sqrt{\frac{1}{M} \sum_{i=1}^{M} \left(R_{\exp} - R_{iCFD}\right)^2}. \tag{8}$$

In the above three formulas, M is the number of measuring points, and R_{iexp}, $R_{iCF\ D}$ is the wind tunnel test result and CFD simulation result at the i-th measuring point, respectively.

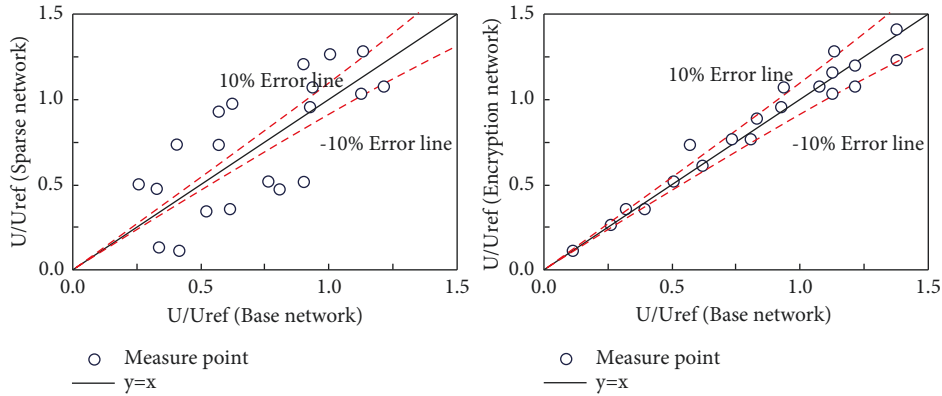
After sorting out the wind tunnel test data, a total of 244 valid data measurement points are collected in the wind tunnel test. Through statistical analysis of these 244 different measuring points, it is found that there are 77 low wind


FIGURE 9: Comparison of wind speeds at different measuring points (buildings).
FIGURE 10: Comparison of inlet and outlet wind speed profiles under different working conditions (building group).
FIGURE 11: Schematic diagram of the calculation of $\theta_{R,\theta}$.

speed measuring points (wind speed ratio R_i is less than 1.0) and 167 high wind speed measuring points (wind speed ratio R_i is greater than 1.0). Therefore, the distribution map of the corresponding simulation results is first given (Figure 6).

From the distribution results of the index q, there is a certain error between different working conditions of the SRAMS model, but the error is mainly concentrated in the low wind speed area, that is, the area where the wind speed ratio R_i is less than 1.0. On the other hand, it performs well in the high wind speed area, that is, the area where the wind speed ratio R_i is greater than 1.0. This is mainly due to the fact that the SRNS model cannot accurately simulate the flow separation phenomenon in the wake area of the building, which makes it poorly simulated in the low wind speed area. The LES condition performs well in both low wind speed and high wind speed regions.

In the CFD numerical simulation, the dimensions of all models are kept consistent with the wind tunnel test. The size of the computational domain is 15H (length) × 10H (width) × 6H (height) (as shown in Figure 7), and the blockage rate of the CFD numerical simulation is less than 3%, which

meets the requirements of computational wind engineering and does not need to be revised. The structured grid is used for division, and the grid is refined at the building wall. The grid height of the first floor is 0.0002 meters. According to the preliminary simulation results, the y value of the building surface is about 30, the grid growth rate is set to 1.1, and the total number of grids for all working conditions is 7×10^7 ∼ 9×10^7.

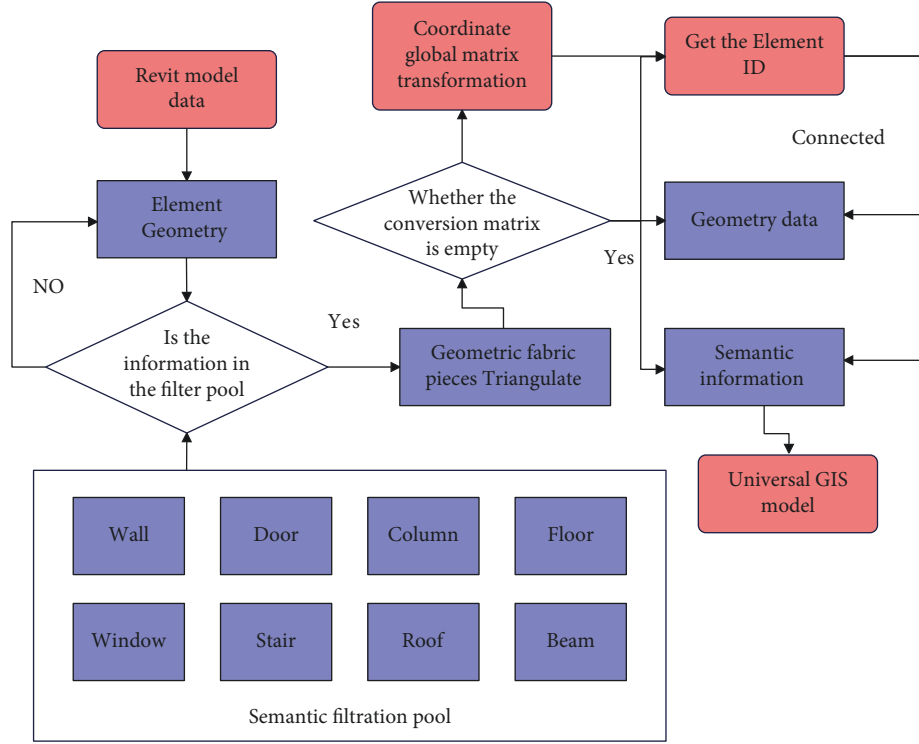
This paper takes the square enclosed layout as an example to verify the grid independence. First, a set of basic grids is established. The height of the first layer grid is 0.0002 meters, the grid growth rate is set to 1.1, and the total number of grids is about 7 million. Secondly, another two sets of grids of different sizes are distributed and established. The grid size of the first layer of the sparse grid is 0.0004 meters, the grid growth rate is 1.1, and the total number of grids is about 4 million. The mesh size of the first layer of the refined mesh is 0.0001 meters, the mesh growth rate is 1.1, and the total number of meshes is about 11 million. The corresponding grid size comparison chart is shown in Figure 8. Furthermore, different grids are used to simulate the pedestrian wind environment, and the


FIGURE 12: Application process of the mathematical method based on improved fuzzy calculation in building and urban design.

calculation results of 26 different measuring points are obtained. The corresponding results are compared in Figure 9.

It can be clearly found that there is a significant difference in the calculation results between the sparse grid and the basic grid, while the difference between the refined grid and the basic grid is very small. This is enough to show that using the basic grid for simulation can not only ensure the calculation accuracy but also ensure that the computing resources are consumed as little as possible, so all the calculation case grids in this chapter are divided according to the basic grid method.

It can be seen from the foregoing that the self-sustainability of the wind speed must be ensured first before CFD numerical simulation is carried out. In this paper, the self-sustainability of wind speed is achieved by modifying the wall function and roughness parameters. The relevant simulation results are shown in Figure 10. The results show that the velocity profiles of the inlet and outlet are relatively consistent and have good self-sustainability in the verification results of the empty wind field.

When evaluating the pedestrian wind environment around a building, the wind speed ratio R_i is often used for analysis, and its related definition is as follows:

$$R_i = \frac{V_i}{V_0}, \tag{9}$$

where V_i is the wind speed at the pedestrian height at the measuring point around the building (this paper is 2 meters above the ground), and V_0 is the wind speed at the entrance pedestrian height when there is no building.

In order to quantitatively analyze the impact of building shape and layout on the pedestrian wind environment of high-rise buildings, this paper uses the maximum wind speed ratio R_{max} and the normalized accelerated area ratio A^{**} to evaluate the wind environment of the building group. The relevant definitions are as follows:

$$R_{max,\theta} = \max(R_{i,\theta}),$$

$$A_{R,\theta}^* = \frac{A_{R,\theta}}{A_T},$$

$$R_{max} = \max(R_{max,\theta}),$$

$$R_{min} = \min(R_{max,\theta}), \tag{10}$$

$$A_{max^*} = \max(A_{R,\theta}^*),$$

$$A_{min^*} = \min(A_{R,\theta}^*),$$

$$A_{R,arg}^* = \frac{1}{N} \sum A_{R,\theta}^*,$$

where $R_{i,\theta}$ is the wind speed ratio in the evaluation area when the wind direction angle is θ, and A_T is the area of the evaluation area. According to the distribution of measuring points, the size of this area is $900 \times 900 \text{mm}^2$. $\theta_{R\theta}$ is the size of the area where the wind direction angle is θ and the wind speed ratio in the area is greater than R (Figure 11).

24	73.25	49	82.78	74	81.34
25	84.09	50	74.67	75	86.60

It can be known from the previous definition that the size of the R value in $A_{R,\theta}$ should be a value greater than 1.0. Regarding the specific value of R, in the absence of meteorological statistics, in order to meet the comfort of the wind environment, the wind speed ratio of the dominant wind direction should not be greater than. Therefore, when conducting research in this paper, $R_i = 1.2$ is selected for research; that is, the magnitude of $A_{R,\theta}$ is calculated for wind environment assessment.

4. Application of Mathematical Methods Based on Improved Fuzzy Computing in Building and Urban Design in the Environment of Industry 4.0

The intelligent model covers the structure and related facilities of the building in all aspects of design, construction, and operation management. It is necessary to simplify the BIM model for different applications, filter the geometric and semantic data irrelevant to the visual analysis, and extract the key elements required for the approval of building spacing. The specific process of extracting key elements is shown in Figure 12.

On the basis of the above research, the effect of the model proposed in this paper is verified. The model in this paper mainly assists the architectural structure design and human experience in urban architectural design. Therefore, this paper combines the simulation test to evaluate the effect of architectural and urban design and evaluates the architectural experience. The results shown in Tables 1 and 2 are obtained.

From the above research, we can see that the urban design intelligent system proposed in this paper meets the needs of urban design in the environment of Industry 4.0.

5. Conclusion

The urban building has a significant impact on the city block in which it is located. In its sheer size and population alone, it is of obvious importance to the concentration of urban blocks, to pedestrians on the street, and to the streetscape itself. Moreover, these can be attributed to the environmental relationship of tall buildings, which must be the subject of effective urban design in a certain location. At this level, the development of urban building can be controlled by planners through local planning. Due to their relative volume and height, high-rise buildings have a great impact on the existing surrounding environment and the scale of the city. Whether standalone or blended into an urban environment, the larger the building's mass, the greater the impact. This paper combines the mathematical method of improving fuzzy calculation to construct the intelligent building and urban design system and improves the effect of urban architectural design through the intelligent model. The simulation results show that the urban design intelligent system proposed in this paper meets the needs of urban design in the environment of Industry 4.0.

Scientific identification of the factors that underpin the success of construction program can effectively promote the success of construction program. Based on literature statistics, this paper developed the measurement items of key success factors of construction program in Chinese context. Based on exploratory factor analysis, seven key success factors of construction program were extracted. Then, the excellence model of construction program was constructed by referring to the ideas, concepts, and theoretical mechanisms of EFQM model. The research conclusions of this paper provide a systematic and holistic guidance for the successful implementation of the program by the construction program organization and promote the success of the program.

1. Introduction

With the economic development having been switched from high-speed development to high-quality development, China is now facing a critical period of development mode transformation, economic structure optimization, and growth momentum conversion. Against this background, the construction industry needs to achieve high-quality development through transformation and upgrading. With the continuous expansion of the scale of the construction industry and the implementation of national strategies such as "Belt and Road Initiative" and "New Urbanization," the number and scale of construction programs are increasing day by day, and the construction program aims to pursue higher values and benefits and achieve the expected goals through unified coordination and management of multiple projects so as to promote the high-quality development of the construction industry. Compared with an individual project, the construction program is not only larger in scale, but also characterized with higher complexity, longer duration, higher cost, and greater risk, and it also has more significant social and economic impact [1]. Therefore, it is of particular importance to think about how to promote the success of the construction program so as to facilitate the

upgrading and transformation of the construction industry and further enhance the competitiveness of the industry. The key success factors of the construction program are the factors that are managed and influenced by the organization in an effort to promote the success of the program. Clarifying the key success factors of the construction program can help managers to figure out the management priorities and difficulties and allocate resources rationally to achieve the purpose of promoting the success of the program [2].

At present, the academic circles in foreign countries have conducted a large number of theoretical and empirical studies on the key success factors of the program, and the scholars have set forth different views on this matter [3,4]. With the development of the theory of construction program management, the research on the key success factors of construction program has gradually developed. Scholars such as Haadir et al. [5] (2011) believe that good communication, support from senior executives, monitoring and feedback, correct project goals, teamwork, power decentralization, and adequate financial support are the key factors to ensure the success of the construction program. Scholars such as Patanakul et al. [6] (2016) put forward six key factors to promote the success of construction programs, namely, the pursuit of nonfinancial target benefits, product

service life, multiple stakeholders, complexity, political environment, and compliance with mandatory project management procedures; scholars such as Gamil et al. [7] (2017) believe that the establishment of an appropriate certification system for contractors and consulting agencies, reasonable cost and time planning, effective communication and co-ordination platforms, and advanced technologies are the key factors for the success of the construction program; Shao et al. [8] (2018) believe that, apart from adequate financial support, delivery capability, organizational capability, innovation capability, organizational adaptability, project flexibility, and organizational stability are also key success factors for the program.

The research results mentioned above have enriched the theoretical system of the key success factors of the construction program and formed a general key success factor model of the construction program. However, the researchers have not reached a unified conclusion as to the key factors that influence the construction program. At the same time, cultural and industrial discrepancy may affect the applicability of the key success factor frameworks of construction program proposed by different scholars (Shao et al., 2012 [9]), and Pellegrinelli et al. [10] (2007) also emphasized the importance of environment for program management. Therefore, it is necessary to study the key success factors of construction program in our country based on the Chinese context. Based on literature statistics and exploratory factor analysis, this paper refines the key success factors of the construction program and builds an excellence model of the construction program by referring to the ideas, concepts, and theoretical mechanism of the EFQM model. The research in this article provides a new framework system of critical success factors for construction program managers and helps them to quickly clarify the dimensions of project management, improve management levels, define development directions, and promote the success of construction programs.

2. Definition of Success Criteria for Construction Programs

There is a causal relationship between the success criteria of the construction program and the key success factors, and different key success factors will be identified for different success criteria. Therefore, defining the meaning and the success criteria of the construction program is the basis for scientifically identifying the key success factors of the program. Based on the previous research, this paper develops the standard measurement items for the success of construction programs in the Chinese context based on literature statistics and China's construction program management practices. On the basis of the data collected by the questionnaire survey, the SPSS22.0 statistical analysis software is adopted as an auxiliary tool to carry out exploratory factor analysis for the success criteria of the construction program, and the success criteria of the construction program are extracted: the success of the construction program management, the success of the

construction program organization strategy, and the harmony of the stakeholders of the construction program.

3. Theoretical Construction of Key Success Factors of Construction Program

At present, the research on the key success factors of construction program is still in its infancy worldwide, and there are few related documents. Seven papers on the key success factors of construction program published in international authoritative journals were selected. By comparing and analyzing the key success factors between construction projects and construction programs, the results indicate that more emphasis is put on the key influence of "executive support," "clear goals," and other factors on the success of the construction program, while more emphasis is put on the key influence of factors such as "team member ability" and "team communication" and other factors on the success of the construction project.

Literature analysis lays the foundation for identifying the key success factors of construction program. Due to the differences in the construction environment of the programs in various countries, this paper draws on the statistical conclusions of literature, the 66 key success factors of construction program proposed by scholars such as Sarmad Kiania [11], and the in-depth interviews carried out with university scholars, program managers, program executives, and other experts to explore the key factors affecting the success of the construction program in China. Also, this paper supplements and discovers the hidden factors of the construction program and summarizes the measurement items for the key success factors of the construction program in the Chinese context, as shown in Table 1.

4. Empirical Analysis of Key Success Factors of Construction Program Based on Exploratory Factor Analysis

This paper adopts questionnaire survey to carry out empirical research on the key success factors of construction program, and a total of 32 valid questionnaires were collected. The subjects of the survey are company executives, program managers, program management support personnel/auxiliary personnel, etc. Most of the subjects are highly educated and have relatively rich work experience, so the questionnaire results are representative, reliable, and authentic.

4.1. Adaptability Test of Factors. In order to analyze the quality of the questionnaires, this paper needs to test the reliability and validity of the scale data. The output results suggest that the correlation coefficient matrix is "nonpositive definite matrix." Neither KMO nor Bartlett's test shows the results. The main reasons mainly come from two aspects: (1) The sample size is too small while there are too many indicators. (2) The correlation between certain variables is too strong. There are 40 measurement items for the key success factors of the construction program, but only 32

TABLE 1: Measurement items of key success factors of construction program.

Key success factors measurement items of construction program
SF1. Clear vision, strategic goals, and mission.
SF2. Well-defined and realistic organizational goals.
SF3. Well aware of opportunities and threats for industry development.
SF4. Have a positive organizational culture and organizational structure system.
SF5. Have a clear and documented accountability system.
SF6. Have a good communication and management system.
SF7. Strategic support from executives.
SF8. The senior executives fully trust and authorize the program/subproject management team.
SF9. The strategic alignment between the objectives of the program and the technology.
SF10. Correct feasibility study.
SF11. Reasonable program financing method.
SF12. Reasonable program delivery system.
SF13. Allocate correct and sufficient resources to each subproject such as funds, materials, and equipment.
SF14. Stable employment of the employee system.
SF15. Regular evaluation of the objectives of the program and subprojects.
SF16. Adequate communication among program stakeholders.
SF17. Clear program objectives, deliverables, and benefits.
SF18. The consistency of the program objectives and organizational strategy.
SF19. Outstanding program/project manager.
SF20. Familiar with the exact information needs of executives.
SF21. Correct program cost estimation.
SF22. Appropriate program budget allocation.
SF23. Effective program cost management.
SF24. Reasonable program/subproject schedule.
SF25. Effective program/subproject schedule management.
SF26. Effective program quality management.
SF27. Effective program change management.
SF28. Effective communication management to control disputes and conflicts.
SF29. Effective risk management.
SF30. Effective stakeholder management.
SF31. Reasonable distribution of benefits among stakeholders.
SF32. Reasonably adjust and guide the program/subproject performance based on the strategic objectives.
SF33. The program manager pays attention to the mutual influence between the program/subproject targets.
SF34. Use mature tools, techniques, and management processes in program management.
SF35. Use integrated and coordinated management to achieve strategic goals.
SF36. There are enough program management business cases/plan charters for reference.
SF37. Provide continuous financial support according to the program budget.
SF38. Powerful and integrated program management office.
SF39. The government's policy affirmation and support for the program.
SF40. Government departments provide efficient services for the program implementation.

questionnaires were effectively collected. The main reason is that the management idea of the construction program has not been effectively promoted in China's program practice. Therefore, there is a need to process the data in order to analyze the key success factors of construction program. The main measure taken is to reduce the number of measurement items. Through the analysis of the correlation of indicators, eleven items were deleted from the key success factor measurement items of the construction program, so as to meet the requirements of the quality inspection of the factor analysis, as shown in Table 2.

4.2. Structural Factor Variant.
SPSS 22.0 tool was used to perform exploratory factor analysis on the scale data, and the common factor is extracted based on the standard where the feature value is greater than 1 and the cumulative contribution rate is greater than 80%, and the factor analysis results are shown in Table 3.

TABLE 2: KMO and Bartlett's validity test.

Kaiser–Meyer–Olkin	Questionnaire adequacy measurement	0.645
Bartlett's sphericity test	χ^2	1035.466
	Df (degree of freedom)	406
	Sig. (significance level)	0.000

From the results in Table 3, it can be seen that the cumulative variance contribution rate explained by the first 6 common factors is 80.583%, indicating that these 6 factors have integrated 80.583% of the information of original 29 success factors from the key success factors of the construction program, which can basically reflect the essential information of the sample.

4.3. Factor Variable Explanation.
In order to further explain the 6 common factors that have been extracted, the maximum variance orthogonal rotation method is used to

TABLE 3: Initial and rotated factor variation contribution rate of indicators.

Factors	Initial eigenvalue			Rotated sum of squares loaded			Rotated sum of squares loaded	
	Total (%)	Variance (%)	Cumulative (%)	Total (%)	Variance (%)	Cumulative (%)	Total (%)	Variance (%)
1	15.985	55.121	55.121	15.985	55.121	55.121	4.875	16.810
2	1.896	6.536	61.657	1.896	6.536	61.657	4.390	15.139
3	1.587	5.474	67.131	1.587	5.474	67.131	4.255	14.673
4	1.431	4.934	72.064	1.431	4.934	72.064	4.101	14.143
5	1.382	4.765	76.829	1.382	4.765	76.829	3.173	10.943
6	1.089	3.754	80.583	1.089	3.754	80.583	2.574	8.876
...								
29	0.001	0.003	100.000					

perform factor rotation on the extracted factors. The rotated factor loading matrix is shown in Table 4. The value in the factor loading matrix reflects the importance of the corresponding key success factor index of the construction program to each factor.

Factor 1 explains the measurement items of SF11, SF36, SF6, SF4, and SF5 and reflects that the completeness of the construction program organization and management system directly affects the success or failure of the construction program, so it is named the organization/management standard system completeness factor.

Factor 2 explains the measurement items of SF27, SF13, SF26, SF29, SF25, and SF37, reflects the connotation of the whole process management of the construction program, and shows that the effective management of the whole process of the construction program is the key factor to promote the success of the program, so it is named excellent program management factor.

Factor 3 explains the measurement items of SF34, SF20, SF19, SF33, SF38, and SF14 and reflects that high competency of the construction program management team can effectively promote the success of the program. Therefore, it is named the excellent program management team factor.

Factor 4 explains the measurement items of SF18, SF40, SF12, SF3, SF39, and SF1. It is divided into two factors since it cannot effectively explain the key success factors of specific construction programs. SF18, SF12, and SF1 explain the organization strategy and goal of construction programs, indicating that organizational strategy has a guiding role in the implementation of the program. Organizational strategy is the basis for the success of the program, so it is named the organizational strategy/clear target factor; SF40 and SF39 explain the role of government support in promoting the success of the construction program, and it is named the government support factor.

Factor 5 explains the measurement items of SF16, SF31, and SF30 and reflects the interest demands and cooperation of the stakeholders of the construction program, so it is named the stakeholder cooperation factor.

Factor 6 explains the measurement items of SF7 and SF8, indicating that the support of senior executives is inseparable from the success of the program, and it is named the senior executive support factor.

4.4. Results and Discussion

4.4.1. Organizational Strategy/Clear Target Factor. Organizational strategy and goals are the blueprint and outlook for the strategic goals and mission scope of the construction program. The implementation of any project/

program is inseparable from a clear organizational strategy and target.

The achievability of the project objectives is the prerequisite for the smooth implementation of a construction project. Researches have shown that the formulation of an implementable plan can substantively improve the possibility of achieving overall success and project progress, thereby improving project performance [12]. Therefore, it is the initial and prior task to formulate reasonable and implementable strategic goals when building the construction program, and clarifying the project/Program targets will help the stakeholders of the construction program to figure out their responsibilities and facilitate the smooth implementation of the project/program. Researchers, such as Shenhar et al. [13] (2001), believe that the organization's strategy and project targets should be well-aligned to ensure their complementarity and directional consistency so as to promote the success of the construction program.

4.4.2. Senior Executives Support Factor. Senior executive support refers to the phenomenon that the senior executives provide various resources as well as written and verbal support to the program team during the whole process of building the construction program. Existing studies believe that senior executive support is one of the necessary conditions for project success (Crosby [14], 2012). Senior executives are the core personnel of project/program and the executive to accomplish organizational strategy and target; through the tactic/strategic support of the senior executives to the project/program, the project/program management process can be improved, which can have a positive impact on the project and program objectives and thereby improve the performance of the program (Duan Zhicheng [15], 2013).

Senior executive support promotes the success of the construction program mainly through the following aspects: The senior executives promise to complete the program; pay attention to the progress of the construction program; actively participate in the program and provide necessary support; ensure that the project/program has an appropriate priority.

4.4.3. Completeness Factor of Organization/Management and Other Normative Systems. Standardization of the organization and management system is the basic element for the success of construction projects/programs. By constructing a positive organization culture and establishing a reasonable organization structure for the construction program, the ability of the organization and individuals can be effectively boosted and the effectiveness of the policy and strategic goals can be improved, so that the management efficiency of construction project/program can be raised to promote the success of the program [15].

The organization of the construction program is determined by the strategic goal of the program, and the organization is an important foundation and support for the realization of the strategic target. Construction program management is a highly integrated management, and the program organization should also achieve the unity of powers, responsibilities, and benefits to ensure that the organization can effectively perform its functions. The larger the construction program and the more complex the task, the more it is necessary to build an effective organization and adopt the correct work process to comprehensively consider the program's targets and resources, so that the program management can be well-organized and the program's strategic targets can be achieved. The positive culture of the construction program has an important impact on the employees participating in the construction program and the program itself (Zuo, Zillante [16], 2005). At the same time, the project/program organizational culture can promote the governance of the project/program, boost employees' work enthusiasm, reduce contradictions and conflicts, and help to harmonize the atmosphere among organizations (Yang et al. [17], 2018).

4.4.4. Excellent Program Management Team Factor. The construction program management team includes the team members with the construction program managers as the core, the management technology used by the managers/team, the application of capabilities, and the needs of the managers/team. Scholars such as Belassi et al. (1996) [18] believe that the management skill of the project manager department is the most important key factor for project success; scholars such as Kog et al. (1999) [19] found that the key factors affecting project success include the project manager's emphasis on the project and the experience of the project manager, etc. Therefore, it is helpful to select an experienced and capable construction program/project manager to improve the organization and individual capabilities and formulate effective strategies and integrate internal and external resources, so as to improve the efficiency of the construction program/project management and effectively promote the success of the program/project [15].

As the core team of the whole process management, the construction program management team plays an important role in dealing with some complex situations and systems and ensuring the implementation of the construction program and the successful delivery of the program. The construction program management office is a project management organization specially set up for project management, which influences the success of the program by providing practical methods for construction program management. The ability of the members of the construction program management team is matched with the application of technology; that is, the stronger the ability of the program team members, the higher the technical requirements, which is conducive to the success of the project. The manager of the construction program can also resolve the errors and conflicts of a certain subproject or unit by allocating resources to ensure the realization of the goal of the construction program.

4.4.5. Excellent Program Management Factor. According to project management theory, project management ability is the key to ensuring project value addition. Construction

program management is the key stage for the completion of the construction program products, which must rely on scientific and effective management methods to grasp the critical points of implementation so as to promote the success of the program. Research results show that 62.4% of experienced project/program managers believe that when the project/program management is successful, the project/program will generally succeed [20]. In this sense, effective program management is the foundation of the success of program [21].

The implementation of the construction program involves the scope, time, cost, quality, human resources, communication, resources, information and risk, and other management fields of the program. In light of the traditional "iron triangle-time management, cost management, quality management", etc., it is necessary to take effective control measures under target constraints. At the same time, control measures shall also be strengthened in management areas such as resource management, information management, and risk management.

4.4.6. Stakeholder Cooperation Factor. The needs, expectations, requirements, and behaviors of the stakeholders of the construction program can impose influence on or are affected by the program to varying degrees. Their duty-performing ability and level of performance are directly related to the success or failure of the program. The satisfaction of the different interest needs of the stakeholders of the construction project/program and the harmonious relationship between the stakeholders, which benefit all participants, are important factors for the success of the project group; and the inability to achieve effective cooperation among the stakeholders of the project/program will cause organizational chaos [22] and may lead to project/program failure.

Strengthening the communication, coordination, and cooperation among the stakeholders of the construction program\project is essential to the stakeholder relationship management of the construction program. It can promote timely communication, reduce adverse effects, avoid conflicts between departments, and resolve incidents that hinder progress and can help to create a coordinated and harmonious environment and improve the management level and operational efficiency of the entire program, thereby promoting the success of the program.

4.4.7. Government Support Factor. In the decision-making and construction of major construction projects/program, the role of the government is irreplaceable, and the relationship between the government and the construction program is inseparable.

Program construction is a large-scale project which entails a lot of attention from the government, and governmental approval is required for various processes involved during the construction process of the program. At the same time, the government also plays a role in the supervision and management of the program construction. Studies have found that the government, which supervises

and regulates the implementation process of the construction program through supervisory and regulatory institutions, can achieve the purpose of preventing corruption and promoting the program performance. Efficient public institutions have a great impact on the success of the project [23], and the higher the efficiency of the government, the faster the construction of the project/program, and the more likely the project/program will be successful. By providing effective guarantees and policy support, the government can promote the success of the program [24]. The support of national policies greatly encourages the government executives to support the construction of the program. The government executives effectively promote the performance of the program by facilitating the project's preliminary consultation and approval process. Government credit is equally important to the success of the project, and the trustworthiness of all stakeholders in the project/program is vital to the continuation of cooperation, and any party's breach of contract may lead to the termination of the project/program.

5. Excellence Model of Construction Program

The EFQM model is the first excellence model selected by the European Foundation for Quality Management through evaluation. The EFQM model measures project performance and shows the ideal strategy and targets of the project to elevate its performance to the highest level (Wongrassamee et al. [25], 2003). Although the analytical methods used by the EFQM model are vastly different from those used in the field of engineering project management, it is found that that there have been research results achieved by applying the EFQM model in construction field [26] according to papers published in this field. The EFQM model embodies the key influence between the facilitation factors (process) and organizational performance (results). Therefore, this paper attempts to introduce the EFQM model into the mechanism of interaction between the key success factors and the success criteria of the construction program to build an excellence model for the construction program.

This paper refers to the thought of Westerveld [27] (2003) to apply the EFQM model in the project success field. Its hypothesis is to divide project management into two fields, namely, the result field and the facilitation field. The result field represents the project success criterion and the facilitation field represents the key success factors. In this light, this paper interprets the key success factors of the construction program as the facilitation field and the success criteria of the construction program as the result field.

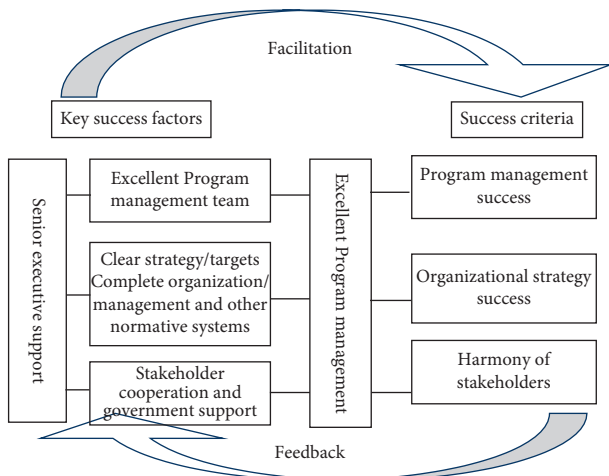
In the facilitation field of the excellence model of the construction program, leadership is a behavior in which managers in an organization use their power to exert influence on their subordinates in order to achieve the goals of the organization. Senior executive support refers to the support of senior executives to their subordinates, and leadership can be interpreted as senior executive support; the personnel, policies and strategies, partners, and resources covered by the facilitation field can be, respectively, interpreted as excellent program management team, clear


FIGURE 1: Excellence model of construction program.

strategies/targets, complete organization/management, and stakeholder cooperation and government support; the process reflects the whole process of constructing the program, and therefore the process can be deemed as excellent program management. In the result field of the construction program excellence model, the dimensions of personnel results and customer satisfaction correspond to the harmony (satisfaction) of stakeholders; social influence reflects the long-term performance of the organization, that is, the success of the organization's strategy; corporate performance is interpreted by the success of project management.

Based on the above analysis, this paper constructs an excellence model of the construction program, which reveals the relationship between the success of the program and the key success factors as well as the enabling paths, as shown in Figure 1.

The excellence model of the construction program based on the EFQM model organically combines the "success criteria of construction program" in the success result field and "key success factors of construction program" in the facilitation field. The two constitute a facilitation-feedback relationship; that is, the key success factors of the construction program facilitate the success of the program while the success of the program reacts upon the whole process management of the program. The scientific definition of the success criteria of the construction program plays a guiding role in defining the key success factors of the construction program managers in the whole process management of the program and helps the managers to judge and effectively control the key success factors.

6. Conclusion

Key success factors of the program play a decisive role in determining the success of the construction program. Therefore, in-depth and systematic research on the key success factors of the program will help the construction program organization to focus on the investment in key factors and increase the likelihood of program success.

Based on literature statistics, this paper explores the key factors affecting the success of construction programs in China, supplements and excavates the hidden factors of the construction program, and develops the measurement items for the key success factors of the construction program in the Chinese context. Using the data collected by the questionnaire survey, SPSS22.0 statistical analysis software is used as an auxiliary tool for exploratory factor analysis of the key success factors of the construction program, and the key success factors of the construction program are refined: Key success factors in seven dimensions, including clear organizational strategy/targets, senior executive support, government support, organization/management and other standard systems, excellent program management team, stakeholder cooperation, and excellent program management. The ideas, concepts, and theoretical mechanisms of the EFQM model construction program are drawn on to organically integrate the "success criteria of construction program" in the result field and "key success factors of the construction program" in the facilitation field to construct an excellence model of the construction program.

The key success factors of the construction program and the excellence model of the construction program established in this paper provide a directional guide for the systematic and holistic success of the implementation of the program by the construction program organization. Real-time monitoring and process control are carried out during the implementation of the program to make the implementation of the program more flexible, reduce the risk of the program, and promote the success of the program.

With the rapid economic development and rising consumption levels in recent years, people are becoming more and more demanding in terms of style and fashion of clothes. As a result, customer demand for personalised clothing is increasing and the need to respond quickly to consumer demands is also becoming a competitive issue for clothing companies. The automation and intelligence of the garment design and production process is an important part of the implementation of intelligent manufacturing in the garment industry and a necessary way to transform and upgrade the garment industry. Successful clothing styles always have a distinct style identity. The style of the garment can not only conveys the designer's vision but also express the emotional needs of the consumer. In contrast, traditional garment design involves only designers and a single style. With so many styles available, the user has only been able to combine them repeatedly and has not been able to create an innovative design. In addition, apparel design and product development is still a highly empirical task. To be specific, most apparel companies can only respond to a rapidly changing market by increasing the number of designers. However, this blind expansion of staff inevitably leads to increased production costs. As a result, how to effectively develop garment products without relying on the empirical knowledge of garment designers is one of the important issues in achieving intelligent manufacturing in garment enterprises. With the rapid development of computer and network technologies, artificial intelligence, machine learning, and expert systems are widely used in various industries. Nevertheless, the application of these advanced technologies in the field of garment design is still not deep enough. This is mainly due to the uncertainty and imprecision of garment design knowledge. Also, with the rapid development of the fashion industry and the arrival of the trend of personalisation, people's demand for clothing has gradually shifted from mass appeal in terms of comfort and aesthetics to personalisation in terms of self-polishing and temperament. The personalisation of clothing encompasses a wide range of preferences in terms of style and fit. The bottom-up design process and the relatively independent setup of functional modules in traditional clothing technology have prevented the different design levels from being interlinked. This does not reflect the composition of the garment elements in the process of forming features and makes it difficult to grasp the overall design state of the garment. Therefore, in order to address these above issues, this paper proposes a garment design model based on the Bayesian classifier and decision tree algorithm to investigate how computer technologies can be applied to model garment design knowledge. This model can enable inexperienced designers to develop garment products quickly and efficiently to meet the customisation needs of customers, thus enhancing the market competitiveness of garment enterprises.

1. Introduction

As an indispensable product for people, clothing has the combined attributes of physiological protection, mobility support, and self-expression [1]. As a result, the design of clothing is based on a combination of protection, fit, personal preference, and social aesthetics. With the rapid economic growth of recent years and the rapid development of clothing-related industries, the supply of clothing products has been greatly enriched [2]. People's demands for clothing have long gone beyond physiological and safety needs to focus on social needs, personality preferences, and

self-realisation. The choice of clothing, in terms of style, stylistic details, and size, has gradually changed from a simple, comfortable, mass-market design to a personalised design that is based on fit, self-fashioning, and self-fulfillment [3]. With the widespread popularity of e-commerce, consumers' demand for personalised products has become increasingly strong [4]. In this context, traditional garment customisation models are no longer able to meet the needs of consumers due to their long production cycles and monotonous styles [5]. As a result, there is a need to provide a personalised apparel design model to achieve zero distance interaction with the customer, thus reducing production costs for the company and increasing customer satisfaction. The personalisation process must be supported by detailed theoretical methods and technical guidance [6]. The modern model of garment design consists mainly of style design, structure design, and process design. The main task of style design is to draw up renderings and style drawings, the main task of structural design is to development patterns, and the main task of process design is to produce process guidance documents [7, 8]. As shown in Figure 1, style design, structure design, and process design are interlinked and they can form the main part of modern garment design. The needs of consumers in the market have changed with the rise in material and cultural standards of living, from the traditional economical to the enjoyable. As a result, traditional mass production methods are no longer able to meet consumers' needs for fashion and individuality [9]. Today, in the pursuit of individuality and fashion, people have new requirements for bespoke garment designs that inspire confidence and satisfaction. Consumers want to participate in the customisation process, expressing their needs through interactive customisation and being able to customise the style of their clothing according to their own wishes [10]. In this way, consumers are better able to personalise their own designs independently and thus create personalised garments for themselves that match their own aesthetics, which has been the most popular industry chain strategy in recent years.

China is currently the world's largest producer, consumer, and exporter of textiles and clothing. As a result, the garment industry plays a vital role in China's national economy [11]. The realisation of intelligent manufacturing in apparel enterprises is of great significance to the upgrading of China's overall manufacturing level. Also, the realisation of intelligent garment design is an important part of the implementation of intelligent manufacturing in apparel enterprises [12]. However, the garment industry is typically a low-tech and labour-intensive industry. With the rapid development of the economy, the consumption habits of customers are constantly changing and the demand for personalisation is increasing [13]. In this context, garment companies need to constantly improve the efficiency of their product development in order to cope with the fierce competition in the market [14, 15]. Over the past hundred years, the production model of apparel companies has evolved from artisanal production to mass production and then to mass customisation in order to keep pace with market changes and customer needs. Mass customisation
Figure 1: Relationship among style design, structure design, and process design.

requires garment manufacturers to produce customised garment products quickly and in large quantities to suit different customer sizes and individual requirements [16]. However, the individual needs of customers increase the difficulty of developing apparel products and prolong the product development cycle. The fast-changing market requires apparel companies to react quickly and shorten the product development cycle as much as possible [17]. In other words, there is always a serious conflict between the individual needs of customers and the demands of the market on product development cycles. In the future, the market will change even more dramatically and consumers' personalisation needs will tend to increase [3]. The question of how to improve the efficiency of apparel product development and shorten the product development cycle while satisfying consumer needs has been a difficult one for apparel companies. There are currently two ways to solve this problem. Firstly, more apparel product developers could be hired to work on the design and production of garments [18]. In addition, the current design methods and processes could be revamped. Hiring more experienced apparel product developers is currently the main solution to this problem, but this approach would significantly increase the cost of product development and would not be conducive to a competitive position in the marketplace [19]. It is clear that optimising and innovating design methods and processes is an effective way of overcoming these challenges in product development for apparel companies.

Clothing is an essential part of the culture of human society and an important expression of human spiritual civilisation [20]. Although the domestic garment industry has been developing for 30 to 40 years, it still seems to be a relatively traditional industry. The traditional domestic garment industry is labour-intensive and has always suffered from low production levels, serious homogenisation of products, and low brand awareness. In recent years, with the emergence and rapid development of big data [21], cloud computing [22], intelligent manufacturing [23], and e-commerce [24], it has become possible to shift from high-end tailoring to large-scale personalised tailoring. This possibility will accelerate the transformation of the garment industry towards the Internet. This breakthrough in the traditional thinking of the manufacturing industry has led to a shift from a closed manufacturing system to an open,

direct-to-consumer production model, allowing consumers to participate directly in the design and production of garments. This type of consumer participation in personalisation has led to the development of a more dynamic apparel industry and an optimised industrial structure. Large-scale personalised tailoring is set to become an important trend in the future development of clothing [25]. The traditional garment design process is shown in Figure 2. This process can be generally divided into three parts: design object determination, garment concept design, and garment production. The first step is to analyse the customer's needs and to define the design plan and concept. While collecting the source material around the design concept and plan, the customer's body size information is collected. A series of variations on the source material is then drawn up, based on the designer's inspiration and experience, to produce a graphic style drawing, which includes the basic elements of the design. Furthermore, the shape of the silhouette, structure, and details of the garment are constructed by dividing, combining, building up, and arranging the three elements. The garment structure is then transformed from a flat to a three-dimensional form by using flat or three-dimensional cutting methods. The three-dimensional shape is then evaluated and fed back into the design for correction and adjustment. Finally, the output is used to assess the feasibility of the finished garment and to adjust the garment structure.

The apparel product development department is one of the core departments of an apparel company [26]. The quality of an apparel product depends to a large extent on the skill level of the product developer. Traditionally, garment design and pattern development is a highly empirical task. After all, a junior apparel product developer needs several years of practical experience to become proficient in apparel design or pattern development. Experienced designers and pattern makers are therefore a scarce resource for an apparel company, and their departure can have a serious impact on the company [27]. During the product development phase, designers, pattern makers, and craftsmen need to communicate and collaborate with each other repeatedly in order to develop a satisfactory garment. This process is tedious and time-consuming and requires the product developer to have a wealth of experience and knowledge. Therefore, there is a pressing need for apparel companies to move away from the traditional overreliance on experienced designers and pattern makers and to be able to develop satisfactory garment products quickly. This will reduce the reliance on designers and pattern makers and increase the efficiency of product development and reduce development costs. The fit of garments is always one of the main concerns of apparel developers and consumers [28]. Fit assessment is a constant part of the apparel product development process, with designers repeatedly trying on samples to check whether a garment is feasible and whether it fits properly. Currently, the fit of a garment can only be analysed by trying on a real garment in person or on a human platform. This process is cumbersome and can significantly increase the cost of developing a garment. While the advent of virtual fitting technology can assist apparel developers in checking the viability of a garment, it cannot effectively determine the fit of a garment. As a result, it is quite important for product development to be able to assess the fit of garments without the need for a real fitting.

With the rapid development of computer information technology in recent years, artificial intelligence [29], machine learning [30], expert systems [31], and system dynamics [32] have been widely used in various industries. However, in the apparel industry, particularly in the area of apparel design and fit assessment, the use of computers is not yet sufficiently advanced. The main reason for this is the uncertainty and inaccuracy of knowledge about garment design and fit assessment. After all, this type of knowledge is more difficult to extract and represent by computer. Recent research has shown that the tacit knowledge involved in apparel design can also be extracted, expressed, and applied through mathematical modelling and computer simulation. It is in this context that this study proposes a model for apparel design based on the Bayesian classifier as well as decision tree algorithm. The model allows for the mathematical modelling of the expert knowledge required for garment design, thus enabling less experienced designers to develop garment products and assess their fit quickly and efficiently.

2. Relevant Algorithm

Mathematical modelling of garment design is the basis for the automation and intelligence of apparel design. Currently, linear regression models are widely used for knowledge modelling in the field of garment design and pattern development, mainly because they are simple to understand and practical. However, there are many aspects of garment design that do not lend themselves to the use of linear regression for knowledge modelling. As a result, this section mainly introduces Bayesian classifiers, decision trees, and neural network algorithms to provide the necessary theoretical support for the construction of garment design models.

2.1. Feature Selection. The main function of feature selection is to eliminate the features with interference factors and find the information feature subset with the least dimension but stronger discrimination ability. With the rapid growth of data scale, the sample size increases and the dimension of feature becomes higher and higher. Furthermore, with the rapid growth of irrelevant features or noise data, the effectiveness of the algorithm gradually decreases. As a result, feature selection is quite necessary, which can select the most effective feature from the original data, so as to reduce the dimension of dataset and improve the performance of learning algorithm. Figure 3 shows the basic framework for feature selection.

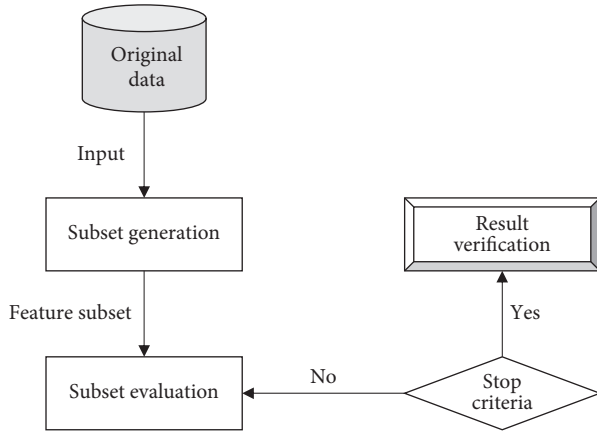
2.2. Bayesian Classifier. Most datasets contain a large number of features, and when training a dataset for classification, it can be seen that the degree to which the features contained in the dataset affect the classification results varies.
FIGURE 2: Traditional garment design process.


FIGURE 3: Basic framework for feature selection.

Generally, the more features there are, the better the classification results are. However, much of the data in the database are unprocessed and contain too many confounding factors that can affect the classification results to some extent, and feature selection can solve this problem. As a result, before using the Bayesian classifier algorithm, feature selection is required in order to obtain a better performance of the trained classifier.

Bayesian classifiers are machine learning algorithms built on the basis of Bayes' theorem. As an early type of Bayesian classifier, the plain Bayesian classifier has high classification or prediction efficiency and good adaptation to new samples. The plain Bayesian classifier treats the properties of classes as isolated and independent of each other, i.e., the class conditions are independent of each other. This hypothesis allows for the handling of otherwise complex class-attribute relationships, and although some data information is lost, the amount of arithmetic involved in the classification process is significantly reduced.

Let $S = \{s_1, s_2, s_3, \ldots, s_n\}$ denote the training dataset, which contains n samples. Also, let $s_i = \{d_{i1}, d_{i2}, d_{i3}, \ldots, d_{im}, k_i\}$ represent the non-category and category attribute values of the ith sample in the training dataset. Therefore, the detailed implementation process can be seen as follows:

(1) Construct the structure of Bayesian classifier.

According to the different values of the class attributes of the training samples, the root node of the non-class attributes is used to construct the structure of the Bayesian model.

(2) Construct parameter table.

According to the training dataset $S = \{s_1, s_2, s_3, \ldots, s_n\}$ and the structure of Bayesian classifier, the relevant parameters can be learned and the parameter table can be constructed.

(3) Calculate posteriori probability.

For a sample $(d_1, d_2, \ldots, d_m)$, the calculation process of its posteriori probability is shown as follows:

$$
\begin{aligned}
P(k^i|d) &= \frac{P(k^i|d) \times P(k^i)}{P(d)} \\
&= \theta \times P(k^i) \times \prod_{j=1}^{m} P(d_1|k^i),
\end{aligned}
\tag{1}
$$

where θ refers to the regular factor of one constant and k^i refers to the value of the category variable.

(4) Distribution of samples.

After obtaining the posteriori probability, the samples can be distributed to the specified attribute.

To sum up, the detailed implementation process of applying the Bayesian classifier can be seen in Figure 4.

2.3. Decision Tree. As shown in Figure 5, decision tree is a knowledge representation method similar to tree organization. All non-leaf nodes of a decision tree represent the non-category attributes of sample data, while all leaf nodes represent the category attributes of sample data. Any unbranched branch in a decision tree, from root to branch to leaf, represents a knowledge rule. The method of knowledge expression and application of decision tree is to make recursive judgment from the root node according to each attribute value of the sample to be evaluated until the leaf node is given to belong to a certain category.

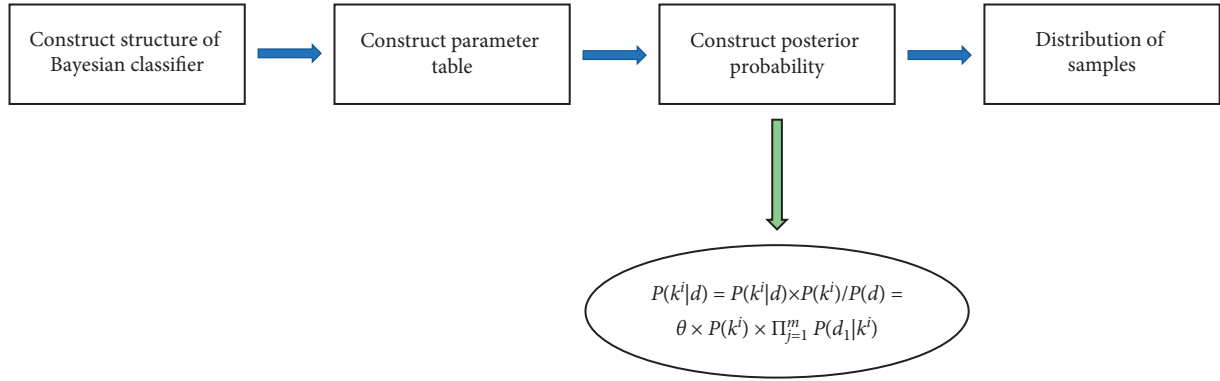
Decision tree algorithm uses information entropy and gain degree in information theory as classification basis to study the classification of things or events. The adequacy of information transfer depends on the degree of uncertainty of the system. The smaller the uncertainty of the system is, the more sufficient the information transfer will be, and vice versa. Therefore, in order to transmit information adequately,


FIGURE 4: Implementation process of applying Bayesian classifier.
FIGURE 5: Example of decision tree.

system uncertainty must be ensured as little as possible. The decision tree algorithm applies the information gain value as the criterion to judge the uncertainty of the system, selects the maximum attribute of the information gain value as the test attribute, and divides the training sample set according to the different values of the test attribute. The calculation method of information gain value is given below.

Let D represent the set of d training samples, and let a denote the number of attribute values. Then, calculation of information entropy is shown below:

$$I(d_1, d_2, \ldots, d_a) = -\sum_{i=1}^{a} P_i \times \ln(P_i), \qquad (2)$$

where P_i refers to the probability of the ith sample.

Next, the calculation of information entropy generated by dividing samples by attribute X is shown below:

$$Y(X) = \sum_{i=1}^{m} \frac{d_{1i} + d_{2i} + \ldots + d_{mi}}{D} \times I(d_1, d_2, \ldots, d_a). \qquad (3)$$

Finally, the calculation of the information gain value generated by dividing the sample set s by attribute X is shown below:

$$G(X) = I(d_1, d_2, \ldots, d_a) - Y(X). \qquad (4)$$

When machine learning algorithm is used to construct classification model, it is necessary to reserve some samples in the total sample set for testing and verifying the prediction accuracy of the built model.

2.4. Neural Network. The human brain is an advanced intelligent signal processing system, which consists of a large number of interconnected neurons, each of which has a series of processing and transmission of electrochemical signals it receives. The electrochemical signal transmission process is as follows. First, the synapse receives a large number of electrochemical signals, which are transmitted through the dendrites to the cell body. The inhibitory and stimulating parts of the electrochemical signal are then superimposed on each other. When the cumulative effect reaches and exceeds a certain threshold, the cell body is excited and outputs an electrochemical signal. Finally, the electrochemical signal is transmitted from the axon to the adjacent neurons, and so on. The neural network structure of the human brain is made up of two parts: nature and learning. In the continuous learning process of external things, some links between neuron cells will slowly disappear, and when these existing links disappear, a large number of new links will be generated. The neural network of the brain continuously learns new knowledge from real things, gradually changes the structure of the network, and can produce new cognition of things.

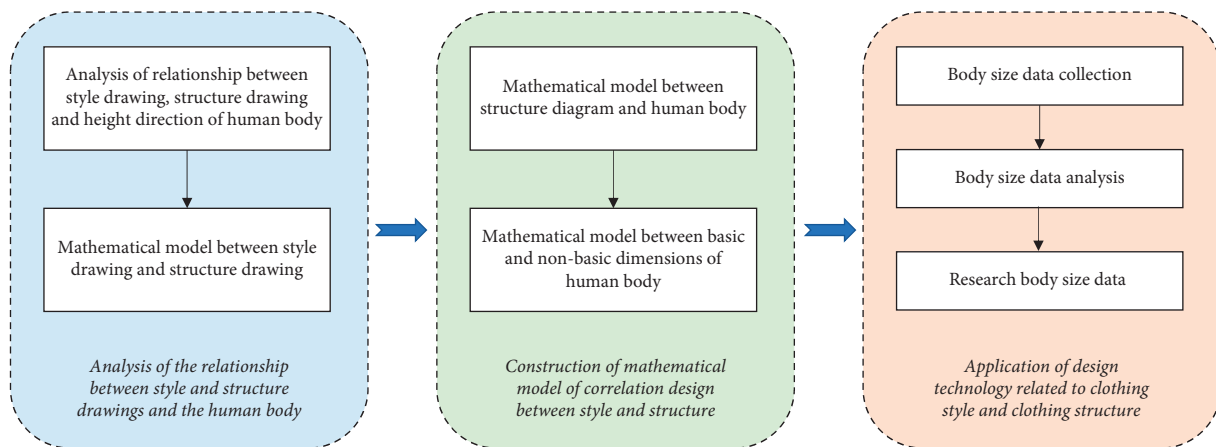
Artificial neural network is an intelligent information processing system based on the working principle of brain neural network. In the construction process of artificial neural network, it is necessary to simulate the main functions of biological neuron cells first and construct the human neuron model with similar functions. As shown in Figure 6, the output function of the artificial neuron model has various forms.
Figure 6: Output function of the artificial neuron model.


Figure 7: Stye and structure correlation design.

3. Garment Design Model

3.1. Style and Structure Correlation Design. The style diagram is used to express the designer's design concept in concrete terms. The structure of a garment is a flat pattern presentation of the garment pieces based on the style diagram. There is a close relationship between the design of the garment style and the construction of the garment, but currently in the garment industry, the two are separate departments, with the designer designing the style and the pattern maker designing the construction. In the product development phase, designers need to communicate with pattern makers in order to avoid poor understanding of styles. The separation of the design and structure of the garment is one of the main reasons for the long product development cycle. If the design and structure of the garment were integrated, the development cycle would be much shorter. To be specific, the stye and structure correlation design can be seen in Figure 7.

3.2. Construction of Mathematical Model. How to obtain satisfactory clothing style is also a problem worth considering. However, due to the complexity of clothing style, the coding scheme based on spline key point parameters has

great instability. Therefore, the model can not only generate new styles but also get user satisfaction.

Body size is the basis of clothing structure design, and clothing style design is based on the comparison of clothing and human body, without measuring the real body size. If the body size is also given to the pattern drawing, then there is a link between the design and structural design of clothing. The basis of the association design technology between garment style and garment structure proposed in this chapter is to assign human body size to the pattern drawing, so that the garment style design and structural design are integrated based on the common human body size. Compared with the traditional fashion design method, this method is a novel design method. Therefore, the design idea of multi-factor combination-driven is based on the analysis of the essence of things to the characteristics and forms of elements, and its methods and related technologies have a wide range of applications. However, in the aspect of clothing design, especially those requiring individuation, most current studies regard the correlation between elements as the influence of one or several parameters and determine these parameters through experience or data fitting. This single reasoning method is difficult to reveal the interaction of different elements and has great limitations.

According to the function and use of clothing, people's perception of clothing can be divided into functional image and emotional image. Functional image mainly expresses the perception of specific functional strength of clothing. Emotional image can meet the needs of functional image on the premise of a certain clothing design, if only the modelling is consistent with the user's personal preferences. Compared with other elements of clothing, specific elements and styles have a greater impact on specific user image and present a stable state of psychological association. Therefore, the research on users' clothing image preference can fully explore the clothing elements and the rules of modelling construction and design the clothing to meet the personalised expectation.

4. Conclusion

This study states the intelligent clothing design system, starting from the research point of clothing style, and human-machine interaction as a main way of clothing innovation design. According to the analysis of users' needs, the style is described, and the style of clothing is studied and analysed to achieve the expression of users' needs. Combined with the characteristics of men's suit design based on biological genes, Bayesian classifier and decision tree algorithm are used to design the suit. Neural network technology was used to extract and express the gene of clothing style samples to obtain the main component gene characteristics of clothing style. Then, this research analyses its characteristics and raises up a kind of new gene definition, sorts out the influence clothing design element, as well as carries on the parametric design.

The research in this paper provides a certain theoretical basis for clothing design and fit evaluation. However, in view of the limitations of knowledge level and research conditions, the following aspects should be explored in the later stage to further improve the research content. First of all, subsequent studies can collect different body size data for different customer groups. In addition, the data are used to construct the correlation design model of clothing style and clothing structure, so that the final design of clothing products will be more targeted. Furthermore, a series of dynamic clothing pressures can be measured, and the dynamic clothing pressures with time series characteristics can be taken as the input of the model. In this case, the prediction accuracy and reliability of garment fit evaluation model based on machine learning are expected to be further improved.

The traditional identification methods of Citrus aurantium diseases and pests are prone to convergence during the running process, resulting in low accuracy of identification. To this end, this study reviews the newest methods for the identification of Citrus aurantium diseases and pests based on a deep convolutional neural network (DCNN). The initial images of Citrus aurantium leaves are collected by hardware equipment and then preprocessed using the techniques of cropping, enhancement, and morphological transformation. By using the neural network to divide the disease spots of Citrus aurantium images, accurate recognition results are obtained through feature matching. The comparative experimental results show that, compared with the traditional recognition method, the recognition rate of the proposed method has increased by about 11.9%, indicating its better performance. The proposed method can overcome the interference of the external environment to a certain extent and can provide reference data for the prevention and control of Citrus aurantium diseases and pests.

1. Introduction

Citrus aurantium (bitter orange) is an herbal medicine collected in the Chinese Pharmacopoeia, and its medicinal source is the dried fruit of the Rutaceae plant lime and its cultivars. The green peel is harvested in July, cut in half from the middle, and dried in the sun or at a low temperature. Citrus aurantium is bitter, acrid, sour, and warm and has the functions of regulating qi and unblocking the stomach, promoting qi, and stopping bloating. It is mainly used to treat diseases such as qi stagnation in the chest, distending pain, undissolved food accumulation, phlegm-rheum collecting internally, gastroptosis, anus prolapse, uterine prolapse, etc. Citrus aurantium is produced in many places in China, mainly in Hunan and Jiangxi provinces. Specifically, Citrus aurantium from Xingan County, Jiangxi Province, is also known as Shangzhou Citrus aurantium and Sanhu Citrus aurantium, with the characteristics of thick pulp, eversion like raspberry, and many orange petals. Its medicinal ingredients are better than other varieties, and it is listed as a protected product of China's National Geographical Indication [1]. With the development of the Citrus aurantium industry, the variety of the diseases and pests of Citrus aurantium has increased and the degree of damage has worsened. It is urgently needed to find ways to quickly and accurately diagnose Citrus aurantium diseases and take corresponding control measures.

In terms of diseases and pests detection, the commonly used method is to manually identify with the naked eye by agricultural experts. This method can compare plant insect and pest samples based on external characteristics, such as shape, color, etc., to obtain identification results. However, because manual identification has certain limitations and subjectivity, and humans cannot continuously work for a long time, the accuracy of manual identification is low, and it is labor-intensive. This has led to the contradiction between the growing demand for identification of crop diseases and pests and the shortage of identification staff in China [2]. For this reason, researchers have put forward a method for the identification of Citrus aurantium pests by combining

computer technology and image processing technology. So far, the research fields related to crop disease image recognition have made some progress and achieved many research results. The existing research results include the proposal of pest identification method based on deep learning [3], machine vision [4], and spatial pyramid pooling [5].

At present, most of the image features are extracted by artificial design or through spectral discrimination. However, the traditional identification methods of Citrus aurantium diseases and pests are prone to convergence during the running process, resulting in low accuracy of identification. Different environmental conditions have a great impact on the recognition results, and the robustness and accuracy are poor. To this end, this study introduces a DCNN algorithm. The DCNN algorithm is a combination of the deep learning algorithm and the convolutional neural network (CNN) algorithm, which solves the problem that the traditional CNN is prone to convergence and falls into local minimum points during the propagation process. In the DCNN algorithm, deep learning technology is used to automatically classify extract features of the images. The application of DCNN method to the identification of Citrus aurantium diseases and pests can improve the identification efficiency and provide effective technical support for the control of Citrus aurantium diseases and pests.

2. Experimental Materials and Methods

2.1. Acquiring the Images of Citrus Aurantium Diseases and Pests. Firstly, the test object of Citrus aurantium was selected. Then, under natural lighting conditions, CCD cameras were to collect the images of Citrus aurantium diseases and pests under three automatic exposure modes with image resolution of 2048×1536, 1600×1200, and 1024×768, respectively. The images were saved in the unity environment in the same format. The specific steps of acquiring the images of Citrus aurantium diseases and pests are shown in Figure 1.

The images of Citrus aurantium diseases and pests were collected in three time periods, morning, middle, and evening. The collection points are randomly and uniformly distributed in the specified area. The camera was made parallel as much as possible to the plane where the leaves of the Citrus aurantium were located to prevent obvious deformation [6].

2.2. Image Preprocessing. There is a certain degree of irrelevant image information in both healthy and diseased Citrus aurantium images. Image preprocessing is to enhance relevant information and eliminate irrelevant information to the greatest extent, thereby improving the reliability of image recognition.

The different sizes of the images are not conducive to the convolution operation in the subsequent network training, and the main information is located in the middle area of the image. Therefore, images should be cropped in batches before classification and identification, and a final image size

of 256×256 in the middle area should be selected. While simplifying the dataset, the number of datasets should remain unchanged, and the information of major diseases should be retained.

Furthermore, the image is directly compressed or expanded into a deep convolutional network model, which requires a fixed input image size. The input format required by the ResNet network model is 224×224, and the input format required by the Inception-v3 network model is 299×299 [7].

Image enhancement techniques include grayscale, binarization, filtering, and smoothing, etc. The commonly used RGB image is subjected to weighting processing on the three components of R, G, and B and then used as grayscale value. The process can be expressed as

$$\text{Gray} = 0.299R + 0.587G + 0.114B, \tag{1}$$

where R, G, and B represent the three components of the color image of Citrus aurantium, respectively, and the calculation result is the gray value of the pixel. On this basis, all the pixels of the original image are calculated, and the grayscale processing result of the color image is obtained. Using the grayscale histogram of the image, the image is divided into objects and backgrounds using a threshold. The expression is as follows:

$$g(x, y) = \begin{cases} 1, & f(x, y) > T, \\ 0, & f(x, y) \leq T, \end{cases} \tag{2}$$

where $f(x, y)$ is the pixel value of point $g(x, y)$ and T is the global threshold of the segmented image. Then, the median filter algorithm is used to filter the images. The median filtering algorithm uses some neighborhood pixels around the pixel to be processed to form a region space, arranges the gray values of all pixels in the region space from small to large or from large to small into a series, and then uses the middle value in the series as the gray value of the center point, as shown by

$$g'(i, j) = \text{Med}\{g(x, y), (x, y) \in S\}. \tag{3}$$

A new image can be obtained by performing the same processing on each pixel in the image in sequence [8]. In equation (3), if there is an odd number of pixels in the field space S, then the gray value of the pixel in the middle after sorting is taken as the gray value of the center point; if there is an even number of pixels in the field space S, the gray value of the middle two pixels is used as the gray value of the center point.

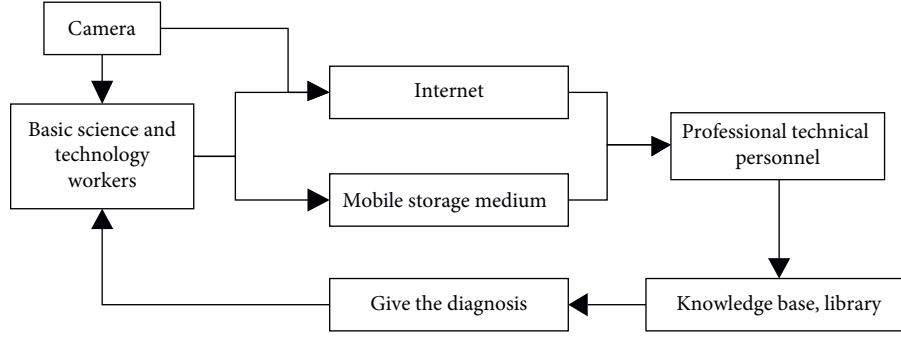
2.2.1. Multiple Morphological Transformation. Mathematical morphology usually has four basic operations, namely, erosion, dilation, closing, and opening [9]. In this study, two transformation methods, i.e., erosion and dilation, are mainly used in processing the images of Citrus aurantium. The corrosion operation is to eliminate boundary points and shrink the boundary inward. Target area of the image of Citrus aurantium is set as the set A which is subjected to


FIGURE 1: Flow chart of the image acquisition of Citrus aurantium diseases and pests.

convolution operation with the kernel B. The processing results are as follows:

$$A \ominus B = \{x \mid (B)_x \subseteq A\}. \quad (4)$$

Equation (4) shows that, after translating B by x pixels, its solution still exists in the set A; then it is said to be eroded by A. Corrosion is mainly manifested as image shrinkage. Furthermore, the role of dilation is to blend the surrounding environment into the target area, so that the boundary expands outward. The result of processing the set A expanded by the set B can be expressed as

$$A \oplus B = \{x \mid [(B)_x \subseteq A] \neq \varnothing\}. \quad (5)$$

When performing polymorphic transformation on an image, the operation of first eroding and then dilating is called the opening operation, which can eliminate the small noise inside the image and smooth the boundary of the object. The operation of first dilating and then eroding is called the closing operation, which can fill the small holes inside the image and smooth the boundaries of objects [9]. After many times of opening and closing operations on the image of Citrus aurantium, morphological transformation is performed on it.

2.2.2. Image Normalization.
The role of the normalization operation in probability theory is to present the statistical distribution of the sample, and the interval is normalized to [0, 1]; then the interval presents the coordinate distribution [10]. To this end, the Z-score method is used to normalize the disease image dataset into the [0, 1] interval to meet the data input requirements of the deep convolutional network model. Its mathematical expression is

$$y' = \frac{y - \mu}{\sigma^2}, \quad (6)$$

where y represents the disease image dataset, the initial μ represents the mean value of the Citrus aurantium disease and pest data, and the parameter σ represents the variance of the Citrus aurantium diseases and pests data.

2.3. Constructing a DCNN.
A DCNN is divided into input layer, feature extraction layer, and output layer from the perspective of data flow [11]. From the structural point of view, the DCNN consists of one or more convolutional layers, pooling layers, and fully connected layers. The two-dimensional image is used as the direct input of the network, and the middle part of the network is alternately connected by convolutional layers and pooling layers. The output layer is usually composed of a fully connected layer and a classifier, and the constructed DCNN structure is shown in Figure 2.

As can be seen from Figure 2, the DCNN consists of three convolutional layers, two pooling layers, and two fully connected layers. The size of the handwritten digit image input is 32×32. In the feature extraction layer, the convolutional layer receives the feature map of the previous layer and affines the convolution of the previous layer with the current layer [12]. The result of the operation is calculated, and the feature map of the layer is obtained through the activation function.

$$\begin{cases} y_j^m = f\left(u_j^m\right), \\ u_j^m = \sum_{i \in M_j} x_j^m * k_{ij}^m + b_j^m, \end{cases} \quad (7)$$

where y_j^m and u_j^m represent the feature map and net activation of the j th convolution kernel of the m th convolution layer, b_j^m represents the bias parameter, k_{ij}^m represents the weight of the j th convolution kernel of the m th layer, and $f(\cdot)$ and $*$ represent the nonlinear activation functions and convolution operator, respectively. The downsampling layer of the DCNN performs aggregation statistics on the upper-layer feature maps through local correlation. By reducing the feature dimension, the signal-to-noise ratio can be improved, and local features can be fused to generate new features [13]. The downsampling extraction of the input feature map can be expressed as

$$\begin{cases} y_j^m = f\left(u_j^m\right), \\ u_j^m = \beta_j^m \, \mathrm{down}\left(x_j^{m-1}\right) + b_j^m, \end{cases} \quad (8)$$

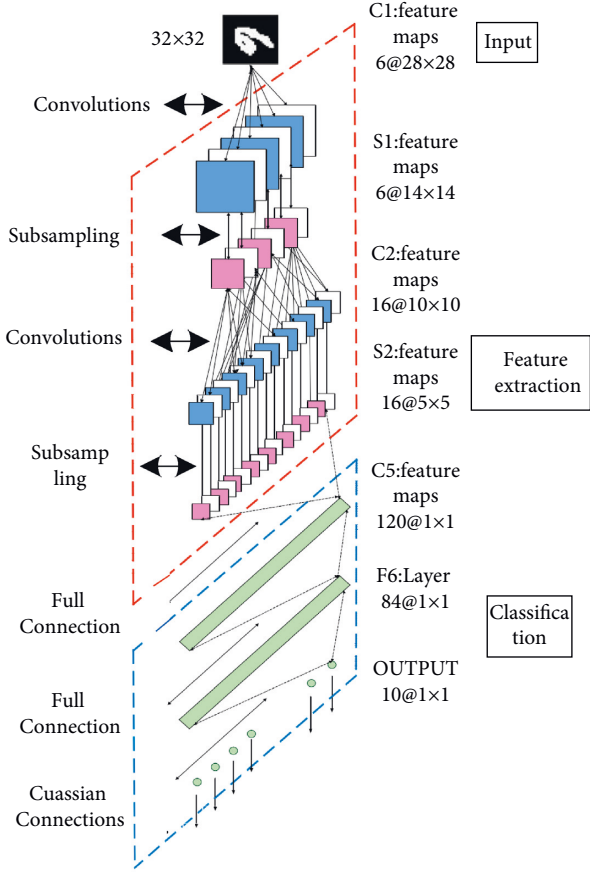
where down$(\cdot)$ represents the downsampling function and β_j^m represents the weight of the j th convolution kernel of the m th downsampling layer. By rasterizing the input pixel values, the two-dimensional feature map is converted into a one-dimensional feature column, and then the output feature map of the fully connected layer is obtained by weighted summation and nonlinear activation function operation:


FIGURE 2: Structure diagram of DCNN.

$$u^m = \omega^m x_j^{m-1} + b_j^m, \tag{9}$$

where ω^m represents the weight parameter of the fully connected layer. To improve the recognition accuracy or meet the needs of specific tasks, multiple auxiliary layers such as dropout, local response normalization, local contrast normalization, and linear activation units are also inserted into the hidden layer in this study [14]. The activation function in the DCNN selects the sigmoid function which has the characteristics of monotonically increasing and inverse functions and can map variables to [0, 1]. The sigmoid function expression is given by

$$\text{Sigmoid}(\alpha) = \frac{1}{(1 + e^{-\alpha})}. \tag{10}$$

The image corresponding to the sigmoid function is shown in Figure 3.

2.4. Segmentation of the Image Area of Citrus Aurantium Disease Spots.
For the Citrus aurantium image, in the context of DCNN, HSI is selected as the color space. Among them, the I component has nothing to do with the color information of the image, while the H and S components are closely related to people's perception of color. Based on this feature, when H belongs to [70, 200] and S belongs to [0.17, 1], the green area of crop leaves can be roughly represented. Using
FIGURE 3: Sigmoid function curve.

the HSI color gamut, the above areas are erased to achieve the purpose of filtering the chlorophyll [15]. Then the gray values of all pixels are traversed to maximize the inter-class variance, and the obtained T is the required threshold. The color interval of each pixel is determined by the solved threshold value to realize the segmentation of pixel values. The final disease spot segmentation result can be obtained by merging multiple segmentation regions.

2.5. Extracting the Characteristics of the Diseases and Pests of Citrus Aurantium.
Using the feature extraction part in the DCNN, the extraction of the diseases and pests features of Citrus aurantium in the image is realized from the aspects of color and texture.

2.5.1. Color Features.
In order to find out the core features of color suitable for Citrus aurantium diseases and pests, according to the color difference of these diseases and pests, multiple characteristic parameters are selected as the color features [16]. We define r_j, g_j, and b_j as the red, green, and blue components of the i th pixel, respectively, and the hue, saturation, and luminance component values of the i th pixel of the converted HSI color space are represented as H_i, S_i, and I_i. Then, the extraction of each color feature can be expressed as

$$\begin{cases} \overline{r} = \dfrac{1}{N} \sum_{i=1}^{N} r_i, \quad \overline{b} = \dfrac{1}{N} \sum_{i=1}^{N} b_i, \quad \overline{g} = \dfrac{1}{N} \sum_{i=1}^{N} g_i, \\[4mm] \overline{H} = \dfrac{1}{N} \sum_{i=1}^{N} H_i, \quad \overline{S} = \dfrac{1}{N} \sum_{i=1}^{N} S_i, \quad \overline{I} = \dfrac{1}{N} \sum_{i=1}^{N} I_i, \end{cases} \tag{11}$$

where $\overline{r}$, $\overline{b}$, $\overline{g}$, $\overline{H}$, $\overline{S}$, and $\overline{I}$ represent the mean values of the red, green, and blue components and the hue, saturation, and luminance components, respectively.

2.5.2. Texture Features.
In the field of pattern recognition, texture analysis is a very important work, which involves the details of the image, such as pattern gray distribution,

gradient direction, roughness, and so on. Because the disease spots produced by different diseases of Citrus aurantium are always different in texture, the texture feature is selected as the supplement of the color feature, and the two cooperate with each other to avoid the defects of single feature classification. Select the gray level cooccurrence matrix to extract texture features. This method mainly obtains its cooccurrence matrix by calculating the grayscale image and then obtains a series of scalars by calculating the grayscale image to represent the texture information of the image. At any point on the grayscale image, another point is kept a certain distance from the point, and the point pair has a grayscale value [17]. Assuming that the grayscale sequence of the image is, then the grayscale values of the two pixels have a total of combinations. On the entire grayscale image, count the number of occurrences of each to obtain a statistical matrix of, which is called the grayscale co-occurrence matrix, and then normalize this matrix to obtain the joint probability matrix of the grayscale distribution of the image. Based on this model, energy, entropy, and moment of inertia are calculated as texture feature quantities, respectively.

By integrating the extraction results of color features and texture features in the collected images of Citrus aurantium diseases and pests, the extraction results of comprehensive features of Citrus aurantium diseases and pests can be obtained.

2.6. Identifying Citrus Aurantium Diseases and Pests.
In the DCNN constructed in this study, the extracted image features are resubstituted. Through network training and iteration, the classification results can be obtained, that is, the function of identifying Citrus aurantium diseases and pests.

The training process of DCNN can be divided into two stages: forward propagation and back propagation. Forward propagation is to obtain the calculation result to be inferred, and back propagation is to update the parameters according to the gradient calculated by the loss. The algorithm calculates the output and loss of each layer through forward propagation of the network and calculates the gradient of the network through back propagation [18]. The parameters are then gradient updated according to the stochastic gradient descent algorithm. After continuous learning to make the final loss meet the accuracy requirements, the parameter values of each layer of the network can be retained without reinitialization the next time the network is used [19].

For the identification of Citrus aurantium diseases and pests, it is necessary to set a comparison standard to clarify the color and texture differences between normal Citrus aurantium and abnormal ones, and to set a specific identification and comparison standard map according to the severity of the disease and pest [20]. Then, the similarity between the standard Citrus aurantium image features in the database and the pest features extracted from the DCNN is calculated to realize the matching of pest features. The calculation formula is given by

$$\text{Sim}\left(F_x, F_y\right) = \left(\sum_{i=1}^{n} \left|F_{x_i} - F_{y_i}\right|^p\right)^{1/p}, \tag{12}$$

where F_x and F_y represent the extracted image features and standard Citrus aurantium diseases and pests features in the database, respectively, and the variable p takes a constant value. By setting the similarity threshold value and combining the results in equation (12), we can obtain the class and severity degree of Citrus aurantium diseases and pests, that is, to obtain the identification results of Citrus aurantium diseases and pests.

3. Results and Analysis

In order to test the performance of the proposed identification method based on DCNN, the following test experiments are designed.

In the experiment, the traditional method based on machine vision (the method in reference [4]) and the method based on spatial pyramid pooling (the method in reference [5]) were used for comparison, including traditional recognition methods and algorithm optimization methods. The recognition rates of different methods were calculated and compared in the same experimental environment.

3.1. Selecting the Citrus Aurantium Sample Dataset.
Three different experimental datasets were employed in the experiment, namely, MalayaKew dataset, P1antVillage dataset, and AES-CD2020 dataset. These MalayaKew leaf datasets were from the Royal Botanic Gardens in Kew, UK, and contain two subsets, MK-D1 and MK-D2, with a total of 44 classes. MK-D1 is a leaf image dataset that performs multi-angle rotation expansion on the collected images to form a training set with 2282 samples and a test set with 528 samples. MK-D2 is an image set formed by local cropping and multi-angle rotation expansion of all leaves in MK-D1. The training set of MK-D2 has 788 images per class, and the testing set has 200 images per class. The P1antVillage dataset is a set of images that contain the health and disease of a variety of plants. There are 38 classes of healthy and diseased images related to crop diseases, more than 50,000 images, and the number of each class of images is uneven.

This study selected 10,478 leaf images of Citrus aurantium collected by P1antVillage, including images of healthy leaves and 5 classes of diseased leaves. The above two experimental sample datasets mainly provide comparison for the experiment. The AES-CD2020 dataset is a dataset composed of images shot on-site. The images in the AES-CD2020 dataset have different sizes, shooting angles, backgrounds, and lighting, etc. The environmental conditions are shown in Figure 4.

All the images in the experimental training set are equally divided into 5 groups, with 200 images in each group. The specific composition of each group of images is
FIGURE 4: Schematic diagram of training set samples in the experiment.

TABLE 1: Experimental group setting.

5		197	98.5
Average		197.8	98.9

shown in Table 1. The data in Table 1 is set as the identification standard data of the experiment.

3.2. *Experimental Environment.* The experiments were designed using the Caffe framework. Caffe is an open source tool for deep learning with CNNs. Caffe supports the languages of are C++ and CUDA and provides MATLAB, Python interfaces, and command lines, where the set_mode interface can be used to switch between CPU and GPU. The selected Citrus aurantium sample dataset was preprocessed to generate a database format. First, Caffe was used to read the data, and then training was performed. Net completed the initialization of the network layer, and

Solver was used to control the model training process. During the training process and at the end of the training, several trained models were saved. Through the configuration of the experimental environment, it is ensured that the constructed DCNN could run normally in the experimental environment.

3.3. Testing Process and Results Analysis of the Identification Methods. The recognition rate is used as the indicator for evaluating the algorithm performance. It can be directly obtained by calculating the ratio of the number of correctly identified samples to the total number of all identified samples. The prepared experimental sample data was imported into the experimental environment, and the resolution of the data sample was adjusted to 600×600. At the same time, the three methods for comparison were imported into the experimental environment in the form of program codes. The identification results were obtained by retrieving data samples.

By comparing the output recognition results with the dataset in Table 1, the results of recognition rate can be obtained, as shown in Table 2.

According to the data in Table 2, the average recognition rates of the methods in [4] and [5] are 87.0% and 91.5%, respectively. By comparison, the DCNN-based identification method proposed in this research shows an average recognition rate of 98.9%, indicating its best performance.

4. Conclusions

In order to achieve effective control and prevention of Citrus aurantium diseases and pests, this study designs a DCNN-based method for identifying Citrus aurantium diseases and pests. The method uses the relevant hardware equipment to collect the initial Citrus aurantium leaf images and complete the image preprocessing. The recognition results are obtained through feature matching.

(1) In order to verify the effectiveness of the proposed method, relevant experiments have been conducted. The experimental results show that the recognition rate of the proposed method is about 11.9% higher than that of the traditional recognition methods, verifying its high recognition rate.

(2) The reason for the high reliability of the proposed method is that it realizes the preprocessing of the initial Citrus aurantium image data through cropping, enhancement, and morphological transformation, etc. This fundamentally avoids the influence of environmental factors on the recognition results.

(3) By using the neural network to divide the disease spots of Citrus aurantium images, accurate recognition results are obtained through feature matching. The proposed method can overcome the interference of the external environment to a certain extent and can provide reference data for the prevention and control of Citrus aurantium diseases and pests.

In order to better mine the value of data, the author proposes a research on the automatic access control of big data open resources multimedia based on blockchain and introduces big data access control BBAC-BD (blockchain-based access control mechanism for big data environment). The author designed a strategy management contract based on the Bloom filter, as a probabilistic data structure with extremely high space utilization efficiency and proposed the strategic management contract (PAP CONTRACT) and the strategic decision contract (PDP CONTRACT). In this way, the nontampering, auditability, and verifiability of the access control information are guaranteed; then, the access control method based on smart contracts is adopted to realize the user-driven, whole-process transparent, and dynamic and automatic access control of big data resources. The simulation results show that the greater the ratio of n/k, the better the optimization effect, and the greater the ratio, the lower the corresponding misjudgment rate, but it will also take up more space costs. At the same time, the true value of the false positive rate is generally less than the theoretical value of the false positive rate. When the performance of Hash (strategy to retrieve) is better, the result of Hash distribution is more uniform. Under the condition of $m = 3$, the misjudgment rate acceptable for the expected use can be achieved, and the increase in the number of Hashes will not bring a significant increase in revenue. Freed from the traditional model of providing access control services based on third parties, solve the problem of transparency of authority judgments; at the same time, through smart contracts, based on the strategy published by the resource owner on the blockchain, realize automatic access control to big data resources; and make the judicial process more flexible and the judgment result more credible. The BBAC-BD mechanism realizes a safe, reliable, and transparent new access control architecture, and it can effectively promote the safe circulation and sharing of big data.

1. Introduction

Human society is accompanied by social networks, e-commerce, and mobile communications, and the rise of the Internet of Things, which has entered the era of big data with data volume, big data analysis, and prediction based on distributed computing. This can make decisions more precise of what people are seeing is just the tip of the iceberg of the true value of big data [1]. Smartphones and wearable devices make every change of our behavior, position, and even physiological information become data that can be recorded and analyzed, but these big data are stored and controlled by various government agencies, business alliances, scientific research institutions, and even individuals,

and the phenomenon of "data islands" is formed [2]. Interconnect and sharing of these scattered big data, in order to obtain products and services of great value, is an urgent need coexisting in business, scientific research, public services, and other fields [3]. In order to realize big data sharing, it is first necessary to connect separate and decentralized data sources [4]. However, due to the lack of detailed and transparent institutional standards, open policies, and pricing mechanisms between enterprises, scientific research institutions, and government departments, it is difficult to achieve fairness and equality between sharing parties [5]. Data diversification, storage structure, and interaction standards are not uniform, and the lack of a transparent communication environment is also hindering data

interaction; the technical architecture of big data access control is shown in Figure 1 [6]. These problems together r cause data connection difficulties. Therefore, a transparent and open data connection method is urgently needed to record data information, access conditions, standards, and other related information to achieve interconnection. Fundamentally speaking, the issue of "data islands" is mainly related to interest and security issues. The data are kept by a large data platform or other intermediary organization. Once the data are uploaded, the owner loses the right to control the data. Regardless of whether it is a government agency or an Internet company, it is very sensitive to data, and once it is leaked, it will have a great social impact.

2. Literature Review

In response to this research question, the author of [7]aimed at third-party collection and control of personal data security vulnerabilities, leading to the problem of user privacy leakage; a distributed personal data management system based on blockchain is proposed to ensure users own and control their private data. For all blockchain transactions, Ansart et al. are transparently embodied in the public network that leads to the leakage of transaction privacy, and they proposed the use of the Hawk protocol based on smart contracts; the agreement encrypts the communication between the parties to the contract to ensure the absolute security of information [8]. Liu et al. addressed the issue of data security and privacy in the Internet of Things, proposed a lightweight blockchain application suitable for IoT devices, and in the smart home scene, they practiced and verified its security, confidentiality, integrity, and availability [9]. Yin et al. adopted an encrypted smart contract, protected public privacy files through public and private keys, and provided auditing and tracking [10]. In terms of data storage and authenticity verification, Xu, J. et al. made an in-depth discussion on the future impact of the audit industry based on big data analysis and blockchain technology, and studied how to incorporate blockchain into future audit procedures based on the existing theoretical framework [11]. Yu et al. proposed using blockchain to build a secure global named storage system, including the three-tier architecture of the blockchain-based naming system. The naming system is divided into three layers: data layer, routing layer, and blockchain layer [12]. Zhang et al. proposed a method for ensuring the authenticity of microbial sampling robot data based on the bitcoin blockchain, which makes the robot not be interfered by human factors in the process of collecting data, especially the malicious tampering behavior of third-party regulatory agencies [13]. Fan et al. aimed at the three types of credibility problems existing in the current Internet of Things data sharing management and proposed blockchain-based solutions, including a decentralized Internet of Things data sharing architecture and smart contract collection [14]. Ling et al. built an access control architecture for the Internet of Things to provide a more flexible management plan [15]. Bera et al. proposed a resource access control method based on blockchain technology and combined XACML with bitcoin to realize the reliable authority control

mechanism based on rules [16]. On the basis of the current research, the author proposes a research on the automatic access control of big data open resources multimedia based on blockchain, using the big data access control BBAC-BD mechanism based on blockchain; it also elaborated and analyzed the basic framework and process of access control in detail. At the same time, for access control strategies based on blockchain transactions and entity attribute information management methods, with the increase of policy rules, the success rate of strategic judgments has decreased, and the BBAC-BD mechanism has realized a safe, reliable, and transparent new access control architecture, and it can effectively promote the safe circulation and sharing of big data.

3. Methods

3.1. Big Data Access Control Architecture. Big data access control involves the collection, aggregation, management, and control of big data resources. The big data access control architecture is mainly composed of 6 parts: data layer, resource aggregation layer, infrastructure layer, transaction layer, consensus layer, and access control contract layer. Each layer structure cooperates with each other and performs its own duties to form a complete big data access control architecture [17].

(1) Data layer: real big data resources, including structured data, unstructured data, and semistructured data distributedly stored in different locations and logically managed by the resource aggregation layer [18];

(2) Resource convergence layer: resource management of big data resources based on blockchain technology to realize the convergence of big data resources from different sources. Although real big data resources are in fact distributed and stored by different data owners, but through blockchain technology, it logically forms a unified management of big data resources. The author's research focuses on the access control mechanism, and the resource aggregation layer will not elaborate [19].

(3) Infrastructure layer: the blockchain platform provides infrastructure for big data access control. It is the foundation of the whole architecture, and the nodes and minors of the entire network are required to maintain the normal operation of the system. It is the carrier of big data access control platform transactions and smart contracts. The transaction layer, contract layer, and resource aggregation layer are all upper-layer applications based on blockchain.

(4) Transaction layer: it includes 4 types of access control transactions: data transaction, strategy transactions, attribute transactions, and contract transactions. Data transactions are used to manage big data resources, which serve at the resource convergence layer. Policy transactions are used to manage access control policies, including the release, update, and sale of strategies to provide data support for PAP
FIGURE 1: Data access control technology architecture.

CONTRACT at the contract layer. Attribute transactions are used to manage the attributes of entities, including the release, update, and sale of properties to provide data support for the contract layer AA CONTRACT, and contract transactions are used to provide an operating environment for smart contracts, which serve at the contract layer [20];

(5) Consensus layer: it mainly includes consensus mechanism, through various consensus algorithms, in order to ensure the consistency and authenticity of access control data among distributed nodes, so as to reach a stable consensus among nodes [21];

(6) Access control contract layer: it includes three types of contracts: PAP CONTRACT, PDP CONTRACT, and AA CONTRACT; PAP CONTRACT is used for access control strategy management, PDP CONTRACT is used for access control request judgment, and AA CONTRACT is used for entity attribute management.

In order to obtain the initial judgment matrix $EQ = (eqij)_{m \times m}$, there are m matrices $E = (e1, e2, \ldots, em)$, and the matrix is concentrated in the importance of ei and ej for binary comparison, which is shown in the following formula:

$$eqij = \begin{cases} 0, & ei < ej, \\ 0.5, & ei = ej, \\ 1, & ei > ej. \end{cases} \quad (1)$$

Convert the initial judgment matrix into a fuzzy consistent matrix, which is shown in the following formula:

$$\begin{cases} qij = \dfrac{qi - qj}{2m} + 0.5, \\ qi = \displaystyle\sum_{k}^{m} = 1eq_{ik}. \end{cases} \quad (2)$$

Calculate the weight vector $W = (w_1, w_2, \ldots, w_m)^T$ of each evidence of a certain m characteristic, which is shown in the following formula:

$$w_i = \frac{\sum_{k}^{m} = 1qik - 0.5}{m(m-1)/2}. \quad (3)$$

Next, the evaluation value matrix of the user behavior characteristic is calculated, and the value on the diagonal of the matrix obtained from the evidence matrix $E = (eij)_{m \times n}$ and the weight matrix $W = (w_{ij})m \times n$ according to $E \times W^T$ is the characteristic evaluation value matrix $F = (f1, f2, \ldots fn)$. The behavioral credit of the final user is shown in the following formula:

$$current\_T(u) = 1 - F \times W_f^T = 1 - \sum_{i=1}^{n} fiwi. \quad (4)$$

$current\_T(u)$ represents the user's current credit rating, and $W_f = (W_{f1}, W_{f2}, \ldots, W_{fn})$ represents the weight of the user's behavioral characteristics. When the user logs in for the first time to perform access control, the system will generate the first historical credit according to the user's software and hardware operations: $History\_T_1(u) = Current\_T_1(u)$. As the number of visits increases gradually, the user's historical credit needs to be gradually changed according to the passage of time as shown in the following formula:

$$History\_T(u) = \begin{cases} 0, & n = 0, \\ \displaystyle\sum_{i=1}^{n} (Final\_Ti(u) \times ti), & n > 0, \\ \displaystyle\sum_{i=1}^{n} ti. \end{cases} \quad (5)$$

$Final\_T_i(u)$ corresponds to the user's final credit at the end of each visit and t_i records the access time. This parameter calculates the total time from the user's login to the end of the user's exit from the system. When $n = 0$, it means that the user has logged into the system for the first time and has no

corresponding historical credit value. When a user visits for the first time, there is no historical credit, and the recommended credit will have a certain reference value. The user's recommended credit is calculated based on the credit between the user and other service organizations. Assuming that there are n credible access organizations $s = (s_1, s_2, \ldots, s_n)$, T and N representing the historical credit value and the number of successful visits of users of service organizations s_i and u_i, respectively, then the expression of the recommended credit is shown in the following formula:

$$
\text{Recommend\_}T(u) = \begin{cases} 0, & n = 0, \\[2ex] \dfrac{\sum_{j=1}^{n}\left(Nj \times T_{ui}^{si}\right)}{\sum_{j=1}^{n} Nj}, & n > 0. \end{cases} \tag{6}
$$

There is a competitive relationship between the chain generated by the honest node and the chain generated by the attacker. When the honest node is ahead, the chain of the honest node is extended by one block; otherwise, the chain of the attacker is extended by one block. The attacker successfully fills the gap behind z blocks, which is similar to the gambler bankruptcy problem, and then the attacker fills the gap and catches up with the honest chain. The probability is shown in the following formula:

$$
q_z = \begin{cases} 1, & p \leq q, \\[2ex] \left(\dfrac{q}{p}\right)^z, & p > q, \end{cases} \tag{7}
$$

where p represents the probability of an honest node gaining ownership of the next node, q represents the probability of an attacker gaining ownership of the next node, and qz represents the attacker filling the gap z blocks behind. When $p > q$, the probability of the attacker successfully attacking the next block decreases with the increase of z. Assuming that honest blocks take the average expected time to generate a block, the potential progress of the attacker is calculated according to the Poisson distribution, and the expected value is shown in the following formula:

$$
\lambda = z \frac{q}{p}. \tag{8}
$$

In order to calculate the probability that the attacker will generate nodes and catch up with the honest nodes in the chain when the attacker is behind, the probability is pz. We compare the Poisson distribution of blocks obtained by the attacker with the potential attack speed and the probability that the attacker can catch up with the honest nodes. The probabilities are multiplied to obtain the following formula:

$$
p_z = \sum_{k=0}^{\infty} \frac{\lambda^k e - \lambda}{k} \cdot \begin{cases} \left(\dfrac{q}{p}\right)^{(z-k)}, & k \leq z, \\[2ex] 1, & k > z. \end{cases} \tag{9}
$$

After simplification, the formula is

$$
\begin{aligned} p_z &= 1 - \sum_{k=0}^{z} \frac{\lambda k_e - \lambda}{k} \cdot \left(1 - \left(\frac{q}{p}\right)^{(z-k)}\right) \\[2ex] &= 1 - \sum_{k=0}^{z} \frac{(zq/p)^k e - zq/p}{k} \cdot \left(1 - \left(\frac{q}{p}\right)^{(z-k)}\right). \end{aligned} \tag{10}
$$

3.2. BBAC-BD Workflow. In the BBAC-BD (blockchain-based access control mechanism for big data environment) proposed by the author, the access control workflow is an extension of the standard ABAC model workflow. The access control workflow can be divided into two phases: the preparation phase and the execution phase. The preparation phase is mainly for the management of access control strategies and attributes, including the release, update, and withdrawal of policies and attributes and the response to the results of the policy and attribute query, and the execution phase is mainly for the judgment, response, and execution of the access request [22].

(1) Preparation stage: from the property release direction to the blockchain, release property, and property relationship information, AA (attribute authority) CONTRACT collects and integrates attribute information in blockchain transactions in advance, for PEP (policy enforcement point) CLIENT and PAP (point administration point) CONTRACT, from the policy release direction, the access control policy is released in the blockchain. PAP CONTRACT combines attribute information to describe, collect, and integrate access control strategies in blockchain transactions, for PDP (policy decision point) CONTRACT to make an access request decision.

(2) Execution stage: when PEPCLIENT receives a request from a user to perform a certain operation on a certain resource, PEPCLIENT analyzes the subject, object, and operational semantics of the original access request, generates an attribute-based access request AAR based on the attribute information obtained from AACONTRACT, sends AAR to PDP CONTRACT, PDP CONTRACT queries PAP CONTRACT for the access control policy set related to the requested big data resource, makes an access control decision, and sends the judgment result response back to PEP CLIENT. According to the response result by PEP CLIENT, authorize access to big data resources, since the access control policy is stored in the blockchain, policy information is verifiable, traceable, and nontamperable to anyone. The access control of big data resources gets rid of the traditional centralized access control management, possible single points of failure, and transparency of access control decisions. It realizes the distributed management of the access control strategy and effectively improves the robustness and credibility of the system. In addition, the decision process of the

access control strategy is realized through the form of smart contract, with no need for the involvement of a third-party central agency, and avoids the possible ultravires behavior of the third-party center, based on the blockchain system to realize the automatic judgment of access control under consensus. It is a truly decentralized access control mechanism, which meets the access control management requirements of big data resources [23].

3.3. Transaction Storage in the Blockchain.

In the blockchain, data are stored in the blockchain in the form of transactions, we use the form of transactions in the blockchain to manage access control policies, the transaction data in the block are stored in the data structure of the Merkle tree based on the HashHash algorithm, and the transaction data of inconsistent size are mapped into a fixed-size character string through a HashHash algorithm, stored on the leaf nodes of the Merkle tree. The nonleaf nodes of the Merkle tree store the HashHash values of its child nodes. The blockchain includes physical accounts, data blocks, transaction set data, and configuration data. The data view relationship between them is shown in Figure 2.

(1) Physical account: it is the initiator of various transaction requests and the owner of related data in the blockchain. It is the actual owner of the data resources in the access control mechanism and has a pair of public and private keys generated by the PKI system. In the system, the account is uniquely identified by the public key, and the transaction data published by the resource owner need to be signed by the entity account with a private key for other users to verify the authenticity of transactions in the block [24];

(2) Data block: it is the underlying data in the blockchain network, and multiple blocks together form a chain structure, persist the transaction processing results within a certain period of time in an immutable form.

(3) Transaction set data: it is based on the access control mechanism of the blockchain and stores data for performing actual business activities, including access control transactions and smart contract transactions. Access control transactions are used for the management of access control policies; it mainly covers the release, update, and cancellation of policy information in policy management. Smart contract transactions are used in the decision process of access control, in response to access requests and generating access control responses. Issuing transactions on the blockchain requires tokens that consume a certain amount of data, as the user's expenses for using blockchain services.

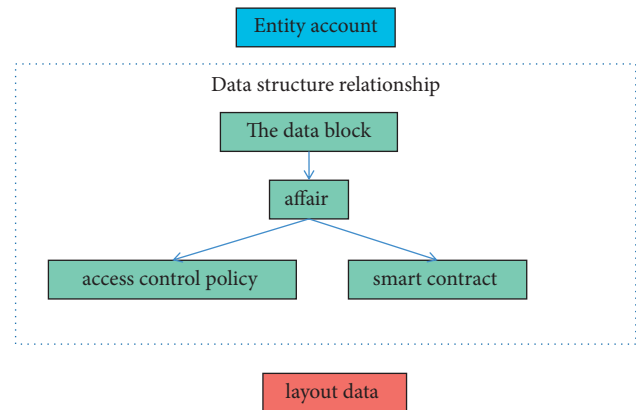
(4) Configuration data: it is the configuration information required for the normal operation of the blockchain system, including configuration information such as protocol version number and communication node information.


Figure 2: The relationship between data view entities in the block.

3.4. Smart Contract for BBAC-BD.

(1) Strategic management contract (PAP CONTRACT).

The flow of the PAP CONTRACT is shown in Algorithm 1.

PAP CONTRACT algorithm flow description.

Analyze the AAR to obtain the requested resource attribute information rttrTuple; traverse the strategic transaction data blocks in each block of the blockchain; obtain the attribute Bloom filter (BF) corresponding to the strategy transaction data block. According to the Hash function corresponding to the BF, calculate the Hash value corresponding to rttrTuple. If the Hash value obtained by calculating rAttrTuple and the corresponding bit in BF are all 1, then add the strategy in the data block in RELEVANT_POLICY_SET; otherwise, there is no rttrTuple related strategy in the data block. When the traversal of strategy transactions in all blocks is completed, return resource-related policy set RELEVANT_POLICY_SET to PDP for permission judgment.

(2) The strategy decision process is carried out by the strategy decision contract (PDP CONTRACT), and the contract flow is shown in Algorithm 2.

PDP CONTRACT algorithm flow description.

Put all pending decisions into UNKNOWN_SET, as a predecision strategy set; traverse the predecision strategy; and get 4 strategy decision result sets:

PERMINT_RESULT_SET DENY_RESULT_SET UNSATISFY_RESULT_SET UNKNOWN_RESULT_SET. According to the judgment result set, the final judgment result of the AAR request is obtained: if there is a conflicting judgment result, the final judgment result is obtained after the conflict is processed, and conflict handling can be based on the principle of affirmative priority or negative priority for conflict resolution.

4. Results and Analysis

4.1. Strategy Retrieval Efficiency Test.

This experiment is aimed at the management method based on the Bloom filter strategy and performed testing on the optimization effect of strategy retrieval efficiency. In the experiment, matching query tests were performed on test sets of different query

scales, set different parameters for the Bloom filter to test the error rate and retrieval delay, which were used to evaluate the impact of different parameters of the Bloom filter on retrieval performance. The calculation method of single time delay is total time delay/total number of matches. The optimization effect is mainly through the strategic management contract. The retrieval delay of the strategy is measured. The smaller the delay, the higher the execution efficiency, and the better the search optimization effect. From the test results of Tables 1 and 2, we can see that the larger the ratio of n/k, the better the optimization effect, and the larger the ratio, the lower the corresponding misjudgment rate, but at the same time, it will take up more space and cost. At the same time, the true value of the false positive rate is generally less than the theoretical value of the false positive rate [25].

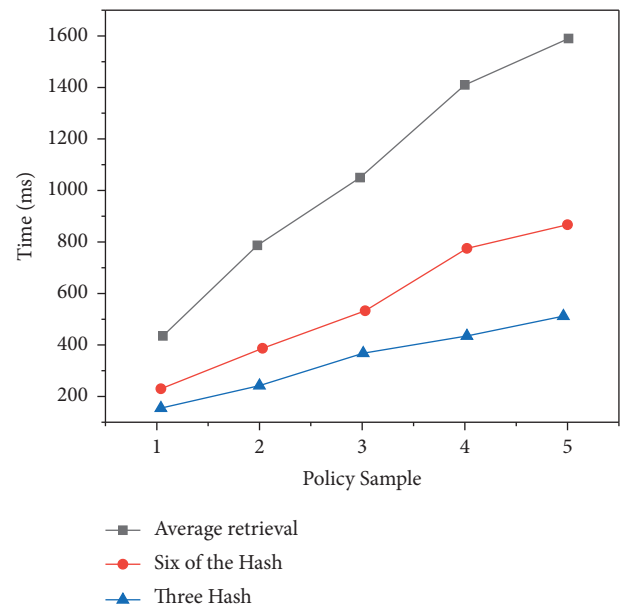
The results of Figures 3 and 4 show that, when the performance of Hash is better, that is, the result of Hash distribution is more uniform, under the condition of $m = 3$. The misjudgment rate acceptable for the expected use can be achieved, the increase in the number of Hashes will not bring a significant increase in revenue. Therefore, when conditions


Figure 3: Comparison of strategy retrieval performance.
FIGURE 4: M value affects the accuracy of retrieval results.

FIGURE 5: Comparison of strategy decision performance.

permit, try to expand the value of n/k and can effectively improve query performance. This is mainly due to the Bloom filter's attribute keyword filtering process of policy detection, the retrieval time is less affected by the scale of the strategy set, so compared to the traversal retrieval process, strategy retrieval and matching based on the Bloom filter can achieve high performance and strategy retrieval based on the Bloom filter can effectively save cache space, reduce the number of requests to the cache, and improve the efficiency of strategy query and the isolation of strategy management services.

4.2. Strategy Decision Function Test. In order to verify the effectiveness of the BBAC-BD access control mechanism, the author under different scales of strategies, judgment function of access control strategy based on smart contract, performed a functional test; the test content includes the efficiency of the strategy decision and the success rate of the

FIGURE 6: Comparison of the success rate of strategy decision results.

decision result. The PolicySamples of 1 to 5 groups correspond to 1000, 2000, 3000, 4000, and 5000 single strategy test set samples, respectively. The test set sample constructs 800 different access requests for 80 user identities; each logo has an average of 5 attribute values, and each request is sent randomly 5 times. The strategy decision delay is obtained by calculating the average response delay of all requests as shown in Figures 5 and 6.

As can be seen from Figure 5, the strategy decision delay is directly related to the strategy scale, with the increase of strategy rules, the delay of access control decision has increased significantly. At the same time, it can be seen from Figure 6 that, as the strategy rules increase, the strategy decision success rate decreases.

5. Conclusion

The author proposes a research study on the automatic access control of big data open resources multimedia based on blockchain. The author uses the big data access control BBAC-BD mechanism based on blockchain. It also elaborated and analyzed the basic framework and process of access control in detail. At the same time, access control strategies based on blockchain transactions and entity attribute information management methods explain that, with the increase of strategy rules, the success rate of strategy decisions decreases. The BBAC-BD mechanism implements a safe, reliable, and transparent new access control architecture, which can effectively promote the safe circulation and sharing of big data. Through smart contracts, based on the strategy released by the resource owner to the blockchain, the automatic access control of big data resources is realized, the judgment process is more flexible, and the judgment results are more credible. The BBAC-BD mechanism is safe, reliable, and transparent. The new access control architecture can effectively promote the safe circulation and sharing of big data. This is because there are

some conflicting strategies in the strategy set. For conflicting strategies, the strategic judgment contract cannot get a consistent judgment result, it should be noted that the author has not yet introduced the strategy conflict handling part into the strategy judgment contract, the conflict resolution has not been effectively resolved, and this part of the content will continue to be improved in the follow-up research work.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

There have been limited studies analyzing the causes of construction workers' unsafe behaviour from the social psychology perspective. Based on a Grounded Theory approach, this study first identified and defined seven coded categories related to workers' dangerous behaviour on construction sites. The original qualitative data were obtained from individual site interviews conducted with 35 construction professionals. These main categories were found connected to workers' status of safety awareness and sense of danger, which affected the type of unsafe behaviours, i.e., proactive, passive, or reactive behaviour. By further integrating social cognitive psychology theories into workers' behavioural decision-making process, the formation mechanism framework and diagram were developed to describe construction workers' unsafe behaviours based on the dynamic process of balancing the individual desires and perceived safety risks. This study advances the body of knowledge in construction safety behavioural management by performing in-depth theoretical analysis regarding workers' internal desires, activated by external scenarios and intervened by a personal safety cognition system, which could result in different motivations and various behavioural outcomes. It is argued that safety cognition serves as a mediated moderation system affecting behavioural performance. Practical suggestions on developing a proper safety management system incorporating safety education in guiding construction workers' site behaviours are presented.

1. Introduction

Construction is generally recognized as a risky industry with high injuries and accidents [1–2]. Besides accidents/incidents and other quantitative measurements (e.g., injury rate), reactive indicators for safety performance and proactive measures have also been developed in construction, such as behaviour-based safety and safety climate/culture [3, 4]. Existing studies (e.g., [5–7]) focusing on these proactive measurements have commonly adopted the questionnaire survey approach. Potential drawbacks of conducting the questionnaire survey method include some questions being incorrectly completed, questions being misunderstood, requiring follow-up in-depth research, and being unsuitable for investigating long and complex issues [8]. In addition, the multiscale data collected through a questionnaire survey may not be sufficient to depict construction workers' subtle mental status and psychological state when conducting unsafe behaviours. Construction site workers before, during, and right after making a behavioural decision could present a dynamic and mixed internal mechanism influenced by external scenarios (e.g., the project's tight schedule). Likewise, an advanced workflow originates from workers' inner desires, which may be

activated by an external scenario and mediated by personal safety cognition, resulting in safety behavioural decisions.

As the alternative approach, qualitative studies (e.g., semistructured interviews) are also adopted in construction safety research, followed by qualitative analysis to define categories related to a specific safety issue, for example, causes of fall accidents from roofs [9]. More alternative analysis approaches from other fields, such as Grounded Theory from social studies, have been applied in the construction field. So far, there have been limited studies [10, 11] that have applied Grounded Theory to construction safety. The rationale of using Grounded Theory in this study to explore the causes of workers' unsafe behaviour is not concurrent with the methodology from prior studies of construction safety. These issues, as mentioned earlier, are mainly due to the desire to link dangerous behaviour to construction sites to a social psychological definition. Furthermore, the desire to articulate the mechanism of workers' behavioural decision formulation process from the perspective of human psychology and what drives the tenants for such desires and motivations is yet another objective. Research questions in social psychology, such as by what processes attitudes towards an object affect behaviour towards the object [12], can be applied in construction safety behaviour to provide a theoretical guide in safety management.

Aiming to address the above issues, this study was designed to answer the following research questions: (1) what are the internal and external causes of construction workers' unsafe behaviour and (2) how would human psychological desires and motivations lead to different behavioural outcomes? This study addresses the research scenarios in construction workers' unsafe behaviours depicting the unique psychological mechanism of behavioural decisions. An alternative method called Grounded Theory is adopted for qualitative analysis. Therefore, this study is seen to contribute to the in-depth theory of the formation of workers' unsafe behaviour by linking workers' behaviour to their safety cognition, internal desire, and the ultimate behavioural outcome. The study provides both theoretical and practical guides for effective construction safety management. Theoretically, it postulates a framework of how internal human desires, insinuated by the mediation and moderation effects of safety cognition, could lead to different behavioural decisions and outcomes; practically, this study sequences the extent to which construction workers' safety behaviours towards a safer and less risky manner can manifest.

2. Literature Review

2.1. Safety Behaviour.
Safety behaviour is a critical theme in managing safety [13]. It crosses different fields such as driving [14], fire service [15], and agriculture [16]. Innovative research theories and methods are required to promote behavioural safety studies [13]. Up to 95% of workplace accidents have been caused by unsafe acts [17]. Occupational safety behaviour significantly affects workplace performance [18]. The management of safety behaviour was identified by

Goh and Ayskar Ali [19] as one key challenge in improving construction safety management. [20] described the intervention process to correct unsafe behaviours by measuring and comparing the frequency, duration, and rate of behaviours before and after the intervention, aiming to change dangerous behaviours. The behaviour-based safety (BBS) could enhance safety performance by monitoring preestablished safety behaviours in construction [21]. However, when adopting behaviour-based management in construction, Lingard and Rowlinson [22] found the behaviour-based limitation and suggested that safe behaviour could only be achieved when a basic safety infrastructure is in place. Further, Eckenfelder [23] criticized BBS for being time-consuming and costly, as safety investment would interact with the construction workforce to affect safety performance [24]. Nevertheless, Cooper [25] showed positive outcomes of applying BBS in improving safety performance. Similarly, the empirical study conducted by Choudhry [26] showed that BBS could be used in any country's culture based on effective communication on-site and committed management. Critical success factors for BBS have been identified, including employee engagement, satisfaction with safety training, and trust relationships among workers [20]. These factors affecting safety behaviour, such as work engagement and management commitment [27], could be important indicators in the safety climate framework.

2.2. Safety Climate.
In the dynamic construction safety management system, Guo et al. [28] suggested considering the interrelationships among factors within the system. One factor within the management system is defined as a safety climate within the workforce. Attitudes towards safety are considered one of the main indicators of safety climate [5]. Safety climate can be measured by workers' safety perceptions [29], and it reflects workers' perception of the role of safety in their jobs [30]. In the safety climate study conducted by Li et al. [7] in China's construction industry, workers' self-perception of safety (e.g., safety awareness), their involvement in safety (e.g., self-protection), peer interaction (e.g., communication and cooperation), safety environment, management involvement, and safety personnel support (e.g., foremen behaviour) were defined as major dimensions. Similar safety climate indicators such as risk perception, workers' perception of safety management, and management attitudes can be found in multiple other studies (e.g., [31, 32]). The effect of safety climate on safety performance has been identified in several previous studies [33, 34]. Safety climate can be multilevel and can be divided into subgroup safety climates according to workers' job position [35, 36] and other subgroup factors such as demographic features [37].

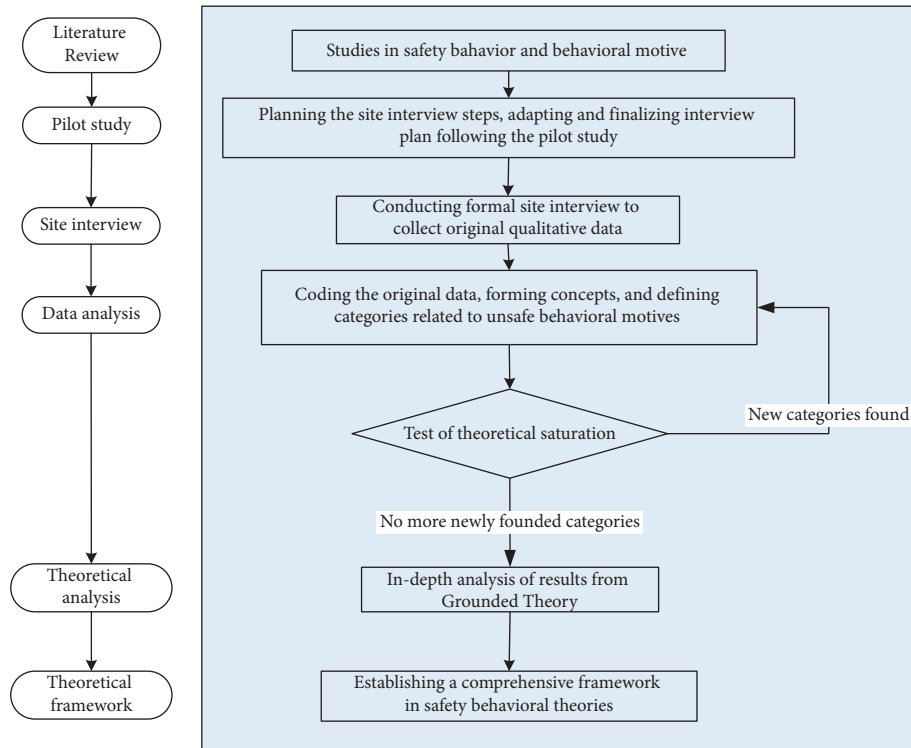
2.3. Safety Cognition.
A safety climate forms a culture that involves knowledge transfer at the organizational level [38] and engages social cognitions [39]. Implicit memory significantly affects unconscious cognition in making judgements [40, 41]. Cognition directly influences behaviour [42]. Individual safety cognition is critical to enhancing safety


FIGURE 1: Description of the research workflow.

performance in the construction industry [43]. Social awareness can be divided into the implicit and explicit levels [39]. The implicit social cognition reflects individuals' internal assumptions that could influence behaviour and group perceptions [44]. In the construction industry, workers' implicit safety cognition is formed based on their prior work scenarios, which further build their safety knowledge [45, 46]. The implicit safety cognition further affects workers' intuition or basic assumptions, which, together with prior scenarios and safety knowledge, affect workers' safety perceptions [39]. Safety perception constitutes the explicit social cognition [46], which, to some degree, is equated to a safety climate based on the measurement criteria [47].

3. Methodology

Investigation of research questions such as "how construction workers form their unsafe behaviours" requires in-depth research as this type of question involves complex issues. Qualitative methods (e.g., site interviews with workers) could overcome the barriers encountered in the questionnaire survey-based approach by investigating the formation of workers' unsafe behaviours. A more qualitative approach can explore insights into human beings' opinions, attitudes, experiences, and behaviours [48]. Face-to-face site interview with individual construction workers to collect qualitative data on reasons for risk-taking behaviours has been adopted in some existing studies, including Guo et al. [28] and Man et al. [11], who assumed the Grounded Theory approach. Grounded Theory aims to generate or discover a theory from data systematically obtained from social research [49]. It has

been successfully adopted to understand a concept or phenomenon in different fields, such as higher education [50], housing policies [51], and healthcare [52]. The methodology adopted in this study is illustrated in Figure 1.

The data analysis method shown in Figure 1 involves the three-step Grounded Theory approach, namely, open, axial, and selective coding, as Strauss and Corbin [53, 54] advised. After capturing the causes of workers' unsafe behaviours, theoretical saturation is tested by utilising the remaining data to ensure that no more new concepts or categories would be found. The Grounded Theory is based on an explanatory approach to investigate a specific occurrence in an inductive way which favours the exact explanation of the phenomenon studied [55]. Researchers also followed other methodological guides in adopting Grounded Theory in this study, specifically: (1) early stages of data collection may involve purposeful sampling [56] as evidenced in the example of MacDonald [57]; (2) as data collection and analysis progress, e.g., concepts and categories summarized and refined from data [58], ideas, and tentative hypotheses could emerge [59]; and (3) pursing theories through data and theoretical sampling [60]. Following the interviews with workers, the qualitative data were recorded and analyzed using the intelligent voice core technological tool developed by iFlytek [61], which assisted speech recognition by analyzing the oral characteristics of human beings.

3.1. Design of Interview Questions. Following the review of safety behaviour-related literature, the open-ended questions for site interviews with construction workers were designed.

TABLE 1: Descriptions of five general questions asked during the formal site interview.

No.	Question	Purpose
1	Could you describe the most unforgettable safety accident that you have heard of or experienced?	This is a starting and guiding question to motivate the interviewee to feel comfortable and become more engaged in the interview process by recalling their past site stories or experience. It also aims to spark the interviewee's thinking about safety.
2	What do you think about the cause of construction safety accidents? For example, are they more due to human mistakes or other reasons?	This commentary question aims to let the interviewee analyze the cause of accidents from the standpoint of a bystander who was not directly involved in the accident. It seeks to capture the core view of the interviewee as a nonbiased witness. It also guides the interviewee to pay attention to human factors related to unsafe behaviours gradually.
3	From your experience, were there some site behaviours of yourself that you feel could be dangerous?	This question serves as a transitional point aiming to shift the focus to the unsafe behaviour of the interviewee. In addition, it aims to let the interviewee realize their prior hazardous behaviour. The question was asked in a self-reflective approach, motivating the interviewee to recall and evaluate their dangerous behaviours (if any).
4	Why did you still decide to behave unsafely if you had realized the danger related to your unsafe behaviour?	This is a core question, continuing from the previous question to obtain the exact reasons that cause site workers to behave unsafely. In addition, it aims to capture site workers' psychological or mental status right before, during, and after conducting unsafe behaviours.
5	What unsafe behaviours do you see other people conduct? And what do you think are the main reasons why they behave unsafely?	This is a wrap-up question by shifting the focus from the interviewee themselves back to others. The interviewee answers the question again as a bystander to evaluate why peers behave unsafely. It is designed to acquire more in-depth thoughts related to unsafe behaviours. Also, because the initial question has been sensitive by asking the self-related dangerous behaviour, this question can relieve the nerve of the interviewee and allow the interviewee further to provide more information.

They underwent the pilot study to ensure that these questions were valid, transparent, and easily understood. Before conducting the pilot study, the research ethics approval was gained from Jiangsu University. A consent form would be provided to each interview invitee before conducting the interview. It was ensured that no personal or company information would be stored in a database. Invitees to participate in the interview would be provided with a clear guide of the purpose of the study, and they could decide whether or not to accept the interview request. They were also allowed to withdraw or terminate the process during the interview.

Considering the generally low level of education that workers had received in China's construction industry and other facts that they tended to hide or withhold sensitive information related to their unsafe behaviours to the interviewer, these questions were designed as simple as possible to be not technical. In April 2018, before conducting the formal site interview, a pilot study involving five site workers was asked these predesigned questions to evaluate the appropriateness and effectiveness of the discussion. These five participants worked as project managers, safety staff, site technicians, crew supervisors, and steelworkers. Their age ranged from 33 to 52, with site experience varying from 9 to 31 years. The interview with each participant lasted from 18 to 57 minutes. Following the pilot study, researchers in this study found that generally, interviewees would be happy to share their experiences regarding safety issues with others when they were just bystanders not involved. However, they would be more nervous or concerned when asked of themselves as the party directly involved in safety issues, despite that they were told that the interview was confidential and anonymous. Therefore, in the finalized questions listed in Table 1, the interview with each participant was designed to start with a relaxing atmosphere in a storytelling style by sharing his or her own site experience.

The five basic questions in Table 1 were designed to be open-ended as they can be easily extended to discover more details contributing to site workers' unsafe behaviour or behavioural decision. They considered the potential psychological status of interviewees progressively. Researchers asked guidance and descriptive and summative questions by starting with the general question with the interviewee as a bystander or witness, then shifting the interviewee's role to be the party directly involved in unsafe behaviour, and finally back to the role as a bystander. Basic information related to dangerous behaviour can be obtained from answers to these questions. More insightful or detailed information could also be acquired by directing these open-ended questions.

3.2. Background Information of Interviewees. Echoing Cutcliffe [56] and MacDonald [57], who indicated the adoption of purposeful sampling in collecting data, this study recruited interviewees based on the critical features known to the researchers. These key features included knowledge or

TABLE 2: Background information of the 35 interviewees.

No.	Age	Site experience (years)	Education level	Profession	Interview duration (min: sec)
1	55	30	Primary school	Concrete worker	27 : 42

33	52	33	Primary school	Steelworker	30 : 05
34	30	7	High school	Form worker	35 : 24
35	45	23	Middle school	Steelworker	40 : 28

experience on the studied phenomenon of interest, availability and willingness to participate, and the ability to communicate experiences and opinions expressively and reflectively, which were defined by Palinkas et al. [62] for purposeful sampling. A total of 35 participants were recruited in the formal site interview conducted from May 2018 to March 2019 in the southeast coastal region of China. The reasons for recruiting participants from the eastern coastal region of China can be more in the prior studies of researchers (i.e., [37, 46]). Basically, as the economically active region of China, the east coastal region attracted labours from the rest of the country to work in the construction industry. These construction workers were also referred to as migrant workers that were considered representative of the workforce sample. The qualitative data for Grounded Theory-based analysis were based on the interview of 30 participants. The remaining five participants' answers to interview questions were used for the later theoretical saturation test described in Figure 1. The background information of the 35 interviewees is provided in Table 2. The professions of interviewees included project manager, quality inspector, general contractor's site

workers, safety staff, crew supervisors, and workers from different trades. The average site experience was 16 years in the interviewee sample, and 60% of them had an education level below or at middle school. The average time lasted in each interview was around 29 minutes.

3.3. Interview Process. A semistructured interview was conducted individually for each participant. The interview process was designed to be interactive, allowing the mutual discussion and questions between the interviewer and the interviewee. Interviewees were encouraged to express their opinions freely. Considering that site workers usually have heavy daily duties in a relatively confined and stressful work environment, the interviews were generally conducted in the evenings after participants completed their daily tasks and were in a relaxing mental state. During each interview, the researcher started with an icebreaker to allow the interviewee to feel comfortable. The interviewer (i.e., the researcher) encouraged the interviewee to move forward with the safety behaviour-related theme by adopting the questions listed in Table 1, simultaneously enabling the

TABLE 3: List of concepts causing unsafe behaviours according to open coding.

Typical example(s) from interviewee's verbal messages	Concept	Frequency
"Sometimes, I prefer not to wear the safety belt when working at a height because that saves my effort."	Saving efforts	34
"The main reason for some unsafe actions is to make more money in less time."	Gaining more income	13
"I don't want to pay much attention to following these cumbersome steps. On the contrary, I want to ignore it and finish my work as soon as possible."	Increasing productivity	10
"The reality is that workers must follow their managers' demands to complete the given tasks in a fast way."	Being pressured	10
"Some guys feel that they are very skilled to perform tasks."	Being overconfident	10
"When the schedule is tight, the boss asks us to work overtime and maintain the efficiency."	Meeting schedule requirements	9
"The main reason for unsafe behaviour is to save time."	Saving time	7
"They think it is their freedom to not wear a hard hat"; "If the manager wants them to wear the hard hat, they may still not fasten the tie of the hat."	Being unwilling to be regulated	6
"The weather in the summer is hot, and not wearing the protective equipment makes me feel more comfortable."	Feeling more comfortable	6
"The manager asks us to do things fast and complete the tasks quickly; otherwise, we could lose our job."	Following the manager's demand	5
"Older and more experienced folks can do things fast without risks"; "Older guys think they know things well enough and do not need to follow the safety education."	Following personal experience	5
"Safety accidents occurred very rarely on sites where I work during my past five years' career. I don't think I would be that unlucky." "They think they are lucky enough to be accident-free by not wearing the safety boots."	Holding a "fortunate" mindfulness	5
"Some guys are rebellious and do not want to follow what their managers say."	Being against the safety demand	4
"Sometimes we want to relax a bit after considerable experience site work, without realizing site safety risks."	Relaxing	4
"A crew foreman just learned that he was about to be fired. He hammered a nail into an electrical cable to show his anger before he left. Later a fire accident happened when the cable was powered."	Venting the negative emotion	3
"Some younger workers behave unsafely to show their own 'tough-guy' image."	Showing off self-capability	3
"Two different woodwork teams needed tower cranes to transport materials, and conflicts happened. Both teams did not want to calm down. One of them broke the electrical cable of the tower crane on purpose."	Escaping responsibilities	3
"Two apprentices were working together with their mentor. One of the apprentices was trying to impress the mentor during the installation of scaffolding when the mentor was not around for a moment. He climbed into the scaffold trying to operate, but later he fell off from scaffolding and was injured."	Demonstrating own skills	3
"This type of part-time guys deliberately waste time, not doing jobs safely."	Dawdling	3
"I just want to operate the machine myself to see how it works."	Satisfying curiosity	2
"The wastes from saw-cuts fell on flammable things, but workers are hungry and want to have their lunch. So they ignore that."	Being anxious to finish work	2
"Some guys walk along the steel pipes without fall protection just to feel excited."	Seeking excitement	2
"Arguments may happen between different trade teams because of interests of conflict."	Defending for the benefit of their team	2
"If everyone else is working unsafely to complete work on time, I will follow them."	Following peer behaviours	2

Note. Table 1 does not cover coding concepts only mentioned once by the 30 interviewees. They include maintaining self-esteem, meeting self-vanity, helping others in an emergency, and horseplaying.

interviewee to be comfortable. Following each response from the interviewee, the interviewer would then continue by asking, "what you just said is insightful. Do you have any other things to share with me?" With each interviewee's full consent and approval, the interview was voice-recorded.

4. Results from Grounded Theory Analysis

The categorization process involves the cyclical workflow of analyzing, inducing, and summarizing the sentences and keywords from original voice messages conveyed by the

interviewees. Coding is a crucial job in the analysis and summary. It involves labelling interviewees' answers and selecting, distinguishing, and categorizing the qualitative data. Therefore, the three main steps, including open, axial, and selective coding, were conducted progressively and concurrently.

4.1. Open Coding Results. Open coding intends to define concepts and categories. The main objective of open coding is to disaggregate original data and reform the concepts until

there is no more suitable code to replace the resulting and improved concepts. Glaser [63] suggested using the gerund format as being more ideal for exploring the concepts of Grounded Theory, for example, "saving effort" instead of "to save effort," as shown in Table 3. In this study, the original data were analyzed on a single-word basis, with the actual words in the text labelled to define the initial factors. During the induction and summarization processes, interviewees' sentences were compared and matched, and prototypical keywords were marked. Initial concepts were extracted based on these labelled concepts and semantic meanings within sentences. Finally, all concepts with similar or consistent attributes were classified into initially coded categories. For example, in the original verbal message, "I feel it cumbersome to wear a safety belt, making me not flexible to do my job," the keywords "cumbersome" and "not flexible" were extracted to form the initial concept of "avoiding cumbersome operation." In another verbal message, "Guys would like to find the most convenient way to work, and it is common to find an easier way to save time," the keywords "convenient" and "to save time" were captured. These similar keywords from other messages were found during open coding, and they were formed into the initial category defined as "saving efforts."

The 255 messages conveyed by the 30 selected interviewees were initially obtained by adopting the iFLYTEK [61] tool. The research team performed a second round of screening by removing codes not related to construction safety. 158 messages were finalized and converted into coded concepts. Table 3 displays some of the concepts associated with typical examples from interviewees' original verbal statements.

These concepts in Table 3 are further coded into initial categories as shown in Table 4.

The open-coding results reveal that site workers who conduct unsafe behaviours may be due to their psychological needs (e.g., seeking excitement) or motivations (e.g., increasing income). It is also indicated that workers' unsafe behaviours are affected by external conditions or site scenarios. For instance, they may desire to follow their peers' behaviours, follow the demand from their team leader to work fast, or even simply help others in an emergency.

4.2. Axial Coding Results.

Following the open coding, axial coding aims to establish a more generalized category through cluster analysis to discover internal connections between these initial categories identified in Table 4. It can be found from Tables 3 and 4 that some of the concepts are strongly correlated, for example, saving time and pursuing work efficiency. According to the behavioural intention and motivations reflected in the open coding, these initially coded categories are redefined into seven main categories listed in Table 5.

These seven main categories listed in Table 5 could be further divided into three different scenarios: (1) reducing physical work, saving time, and increasing income are motivations that workers hold to enhance their input-to-output efficiency. Workers desire to meet these personal needs. Under

this scenario, they behave unsafely in a proactive way to achieve personal needs; (2) relieving stress and wishing to be part of the team are scenarios that drive workers to adjust themselves in a specialized circumstance, although it may not be their original intention to make these adjustments. They adopt unsafe behaviours to cater to the external scenario (e.g., managers' demand to work fast) in a passive manner; (3) different from the prior two scenarios, workers desire to help others, especially under emergent situations, despite their lack of safety knowledge or competency. Their unsafe behaviour manifests reactively.

4.3. Selective Coding Results.

The principles of selective coding were defined by Strauss and Corbin [53, 54] as the process of selecting the main category, relating it to other types, and analyzing the relationships between categories. Selective coding was conducted through text analyses to identify the internal connections for each main category defined from axial coding, workers' individual safety perception, and the corresponding and resulting unsafe behaviour type. Each coded main category is listed in Table 5, with individuals' safety perception status, and the potential behavioural outcomes are described in Table 6.

It is seen that individual desire or needs, activated by one of these main categories, linked to the unique perception status, could potentially lead to unsafe behaviour. Based on the qualitative data obtained and processed from the initial steps, the safety perception status of individuals can be defined in distinct types according to their safety awareness and fear of danger. The perception status described in Table 6 indicates that safety education is imperative for individuals to be equipped with sufficient safety awareness and the correct perceptions of the ensuing danger. Their unsafe behavioural outcome can also be divided into proactive, passive, and reactive types. These various perception statuses and types of the behavioural effect can further be described as (1) the intention of saving time, reducing labour inputs, or increasing personal income, all of which have the potential to reward the respective workers themselves; moreover, behind the income-driven motivations is the devastating effect of proactive unsafe behaviours; (2) relieving stress and the desire to be part of the team could induce workers to behave unprofessionally due to the external stress or peer pressure; and (3) in a less common case, helping or rescuing others on-site under emergency also causes unsafe behaviours. This scenario can be defined as workers' reactive behaviour stimulated by unexpected stresses.

4.4. Test of Theoretical Saturation.

Following the preliminary three-step coded analysis of qualitative data from the 30 interviewees, data from the remaining five interviewees were adopted for the theoretical saturation test. Following the same three-step analysis in Grounded Theory, no new concepts or categories were different from the previously defined categories. Therefore, it was indicated that the current coded categories and their connections, as described in Table 6, had encapsulated the significant causes and features of unsafe behaviours on construction sites

TABLE 4: Initial categories summarized through open coding.

Initially coded category	Defined feature	Mentioned by number of interviewees
Saving effort	Some workers consider the standard practice cumbersome and desire that the task be completed in a relatively more straightforward manner, such as throwing tools to deliver them between peers, crossing the safety fence, installing the scaffolding without fall protection, and randomly placing tools/materials on-site for the sake of convenience.	13
Gaining more income	Some workers perform their jobs with sicknesses or fatigue to gain more income or bonus.	11
Being overconfident	Some workers underestimate the risk of their behaviours and overestimate their capability to control risks.	8
Fearing losing jobs	Some workers opt to do unsafe work if their managers require them to finish on time or catch up with the construction schedule.	7
Meeting the scheduling needs	Some workers work overtime under fatigue to catch up with the scheduling requirements.	7
Saving time	Some workers skip steps in the standard construction workflow by violating safety regulations to save time. Some crew miss the safety education just to gain more time performing site duties.	7
Pursuing work efficiency	Some workers desire to complete duties in less time and behave in more risky ways, such as dropping the concrete formwork and scaffolding fasteners and manually carrying heavy items on-site.	5
Coping with safety inspection	Some site workers conceal or temporarily hide site items that do not comply with safety regulations to cope with periodic safety inspections from authorities or third parties.	5
Relying on personal experience	Some workers highly rely on their past site experience to judge the risk of their behaviour, and some unsafe behaviours may occur due to their long-term risk-taking habits or experience.	5
Holding the "being lucky" mindset	Some workers underestimate the safety issues, being even more "optimistic" towards safety if their past violation of safety rules did not cause accidents. However, they also believe that they would not be unfortunate to be involved in accidents.	5
Seeking comfort	Workers feel that wearing a hard hat, fastening safety belts, or using other safety protective equipment would make them even more uncomfortable in the hot weather.	4
Following the manager's demands	Workers feel unable to resist the commands of their crew leader. They feel obliged to perform risky duties and require high professional skills beyond their capability. As a result, they violate safety regulations to prevent project delays.	4
Resisting being regulated	When facing the blame or punishment for a safety violation, some workers turn out to be rebellious and feel unfairly treated and desire to continue their unsafe behaviours.	4
Reducing fatigue or pressure	Labour-intense duties and uncomfortable site conditions (noisy and hot) make workers feel exhausted and drive them irritable. As a result, some may smoke, snore, or even drink alcohol on-site.	3
Expressing emotions	Some workers are annoyed and angered for several reasons, including being rudely treated or blamed by site management personnel, family issues, and fairly punishment; as a result, they behave on purpose against the demands of their managers as a way to express their anger, such as by not attending mandatory safety education.	3
Escaping responsibilities	Some site workers lack a sense of responsibility, feel reluctant to be part of the site inspection, hide unsafe conditions or not report safety accidents, or blame others for the aroused safety issues.	3
Revenging	Conflicts may happen between workers and management personnel or among different trades. Some site workers seek opportunities to revenge by damaging others' work outputs.	3
Demonstrating capability	Some workers desire to impress their managers and demonstrate their capabilities by behaving differently from their peers.	3
Showing a "tough guy" image	Some workers desire to show their "tough guy" image to their peers and line managers. They do not follow management guidelines and pretend that they are experienced and know what they would perform, resulting in risky behaviours and safety violations.	2

TABLE 4: Continued.

Initially coded category	Defined feature	Mentioned by number of interviewees
Idling	Some part-time workers do not care about safety or perform their high-quality jobs. Instead, they mainly focus on gaining their daily income by spending their time on-site.	2
Hurrying to complete work	Once upon completing their daily duties, some workers are anxious to return home by finishing the last piece of work in a hurry and further cause accidents, e.g., falling from height.	2
Satisfying curiosity	Some workers feel curious and operate equipment (e.g., tower crane) without proper training.	1
Seeking excitement	Some workers behave unsafely by jumping on-site, throwing tools to deliver them, horseplaying, or playing in dark and confined spaces (e.g., basement, culverts).	1
Following peers	Although they do not agree with some unsafe actions conducted by co-workers, some workers still decide to follow their peers' unsafe behaviours to be social in their workgroup.	1
Maintaining self-esteem	When some workers feel insulted on-site, they may react in an extreme or unsafe way to defend their self-esteem.	1
Enhancing self-vanity	Some workers perform risky tasks beyond their control to gain praise from others.	1
Disturbing other trade teams' work	Some workers use the tools or equipment from other trade groups without permission just to benefit their group.	1
Reacting in emergency	Some workers, although without sufficient safety training, react in an emergency by trying to help others in danger.	1
Avoiding being monitored	Some workers deliberately hide from their managers to act unsafely.	1
Being distracted	Some workers are thinking of other nonwork-related things when working on-site.	1

TABLE 5: Coded main categories linked to initially coded categories.

Main category	Initially coded categories	The intention or motivation of unsafe behaviours
Reducing physical work	Saving effort; coping with safety inspection; seeking comfort; idling	Minimizing discomfort at work; reducing labour input
Reducing time input	Saving time; pursuing work efficiency; hurrying to complete work	Reducing the time spent on performing duties
Meeting internal desires	Being overconfident; relying on personal experience; holding the "being lucky" mindset; resisting being regulated; expressing emotions; escaping responsibilities; revenging; showing a "tough guy" image; demonstrating capability; satisfying curiosity; seeking excitement; enhancing self-vanity; maintaining self-esteem; avoiding being monitored; being distracted	Meeting a specific psychological need or desire; seeking a specific type of internal satisfaction (e.g., curiosity)
Relieving stress at work	Fearing of losing jobs; meeting the scheduling needs; following the manager's demands; reducing fatigue or pressure	Relieving stress driven by a specific type of external scenario
Increasing income	Gaining more income	Gaining more income from work
Being part of the team	Following peers; disturbing other trade teams' work	Demonstrating self-conformance to the own social or workgroup
Helping others	Reacting in emergency	Saving others from danger despite self-incompetency

comprehensively. Further discussion and in-depth theoretical analysis could then be conducted.

5. Discussion

5.1. Analytic Framework in the Formation of Safety Behavioural Decision. Following the Grounded Theory analysis, the process from construction workers' internal desires or motivations to behavioural outcomes is analyzed by introducing the social psychology theories as demonstrated in Figure 2.

5.1.1. Definition of the Analytic Framework Involving Mediated Moderation Effects in Safety Behavioural Outcomes. The framework shown in Figure 2 is considered a combination of mediation and moderation, according to Baron and Kenny [64]. The difference between a moderator (e.g., implicit safety cognition) and a mediator (e.g., explicit awareness) lies in that a moderator serves as an independent variable. Still, a mediator works as an intervening factor between an independent variable and the outcome [64]. As seen in Figure 2, workers' implicit safety cognition is at the

TABLE 6: Internal connections for each coded category, individual status of safety perception, and the corresponding behavioural outcome.

Connection among each coded category, individual safety perception status, and potential behavioural outcome	Definition
Reducing physical work → With safety awareness but without fear of danger → Proactive unsafe behavior	Before conducting unsafe behaviour, workers have a certain understanding of the risk involved in their unsafe actions. However, they either underestimate the danger, hold the "fortunate" mindset believing that accidents are not likely to occur to themselves, or desire to seek convenience or comfort.
Reducing time input → With safety awareness but without fear of danger → Proactive unsafe behavior	Before conducting unsafe behaviour, workers have a certain understanding of the risk involved in their unsafe actions. However, they underestimate the danger or hold the belief that they should not be that unlucky to become victims of accidents. They also care more about completing site work in less time.
Meeting internal desires → With safety awareness but without fear of danger → Proactive unsafe behavior	Before conducting unsafe behaviour, workers thoroughly understand the risk involved in their unsafe actions. But they also desire to satisfy specific internal needs by ignoring or underestimating the danger and violating safety rules.
Relieving stress at work → Without safety awareness but with fear of danger → Passive unsafe behavior	Before conducting unsafe behaviour, workers have a certain degree of fear of the potential danger. However, they still run dangerous behaviours due to stress caused by external scenarios and improper safety awareness due to a lack of professional knowledge.
Increasing income → With safety awareness but without fear of danger → Proactive unsafe behavior	Before conducting unsafe behaviour, workers have a specific understanding of the risk involved in their unsafe actions. However, they underestimate the danger or hold the belief that they should not be that unlucky to become victims of accidents. They also care more about earning more rather than safety.
Being part of the team → Without safety awareness but with fear of danger → Passive unsafe behavior	Before conducting unsafe behaviour, workers have a certain degree of fear of the potential danger. But they lack sufficient knowledge of the risk related to their hazardous behaviour. Peers' unsafe behaviour would encourage them more to behave unsafely in order to show themselves as part of the team.
Helping others → Without safety awareness and without fear of danger → Reactive unsafe behavior	Workers may not have sufficient safety knowledge of risks, and nor do they fear the danger involved. They desire to help other people on-site, under unexpected conditions or emergencies.

same level as the external scenario as an independent variable that may affect the outcome, which is the worker's behavioural decision of whether to behave unsafely. The external methods can activate these coded main categories shown in Table 5, such as the desire to save effort or gain more income. According to Scheier [65] and Snyder [66], self-monitoring or self-consciousness, once becoming the moderator variable, can improve the traits and attitudes. In this study, workers' self-monitoring or self-consciousness of safety can be reflected in the implicit safety cognition as moderating variables to the external scenarios. In this dynamic framework involving multiple variables affecting the behavioural outcome, self-monitoring within the implicit safety cognition, as a moderator variable, divides workers into subgroups according to their traits, for example, by demographic factors [67], job trades [68], or experience level [37]. These subgroup factors could cause workers' safety perceptions [46].

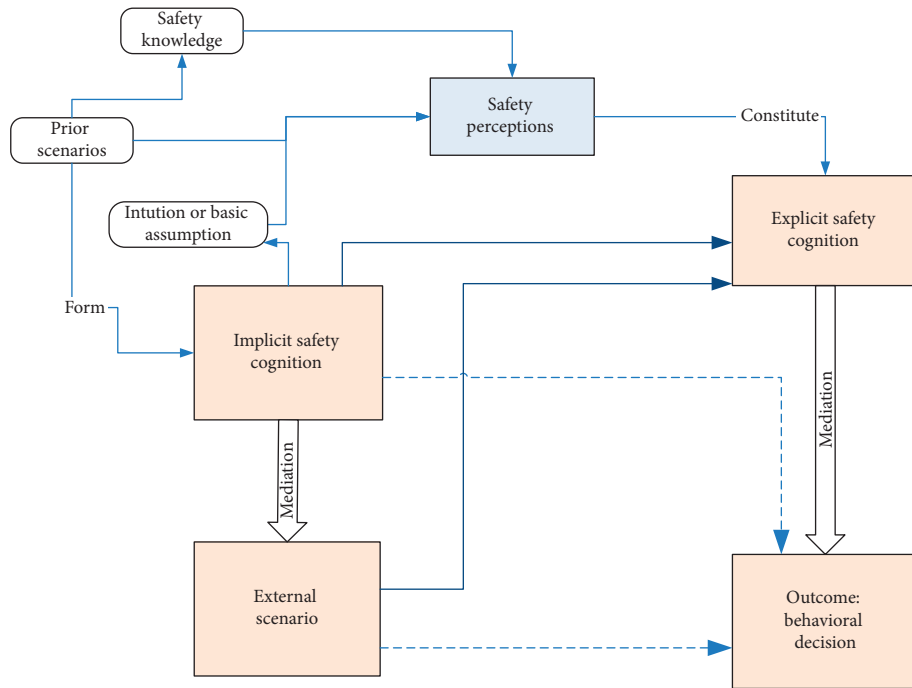
5.1.2. Extending the Social Psychology Theory into Safety Behavioural Science.
Applying the social phycology theory described in Baron and Kenny [64] and following the dynamic framework displayed in Figure 2, it is seen that the implicit safety cognition moderates the effects of the external scenarios in their behavioural decision, and the explicit safety cognition works as the mediator who could significantly intervene the decision. The behavioural decision could be different depending on the interacted effects of these variables. This interacted effect can be through different routes by extending the theory of Baron and Kenny [64]. The implicit cognition and the external scenario may significantly affect the behavioural decision (as seen in the dashed lines in Figure 3 from implicit safety cognition and external scenario to the outcome). The interaction of explicit cognition and external scenario indicates moderation. Explicit cognition can mediate the relation from the external scenario to the outcome, meaning that the external distraction from these aforementioned coded categories (e.g.,


FIGURE 2: Analytic framework of mediated moderation informing construction workers' safety behavioural decision (source adapted by integrating the theories of Baron and Kenny [64] and Han et al. [46]).
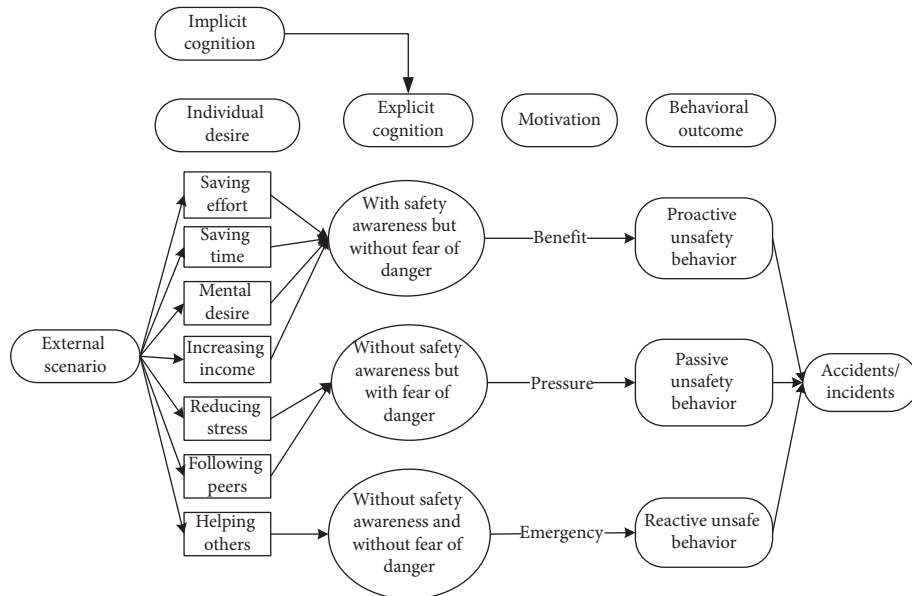

FIGURE 3: Diagram describing the formation of workers' unsafe behaviours driven by various individual desires under different explicit cognition patterns.

desire to increase personal income) does not necessarily cause unsafe behaviours if the worker has the correct safety perception to resist the temptations activated by the external scenarios. If that mediation is complete, these temptations that are driven by the external site scenarios to work unsafely would not result in unsafe behaviours. Indeed, to strengthen the explicit safety cognition (i.e., safety climate), implicit safety cognition should strongly affect clear awareness.

By extending the social psychology theory described by Baron and Kenny [64], it is indicated that the interaction effect from explicit cognition and the initial external scenario would strongly affect the behavioural decision. However, through the mediation effect from clear cognition, and depending on the level of mediation, workers could redirect their own safety behaviours from being risky to behaving safely. This level of deviation

would highly depend on the effectiveness of safety programs [69] and safety training [46] which could improve a positive safety climate.

5.2. Formation Mechanism of Construction Workers' Unsafe Behaviours.
The analytic framework shown in Figure 2 can be further extended into the formation process based on the coded categories generated from Grounded Theory. Continued from Table 6, it is seen that unsafe behavioural outcomes are formed through one of the dynamic routes shown in Figure 3. Therefore, for any unsafe behaviour to occur, an external scenario that activates one individual desire, intervened by personal safety cognition, would drive the formation of the dominating motivation (i.e., benefit, stress, or emergency). It is stated in the Self-Determination Theory [70] that distinct types of motivations drive human behaviour. The motivation-driven behaviours could be performed to simply satisfy the innate psychological needs [71]. This need or desire is a necessary condition but not a sufficient condition for unsafe behaviour.

5.2.1. Individual Desire Is Linked to Construction Workers' Unsafe Behaviour.
The seven individual desires listed in Figure 3 reflect the need for workers and can be considered reasonable and regular human needs. Compared to other industries, the construction industry has more adverse and diverse site working conditions (e.g., hot to cool outdoor environments) and is deemed riskier in terms of health and safety. The subcontracted work in China's construction industry is more commonly based on a fixed amount, meaning that workers would gain the same payment by completing the given tasks. Hence, many workers prefer to save labour input and time to complete a fixed amount of work. Many workers migrate to urban areas of more economically developed regions in China in search of better-paying jobs. They may feel socially isolated and desire to be part of a social group. Therefore, they tend to follow peers' behaviours. The social outcome, defined by Man et al. [11], could be considered necessary for workers to enhance their image or status in the social system. External factors could also increase the probability of unsafe behaviour.

In many cases, construction projects in the urban areas of China are under a tight schedule to meet deadlines. As a result, it is common to see site workers committing to work overtime, including weekends. Therefore, any demands from the management that work should be completed earlier would result in more stress.

It should be a concern if workers' unsafe behaviours originate from their reasonable and rational human needs. It could be said that the unsafe behaviour is a by-product of the site work, meaning that the personal desire or conditions do not necessarily result in dangerous behaviours. It is not possible to eliminate these internal needs. What is more practical and feasible in safety management is to provide proper education by targeting workers' common personal needs, primarily to prevent them from conducting unsafe behaviours.

5.2.2. The Effect of Safety Cognition on Unsafe Behaviours.
Unsafe behaviours could allow an individual worker to achieve their own desired outcomes with positive or negative consequences (e.g., injuries). Therefore, before making a behavioural decision, each individual has to weigh the risk and benefits associated with a decision [72]. Indeed, construction workers would perceive it as worthwhile in trying a risky approach if there is a significant return from pursuing such unsafe behaviour. An immediate example is when having to save the lives of people in case of emergency or just simply to demonstrate their own "tough guy" syndrome [10] to peers and managers. Over time, and with sufficient safety awareness and perception of danger, workers may not decide to behave unsafely despite the benefits brought by the risky behaviour. The safety cognition system described in Figure 2 is insinuated as the mediated moderation factor between persona desire under specific external scenarios and the resulting motivation leading to a behavioural outcome. Furthermore, as workers gain more site experience and dexterity in perfecting their trade skills and routinely accomplish their work safely on a consistent level, safety awareness also increases at the same exponential knowledge of compliance. Therefore, it is more common to see workers being proactively and routinely safe by understanding how to conform to safety regulations. This is exhibited through increased avoidance of unsafe behaviours. Invariably, the antithesis is also actual. When workers behave unsafely, they are more likely to have sufficient safety awareness but exhibit low sensory understanding or anticipation of risks, hazards, and resulting harm or looming danger.

According to the Weber-Fechner Theory [73], human beings tend to become less sensitive to danger as their experience and skill grow, with less fear of danger. Almost befitting this theory is the expression that "familiarity breeds contempt" to warrant an effective response to compliance. There is virtually an infinite false sense of safety, qualified by unsafe behaviour. Expressing the same concern, Han et al. [37] compared their entry-level peers. They found that construction workers, in their middle careers, were more prone to underestimate the danger associated with site hazards. This conclusion is also prominent among workers who behave riskily but end up without encountering any negative consequences due to their behaviour. As for this group of workers, Kasperson et al. [74] have warned that the absence of negative experiences creates a false sense of safety. This predisposition to no harm leads to falsification of the actual benefits enshrined in full compliance, and conformance to safety standards has negative safety behaviour: workers become less sensitive to the potential risk-led dangers, are slow to be proactive, and become a danger to themselves and their fellow workers [74]. Workers' "fortunate" mindset would be strengthened under this scenario by relying on the superior supervision of foremen and sectional managers and the personal experience of co-workers. Holding the belief that accidents would not happen to themselves is what triggers or generates overconfidence and could deviate workers' safety perception and ability to improve their dexterities in their trade, and heighten the precipitation of perpetual acts of unsafe behaviours.

The factor of focusing on the end benefit (or benefit-driven) in addition to external pressure-induced desire is also a common trigger for unsafe behaviours. The explicit safety cognition (i.e., safety climate involving safe perception and safety awareness) plays a vital role as an intervening mediator to impact the behavioural decision. Under the proper mediation of safety cognition, workers could be equipped with sufficient safety awareness and sense of danger and hence not behaving unsafely. The occurrence of unsafe behaviour is not because of the internal personal desire but the failure of the mediated-moderation mechanism involving the safety cognition. Behaving unsafely but not causing accidents can strengthen and precipitate the "fortunate" behavioural syndrome mindset, thereby deteriorating the mediated moderation agent. Therefore, training workers with proper safety cognition to correct this bias of the "fortunate" attitude plays a key role.

5.2.3. The Dynamic Mechanism in the Formation of Behavioural Decision. It is workers themselves who decide their behaviours. In other words, they can self-direct their motivation and behaviours. Despite the sufficient safety knowledge, site experience, and level of safety awareness, as well as the sense of danger due to unsafe behaviours, the internal desire (e.g., gaining more income) and external inducer (e.g., tight project schedule) may affect the behavioural decision-making according to the analytic framework in Figure 2. This dynamic mechanism also means that which motivation dominates can keep changing. For example, workers may feel uncertain in weighing the benefits and risks. The mediated moderation from safety cognition aims to guide workers towards safety-dominating motivation. The Protection Motivation Theory (PMT) [75] indicates that human beings naturally tend to protect themselves from danger if they can correctly sense the danger. According to PMT [75], the key is to nurture the proper sense of danger for workers, besides the education on safety awareness.

On the other hand, the Risk Homeostasis Theory [76] proposes that human beings opt to take more risks if they have a strong sense of safety. Workers may behave at different risk levels depending on the external conditions [77]. It happens that workers work in a more risky way because they believe that the superior safety devices can protect them from injuries, hence underestimating the site risks due to their unsafe behaviours. Klen [78] reported that workers behaved more carelessly in a riskier manner when equipped with protective equipment. However, this is not to deny the importance of wearing safety equipment. Instead, it highlights that the malfunctioning safety cognition system as the mediated moderation mechanism should be corrected to prevent unsafe behaviours.

5.2.4. External Conditions That Affect Workers' Behavioural Decision. The adverse external conditions, such as high humidity and hot weather in summer construction and poor management commitment to safety, could exert a negative influence on workers' behaviours. This external influence cannot be ignored. The qualitative studies conducted in China's construction industry [10, 11] confirmed that workers are likely to be influenced by their peers' behaviours and the social values of their groups. If most other peers are working in an unsafe way, those minorities who behave in a standardized, safe manner may feel isolated and perhaps taken for granted. Safety management, therefore, plays a vital role in workers' behaviours. In some cases, workers quickly perform duties because they fear losing part of their income for failing to complete the job on time. Sometimes they must focus more on work efficiency to avoid being blamed by their managers.

Skinner's [79] theory indicates that timely and effective punishment for unsafe behaviour could prevent unsafe actions and motivations from reoccurring. However, insufficient safety monitoring and management system, which fails to handle safety violations timely and adequately, could motivate workers to behave unsafely and negatively affect their preestablished safety cognition system. A good safety management program is critical to forming a positive safety climate. The safety climate forms part of the safety cognition, which directly affects human behaviour [42]. A hostile site atmosphere (e.g., managers' emphasis on work efficiency and indifference to health and safety) could lead to the failure of the mediated moderation mechanism brought by the safety cognition system.

6. Conclusion

This study adopts a Grounded Theory approach to assist the investigation of the formation mechanism of construction workers' unsafe behaviour. Following site interviews with a total of 35 construction professionals, seven main categories were defined to describe workers' psychological needs or personal desires that led to unsafe behaviours. These seven categories, joint with the individual safety perception status, could lead to dangerous behaviours. The safety perception status measured by safety awareness and sense of danger could be incorporated into the explicit safety cognition. Individuals' psychological needs, activated by external scenarios and mediated by clear safety cognition, led to the behavioural outcome. The unsafe behaviour, according to the qualitative data obtained from this study, could be divided into proactive, passive, and reactive types, driven by different internal needs and external conditions on construction sites.

Following the data analysis adopting Grounded Theory, social psychology theories were applied in the context of construction safety behaviour. An analytic framework illustrating the formation of the behavioural decision was initiated by integrating the ideas of social cognitive psychology and safety cognition of construction workers. Social psychology highlighted the effects of two different factors (i.e., mediator and moderator) in affecting the behavioural outcome. The individual desire activated by an external scenario serves as one independent variable, which is one necessary but not sufficient condition for unsafe behaviours. The social psychology theories infer that construction workers' safety cognition system, consisting of implicit (e.g., safety knowledge and previous experience) and explicit (i.e., safety climate) cognitions, work as the mediated-moderation

mechanism affecting the behavioural outcome. This is a dynamic mechanism involving workers' safety awareness and sense of danger, which intervene in their individual desires activated by external scenarios workers.

By integrating the results from Grounded Theory and the analytic framework, a further diagram was developed to describe the formation process of construction workers' unsafe behaviours. This diagram was discussed in depth in terms of four main aspects, namely, the original desires causing unsafe behaviours, the effects of safety cognition in unsafe behaviours, the dynamic mechanism informing behavioural decisions, and external conditions that affect workers' behavioural decisions. By applying a variety of social psychology theories, the diagram provides practical suggestions to properly guide construction workers' behaviours, including (1) an effective safety management program to provide effective training addressing workers' personal needs instead of ignoring or denying these needs or desires; (2) establishing a positive safety climate to develop workers' safety perception with sufficient safety awareness and sense of danger; and (3) periodic safety orientation targeting individuals' safety cognition system, not only for new workers but also especially for experienced workers. More specifically, many construction workers might not have received a university-level education, and alternative training manners other than toolbox meetings could be adopted, e.g., virtual reality-based site tour and video plays of safety hazards/accidents. Other measures to increase the safety awareness and sense of danger could include but be not limited to a proper frequency of safety inspection of workers on-site and an established management scheme between incentive and punishment to regulate safety behaviours.

One limitation of this current study is that all interviews were conducted in China's most economically active region, where construction projects are mostly under tight schedules with productivity highly stressed. More future work could be done to evaluate these defined categories from Grounded Theory in different regions or countries. The developed analytic framework and diagram can also be further applied in other regions or countries' construction sites. More future work can also investigate the effects of safety incentives and punishment policies in safety cognition development.

Abnormal target detection in hyperspectral remote sensing image is one of the hotspots in image research. The image noise generated in the detection process will lead to the decline of the quality of hyperspectral remote sensing image. In view of this, this paper proposes an abnormal target detection method of hyperspectral remote sensing image based on the convolution neural network. Firstly, the deep residual learning network model has been used to remove the noise in hyperspectral remote sensing image. Secondly, the spatial and spectral features of hyperspectral remote sensing images were used to optimize the clustering dictionary, and then the image segmentation containing target information is completed. Finally, the image was input into the deep convolution neural network with a dual classifier, and the network detects the abnormal target in the image. The test results of this algorithm show that the structural similarity of the denoised image is higher than 0.86, which shows that this method has good noise reduction performance, image details will not damage, segmentation effect is good, and it can obtain high-definition target image information and accurately detect abnormal targets in the image.

1. Introduction

Remote sensing images, also known as remote sensing images, include aerial photos and satellite photos. Therefore, the imaging methods of remote sensing images include aerial photography, scanning, or microwave radar scanning [1]. With the continuous development of remote sensing technology, the requirements for the imaging effect and quality of remote sensing images are gradually improved, from the basic monitoring application to the detection of abnormal targets through remote sensing images. Therefore, the resolution of remote sensing images needs to reach a certain standard. Based on this, hyperspectral is applied in the field of remote sensing and combined with remote sensing technology to obtain hyperspectral remote sensing images with better resolution [2]. Hyperspectral image refers to the resolution of $10-2\lambda$ for images of orders of magnitude, and spectral sensors are deployed on different space platforms to image the target area [3], which can obtain its

surface image and spectral image at the same time, to realize the combination of spectrum and remote sensing. The convolution neural network is a kind of network with the ability of convolution calculation and representation learning. It is widely used in image and object recognition, pose estimation, natural language processing, and so on. Moreover, the network has a good effect in processing the geometric, texture, and spatial distribution characteristics of remote sensing images and can identify the target objects in remote sensing images. In order to realize the detection of abnormal targets in hyperspectral remote sensing images [4], after relevant research in the literature [5] and [6], a correlation detection method based on spatial spectrum joint anomaly degree and spectral difference equalization interval screening is proposed. In the detection process, the above method has no segmentation effect and cannot accurately obtain the target area information. Therefore, there is a certain error in the detection result of the above method. Therefore, this paper proposes an abnormal target detection

method of hyperspectral remote sensing image based on the convolution neural network. Firstly, the high-frequency layer with noise information is studied in multiscale space by the residual network, and the residual remote sensing image is generated by residual mapping. Finally, the complete denoising result is obtained by jump connection. Then, the dictionary learning model is used to obtain the sparse representation of the brightness component and color image of the remote sensing image, reconstruct and compensate the missing high-frequency information in the remote sensing image, retain the high-resolution of the image, and retain the spectral information and spatial detail information in the remote sensing image. Finally, the convolution neural network is used to segment the hyperspectral remote sensing image after extracting the features and finally complete the image abnormal target detection.

2. Detection of Abnormal Targets in Hyperspectral Remote Sensing Images

2.1. Denoising of Hyperspectral Remote Sensing Image Based on Depth Residual Learning. In the process of imaging acquisition of hyperspectral, remote sensing images, under the influence of environment, equipment, and other factors, there will be noise in the acquired images, which will affect the detection results [7]. Therefore, in order to ensure the accuracy of abnormal target detection in hyperspectral remote sensing images, this paper uses depth residual learning to denoised the images.

Deep residual learning is a deep network model including residual module, which is composed of residual units. There is a mapping relationship between hyperspectral remote sensing images before and after noise reduction, which is nonlinear. The mapping relationship is realized by inputting the high-frequency band noise data in the image into the residual module technology. Multiple data nodes are connected by jumping, and each module can be effectively connected, so as to retain more edge information in the semantic feature difference information. The core of the network is the residual of the connection depth (shortcut connections), introducing branches to ensure smooth network data transmission and avoid under fitting caused by gradient disappearance and degradation.

2.1.1. Input Layer. The original hyperspectral remote sensing image $y\,(x)$ is used as the input of the model and input by the input layer.

2.1.2. Feature Extraction Layer. This layer completes the feature extraction of hyperspectral remote sensing image in the form of image block. In this process, the feature is extracted to ensure that the image features will not change after noise reduction. Map the image block originally located in the image space to the feature space, complete the learning of image features, and take the feature as a filter to participate in the convolution operation of the original hyperspectral remote sensing image. Its purpose is to obtain the activation value, which belongs to different positions and

features of the original image. In this layer, the activation function and convolution kernel are used to extract the eigenvalues of the image block, and the obtained neurons are transmitted to the residual module.

2.1.3. Residual Module. It mainly completes the residual learning between the input and output of the whole model. In order to ensure the integrity of image detail information in the learning process, this paper introduces local residual learning and recursive block and adjusts the residual module so that the input of identity branch and residual branch are in two states in the model and recursive block. The former is difference, and the latter is the same. In this way, the path between the input and output of recursive block is multi-path, which can effectively avoid the phenomenon of overfitting. To improve the learning performance of the model, formula (1) of the residual unit is as follows:

$$H^u = g\left(H^{u-1}\right) = \left(F_{H^{u-1}}, F_W\right) + H^0, \qquad (1)$$

where g represents the function, corresponding to the residual unit; F_W represents residual function; and both H^0 and H^u represent the output. The former corresponds to the first convolution layer, and the latter corresponds to the residual unit; $F_{H^{u-1}}$ is the input of the unit; u represents quantity, corresponding to residual unit. The original expectation mapping skips one or more layers of network structure and realizes identity mapping. With the increase of network depth, the weight of the convolution layer is constantly updated, and the weight value iterates in the direction of gradient descent.

2.1.4. Network Reconstruction Layer. After learning, the residual unit outputs the characteristic map of the image block and transmits it to this layer to form a hyperspectral mapping image, and its number is the same as the original image. After fusion processing through convolution calculation, a complete hyperspectral remote sensing image is formed. This layer can complete the prediction and removal of noise components in the image [8], so as to obtain the denoised hyperspectral remote sensing image. Then, the calculation formula is as follows:

$$X_x = x \times \left(H^u - s\right), \qquad (2)$$

where x represents the image after noise reduction; X_x represents the residual noise image after residual learning. The network learns the mapping from noise image to noise distribution. Using the characteristics of the neural network and global jump connection, x is subtracted to obtain a complete denoised image, and the multiplicative noise is removed indirectly by subtraction.

2.2. Feature Extraction of Hyperspectral Remote Sensing Image. In the abnormal target detection of hyperspectral remote sensing image, it is necessary to accurately extract the target information in the image. Therefore, this paper guarantees the definition of remote sensing image on the

basis of noise reduction and then carries out feature segmentation on x to remove the background in the image and retain the feature information. This paper uses the clustering dictionary learning method combined with the residual network model to complete the image pixel segmentation.

Determine the cluster center, use the dictionary representation, determine the category attribution, and complete the dictionary learning, which are completed according to the sparse representation and the elements in the cluster, respectively. In order to better characterize the image features [9], the dictionary atom is described based on the region image block. The dictionary is optimized by combining the two characteristics of wide band range and high-spectral resolution of hyperspectral remote sensing image, and the segmentation is completed by using the optimized DICTIONARY [10].

The purpose of clustering is to realize the division of clusters, which is completed according to the similarity of images, so that the elements with increased similarity are located in the same cluster, as shown in the following formula:

$$W_a = \min \sum_{i=1}^{K} R(x_i, v_i), \tag{3}$$

where K represents the number of clusters; x_i represents the i cluster, and v_i represents its cluster center; R represents the input hyperspectral remote sensing image, and $R(x_i, v_i)$ represents the distance, corresponding to the distance between x_i and v_i. The smaller the distance, the higher the degree of similarity between the two.

x_j is classified according to V_i. On this basis, a new clustering center is obtained, and the clustering is completed after complete convergence through cyclic iterative processing between them.

The center point is determined and represented by any pixel in x_j. In order to obtain the column vector set and contain n elements, the neighborhood image is processed by transformation, and the set is used as the input signal. The objective function of the method is shown in formula (1):

$$\min_{w_{ij}, D_j, C_j} J = \min_{w_{ij}, D_j, C_j} \sum_{j=1}^{k} \sum_{x_i \in C_j} (x_i - D_j w_{ij}), \tag{4}$$

where k represents the limit; J represents the sparse vector value; C_j represents the number of atoms; D_j stands for dictionary, corresponding to C_j; m_j represents the number of atoms, corresponding to D_j; w_{ij} represents sparse vector, corresponding to any signal x_i; T represents the limit, corresponding to sparsity; $R(D_j)$ represents the function, which is used to judge the consistency within D_j; δ means to set the fluctuation threshold. The smaller the value, the higher consistency of atoms in the dictionary.

After completing the construction of D_j, each w_{ij} has corresponding pixels in different clustering dictionaries. Therefore, the former can be determined according to the image signal corresponding to the latter. If you get $\|x_i - D_j w_{ij}\|$ with the smallest D_j, it indicates that the similarity

between D_j and x_i is high, you can classify the latter into the former.

During image segmentation [11], the neighborhood information of each pixel of hyperspectral remote sensing image is processed by transformation to form a one-dimensional vector x_i. In order to obtain the input signal set X, all signals are integrated to obtain x_i, which belongs to spectral remote sensing image. After the sparse representation of X is completed by sparse coding, X_i is segmented by clustering. In order to ensure the matching degree between the dictionary and the signal, the dictionary update needs to be completed, which is completed according to the signal in the cluster. After realizing the convergence of the energy function value J according to the cyclic interactive iteration, the clustering segmentation of hyperspectral remote sensing image is completed, and the segmented image $\tilde{X}$ containing target information is obtained.

2.3. Abnormal Target Detection Based on Deep Convolution Neural Network. After image clustering and segmentation, this paper uses the deep convolution neural network (DCNN) model to complete the final hyperspectral remote sensing image abnormal target detection. The model adopts dual classifier. The classifier is a machine learning method based on quadric surface and a general abnormal target linear classification method. Thus, the final abnormal target detection is completed, and the model structure is shown in Figure 1.

Take $\tilde{X}$ as the input of the model, and the convolution layer extracts the feature of $\tilde{X}$. Through convolution operation, the feature signal of the image can be enhanced, and the edge detection of the image can be sharpened and blurred [12]. The formula of convolution operation process is shown in

$$a_{j,l} = f \sum_{i \in M_j} \tilde{X} a_{j,l-1} * f \kappa_{i,j,l} f b_{j,l}, \tag{5}$$

where $a_{j,1}$ represents the activation value, corresponding to the output characteristic image j, and belongs to layer l; $k_{i,j,1}$ represents the kernel, which is used to connect two characteristic diagrams, which are located in layer l and layer $l-1$, respectively; $b_{j,1}$ represents the addition deviation, which corresponds to the output characteristic image j, and belongs to layer l; $f(\cdot)$ represents Relu function; M_j represents the characteristic diagram j and is linear.

The pooling layer can realize subsampling processing, which belongs to image features and needs to be based on the local correlation of the image, so that the valuable information in the image can be retained to the greatest extent [13]. The calculation formula of this layer is

$$a_{j,l} = f \beta_{j,l} \text{down}(a_{j,l-1}) \tilde{X} + f \alpha_{j,l} b_{j,l}, \tag{6}$$

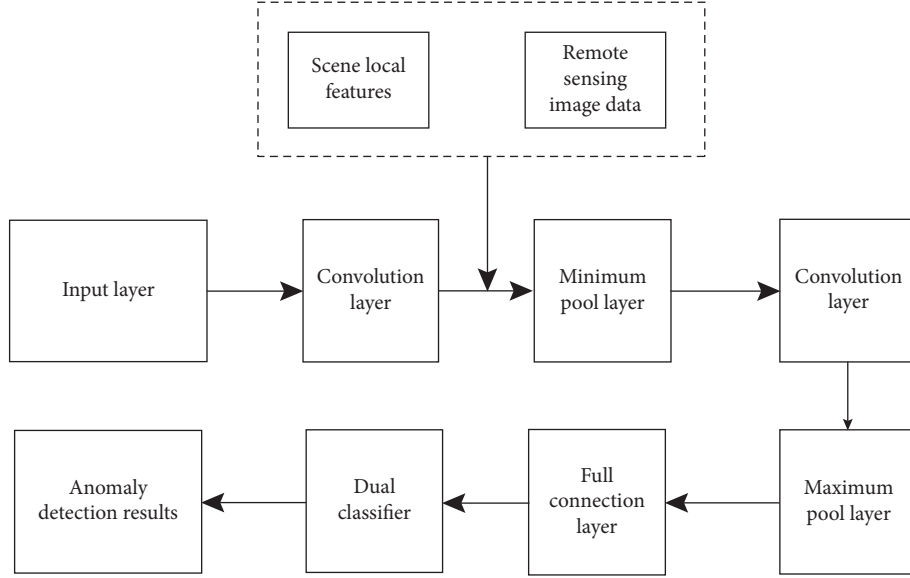
where $\text{down}(\cdot)$ represents the function, corresponding to subsampling; $\beta_{j,1}$ and $\alpha_{j,1}$ represent multiplication bias, corresponding to the output characteristic image, and belong to the layer l.


FIGURE 1: Abnormal target detection model based on DCNN hyperspectral remote sensing image.

When detecting abnormal targets in hyperspectral remote sensing images [14], there are obvious quantitative differences between classes. Therefore, in order to ensure the accuracy of detection results, weight is introduced to restrict each class of the image, larger weight is added to smaller classes, and smaller weight is added to larger classes; then, as shown in the following formula,

$$L(W, b) = \frac{1}{2}\left[\frac{\sum_{i=1}^{z}\mu_i\left\|y_j^{z_i} - \widehat{y}_j^{z_i}\right\|^2}{mn} + \lambda W^T W\right], \qquad (7)$$

where μ_i represents the weight, which is used for different types of constraints; L represents the deformation of norm; z_i represents the quantity, corresponding to the selected hyperspectral remote sensing image sample points; λ, m, and n are constants; W represents the weight matrix; $y_j^{z_i}$ and $\widehat{y}_j^{z_i}$ represent the feature value and feature approximation of the selected image, respectively.

The dual classifier in the model is a two-layer stack. The first layer is used as the training set of the second layer after completing the feature reconstruction of hyperspectral remote sensing image [15]. The dual classifier has the ability of spectral remote sensing image feature fusion, which can fuse the original features and extracted new features in the image, and process the fused features by means of standardization and normalization, to improve the detection accuracy of abnormal targets.

3. Experimental Analysis

In order to test the application performance and effect of this method on the abnormal target detection of hyperspectral remote sensing image, this method is used to detect the remote sensing image of land resource management in a province. The purpose of detection is to determine the abnormal illegal construction or illegal occupation of cultivated land based on hyperspectral remote sensing image
FIGURE 2: Test results of the structural similarity index.

and cooperate with relevant departments to complete land resource management. Hyperspectral remote sensing image detection is used to collect abnormal information. In the process of real-time abnormal target detection, line images need to be collected, so a 2-way blade server is used as the image server. Considering the running time, a disk array with a capacity of 8 t will be selected for the amount of data collected, so as to ensure the safety of abnormal target detection in hyperspectral remote sensing images.

3.1. Denoising Test. In order to test the drying performance of this method, structural similarity $S_{SSIM}(x, y)$, image information entropy H, and average correlation coefficient $\overline{C}$ are used as rating indicators, in which structural similarity
FIGURE 3: Test results of the image information entropy index.

FIGURE 4: Test results of the average correlation coefficient index.

refers to the measurement of macromolecular structural similarity; image information entropy refers to the average number of bits in the gray level set of hyperspectral remote sensing images; average correlation coefficient refers to the amount of linear correlation between abnormal target detection variables in hyperspectral remote sensing images, which usually represents an uncertain relationship. Test the results of three indexes after image denoising with different noise levels, as shown in Figures 2–4. The calculation formulas of the three indicators are as follows:

$$S_{\text{SSIM}}(x, y) = \frac{2\varepsilon_x \varepsilon_y}{(\varepsilon_x + \varepsilon_y)^2} \frac{2\sigma_{xy}}{(\sigma_x + \sigma_y)^2}, \tag{8}$$

$$H = -\sum_{i=0}^{1} p(i)^2 \ln, \tag{9}$$

$$\overline{\vartheta} = \frac{\sum_{i=1}^{m} \sum_{j=1}^{n} \vartheta_{od}(i, j)}{mn}, \tag{10}$$

where x and y represent two hyperspectral remote sensing images, and their mean values are represented by ε_x and ε_y, respectively. The covariance between them is σ_{xy}; $P(i)$ represents the probability density function, corresponding to the gray value i. $\vartheta(i, j)$ represents the correlation coefficient, which belongs to the spectral vector before and after noise reduction and corresponds to the pixel at (i, j) of the hyperspectral remote sensing image; m, n represent the number of rows and columns of hyperspectral data, respectively. The larger the value of the three index results, the better the noise reduction performance of this method, and the more the details and quality of the denoised image can be guaranteed. The expected standard is that the results of the three indexes are higher than 0.86.

According to the test results of Figures 2–4, under different image sizes, with the gradual increase of noise, the three indicators of this method show corresponding differential changes, but the change results meet the expected standard requirements, even if the image size is 80×80, when the noise is 20 dB, the results of the three indexes are 0.91, 0.90, and 0.88, respectively. Therefore, this method has good noise reduction performance.

In order to measure the noise reduction effect of this method, a remote sensing image of land resource management is randomly selected for noise reduction and the image results before and after noise reduction are obtained to judge the noise reduction effect of this method, as shown in Figure 5.

3.2. Image Classification and Evaluation.

In the experiment of remote sensing image classification, this paper uses 2DCNN, 3DCNN, and ResNet to compare and analyze the classical Indian pins set of remote sensing data, so as to further verify the training advantages of residual network. As shown in Table 1, the OA of remote sensing image classification completed by the reset model is as follows: the value is 0.966385; the value of AA is 0.967972; and the value of kappa is 0.960746.

Figure 6 shows the confusion matrix of the classification of Indian pins common data set. It is found that the position of each measured pixel shows better accuracy compared with the corresponding position of the actual image. Figure 7 shows the iterative values of loss, accuracy, val_loss, and val_loss, which further shows that this method has a good effect on the classification of multiband remote sensing images after noise removal.

According to the test results in Figures 5–7, it can be seen that there is noise influence in the image before noise reduction, and there is fuzziness in the image. After noise reduction, the clarity and brightness of the image are significantly improved. The results intuitively show that the noise reduction effect of this method is good, and the noise removal in the image can be completed on the premise of ensuring the quality of image details.
Figure 5: Test results of noise reduction effect.

Table 1: Comparison of classification accuracy of remote sensing images.

Network type classification criteria	OA	AA	Kappa
2DCNN	0.761929	0.767287	0.728459
3DCNN	0.949264	0.970596	0.940559
ResNet	0.966385	0.967972	0.960746
Figure 7: Precision contrast of the residual network.
Figure 6: Confusion matrix of the residual network.

Figure 8: Test results of the gray mean index.

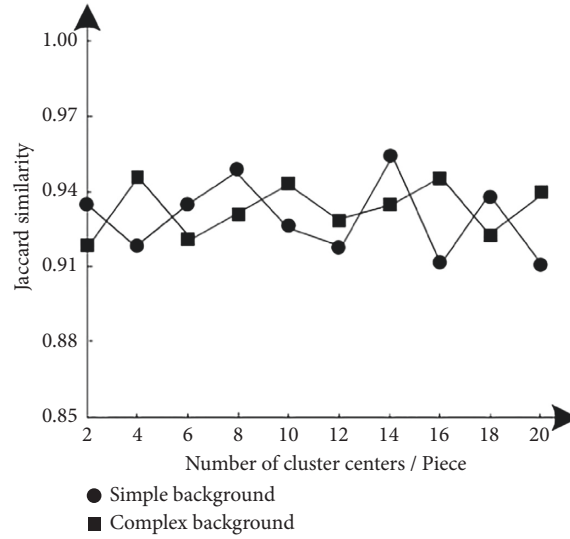
In order to test the image segmentation effect of the method in this paper, the gray mean and Jaccard similarity are used as evaluation indexes, and their calculation formulas (11)-(12) are as follows:


FIGURE 9: JAC similarity index test results.
FIGURE 10: Abnormal target detection test results.

$$\mu = \frac{1}{mn} \sum_{i=1}^{m} \sum_{j=1}^{n} x_{ij}, \tag{11}$$

$$\text{JAC}(A, B) = \frac{|A \cap B|}{|A \cup B|}, \tag{12}$$

where x_{ij} represents the gray value of the image after noise reduction and corresponds to the pixel point at (i, j); A, B represent two different sets. The average gray level can reflect the gray level of the image, that is, the brightness of the image, and the expected standard is between 0.4 and 0.6. The closer the JAC similarity is to 1, the better the quality of the segmented image. The expected standard in this paper is more than 0.85.

The image segmentation results of the method in this paper are obtained according to formulas (9) and (10), as shown in Figures 8 and 9.

According to the test results of Figures 8 and 9, with the gradual increase of the number of segmentation of

hyperspectral remote sensing images, the results of gray mean fluctuate within the standard range. The results show that even if the number of segmentation is large, the basis can ensure the image quality. Therefore, it also indirectly shows that. The segmentation effect of this method is still good for images with complex background. In addition, with the gradual increase of clustering centers in the image, the results of JAC similarity fluctuate irregularly, but the variation range is about 0.9. Therefore, the image segmentation effect of this method is good and can obtain the target image information with high definition.

3.3. Target Monitoring Results. In order to test the abnormal target detection of hyperspectral remote sensing image in this method, this method is used to detect the abnormal target in the denoised image in Figure 5. There are abnormal illegal buildings in this image. The detection results of this method are obtained, as shown in Figure 10.

According to the test results in Figure 10, this method can complete the detection of abnormal targets in hyperspectral remote sensing images and obtain abnormal illegal buildings in the images. After confirmation, the detection results are consistent with the actual results. Therefore, this method has the effect of abnormal target detection in hyperspectral remote sensing images, and the detection results have good reliability.

4. Conclusion

Hyperspectral remote sensing images are used in more and more fields. It is an important detection method to complete abnormal target detection based on remote sensing images. In order to ensure the reliability of hyperspectral remote sensing image abnormal target detection, a hyperspectral remote sensing image abnormal target detection method based on the convolution neural network is proposed in this paper. The convolution neural network is used to classify the image to obtain the high-spectrum remote sensing image with target features, which is introduced into the convolution neural network with dual classifier to detect it. The results show that the abnormal target detection method of hyperspectral remote sensing image based on the convolution neural network has good noise reduction performance and can complete the noise processing in the image under the condition of ensuring the image quality and fine grain level. At the same time, it can also better complete the classification of target areas, and the display effect of various indicators is good. After segmentation, the quality of hyperspectral remote sensing image is intact, which plays an important role in accurately detecting abnormal targets in the image.

Research Article

Differentiation in Emotional Investments in Work Groups among Different Social Status of Construction Industry Practitioners: A Perspective from the Social Exchange Theory

Wenqing Zhang [iD] **and Dingzhou Fei** [iD]

Department of Psychology, Wuhan University, Wuhan, China

The construction industry is characterized by a high level of mobility and a diverse range of practitioners from different social status, which can affect the industry's group management processes. The exploration of the mechanisms involved is an important task for theoretical research and a challenge for management practices. This study examines three relevant aspects of work-group behavior in the construction industry from a social exchange perspective: the individual's evaluation of the level of the emotional investment of members in the work team and their assessment of personal rewards and costs. The study of 71 construction industry workers through the development of a cost-benefit inventory questionnaire of individual-team exchange relationships revealed that their level of emotional investment in the work group can be predicted by assessing their awareness of personal rewards and costs. A further clustering algorithm revealed that an individual's social status had a significant impact on their level of affective investment, but there was no significant correlation between an individual's wage and their level of emotional investment in the work team. The findings deepen our understanding of group behaviors in the construction field by explaining the interactions between individuals and organizations in work groups while emphasizing the indispensable role of emotional factors in group development.

1. Introduction

1.1. The Current Situation of Construction Industry Workers.
After a long period of market system construction and effective regulation and rectification, the construction industry is steadily developing. At the same time, some social problems caused by the nature of the long project cycle, many projects, and complex environment have been exposed. Among them, the emotional problems of workers are coming to the fore more and more. Workers who are highly mobile due to site changes and need to move around all year round are usually far away from the city and their families and friends, and the resulting work-family conflicts can affect the social behavior of construction workers [1], and kinship plays an important role in the effectiveness of relational governance mechanisms in projects [2]. In addition, construction industry workers have a complex composition and diverse social backgrounds and are forced to accomplish

demanding and urgent tasks in an undesirable living environment and monotonous life. In such a work and life environment, it is imperative to pay attention to the emotional state of construction workers who are motivated by different social classes [3]. In addition, the current external competition of construction enterprises is becoming increasingly fierce, and in order to cope with the external pressure, enterprises need to give full play to their talents and mobilize the emotional engagement of their employees to cope with the market demands.

1.2. Social Exchange Theory. As one of the major theories of social interaction in the social sciences, theoretical and empirical applications involve extending the work of social exchange theory to the analysis of power and dependency, social networks, reciprocity, equity, social cohesion, and solidarity [4].

Airman and Taylor [5] studied relationship development from the perspective of social penetration, which led to the formulation of the well-known social exchange model of interpersonal interactions. Social penetration is viewed as a systematic process of self-revelation among individuals in interpersonal interactions in which people continually assess the quality of their interactions to determine whether they need to continue to invest. In contrast, the behaviors exhibited in social systems are the result of individual decision-making, where group members exchange various types of resources based on their assessment of and dependence on others. In previous research, the social exchange and exchange of information among construction industry practitioners can influence decisions on construction projects, which in turn affect work health and safety [6]. In addition, components of the emotional exchange model are often used to explain dynamic relationships such as emotional experience and expression [7]. It was also found that interpersonal relationships are continuously socially exchanged in a continuous developmental process and have a tendency to be increasingly rewarding.

1.3. Emotional Investment.
Emotional investment is a relational orientation in which individuals show loyalty and commitment to their work group and show mutual concern for their colleagues, and trusting interactions between participants help foster beneficial relational behaviors that in turn improve team performance [8]. It helps to improve team communication and thus effectively increases team effectiveness [9] As members' mutual interest increases, personal relationships accumulate and relationships with others become closer, and individuals make ongoing emotional investments in relationships [10], while each successful social exchange increases interdependence and commitment among work group members [11]. With increased interdependent communication, more and more team members have a higher level of emotional investment, which in turn leads to more effort for the team's goals and increases the satisfaction of other members. At the same time, the team environment evolves away from the previous mutual exchange of resources among group members to one in which the individual needs of members are met within the work group. Current research hot spots for emotional investment are applications to family groups of foster children [12, 13] and social media [14, 15], but we believe emotional investment can be applied to a broader range of domains.

1.4. Personal Rewards and Personal Costs.
Personal rewards refer to enjoyable or appreciated relational attributes that an individual receives in a relationship. Rewards are usually divided into six categories: money, status, love, information, things, and services. Each person defines rewards differently; what one person seeks may be worthless to another. Personal costs refer to the relationship attributes that individuals pay for in relationships that are annoying or disliked. For social exchange theory, successful resource exchange means that rewards can be maximized in exchange for the smallest possible personal cost. When this ideal social exchange is

achieved, group members increase their mutual contribution and commitment (e.g., [16]). Reciprocity signifies engagement and attachment among members, and the results of Xerri's [17] self-reported survey of 255 Australian engineering asset management employees indicated that the organizational support for members can positively predict employees' emotional attachment to the organization. Moreover, organizational support, emotional commitment to the organization, and employees' psychological well-being are mutually reinforcing, so individual rewards may be a more reliable predictor of reciprocity than costs. Therefore, we consider that personal rewards may be a better predictor of emotional investment than personal costs.

1.5. Adopting a Social Exchange Perspective to Analyze the Construction Industry.
To analyze in depth the attachment and especially the loyalty of construction workers to their groups, we applied social exchange theory to workers and managers in the construction industry, and to examine what characteristics this affective investment has due to the high mobility of the construction industry and how it relates to the social status of construction workers, an important aspect of construction project management theory has to be questioned. Our study is dedicated to find the correlation between social status and emotional investment in the context of a highly mobile profession like the construction industry. Behavior can be seen as the result of an individual's decision to make a trade-off between rewards and costs, a strategic framework for a game in which individuals or groups interact with society and the environment.

We emphasize the role of emotional investment in promoting work group survival and interdependence among team members, as quality relationships within the work group are the foundation for unlocking the individual potential for improved performance in the project environment [18]. In contrast, most studies on work groups emphasize group efficiency and output without examining the costs and rewards perceived by individual group members or the emotional investment members make in the group [19]. But an overemphasis on group output in the short term can have negative effects on group members' psychological well-being and performance and even on the long-term development of the group [20]. The reasons for this are as follows: first, if individuals feel a lot of pressure to perform in the short term and do not receive the emotional attention or personal rewards that are commensurate with the cost, group continuity is difficult to maintain and the long-term development of the group is not guaranteed [21], and group members may choose to leave, so long-term work group performance will be negatively affected. Second, if short-term team performance goals are overemphasized and members are required to sacrifice their personal interests to achieve them, members may reduce their efforts and knowledge contributions to the team [22], and in this case, although members do not terminate their ties to the group, their social interactions are reduced, individual emotional ties with other members are neglected, and the performance of the work group is similarly affected. Emotional support

such as motivation has been found to help with multiproject management in the industry, reduce burnout, and help retain project members [23].

As a human resource that needs to be developed in the current situation, the emotions of employees can have a significant impact on the dedication of corporate workers and the development and implementation of corporate systems [24]. In a study of the stress and burnout tendencies of members of different project groups, Pinto [25] found that project managers and construction workers had significantly higher levels of emotional exhaustion relative to other job types, so the construction industry should focus more on the social stratification of the practitioners in order to provide emotional de-escalation and management for groups vulnerable to psychological problems [3]. In view of the special characteristics of the work of employees in the construction industry, part of the employees are migrant worker groups with high job mobility and relatively high wage levels for some skilled workers with little room for promotion, and part of the employees are regular employee groups in construction enterprises with more stable jobs and relatively low wages, but with room for promotion within the enterprises. However, due to the inevitable existence of social prejudice, this paper classifies the group of migrant workers or contract workers as a group with relatively low social status and the group of regular employees within the enterprise as a group with relatively high social status. This paper examines team members' evaluations of personal costs and rewards and their own emotional investment in the work group and compares whether there are significant differences in the levels of emotional investment between the two groups and how their evaluations of personal costs and rewards affect their levels of emotional investment. In a social group, people with high social status usually interact emotionally with the group more than people with low status in the group.

In summary, this study focuses on the role of emotional investment generated by construction industry practitioners in the work group and its influencing factors. We consider the emphasis on affective investment and the focus on stratification of construction workers and the work environment as the main contributions of this study.

Based on the above statements, we build on the construction industry group and adopt a social exchange perspective to propose three hypotheses.

- (H1) People with high socioeconomic status have a higher level of emotional investment in the group
- (H2) High income does not affect the level of the emotional investment of individuals in the work group
- (H3) Personal rewards can be a better predictor of emotional investment than personal costs

2. Methods

The methods of this work consist of participants for surveys, questionnaires revised for Chinese contextures, and clustering analysis for defining the major factor affecting the emotional investments in the work groups.

Table 1: KMO and Bartlett test.

KMO measure of sampling adequacy		0.758
Bartlett's test of sphericity	Approx. chi-square	397.199
	df	36
	Sig.	0.000

Participants: due to the low participation of women in the architectural, engineering, and construction industry [26], a total of 71 (including 12 women) construction workers were selected to participate in this questionnaire for this study.

Objective of the surveys: to collect construction workers' level of emotional investment in work teams and team members' assessments of individual costs and personal rewards (including regular, contract, and migrant workers) by questionnaire survey method.

Study steps: this task focused on developing questionnaires and scales. The original scales and questionnaires were in English, and to translate all survey items from English to Chinese, we used the translation/back-translation procedure of Brislin [27] and then adapted them to the Chinese context. Finally, the adapted questionnaires and scales were tested for reliability and validity.

To test our proposed hypotheses, we conducted analyses at the individual level. We referred to Saavedra and Dyne [28] and selected three separate items from the cost-benefit inventory developed by [29, 30] based on social exchange in interpersonal relationships to assess individuals' perceptions of rewards and costs. Considering the purpose of this study is to examine the personal trait attributes and relational attributes of the different social status of practitioners within the construction industry, the items focus on the exchange of nonmaterial resources [28]. To measure affective investment, we used three items from Hackman's [21] assessment of members' perceptions of group well-being. A principal components analysis was conducted on nine items to ensure that the scale we used would achieve the predicted effect. The results indicated that the three factors, emotional investment, rewards, and costs, together accounted for 77% of the variance. Table 1 examines the suitability of the scales we used for principal components analysis, and Table 2 lists the individual items and the factor loadings for each item.

This study used the KMO (Kaiser–Meyer–Olkin) test to statistically compare the correlation coefficients between the variables, which yielded a KMO value of 0.758, which is greater than 0.7 (KMO takes values between 0 and 1, and the larger its value, the more suitable the original variables are for factor analysis). In addition, Bartlett's test $P < 0.05$, the above data indicate that it is appropriate to do factor analysis on the above items.

In addition, we conducted separate reliability analyses for the items measuring each factor in the scale, and Cronbach's α coefficients for each item measuring the three factors of emotional investment, personal cost, and personal reward were 0.857, 0.739, and 0.893, respectively, all greater than 0.7, meaning that the reliability of each item in the questionnaire was high.

TABLE 2: Factor analyses of self-report items.

Items	F1 personal rewards	F2 emotional investment	F3 personal costs
1. The members of my work team listen to me.	0.831	0.208	0.080
2. I feel needed by my work team.	0.863	0.376	0.068
3. I feel comfortable when I voice my work in work group.	0.835	0.348	079
4. Our team members have a strong sense of loyalty to the team.	0.235	0.925	0.010
5. Our work team members care about the collective and are committed to making it better.	0.370	0.888	0.021
6. I do not want to change the members of our work group.	0.442	0.597	0.128
7. Since I am friends with the members of my work team, I undertake a lot of extra responsibilities.	0.210	0.205	0.832
8. I often compromise my ideas by considering the preferences of other team members.	0.084	0.064	0.826
9. To integrate into the work group, I must sacrifice a great deal of personal independence.	0.223	0.043	0.765

3. Results

To test whether social status affects the level of individual affective investment, we conducted an independent sample t-test on the overall affective investment level between the regular and migrant worker groups, and the results are reported in Tables 3 and 4.

From the results of the independent sample t-test, it can be concluded that within the confidence interval of 99%, the level of emotional investment between regular and migrant worker groups is significantly different, and the level of the emotional investment of regular workers is significantly higher than the level of the emotional investment of migrant workers in work groups (The Emotional Investment Questionnaire items were selected on a seven-point scale, with a choice of 1 meaning strongly agree and a choice of 7 meaning strongly disagree). The formal worker group and the migrant worker group have different socioeconomic status, and it follows that socioeconomic status affects the emotional investment of individuals in the work group, and individuals with higher socioeconomic status have higher emotional investment in the work group; therefore, H1 is confirmed.

In order to describe the intergroup differences more intuitively in the overall level of emotional investment in different social status within the construction industry, we conducted a cluster analysis of the results of the emotional investment survey, the results of our survey on sentiment investment were analyzed in Origin using the K-mean algorithm for clustering. As a mainstream data analysis software, Origin has two main functions: data analysis and plotting. Origin's data analysis includes a variety of sophisticated mathematical analyses such as statistics, signal processing, image processing, peak analysis, and curve fitting. We use K-means, an unsupervised learning algorithm for solving clustering problems. The K-means method is a classical algorithm in clustering, one of the top ten classical algorithms for data mining; the algorithm receives the parameter k and then divides the n data objects entered in advance into k clusters, in order to satisfy that the objects in the clusters are more similar, while the objects in different clusters are less similar. The idea of the algorithm is to cluster

TABLE 3: Analysis of social status among construction workers.

	Overall emotional investment level			
	N	Mean	SD	Std. error mean
Regular worker	36	6.8333	3.48727	0.46601
Migrant worker	35	6.8857	3.28194	0.49477

the k points in the sample space, grouping the objects closest to them and updating each cluster centre one by one by iterative methods. The results are shown in Figure 1.

From the results of the cluster analysis, the distance of the vertical coordinate represents the difference in the level of emotional investment between the samples, and the horizontal coordinate represents the individuals; it can be seen that individuals belonging to the same social class are more aggregated and show more similarity in emotional investment, thus concluding that the social stratification in the construction field is obvious, and different groups based on different social classes differ in the characteristic of emotional investment level, while within the group, this characteristic is similar. The characteristics are similar within groups.

In addition, this study tested whether the level of personal income affects the emotional investment of individuals in the work group. The mean of the income levels of the 71 construction industry workers collected in this study was 1068.5 US$, so we used 1068.5 US$ as a cut-off for high- and low-income levels, with those below the mean income considered as a low-income group and those above the mean income considered as a high-income group, and conducted independent sample t-tests on the overall emotional investment levels of the two groups. The results are reported in Tables 5 and 6.

As can be seen in Table 6, the difference in the overall level of emotional investment between the high-income group and the low-income group is not significant at a confidence interval of 99%, indicating that there is no significant effect of high income on the level of the emotional investment of individuals; therefore, H2 is proved.

TABLE 4: Differentiation in the level of emotional investment across social classes is shown by t-test.

		t	df	Sig (2-tailed)	Mean difference	Std. error difference	99% confidence interval of the difference	
							Lower	Upper
Overall emotional investment level	Equal variances assumed	−5.76	69	0.000	−3.80049	0.66535	−5.5926	−2.0677
	Equal variances not assumed	−5.76	44	0.000	−3.80049	0.69693	−5.7071	−1.9532
FIGURE 1: Intergroup differentiation in the level of emotional investment between regular workers and migrant workers through cluster analysis (RW = regular workers, MW = migrant workers).

We used hierarchical regression analysis to test H3, and the results are shown in Table 7. When both costs and rewards were regressed on affective investment, only rewards contributed unique and significant variance, indicating that individual rewards were the best predictor of affective investment among work groups in the construction industry; therefore, H3 is confirmed.

4. Discussion

Our goal is to illustrate the dynamics of relationships in the construction industry's work community on an emotional dimension, integrating concepts such as satisfaction, investment, and commitment. In the construction industry, construction workers are usually part of a work team, and

TABLE 5: Analysis of the income level of construction workers.

	Monthly income level	N	Overall emotional investment level		
			Mean	SD	Std. error mean
High-income group	≥1068.5 US	36	6.8333	3.48727	0.46601
Low-income group	<1068.5 US	35	6.8857	3.28194	0.49477

TABLE 6: The relationship between income level and emotional investment is illustrated by t-test.

		t-test for equality of means						
		t	df	Sig (2-tailed)	Mean difference	Std. error difference	99% confidence interval of the difference	
							Lower	Upper
Overall emotional investment level	Equal variances assumed	−0.7	69	0.98	−0.05238	0.80755	−2.1916	2.0868
	Equal variances not assumed	−0.7	69	0.948	−0.05238	0.80709	2.1903	−2.0856.

TABLE 7: Hierarchical regression analysis of emotional investment and personal costs and rewards.

Dv	IV	Adj. R^2	F	Beta for IV's
Emotional investment	Rewards	0.472	62.566	0.692
Emotional investment	Costs	−0.008	0.421	0.078
Emotional investment	Rewards Costs	0.464	30.883	0.690 0.022

poor work team relationships predict the work stress of construction workers, and their psychological perceptions greatly influence their behavioral and safety performance, and it is particularly important to study the impact of the work team on construction workers as key and indispensable contributors to each construction project [31]. Research sponsored by the American Society for Quality Control in conjunction with Fortune 500 companies shows that employees see teams as both a platform for personal development and a way to promote [32]. Studies have shown that construction workers with different levels of perception of group norms exhibit different personal safety behaviors at work. In addition, when construction workers were in different groups (e.g., work groups, projects), their perceptions of identity showed significant differences, thus introducing the idea that social identity with a group can moderate the effect of group norms on construction workers' personal safety behavior standards [33]. These findings also suggest new ideas for the management of the construction industry: improving the level of social identification and emotional investment of construction workers in their work group, which in turn improves communication in the team, and effective communication is an important factor in improving team effectiveness, thus enabling construction workers to have better emotional states while improving construction worker safety behaviors and increasing the efficiency of construction project completion.

Furthermore, most research on social exchange has focused on the cognitive aspects of relationships and has mostly examined binary exchanges between individuals, rarely addressing the affective aspects of social exchange. Therefore, this study examines the affective aspects of social exchange in structurally diverse pluralistic work groups within construction companies, extending the scope of the application of social exchange theory. However, excessive emotional attention may lead to a marked decrease in group members' openness to dissenting opinions [34]. By ignoring and excluding different insights and irreconcilable information, groups may make decisions that have serious adverse consequences. These problems are particularly evident in the construction industry, where the completion of projects in the construction industry relies on a variety of task environments such as raw materials, construction personnel, and market research in order to achieve them. Therefore, a balance between efficiency and emotion is needed to solve these problems.

The limitations of this paper are mainly reflected in the following aspects, which we will improve in our future research: firstly, due to the special nature of the sample of construction industry practitioners, the sample size we collected was not very large, but in future research, we will try our best to seek the cooperation of relevant construction companies in the hope that a larger sample size can be obtained. Also, during the data collection process, we discovered an interesting phenomenon: the vast majority of those working in the construction industry are men. This gap persists despite efforts to close the gender gap in the construction and engineering workforce and advocate for gender diversity over the past few decades [35, 36]. Outside of gender, age may have an impact on respondents' level of emotional investment [37], which needs to be refined in the future research. Perhaps in a more in-depth study in the future, we can make a more nuanced segmentation of construction industry practitioners to further explore the

social exchanges they engage within their work groups. Finally, this study did not include team performance in the overall structure, and in further research, we plan to explore the impact of emotional investment in work teams on team performance and create a more comprehensive research system considering that emotional investment may cause individuals to overestimate their actual abilities [38].

With the emergence of the Industry 4.0 era in China, more refined methods are being proposed for healthy living requirements for human settlements. Since the rural human settlements in China are relatively backward, this study aimed to investigate the influencing factors of human health. First, through field surveys and questionnaires conducted with villagers in Xiangxi's traditional villages in Hunan Province, we analyzed the factors affecting human health qualitatively and quantitatively using the SPSS software. We identified three main dimensions affecting human health in rural human settlements including human behavioral activities, physical environment, and natural environment. Then, we used correlation analysis and multiple linear regression analysis methods to analyze the correlation between environmental factors and human health. The results showed that human activities, building physical environment, and natural environment are significantly correlated with human health. Among them, human behavior has the strongest correlation with health. This research contributes to creating healthy human settlements and guiding the creation of a healthy environment in rural China.

1. Introduction

Under the backdrop of the Industry 4.0 paradigm, various industries around the world are gradually intelligent, integrated, and automated. Big data, interconnections, and artificial intelligence have been applied in the construction elements, which tend to develop in the directions of digitized, multifunctional, and health promotion [1–10]. Compared with traditional construction methods, Industry 4.0 has brought an innovation orientation and technological advancements to China's construction industry and improved the quality of human settlements, efficiency, and safety of construction processes [11–17]. With the increased emphasis on health performance in settlements, how to build a living environment that meets the needs of human health in the era of Industry 4.0 remained unclear, especially on environmental factors that affect health in different settings. Existing research on healthy architecture and living environments is valuable and involves multidimensional and multilevel fields, such as medicine, psychology, society, and planning [18–21].

In recent years, under the background of Industry 4.0, science and technology have developed rapidly in China. Research on the health of human settlements has been extensive, but most of it relates to urban settlements, while studies on the construction of traditional villages have been rare [22]. The production mode of construction industrialization has many advantages, including high production efficiency, good quality, low construction cost, saving resources, and protecting the environment. It can greatly improve the problems existing in rural housing, with the following positive effects:

① Improve the quality of housing construction

② Improve energy conservation and emission reduction

③ Improve the style of rural housing

④ Improve the construction speed

⑤ Improve the comfort of living environment

⑥ Reduce construction costs

⑦ Stimulate rural economic growth and resolve excess capacity [23, 24]

Therefore, the industrialized production of construction is the development trend of the construction mode of new rural construction in the future, and the state has issued a series of policies and measures to promote the industrialized construction and development of rural areas. To further promote the steady and healthy development of industrialization in rural areas, the healthy living environment in rural areas [23, 24]isfocused. Due to the acceleration of China's economic, social development, and process of urbanization, a large number of young laborers from rural areas have poured into cities, resulting in the widespread phenomenon of elderly people and children left behind in rural areas and even the emergence of "ghost villages." Numerous theoretical studies have shown that the living environment is directly related to the physical and mental health of the residents[25–27]. The rural environment in China is significantly different from the urban environment in terms of infrastructure, humanities and culture, and living conditions, thus resulting in significant differences in the physical and mental health levels of different groups of residents [28–30]. Generally, the village environment is rich in green resources and has good geography. In addition, the layout of the village and the housing structure follow the traditional idea of harmony between man and nature. These factors have a positive impact on human health. At the same time, bottlenecks in transportation, poor infrastructure construction, and physical environment need urgent improvements as such problems have a negative effect on people's physical and mental health. Therefore, to optimize rural human settlements and improve their physical and mental health, we aimed to conduct a correlation study on the influencing factors of health among rural humans.

2. Literature Review

Human health is a complex and comprehensive research topic involving multiple fields of study, such as medicine, sociology, and environmental science. Human settlement is a complex manifestation of many factors related to humanity, nature, and society. A healthy and comfortable human settlement can stabilize people's emotions and is conducive to physical and mental health; hence, building healthy human settlements is one of the trends of the construction industry under the background of Industry 4.0. In foreign countries, they have paid more attention to the construction of healthy human settlements earlier and have obtained substantial research results. Many international organizations, such as the World Health Organization, the European Environment Agency, and the United Nations Environment Program, have issued a series of guidelines and standards for healthy environments [31, 32]. In recent years, the WELL building standards released in the United States have established indicators for assessing the building environment across seven areas, namely air, water, nutrition, light, fitness, comfort, and mood. The associated research has presented various perspectives [33]. Previous research scholars have used different methodologies and techniques to systematically assess the health performance of living environments involving different spatial environments and

specific populations [34, 35]. In addition, previous mixed-methods studies have examined the interactions and feedback between multiple environmental physical factors and human health and propounded the possibilities and ways to achieve healthy living in an increasingly urbanized built environment [25, 36–44].

With the emphasis on healthy human settlements in China, deep and relevant research in multiple fields has been developed. Numerous scholars have analyzed in detail the health indicator systems of different urban environments, including transportation systems, infrastructure, air quality, sewage treatment, health care, social development, environmental management, and lifestyles. Many analysis methods have also been used to conduct relevant health assessments on environmental factors [45–52]. Most studies on healthy human settlements in China have focused on urban areas, whereas the rural environment in China has significant differences from urban areas in terms of spatial distribution, lifestyle, humanistic characteristics, infrastructure, and other environmental factors. Many studies have shown that various environmental factors with distinct rural characteristics influence people's lifestyles and behaviors at the social, humanistic, and material levels, which in turn have positive or negative effects on human physical and mental health [53–58]. Therefore, this work took Xiangxi's traditional villages in China as an example and conducted a correlation study on their human settlements related to human health.

3. Research Plan Design

3.1. Research Object. There are many traditional Chinese villages with obvious and different characteristics. With regard to the list of five batches of "Chinese traditional villages" published, the number of traditional villages distributed in Xiangxi has reached 172. At the same time, due to the special geographical and ecological environment and historical changes, Xiangxi still retains a relatively complete village form and humanistic tradition. Since ancient times, many ethnic groups, including Miao, Han, Tujia, Dong, and Yao, have been living in the area, with strong ethnic characteristics and living features. Therefore, we selected traditional villages with essentially complete settlement patterns as the main research focus. Our list comprised Lahao Village in the Duli Township of Fenghuang County, Laodong Village in the Machong Township, and Guantianshan Village (Figure 1). The long-term residents of the village were randomly selected as the study participants. Following uniform standards, we adopted methods such as the interview and participatory observation method to obtain information from the participants. Basic data were obtained by mapping and basic testing the human settlements of the villages.

3.2. Research Methods. To obtain the health indicators of the permanent residents in the Xiangxi rural environment, this study used the SF-36 scale to measure the eight dimensions of general health, physical function, physical role, somatic pain,

Figure 1: Area where the Xiangxi villages are located.

vitality, social function, emotional function, and mental health [59, 60]. The average of the total scores of the eight dimensions was used as the dependent variable y as an overall indicator for health evaluation. Second, according to the survey indicators of the human settlements, a questionnaire for the healthy villages' human settlements was constructed by reviewing the literature and consulting experts while considering the operability of data collection and the specificity of village lifestyles. When screening the evaluation indicators of the questionnaires, the first-level criteria layer was determined as the three dimensions of human behavior, natural environment, and physical environment by literature review. The secondary evaluation factors were 16 relevant environmental evaluation indicators based on existing studies, and after consulting with relevant scholars and experts by email in various fields such as architecture, planning and design, and landscape professionals, the evaluation feedback was filtered and modified based on expert feedback. After multiple additions and deletions of evaluation factors, a total of 18 factors were determined from three dimensions of human behavior, natural environment, and building physical environment. Related questions were set up around the 18 factors to form a structured questionnaire (Table 1). By designing a Likert scale, this study divided the evaluation factors of the environment into five evaluations based on the statements regarding the attitudes of approval or disapproval: very good, good, fair, poor, and very poor. We transformed the scale into a fixed-distance evaluation level of subjective evaluation [61, 62].

Correlation analysis was performed on the health self-assessment results and environmental influences. Subsequently, multiple linear regression analysis was used to establish regression equations to further explore the association between health and environment. All analyses were performed using SPSS.

3.3. Research and Analysis

3.3.1. Sample Characteristics. Of the 160 questionnaires distributed, 153 participants completed the assessment. The effective response rate was 95.6%. Among the 153 qualified

Table 1: Human settlement assessment factors of Xiangxi villages.

Dimension (A)	Evaluation factor (B)
Human behavior (A1)	B1 daily physical pattern and frequency B2 daily walking distance B3 frequency of communication with neighbors B4 daily hobbies and interests B5 daily cooking style B6 understanding of and access methods to health knowledge
Natural environment (A2)	B7 air quality of the natural environment B8 climate temperature and humidity comfort B9 daily noise pollution B10 waste disposal methods B11 medical level and care
Physical environment (A3)	B12 living house orientation B13 indoor temperature and humidity in summer and winter B14 construction methods and materials of the houses B15 indoor hygienic environment conditions B16 indoor ventilation and lighting conditions B17 indoor and outdoor vegetation and greenery B18 embodiment of regional culture decoration

participants, 73 (47.7%) were aged over 60 years and 83 (54.2%) were female (Table 2). In the SF-36 health assessment, 19 (12.4%) rated their overall health status as "excellent," 53 (34.6%) as "very good," 45 (29.4%) as "good," 35 (22.9%) as "fair," and 1 (0.7%) as "poor."

Xiangxi is in the northwestern part of Hunan Province, China, east of the Wuling Mountains areas of the Yungui Plateau. In total, 401 villages in Hunan Province are included in the fifth batch of the list of traditional villages in China, and Xiangxi accounts for 90 villages. Xiangxi is dotted with many Miao traditional villages of different forms and long histories. The climate in Xiangxi has four distinct seasons, with rainfall concentrated between April and June, accounting for 41–47% of the annual precipitation. Due to the complex terrain and the influence of airflow, the amount of solar radiation received varies, and the lighting and temperature of each region are different.

As an example, a typical local traditional residential building was mapped and tested for temperature, humidity, and light level. Using a French KIMO HD100S portable hygrometer thermometer with a temperature and humidity monitor, measurements were taken during the hours of 8 : 00–19 : 00 from January 15 to January 17 in a typical local winter season and from July 9 to 11 in a summer season, and the temperature and humidity of the measurement points (at 1.1 m from the ground) were recorded with an interval of 30 minutes. The measurement points were at five locations: outdoor courtyard, lobby, bedroom, kitchen, and fire pit, as shown in Figure 2 and Table 3. The results showed that the

TABLE 2: Summary of basic information of the questionnaire.

Statistical index		Frequency	Proportion (%)
Gender	Male	70	45.8
	Female	83	54.2

5	29.1	89.2
1	6.4	75.7
2	7.3	78.5
3	7.1	77.7
4	7.9	79.6
5	8.5	76.9

indoor and outdoor humidity was generally high, and the difference between the indoor and outdoor temperatures in summer and winter was within 3 °C due to the influence of the houses' construction materials and methods. The residential heating in winter mainly relied on firewood, which causes pollution.

TABLE 4: Illuminance data of the measurement points in summer and winter.

Measurement point	Summer illuminance (lux)	Winter illuminance (lux)

2	330	281
3	236	168
4	305	204
5	179	115
6	158	177

TABLE 5: Reliability test results.

Cronbach's coefficient	Number of terms
People 0.723	4
Building 0.972	10
Nature 0.849	4

To measure the indoor and outdoor illumination conditions, a Sigma AS82 handheld illuminance meter was used, and measurements were made at 12:00 noon on January 15 in winter and July 9 in summer. The weather we chose to measure was cloudy days without precipitation in winter and sunny days in summer, as shown in Table 4. Considering the different degrees of the influence of illumination on functional rooms, the measurement points included the outdoor courtyard, foyer, bedroom, kitchen, and fire pit. In addition to the five measurement points, the bathroom was also included as an illumination measurement point, as shown in Table 4. Due to the long scale of building depth and the limitation of building materials for the window and door openings, the indoor lighting was fair.

3.3.2. Reliability and Validity Test. This study used Cronbach's alpha coefficient to test the inherent reliability of the survey questionnaire. The range of Cronbach's alpha coefficient is between 0.00 and 1.00, with higher values indicating higher reliability and lower values indicating lower reliability. The survey results show that the overall Cronbach's alpha coefficient of the dimension of human behavior in the questionnaire was 0.723; the coefficient of the second dimension of the questionnaire of the physical environment of the building was 0.972; and the coefficient of the third dimension of the natural environment was 0.849, indicating that the questionnaire had good reliability and the measurement results were reliable (Table 5).

Validity tests were conducted using structural validity, and the KMO test and the Bartlett sphere test were used. When the KMO test coefficient is greater than 0.50 and the Bartlett sphere test, X2 has a P value less than 0.05, and the research questionnaire has structural validity. Validity tests were performed on the three dimensions, and the respective KMO test values were 0.702, 0.903, and 0.801, all of which were greater than 0.70. The corresponding P values were less than 0.05. The significant difference between the correlation coefficient and the unit matrix indicates that there is a

**$P < 0.01$. *$P < 0.05$.

correlation among the survey data. Therefore, the questionnaire has structural validity.

3.3.3. Correlation Analysis.
Through the analysis of the questionnaire, the total score of the eight dimensions of the SF-36 health evaluation result was used as the dependent variable y, and the 18 environmental factor assignment calculations were divided into three dimensions using SPSS for correlation analysis. The Pearson correlation value is between [−1, +1]. A value greater than 0 means positive correlation, and a value less than 0 means negative correlation. The closer the absolute value is to 1, the stronger the correlation is. Since the data belonged to different populations, to decrease potential confounding of health status, gender, age, and education level were added to the correlation analysis as independent variables. In the correlation analysis results, the significance of the four variables of people, build, nature, and age is 0.000, 0.039, 0.009, and 0.000, all of which were less than 0.05 and statistically significant. Among population attributes, gender, education level, and health status had no significant correlation, while age and health status were significantly negatively correlated. In addition, the Pearson value corresponding to age is -0.495, indicating a negative correlation, and the older the age, the worse the health. In the three dimensions of people, build, and nature, the value of the Pearson correlation with y was 0.520, 0.167, and 0.211, all of which are positive numbers, suggesting that the variables of the three dimensions are positively correlated with the dependent variable y. Table 6 shows that human behavior has a stronger correlation with health status, whereas the correlation between the physical and natural environment of the building and health status is weak. Among these three dimensions, the factors that have the strongest correlation with health status are "daily physical activity level," "summer indoor temperature evaluation," and "housing orientation evaluation."

3.3.4. Regression Model Establishment.
The independent variables were quantitative and more than one in number in our research, so we choose the multiple linear regression analysis method to examine the relationship between the independent variables of the three dimensions and health status. The mathematical model of multiple linear regression is $E(y) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_p$, where x_p explains the linear change in y caused by the change in variable x; $x_p (i = 1, \ldots, p)$ is the independent variable; p is the number of independent variables; β_0 is the constant term of the regression equation; and $\beta_p (i = 1, \ldots, p)$ is the regression coefficient.

The scores of gender, age, education level, mean values of the scores of human behavior, building physical environment, and natural environment were taken as the six independent variables, and regression analysis was performed with the dependent variable as health status. The results show that the D-W test value was 1.630 and its value tended to 2, indicating that there was no autocorrelation. That is, heteroscedasticity was considered not to exist (Table 7). R^2 was 0.508, which suggested that the independent variables of the three dimensions could jointly explain 50.8% of the dependent variable.

We performed the F test on the model, and the model's P value is less than 0.001, indicating that the model passed the F test, and the linear relationship was valid. At the same time, the statistical significance of the regression model also indicated that compared with the null model, the inclusion of independent variables helped to predict the dependent

TABLE 7: D-W test results.

Dependent variable: y.

variable, or that the model was better than the null model; that is, at least one of the six independent variables could affect the health status (Table 8).

Through the verification analysis, the results of the histogram showed that the curve was roughly normal distribution; the closer the distribution of each point in the normal P-P graph was to the diagonal line, the closer the data were to the normal distribution. Figures 3 and 4 depict that the residuals were approximately normally distributed, and the regression model was statistically significant.

In the regression, the dependent variable y was health status; the independent variables were gender, age, education level, people, building, and nature, which represented the four independent variables of age, human behavioral activities, building physical environment, and natural environment, respectively. The P value for each of these four independent variables was less than 0.05. The following equation was established:

$$\begin{aligned} Y = {} & 122.422 - \text{gender} * 2.230 - \text{age} * 10.395 \\ & - 1.312 * \text{education level} + \text{people} * 12.095 \qquad (1) \\ & + \text{building} * 4.259 + \text{nature} * 5.122. \end{aligned}$$

That is, for each additional person, y increased by 12.095 units; for each unit increase in building, y increased by 4.259 units; for each unit volume increase in nature, y increased by 5.122 units; and for every unit increase in age, y decreased by 10.395 units (Table 9).

4. Conclusions and Recommendations

With the acceleration of China's economic and social development and urbanization, the population structure of China is gradually changing into an aging population. In this study, 47.7% of the study participants were aged 60 years and above; most of the elderly were unaccompanied by children at home; and their physical functions have reduced over time. Some studies have shown that age is one of the main elements affecting health assessment, followed by gender, income, physical environment, health-related behaviors, and regional medical level. These are all factors relevant to health status [63–67].

The results of the univariate analysis in this study show that age was correlated with overall health negatively and significantly; that is, the higher the age, the lower the health self-assessment score. Income and education were not significantly correlated with health assessment results, and this result was related to the overall low income and low education level of the research subjects. At the same time, the results of this survey show that gender was not significantly correlated with health assessment results, because within the scope of the survey, gender differences are associated with cultural, social status, division of labor, living habits, etc., all of which can indirectly affect physical health [68, 69]. Among the eight dimensions of health assessment, older adults had lower mental health scores and generally were depressed and had negative emotional conditions due to lack of family companionship and recreational life. Some scholars have found that gender, age, ethnicity, hobbies, life satisfaction, and physical health were associated with mental health among the Xiangxi older adults [70–72].

Second, about 82.4% of the villagers among the research subjects needed to perform daily work activities and therefore maintained a certain amount of daily exercise. In the correlation analysis of this study, the factor "daily physical activity level" in the dimension of "human behavior" was significantly correlated with the health status. In the specific environment and cultural background of rural areas in China, work activity is an essential life support behavior, and this necessary lifestyle has a positive impact on the health of the research subjects. In the survey area, many medical records and surveys have shown that the lifestyle, medical condition, and labor intensity had a certain impact on human physical and mental health, and the health level of urban and rural residents is different [73–75].

The building physical environment has a direct impact on human perception, and the results of this study show that the "building physical environment" has a significant correlation with health status. We investigated the issues related to the setting of room temperature and humidity, kitchen drainage, and room spatial scale in the building physical environment. The strongest correlation with the dependent variable health status was the "summer indoor temperature evaluation." This is consistent with many existing research results such as indoor air pollution, heat, and humidity conditions affecting human health [76].

The natural environment is closely related to human health. In traditional Chinese culture, related theories emphasize the harmonious relationship between nature, architecture, and human beings. Our findings suggested that the natural environment and health status have a significant correlation, among which the univariate analysis showed that the "housing orientation evaluation" under the "natural environment" dimension had the strongest correlation [77–80].

Lastly, we proposed the following suggestions for healthy rural human settlements in Xiangxi. (1) Pay attention to the physical and mental health of the elderly living in the villages; increase the village infrastructure for adapting to the aged; improve the medical service system; enrich the recreational life of the middle-aged and elderly; and realize "healthy elderly care." At the same time, promote healthy lifestyles and popularize knowledge about healthy living for all. (2) Improve the living environment of villages and improve the comfort and convenience of the indoor environment of buildings. Modernize and renovate the pollution sources of the indoor environment and pay attention to the heat insulation performance of the houses. (3) Consider the orientation and the influence of light in the layout and site selection of the building. Draw lessons from the traditional village Taoist law of nature, the harmony between man and nature, and the movement according to time. Focus on the relationship between man and nature in urban architectural design to promote a positive impact on human health.

The questionnaire design in this study considered limited dimensions and factors. Considering the operability and practicality of the data, it mainly focused on architecture and environmental psychology, but many environmental impact factors were not included. Future studies should consider including more covariates.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare no conflicts of interest.

Authors' Contributions

S.T., Y.Z., and Z.L. conceptualized the study. S.T. and Y.Z. developed methodology, performed formal analysis, and wrote and prepared the original draft; S.T. and Z.L. reviewed and edited the manuscript. Y.Z. visualized the study; S.T. supervised the study and administered the project; and Z.L acquired funding. All authors have read and agreed to the published version of the manuscript.

In order to explore the architectural space model of design, a visualization method based on big data map is proposed. Referring to the tile pyramid model, a multidimensional aggregation pyramid model (MAP) is proposed, which extends the 2D spatial hierarchical aggregation of tile pyramid to the multidimensional of time/space/attribute and supports the multidimensional hierarchical aggregation of time, space, and attribute. Then, taking spark cluster as the parallel preprocessing tool and HBase distributed database as the persistent storage of map model data, an open-source distributed visualization framework (MAP-Vis) is realized. Then, the BIM model is reconstructed, and a component instance hierarchical splitting strategy based on IFC structure tree is proposed to separate the digital and analog of the original IFC file. The reconstructed IFC model file is transformed into glTF format file, and the dual relationship mapping of geometric space and semantic attributes is completed in the transformation process. Finally, the visibility detection algorithm of BS-AB scene components based on the hierarchical bounding volume (BVH) structure is proposed to eliminate the visibility of building components. The experimental results show that BIMviews is slow to load the IFC file of the experimental object and obtain the model data, with an average of about 40 s, and the Caton is obvious. However, it only takes about 7 s to load glTF file into big data map visualization design by Three.js. It is verified again that glTF format is more suitable for BIM model data than IFC format. The visualization design, display, and interaction based on big data map are based on glTF format. It proves the effectiveness of big data map visualization.

1. Introduction

With the maturity and diversification of data acquisition means such as personal intelligent devices, floating car GPS, Internet of things, and social media, the data sources are becoming richer and richer, and the amount of data collected is increasing explosively. These big data with huge volume, stream generation, numerous types, and value contain both space-time and high-dimensional characteristics [1]. Spatiotemporal features refer to data with spatial location and time tag or attribute fields that can reflect spatiotemporal location. High-dimensional feature refers to that the data contain other feature attributes except time and space, and the information law reflected by these attributes is often more valuable for research. Visualization is an important step and means of analyzing and mining spatiotemporal big data, which can directly reflect the patterns and

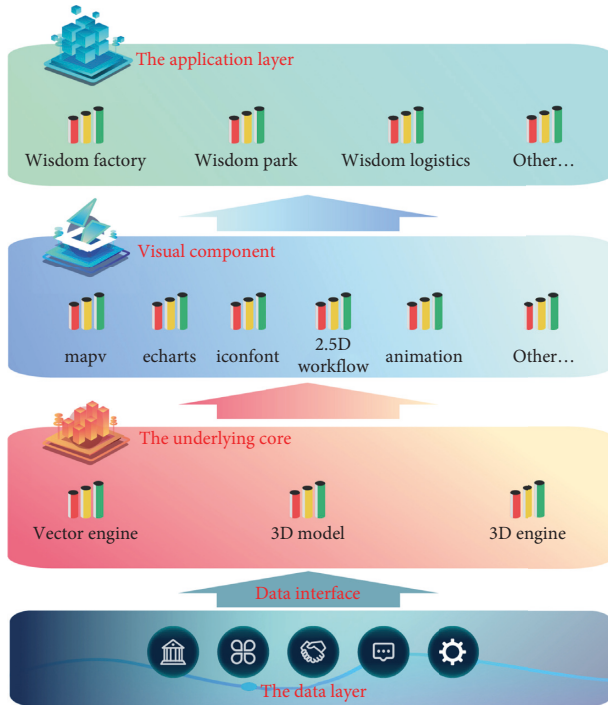
laws contained in the data. The building information model (BIM) provides advanced digital tools and information-sharing platform for the information management of the whole life cycle of construction projects. It solves the problems of information transmission fault and data-sharing difficulties faced by traditional facility engineering and has been widely used in architecture, engineering, construction, and facility management (AEC/FM) [2] (Figure 1). The greatest value of BIM lies in the efficient collaboration between multiple participants and multiple disciplines. With the continuous increase of building scale and the increasing complexity of building information data, its model visualization and massive data management become more and more difficult so that it cannot meet the current BIM localization application requirements of engineering construction information data management, sharing, and synchronization. Obviously, while meeting the


FIGURE 1: Big data map visual design.

needs of multiple users to access anytime and anywhere under different devices and different operating systems, it is particularly important to effectively ensure the integrity semantics of BIM model and data interoperability [3].

2. Literature Review

Zhu W. puts forward the general laws and characteristics of the thinking process of architectural creation and combined and summarized the visual expression and design tools [4]. Zhao L. divided the visual media of design into three aspects, drawing, solid model, and digital design, and analyzed how it affected the design information, so as to better complete and express the design [5]. MW Kowalczyk attempts to visualize the architectural design process from the perspective of computer programming [6]. Djari C. systematically summarized the development of relevant factors, information sources, design carriers, and expression tools of visualization technology and theory and discussed the specific application in different stages of the design process, to provide effective visual expression ways for designers in the process of architectural design [7]. Ladlf Su á rez proposed sequence snapshot and model in "time in GIS." The sequence snapshot model is the simplest spatiotemporal data model at present. It is widely used in various temporal GIS systems. This data model completely stores the state data at different times in the study area so that the objects that have not changed are repeatedly saved, resulting in data redundancy and reducing the use efficiency of the system [8]. Haiyan et al. proposed a ground state correction model on this basis, which only saves the initial state data and the change amount of the change part relative to the initial state in the study area, greatly reducing the data redundancy. However, these

models are only simple time simulation and do not really solve the problem of space-time combination [9]. Guan proposed a spatiotemporal composite model for the vector model, which divides space into a set of spatiotemporal composite units representing the same time process [10]. The spatiotemporal object model proposed by Zou Y. introduces the time dimension to make it orthogonal to the two-dimensional space and abstracts the real world into a discrete object set composed of spatiotemporal atoms. This kind of model mainly tends to the spatial change of geospatial entities with time, which is a simple simulation of the spatiotemporal change process of the research object [11]. Fu et al. proposed a three-domain model of space-time. They believed that simply introducing time as a new dimension into the space-time data model could not fully express and display the world, so they organized the space-time data from the perspectives of location, time, and object. With the emergence of object-oriented technology in computer, the real world is abstracted into a set composed of different types of objects (entities), and an object-oriented spatio-temporal data model is established. This model has great advantages in describing complex phenomena [12]. Mehta extended the spatiotemporal atomic structure by using Brisson lattice complex and proposed an object-oriented spatiotemporal data model based on lattice tuples [13].

Based on the current research, a method of map visualization based on big data is proposed. Referring to the tile pyramid model, a multidimensional aggregation pyramid model (map) is proposed, which extends the 2D spatial hierarchical aggregation of tile pyramid to the multidimensional of time/space/attribute and supports the multidimensional hierarchical aggregation of time, space, and attribute. Then, the BIM model is reconstructed, and a component instance hierarchical splitting strategy based on the IFC structure tree is proposed to separate the digital and analog of the original IFC file. The reconstructed IFC model file is transformed into glTF format file, and the dual relationship mapping of geometric space and semantic attributes is completed in the transformation process. Finally, the visibility detection algorithm of BS-AB scene components based on the hierarchical bounding volume (BVH) structure is proposed to eliminate the visibility of building components.

3. Visualization Design of Big Data Map

3.1. 2D Pyramid Model. In the geographic information system (GIS), the tile map pyramid model is often used for 2D map display. It is a multiresolution hierarchical model. From the bottom to the top, the resolution of pyramid is getting lower and lower. The pyramid contains multiple layers. Each layer is spliced by multiple square tiles, and each tile is composed of pixels (the default resolution is generally 256×256 pixels). In order to describe the construction process of the 2D pyramid model more accurately, the following concepts are defined in this study:

(1) Pixels: the pixel is the smallest data unit of the pyramid model; that is, a single pixel in the tile in the tile pyramid level is expressed as

$$\text{pixel} = \{l, x, y, p\}, \tag{1}$$

where l is the hierarchy of the pyramid, X and y are the spatial range contained in the pixel, and p represents the characteristic sampling values within the spatial range corresponding to the pixel, such as aggregate statistical values, such as mean and sum.

(2) Tiles: tiles in the tile pyramid model are a combination of pixels adjacent to space, and the default resolution is 256×256 pixels, which is expressed as

$$\text{tile} = \left\{l, X, Y, \overset{w \times w}{\underset{i=1}{\cup}} \text{pixel}\right\}, \tag{2}$$

where l is the hierarchy of the pyramid, X and y are the row and column numbers of the tiles, w is the resolution of the tiles, and the last union represents the set of pixels within the space of the tiles [14].

(3) Pyramid: pyramid is a spatial multiscale model composed of tiles at all levels and is expressed as

$$\text{pyramid} = \sum_{i=1}^{n} \sum_{j=1}^{M} \sum_{k=1}^{N} \text{tile}\left\{l_i, X_j, Y_k, \overset{w \times w}{\underset{i=1}{\cup}} \text{pixel}\right\}. \tag{3}$$

Based on the above concepts, the construction of the pyramid model also needs corresponding operations to jointly complete the hierarchical aggregation of spatial dimensions. The four basic operations defined are as follows:

(1) Extract operation: it is responsible for mapping each original record to the pixel unit. A pixel may correspond to one or more original records. The extract operation is

$$\text{Extract}\left(l_n, \{Lon, Lat\}, w\right) = \text{pixel}\{l_n, x, y, p\},$$

$$\begin{cases} x = \dfrac{Lon + 180}{360} \bullet 2^{l_n + r}, \\[2mm] y = \left(1 - \dfrac{(\tan(Lat \bullet \pi/180) + 1/\cos(Lat \bullet \pi/180))}{\pi}\right) \bullet 2^{l_n + r - 1}, \\[2mm] r = \log_2 w. \end{cases} \tag{4}$$

(2) Group operation: it is mainly to establish the corresponding mapping relationship between pixels and tiles, that is, to obtain the specific tiles to which the pixels should belong. The operation formula is

$$\text{Group}\left(\text{pixel}\{l_n, x, y, p\}\right) = \text{tile}\left\{l_n, X, Y, \overset{w \times w}{\underset{i=1}{\cup}} \text{pixel}\right\},$$

$$\begin{cases} X = \left(\dfrac{x}{w}\right), \\[2mm] Y = \left(\dfrac{y}{w}\right). \end{cases} \tag{5}$$

(3) Key value operation: the largest level of tiles and their aggregate data are obtained through group operation. The key can be the quadtree/space filling curve code of the tile, the value is the set of pixels of the tile, and its key value will be converted. The tiles will be stored in the form of key value pairs to establish the foundation for subsequent distributed storage.

(4) Aggregate operation: unlike the group operation, which combines pixels within a single tile, aggregate is the aggregation of tiles between levels. Extract, group, and key value operations obtain the tile set of the largest level of the pyramid. Next, they need to aggregate up level by level to get the tiles of each level and finally get the pyramid model. The aggregate operation formula is

$$\begin{aligned} Agg\Big(& \text{tile}\left\{l_n, X_{2i}, Y_{2i}, \overset{w \times w}{\underset{i=1}{\cup}} \right\}\text{pixel}\Big), \\ & \left(\text{tile}\left\{l_n, X_{2i}, Y_{2i+1}, \overset{w \times w}{\underset{i=1}{\cup}} \right\}\text{pixel}\right), \\ & \left(\text{tile}\left\{l_n, X_{2i+1}, Y_{2i}, \overset{w \times w}{\underset{i=1}{\cup}} \right\}\text{pixel}\right), \\ & \left(\text{tile}\left\{l_n, X_{2i+1}, Y_{2i+1}, \overset{w \times w}{\underset{i=1}{\cup}} \right\}\text{pixel}\right) = \left(\text{tile}\left\{l_{n-1}, X_i, Y_i, \overset{w \times w}{\underset{i=1}{\cup}} \right\}\text{pixel}\right). \end{aligned} \tag{6}$$

3.2. Multidimensional Aggregation Pyramid Model.

The multidimensional aggregation pyramid (map) model is a spatiotemporal multidimensional hierarchical aggregation model based on the traditional tile pyramid model. Among them, the temporal dimension and spatial dimension belong to positioning features. The whole composed of the two identifies a spatiotemporal unit and serves as the key of the spatiotemporal unit. The discrete attribute dimension aggregation tree is value, and the two correspond in the form of key value pair. In this way, while realizing spatiotemporal aggregation, attribute dimensions are also aggregated, and a multidimensional spatiotemporal aggregation pyramid model containing space, time, and attribute dimensions is obtained [15].

(1) Aggregation tree (faa_tree): attribute aggregation tree is a tree structure formed by aggregating each dimension unit of the attributes of spatiotemporal objects, which simplifies the actual storage space with the result of breadth first traversal. Obtain a fixed length 1-dimensional array that can be stored structurally, and the formula is

$$faa\_\text{tree} = \{a_{\text{all}}, a_1, a_2, \ldots, a_n\}, \tag{7}$$

where $a_{\text{all}}, a_1, a_2, \ldots, a_n$. The node array sequence is obtained by traversing the attribute aggregation tree according to the hierarchy. Compared with tree structure, the fixed length array structure provides great convenience for subsequent storage and processing.

(2) Spatiotemporal pixel (st pixel): different from the zero-dimensional characteristics of pixels in 2D map

tiles, spatiotemporal pixels are a one-dimensional structure, a container for attribute dimensional information, and the smallest data unit of the map model. Spatiotemporal pixels extend the connotation of the concept of tile pyramid pixels. In addition to the range of spatial coordinates, they also add time scale coordinates. The formula is

$$ST - \text{pixel} = \{l, x, y, t, faa\_\text{tree}\}, \tag{8}$$

where t represents the scale coordinates of the preset time granularity and tree is the attribute aggregation $faa\_$tree, which is the real source of visual content.

(3) St tile: the concept of spatiotemporal tile is like that of the 2D model, which is composed of spatiotemporal pixels. Spatiotemporal tiles contain spatiotemporal pixels. Spatiotemporal pixels mount the attribute dimension aggregation tree to form a spatiotemporal cube that can realize hierarchical aggregation. Spatiotemporal tile is the basic unit of map model display. It is a 5-tuple, defined as

$$ST - \text{tile} = \{L, X, Y, T, \text{Tile}\_faa\}, \tag{9}$$

where l is the level of pyramid, X and y are the row and column numbers of tiles, and T represents the scale coordinates with preset time granularity, and Tile _faa formula is

$$\text{Tile}\_faa = \{A_{\text{all}}, A_1, A_2, \ldots, A_n\}, \tag{10}$$

where $A_{\text{all}}, A_1, A_2, \ldots, A_n$ is the attribute aggregation tree at tile level obtained by accumulating the subscripts corresponding to the array sequence faa_tree of attribute aggregation trees of each pixel in the tile.

It can be seen from (10) that the defined space-time tile is no longer a two-dimensional plane in concept, so the basic operations in the two-dimensional need to be further expanded.

(1) Extract operation: in addition to extracting geographic location information, it is also necessary to extract time information and attribute dimensions, generate attribute aggregation tree, and list them in order. The operation is

$$\text{Extract}(l, Lon, Lat, w) = ST - \text{pixel}\{l, x, y, t, faa\_\text{tree}\}. \tag{11}$$

(2) Group operation: there are two steps. The first step is mainly to establish the corresponding mapping relationship between spatiotemporal pixels and spatiotemporal tiles, that is, to obtain the specific tiles to which the pixels should belong, so as to locate not only in space but also in time. The formula is

$$\text{Group}(ST - \text{pixel}\{l, x, y, t, faa\_\text{tree}\}) = ST - \text{tile}\left([l_n, X, Y, T, \text{Tile}\_faa]\right), \tag{12}$$

where t and T represent the time limit required for group operation. Therefore, the spatiotemporal unit to which each pixel belongs can be found through (12), and the spatiotemporal pixels can be mapped to specific spatiotemporal tiles.

The second step of group operation is to reduce all spatiotemporal pixels mapped to the same spatiotemporal tile and aggregate all pixels in the tile under the same time granularity and the same geographical range. At the same time, the aggregation tree tile of the spatiotemporal Tile_faa st tile is the accumulation of the corresponding positions of the 1-dimensional fixed length array faa_tree of all spatiotemporal pixels, and the formula is

$$ST - \text{Tile}\_faa = \sum_{i=1}^{N=n} ST - \text{pixel}.faa\_\text{tree}. \tag{13}$$

(3) Key value operation: split tile_. For each node in FAA, the node is jointly encoded with the quadtree and time t of the tile to generate the key. Then, take the pixel set corresponding to each node as a value to generate a key value pair. The true meaning of the key value operation is the statistical result of the event of an attribute node within the tile space within the time period T.

(4) Aggregate operation: it needs to be limited to the same time t, that is, aggregate the tiles after key valued and finally obtain the multidimensional pyramid model. The formula is

$$\begin{aligned}
&\text{Agg}\left(ST - \text{tile}\left(l_n, X_{2i}, Y_{2i}, T, \text{Tile}\_faa\right)\right), \\
&ST - \text{tile}\left(l_n, X_{2i}, Y_{2i+1}, T, \text{Tile}\_faa\right), \\
&ST - \text{tile}\left(l_n, X_{2i+1}, Y_{2i}, T, \text{Tile}\_faa\right), \\
&ST - \text{tile}\left(l_n, X_{2i+1}, Y_{2i+1}, T, \text{Tile}\_faa\right) = ST - \text{tile}\left(l_{n-1}, X_i, Y_i, T, \text{Tile}\_faa\right).
\end{aligned} \tag{14}$$

3.3. Scenario Management Strategy. In the actual rendering process, there are usually tens of thousands of building components in a rendered scene, and the network bandwidth, memory capacity, and rendering performance are often limited. If all components in the rendered scene are rendered indiscriminately, it will cause great performance sales to GPU and reduce the efficiency of graphics rendering. Therefore, it is very important to optimize the organization, management, and scheduling of rendering scenes. There are many solutions for the management and optimization of rendered scenes, such as visibility culling, region of interest setting, LOD index structure, and batch call rendering [16].

The view range of browser model data is composed of viewpoint position and view cone, which is usually only a part of the whole rendered scene. Therefore, the organization and management of rendering scene through visibility culling is a widely used scene management method. Visual cone culling, back face culling, and occlusion culling are three widely used visibility culling technologies. The technical comparison is shown in Figure 2.

The back culling is carried out in the rasterization stage. It improves the rendering performance by culling the pieces back to the viewpoint. It is a visibility culling algorithm supported by the native OpenGL. Occlusion elimination can eliminate invisible objects blocked by visible objects. Although it can reduce the performance overhead of rendering pipeline and GPU, it is implemented based on hardware and needs to collect the location information of occluded objects and occluded objects, which occupies CPU resources. Visual cone culling exists in many real-time renderings. It is used to cull polygons or objects outside the visual cone view and render only the geometric graphics within the visual cone view, to improve the efficiency of graphics rendering. Relatively speaking, the visual cone elimination algorithm is suitable for the organization and management of rendered scenes [17]. In this study, BSphere volume and AABB box collision detection algorithm are introduced to construct the visual cone elimination algorithm based on BVH.

3.4. Experimental Method and Process

3.4.1. Model transformation. The original IFC file usually contains geometric information (spatial position and spatial relationship, etc.) and nongeometric information (attribute type and material map, etc.), and in the process of model conversion, it will often cause the lack of architectural object semantic attribute information, resulting in the lack of model information integrity. Therefore, it is necessary to separate the BIM model from the digital model and store and load the geometric space information and semantic attribute information separately, to ensure the integrity and semantics of the BIM model. IFC organizes and manages the building and component information of the BIM model in the form of the tree structure. Each building component instance is a node on the IFC structure tree, and each node has spatial or attribute relationships such as inclusion and association with its parent node or through its parent node and other child nodes. For example, each IFC wall instance is included in the
FIGURE 2: Comparison of common visibility culling techniques in rendering process.

IFC wall parent node as a child node, and similarly, the IFC wall parent node is included in the IFC building element as a child node, which is associated with the IFC door. By recursively accessing each node of the IFC structure tree and exporting the geometric attribute information of building component instances or other BIM scene information hierarchically, it can not only effectively manage IFC files and reduce IFC data redundancy but also lay a foundation for component batch rendering.

BIM server provides IFC file management, data analysis, formatted output, and other functions. This study will also traverse and retrieve the hierarchical relationship of the whole building model through the BIM server and split the building model into corresponding IFC model files and JSON text files through recursive access to the IFC structure tree. IFC model files store BIM spatial and geometric information, while JSON text files store BIM attribute and type information [18]. The digital analog separation process is shown in Figure 3.

In the past research studies, there are many solutions to convert IFC format files into GLTF format files. Select OBJ files as the intermediate format. First, call the IFC convert tool in the Ifc open shell library to convert IFC files into OBJ files and then convert OBJ into GLTF format files through the obj2gltf tool launched by AGI (analytical graphics, Inc.), so as to realize the overall conversion from IFC to glTF. By calling Revit API and inheriting IExternal Command and IExternal Application interfaces, this study constructs IFC glTF conversion framework based on c# language and realizes glTF model file output through Revit2gltf. The data conversion process is shown in Figure 4 [19].

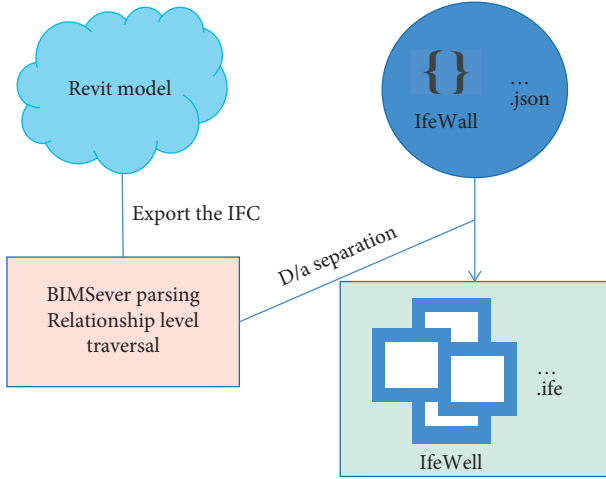
Usually, in the process of BIM model transformation, it is necessary to complete the spatial relationship mapping from geometric information to WebGL. This is because the component position coordinate information in IFC file is defined by IfcLocalPlacement attribute, which usually


FIGURE 3: Digital analog separation process.

FIGURE 4: Data conversion process.

adopts the local coordinate system, while WebGL is the global coordinate system. Therefore, to establish the connection between IFC model components and WebGL camera, coordinate system space transformation must be carried out, mainly including model transformation and visual transformation. The coordinate transformation from the local coordinate system to the world coordinate system is the transformation of spatial geometry by translation, scaling and rotation alone or in combination [20]. Considering that the Cartesian coordinate system adopts the right-hand rule, take the z-axis as an example, as shown in Figure 5.

Usually, a point $V(x, y, z, 1)$ in space will pass through 4×4 matrix M transformation in (15) to get a new point $V'(x', y', z', 1)$:

$$\begin{bmatrix} a & b & c & d \\ e & f & g & h \\ i & j & k & l \\ m & n & o & p \end{bmatrix} \times \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} = \begin{bmatrix} x' \\ y' \\ z' \\ 1 \end{bmatrix}. \tag{15}$$

If a vertex $V_{\text{Local}}(x, y, z, 1)$ in the local coordinate system translates the distance T_x, T_y, T_z on the x-axis, y-axis, and z-axis, respectively, to obtain $V_{\text{Global}}(x', y', z', 1) = V_{\text{Local}}(x + T_x, y + T_y, z + T_z, 1)$, and substituting it into (15), we can obtain the translation matrix, i.e.,

$$T = \begin{bmatrix} 1 & 0 & 0 & T_x \\ 0 & 1 & 0 & T_y \\ 0 & 0 & 1 & T_z \\ 0 & 0 & 0 & 1 \end{bmatrix}. \tag{16}$$

If the point is scaled with the origin as the base point and S_x, S_y, and S_z times are scaled in the x-axis, y-axis, and z-axis directions, respectively, the point $V_{\text{Global}}(x', y', z', 1) = V_{\text{Local}}(x + S_x, y + S_y, z + S_z, 1)$ will be obtained, which can be substituted into (15) to obtain the scaling matrix, i.e.,

FIGURE 5: Schematic diagram of translation, zoom, and rotation of spatial graphics.

$$S = \begin{bmatrix} S_x & 0 & 0 & 0 \\ 0 & S_y & 0 & 0 \\ 0 & 0 & S_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}. \tag{17}$$

If the figure rotates around the Z-axis, as shown in Figure 6, the Z value transformation can be ignored because the Z value remains unchanged. At this time, set R as the distance from the origin o to the point $V_{\text{Local}}(x, y, z)$. α is the angle the X-axis rotates to this point. According to the trigonometric function equation, the rotation matrix when the point $V_{\text{Local}}(x, y, z)$ rotates at angle β around the Z-axis can be obtained, i.e.,

$$R_z = \begin{bmatrix} \cos \beta_z & -\sin \beta_z & 0 & 0 \\ \sin \beta_z & \cos \beta_z & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}. \tag{18}$$

Similarly, the rotation matrix R_x when rotating angle B around the X-axis and the rotation matrix R_y when rotating angle ß around the Y-axis can be obtained.

To sum up, the geometric information of IFC model file can be transformed into the spatial coordinate system through (19) to complete the spatial relationship mapping from component geometric information to WebGL, that is,

$$V_{\text{Global}} = V_{\text{Local}} \times (T \times s \times r), \tag{19}$$

where $R = R_x R_y R_z$ is the rotation conversion matrix when the vertex rotates around the coordinate axis. After digital analog separation and data conversion, glTFmodel file and JSON semantic attribute file are introduced into the same scene object through the constructor "Loader" in Three.js to complete the loading of geometric model and semantic attribute information in WebGL [21].

3.4.2. Scene Management. Visual cone culling uses the spatial correlation in the rendered scene to judge whether the scene model is inside or intersecting with the visual cone. The viewing cone itself is usually composed of 6 cutting planes, and the right section of the cutting plane is shown in Figure 6. The opening angle is in the vertical direction of the apparent cone. Dn and Df are the distances from the viewpoint to the near clipping plane and the far clipping plane, respectively. Hn and Hf are the heights of the near clipping plane and the far clipping plane, respectively.

Suppose the aspect ratio of the camera is k and a vertex P (XO, Jo, Zo) is on the side of the right clipping plane. According to the geometric relationship, the distance between the vertex and the right clipping surface can be calculated through equation (6), to judge the spatial relationship between the vertex and the right clipping surface, i.e.,

$$d = \frac{|x_0 + k \tan \theta/2 z_0|}{\sqrt{1 + k^2 \tan^2 (\theta/2)}}. \tag{20}$$

If $d < 0$, the apex is outside the visual cone. If $d \geq 0$, the apex is inside the visual cone. This is because when the clipping space changes, the left- and right-hand coordinate system changes, and the normal vector of the clipping surface points to the viewing cone. According to the spatial relationship between all vertices of a component and the clipping surface, it can be determined whether the whole component and the viewing cone have an inclusion, intersection, or separation relationship, to determine whether to load and render the component.

(1) BVH-based visibility detection algorithm for BS-AB scene components: using the spatial data structure with hierarchical structure to organize the scene and build a bounding box approximate description component with
FIGURE 6: Section of the right cutting surface of the cone.

slightly large volume but relatively simple geometric features is a favorable way to solve the low efficiency of linear array traversal in complex scenes and the difficulty of visual cone intersection test of complex components. Hierarchical bounding volume (BVH) is a commonly used spatial data structure. It organizes and manages the objects in the scene in a hierarchical tree structure based on spatial information, including internal nodes and leaf nodes from the root node down.

Therefore, the BVH structure tree can be created according to the IFC component tree. Here, the cone scene is regarded as a root node, and each Ifc Building Element (such as IfcWall and IfcDoor) is placed in the internal node as a category; then, the family under each category is the leaf node. When there are still different components in the leaf node, continue to build the BVH tree according to the family and family type until the leaf node contains family instances. The purpose of adding enclosures in the scene is to filter the geometry outside the enclosure through accurate collision detection. Commonly used bounding bodies include BSphere body and AABB box. Bsphere volume algorithm is based on the sphere radius R and the distance d from the sphere center to the cutting surface of the viewing cone. If $d < r$, the sphere is separated from the visual cone without loading. If $|d| < r$, the sphere intersects with the visual cone for loading. If $d > r$, the sphere is loaded in the viewing cone, and its structure is shown in Figure 7. The AABB box algorithm is based on the distance between the vertex of the bounding box and the cutting surface of the viewing cone. Whether to load the bounding box is determined by judging whether the vertex of the bounding box is in the viewing cone or whether the connecting line between two points passes through the viewing cone. Its structure is shown in Figure 8.

When collision detection is performed between the visual cone and the hierarchical bounding body, BSphere predetection is performed first, and recursive access is performed to each node from the root node in turn. The separated internal nodes and leaf nodes are eliminated, and the leaf nodes contained in the internal nodes and the internal nodes intersecting with the visual cone are loaded. In addition, the leaf nodes that still intersect the visual cone in the internal nodes intersecting the visual cone are detected by AABB box, and the bounding boxes that are separated
FIGURE 7: Schematic diagram of sphere hierarchical bounding box tree structure. (a) Surround scene components with spheres. (b) Hierarchy tree.

from the visual cone are eliminated. Based on ensuring the efficiency of visual cone elimination, this algorithm not only reduces the performance overhead of rendering pipeline but also improves the accuracy of visual component detection [22].

Sphere structure and intersection test are simple, but the tightness is too poor. Although AABB box supports dynamic update and detection is more accurate, the update efficiency is too low. Therefore, this study proposes to carry out sphere predetection on scene components, eliminate rough and loose components, and then further screen through AABB box detection to quickly achieve the optimal detection results.

4. Experiment and Result Analysis

In order to verify the effectiveness of model transformation strategy and scene management strategy, this study collects 10 experimental data of building scene composition from the open IFC model repository and BIM model databases for example verification. This example verifies that it is configured as Intel(R) Core (TM) i7-8700@3.20GHZ six core processor, 16 GB memory, NVIDIA GeForce GTX 1060 graphics card, and notebook computer with 64 bit Windows10 operating system is implemented based on Chrome browser and Three.js framework. The IFC version of all test data in the experiment is IFC2X3, as shown in Table 1.

4.1. Effectiveness Analysis of Model Transformation Strategy. In this study, glTF is proposed as the target format of model transformation to realize network loading. In this study, the model transformation experiment of IFC model file without semantic attribute is carried out. It can be seen from Figure 8 that, as the volume of model files increases, the volume of glTF increases slowly, while the growth of obj is larger and much larger than that of glTF files. This is because after digital to analog separation and format conversion of the original IFC file, only a small amount of information is stored in the glTF file, while most of the information is stored in the bin file.

It can be seen from Figure 9 that although the overall file size and conversion time of the converted model are
FIGURE 8: Size of the converted model file.

different due to different architectural scenes, the compression rate of gLTF format is more than 90%, which has obvious compression advantages compared with obj format. Therefore, taking gLTF as the target, the format of model conversion is effective to reduce the loading of 3D model data, and it will also be more conducive to the rapid loading of 3D model data on the web.

4.2. Effectiveness Analysis of Scenario Management Strategy. Aiming at the problem of low rendering frame rate caused by poor visibility detection effect of scene components, this study proposes to use BS-AB scene component visibility detection algorithm based on BVH to detect and eliminate the visibility of building components. In this study, Medel 10 is taken as the experimental object, and 10 cone scenes with the same angle and the same viewpoint but different distances between the viewpoint and the model are set, as shown in Figure 10. Then, in different cone scenes, the performance is compared with other rendering systems in

Table 1: Experimental test dataset.

Model ID	Model name	Size (MB)
1	231110AC11-institute-var-2	2.705

Figure 10: Model conversion results.

Figure 9: BIMServer FPS.

Figure 11: BS-AB FPS.

terms of FPS value and single rendering time, to verify whether this strategy is effective for scene visual component management.

In the experiment, the version of BIMviews that BIM-Server depends on is BIMServer1.5.88. Chrome web browser is a 64 bit version of 84.0.4147.89. During the experiment, start the FPS mater in the rendering listener of Chrome browser to monitor the rendering area of 3D scene. Use the stats.js library to monitor the rendering time of the scene area. In addition, BIMviews load IFC model files, and other methods load glTF files.

The experimental results are shown in Figures 9–14. It can be seen from Figures 11 and 12 that, as the distance between the viewpoint and the model decreases, the number of components in the visual cone decreases, and the overall FPS value is gradually increasing, but the increase of the other two methods is small and unstable. After Distance 5, the number of components in the visual cone is greatly reduced. The visual cone elimination effect of this method is obvious, and the rendering frame rate increases steadily. It can be seen from Figure 14 that, before Distance 5, there is little difference in the single rendering time of the two methods, but after Distance 5, the rendering time of the method used in this study decreases significantly. Through experimental comparison, the feasibility of the BS-AB scene

Figure 12: Three. js FPS.

Figure 13: Three.JS rendering time.
Figure 14: BS-AB rendering time.

component visibility detection algorithm and the effectiveness of the scene management strategy are verified, which can meet the smooth needs of BIM model data network visualization. In addition, during the experiment, it was found that BIMviews were slow to load the IFC file of the experimental object and obtain the model data, with an average of about 40 s, and the Caton was obvious. However, it only takes about 7 s to load the glTF file to the complete display of the big data map visualization design by using Three.js. It is verified again that the glTF format is more suitable for the display and interaction of BIM model data based on the big data map visualization design than the IFC format.

5. Conclusion

The visibility of scene components is eliminated by BS-AB scene component visibility detection algorithm based on BVH. The experimental results show that this method greatly reduces the amount of BIM model data, improves the

detection accuracy of visual components of the model, and has a good effect of web model loading and rendering. The visibility of components (e.g., building models) cannot be detected by different methods, but the visibility of components (e.g., building models) cannot be detected. The follow-up work will start with LOD and occlusion elimination algorithm to further optimize the performance overhead of rendering pipeline and GPU after rendering scene visual cone elimination.

In order to improve the evaluation effect of the economic and social development pioneer area, this paper constructs the evaluation index system of the economic and social development pioneer area based on the spatial network structure analysis method and obtains an intelligent analysis system. Moreover, from the perspective of economic development information flow, this paper uses information flow direction analysis method and advantage flow analysis method to discuss the structural characteristics of urban economic development network in the economic belt, providing new methods and perspectives for the study of urban economic development flow. In addition, this paper attempts to propose a universal method for quantitative research on the "flow space" structure of urban economic development as the forward-looking content of urban economic development. According to the simulation test results, it can be seen that the evaluation index system of the economic and social development pilot area based on the analysis of the spatial network structure proposed in this paper has a good effect.

1. Introduction

The new development concept is an inseparable organic whole. In this organic whole, innovation is the internal driving force leading development and must be placed at the core of development, including innovation in theory, system, technology, culture, and other aspects. Coordination is the principal requirement of development, and the concept of coordinated development pays more attention to integrity, systematization, and balance and must correctly handle major relations in development and solve the problem of unbalanced and insufficient development [1]. At the same time, green is a necessary condition for development, and green development focuses on solving the problem of harmonious coexistence and coexistence between man and nature. While continuing and emphasizing adherence to the basic national policy of resource conservation and environmental protection, it is necessary to achieve synergy between economic and social development and ecological and environmental protection and create a good production and living environment for the people. Opening up is the environmental layout of development. To solve the problem

of developing internal and external linkages, a higher-level open economy must be developed to expand opening up and promote reform and development [2]. In addition, sharing is the fundamental purpose of development, focusing on solving social fairness and justice issues and continuously promoting the common prosperity of all people. The five development concepts are interconnected, and promote each other, constituting a brand-new concept and action guide to guide and lead today's development. Moreover, high-quality development under the guidance of new development concepts will surely become the normal state of development in the new era [3].

At present, the research on the airport economy at home and abroad is generally summarized from the aspects of case analysis and planning and construction, focusing on basic theoretical research such as basic concepts, characteristics, and development models at the macro level. However, there is a lack of specialized research on the airport economy industry from the perspective of regional economics, management, and industrial economics, as well as micro-subjects. It is necessary to select and plan the airport industry based on the development time sequence by using the

analytic hierarchy process in combination with the types of airport economic industries. At the same time, it is necessary to rationally plan and lay out the industrial space according to the industrial space structure layout of the airport area and combine the regional characteristics of the economic demonstration area so as to enrich the theoretical research system of the airport economy.

Based on the spatial network structure analysis method, this paper constructs the evaluation index system of the economic and social development pioneer area and obtains an intelligent analysis system, which provides a reference for the subsequent evaluation of the economic and social development pioneer area.

2. Related Work

The evaluation theory of economic and social development is a process of continuous evolution, and the evolution process is consistent with the development of the context and the theory of economic and social development. Through the study of relevant literature, it can be seen that the theory of economic and social development will affect the theory and connotation of measurement and evaluation. The changes of economic and social development theory with time and environment will inevitably lead to changes in the content of economic and social measurement and evaluation [4].

The social development concept of one-sided pursuit of economic growth has its profound and complicated historical reasons. The two world wars severely damaged the economy of the traditional capitalist powers. With the collapse of the world colonial system, the rise of independent democratic movements in the colonies directly shook the economic foundation of imperialism [5]. After the Second World War, the primary task of traditional capitalist powers was to restore and develop their own economies. Countries that have just gotten rid of the colonial system and become independent and countries that have just begun to industrialize have become developing countries. The primary task of developing countries is to develop their economies. In this way, the world is pursuing economic growth. Therefore, the development of this period mainly refers to the economic development. Due to special historical reasons, people at that time believed that the cause of social problems was the low economic aggregate, and rich material wealth could solve all social problems. Typical theories include Lewis's [6] dual structure theory, Rostow's economic development stage theory [7], Kuznets' statistical theory [8], and Chenery's econometric theory [9]. Under the guidance of this concept, the total economic volume has increased significantly, the progress of other aspects of society has been slow, or even counterproductive, and problems such as social unrest, political corruption, and unfair income distribution have emerged one after another. The concept of one-sided pursuit of economic growth began to be questioned.

Under the guidance of the one-sided pursuit of economic growth, other aspects of society have not achieved the expected progress, and people have begun to realize that simple economic growth cannot solve problems such as poverty, unemployment, and inequitable distribution [10]. The development theory has evolved from economics to a multidisciplinary comprehensive theory, which affirms the basic status of economic growth while taking into account other aspects of society. However, the focus of this period was mainly on social welfare, aiming to solve poverty, unemployment, and inequitable distribution. The focus is on raising the income of the poor, increasing the employment rate and improving the social security system [11]. Literature [12] believes that development should include economic, political, and cultural development and believes that as long as poverty, unemployment, and inequality are reduced, it belongs to development. Literature [13] proposed that development is a multidimensional process that includes the combination of the entire economy, society, culture, technology, ecology, and other elements and internal reorganization, including changes in economic aggregates, economic income growth, social systems, social structures, and even people's beliefs, habits, and other related content that cannot be regarded as a simple process.

In the process of industrialization, human beings have experienced an extensive economic development model. In this process, human beings exploit resources plunder, destroy the ecological environment, pursue short-term interests, and make economic development unsustainable [14]. Literature [15] believes that sustainable development mainly includes two cores, namely, the welfare problem in the economic growth period and the constraint problem of economic growth. The optimal growth path under different intergenerational goals and resource constraints is studied, and it is found that the optimal growth path is the path of sustainable development most of the time. Some scholars put forward another view. Literature [16] believes that the systematic interpretation of the connotation of "sustainable development" should be carried out from three aspects: economic sustainability, environmental sustainability, and social sustainability. With the deepening of research, the academic community has further enriched the theoretical framework of sustainable development and believes that the theoretical connotation of sustainable development includes five aspects: multidimensional development, common development, fair development, coordinated development, and efficient development. The indicator system of the United Nations Commission on Sustainable Development covers the four major systems of economy, society, environment, and system, including 142 indicators designed by driving force, state, and response model. The US Sustainable Development Indicator System consists of ten goals, including 54 indicators including health and the environment, equality, sustainable society, economic prosperity, public participation, protection of nature, and education. The UK sustainable development indicator system includes 21 aspects including economy, transportation, overseas trade, energy, land use, water resources, forests, atmosphere, waste, and radioactivity, with a total of 123 indicators [17].

3. Analysis Model of Spatial Network Structure

The city network mainly refers to the connection between cities. The relational data between cities is particularly critical to the study of urban networks, which can be roughly divided into attribute methods and relational methods. The data with realistic or abstract meanings that can reflect and carry various associations between cities, such as the flow of people, material exchange, and information exchange between cities, can be understood as relational data. The traditional urban network research is mostly carried out from the mode of urban hierarchy, scale, core-periphery, and so on. However, the urban network studied in this paper refers to the urban network in which the economic development information flow represents the abstract meaning perspective, and this paper reveals the connection between urban tourism through the abstract research perspective.

The central place refers to the place where goods and services can be provided to consumers in the surrounding area, such as a residential distribution point, a commercial center, or a city. Centrality is the degree to which a central place plays a central role relative to its surrounding areas, that is, its relative importance. Centrality can be expressed as follows [18]:

$$C = C_1 - C_2. \tag{1}$$

Among them, C_1 is the total amount of goods and services provided by the center, C_2 is the amount of goods and services provided by the center for itself, and C is the centrality, which refers to the amount of goods and services provided by the center to surrounding areas.

The central place theory is regarded as the basic theory of urban geography and regional economics research, as well as the foundational theory of urban system spatial structure research. The central place theory is a theory about the size of urban functions and the distribution of spatial structure in the region. It reveals the basic characteristics of the spatial structure of the central place system. In the tourism practice research, the urban tourism architecture mainly studies the system level division, the spatial layout in a certain area, and the connection between each other. The urban tourism grade is analyzed to provide support for the next regional tourism spatial structure.

The core idea of growth pole theory is that economic growth does not occur at the same speed in every location at the same time. Generally, the growth rate of a dominant economic sector or an innovative industry is the fastest, and these sectors and industries tend to gather in the best location. The location is usually a large- or medium-sized city within the region. Therefore, these large- and medium-sized cities gradually form regional growth poles and drive regional development through diffusion effects.

This theory provides a basis for the priority development of regional tourism. Due to the comprehensive characteristics of the tourism industry, the linkage effect of the tourism industry is extended to a larger area through the gathering and diffusion of regional tourism growth poles. In addition, regional tourism is not initially developed in a balanced way.

According to the development model of this theory, priority development areas can be used to drive tourism development in other regions so that it can play a role in the aggregation and diffusion of growth points and drive the economic growth of the entire regional tourism industry. The theory is mainly used in the two forms of the point axis structure and the network structure in the tourism space structure.

The point-axis theory is formed on the basis of the growth pole theory, which holds that the "point" is the node (city) at all levels, and the "axis" is the industrial belt formed by connecting the nodes at all levels in a certain direction. The point-axis structure is formed by a number of isolated nodes through the connection of the development axis and gradually develops to form a certain spatial network structure. Cities in a certain area are distributed hierarchically, so the development axis connecting each city is also hierarchical, and cities and axes with different levels have different attractiveness.

In the related research, the measurement methods used by most scholars to study the evolution law and trend of regional tourism development differences are basically based on the relevant methods of income distribution differences in economics. The specific measurement methods used in this paper are as follows:

(1) *Standard Deviation (VOC)*. It is the arithmetic square root of the ratio between the sum of squared deviations of the sample data and the total sample size. It reflects the absolute degree of dispersion between sample individuals and can be used to represent the absolute difference in economic scale between cities. The larger the value, the greater the absolute difference.

$$\text{VOC} = \sqrt{\frac{\sum_{i=1}^{n} (x_i - \overline{x})^2}{n}}. \tag{2}$$

(2) *Coefficient of Variation (CV)*. It is the quotient between the standard deviation and the mean. It can eliminate the interference of different sample averages on the degree of sample variation, reflect the relative dispersion of samples, and can be used to characterize the relative difference of tourism scale between cities. The smaller the value, the smaller the relative difference.

$$\text{CV} = \sqrt{\frac{\sum_{i=1}^{n} (x_i - \overline{x})^2 / n}{\overline{x}}}. \tag{3}$$

(3) *Gini Coefficient (G)*. It is combined with the coefficient of variation to determine the relative difference of urban tourism scale. The larger the value is, the larger the tourism scale gap between cities is.

$$G = 1 + \frac{1}{n} - \frac{1}{n^2 \overline{y}} (y_1 + 2y_2 + 3y_3 + \cdots + ny_n). \tag{4}$$

(4) *Growth Rate*. It can analyze the differences in the speed of regional tourism development, but the bases

of cities are different, and the same growth rate will lead to large differences in actual growth. In order to eliminate the above situation, this paper introduces the relative development rate (Nich) to measure the spatial difference of the relative development speed of urban tourism in the economic belt.

Nich is the relationship between the change of the economic development scale of each city in a certain period and the change of the average economic development scale of the whole region in the same period:

$$\text{Nich} = \frac{(Y_{2i} - Y_{1i})}{Y_1 - Y_2}. \tag{5}$$

In the formula, Y_{1i}, Y_{2i} is the economic development scale of city i at time 1 and 2, and Y_1, Y_2 is the average economic development scale of the region at time 1 and 2. Nich > 1 means that the growth rate of the economic development scale of city i is higher than the regional average level, $0 < \text{Nich} < 1$ means that the growth rate of the economic development scale of city i is lower than the regional average level, and Nich < 0 means that the economic development scale of city i has negative growth.

(5) *Herfindahl Coefficient (Hn)*. It is an index reflecting the scale and agglomeration degree of urban economic development. The larger the value, the higher the degree of concentration, and the more uneven the development.

$$H_n = \sum_{i=1}^{n} p_i^2. \tag{6}$$

(6) *First Degree (S)*. It is the quotient between the measures of the economic development scale of the first and second largest cities. It reflects the aggregation degree of urban economic development scale distribution. The larger the value, the more concentrated the distribution. When $S > 2$, the regional structure is considered unreasonable, and it is called the primacy distribution. When $S < 2$, the regional structure distribution is considered to be relatively reasonable.

$$S = \frac{P_1}{P_2}. \tag{7}$$

In formulae (1)–(6), X_i is the value of index i, $Y_1, Y_2, Y_3 \cdots Y_n$ is the index value from large to small, $\overline{X}$ and $\overline{Y}$ are the mean values of the indexes, and n is the total number of samples, P_i is the proportion of index i, and P_1, P_2 is the index value of the first and second largest cities.

3.1. Research Methods of Economic Development Scale Distribution. In order to better present the overall distribution of the economic development scale of cities in the economic belt. In this paper, the Rothko-type rank-scale distribution is used to measure the economic development scale distribution of cities in the economic belt. The formula is [19]

$$P = KR^{-q}. \tag{8}$$

Among them, P is the scale of urban economic development, R is the rank, K is the ideal scale of the first city, and q is the concentration index. According to the q-value, the scale distribution of urban economic development is divided into first type $(q \geq 1.2)$, concentrated type $(0.85 < q < 1.2)$, and balanced type $(q \leq 0.85)$.

In order to scientifically use the sample data for regression analysis, the natural logarithm of formula (7) is taken and sorted out:

$$\ln p = \ln k - q \ln R. \tag{9}$$

This paper uses the index of the total number of people received by the city's economic development to measure its functional scale and the index of the proportion of total economic development revenue to GDP to measure its functional status. Moreover, this paper uses Nelson's method to define the functional strength of each city. First, the sample mean $(\overline{X})$ of each city's functional indexes is calculated as the threshold for judging urban specialized departments; then, the sample standard deviation (σ) of each city's functional indexes is calculated, and then the coefficient (K_i) of each city's functional intensity is calculated.

$$\overline{X}_i = \frac{1}{n} \sum_{i=1}^{n} X_i,$$

$$\sigma_i = \sqrt{\frac{\sum_{i=1}^{n} (X_i - \overline{X})^2}{n}}, \tag{10}$$

$$K_i = \frac{X_i - \overline{X}}{\sigma}.$$

Each dimension is divided into 3 intervals according to the value of K_i. The specific description is as follows. In the dimension of functional scale, it is divided into small, medium, and large cities. In terms of functional status, cities are divided into low, medium, and high specialization cities.

The mean value of the total number of people received by the economic development of cities in the economic belt is expressed by $\overline{X}$, and the standard deviation is expressed by σ. After calculation, it is found that the original sample of functional scale is nonnormal. Therefore, this paper corrects it as follows:

$$T_i = \begin{cases} \text{small} - \text{scale } T_i \leq \overline{X}\tau, \\ \text{medium} - \text{sized } \overline{X}\tau < T_i < \overline{X}\tau + \sigma_i, \\ \text{large } T_i \geq \overline{X}\tau + \sigma_i, \end{cases}$$

$$S_i = \begin{cases} \text{Low specialization } S_i \leq \overline{X}_S, \\ \text{Specialization in secondary schools } \overline{X}_S < S_i \leq \overline{X}_S + \sigma_i, \\ \text{High specialization } S_i \geq \overline{X}_S + \sigma_i. \end{cases} \tag{11}$$

Among them, T_i is the functional scale of urban economic development, and S_i is the functional status of urban economic development.

The two dimensions are combined with each other to form 9 types of urban economic development functions (Figure 1).

With the rapid development of information technology, the popularization of the Internet and the economic development reservation system has largely changed the market conditions of the economic development industry. Moreover, the application of information technology in the economic development industry is becoming more and more extensive, and the influence of information flow on the economic development flow is gradually increasing. The guidance of economic development information flow to economic development flow is a process of information decision-making and implementation; in this process, "quasitourists" have been largely controlled by economic development information flow. On the one hand, the flow of economic development information enhances the flow of economic development, and on the other hand, the two can even replace each other in quantitative relationship. In the context of the rapid development of the Internet, the purchasing decisions and behaviors of economic developers are increasingly dependent on the Internet. Website information flow is the basic form and the only medium of Internet information transmission, and it plays a huge guiding role in the generation and change of people flow and is the most influential "flow" among many "flow" elements. Therefore, from the perspective of economic development information flow, this paper avoids the obstacles caused by the lack of statistics on domestic economic development flow data.

From the perspective of economic development information flow, this paper uses information flow direction analysis method and advantage flow analysis method to discuss the structural characteristics of urban economic development network in the economic belt, providing new methods and perspectives for the study of urban economic development flow. Moreover, this paper attempts to propose a universal method for quantitative research on the "flow space" structure of urban economic development as a forward-looking content of urban economic development so as to make up for the deficiencies of related research caused by the lack of information on the flow and flow of domestic actual economic development and to provide certain basic materials for later scholars to study the flow of economic development information. To a certain extent, it provides decision-making reference for economic development marketing, economic development e-commerce and economic development planning and provides a scientific basis for promoting the integrated construction and development of economic development.

This paper introduces C-value and D-value as two indicators to measure the status and level of each city in the urban economic development network. The formula is

$$C = \text{Ln} \frac{C_c}{C_s},$$

$$D = C_c - C_s. \tag{12}$$

Among them, C_c represents the amount of economic development information output by a city, and C_S
FIGURE 1: Types of urban economic development functions.

represents the amount of economic development information received by the city. If a city's economic development information output is greater than its information reception, that is, $D > 0$, the city is the control node (city) of the economic development information flow network. On the contrary, the city is considered as a subsidiary node (city).

In the process of data processing, it is found that, under normal circumstances, the amount of economic development information received by popular cities or cities with more developed economic development industries is often greater than the amount of economic development information output. The information flow of economic development from low to high is relatively large, while the amount of economic development information output from high to low is less. Therefore, C_c represents the amount of economic development information received by a city, and C_S represents the amount of economic development information output by the city.

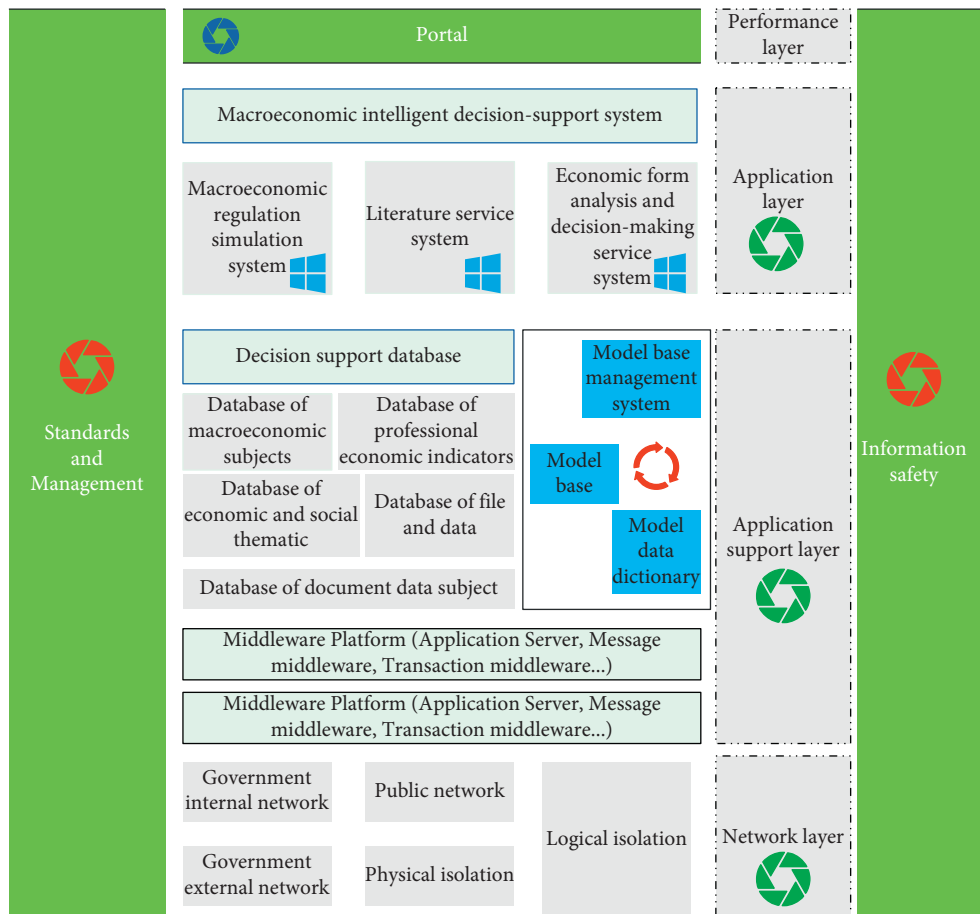
The basic idea of the dominant flow analysis method is to judge the status of a city (A) in the urban system according to the maximum flow of economic development information of a city (A), the scale of urban economic development, and the flow between the city (A) and other cities. From this, the position of the city (A) in the network structure is obtained, and the position determines its influence in the spatial interaction. On this basis, Song Wei and other scholars divided cities into three types: dominant, subdominant, and subordinate cities. Based on the scale of urban economic development level obtained in the previous study, the level of the dominant stream is divided. The detailed contents are explained as follows. If the largest economic development information flow of city (A) is to city (B) with a smaller economic development scale, then city (A) is considered to be dominant. If city (B) has the largest economic development information flow to a city with a relatively large economic development scale, and at the same time there is one or more cities $(C_1, C_2 \cdots)$ whose economic development scale is smaller than the largest
FIGURE 2: Kohonen network structure.


FIGURE 3: Overall architecture of the system.

economic development information flow to it (B), then city (B) is considered to have secondary dominance. If city (C) has the largest economic development information flow to the subdominant city (B), and there is no city (D) whose economic development scale is smaller than the largest economic development information flow to it (C), then it is determined that city (C) has a subordinate attribute.

4. Evaluation Index System of Economic and Social Development Pilot Area Based on Spatial Network Structure Analysis

The Kohonen network simulates the structure of neurons in the cerebral cortex as a two-dimensional spatial lattice. Functionally, through the interaction and competition
Figure 4: System flowchart.
Figure 5: Schematic diagram of the decision support system based on data warehouse.

between neurons in the network, the clustering function and self-organization and self-learning functions of brain information processing are simulated. The Kohonen network structure is shown in Figure 2, which consists of an input layer and a competition layer.

This paper makes comprehensive use of multidisciplinary theories and technologies such as systems science, information science, dynamic econometrics, artificial intelligence, data warehouse, data mining, online analytical processing, and intelligent decision-making analysis tools and methods. Through the collection, storage, analysis, processing, and presentation of various data and related information, high-level information services and support are provided for leaders, and scientific and standardized decision-making is realized. The overall architecture of the system is shown in Figure 3.

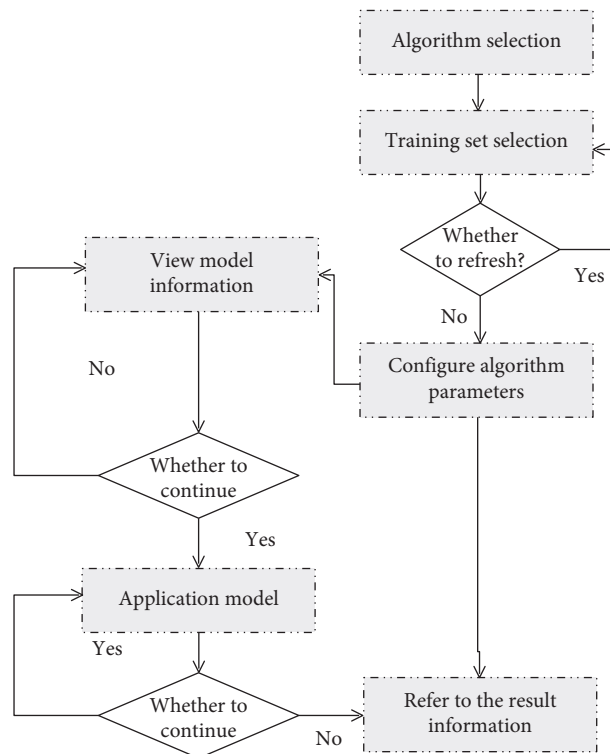
The flowchart of the macroeconomic intelligent decision support system is shown in Figure 4.
FIGURE 6: Interface design of data mining server.


FIGURE 7: Overall activity diagram of data mining module.

The intelligent decision support system based on data warehouse takes data warehouse and model base (MB) as the main structure, supports online analytical processing, and applies data mining to knowledge discovery in the database, as shown in Figure 5:

The data mining server extracts data from the data warehouse and then sends the results to the front-end for display after mining and processing. The interface design of the data mining service is shown in Figure 6 below.

The mining steps of the data mining system are as follows: (1) The system selects an algorithm. (2) The system selects the training set and determines whether to refresh. If it needs to be refreshed, the system repeats step 2; otherwise, it goes to step 3. (3) The system configures the algorithm parameters. (4) The system checks the model information and chooses to continue to step 5; otherwise, it goes back to step 3. (5) The system uses the model to determine whether to refresh. If it needs to be refreshed, the system repeats step

5; otherwise, it goes to step 6. (6) The system checks the result information. The overall activity diagram of the data mining module is as shown in Figure 7.

Figure 8 shows the analysis model of the spatial network structure constructed in this paper.

This paper obtains a large amount of data from the network to verify the effect of the model in this paper and calculates the effect of the model constructed in this paper in the evaluation index analysis of the economic and social development pilot area and compares it through multiple sets of data. Moreover, this paper obtains the results shown in Table 1 and Figure 9.

From the above research, it can be seen that the evaluation index system of the economic and social development pilot area based on the analysis of the spatial network structure proposed in this paper has a good effect.
FIGURE 9: Statistical diagram of the evaluation of economic and social development pilot areas.

5. Conclusion

The construction and development process of the "two first districts" is the implementation of the five development concepts of innovation, coordination, greenness, openness, and sharing and is the development under the strategic guidance of the five development concepts. Therefore, the construction of the evaluation index system of the economic and social development pilot zone must be based on five development concepts. Moreover, it needs to take the five development concepts as the first-level indicators for evaluation and further select the second-level indicators and the third-level indicators according to their connotations and the actual construction. In addition, it provides a theoretical reference for the formation of the basic framework and the selection of specific indicators for the evaluation index system of the economic and social development pilot zone. At the same time, it can reveal the status quo, characteristics, and problems of economic and social development under the guidance of new development concepts and has certain practical value for guiding government departments to solve economic and social development problems according to the development requirements of new concepts. Based on the analysis method of spatial network structure, this paper constructs the evaluation index system of the economic and social development pilot area and obtains an intelligent analysis system. The simulation test study shows that the evaluation index system of the economic and social development pilot area based on the analysis of the spatial network structure proposed in this paper has a good effect.

In order to cope with the challenges that operators face after the impact of diversified social channels in the field of interactive services, we actively build a new generation of intelligent interactive systems based on artificial intelligence technology, a semantic understanding, and intention recognition, covering rich media content, omnichannel coverage, high-frequency knowledge updates, consistent service response, high-quality, and low-cost intelligent interactive solutions is proposed. The solution provides overall business modeling for scenario design and a scenario-based knowledge expression system, with the function of fragmented knowledge processing. With complete text and voice information, combined with pictures, text, audio, video, and other multimedia, we intelligently interact with users, allowing users to obtain required information and solve problems in a pleasant and relaxing interaction. Therefore, the research and exploration of the intelligent interactive system architecture based on artificial intelligence is a useful practice and strong support for operators to redefine the connotation and elements of "smart service" in the process of building "smart operation." Through repeated tests, it can be seen that the language similarity has reached 0.75549, which is very close to 1.0000. It can be seen that the design of this platform has been successful.

1. Introduction

Since the 21st century, with the rapid development of computers and networks, artificial intelligence has become the most popular technology term today. The development of artificial intelligence affects the development of all walks of life. The development of robotics, autonomous driving technology, image recognition, and other technologies indicates that artificial intelligence is getting more and more attention from people, and its development has great potential. Big data plays a vital role in the development of artificial intelligence. Through the relationship between artificial intelligence and big data, starting from their development status, this article describes in detail the future development trend of artificial intelligence in the big data environment. The robot operating system ROS is easy to use

[1]. After determining the functional modules that the human-machine voice interaction system should have, we use the topics and services provided by ROS to realize the communication between related modules in the system and define the information format during communication. ROS originated from the cooperation between the STAIR project of the Stanford University Artificial Intelligence Laboratory in 2007 and the personal robot project of the robotics company Willow Garage. After 2008, Willow Garage promoted its development. ROS is an open-source meta-operating system suitable for robots. It provides the functions that the operating system should have, including hardware abstraction, low-level device control, realization of common functions, interprocess information transmission, and software package management. In addition, it also provides the tools and libraries needed to compile, write, and execute

programs across multiple computers [2]. ROS is similar to Player, YARP, Orocos, CARMEN, Orca, MOOS, and Microsoft Robotics Studio robot frameworks in some respects. The "blueprint" of the ROS runtime is a loosely coupled point-to-point process network based on the ROS communication infrastructure. ROS has several different communication methods, including a service mechanism based on synchronous remote procedure call protocol (Remote Procedure Call Protocol, RPC) communication, a topic mechanism based on asynchronous streaming media data, and a parameter server for data storage [3]. Figure 1 shows the flow chart of the intelligent interactive system management platform. Big data uses the increasingly mature cloud computing technology to obtain valuable information from the vast ocean of Internet information for information induction, retrieval, and integration, providing a software foundation for Internet information processing. Both require the participation of artificial intelligence, which is a commercial application after the order of the Internet information system. That is the real outlet for cloud computing and big data.

2. Literature Review

Tekerek A. and others said that the arrival of the era of intelligence and big data, and the social impact brought about by the industrial revolution in history, have inherent laws that are similar in appearance and similar in quality to the contradictions and mutual influences between productivity and production relations [4]. Ha T. and others stated that the era of intelligence and big data seems to have provided greater "convenience" for "distrust, disorder, and monopoly," and at the same time put forward higher requirements for "trust, order, and sharing [5]." Kyivska K. and others said that in the past 20 years, with the rapid development of artificial intelligence technology, especially the intelligence and big data information economy characterized by "Internet +," it has almost reshaped the production and operation models of enterprises and people's way of life has had a significant impact on the transformation of the paradigm of human "technology-economy-society" and the progress of social civilization [6]. Ongena et al. said that with the widespread application of computer technology, the continuous increase in data accumulation, and the continuous innovation and enhancement of algorithms and computing power, the current society has entered the era of intelligence [7]. Through research, Bhargava et al. have obtained the development of the "four major catalysts" of massively parallel computing, big data, deep learning algorithms, and smart chips, as well as the reduction of computing costs, which has enabled artificial intelligence technology to advance by leaps and bounds [8]. Fanea and others said that artificial intelligence has become the most exciting and most anticipated technology of this era, and it will become the focus of the development of the IT industry in the next 10 years and beyond [9]. Naghizade et al. found through investigations that the current operators are also facing the impact of the mobile Internet. Diversified service requirements, diversified service scenarios, and fragmented

social service models are all impacting the traditions of operators from all angles. *Service interaction mode* [10]. Zhang et al. said that the response speed and service satisfaction of interactive services force operators to innovate the service interaction model. The high-frequency requirements for service personnel knowledge update and training cost control have promoted the traditional interactive service model to the network. Development in the direction of automation, automation, and intelligence, through rich media and multichannels to achieve intelligent interaction with users, and effectively reducing service costs, improving service quality, and increasing user perception are the current urgent needs, which have been listed by operators as building the key issue of "smart operation" [11]. Elayyan and others said that with the development of artificial intelligence, the research of robots has also made great progress. Robots of various forms and functions have appeared one after another, and some robots have even entered people's homes and become members of the family [12]. Batarseh and others stated that the most important way for humans to interact with robots is through voice, which is more direct and convenient than other methods such as buttons, touch screens, and remote controls. Therefore, a human-machine with good performance is designed in the development of robots. The voice interaction system is very important. The intelligence of the robot must first be manifested in the smooth human-machine voice interaction function. The human-machine voice interaction system has become the most basic functional design requirement [13].

This paper combined with the requirements of information technology service-related standards and specifications, as well as the operation and maintenance project implementation experience and the key generic technology for information system operation and maintenance, provide system support for information system operation and maintenance specification, realize the information system operation and maintenance support system software industrialization and operational service interactive development pattern, drive the market demand of information system operational service, and promote the rapid formation and healthy development of operation and maintenance service industry chain.

3. Method

3.1. Use Bayesian Algorithm to Achieve Text Classification. Big data has now been summarized as having the characteristics of 4v: volume, velocity, variety, and value. The total data growth is shown in Figure 2.

Big data is a brand-new business model, life philosophy, and ideology developed on the basis of multiple data and cross-domain associations. This new approach to tools will have a huge disruptive impact on all aspects of our society. This is summarized on the basis of the characteristics of big data. With the continuous development of big data, when it reaches the advanced stage, it will generate new value and bring a qualitative leap to all aspects of society such as enterprises and schools [14]. There are many classic classification methods in machine learning, such as decision tree
Figure 1: Flow chart of the intelligent interactive system management platform.

— The total amount of data grows
Figure 2: Growth graph of total data.

algorithms, support vector machines, Bayesian classification algorithms, artificial neural networks, and k-nearest neighbors. To process the text recognized by the speech recognition function, and to deal with the text classification problem, the naive Bayes classifier is one of the most effective algorithms. There are three reasons why Bayesian algorithm is often used to achieve text classification. First, the Bayesian algorithm is simple; second, it is easy to get the probability value required to train the Bayesian classifier based on the training text; third, naive Bayes classifier is comparable to other algorithms in most cases, and in some cases even better than other algorithms. The classification problem is the process of finding the best hypothesis from the hypothesis space given the training data. For sentence text Q, we can denote it as $\langle a_1, a_2, \ldots, a_n \rangle$ after word segmentation, where $a_i\,(1 \leq i \leq n)$ represents the word in sentence Q [15]. The classification of Q in this article is to divide it into a certain category of daily life frequently asked question and answer library, professional field frequently asked question and answer library, real-time question library, or control instruction library, that is, to deal with the following questions:

$$v_{\text{MAP}} = \arg\max_{v_j \in V} P(v_j | a_1, a_2, \ldots, a_n), \quad (1)$$

where v_{MAP} represents the maximum posterior value; V represents the category set of the library composed of the daily FAQ library, the professional field FAQ library, the real-time question library, and the control instruction library; and the v_j is the category that Q can be divided into [16]. Using Bayesian formula, formula (1) can be rewritten as

$$v_{\text{MAP}} = \arg\max_{v_j \in V} \frac{P(a_1, a_2, \ldots, a_n | v_j) P(v_j)}{P(a_1, a_2, \ldots, a_n)}$$

$$= \arg\max_{v_j \in V} P(a_1, a_2, \ldots, a_n | v_j) P(v_j), \quad (2)$$

where $P(v_j)$ represents the probability of each target value v_j and $P(a_1, a_2, \ldots, a_n | v_j)$ represents the probability of

5 under the condition of the target value v_j. We can get $P(v_j)$ by counting the number of frequently asked questions in daily life, frequently asked questions in professional fields, real-time question banks, or control instruction banks. But to get the value of $P(a_1, a_2, \ldots, a_n | v_j)$, a large training data set is required. In order to reduce the amount of calculation, it can be assumed that the words $a_i \, (1 \leq i \leq n)$ in the sentence are independent of each other, which reduces the problem to a naive Bayes classification problem. The corresponding formula (2) can be simplified as follows:

$$
\begin{aligned}
v_{NB} &= \arg\max_{v_j \in V} P(a_1, a_2, \ldots, a_n | v_j) P(v_j) \\
&= \arg\max_{v_j \in V} P(v_j) \prod_i P(a_i | v_j),
\end{aligned}
\tag{3}
$$

where v_{NB} represents the target value output by the naive Bayes classifier, $P(v_j)$ represents the probability of each target value v_j, and $P(a_i | v_j)$ represents the probability of word $a_i \, (1 \leq i \leq n)$ under the condition of the target value v_j. To use the naive Bayes classifier to deal with the sentence text classification problem, at this time, we only need to estimate $P(v_j)$ and $P(a_i | v_j)$ from the training data [17].

3.2. Human-Machine Voice Interaction System Based on ROS.
The execution process of the designed ROS-based human-machine voice interaction system is shown in Figure 3.

The main functions in the human-machine voice interaction process are described in detail below.

3.2.1. Voice Information Collection.
The voice information is collected through the external microphone of the robot, and the collected voice information is stored as an audio file. The quality of user voice information collected in a noisy environment will be disturbed by noise. In addition, it is impossible to know in advance when the user will speak to the robot, whether he is talking to the robot, and the duration of the speech. Therefore, the problems of noise interference, when to collect the user's voice information, and the collection time must be solved first [18]. These problems can be solved by voice activity detection (voice activity detection, VAD) technology. Voice endpoint detection technology is a basic link in speech recognition and speech processing, and it is also a popular field of speech recognition research. Its main purpose is to distinguish speech and nonspeech from the input speech. The main functions are automatic interruption, removal of silent components in the voice, obtaining effective voice in the input voice, and removing noise to enhance the voice. The open-source project pyVAD on GitHub is used to implement endpoint detection on the voice data read in real time.

3.2.2. Voice Recognition Node.
The voice recognition node is responsible for recognizing the collected voice information as text information. This article uses the REST API provided by Baidu voice to implement speech recognition. The speech recognition REST API provides developers with a universal HTTP interface that supports the POST method [19]. Based on this interface, developers can easily implement speech recognition functions. The API supports the recognition of the entire recording file; that is, the user needs to upload the entire voice, but the original voice file must conform to the specified format.

3.2.3. Speech Synthesis Node.
The speech synthesis node is responsible for synthesizing the requested information into audio. The speech synthesis is realized by using the REST API provided by Baidu voice. Speech synthesis REST API supports the synthesis of a paragraph of text, but the text must be encoded in UTF-8, and the text length must be less than 1024 bytes [20]. Currently, the interface supports both POST and GET methods.

3.2.4. Semantic Analysis Node.
The semantic analysis node has the function of understanding the request information received from the speech recognition node to determine what operation the robot should perform. The semantic analysis node must not only provide services to the speech recognition node but also must be able to request services provided by other nodes or publish information on specific topics [21].

3.2.5. Real-Time Information Acquisition Node.
Through real-time information acquisition nodes, real-time changing information content, such as time, date, weather, and news, can be obtained. Nodes that provide time and date information access services, and nodes that provide weather access services in major cities are now implemented [22].

3.2.6. Robot Control Function Node.
The robot control function nodes include nodes that control the robot to walk, avoid obstacles, and reach designated positions. These nodes need to be developed separately. On the PC side, the robot's walking function is tested and controlled by the turtlesim software package officially provided by ROS, and the function of playing music through voice control is also realized. On the built robot platform, the Python program that controls the movement of the motor is written through the GPIO port to realize the control of the robot [23].

4. Results and Analysis

Through analysis, the steps to classify sentence text Q are as follows:

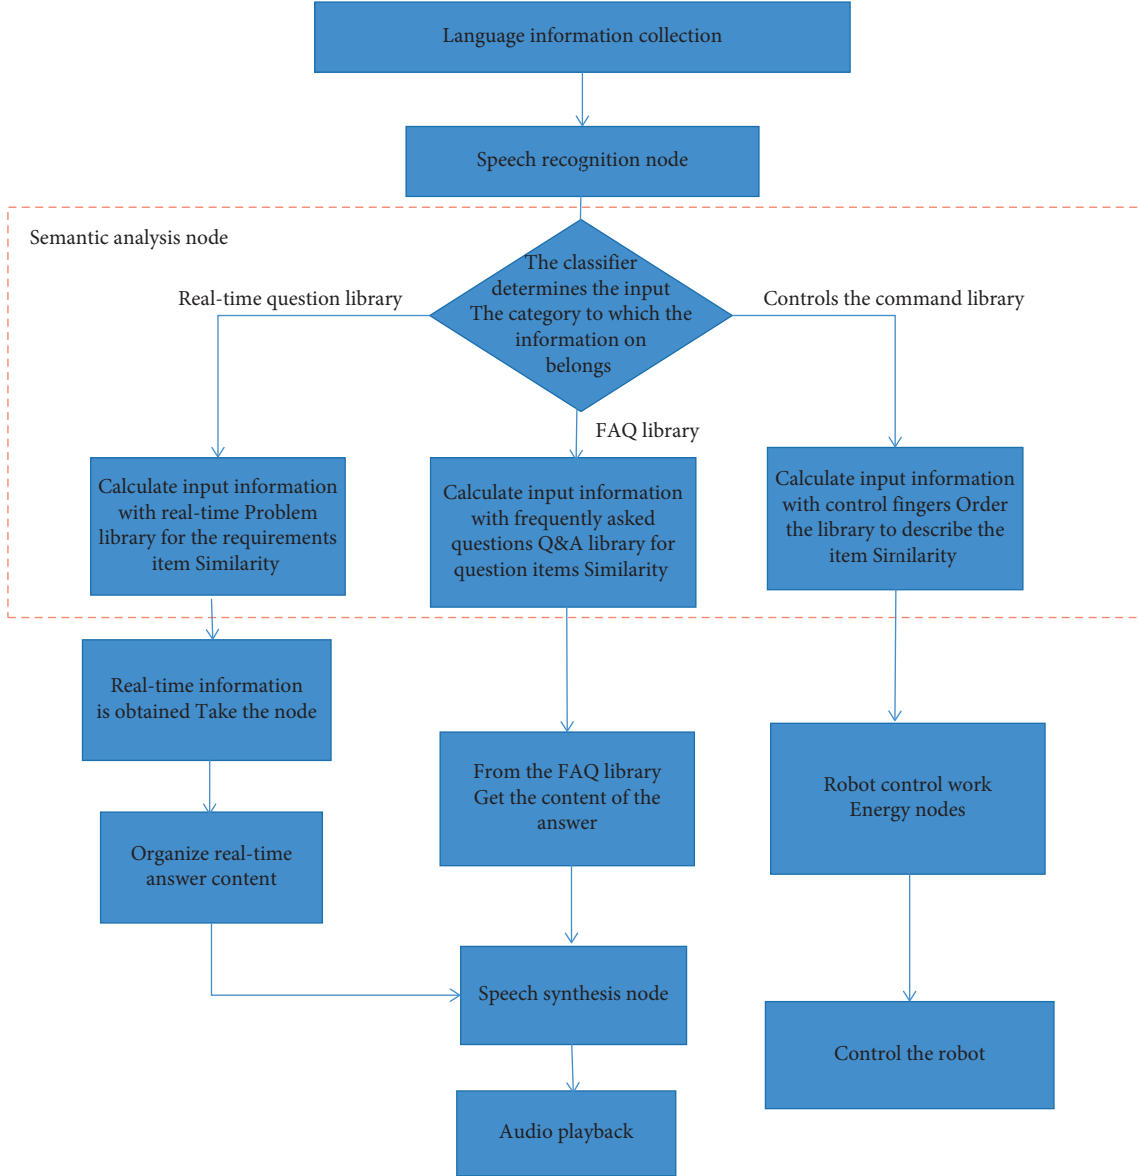
Step 1. Collect and connect the question item in the FAQ database of daily life as a document and record it as category 1. Collect and connect the question item in the FAQ database of each professional field as a document and record it as category 2 (for convenience Explain that it is assumed that there is only one frequently asked question library in the professional field); the question item in the collection and connection real-time question library is a document, which is recorded as category 3; the question item in the collection


FIGURE 3: Human-machine voice interaction system execution process.

and connection control instruction library is a document, and is recorded as category 4 [24].

Step 2. Combine all categories of documents into a document, use Chinese word segmentation method to segment the Document, collect all the words in the Document, and form a collection Vocabulary. All categories form a set V, that is, $V = \{$category 1, category 2, category 3, category 4$\}$.

Step 3. For each target value v_j in V, calculate the probability term $P(v_j)$:

$$P(v_j) = \frac{|\text{docs}_j|}{|\text{Document}|}, \tag{4}$$

where docs_j is the subset of documents whose target value is in Document, $|\text{docs}_j|$ is the number of elements it

has, and $|\text{Document}|$ is the total number of category libraries that Document has [25].

Step 4. For each target value v_j in V, connect all members in docs_j to build a document Text_j, use Chinese word segmentation method to segment Text_j, and count the number n of different words in Text_j.

Step 5. For each word a_i in Vocabulary, calculate the probability term $P(a_i|v_j)$:

$$P(a_i|v_j) = \frac{n_k + 1}{n + |\text{Vocabulary}|}, \tag{5}$$

where n_k is the number of occurrences of word a_i in Text_j, and $|\text{Vocabulary}|$ is the total number of words that Vocabulary has [26].

Step 6. Use the Chinese word segmentation method to segment the sentence Q to get $\langle a_1, a_2, \ldots, a_n \rangle$, where a_i represents the word that appears at the i-th position in Q.

Step 7. Get the category v_{NB} to which Q belongs

$$v_{NB} = \arg\max_{v_j \in V} P(v_j) \prod_{i \in \text{positions}} P(a_i | v_j), \qquad (6)$$

where positions are the position where all words appear in Q. Any words that appear in Q but not in the documents in the training set will be simply ignored [7].

In order to verify the performance of the proposed ROS-based human-machine voice interaction system, experiments were carried out on the PC terminal and the robot platform built in the laboratory to test the human-machine voice question and answer function and the robot control function [27]. PC environment: Ubuntu 12.04, 32-bit operating system, the processor is Pentium(R) Dual-Core CPU E6500 @2.93 GHz 2. Install the robot operating system ROS on the Ubuntu system and choose Hydro as the ROS version. Sound collection device: USB microphone. Audio playback equipment: USB stereo. The robot platform is built on the HCR (Home Care Robot) omnidirectional wheel development platform. The central processor of the robot platform uses Raspberry Pi 2B, and the system installed on the Raspberry Pi is Raspbian wheezy. Install ROS on the Raspberry Pi, and the ROS version is Hydro. The GPIO port is used to control the rotation of the motor to make the robot walk. The motor drive module adopts SKU: DRI0018. Use a USB microphone to collect voice information and use a USB speaker to play audio.

As can be seen from Figure 4, after data smoothing, the obtained sample data are sorted from small to large. In order to ensure that all data are generated under nonabnormal conditions, the smallest and largest numbers need to be eliminated. The obtained data are as follows: [24, 34, 38, 39, 39, 39, 41, 41, 51, 53, 54, 56, 63, 63, 66, 67, 69, 73, 78, 79, 79, 79, 81, 87, 89, 91, 94 ,99, 102, 103]. Determine the range of 5 intervals, 103/5 = 21, namely, [0~21], [21~42], [42~63], [63~84], and [84~105]. Distribute the remaining 28 numbers after removing the abnormalities into these 5 intervals (interval minimum value ≤ N < interval maximum value). Interval 1 = []; Interval 2 = [34, 38, 39, 39, 39, 41, 41]; Interval 3 = [51, 53, 54, 56]; Interval 4 = [63, 63, 66, 67, 69, 73, 78, 79, 79, 79, 81]; interval 5 = [87, 89, 91, 94, 99, 102]. After interval allocation, it can be seen that the number of data in interval 4 is the largest. Therefore, the data in interval 4 and the upper and lower adjacent intervals 3 and 5 are taken. If there are no data in the upper and lower adjacent intervals, it is not necessary to take them. 21 data can be obtained [28].

The daily life frequently asked question and answer library established during the experiment contains 15 question and answer pairs, the library frequently asked question and answer library contains 50 question and answer pairs, the real-time question library contains 19 questions, and the control instruction library contains 30 instructions. The similarity value is a unitless real number in the interval of $[0, 1]$. The closer the value is to 1, the more similar the
Figure 4: Data smoothing calculation data diagram.

meaning of the two sentences, and vice versa. Regarding the calculation of similarity, several existing basic methods are all based on vectors. In fact, it is to calculate the distance between two vectors. The closer the distance is, the greater the similarity. In the recommended scenario, in the two-dimensional matrix of user-item preferences, we can use a user's preference for all items as a vector to calculate the similarity between users, or use all users' preferences for an item as a vector A vector to calculate the similarity between items.

In order to test the performance of the similarity calculation method, three question items from the daily FAQ database were selected as "question sentences," and the similarity values between these three questions and each question item in the daily FAQ database were calculated. Table 1 lists the first three largest similarity values obtained in each calculation. The similarity value of each question in the table with itself is 1.00000.

Table 2 shows the similarity values between the three question sentences and the three question items in the library frequently asked questions and answers library.

Table 3 shows the similarity values between the question sentences expressing the same meaning and the question items in the library frequently asked questions. From the results in Table 3, it can be seen that for the same subject matter, if different questioning methods are used, it can also be well matched to the question item in the library. The adopted sentence similarity calculation method has strong adaptability to a variety of questioning methods.

Three question items are selected from the real-time question database as question sentences, and the similarity values between these three question sentences and each question item in the real-time question database are calculated, respectively. Table 4 lists the first three largest similarity values obtained in each calculation. The similarity value of each question in the table with itself is 1.00000.

The question "What's the time now?" is the same as the question item "What time is it now" and "Do you know what

What should I do if the journal I want to borrow is not in the library?	What if the library does not have the books and periodicals I need?	0.65000
	My library personal information	0.49027
	What is my library account password?	0.47153

Table 4: Examples of sentence similarity calculation results under the real-time question bank.

Question	The question item in the frequently asked questions and answers library of daily life	Similarity value
What time is it now?	What time is it now?	1.00000
	What time is it now?	0.88205
	Do you know what time it is now?	0.82591
Do you know what's the date today?	Do you know what's the date today?	1.00000
	What's the date today?	0.62517
	Tell me today's date?	0.28405
How's the weather today?	How is the weather today?	1.00000
	How is the weather tomorrow?	0.75755
	Tell me how is the weather today?	0.74058

time it is?" The question "Do you know today's date?" expresses the semantic content of "date query," and the question item "What is today's date?" The similarity value is 0.62517. The question item "Tell me today's date?" is the same as the semantic content of the question sentence, but the similarity value between the two is relatively small. It can also be seen from this that only relying on the Chinese knowledge dictionary and the number of identical words contained in the two sentences to measure the similarity between sentences cannot achieve very good performance, and the similarity calculation method can be further optimized.

5. Conclusion

From Table 1 above, it can be seen that the question "What is your name?" and the question item "What your name is it?" express the same semantic content, and the similarity value calculated by the experiment is 0.74825. And "Do you know what my name is?" is different from the semantic content of the question sentence, "Do you know what my name is?" is the user asking the robot his name, and "What is your name?" the user asking the name of the robot. Although the two sentences are intended to obtain names, the objects of the names to be obtained are different, so the calculated similarity value is relatively small. The question "What do you do?" and the question item "What can you do?" express the same semantic content, but the calculated similarity value is 0.48597, which shows that the sentence similarity calculation method adopted has room for improvement. The question "Do you know me?" and the question "Do you know what my name is?" are both the user asking the robot for his name. The calculated similarity value is 0.75549, which is very close to 1.00000.

The combination of interactive systems and artificial intelligence has greatly improved the accuracy and friendliness of interactive services. But at the same time, higher requirements are put forward for knowledge processing and learning, semantic intent recognition, interactive scenarios, and multiple channels. From the perspective of "achievable and deployable," the construction of an intelligent interactive system architecture based on artificial intelligence provides functional design and optimized solutions to current problems and challenges, so as to further make interactive services more intelligent and rich, humanized, and convenient. It lays the foundation for the subsequent formation of an intelligent interactive product system that can be promoted, replicated, and reduced in cost and increased efficiency. The experimental results show that the design achieves small positioning error; improves the system accuracy; greatly facilitates the installation, debugging, and maintenance of the positioning network; and reduces the labor cost of the network layout.

The implementation of the information operation and maintenance comprehensive supervision system has undergone a lot of preparations, but due to the large number and variety of information system equipment involved in the monitoring of the system, the realization of some functions in the implementation process is not satisfactory, and the system is still in application. There are areas that need further improvement, and its shortcomings are summarized as follows:

(1) The host, network, middleware, database, information security, and terminal equipment in the implementation of the information operation and maintenance comprehensive supervision system all involve alarm content. Due to the limited display interface, it cannot be displayed on the same interface. The real-time monitoring of information system monitoring personnel monitoring work increases the workload.

(2) Since there are many types of information system software and hardware that enterprises need to monitor, the display center needs to display network, application system, and performance data on multiple interfaces, which brings a lot to the daily monitoring work of operation and maintenance monitoring personnel of greater pressure.

China's huge regional differences are taken into consideration to study the influencing factors and their differences in CO_2 emissions of the power industry from different regions. This study aimed to improve the efficiency of CO_2 emission reduction policies. From the production and consumption perspectives, this study analyzes the influencing factors of CO_2 emissions and utilizes the Logarithmic Mean Divisia Index (LMDI) to decompose CO_2 emissions with consideration of the cross-regional power dispatching in the power industry. The results indicate that the trend of CO_2 emissions in the eastern, central, and western China seems similar during years 2005 to 2017 no matter from which perspective. From the production perspective, power consumption is the main factor in CO_2 emission increase and its affect extent may vary from different regions over a period of time. Energy efficiency inhibits CO_2 emission increase in all regions. The power structure and power distribution across regions affect CO_2 emissions significantly different in amount and direction from region to region. From the consumption perspective, economic activity plays a major role in CO_2 emission increase and plays a similar role in the trend of CO_2 emissions in three regions, but its affect extent on CO_2 emissions varies in different regions. Targeted policy recommendations are provided to reduce CO_2 emissions more effectively from China's power industry.

1. Introduction

Climate change caused by excessive carbon emissions is a serious threat to nature. China replaced the United States in 2006 to become the world's largest carbon emitter along with rapid economic development. After realizing the urgency of reducing CO_2 emissions, the Chinese government has decided to reduce carbon intensity by between 55% and 60% [1]. In addition, China committed to peak carbon emissions by 2030 at the Asia Pacific Economic Cooperation (APEC) in 2014 [2], but it is not easy for China to fulfill this commitment [3]. The power industry in China is high in energy consumption and emission, which accounts for 50% of coal consumption and 40% of CO_2 emissions in China [4]. Apparently, the power industry should therefore be the priority to reduce CO_2 emissions. However, China is with regional differences in natural resources, economy,

population, and technology. Taking this into account, we aimed to study the regional differences in CO_2 emissions in the Chinese power industry in order to improve the carbon emission efficiency.

It is noteworthy that more scholars began to pay attention to the influencing factors of regional differences in CO_2 emissions. Some scholars have analyzed carbon inequality between countries and explained the root reasons for global inequality during the sample period [5, 6]. Malla (2009) [7] discussed the factors influencing the evolution of carbon emissions from the power industry in several countries. Its results have shown that the influencing extent of factors on CO_2 emissions varied in different countries. Except for studies among countries, some research studies have examined differences among regions in emissions within a broad country such as China. Liu et al. [8] studied GHG emission characteristics, trends, and influencing

factors of four Chinese cities and concluded that emission reduction policies should vary in different cities. Chen et al. [9] studied regional differences in CO_2 emissions generated by coal consumption and explained that the root reason for emission differences is the disparity in economic growth. Moreover, some scholars have studied interregional differences in CO_2 emissions in the power industry. Wen and Yan [10] used a panel data model to study factors driving CO_2 emissions from the Chinese power industry from the regional and provincial perspectives. The results have shown that the impacts were different across regions. Zhou et al. [11] assessed the multiple factor impact of CO_2 emissions from power generation at the regional grid level from 2004 to 2010. The research found that the power grid in the northern China performed poorly. Yan et al. [12] further analyzed regional differences in power consumption and predicted CO_2 emissions for each region from 2013 to 2020 on the basis of Zhou et al.'s [11] paper.

Nevertheless, previous research studied the regional differences and driving factors of CO_2 emissions in the power industry only from a single perspective of production and did not consider the balance between producer responsibility and consumer responsibility in emissions, which to some extent weakens the emission reduction effect. Carbon leakage is likely to be caused when producer responsibility is employed to calculate CO2 emission of power industry which means CO2 emission from the power industry in each region is equal to direct CO2 emission from thermal power generation. This method ignores the phenomenon of carbon leakage in interprovincial power dispatching and characteristics of interregional power dispatching.

Scholars have studied regional carbon emissions from the consumption perspective due to power dispatching complexity. Wang et al. (2017) [13] extended the methods of Kang et al. (2012) [14] and Ji et al. (2016) [15] to propose a new estimation method, which is relatively accurate to measure CO_2 emissions of regional consumer. There is vast power dispatching around China with the power grid construction to solve the contradiction of power supply and demand. Some scholars have proved that CO_2 emissions are significantly different under different measurement perspectives. It is unilateral for either producers or consumers to undertake emission reduction obligations. The accounting scheme of carbon emission responsibility based on producers and consumers should be adopted to solve the imbalance of CO_2 emissions in the regional power industry [16].

The paper adopts the method of Wang et al. [13], Kang et al. [14], and Ji et al. [15] to calculate regional CO_2 from both production and consumer perspectives. The core idea of "carbon accounting" schemes is to consider the spatial transfer of emissions caused by power trading to fully reflect consumers' environmental responsibility. It is more conducive to reveal the real situation of carbon emission transfer among regions to study from both production and consumption perspectives and provide correct suggestions for carbon emission reduction. Therefore, this study employs Wang et al.'s [13] method to calculate regional CO_2 emissions from the production and consumption perspectives.

The commonly used approach in previous papers to study the impact of factors on carbon emissions from the energy industry is the LMDI due to its adaptability, availability, and easy interpretation of results (Ang 2004) [17]. The main driving factors at present affecting CO_2 emissions from the power industry are divided into economic and social factors (economic activities, population, etc.), structural factors (energy structure, industrial structure, etc.), and efficiency factors (energy efficiency, consumption efficiency, etc.) [4, 10, 18–20]. However, seldom scholars regard power dispatching as a factor affecting carbon emissions. With the power dispatching increase, it should be considered as an influencing factor of CO_2 emissions caused by power generation [20]. Even if some scholars have taken power dispatching as a driving factor in carbon emission, research was studied at the national level but without taking regional differences into account. We argue that there should be differences in the impact of power dispatching on carbon emissions in power import and export regions.

The current existing literature rarely considered power dispatching as a driving factor when studying regional differences in CO_2 emissions in the power industry. This usually leads to deviations in the accuracy of assessment results. On this basis, we first divide China into three regions based on different economic and geographic distributions and then calculate regional CO_2 emissions from the power industry from the production and consumption perspectives, respectively. Finally, we employ the LMDI method to determine the factors influencing the regional CO_2 emissions of China's power industry from two perspectives. Compared with existing research, we intend to contribute in two ways: (1) this study analyzes the variation trend of regional carbon emissions from both production and consumption perspectives under consideration of mass cross-regional power dispatching in China's power industry, which makes the analysis results more systematic and comprehensive. (2) Moreover, this study also divided CO_2 emission influencing factors from the power industry into production factor and consumption factor, which can determine influencing factors on CO_2 emissions from the regional power industry more accurately, and provided valuable suggestions for China to formulate more effective policies on carbon emission reduction.

The rest of the study is structured as follows. Section 2 introduces the main calculation method and data description. Section 3 presents the decomposition results and discussion. Section 4 summarizes the paper and provides policy recommendations.

2. Methods and Theory

2.1. Production Perspective

2.1.1. Estimate CO_2 Emissions from the Production Perspective. We apply the method provided by the Intergovernmental Panel on Climate Change (IPCC) to calculate CO_2 emissions from thermal power generation in one region from the production perspective without

considering power dispatching across regions. The CO_2 emission formula for the given region is as follows:

$$C^a = \sum_i C_i^a = \sum_i F_i \times K_i \times \varepsilon_i \times \gamma_i \times \frac{44}{12}, \quad (1)$$

where C^a is the CO_2 emission amount from burning of fossil fuels in one area. i is the fossil fuel type. F_i is the quantity of the ith fossil fuel in this area. K is the net heating value. ε_i is the oxidizer of carbon. γ_i is the carbon emission coefficient. 44/12 is the molecular weight ratio. We assume that the carbon emission coefficients of various fuels remain constant during the study period. Although the coefficients vary over time due to changes in fossil fuel grade, these changes are relatively small. Therefore, it can be ignored in the analysis of more important coefficients in CO_2 emissions [18].

2.1.2. Decomposition Method from the Production Perspective. Decomposition from the production perspective of CO_2 emission is expressed as follows:

$$C^a = \frac{C^a}{E} \frac{E}{Q_F} \cdot \frac{Q_F}{Q_P} \cdot \frac{Q_P}{Q_T} \cdot Q_T, \quad (2)$$

where E is the fossil fuel consumption for thermal power generation in the region. Q_F is the thermal power generation in the region. Q_P is the overall amount of power generated in the region (including thermal power and hydroelectric power). Q_T is the total power consumption in the region (including final consumption and transmission loss).

Equation (2) is equivalent as follows:

$$C^a = CC \cdot EE \cdot ES \cdot IO \cdot Q. \quad (3)$$

The function could be edited as follows according to the LMDI additive decomposition method:

$$\Delta C^a = C_{t_2}^a - C_{t_1}^a = \Delta C_{CC} + \Delta C_{EE} + \Delta C_{ES} + \Delta C_{IO} + \Delta C_Q. \quad (4)$$

According to the LMDI additive decomposition method, we decompose the overall change amount ($\triangle C$) of CO_2 emission from the power industry into five influencing factors based on the producer responsibility in the base year and target year. CC is the carbon emission coefficient. ΔC_{CC} is the impact of the fossil fuel structure change. EE is the energy efficiency of thermal power. ΔC_{EE} is the influence of the energy conversion efficiency change in thermal power. ES is the power structure. ΔC_{ES} is the change influence of power structure on CO_2 emission. IO is the power dispatching across regions. ΔC_{IO} is the impact of changes in power distribution across regions. Q is the power consumption. ΔC_Q is the impact of changes in power consumption on CO_2. t_2 and t_1 are base year and target year, respectively ($t_2 > t_1$).

We utilize the following formulas to calculate these driving factors:

$$\Delta C_{CC} = L\left(C_{t_2}^a - C_{t_1}^a\right) \cdot \ln\left(\frac{CC_{t_2}}{CC_{t_1}}\right), \quad (5)$$

$$\Delta C_{EE} = L\left(C_{t_2}^a - C_{t_1}^a\right) \cdot \ln\left(\frac{EE_{t_2}}{EE_{t_1}}\right), \quad (6)$$

$$\Delta C_{ES} = L\left(C_{t_2}^a - C_{t_1}^a\right) \cdot \ln\left(\frac{ES_{t_2}}{ES_{t_1}}\right), \quad (7)$$

$$\Delta C_{IO} = L\left(C_{t_2}^a - C_{t_1}^a\right) \cdot \ln\left(\frac{IO_{t_2}}{IO_{t_1}}\right), \quad (8)$$

$$\Delta C_Q = L\left(C_{t_2}^a - C_{t_1}^a\right) \cdot \ln\left(\frac{Q_{t_2}}{Q_{t_1}}\right). \quad (9)$$

L is the logarithmic mean value:

$$L(x, y) = \begin{cases} y - x/\ln y - \ln x, & x \neq y \\ x, & x = y \end{cases}.$$

2.2. Consumption Perspective

2.2.1. Decomposing CO_2 Emissions from Consumption Perspective. Local power consumption should be taken into account when calculating the overall CO_2 emissions in the region. CO_2 emissions from power utilization are estimated as follows:

$$C = C^a + C^b, \quad (10)$$

where C is the actual CO_2 emissions in the region based on consumer responsibility. C^b is the CO_2 emission allocation due to cross-regional power dispatching, which will be discussed in the next section. C^a is the CO_2 emissions from thermal power in the region. C^b is the CO_2 emission allocation in the region. We classify all provinces into two types according to Wang et al. (2017) [13].

$$\Delta = I - O, \quad (11)$$

where Δ is the net power consumption of one province. O is the output power from one province, while I is the input power from other provinces. $\Delta > 0$ means that the input power exceeds output power, and the province will be regarded as power import province. $\Delta < 0$ means that the output power exceeds input power, and then, the province will be regarded as power export province. We assume that each province gives priority to power production of its own.

2.2.2. Decomposing CO_2 Emissions in Power Export Provinces

$$C_m^b = \Delta \times \frac{Q_{F_m}}{Q_{P_m}} \times \frac{C_{F_m}}{Q_{F_m}}, \quad (12)$$

where C_m^b is the power export province. m is CO_2 emission dispatching. Q_{F_m} is the thermal power produced by province m. Q_{P_m} is the overall power produced by province m (including thermal power generation and hydroelectric power generation). Q_{F_m}/Q_{P_m} is the ratio of the thermal power

generation to total power generation in province m. C_{F_m} is the CO_2 emissions from thermal power generation in province m. C_{F_m}/Q_{F_m} is the emission factor of the thermal power generation.

2.2.3. Decomposing CO_2 Emissions in Power Import Provinces.

$$C_n^b = \Delta \times \frac{\sum_{m=1}^{m} |C_m^b|}{\sum_{m=1}^{m} Q_{F_m}} \times \frac{\sum_{m=1}^{m} Q_{F_m}}{\sum_{m=1}^{m} Q_{T_m}}, \tag{13}$$

where C_n^b is the dispatch of CO_2 emissions in the power import province.

$\sum_{m=1}^{m} |C_m^b| / \sum_{m=1}^{m} Q_{F_m}$ is the power emission factor of the total output thermal power generation, and Q_{F_m} is the thermal power generation distributed from province m.

$\sum_{m=1}^{m} Q_{F_m} / \sum_{m=1}^{m} Q_{T_m}$ is the ratio of dispatching amount on thermal power generation to total power dispatching. Q_{T_m} is the total export power of the power output province (including thermal power generation and hydroelectric power generation).

2.2.4. Decomposition Method from the Consumption Perspective.

According to Kaya (1989) [21] and considering the importance of industrial structure change, we decompose the exponent of CO_2 emissions from consumption perspective as follows:

$$C = \frac{C}{Q_T} \cdot \frac{Q_T}{GDP} \cdot \frac{GDP}{P} \cdot P. \tag{14}$$

Its abbreviation is as follows:

$$C = CI \cdot EI \cdot EA \cdot P. \tag{15}$$

GDP is the gross domestic product of the region. P is the resident population of the region. Similar to the above description, the annual rate of CO_2 increase can be decomposed into the following formula:

$$\Delta C = C_{t_2} - C_{t_1} = \Delta C_{CI} + \Delta C_{EI} + \Delta C_{EA} + \Delta C_P, \tag{16}$$

where CI is the carbon intensity of power consumption, reflecting the cleanliness of power consumption in the region. ΔC_{CI} is the influence of power consumption on carbon intensity changes. EI is the power intensity, which reflects the industrial structure. ΔC_{EI} is the impact of power intensity changes. EA is the economic activities. ΔC_{EA} is the impact of economic development and change. ΔC_P is the impact of population size fluctuations.

The right side of (15) can be computed as equations (5)–(9), which are not listed here due to limited space.

2.3. Data Description.

Considering the data accessibility and the impacts of COVID-19 pandemic on energy consumption in 2020, the Chinese power industry data from 2005 to 2019 were used in this study. We employ data on energy consumption caused by power generation in different provinces from the China Energy Statistical Yearbook (2005–2019).

Besides, population data and GDP data came from China Statistical Yearbook (2005–2019). Regional GDP from 2005 to 2019 was converted on the basis of the price level in 2005. The IPCC effective CO_2 emission factor and net calorific value of fuel were also considered. According to the geographical distribution and economic level, 30 provinces in China (Tibet, Taiwan, and Hong Kong were excluded) were divided into three parts. The detailed classification is listed in Table 1.

3. Results and Discussion

3.1. Outline of CO_2 Emissions from the Power Industry.

As shown in Figure 1, the CO_2 emissions in three regions from 2005 to 2017 mainly go through two phases, and their trends are also similar no matter from which perspective. The first phase is from years 2005 to 2011, and the CO_2 emissions in all regions increased significantly over time. The second phase is after 2011, and CO_2 emissions in each region are only slightly increased and even decreased in some years. The trend of CO_2 emissions in recent years proves that the Chinese green and low-carbon policies in the power industry have been effectively implemented. Although the overall trend of CO_2 emissions in three regions is almost the same, it is obvious that CO_2 emissions look higher from the consumption perspective than those from the production perspective in all tress regions.

The growth rate of CO_2 emissions in central China was lower than the other two regions from the production perspective. The CO_2 emissions in western China exceeded the central China from 2010 to 2011. This is mainly due to two main reasons: economic development is positively correlated with power consumption, so the developed eastern China requires a large amount of power to support its high economy. On the other hand, the economic development of western China is mainly extensive and it has carried on enterprise with high CO_2 emissions from other regions during industrial development and upgrading of China's industries.

The growth rate of CO_2 emissions in the eastern China was apparently the highest from consumption perspective. The current economic development needs power support, and the high economic aggregate in eastern China is precisely supported by large quantities of power consumption. This will become even more evident under the principle of "People who consume who take the responsibility." In general, the eastern China is with the highest carbon emissions from either production perspective or consumption perspective. Therefore, the eastern China should play a leading role in carbon reduction projects in the power industry. In addition, Figures 1(a) and 1(b) indicate that the regional amount and growth rate of CO_2 emissions are significantly different and the consumption side is higher than the production side in three regions from both perspectives.

Therefore, the analysis from two perspectives can provide a more systematic and comprehensive understanding of regional differences in CO_2 emissions in the power industry.

TABLE 1: Detailed classification of the Chinese regional divisions.

Regions	Provinces
East regions	Beijing, Tianjin, Hebei, Liaoning, Shanghai, Jiangsu, Zhejiang, Fujian, Shandong, Guangdong, Hainan
Central regions	Shanxi, Jilin, Heilongjiang, Anhui, Jiangxi, Henan, Hubei, Hunan
West regions	Chongqing, Sichuan, Guizhou, Yunnan, Shaanxi, Gansu, Ningxia, Qinghai, Xinjiang, Guangxi, Inner Mongolia
FIGURE 1: CO_2 emissions from the power industry in three regions from 2005 to 2017: (a) CO_2 emissions in three regions from the production perspective. (b) CO_2 emissions in three regions from the consumption perspective.

3.2. Results and Discussion from the Production Perspective. We discuss the impact of driving factors of three regions on CO_2 emissions from the Chinese power industry in this section. The power consumption is the most important factor for CO_2 generation in all regions, which is known from results (as shown in Figure 2 and Table 2). The energy efficiency is the major factor in restraining every region's CO_2 emissions even though the energy efficiency improvements in the west were not significant at the beginning of the study. The power generation structure and cross-regional power distribution have different effects on CO_2 emissions in terms of scale and direction in three regions. The carbon emission coefficient is not the main driving factor compared with other factors during the study period. We will discuss more details in the following parts.

3.2.1. Carbon Emission Coefficient and Energy Efficiency. Changes in carbon emission coefficient have a relatively low impact on CO_2 emissions compared with other factors in all regions. It reflects that the change in fossil fuel structure in the thermal power generation is small. The ratio of coal in total fossil fuel for the thermal power generation has always remained above 90% and has no signs of decline as shown in Table 3. Generally speaking, the fossil energy structure mainly depends on the overall regional resources. In China, the structure of fossil energy has been in a state of "more coal, less oil, and shortage of natural gas." The raw coal occupies 70% of energy consumption and will not change greatly in a short time [16]. The results show that the changes in fossil fuel structure affecting CO_2 emissions in the power

industry are weak. It also proves that there is still a long way to change the mix of fossil fuels in the thermal power generation in all regions.

The energy efficiency of thermal power generation is the main factor to restrain CO_2 emissions from the power industry in all regions. The CO_2 emission reductions in the eastern, central, and western China reached 43.25%, 39.86%, and 21.05%, respectively (Table 2). Although energy efficiency increased in all regions from 2005 to 2019, it had a smaller impact on CO_2 emission reduction in the western China than in the rest of the two regions. Additionally, we can see from Table 4 that the initial energy efficiency level is inconsistent in three regions during the study period and decreased from the east to the west. These phenomena are mainly caused by two reasons: (1) the economy of the central and western regions is relatively backward, which still keeps following the traditional extensive growth model. Both the central China and western China pay little attention to environmental protection; (2) it is also directly related to the resource they owned. For example, the environmental cost of hydro-rich provinces such as Sichuan and Yunnan is lower than the cost of coal-fired power. As a result, the production capacity of thermal power in these regions is not fully utilized and the energy efficiency of thermal power generation is low. Based on differences in energy efficiency in regions, the central China and western China have great potential to improve technologies of energy conversion.

3.2.2. Power Generation Structure and Cross-Regional Power Consumption. Hydropower is taken as the main comparison of power generation structure change. The power

$\triangle Q$ power consumption	1358.57	161.21%	761.03	155.32%	1067.27	134.55%

generation structure influences CO_2 emissions in three regions varied in scale and direction. The total CO_2 emission changes in the eastern, central, and western China are 3.09%, 3.79%, and -18.79%, respectively. As Figure 2 demonstrates, power generation structure changes slightly influence CO_2 emissions in eastern China, while greatly influencing fluctuations of CO_2 emissions in central China and greatly restraining CO_2 emissions in western China. These differences are mainly caused by uneven resource distributions in

regions. There is around 70% of hydroelectric power generated from western China from a national perspective. However, it is 40% of hydroelectric power generated from the west and less than 10% of hydroelectric power generated from the east from a regional perspective (Figure 3). Although the eastern China takes a low ratio in hydropower generation, it has little potential to increase this proportion (from technology perspective). The exploitable hydropower in the east coast of China only accounts for about 6% of the

total power supply, while the exploitable power in the southwest, northwest, south, and central China accounts for 92%. Hence, by the end of March 2021, there is no room for hydropower exploitation on the east coast of China, compared with more than 50% exploitable space in the western China [22]. Therefore, China should focus on optimizing the energy structure of power generation in the central and western China, especially in the western China, which is rich in natural resources. Power generation structure improvement is an efficient measure to reduce emissions, which can not only ensure the power generation but also avoid environmental pollution.

The unbalanced distribution of regional natural resources is also one of the reasons affecting power dispatching. China has begun to implement power distribution measures since the 1990s to solve the mismatch problem of regional power supply and demand. Figure 2 illustrates that the impact on scale and direction of power distribution on CO_2 emissions is inconsistent among regions. The power dispatching increases CO_2 emission in eastern and central China while promoting the CO_2 emissions in western China.

Although power dispatching plays different roles in different regions, it is beneficial to restrain CO_2 emissions from the power industry. Thus, increased efforts will continue to make power dispatching. The suppression effect on CO_2 emission of power transfer in eastern China is mainly because power import can not only solve the problem of

insufficient power supply but also has a relatively low cost compared with power generation technology improvement. Therefore, the ratio of power imports is increasing year by year.

The effect of power dispatching on CO_2 emissions in western China is by promoting to suppress, and it is because the western China has already transferred natural resource advantage into economic advantage through power dispatching. With hydropower ratio growth, the western China benefits from providing clean energy to the east and reduces local environmental pollution as well [23, 24]. In addition, the import power of central China declines, indicating that power generation pressure in the central China has shifted in search of lower economic costs. China will continue to vigorously promote power dispatching to address the imbalance between supply and demand and reduce emissions by current policies. Thus, western China should accelerate the improvement of energy efficiency and power generation structure with increased power dispatching.

3.2.3. Power Consumption. Power consumption is the primary factor that increases CO_2 emissions of the power industry with an impact of 158.39%, 170.12%, and 147.91% on overall CO_2 emissions in eastern, central, and western China, respectively. According to Figure 2, the impact of power consumption on CO_2 emissions from the power industry is almost consistent with the economic cycle. Mi and Zhao (2012) [25] have verified the Granger causality between power consumption and economic development. They believe that economic development inevitably leads to power consumption, and power consumption will support economic development in turn. It is interesting to find out that although three regions are different in initial economic levels, the power consumption has almost the same tendency to affect CO_2 emissions from the power consumption. As a result, we could not simply assume that the CO_2 emission growth rate caused by power consumption is lower in central and western China because of the lower level of economic development.

Moreover, Figure 2 indicates that the enhancement effects of power consumption on CO_2 emissions in the power industry reduce in all regions since 2011, especially in the central China. Nevertheless, the power consumption restriction has its limitation in reducing CO_2 emissions due to tons of power required in regional development. High economic development and intensive population in eastern China lead to high power consumption demand. The acceleration of industrialization also required huge amounts of power in western China. Compared with western and eastern China, the central China is a transitional zone and its power consumption has a relatively lower impact on CO_2 emissions, but its power consumption, which remains stable, has no trend of decline.

3.3. Results and Discussion from Consumption Perspective. Economic activity is the main factor leading to CO_2 emission increase in three regions, and affecting trends in all regions seem similar, but CO_2 emissions in 2017 from economic activity in eastern China increased rapidly. Still, the carbon intensity and power intensity of power consumption are two key factors to restrain CO_2 emissions and these two factors influence CO_2 emissions, which vary from region to region. The population density has a relatively lower effect compared with other drivers.

3.3.1. Carbon Intensity of Power Consumption. The carbon intensity of power consumption is an intensity index to measure the cleanliness of regional power consumption from the consumption perspective. It plays a positive role in reducing CO_2 emissions, which accounts for -46.82%, -46.19%, and -61.83% of overall CO_2 emission changes in eastern, central, and western China, respectively, during the study period (Table 5). Contrary to the above energy efficiency factors, the carbon intensity of power consumption in western China is the lowest, indicating that power consumption in western China has the highest cleanliness (Table 6).

The western China has no responsibility to bear CO_2 emissions generated by power output, and its carbon intensity of power consumption can accurately measure the power consumption cleanliness. However, the power consumption cleanliness in western China decreased in 2017, which might be affected by extensive industry migration. Besides, the clean energy development in central and western China is also an important reason for the highest cleanliness of power consumption in the western China. As Figure 4 demonstrates, the carbon intensity of power consumption has a low impact on CO_2 emissions in three regions at the beginning of the study while increases significantly in the later stage, which is mainly attributed to the cleanliness improvement of power consumption due to the rapid growth of hydropower in the central and western China at the end of the study. The power consumption cleanliness improves greatly and plays a role in restraining CO_2 emissions in the eastern China due to the implementation of power transmission project. The carbon intensity of power consumption is an index influenced by multiple factors, including the cleanliness of region that only produced power and imported power. Everyone should work together to improve the power consumption cleanliness.

3.3.2. Power Intensity. Power intensity represents the dependence of GDP on power consumption. Its change reflects the influence of industry structure change. Although the power intensity promotes the CO_2 emissions in western China during the study period, it is the main factor in reducing CO_2 emissions in all regions. Compared with eastern and central China, the change in power intensity in western China has less impact on CO_2 emissions. This is mainly due to different industrialization levels in three regions. Table 7 demonstrates that there are significant differences in power intensity levels of three regions. The power intensity decreases progressively from east to west, which reflects the differences in the original industry structure among regions.

The greater the dependence of GDP on power consumption, the greater the ratio of secondary industry in the region.

After a series of national strategies issued, some high-consumption and high-polluting industries have been moved inland and the overall economic growth disparities among regions have been gradually reduced [26, 27]. The results indicate that the reduction in secondary power consumption in western China is not obvious, but the industry structure has gradually improved in the western China. Actually, the Chinese government acknowledges that the industry transfer can only eliminate regional economic differences, but not reduce total CO_2 emissions. Thus, the backward heavy industry technologies and industries in all regions should be eliminated to reduce total carbon emissions.

3.3.3. Economic Activity. The per capita GDP is a comprehensive indicator reflecting economic growth and quality of life. Figure 4 indicates that economic activity is the first driving factor for CO_2 emission increase from the power industry in all regions. The overall change in three regions increased by 177.50%, 209.06%, and 178.44%, respectively. This finding is in line with the results of Yang and Lin (2016) [4] and Zhang et al. (2013) [18]. The power generation, which is an essential element of productive activity, supports economic development. The economic development in turn gives rise to power demand and CO_2 emission increase. There are obvious economic level differences among regions in China since the reform and opening-up [28]. However, the influences of economic activity on driving CO_2 emissions in the three regions are in the same manner and fluctuate with the economic cycle. This is because economic activity (GDP/P) changes with the economy when the fluctuation of population scope in a region is very small. With the Chinese economy entering the new normal, the GDP growth has been transformed from rapid growth into medium-high-level growth since 2013. The economic activity makes a lower contribution to decreasing CO_2 emissions with the development of high-quality economy.

Scholars have proved that economic growth and environmental pollution have an inverted U-shaped relationship. There is still a long way for eastern China to reach the inflection point of inverted U shape of the most economically developed region in China. Thus, the economic activity will become the major driving factor in environmental pollution for a long time [29, 30], but economic activity can restrain CO_2 emissions from the power industry to some extent. For instance, officials in prosperous regions have a strong sense of environmental protection, while officials in impoverished regions are limited to economic development. Therefore, maintaining high-quality economic development is an effective way to slow down CO_2 emissions.

3.3.4. Population Size. The impact of population size on CO_2 emissions can be ignored compared with other influencing factors. The change in population size influences CO_2 emissions more obvious in eastern China compared with the rest of the two regions. The eastern China has a large population, which is mainly because of massive influx of people attracted by its blossom. Overall, population size has little effect in CO_2 emissions and it will not change much in the coming years [19].

4. Conclusions

This study aims to study regional differences in CO_2 emissions from China's power industry. Due to the universality of cross-regional power dispatching in the power industry, different regions have different CO_2 emission responsibility from the production and consumption perspectives. This study decomposes CO_2 emissions by LMDI and determines the factors affecting CO_2 emissions from both mentioned perspectives. Based on the decomposition results from 2005 to 2017, we observe significant differences in factors influencing CO_2 emissions from the power industry in scale and direction among regions. Therefore, measures to reduce CO_2 emissions from the power industry should vary from region to region.

This research has mainly discussed the impact of energy supply and demand distribution on carbon emissions from perspectives of energy supply and demand and power dispatching, and we aim to provide a reference for planning decision-makers and institution makers.

From the production perspective,

(1) Although power consumption has a decreased influence on CO_2 emissions in recent years, it remains the leading factor increasing CO_2 emissions in all regions. It is unrealistic in practice to control CO_2 emissions by restraining power consumption, especially in the eastern and western China. However, the Chinese government can enforce economic regulations to avoid excessive demand, which will contribute to reducing CO_2 emissions.

(2) Energy efficiency is the main factor restraining CO_2 emissions in all regions, but the initial levels of energy efficiency in different regions are significantly different. The central China and western China still have plenty of room to improve energy efficiency compared with the eastern China. Thus, the government should increase financial investment in energy efficiency in these two regions, such as continuing to restrict small-scale power generation enterprises and encouraging advanced energy conversion technologies.

(3) In addition, power structure and power distribution affect CO_2 emissions differently in scale and direction in three regions. Therefore, measures to reduce CO_2 emissions should vary from region to region. For example, the central and western China should take advantage of rich resources to optimize the power generation and thus reduce carbon emissions. Moreover, the eastern China should increase the dispatching of project to send power from the west to the east with the increase in hydroelectric power generation, so that the eastern China can fully benefit from hydropower of other regions.

From the consumption perspective,

(1) Economic activity is the major factor to increase CO_2 emissions in all regions, and its influences on increasing CO_2 emissions in all regions bear out the similar trend. As the economy grows, the local government should increase fiscal spending on environmental protection, especially in less developed areas where officials lack adequate awareness of environmental protection. In addition, China should always pay attention to the economic growth quality and accelerate the transformation of economic model from extensive to intensive.

(2) The power intensity should keep improving despite that the overall CO_2 emissions continue to rise. The carbon intensity of power consumption and power intensity are main restraining factors to CO_2 emissions in all regions, and their influences vary in different regions. It is wisdom for the Chinese government to implement industry transformation policies given that different regions are different in industrialization and economic development. The eastern China has transferred energy-intensive and heavily polluting industries to the central and western China as they have abundant natural resources and favorable markets, which can reduce the energy loss and cost during transportation.

However, the regions that industry moves into should reject the backward industries to avoid carbon leakage and achieve the overall goal of low CO_2 emissions. To sum up, reducing CO_2 emissions is not a simple unilateral action. The Chinese government should recognize regional differences and adopt targeted policies from the production and consumption perspectives to create a "low-carbon environment" for the power industry.

From the perspective of cross-region power dispatching policy:

(1) This study discussed the cross-region power allocation, which was viewed as an effective energy-carbon allocation measure. Currently, from the perspective of practice, the effectiveness of this allocation measure is mainly reflected in two aspects: (1) the cross-region power dispatching is in accord with the reality that the energy distribution does not match with the population and industry distribution in China. The energy supply in China is mostly located in the western region, while the major electricity demand from production and life is located in the coastal economic belt. Without long-distance power dispatching, most renewable energy could not be totally consumed by the local region. (2) In China, most of the renewable energy supply comes from underdeveloped regions, which have low payment capacity for energy consumption. The cross-region power dispatching could effectively improve the economy of renewable energy from the demand side, which would contribute to the carbon emission reduction process in China. This effectiveness could be viewed as the imbalance consideration of natural distribution on the supply and demand side in regional energy planning. Hence, cross-region power

dispatching is generally an irresistible choice, which is similar in developed regions such as Europe and the United States. In fact, although the new petrochemical power company in the western China would generate large carbon emissions, the cross-regional scheduling is beneficial due to the advanced energy efficiency and its contribution to the stability of the power system. This is also an episode in the process of technological change in the power industry.

4.1. Based on This, We Further Discuss Two Issues. When will this trans-regional power dispatching be ineffective? Apparently, it will result in an overall carbon emission increase to relocate power supply utilities from developed regions to underdeveloped regions simply because of carbon regulation. Moreover, the trans-regional power dispatching might result in comparative advantages of carbon permit only because of the difference in development among regions. To be specific, the carbon price is low in central and western regions thanks to abundant carbon sinks, while traditional power generation enterprises move westward because of the shortage of carbon permit. In this vein, trans-regional power dispatching should be assessed whether the increase in the economic development of western underdeveloped regions by this dispatching is worth the carbon emission generated by it. In the context of global carbon neutrality, this comparative advantage will disappear with the improvement of the balanced regional development and the diffusion of low-carbon technologies. As a result, the extent of trans-regional power dispatching will be suppressed.

Under what circumstances would this trans-regional power dispatching be more effective? In addition to the trans-regional power dispatching driven by high demand, the difference in the development intensity and potential of renewable energy among different regions are the natural driving factors for trans-regional power dispatching. From the perspective of supply side, preferential access, preferential dispatching, and preferential pricing of low-carbon power are the institutional motivation of trans-regional dispatching. From the demand side, the pricing system of integrated energy price, which includes carbon price, trading system of power system, and subsidy system of low-carbon electricity, will make it more feasible and efficient to promote trans-regional power dispatching of renewable energy power. Generally speaking, pricing market transactions and priorities of supply and demand can not only directly affect the supply and demand relationship of low-carbon power but also affect the possibility and utility of trans-regional power dispatching of low-carbon power.

Finally, we try to discuss the similarities and differences between China and Europe in power dispatching and relevant policies. Since the operation of ENTSO-E in 2009, the EU has established a unified power market in the form of an operator alliance, and the proportion of transnational exchange electricity is about 15%. In particular, typical countries include Denmark (dominated by thermal and wind power), Norway (dominated by hydropower), and Sweden (dominated by hydropower and nuclear power). Due to the differences in energy distribution and demand,

electricity exchange between countries is common. The unified grid connection and standard would be valuable for Europe, and a flexible electricity price system and even negative electricity price (encouraging users to use off-peak electricity) and accurate power accounting ability in Europe would be valuable for China. Besides, studies in Europe show that carbon tax, carbon price, and the improvement of cross-border transmission capacity could contribute to the production of low-carbon electricity [31, 32].

In order to accurately analyze the influence of electromagnetic transient signals on the jointless track circuit when the electromagnetic transient signal propagates in the rail, it is necessary to consider the frequency-variable load terminated in the ZPW-2000A jointless track circuit and the frequency-variable loss inside the rail. A method is proposed for calculating the transient response of transmission lines system with frequency-variable end load of jointless track circuit. Firstly, the transmission lines model of jointless track circuit is established, based on multiconductor transmission lines theory, the model equation is deduced and discretized by finite difference time domain (FDTD). The vector fitting method is used to express the admittance of the tuning region in the track circuit, and the rational approximation function of the tuning region is derived from the poles, residues, and constants. The voltage and current at nodes in the tuning region are calculated by piecewise linear recursive convolution algorithm. Combined with the discrete transmission line equation, the current and voltage expression of the transient electromagnetic signal at the receiving end of the track circuit in time domain is obtained. Compared with state variable method, the error is less than 6%, which verifies the correctness of the proposed method. Finally, this paper studies the influence laws of different factors on the overvoltage at the receiving end of jointless track circuit and the weak links of jointless track circuit under the influence of transient electromagnetic signal. It provides theoretical reference for fault research and anti-interference analysis of ZPW-2000A jointless track circuit.

1. Introduction

Jointless track circuit is the key equipment used to detect the occupancy of train section, the integrity of rail, and the transmission of running information in railway line, which is an important basic equipment to ensure the safe operation of high-speed railway [1]. With the increasing complexity of railway construction environment, the rail and signal transmission equipment laid outdoors are easily disturbed by strong electromagnetic signals. Electromagnetic interference signals use rail as transmission medium to produce conduction interference or radiation coupled interference on jointless track circuits [2]. The investigations show that lightning strikes can cause failures of trackside tuning matching units, signal transmission cables and lightning protection analog network disks, transmitters and receivers, etc. Jointless track circuit is easy to make wrong responses by

this disturbance, which will threaten the safety of train running. Therefore, it is important to analyze the interference of transient electromagnetic signal to track circuit.

The theory of multiconductor transmission lines is the theoretical basis of time-domain transient analysis of track circuits. Kunz and Luebbers [3] first solved the transmission lines equation by FDTD method, which provided a theoretical basis for time-domain solution of transmission lines. With the complex changes in transmission lines termination equipment, Wang et al. [4–6] respectively proposed a numerical algorithm based on Thevenin equivalent circuit method, state variable method, etc., to solve the terminal frequency-varying load and combined with the transmission line equation to solve the electromagnetic impulse response of the system. In the study of transient response of jointless track circuits. Mazloom et al. [7] proposed a method based on transmission line equation and ATP-EMTP simulation

model to analyze the voltage response of track circuit at the moment of train entering and clearing. Zhao et al. [8] obtained the general solution of current and voltage of rail line by Laplace transformation of the transmission line equation of track circuit, which simplified the calculation model and ignored the electrical insulation section; Yong-jian [9] used the state variable method to analyze the receiving end of the DC track circuit and solved equation of the track circuit by combining the transmission line equation, but it was difficult to write the state equation when the circuit structure was complex. Zhichao et al. [10] analyzed the overvoltage of each signal equipment during lightning strike catenary by establishing lightning strike simulation model of signal system.

ZPW-2000A jointless rack circuit includes parallel nonlinear equipment and rail with frequency variation characteristics. In order to accurately calculate the electromagnetic transient response of track circuit transmission line system, the influence of terminating frequency variation load and rail frequency variation loss must be considered. Firstly, according to the transmission characteristics of ZPW-2000A jointless track circuit, the transmission line model of track circuit is established. The model cannot be calculated directly due to the presence of parallel or terminated nonlinear lumped elements in the track circuit. Based on the multiconductor transmission lines theory, the model equation is solved by FDTD. The vector fitting method is a powerful tool for the modeling analysis of frequency-dependent systems, which is used to fit the admittance of the tuning region. The rational approximation function of the track circuit is derived from the poles, residues, and constants. The relationship between voltage and current at both ends of the admittance is derived by piecewise linear recursive convolution, which is submitted into the discrete equation of transmission lines. Finally, the time-domain expression of the current and voltage at the receiving end of the track circuit is obtained. Compared with the state variable method, the error is less than 6%, which verifies the correctness of the proposed method. This method is used to analyze the influence of lightning stroke distance, electromagnetic signal frequency, and track bed resistance on the overvoltage at the receiving end of track circuit; it provides a theoretical basis for the anti-interference analysis of track circuit.

2. Modeling of Transmission Line of Track Circuit with Frequency-Variable Load Terminated

The outdoor equipment of jointless track circuit is composed of steel rail, tuning unit (BA), air-core coil (SVA), signal cable, matching unit and compensation capacitor, etc. The tuning unit and the air-core coil part form an electrical insulation section to prevent cross-zone signal transmission from adjacent sections. The compensation capacitor is used to improve the transmission performance of the track circuit and increase the transmission distance of the track circuit

information. According to the transmission characteristics of track circuit, the rails are equivalent to uniform transmission lines [11]; it is characterized by two asymmetrical currents, one of which leaks into the ground, and the other flows from one rail to the other through ballast and sleepers. Taking a certain interval of track circuit as an example, the MTL equivalent model of jointless track circuit is established [12], as shown in Figure 1.

Here, r_1 and r_2 are the self-resistance of the rail; l_{11} and l_{22} are the self-inductance of the rail; l_{12} is the mutual inductance between rails; g_{11} and g_{22} are the leakage conductance between rails and Earth; g_{12} and g_{21} are the ballast resistance parameter of track characterized by conductance; c_{11} and c_{22} are the self-capacitance of the rail; c_{12} is the mutual capacity of the rails; and z_1 and z_2 represent the tuning region, respectively.

Transmission line losses are reflected in the conductor and the surrounding mediums; in general, these losses are frequency dependent, and the increase of frequency will lead to additional high-frequency losses. The most important is caused by the skin effect in the conductor and the polarization in the dielectric. Dielectric loss has little influence on transmission lines and can be ignored [12]. Therefore, the frequency domain expression of transmission line equation based on multiconductor transmission lines theory is

$$\frac{d\widehat{V}(z,w)}{dz} = \left[r(w) + jwl_i(w)\right]\widehat{I}(z,w) - jwl\widehat{I}(z,w)$$
$$= -\widehat{z}(w)\widehat{I}(z,w), \tag{1}$$

$$\frac{d\widehat{I}(z,w)}{dz} = -g(w)\widehat{V}(z,w) - jwc\widehat{V}(z,w)$$
$$= -\widehat{y}(w)\widehat{V}(z.w), \tag{2}$$

where impedance and admittance are, respectively, $\widehat{z}(w) = \widehat{z}_i(w) + jwl$, $\widehat{z}_i(w) = r(w) + jwl_i(w)$. $\widehat{y}(w) = g(w) + jwc$.

Converting the frequency domain equations of (1) and (2) is transformed by Laplace transform into the time domain given the convolution equation as

$$\frac{\partial \mathbf{V}(z,t)}{\partial z} = -z_i(t) * \mathbf{I}(z,t) - \mathbf{l}\frac{\partial \mathbf{I}(z,t)}{\partial t}, \tag{3}$$

$$\frac{\partial \mathbf{I}(z,t)}{\partial z} = -\mathbf{g}\mathbf{V}(z,t) - \mathbf{c}\frac{\partial \mathbf{V}(z,t)}{\partial t}. \tag{4}$$

In the case of high frequency, unit length resistance, internal inductance, and unit length conductance of conductor loss parameters are functions of frequency. The approximate formula $A + B\sqrt{s}$ for conductor losses is based on the transformation pair conversion; the inverse Laplace transform of the impedance in the conductor is

$$\widehat{z}_i(s) = A + B\sqrt{s} = A + B\frac{1}{\sqrt{s}}s \Leftrightarrow A + B\frac{1}{\sqrt{\pi}}\frac{1}{\sqrt{t}}\frac{\partial}{\partial t}, \tag{5}$$

where $A = r_{dc}$, $B = r_{dc}/\sqrt{\pi}\sqrt{f_0}$, r_{dc} is DC resistance.

The convolution of the calculation in (3) is expressed as

$$z_i(t) * I(z,t) = \int_0^t z_i(\tau)I(z,t-\tau)d\tau$$

$$= AI(z,t) + B\frac{1}{\sqrt{\pi}}\int_0^t \frac{1}{\sqrt{\tau}}\frac{\partial I(z,t-\tau)}{\partial(t-\tau)}d\tau. \tag{6}$$

The convolution term (6) is discrete with time step and divided by Δt segment. Discrete convolution is approximated in the following way:

$$\int_0^t \frac{1}{\sqrt{\tau}}F(t-\tau)d\tau \cong \int_0^{(n+1)\Delta t}\frac{1}{\sqrt{\tau}}F((n+1)\Delta t - \tau)d\tau$$

$$\cong \sum_{m=0}^n F^{n+1-m}\int_{m\Delta t}^{(m+1)\Delta t}\frac{1}{\sqrt{\tau}}d\tau \tag{7}$$

$$= \sqrt{\Delta t}\sum_{m=0}^n F^{n+1-m}Z_0(m),$$

where $F(t) = \partial I(z,t)/\partial t$, $Z_0(m) = \int_m^{m+1}1/\sqrt{\tau}\partial\tau$.

According to the FDTD algorithm, the position length of the transmission line is discretized by Δz, and the time length is discretized by Δt. The whole transmission lines are divided into NDZ segments, and the total solution times are divided into NDT segments. In order to ensure the stability of discrete calculation, the voltage of $NDZ + 1$ at discrete point $V_1, V_2, \ldots, V_Z, V_{NDZ+1}$ and the discrete point current $I_1, I_2, \ldots, I_{NDT}$ does interleaving calculation. Then, (3), (4), and (7) can be discretized as

$$\frac{\mathbf{V}_{k+1}^{n+1} - \mathbf{V}_k^{n+1}}{\Delta z} + \mathbf{l}\frac{\mathbf{I}_k^{n+3/2} + \mathbf{I}_k^{n+1/2}}{\Delta t} + A\frac{\mathbf{I}_k^{n+3/2} + \mathbf{I}_k^{n+1/2}}{2} +$$

$$\frac{\sqrt{\Delta t}}{\sqrt{\pi}}B\sum_{m=0}^n\left[\frac{\mathbf{I}_k^{n+3/2-m} + \mathbf{I}_k^{n+1/2-m}}{\Delta t}\right]Z_0(m) = 0, \tag{8}$$

$$\frac{\mathbf{I}_k^{n+1/2} - \mathbf{I}_{k-1}^{n+1/2}}{\Delta z} + \mathbf{g}\frac{\mathbf{V}_k^{n+1} + \mathbf{V}_k^n}{2} + \mathbf{c}\frac{\mathbf{V}_k^{n+1} - \mathbf{V}_k^n}{\Delta t} = 0.$$

The recursive relation of current at discrete points inside the transmission line is

$$\mathbf{I}_k^{n+3/2} = \mathbf{F}^{-1}\left(\mathbf{l}\frac{\Delta z}{\Delta t} - A\frac{\Delta z}{2} + B\frac{1}{\sqrt{\pi}}\frac{\Delta z}{\sqrt{\Delta t}}Z_0(0)\right)\mathbf{I}_k^{n+1/2}$$

$$- \mathbf{F}^{-1}B\frac{1}{\sqrt{\pi}}\frac{\Delta z}{\sqrt{\Delta t}}\sum_{m=1}^n\left[\mathbf{I}_k^{n+3/2-m} - \mathbf{I}_k^{n+1/2-m}\right],$$

$$Z_0(m) - \mathbf{F}^{-1}\left(\mathbf{V}_{k+1}^{n+1} - \mathbf{V}_k^{n+1}\right), \tag{9}$$

$$\mathbf{F} = \mathbf{l}\frac{\Delta z}{\Delta t} + A\frac{\Delta z}{2} + B\frac{1}{\sqrt{\pi}}\frac{\Delta z}{\sqrt{\Delta t}}Z_0(0).$$

3. Tuning Region Transient Modeling

In the ZPW-2000A jointless track circuit, the electrical insulation section realizes the electrical isolation of adjacent track and the stable output of local signal by forming series and parallel resonance for different carrier frequency signals. In the matching part, the rail impedance and cable impedance are matched to realize the output of high power signal to the rail [14]. The structure of electrical insulation section in jointless track circuit is shown in Figure 2.

Firstly, the transient model of tuning matching unit is established, and the drive point admittance of the tuning unit port is obtained by the short-circuit test method. The frequency domain admittance is fitted to a rational function expression by the vector matching method, as shown in (10). Secondly, the frequency domain rational function is transformed into time-domain expression by inverse Fourier transform. Finally, based on the piecewise linear recursive convolution method, the recursive iterative relation of admittance current is derived in (14). The admittance can be fitted to a rational function in the complex frequency domain by the vector matching method and the objective function $Y(s)$ expresses its s-domain admittance in pole and residue form [13]:

$$Y(s) = \sum_{i=1}^n \frac{a_i}{s - c_i} + sh + g = \sum_{i=1}^n Y_i(s) + Y_0(s), \tag{10}$$

where n is the order, i is an integer ($i = 1,2, \ldots, n$); a_i is the residue, and c_i is the pole, both are real numbers or conjugate complex number pairs, sh is the coefficient of the first term, and g is the constant term.

The fitting order of the poles in the tuning area is 12 to achieve appropriate fitting effect. The amplitude characteristic and phase angle characteristic function are fitted according to the pole and residue values. Compared with the admittance model of the tuning unit, the results are shown in Figures 3 and 4.

The results of admittance fitting of the tuning element are consistent with those of the exact value and meet the requirements of calculation. According to the admittance rational function, the current equation of the connection node is derived. The voltage current relationship of the tuning unit in time domain is expressed as $I_z(t) = Y(t) * V_z(t)$. Defining two parameter variables [5],

$$\chi_m = \int_{m\Delta t}^{(m+1)\Delta t} Y(\tau)d\tau,$$

$$\xi_m = \frac{1}{\Delta t}\int_{m\Delta t}^{(m+1)\Delta t} (\tau - m\Delta t)Y(\tau)d\tau. \tag{11}$$

Using piecewise recursive convolution integral, we know that if the two variables are satisfied,

$$\rho = \frac{\xi_m}{\xi_{m-1}} = \frac{\chi_m}{\chi_{m-1}}. \tag{12}$$

Then, the time-domain current I_z^n can be written in the recursive iterative form:

$$I_z^{n+1} = (\chi_0 - \xi_0)V_z^{n+1} + \xi_0 V_z^n + \rho I_z^n. \tag{13}$$

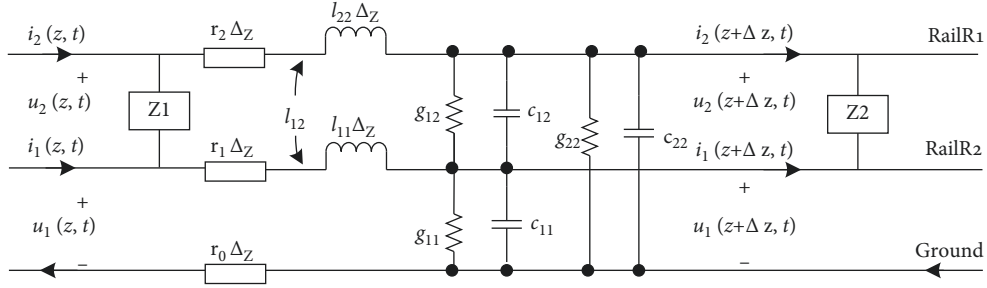
There are number of real numbers N_r and conjugate pairs N_g in the fitting residues of loads in residue regions and the poles, then the total current of the connected nodes is


Figure 1: Equivalent circuit diagram of track circuit transmission line.
Figure 2: Structural schematic diagram of tuning unit.
Figure 3: Vector fitting matches amplitude and model amplitude.

Figure 4: Vector fitting matches phase angle with model phase angle.

4. Transmission Line Voltage Equation of Track Circuit

When the transmission line load is pure resistance load, the current is $I_0 = (V_0 - V_1)/R$. The central difference method is used to discretize it.

$$\mathbf{I}_0^{n+1/2} = \frac{\left(\mathbf{V}_0^{n+1/2} - \mathbf{V}_1^{n+1/2}\right)}{R} = \frac{1}{2R}\left[\left(\mathbf{V}_0^{n+1} + \mathbf{V}_0^n\right) - \left(\mathbf{V}_1^{n+1} + \mathbf{V}_1^n\right)\right]. \tag{16}$$

According to the average value of power supply I_S current, (3) and (4) can be discretized:

$$\frac{1}{\Delta z/2}\left[\mathbf{I}_1^{n+1/2} - \frac{\mathbf{I}_0^{n+1} + \mathbf{I}_0^n}{2}\right] + \frac{1}{2}\mathbf{g}\left[\mathbf{V}_k^{n+1} + \mathbf{V}_k^n\right] + \frac{\mathbf{c}}{\Delta t}\left[\mathbf{V}_k^{n+1} - \mathbf{V}_k^n\right] = 0. \tag{17}$$

The initial voltage expression of the transmission line equation of the track circuit is

$$\mathbf{V}_1^{n+1} = \left(1 + \frac{\Delta z}{\Delta t}\mathbf{c}R_s + \frac{\Delta z}{2}\mathbf{g}R_s\right)^{-1}\left[\left(\frac{\Delta z}{\Delta t}\mathbf{Rc} - \frac{\Delta z}{2}R_s\mathbf{g} - 1\right)\mathbf{V}_1^n\right.$$
$$\left. - 2R_s\mathbf{I}_1^{n+1/2} + 2\mathbf{V}_0^{n+1/2}\right]. \tag{18}$$

$$I_z^{n+1/2} = PV_z^{n+1} + QV_z^n + I_t^{n+1}, \tag{14}$$

where $P = \chi_{0,t} - \xi_{0,t} + g/2 + h/\Delta t$, $Q = \chi_{0,t} + g/2 - h/\Delta t$;

$$\xi_{0,t} = \frac{1}{2}\sum_{i=1}^{Nr}\xi_{0,i} + \sum_{i=Nr+1}^{Nr+Ng}\mathrm{Re}\left(\xi_{0,i}\right)\chi_{0,t}$$

$$= \frac{1}{2}\sum_{i=1}^{Nr}\chi_{0,i} + \sum_{i=Nr+1}^{Nr+Ng}\mathrm{Re}\left(\chi_{0,i}\right), \tag{15}$$

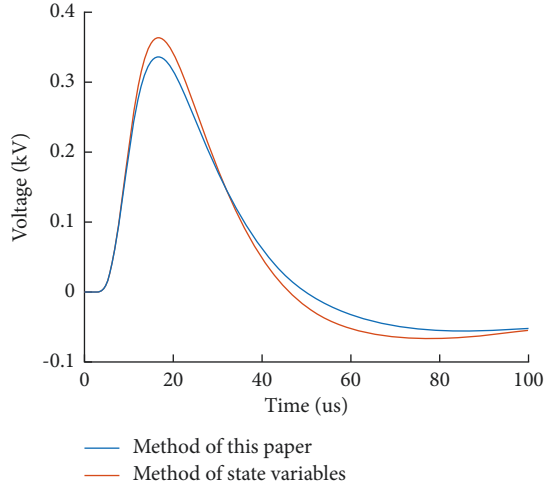
$$I_t^n = \frac{1}{2}\sum_{i=1}^{N_r}\left(\rho_i + 1\right)I_{z,i}^n + \sum_{i=N_r+1}^{N_r+N_g}\mathrm{Re}\left[\left(\rho_i + 1\right)I_{z,i}^n\right].$$


Figure 5: Comparison of calculation methods of overvoltage at receiving end of track circuit.

Figure 6: Error diagram of calculation results.

The internal point voltage iteration formula of the equation is

$$\mathbf{V}_k^{n+1} = \left(\frac{\Delta z}{\Delta t}\mathbf{c} + \frac{\Delta z}{2}\mathbf{g}\right)^{-1}\left[\left(\frac{\Delta z}{\Delta t}\mathbf{c} - \frac{\Delta z}{2}\mathbf{g}\right)\mathbf{V}_k^n - \left(\mathbf{I}_k^{n+1/2} - \mathbf{I}_{k-1}^{n+1/2}\right)\right]. \tag{19}$$

According to the average value of load current I_L at the load at the end of the transmission line, the transmission line equation can be discretized as follows:

$$\frac{1}{\Delta z/2}\left[\frac{\mathbf{I}_L^{n+1} + \mathbf{I}_L^n}{2} - \mathbf{I}_{\text{NDZ}}^{n+1/2}\right] + \frac{1}{2}\mathbf{g}\left[\mathbf{V}_{\text{NDZ}+1}^{n+1} + \mathbf{V}_{\text{NDZ}+1}^n\right]$$
$$+ \frac{\mathbf{c}}{\Delta t}\left[\mathbf{V}_{\text{NDZ}+1}^{n+1} - \mathbf{V}_{\text{NDZ}+1}^n\right] = 0. \tag{20}$$

When the nonlinear lumped element of a track circuit is terminated with a tuning unit as the terminal condition, the terminal condition gives the relation IL between voltage and current at the same time and position. According to (14), the current and voltage equation I_L at its endpoints is

$$\mathbf{I}_L^{n+1/2} = P\left(\mathbf{V}_{k+1}^{n+1} - \mathbf{V}_L^{n+1}\right) + Q\left(\mathbf{V}_{k+1}^n - \mathbf{V}_L^n\right) + \mathbf{I}_t^{n+1}. \tag{21}$$

The terminal voltage equation of the transmission line equation of the track circuit is

$$\mathbf{V}_{\text{NDZ}+1}^{n+1} = \left(P + \frac{\mathbf{c}\Delta z}{2\Delta t} + \frac{\mathbf{g}\Delta z}{4}\right)^{-1}\left[\left(\frac{\mathbf{c}\Delta z}{2\Delta t} - \frac{\mathbf{g}\Delta z}{4} - Q\right)\mathbf{V}_{\text{NDZ}+1}^n\right.$$
$$\left. + P\mathbf{V}_L^{n+1} + Q\mathbf{V}_L^n - \mathbf{I}_t^n + \mathbf{I}_{\text{NDZ}}^{n+1/2}\right]. \tag{22}$$

5. Method Validation

To verify the validity of the constructed track circuit model and the transient response formula, taking P60 rail carrier frequency signal 2300 Hz and 1.4 km track section as an example, the lightning wave adopted the double exponential lightning electromagnetic signal with wave head of $T_1 = 1.2\,\mu$s and wavelength of $T_2 = 50\,\mu$s, recorded as $1.2/50\,\mu$s standard lightning wave [15], and the amplitude was 30 kA for simulation. According to the transmission line model of track circuit, the overvoltage of track surface at the receiving end of track circuit is solved. The state variable method is used to compare the response results with the proposed method.

It can be seen from Figures 5 and 6 that the numerical algorithm for transient response of track circuit proposed in this paper is consistent with the calculation results of state variable method. The calculation error is less than 6%.

5.1. Impact Tolerance Level of Signal Equipment. When the electromagnetic field induced by lightning reaches a certain level, the signal equipment will work improperly or be damaged. The lightning tolerance level of signal equipment terminals is obtained through the destructive lightning shock tolerance experiment, which is the key factor to determine the lightning resistance of signal system equipment [10], as shown in Table 1.

6. Analysis of Influencing Factors

6.1. Influence of Lightning Transmission Distance on Rail Surface Voltage. When lightning strikes the rail, the change of track surface overvoltage with distance between the lightning point and the tuning area of the track circuit is shown in Figure 7.

It can be seen from Figure 7 that with the increase of the distance between the lightning point and the receiving end of the track circuit, the rail surface overvoltage decreases rapidly with the increase of the distance. Especially when the transmission distance is less than 700 m, the overvoltage generated by lightning will exceed the withstand voltage range of the tuning unit end, and there is a risk of breakdown of trackside electronic equipment.

6.2. Considering the Influence of Different Frequencies on Rail Surface Voltage. In ZPW-2000A jointless track circuit, the rail is used as the transmission channel of frequency shift

TABLE 1: Lightning resistance of signal system.

Device	Port	Shock withstands voltage/kV
Power box	Power terminal	$5 \sim 8$
Discrete component	(Resistance, capacitance) circuit	$3 \sim 5$
Tuning matching unit	Rail side to cable side	15
Signal cable	Core pair shielding layer	10
	Core pair	15
FIGURE 7: Influence of distance between lightning strike point and receiving end of track circuit on rail surface voltage.
FIGURE 8: Rail surface voltage at receiving end of track circuit with different frequencies.

signal, and the rail parameters have the characteristics of frequency change. In the high-frequency electromagnetic environment, the load at the end of the transmission line usually shows the frequency change effect. In order to analyze the variation rules of signal overvoltage at the receiving end of track circuit when interference signals of different frequencies act on track circuit, the calculation results are shown in Figure 8.
FIGURE 9: Influence of ballast resistance on rail surface overvoltage.

In Figure 8, the simulation results show that the frequency of electromagnetic interference signal has a great influence on the voltage amplitude at the receiving end of the rail surface. At the same time, the higher the frequency of the interference signal is, the smaller the amplitude of the rail surface voltage is at the receiving end. With the increase of signal frequency, the rail impedance increases, the loss of interference signal on the track circuit increases, and the rail voltage amplitude decreases at the receiving end. The internal frequency loss of the transmission line is very little affected by the change of frequency and can be ignored in the future research.

6.3. Influence of Track Bed Resistance on Rail Surface Voltage. The primary side parameters of the jointless track circuit will affect the transmission of interference signals on the rail. The P60 rail is selected, its impedance value is a certain value, while the resistance of the track bed will change with the difference of ambient temperature and humidity [16]. In order to study the influence rule of track bed resistance on rail surface voltage at the receiving end of track circuit, when the resistance value of track bed is $2\,\Omega\cdot$km, $2.5\,\Omega\cdot$km, $4\,\Omega\cdot$km, and $5\,\Omega\cdot$km, the influence rule of different track bed resistance on rail surface overvoltage is analyzed, as shown in Figure 9.

As shown in Figure 8, the greater the ballast resistance is, the greater the overvoltage is. Meanwhile, the faster the rate of rise and attenuation of overvoltage are. With the decrease of track ballast resistance, the amplitude of rail surface voltage decreases at the receiving end.

7. Conclusion

(1) The transient response model of track circuit is established. A numerical calculation method of transient electromagnetic response of track circuit transmission line system considering terminated frequency-varying load and frequency-varying loss is proposed, which is suitable for the analysis of transmission line model with terminated frequency-varying load. It provides theoretical reference for the transmission performance of jointless track circuits and the anti-interference design of track circuits.

(2) The frequency of electromagnetic interference signal has great influence on the amplitude of rail voltage at the receiving end. However, the frequency has little effect on internal loss of rail. The overvoltage and the time of signal attenuation to stability increase with increasing of the ballast resistance.

(3) According to withstand voltage level of the signal equipment, when the distance between the lightning strike point and the receiving end of the track circuit is small, there is a risk of insulation breakdown on the rail side of the tuning unit, so measures need to be taken to strengthen the protection of the signal equipment.

Deep neural networks are efficient methods of recognizing image patterns and have been largely implemented in computer vision applications. Object detection has many applications in computer vision, including face and vehicle detection, video surveillance, and plant leaf detection. An automatic flower identification system over categories is still challenging due to similarities among classes and intraclass variation, so the deep learning model requires more precisely labeled and high-quality data. In this proposed work, an optimized and generalized deep convolutional neural network using Faster-Recurrent Convolutional Neural Network (Faster-RCNN) and Single Short Detector (SSD) is used for detecting, localizing, and classifying flower objects. We prepared 2000 images for various pretrained models, including ResNet 50, ResNet 101, and Inception V2, as well as Mobile Net V2. In this study, 70% of the images were used for training, 25% for validation, and 5% for testing. The experiment demonstrates that the proposed Faster-RCNN model using the transfer learning approach gives an optimum mAP score of 83.3% with 300 and 91.3% with 100 proposals on ten flower classes. In addition, the proposed model could identify, locate, and classify flowers and provide essential details that include flower name, class classification, and multilabeling techniques.

1. Introduction

Flower identification is extremely important in agricultural production, forest management, and other allied sectors. Because of their enormous presence, complex structure, and unpredictable diversity of classes in nature, automated species identification was initially presented 17 years ago [1]. In recent years, the rapid development of technology, flower segmentation, and identification has been an interesting area of research in the image processing and computer vision community. Previous research mostly focused on flower recognition using a conventional detector and technique. Gaston and O'Neill [1] argued that advances in artificial intelligence and digital image processing might generate automated species identification a reality. The rapid development and growing prevalence of key information technologies, along with the widespread availability of compact devices such as digital cameras and smartphones, have resulted in a huge quantity of digital pictures that have been gathered in online databases. As a result, their vision is now almost tangible: mobile devices are utilized to photograph specimens in the field and then identify their species.

With the debut of smartphones and mobile applications, millions of plant pictures have been acquired [2]. Real-world social-based ecological surveillance [3], invasive exotic plant monitoring [4], environmental science popularization, and

other applications rely on mobile-based automated plant identification. Scholars and engineers are paying more attention to improving the effectiveness of mobile-based plant identification models [5]. On an extensive dataset, the researchers used a combination of characteristics to enhance flower classification efficiency. The local form/texture, the shape of the border, the overall geographical distribution of petals, and the color are all defined by distinct characteristics. A multiple support vector machine (SVM) classifier was utilized for classification. Fernando [6] developed an image classification-based approach for differentiating feature fusion, in which the color and shape characteristics are merged by the logistic regression strategy for flower picture classification. However, developing an automated flower category classification system remains a difficult challenge due to certain similarities within classes. The textural characteristics from the Gabor replies and the intensity co-occurrence matrix were utilized to automatically classify flowers using the K-nearest neighbor (KNN) classifier [7]. Color texture moments, gray-level co-occurrence matrix, and Gabor responses were used to classify flower pictures [8]. A classifier was built using a probabilistic neural network. The author [9] used a neural network for logistic regression on flower picture characteristics to solve the problem of flower classification. An aspect-based method for flower identification has been proposed in [10]. Visual characteristics were retrieved and generalized to fresh photographs of unidentified flowers to characterize flower pictures. A sparse representation classifier forecasted the characteristics of a particular flower picture. Several techniques depend on human participation [11]. Following years of research and development, smartphone applications like LeafSnap [12], Pl@ntNet [2], and Microsoft Garage's Flower Recognition app [13] are used to identify flowers rapidly.

The technique of flower identification is an essential component of conventional plant ecology research processes. In this research work, photos of various flowers using mobile devices or digital cameras subsequently have been acquired. The name and other information about the blooms from the horticultural expert of MNS-UAM were found uot. It would be really useful to accelerate this work and make it more accessible to nonexperts. Manual flower species identification may be difficult to scale to high-throughput needs even for specialists although it may be prohibitively time-consuming and erroneous for nonexperts. Furthermore, existing models only classify images, limiting the model's ability to recognize numerous flowers in a single image. In contrast, our proposed framework classifies with localization, allowing it to recognize countless flowers in a digital image by placing a boundary box around the identified flower with the label.

2. Proposed Methods

We used an eighth Generation Core i7 Quad-Core Processor with 8 GB RAM, 8 GB NVIDIA, and a 520 GB SSD hard drive for our research. This research is divided into four different sections. The first section discusses dataset collection. Image labeling is described in the second section. The third section contains the training of the model on different hyperparameters. The fourth and final section illustrates the model's testing and evaluation with varying inputs from different angles.

2.1. Implementation Detail. Some key hyperparameters are introduced to the proposed network, such as the anchor initialization, the maximum number of bounding boxes retained, and the learning rate decay. We initialize our anchors on each pixel of the feature map obtained from the base net. This equates to placing anchors every 16 pixels on each screen dimension. An initialized total of nine anchors will be created for each pixel of the feature map. Three different scales and three different height-width ratios are used to create the nine anchors in the image. 0.5, 1.0, and 2.0 are the scales we use. It has 0.5, 1.0, and 2.0 dimensions. We also need to use the target bounding boxes as labels to train our RPN. Anchors that overlap with the ground-truth box more than RPN POSITIVE OVERLAP = 0.60 are chosen as foreground labels. Anchors that overlap with any ground-truth box less than RPN NEGATIVE OVERLAP = 0.40 are chosen as negative or background labels. Table 1 shows the training hyperparameters for four nets we trained, inception V2, ResNet50, ResNet101, and MobileNet V2 SSD.

2.2. Image Acquisition. This research adopted specific techniques to collect datasets inspired by Michael Rzane and Zhenzhen Song's papers [1, 2]. An image-capturing scheme was developed to collect data on different classes of flowers. The dataset was collected by ourselves, and therefore no web scraping tool was used. A Canon EOS 2000D DSLR was employed to collect data and yield high-resolution images with 2976 × 1984 dimensions with a bit depth of 24. The ordinary lens of the Canon EOS 2000D DSLR with "IntelliAuto mode" was used to capture images. The color representation of each image is sRGB with 72dpi horizontal and vertical resolution. Out of 10 classes, seven classes were obtained from the university garden and 3 classes from the local park. The images were captured from different angles and lens focus (Zoom In, Out).

For an entirely distinct dataset, images of each class were taken at different periods (morning, afternoon, and evening) with different lighting conditions, direct sunlight, shadows, and flashlight in the evening. The images were saved in JPEG format. Each class comprises three images of the same flower from predefined perspectives (entire flower, frontal, and lateral view); (1) the whole flower: it is an image of the whole flower from its natural position on the plant; (2) although the side view of the flower in this group will be comparable to the entire flower image, this study primarily focused on the side view of the flower in this group; (3) flower top view: for this view, we used focus mode instead of "IntelliAuto mode" to focus on all the flower's leaves. Most of the images are of this type in the dataset.

The ten summer season classes are selected for the dataset category containing ten species of flowers as shown in Figure 1 such as Petunia, Dianthus, Jatropha, Periwinkle, Europhobia Milli Phlox, Ixora, Tacoma, Anthurium, Bounganwellia.

TABLE 1: Selected hyperparameters.

Net	Optimizer	Decay epoch	Total epoch	Bach size	GPU
Inception V2	Momentum	8	30k	4	2
ResNet50	SGD	8	50k	4	2
ResNet101	SGD	8	55k	4	2
MobileNet V2 SSD	Momentum	8	200k	4	2

FIGURE 1: Categories of flowers.

FIGURE 2: Dataset splitting ratio.

2.3. Data Labeling. In this study, 2000 pictures are captured. There are up to 15 target flowers objects in each picture, with a resolution of 2976×1984 pixels (ROI). To identify pictures with localization, we categorized the flower dataset with annotation comprising ten types of flowers, each with roughly 200 images. When we label the 2000 images, we get 3500 total objects. To acquire the ROI (Region of Interest), we used the GitHub application tools named tagging and marked the area to be selected and then identified photos one by one to offer information about the images. The data labeling is saved in an XML file once the image has been tagged. The XML file includes variables (w = width; h = height) that form a rectangle in the picture. Since these flowers are usually in the shape of a group, we labeled this composite flower a single flower head (i.e., Ixora). Each class's dataset is split into three folders at random: training, validation, and testing, as shown in Figure 2.

2.4. Data Augmentation. Data augmentation is a technique used to increase data size by adding slightly modified copies of existing data or creating new synthetic data from existing data. This technique is used to reduce overfitting when training machine learning models.

We have used adding noise, cropping, flipping, scaling, brightness, and rotation for data augmentation. In adding noise, we added some noise like a blur for viewing the data more accurately. In cropping, we select some parts, crop the image, and resize the original image size. While flipping, the images are flipped horizontally and vertically. While scaling, we scaled the images outward and inward; this way, an image can be more minor and more significant by its original size.

Brightness is a process in which we can change an image into brightness and darkness. This technique allows the model to view an image as brightness and lighter. In rotation, the idea is to rotate by a degree ranging from 0 to 360 degrees from its original position. Every rotated image will have a unique representation in the model. When we complete the data augmentation, we have 6540 whole ideas and obtain 10080 natural objects.

2.5. Construction of SSD MobileNetV2. The SSD (Single Shot MultiBox Detector) is a fast flower identification detection model based on a single deep neural network [14]. An SSD could simultaneously eradicate multiple target detection and forecast targeted segments and binding boxes.

The feedforward convolutional network is being used in the SSD model. Its backbone is VGG16, and it follows the primary network with six layers of different characteristics. The size of the inserted map is decreased layer by layer, employing six distinct feature layers to achieve a target of varied scales: low predictive levels and high predictive levels. To forecast the bounding box set of various sizes, the range of objects, and associated confidence, a substantial majority of multiple-choice selections are performed on distinct levels of information. To address the issue of excessive parameter size and training model efficiency, the convolution layer on the actual SSD is substituted by a mobile net splitting layer, which enhances the efficiency and performance of real-time flower recognition as shown in Figure 3.

Real-time object accessibility is also available in the app store, thanks to the MobileNetV2 developers. SSDLite, a hybrid of SSD Object Detector and MobileNetV2, was introduced. Remember how, in the CNN Model, we employed ssd_mobilenetv2 to identify a flower object in images? SSDLite is just the same way. The purpose of using an SSD is straightforward. Since the SSD lacks a whole network, conferences are substituted by a highly fragmented convolution. For MobileNetV2, the very first layer of SSDLite is attached to the extension of layer 15. The set of parameters required by the network to detect an item is substantially reduced when the usual combination is supplanted by intensely split convolution.

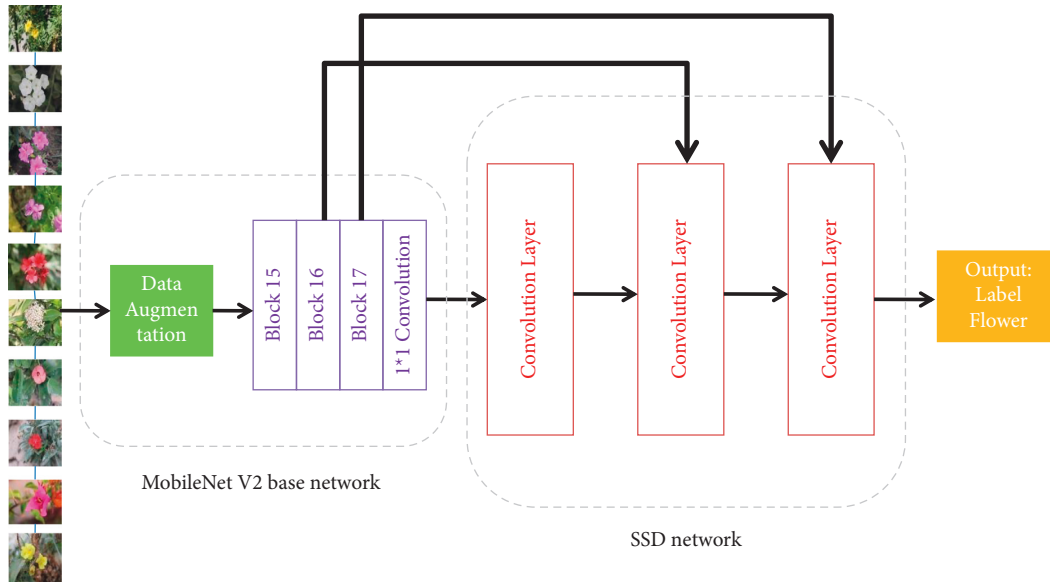
When we apply the construction of SSD MobileNetV2, first we apply Data Augmentation, which means the images will be trained in a different dimension; after that convolution filter will be used and the output image is obtained.


FIGURE 3: SSD mobile net V2 framework.

2.6. Construction of Faster R-CNN Inception V2. Faster region-based convolution neural network architecture is shown in Figure 4. This architecture was proposed by [15], and it uses Inception V2 for feature extraction, as explained in [16]. Each image was parted into subregions during the preprocessing of the model, as shown in Figure 4, "image division with overlay."

After that, inception V2 [15] generates the convolutional map feature that has been used in two stages Inception V2 [15] and Faster-RCNN [16]. In Regional Proposed Network (RPN), a convolutional network is used at the first stage that relays over the feature map, extracted by Inception V2, while anchors are placed on each point. Using two similar fully connected layers, the coordinates of the rectangular box around the flower and its probability of accuracy to matching class are determined. In the next step, the determined regions of the image are used to draw a feature map and classify each and every ROI (Region of Interest) with localization. After that, all extracted ROIs are passed through the pooling layer and fully connected layer to determine their probability of classification and localization [17]. These ROIs define the flower's location with a matching class in the output image, as shown in Figure 4.

At last, all output images are transposed and joined to show the original image as they are "divided with overlay" in Figure 1 and they came from training or testing datasets. The bounding boxes were refined and decreased in number by using the suppression algorithm [18]. All this was done by using Tensor Flow and anaconda prompt. Final selected hyperparameters for the next model Faster-RCNN are shown in Table 1 after refining. We give input image to the model Inception V2 applied on it, and feature extraction has been applied. RPN (Region Proposal Network) has been implemented using fully connected layers, activation

function, regression feature vector, and ROI pooling. After the proposed region is located in the image, it converts into a Box Classifier, in which two functions are performed: (1) Bounding Box Coordinates and (2) Object Probabilities. The output shows the classification of the input image with a boundary box around the flower.

The output shows the classification of an input image with a boundary box around the flower.

2.6.1. Inception V2. The Inception V2 package was created to decrease the intricacy of the convolution network in flower identification. This control system expands the convolution network rather than making it deeper. Functionalities in Inception V2 are classified into three modules: A, B, and C. It substituted a 3×3 convolution for the 5×5 convolution. This adheres to the idea that spatial aggregation may be performed over lower-dimensional embedding with little or no loss of representational capacity. Convolution performance was improved by using the 3×3 convolution. They discovered that dividing convolution filter size $n \times n$ into $1 \times n$ and $n \times 1$ convolutions made their technique 33% cheaper than a single 3×3 convolution. Additionally, the filter was enhanced to adhere to the concept that higher-dimensional depictions are simpler to process natively inside a network as shown in Figure 5.

2.6.2. ResNet 50. There are 48 Convolution layers in ResNet50 [19, 20], 1 MaxPool layer, and an Average Pool layer. The layers fitted a residual mapping and labeled it as $H(x)$, and the nonlinear layers fitted another mapping $F(x) = H(x) - x$, so the original mapping became $F(x) + x$. The total number of floating-point operations is $3.8 \times 10 * 9$.
FIGURE 4: Faster R-CNN flower identification using Inception V2 architecture for feature extractor.

2.6.3. ResNet 101.

Residual connections can be divided into two categories:

(1) Identity shortcuts (x) may be directly used for inputs and outputs with the exact dimensions.

$$y = f(x, \{W_i\}) + X. \qquad (1)$$

Residual block function is with the same input and output dimensions as Equation (1).

(2) When the dimensions change, (A) identifiability mapping is still performed, with extra zero entries padded with the increased dimension. (B) Using a projection shortcut, the dimension can be matched (for example, by using $1 * 1$ Conv) using the following formula:

$$y = f(x, \{W_i\}) + W_s X. \qquad (2)$$
FIGURE 5: Inception V2 modules A, B, and C using 3×3 convolution.

Equation (2) deals with residual block function, which has different input and output dimensions.

3. Experiment Results and Performance Analysis

A series of comparisons of different object detection models have been conducted to evaluate the effectiveness of the proposed integrated approach. In this research, three object detection models are implemented. During the experiment, we have (1) trained the SSD and Faster-RCNN over ten flower clas images and analyzed its performance and (2) trained the object detection models using a transfer learning approach on different backbones that include Inception V2, ResNet 50, ResNet 101, and Mobile Net V2.

3.1. Quantitative Analysis of Flower Detection Performance. Furthermore, the performance of both approaches using qualitative and quantitative measurement methods has been compared. Several evaluation metrics were used to measure the effectiveness of flower detection for quantitative analysis, including the Mean Average Precision (mAP), Average Recall (AR), and average precision (AP). It is most commonly used to calculate the Precision and Recall of measurement systems based on the following equations:

$$Precision = \frac{TP}{TP + FP}, \tag{3}$$

$$Recall = \frac{TP}{TP + FN}, \tag{4}$$

$$F1 = \frac{2 * Precision * Recall}{Precision + Recall}. \tag{5}$$

TP stands for true positives, FP for false positives, and FN for false negatives. Further, the correctness of a positive is assessed through FPs and FNs evaluated by the intersection over union (IoU) overlap with the corresponding ground-truth bounding box [21]. It is calculated according to the following equation:

$$IoU = Area \frac{of \cap}{Area of \cup}. \tag{6}$$

Detected objects that were not matched to the ground-truth bounding box were considered false positives (FP). If the IoU (6) exceeded the threshold, it was considered a true positive (TP). Furthermore, a false negative (FN) is identified in the missed ground-truth bounding box. We have chosen 0.5 and 0.75 as the threshold values for this study. Detection performance has been determined by averaging the mean average precision (mAP) score and AP values from all classes [22]. As mAP increased, the overall performance of the flower dataset improved. Tables 2 and 3 show that these different object detection models have different detection performance results [20].

A summary of the Precision (given equation (3)) and Recall (given equation (4)) of different detection models is presented in Tables 1 and 2. With the different AP IoU (0.5: 0.95, 0.50, and 0.75) 0.81, 0.92, and 0.91, the proposed model Faster R CNN inception V2 with 100 proposals gives the best performances. Moreover, the values of different AR detections (1, 10, and 100) were 0.77, 0.91, and 0.89, respectively. We calculate $F1$-score using mean precision @0.5 IoU and recall @10 concerning 100 and 300 proposals, as shown in Table 4.

3.2. Qualitative Analysis for Different Flower Detection Experiment Results. The intersection qualitatively evaluates the correctness of a detected object over union (IoU) overlap with the corresponding ground-truth bounding box [14]. The ground-truth bounding boxes are those hand-labeled boxes from the training set indicating where the flowers are on the image. An example of the IoU overlap is seen in Figure 6, and this suggests that the prediction bounding box will be evaluated using IoU (i.e., prediction of object detection model).

Across all object detection models, the flower dataset has shown good performance. The red box indicates the ground-truth label, and the boxes of colored lines indicate prediction bounding boxes [23]. We compared the object detection model results to examine the effect of different pretrained CNN

TABLE 2: The performance of Average Precision (AP) for different object detection models.

architectures on flower detection performance [24]. Figure 6 shows some quantitative results for flower classes. Figure 7 shows the performance of Faster-RCNN. Figures 7(a) to 7(j) are part of the dataset, and Figures 7(k) and 7(l) are not part of the data used to determine the model generalization.

4. Conclusion

An efficient and generalized deep convolution neural network (DCNN)-based model for flower detection, localization, and classification has been proposed. The proposed model localization and recognition of flower species provide flower names, class classification, and multilabeling techniques. This study demonstrated that some classes are very similar in shape and color. In contrast, others can be distinguished better by their external shapes than their internal shapes and vice versa. Faster-RCNN and other object detection models have been evaluated using pretrained models of the COCO dataset. The proposed model provides an optimum mAP score of 83.3% with 300 and 91.3% with 100 proposals on the flower class dataset up to 100% accuracy confidence. However, it still has some limitations due to color similarity between the two classes of flowers, as shown in Figures 7(c) and 7(i). Furthermore, a multilabel classification model provides botanical information about a flower to help farmers, horticulture, and nonbotanists understand what type of flower it is. We should jointly train the models with visually similar classes as a future step.

The information age of rapid development of tourism industry provides abundant travel information, but it also comes with the problem of information overload, which makes it difficult to meet the growing personalized needs of people. The traditional collaborative filtering recommendation algorithm (CFA) also suffers from the problem of data sparsity when the user population increases. Therefore, this study optimizes the CFA through the similarity factor and correlation factor and enhances the tourism sense of travel experience through the satisfaction balance strategy. The experimental results show that the improved CFA method has the highest average accuracy on the overall dataset and the best recommendation performance of the satisfaction balance strategy. Overall, the recommendation model in this study is useful for attraction selection of users and marketing optimization of travel companies.

1. Introduction

With the development of information technology and the Internet, network information is becoming an important source of information for the public to plan travel routes, and people are gradually entering the era of big data from the era of lack of information [1]. In the context of massive data, how to quickly find the information of the best value for users is of great significance, and various recommendation systems have emerged with the needs of users. The recommendation systems [2] involved in the existing literature mainly focus on a single user and have achieved good results in TV programs, music, movies, news, and so on. In the tourism industry, the recommendation system is still in the initial stage of development and needs to be continuously improved. Compared with recommendation systems such as movies and music, it is difficult to obtain the ratings of scenic spots in the tourism field, and the user's rating matrix is relatively sparse. In addition, the selection of travel routes usually needs to consider the preferences of multiple users, so a recommendation system that combines all users participating in travel is a research hotspot in the field of travel recommendation [3].

In the recommendation system based on collaborative filtering, the rating of a single user needs to be predicted first. However, when calculating the similarity between users or items, the traditional collaborative filtering algorithm does not consider the impact of the number of items jointly rated by users and the degree of correlation between ratings on the similarity. For example, two tourists with different interests may have fewer attractions at the same time. When the users have fewer common ratings, the traditional collaborative filtering algorithm cannot accurately measure the similarity of users [4]. Therefore, it is necessary to consider fusing the prediction results of a single user. Practice shows that the recommendation effect of mean value strategy and least pain strategy is better. The average strategy takes the user's average rating on the item as a comprehensive evaluation result, but does not consider the dissatisfaction of a few members. The least misery strategy selects the member's lowest rating on the item as the comprehensive evaluation result, which ignores the preference of the majority of members.

Recommendation system refers to defining a function F to calculate the probability that an item $i \in I$ (I am the set of all items) is recommended to a certain user $u \in U$ (U is the

set of all users) [5]. Recommendation algorithms find the most interesting items for users by calculating probabilities. Algorithms are the core of recommendation systems, and using efficient and accurate recommendation algorithms is the key to achieving good recommendation results. According to the different recommendation principles, it can be divided into popularity-based, social network-based, demographic-based, content-based, collaborative filtering-based, model-based, and hybrid recommendation algorithms. Recommendation based on popularity is to recommend hot content to users first, which can cover most of the content needs. Recommendations based on social networks include neighborhood-based social recommendation and graph-based social recommendation algorithms [6]. Demographic-based is to use the basic information of users, including age, gender, and place of residence, to calculate the degree of correlation between users and then make recommendations to users. The content-based recommendation algorithm recommends content like the items that they were interested in to users based on the attributes of the item itself [7]. The collaborative filtering algorithm proposed by Goldberg et al. is based on the assumption that if users X and Y rate t items similarly or have similar behaviors; then, users will rate or behave similarly to other items. It collects the user's past behavior to obtain the user's explicit or implicit information about the product, obtains the relevance of the product or user, and then recommends based on the relevance. Hybrid recommendation algorithms can combine the advantages of multiple algorithms to improve the performance of recommendation systems [8]. Hybrid recommendation algorithms include weighted type, switching type, intersection type, feature combination type, waterfall type, feature incremental type, and metalevel type [9]. According to the characteristics of travel recommendation and user needs, the recommendation algorithm based on collaborative filtering can better meet the recommendation requirements without causing excessive calculation. Nilashi et al. [10] used expectation maximization to construct a multicriteria collaborative filtering recommendation system for travel and tourism. Mehrbakhsh et al. [11] developed a collaborative filtering recommendation system based on ontology and dimensionality reduction techniques. Li et al. [12] proposed a combined recommendation algorithm based on improved similarity and forgetting curve.

In the process of travel recommendation, this study firstly improves the user-based and item-based collaborative filtering algorithms. The improved CFA combines the similarity factor and the correlation factor, which can better solve the problem of data sparsity in travel recommendation. Secondly, on the basis of average strategy and least misery strategy, a new user preference fusion strategy—satisfaction balance strategy—is defined. The strategy comprehensively considers the user's local satisfaction and overall satisfaction. Finally, through the experimental analysis based on the relevant tourism dataset of the city of Chongqing, it is verified that the improved method in this study can effectively improve the quality of tourism recommendation.

2. Recommendation Method

Collaborative filtering algorithm (CFA) is one of the most commonly used recommendation algorithms in the field of e-commerce recommendation, which does not require users to actively provide information about their personal needs, but obtains their potential preferences based on existing rating records. This study is based on the key techniques of recommendation for CFA applications, including fusion methods and fusion strategies. The fusion method is divided into model fusion and recommendation fusion. Model fusion generates recommendation combinations based on user preference models. Recommendation fusion, on the contrary, requires fusion based on prediction scores of each user after obtaining the prediction scores based on traditional algorithms and can also fuse the list of recommended items. The commonly used fusion strategies in recommendation key techniques include mean strategy, least pain strategy, and happiest strategy. Masthoff et al. [13] evaluated through a series of experiments that multiplication strategy, mean strategy, least pain strategy, and pain avoidance mean strategy are better. Zhang et al. [14] analyzed through literature studies and found that the most used strategies are mean strategy, pain mean value avoidance strategy, and minimum pain strategy, but the applicability of these strategies varies for clusters with different characteristics.

2.1. Recent Neighborhood Recommendations. CFA is often applied as a basic method in recommendation systems. The recommendation technique based on CFA includes four stages [15], such as similarity metrics, selecting neighbors, predicting ratings, and determining recommended items. Firstly, the similarity between every two users is calculated by the ratings of users in the rating matrix, then the ratings of current users for unknown items are predicted based on the K-nearest neighbor approach, and finally the recommendation list is generated by combining the preferences of all group members through a fusion strategy. The overall framework of the CFA-based recommendation technique is shown in Figure 1. Among them, CFA can be divided into user-based nearest neighbor recommendation and item-based nearest neighbor recommendation.

User-based nearest neighbor recommendation refers to the assumption that the current user will like the items liked by users with similar preferences. Currently, similarity calculation methods commonly used in practice include Cosine similarity and Pearson correlation coefficient. In this study, the main choice of similarity is defined as shown in the following equation:

$$c\text{sim}\,(p,q) = \frac{\sum_{i \in I_{pq}} R_{p,i} \cdot R_{q,i}}{\sqrt{\sum_{i \in I_p} R_{p,i}^2}\sqrt{\sum_{i \in I_q} R_{p,i}^2}}, \tag{1}$$

where $c\text{sim}\,(p,q)$ denotes the cosine similarity of users P and Q, $R_{p,i}$ and $R_{q,i}$ denote the ratings of user P and user Q for item i, respectively, I_p and I_q denote the set of items rated by user P and Q, and I_{pq} denotes the set of items jointly rated by user P and Q. By finding the set of users who have the
FIGURE 1: The framework of recommendation-based CFA.

similarity preferences to the current user P, as KQQ_a, then the predicted ratings of user P for item i are as in equation (2), where $\overline{R_p}$ and $\overline{R_q}$ denote the average ratings of user P and Q, respectively:

$$G_{p,i} = \overline{R_p} + \frac{\sum_{q \in KQQ_a} c\text{sim}(p,q) \times \left(R_{q,i} - \overline{R_q}\right)}{\sum_{q \in KQQ_a} \left|C_{\text{sim}(p,q)}\right|}. \tag{2}$$

The nearest collar recommendation based on the item uses the user's rating of the item to calculate the similarity, which is chosen in this study as shown in the following equation:

$$g\text{sim}(i,j) = \frac{\sum_{p \in R_{ij}} \left(R_{p,i} - \overline{R_i}\right)\left(R_{q,i} - \overline{R_j}\right)}{\sqrt{\sum_{p \in R_{ij}} \left(R_{p,i} - \overline{R_i}\right)^2} \sqrt{\sum_{p \in R_{ij}} \left(R_{p,j} - \overline{R_j}\right)^2}}, \tag{3}$$

where $g\text{sim}(i,j)$ denotes the Pearson similarity of item i and j, $\overline{R_i}$ and $\overline{R_j}$ denote the average scores of items i and j, and R_{ij} denotes the set of items that have scored both items i and j. By finding the set of items which have the similarity preferences to the current item i, as KQQ_i, then the predicted ratings of user Q for item i are as in the following equation:

$$G_{p,i} = \overline{R_i} + \frac{\sum_{j \in KQQ_i} g\text{sim}(i,j) \times \left(R_{a,j} - \overline{R_j}\right)}{\sum_{j \in KQQ_i} |g\text{sim}(i,j)|}. \tag{4}$$

2.2. Algorithm Improvement. Similarity is an important metric in CFA that determines how well a prediction is scored. In the travel field, the user's own combination of factors makes travel recommendations different from general e-commerce. For example, the frequency of users watching movies and online shopping in a year will be much greater than their frequency of travel. Therefore, the problem

of data sparsity is more prominent in travel recommendation. The traditional similarity calculation method can give good results when the rating data are abundant, but in travel recommendation, the traditional recommendation method may ignore the influence of the sparsity of user rating data on the similarity calculation result when calculating the similarity between users or items.

Chongqing is one of the most popular tourist cities in China. This study takes the scoring matrix of famous scenic spots in the city by different users as an example to discuss this issue.

From the data in Table 1, the number of attractions rated jointly by users A and B is more than that of users A and E. Therefore, the similarity of users A and B should be higher. However, the cosine similarity between users A and B is calculated to be 0.724 and the similarity between users A and E is 0.871. Therefore, traditional similarity calculation methods cannot correctly account for the correlation between user ratings. To solve this problem, this study uses the relationship between the number of common user ratings of attractions and the total number of user ratings of attractions to adjust the similarity between users, that is, the similarity influence factor s_i, and is defined as shown in the following equation:

$$s_i = 2\sqrt{\frac{I_{pq}}{I_p \cup I_q}} - 1, \tag{5}$$

where I_p is the set of attractions rated by user P and I_q is the set of attractions rated by user Q. The larger the number of attractions jointly rated by users P and Q in the total number of rated attractions is, the larger the corresponding similarity influence factor and the larger the value of similarity may be; conversely, the smaller the value of similarity may be.

TABLE 1: User rating matrix.

User	Hong Ya Dong	Dream Ordovician	Ciqikou ancient town	Wulong fairy mountain
A	5	3	3	1
B	3	3	0	4
C	4	5	4	0
D	3	5	0	2
E	5	0	4	0
F	5	3	0	0

User D and User F have a cosine similarity of 0.835, indicating that they have similar preferences, while their Pearson and modified cosine similarity calculations are negative, indicating that they have opposite preferences. Both calculations deviate from the actual situation. As the size of users and rating matrices increases, situations like this can also affect the accuracy of recommendation results. To solve such problems, this study uses the correlation of user ratings to adjust the similarity between users; the closer the common rating vectors of users are, the larger the value of similarity may be and vice versa, the smaller the value of similarity may be. The correlation factor s_i' is defined as the following equation:

$$s_i' = 1 - \sqrt{1 - \left[\frac{\sum 2R_{m,i}R_{n,i}}{\sum \left(R_{m,i}^2 + R_{n,i}^2\right)}\right]^2}. \tag{6}$$

The calculation of similarity is the most important step in collaborative filtering. The data sparsity problem faced by the travel domain makes it difficult for the original similarity methods to accurately measure the similarity among users. This is because in the case of sparse user rating data, traditional methods mainly consider the similarity between users' common ratings, but ignore the phenomenon that users are not necessarily similar on other items. Users' preferences can be considered similar only when they rate similarly on a relatively large number of items; moreover, traditional methods cannot accurately distinguish the similarity between some users with the same similarity but very different preferences.

The similarity influence factor s_i and correlation factor s_i' proposed in this study comprehensively consider the influence of common user rating items and rating correlation on the similarity measure, which can effectively alleviate the problem of inaccurate similarity calculation due to the data sparsity problem. Improved similarity $csim(p, q)_i = s_i[\theta \cdot csim(p, q) + (1 - \theta) \cdot s_i']$, and θ is a parameter of [0, 1]. Through substituting $csim(p, q)_i$ into equation (2), we can yield the user's predicted score for the scenic spot.

2.3. Modified Preference Fusion Strategy.
On the basis of individual users' prediction and scoring of items, the fusion strategy can fuse the user's preferences to obtain the overall evaluation value of each item and generate the final recommendation result according to the score. Since user preferences may vary, individual member preferences cannot represent overall preferences. How to obtain the common preferences of the overall users to alleviate the conflict is a problem that needs to be solved. Currently, the more commonly used preference fusion strategies include average strategy and least misery strategy. The average strategy selects the average of the user's rating on the item as the score of the item to be recommended. The calculation process is shown in the following equation:

$$R_{g,i} = \text{avg}\left(R_{a,i} : a \in g\right). \tag{7}$$

The least misery strategy refers to taking the minimum rating of the item among users as the score of the item to be recommended, as shown in the following equation:

$$R_{g,i} = \min\left(R_{a,i} : a \in g\right). \tag{8}$$

The average strategy only considers the average preference degree of users participating in the rating and may ignore the dissatisfaction degree of a few users. The least misery strategy is based on the minimum rating of the user to evaluate the project, which may be the feeling of the majority of households. To this end, this study considers the shortcomings of the above two strategies and defines a satisfaction balance strategy, which is used to balance the relationship between the user's local satisfaction and overall satisfaction. The definition is shown in the following equation:

$$B_{g,i} = \text{avg}\left(R_{a,i} : a \in g\right) + \frac{1}{S} \, avg\left(R_{a,i} : a \in g\right) * \min\left(R_{a,i} : a \in g\right), \tag{9}$$

where S denotes the number of users who evaluates the items. Based on the above strategies, we list four users and their evaluations of the five attractions, as shown in Table 2. The table shows the attractions scores under the average strategy, the least misery strategy, and the satisfaction balance strategy. According to the average strategy, S_2 and S_3 are equivalent for the surveyed users, but for S_1, the mean strategy does not consider the feelings of U_4. According to the least pain strategy, S_1 and S_2 are equivalent to the surveyed users. Compared with S_3, users are more interested in S_4. The least misery strategy only considers the minimum satisfaction of members but ignores them, the preference of most people. Obviously, the result calculated according to the satisfaction balance strategy can better reflect the user's overall interest in the scenic spots. According to the revised fusion strategy, the recommended list can be obtained as S_4, S_3, S_2, and S_1.

3. Experimental Design

3.1. Experimental Data.
There are no publicly available experimental datasets in the field of travel recommendation, and the data used in academic studies at home and abroad

Table 2: Different aggregation strategy examples.

Users	S_1	S_2	S_3	S_4
U_1	5	4	4	5
U_2	4	5	5	4
U_3	3	2	4	5
U_4	2	5	3	4
Average	3.5	4.00	4.00	4.50
Least misery	2.00	2.00	3.00	4.00
Satisfaction balance	5.25	6.00	6.00	6.75

Note: S_n denotes the different scenic spots; U_n denotes the different users.

are mainly from travel websites or questionnaires. There are two problems in the data obtained by means of questionnaires in terms of data volume and subjective bias. In this study, we have crawled 2874 travel notes related to "Chongqing" from https://Qunar.com and use 49,318 scores as the experimental dataset, with a score ranging from 1 to 5 points.

In order to reduce the error, this study preprocesses the acquired data, and users with duplicate records for the same user, attractions with unclear ratings, and users with less than 3 rating records are removed. The final number of valid users is 4072, the total number of ratings is 25894, and the sparsity level is 0.965.

3.2. Accuracy Evaluation. Mean absolute error (MAE) and root-mean-square error (RMSE) are the two most common metrics for continuous variables. MAE is a linear score that represents the mean of the absolute error between the predicted value and the observed value. RMSE represents the sample standard deviation of the difference between the predicted and observed values (called residuals) and is used to indicate the degree of dispersion of the sample. In this study, the accuracy of individual prediction results is tested using MAE and RMSE, as shown in the following equation:

$$\text{MAE}(X, R) = \frac{1}{m} \sum_{i=1}^{m} |R_i - y_i|; \text{RMSE}(X, R) = \sqrt{\frac{1}{m} \sum_{i=1}^{m} (R_i - y_i)^2},$$

(10)

where R and y denote the predicted and true user ratings of the items in the test set, respectively, and m is the number of ratings.

There are many evaluation metrics commonly used in recommendation systems. The main idea of Discounted Cumulative Gain (DCG) is that a user's favorite item being ranked in front of the recommendation list will increase the user experience to a greater extent than being ranked at the back, as defined in the following equation:

$$\text{DCG}(b, L) = \sum_{i=1}^{b} r_i + \sum_{i=b+1}^{L} \frac{r_i}{\log_b i},$$

(11)

where r_i indicates whether the product ranked i is preferred by the user, $r_i = 1$ indicates that the user likes the product, b is a free parameter, and L is the length of the recommendation list. Since DCGs are not directly comparable between

users, we normalize them by dividing the original DCG by the ideal DCG to obtain the normalized discounted cumulative gain (NDCG). NDCG is a number between 0 and 1. The larger the value of NDCG, the more accurate the ranking of the items in the recommendation list and the higher the accuracy of the recommendation.

4. Experimental Results and Analysis

We randomly select 70% of the rating records in the travel dataset as the training set and 30% as the test set and observe the performance of the recommendation algorithm when the number of neighbors K increases from 5 to 30 by 5 each time after several experiments, taking $\theta = 0$. From Figures 2 and 3, it can be obtained that, for the traditional user (uCFA)- and project (pCFA)-based methods, s_i and s_i' proposed in this study (uCFA-I; pCFA-I) are more effective in improving the CAF on MAE and RMSE. It shows that the improved method can provide better results in calculating the similarity between users or projects, which in turn improves the accuracy of prediction scores. The problem that traditional methods ignore the differences in users' interests for different attractions is reasonably solved.

Nowadays, people are more inclined to travel in groups, so it is important to fuse strategies for different users. Based on predictive scoring of users using a modified CFA, we compare the experimental results of the satisfaction balance strategy (SB) proposed in this study with the commonly used fusion strategies presented in Chapter 2.3 (AVE; LM) on a tour dataset. As can be seen from Figure 4, the NDCG values of the SB fusion strategy are the highest for different user sizes. AVE only considers the overall satisfaction of all members when recommending items to different users, but ignores the individuality of members' feelings; the LM strategy uses the opinions of a few members to decide the choice of the whole group, and the recommended items do not have a high probability of making the highest satisfaction of all members. And SB takes into account the relationship between overall and local user satisfaction, allowing the recommended projects to better reflect the preferences of the entire group.

Besides, regardless of the fusion strategy, the number of users at 4 makes NDCG take the highest peak. This also shows that, in the present social context, small groups of four are the most popular way to travel. On this basis, user satisfaction decreases as the number of people increases. This is also in line with the actual situation; as the more people there are, the greater the difference in interests is and the more difficult it is for the group to reach the peak of satisfaction with the same attraction.

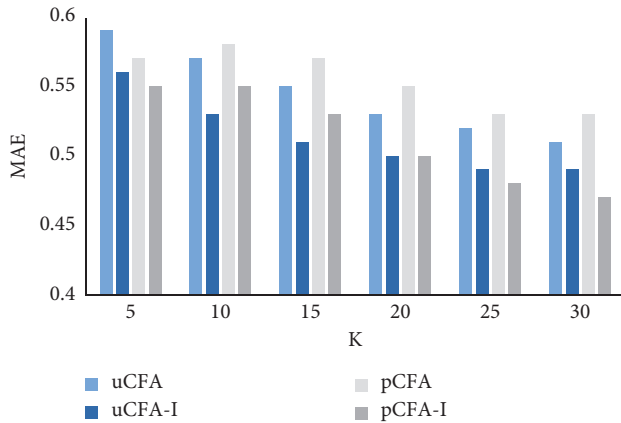
Tourism market is very necessary for the development of cities. The model proposed in this study can help people to make decisions when traveling. Nowadays, there are various methods of travel recommendation, and only the method with outstanding accuracy and recommendation performance can stand out. In this study, we have proposed two improvement factors based on the common CFA, which can make the user get a better experience. Nowadays, travel companies should customize their marketing with full


FIGURE 2: MAE comparison chart.
FIGURE 3: RMSE comparison chart.
FIGURE 4: NDCG comparison chart.

consideration of user preferences, so the data source for this study's improved CFA method is web travel data that incorporate user interests. As society develops and incomes increase, marketing of tourism should adapt to the trend of increasing personalized demand by creating a user demand base. Also, tourism companies can use the method in this study to obtain the user satisfaction of different attractions

so that they can identify the attractions with more commercial value or business potential, improve their marketing and achieve greater economic benefits. For example, a group cruise or skiing program for four people can be developed at natural landscapes such as Fairy Mountain to make the tour small groups, reduce the probability of group members separating, and improve the overall satisfaction of the tour.

5. Conclusion

In response to the team-based nature of tourists, this study proposes a travel recommendation method that integrates users' personalized needs and maximizes team satisfaction based on the improved-CFA method. The method uses the massive rating information about tourist destinations on the web to build the basic framework of the travel recommendation method. The problem of sparsity of CFA data is solved by two factor corrections based on users and items. In the instance validation of https://Qunar.com, the improved CFA method in this study has significantly lower MAE and RMSE than the nonoptimized CFA method for different K. The satisfaction equalization strategy used in this study is also due to the conventional fusion strategy for different number of users. This shows the superiority of the method in this study and also greatly helps tourism companies to come up with better marketing strategies under complex market conditions. The recommendation algorithm in this study has room for improvement in accuracy, and future work will focus on the improvement of model accuracy and relevance of user preferences.

In order to improve the artistic expression effect of photographic images, this article combines the deep learning model to conduct multicamera photographic image art research in BERT motion. Moreover, this article analyzes the external parameter errors caused in the calibration process and uses the checkerboard in the common field of view to calibrate the spatial coordinates of the corners of the board in multiple camera coordinate systems. In addition, this article aims to match the spatial coordinates of the corresponding points to each other and solve the rotation and translation matrix in the transformation process. Finally, this article uses the LM algorithm to optimize the calibration parameters of the camera and combines the deep learning algorithm to perform image processing. The experimental research results show that the research method of multicamera photography image art in BERT motion based on the deep learning mode proposed in this article can effectively improve the expression effect of image art.

1. Introduction

In people's daily life, as one of the main tools for image dissemination, photography has become ubiquitous to record and discover different visual possibilities. However, photography and photographic art are two completely different concepts, and photography is not related to all art. Photography is recognized as a relatively recent thing in the field of culture and art. In the 1970s, a large number of art festivals, periodicals, and galleries were launched in Western countries. Immediately afterwards, some colleges and universities set up professional photography colleges and photography departments. In addition, the research on the history of photography in the academic field is also deepening, a large number of photographic works have been included in the art collection, and more and more artists have begun to create photography. In short, the practice and dissemination of photography are no longer confined to a narrow field of practice but lead to the palace of art and culture. At the same time, people's concept of photography is constantly updated. When photography was invented, it was used only as a service tool. Today, however, it is increasingly being discussed and appreciated as the artwork itself. As a result, the public's attitude towards the practicality of photography has changed, attention has been drawn from the perceptual and rational nature of images, and the production, dissemination, and circulation of photography, as well as the form, value, and use of photography, have also changed accordingly.

Some people simply regard the art of photography as craftsmanship based on the principles of optics, chemistry, and mechanics with purity. To put it more frankly, they believe that photography is a kind of performance art of taking pictures, which leads them to ignore the lofty status of photography and its outstanding contribution to the development history of human society. In addition, the importance of photographic practice is generally ignored by some people, who only pay attention to theoretical knowledge and believe that it is enough to master the classic theories, such as visual aesthetics, cultural studies, and image expression in photographic art, and do not pay attention to photographic practice. These understandings of photography art are one-sided and not objective.

Photography art is a comprehensive artistic behavior. It is inclusive and has different connotations in different

situations. Sometimes it pays more attention to the connotation of the technical level, and sometimes it focuses more on the expression of culture and emotion. Today's photographic art is specifically a type of modern plastic art. A camera is a tool for photographic creation. Taking the photographer's creative concept as the basic starting point, they use the camera to take pictures of people or things in the real world and uses certain modern processing methods, perform artistic processing on the photographed things, and finally complete the creation of photographic works of art. Through the works showing the living conditions of human beings in the current society, at the same time, it can express the author's thoughts and feelings. Aesthetic features are more of an attribute, the presentation of their own aesthetic features. Photography, as one of many art categories, has aesthetic characteristics similar to other aesthetic activities, that is, the commonality of photography aesthetics and other aesthetic activities. In addition, photography art also has its own characteristics; it belongs to a branch of visual plastic art.

This article combines the deep learning model to study the multicamera photographic image art in BERT motion to improve the performance of photographic image art.

2. Related Work

From the perspective of the development process of image text description, it can be divided into three stages: template-based image text description method; retrieval-based image text description method; deep learning-based image text description method [1]. Before the deep learning method was proposed, most of the image description methods used template-based and retrieval-based methods. The template-based image text description method is mainly to annotate the image content, which is based on image annotation technology [2]. Template-based methods rely on visual perception of the relationship between image objects and components and describe images using representations of subject, predicate, environment, and preposition collocations [3]. Reference [4] used the method of image context subject, object, and their relationship to describe the image, used the neighbor similarity algorithm to calculate the matching degree between adjacent tuples, finally calculating the score, and the score is proportional to the matching degree. Reference [5] proposed a Conditional RaIldom Field (CRF) algorithm, the central idea of which is to generate text descriptions for predicted text labels according to template matching rules. Reference [6] improved the template in the image text description task and used the hidden Markov model to fill the template with sentences. Reference [7] applied syntactic analysis to the image text description task, used the VDR (Visual Dependency Representation) method to represent the object relationships contained in the graph with a dependency graph, and then represented the image as a VDR and then traversed the VDR, fully considering the VDR. Syntax tree relationships to fill in gaps in sentences. Template-based image text description methods may be grammatically correct in language descriptions, but the output descriptions are highly template-dependent, have

poor generalization performance, and generate text sentences that lack diversity. Due to the backwardness of this method, the image text description task is no longer used [8]. Searching for the relationship between matching text and images is the main purpose of the retrieval-based image description generation task. Retrieval-based image description also includes vision-based retrieval and multi-modal-based retrieval methods [9]. The retrieval method based on visual space is to obtain textual information from the features of similar parts in the image. The image retrieval dataset established by the literature [10], for each image, uses appropriate words to describe the image. Reference [11] proposed a large dataset, which includes attribute annotations of objects, which can be used to train attribute classifiers, predicted object attributes, and improved the quality of image text descriptions. The retrieval method based on multimodal space is to perform a multimodal representation of all images and text sentences in the training corpus. For the image to be tested, retrieval is performed in the multimodal space after the image and the text are jointly mapped. First, a set of similar images of the image to be tested is obtained, and the text description corresponding to the test image is obtained according to the text description of the similar image. In [12], the authors proposed to learn multimodal space representation, use kernel function calculation method to extract high-dimensional image features, in the multimodal space represented by image and text jointly, use a sorting algorithm according to the high-dimensional features of images, and find candidate text for the set of similar images of the target. Finally, the candidate text is screened according to a certain sorting algorithm, and the text description corresponding to the image is obtained. Reference [13] applied the neural network with stronger expressive ability in the field of image text description. It makes the image text description generated in the multimodal space more accurate and of higher quality. The retrieval-based method makes full use of the dataset, but the generated image text description largely depends on the dataset. When the gap between the target image and the training data set is large, the effect of the generated text description will be poor, and only the generated text description can be generated. Human-annotated sentences are already in the dataset. Retrieval-based image description methods have better expressiveness, mobility, and practicality. Although some excellent results have been obtained, the retrieval-based method still has dependencies. The production text description is highly dependent on the training corpus, and there are problems such as high complexity, which are seriously affected by human intervention, which makes the generated text description sentences simple and ineffective. With rich semantic information, researchers continue to explore new text description methods [14]. With the popularization of deep learning knowledge, researchers have proposed new methods based on deep learning methods. The advanced and commonly used method is the end-to-end model. On the one hand, deep convolutional neural networks can be used to create models for object features in images; on the other hand, recurrent neural networks can be used to create

language models for text [15]. Reference [16] proposed a deep semantic alignment model. The model echoes images and text descriptions by aligning them. In terms of images, a region-based convolutional neural network is used for pretraining, and the features of the images are mapped to the feature space of word vectors to match the two-part features. Descriptions are generated using recurrent convolutional networks in terms of language models. The NIC model based on the English dataset proposed in [17] uses the advanced Inception V3 network to extract image features and uses LSTM to generate descriptions in the language generation model stage. This method plays an important role in the image description task. Reference [18] proposed a hard attention mechanism and a soft attention mechanism, used the combination of the attention mechanism and the LSTM network to obtain the image information of each step, and improved the expressive ability of the image description.

3. Global Calibration Optimization of Multicamera System Based on Levenberg–Marquardt Algorithm

Camera calibration has two important functions. One is to construct the relationship between the image plane coordinates and the camera space coordinates, which is explained in detail in the principle of calibration and the principle of binocular stereo imaging. The other is to construct the rotation and translation relationship between the camera coordinate system and other camera coordinate systems.

As shown in Figure 1, there are two coordinate systems in space, (o-x-y-z) and (O-X-Y-Z), and o and O are the origins of the two coordinate systems, respectively. Moreover, there is a straight line between the two origins, and the same straight line forms different vectors at different coordinates. Among them, the o point and the O point are both (0, 0.0) in their respective coordinates, and the vector from the o point to the O point is (x_1, y_1, z_1). It can also be interpreted as the coordinate of the point O in the (o-x-y-z) coordinate system is (x_1, y_1, z_1).

In the same way, the vector from point O to point o is (x_2, y_2, z_2), which is interpreted as the coordinate of point o in the (O-X-Y-Z) coordinate system is (x2, y2, 2). Since the directions of each axis corresponding to the two coordinate systems are different, these two vectors are not two opposite vectors, but the length of the same straight line is unchanged. Therefore, the magnitudes of these two vectors are the same, as shown in the following formula:

$$x_1^2 + y_1^2 + z_1^2 = x_2^2 + y_2^2 + z_2^2. \tag{1}$$

A coordinate system with two origins that do not coincide cannot discuss rotation. Therefore, we first move the (o-x-y-z) coordinate system to the vector (x_1, y_1, z_1) until its origin coincides with the origin of the (O-X-Y-Z) coordinate system.

As shown in Figure 2, in order to make the two coordinate systems completely coincide, the o-x-y-z coordinates will be rotated around the origin, and the counterclockwise
Figure 1: Coordinate system translation.
Figure 2: Coordinate system rotation.

direction is the direction of the rotation angle increment. The process is mainly divided into the following three steps.

The first step, which keeps the z-axis stationary, rotates the x-axis and the y-axis counterclockwise around the z-axis by an angle of a. At this time, x reaches the N-axis position, and a rotation variable $R_z(\alpha)$ is generated, and its matrix is shown in the following formula:

$$R_z(\alpha) = \begin{bmatrix} \cos \alpha & -\sin \alpha & 0 \\ \sin \alpha & \cos \alpha & 0 \\ 0 & 0 & 1 \end{bmatrix}. \tag{2}$$

In the second step, it keeps the x-axis stationary, which is the current N-axis, and the y-axis and the z-axis rotate counterclockwise around the x-axis by an angle of ß. The z-axis just coincides with the z-axis, and a rotation variable

$R_x(\alpha)$ is generated, whose matrix is shown in the following formula:

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \beta & -\sin \beta \\ 0 & \sin \beta & \cos \beta \end{bmatrix}. \tag{3}$$

The third step, which again keeps the z-axis stationary, rotates the x-axis and the y-axis counterclockwise around the z-axis by a y angle. At this time, the x-axis coincides with the X-axis, the y-axis coincides with the axis, and a rotation

variable $R_z(\gamma)$ is generated, whose matrix is shown in the following formula:

$$R_z(\gamma) = \begin{bmatrix} \cos \gamma & -\sin \gamma & 0 \\ \sin \gamma & \cos \gamma & 0 \\ 0 & 0 & 1 \end{bmatrix}. \tag{4}$$

The whole process consists of three independent rotations, generating a rotation matrix R, where R is the product of $R_z(\alpha)$, $R_x(\alpha)$, and $R_z(\gamma)$, and the calculation result is shown in the following formula:

$$R = \begin{bmatrix} \cos \alpha \cos \gamma - \cos \beta \sin \alpha \sin \gamma & -\cos \beta \cos \gamma \sin \alpha - \cos \alpha \sin \gamma & \sin \alpha \sin \beta \\ \cos \gamma \sin \alpha + \cos \alpha \cos \beta \sin \gamma & \cos \alpha \cos \beta \cos \gamma - \sin \alpha \sin \gamma & -\cos \alpha \sin \beta \\ \sin \beta \sin \gamma & \cos \gamma \sin \beta & \cos \beta \end{bmatrix}. \tag{5}$$

As shown in formula (6), the two vectors (x_1, y_1, z_1) and (x_2, y_2, z_2) in the above two camera coordinate systems can be converted to each other under the action of the rotation matrix R. It can be seen that the rotation-translation matrix is invertible, and the inverse matrix of the rotation matrix is its own transpose matrix, as shown in the following formula:

$$\begin{bmatrix} -x_2 \\ -y_2 \\ -z_2 \end{bmatrix} R = \begin{bmatrix} x_1 \\ y_1 \\ z_1 \end{bmatrix}, \tag{6}$$

$$R^{-1} = R^T. \tag{7}$$

When multiple cameras are calibrated, due to the accuracy of target positioning and the minimization of the global error of the pursuit, as shown in formula (8), there is a very small error in the external parameters, and the same point corresponds to different coordinates in the two camera coordinate systems. Among them, the coordinate of this point in a camera coordinate is (x_m, y_m, z_m). The other camera coordinate system is converted to this camera coordinate system through the rotation and translation matrix after calibration. The corresponding coordinate is (x_n, y_n, z_n). Because it is the same point in the real space, it should coincide in the unified coordinate system. If there is no coincidence, there must be an error in the rotation and translation matrix. Therefore, this error needs to be analyzed.

If the origin of the camera coordinate system coincides after the transformation, according to the coordinate transformation process, the relative position of the points in the same coordinate system does not change, then the distance between the two points and the origin should be equal. At this time, the point coordinate can be regarded as a vector; that is, the vector's modulus is equal, as shown in the following formula:

$$x_m^2 + y_m^2 + z_m^2 = x_n^2 + y_n^2 + z_n^2. \tag{8}$$

When the origins are coincident, there is no need to retranslate the camera coordinate system, and only the

parameters in the rotation matrix need to be calculated accurately. Finally, the translation vector is transformed once using (6) to reduce the error. Therefore, there is a very small angular rotation between the two coordinates, and the camera coordinate system that needs to be aligned is rotated by three angles in turn according to the rotation method shown in Figure 2.

We assume that the vectors (x_m, y_m, z_m) and (x_n, y_n, z_n) form a small angle θ. The relationship between the included angle θ and the two vectors is shown in the following formula:

$$\sin \frac{\theta}{2} = \frac{\sqrt{(x_m - x_n)^2 + (y_m - y_n)^2 + (z_m - z_n)^2}}{2\sqrt{x_m^2 + y_m^2 + z_m^2}}. \tag{9}$$

When the included angle θ is very small and approaches 0, the values of θ and $\sin \theta$ are equal, and its geometric meaning is the ratio of the distance between the two points to the vector modulus. Because the viewing angle of the camera is limited to a certain extent, in order to obtain a wider field of view, the camera will be arranged in a relatively far position, and the modulus of the camera coordinate vector will also increase accordingly. Moreover, the common field of view formed by binocular imaging is further compressed, and the measurement area will be divided into multiple segments, which will cause the measurement points in other camera coordinate systems to be converted into the global coordinate system and cause great errors. In order to avoid great errors, further optimization of the calibration external parameters must be carried out.

Another case is when the lengths of the two vectors (x_m, y_m, z_m) and (x_n, y_n, z_n) are not equal. Then, the relationship between the included angle θ and the two vectors is shown in the following formula:

$$\cos \theta = \frac{|x_m x_n + y_m y_n + z_m z_n|}{\sqrt{x_m^2 + y_m^2 + z_m^2} + \sqrt{x_n^2 + y_n^2 + z_n^2}}. \tag{10}$$

At this time, it is not only the rotation angle that causes the camera coordinate system error but also the translation

vector error. The allowable range of this error should consider the difference between the lengths of the two vectors and the distance between the two measurement points. In general, the optimization of the overall parameters of the camera during measurement will rarely cause a large change in the translation vector; that is, the distance between the origins of the two coordinate systems will not be very far. Therefore, the vector length difference will not exceed the measurement spread.

The conversion relationship between the two coordinate systems is calculated and obtained according to the geometric relationship between the coordinate systems of each camera in the process of constructing a large field of view in a multicamera system. Global calibration is to calibrate the overall measurement system to obtain the conversion relationship between all camera coordinate systems and reference coordinate systems. Taking a dual-camera station system composed of four cameras as an example, the multicamera global calibration process is described in detail with reference to Figure 3.

According to the definition of each coordinate system, it can be known that the transformation relationship between the camera coordinate systems of each camera in the entire measurement system is as follows:

The transformation of the A camera coordinate system and the B camera coordinate system of the measurement system 1 is as follows:

$$\begin{bmatrix} x_A \\ y_A \\ z_A \end{bmatrix} R_{BA} = \begin{bmatrix} x_B \\ y_B \\ z_B \end{bmatrix} + T_{BA}. \tag{11}$$

The conversion of the c camera coordinate system of the measurement system 2 to the D camera coordinate system is as follows:

$$\begin{bmatrix} x_C \\ y_C \\ z_C \end{bmatrix} R_{DC} = \begin{bmatrix} x_D \\ y_D \\ z_D \end{bmatrix} + T_{DC}. \tag{12}$$

In the above, R_{BA} and T_{BA}, R_{DC} and T_{DC} can be directly solved by the camera calibration principle. Among them, the R matrix and the T matrix can complete the inverse transformation of the two coordinate systems by formulas (6) and (7). In order to realize the coordinate conversion between the two measurement systems, the rotation matrix R_{CA} and translation vector T_{CA} of the A camera coordinate system and the C camera coordinate are directly solved by calibration. It can be solved indirectly by C camera calibration and B camera calibration rotation matrix R_{CB} and translation vector T_{CB}, or by constructing D camera and A camera calibration parameters rotation matrix R_{DA} and translation vector T_{DA}.

$$\begin{aligned} R_{CA} &= R_{BA} R_{CB}, \\ R_{CA} &= R_{DA} R_{CD}, \\ T_{CA} &= R_{DA} + T_{CD} + T_{DA}, \\ T_{CA} &= R_{BA} + T_{CB} + T_{BA}. \end{aligned} \tag{13}$$

The same target point exists in the common field of view, and the relationship between multiple target points $P_A(x_{Ai}, y_{Ai}, z_{Ai})$ in the A camera coordinate system and the corresponding target point $P_C(x_{Ci}, y_{Ci}, z_{Ci})$ in the C camera coordinate system is constructed, where $i = 1,2,3, \dots$. The parameters in the transformation matrix and transformation vector that satisfy multiple target points are solved.

$$\begin{bmatrix} x_{Ai} \\ y_{Ai} \\ z_{Ai} \end{bmatrix} = \begin{bmatrix} r_1 & r_2 & r_3 \\ r_4 & r_5 & r_6 \\ r_7 & r_8 & r_9 \end{bmatrix} \begin{bmatrix} x_{Ci} \\ y_{Ci} \\ z_{Ci} \end{bmatrix} + \begin{bmatrix} t_x \\ t_y \\ t_z \end{bmatrix}. \tag{14}$$

If it is assumed that there is a matrix A, then A^T represents the transposed matrix of A. Similarly, $\|A\|_2$ and $\|A\|_\infty$ represent the spectral norm and row sum norm of matrix A, respectively. The singular values of matrix A are to be solved, the largest of which is the spectral norm of the matrix A. The sum of the absolute values of the elements in each row of matrix A is calculated, the largest of which is the row sum norm of matrix A.

f is a functional relationship that maps the parameter vector $P \in R^m$ to the estimated measurement vector $\hat{x} = f(p), \hat{x} \in R^m$. An initial estimated parameter p and a measurement vector x are provided, and it is expected to find $p +$ the vector f that best satisfies the functional relationship, that is, minimize the squared distance $\varepsilon^T \varepsilon$, where $\varepsilon = x - \hat{x}$. The basis of the LM algorithm is to solve a linear approximation f in the neighborhood of δ_p. For a very small value of d, the Taylor series expansion approximation is as follows:

$$f(p + \delta_p) \approx f(p) + J\delta_p. \tag{15}$$

Among them, J is the Jacobian matrix $\partial f(p)/\partial p$. Like all nonlinear substitution methods, LM is iterative, starting from a chosen starting point p_0. This method generates a series of vectors $p_1, p_2, p_{3,\dots}$. These vectors converge to the local minima $p+$ with respect to the functional relation f. Therefore, at each step, it is necessary to find a suitable value δ_p to minimize the overall value $\|x - f(p + \delta_p)\| \approx \|x - f(p) - J\delta_p\| = \|\varepsilon - J\delta_p\|$, and finding δ_p is the solution to a linear least-squares problem. When the column space of $J\delta_p - \varepsilon$ and J is orthogonal, δ_p reaches the minimum value z and $f J^T(J\delta_p - \varepsilon) = 0$ can be obtained, and the resulting value 6 can be used as the solution of the normal equation.

$$J^T J \delta_p = J^T \varepsilon. \tag{16}$$

The $J^T J$ in the matrix on the left side of the equation is an approximation to the Hessian matrix, that is, to the second derivative matrix. The LM method actually solves for small changes in the equation, which can be called augmented regular equations.

$$N\delta_p = J^T \varepsilon. \tag{17}$$

Among them, the off-diagonal elements of N are the same as the corresponding elements in $J^T J$, and its diagonal elements are $N_{ii} = \mu + [J^T J]_{ii}$, where $\mu > 0$. The process of changing the diagonal elements of $J^T J$ is called damping,
FIGURE 3: Schematic diagram of coordinate system transformation in a multicamera system.

and μ is the damping factor. In the iterative process, if a new parameter vector $p + \delta_p$ is obtained, which reduces the error ε, where δ_p can be calculated by the equation, the new parameter vector can be made closer to the optimal solution. Moreover, the iterative process is repeated with the aim of reducing the damping value.

If the new parameter vector $p + \delta_p$ is obtained and the error ε becomes larger or does not change, the damping value is increased, the augmented canonical equation is solved again, and the algorithm iterates until a value δ_p that reduces the error is found. In the equation, the solution is repeated for different damping factors μ until a parameter vector $p + \delta_p$ that is closer to the approximation is found. This update process corresponds to one iteration in the LM algorithm.

In the LM algorithm, the damping factor μ is adjusted during each iteration to ensure that the error can be reduced. If damping is set to a large value f, the matrix N in the equation used is almost on the diagonal and the LM update step value δ_p is close to the direction of the steepest descent. Also, the value of δ_p decreases in this case. Damping also handles the case of insufficient Jacobian elements, thus making $J^T J$ a singular matrix.

The LM algorithm terminates when at least one of the following conditions is met:

(1) The gradient size of $\varepsilon^T \varepsilon$ and $J\varepsilon$ on the right side of the equation will drop below a threshold.

(2) The relative change of the size of the step value δ_p falls below another threshold ε_2.

(3) The error $\varepsilon^T \varepsilon$ falls below another threshold ε_3.

(4) The maximum number of iterations k_{max} is completed.

$$ J^T \sum_x^{-1} J \delta_p = J^T \sum_x^{-1} \varepsilon. \tag{18} $$

If the covariance matrix Σ_x for the measurement vector x is available, $\sum_x^{-1}$ and the norm $\varepsilon^T \sum_x^{-1} \varepsilon$ can

be incorporated into the LM algorithm by minimizing squares instead of directly solving for $\varepsilon^T \varepsilon$. Therefore, a least-squares problem with minimum weights defined by weighted canonical equations is solved.

(4) Research on multicamera photography image art in BERT motion is based on the deep learning model

The image sentiment analysis model of sample selection and image content generation based on BERT features includes four parts: "image content generation," "text feature extraction," "sample selection based on BERT features," and "image sentiment analysis." The image is processed through deep learning, as shown in Figure 4.

The specific process of image content generation is shown in Figure 5.

Figure 6 shows the flowchart of the binocular stereo vision measurement procedure. The binocular cameras are synchronously triggered to capture a frame of pictures and then transfer them to the computer memory through the USB 3.0 interface. Then, it calls the image data to perform a series of tasks such as marker point detection and image point matching with the same name, then solves the pixel coordinates of the center of the marker point, and then performs 3D reconstruction to obtain the coordinates of the marker point in physical space and output the data.

According to the actual measurement needs, a CCD camera bracket and a fixed platform, lighting equipment, etc. are added to the system as auxiliary. The connection diagram of the main part of the system is shown in Figure 7.

The camera coordinate system and the imaging plane coordinate system are established. As shown in Figure 8, the world coordinate system in this section is selected on the target plane containing low-rank textures. For the convenience of description, the following two definitions are made first. When there is no rotation of the camera imaging plane coordinate system relative to the xw0wYw plane of the world coordinate system, the image captured at this time is called a

facing image. When the camera imaging plane coordinate system and XwDwYw, the plane has some unknown rotation and translation, the image captured at this time is called an oblique captured image. Obviously, compared with the original low-rank texture image, the front-facing image has no deformation, only scaling, and still retains the low-rank characteristic. When shooting at an angle, the image no longer retains low-rank properties due to projection distortion.

On the basis of the above research, the system model proposed in this article is verified, and the expression effect and image art of the multicamera image are evaluated, and the results shown in Tables 1 and 2 are obtained.

From the above research, it can be seen that the research method of multicamera photography image art in BERT motion based on the deep learning model proposed in this article can effectively improve the expression effect of image art.

4. Conclusion

Photography is a kind of visual art, but its expression must be carried out through forms, and different forms bring completely different visual experience. There are many forms of expression, and as one of the visual arts effects, ordering cannot be underestimated. "Ordering" as a guideline in graphic design can make the design more organized and normative. Similarly, for photography, "ordering" will make the photographic work have different formal meanings and show a strong sense of design order. There are many aspects to the formal expression of order in photography, such as symmetry and balance, repetition, and gradual change. These forms of order are often used in graphic art design, which can make the designed picture produce a visual experience of different orders. This article combines the deep learning model to conduct multicamera photographic image art research in BERT motion. The experimental research results show that the research method of multicamera photography image art in BERT motion based on the deep learning mode proposed in this article can effectively improve the expression effect of image art.

In bearing fault diagnosis, due to the insufficient obtained supervised data and the inevitable noise contained in the vibration signals, the problem of clustering bearing fault diagnosis with imbalanced data containing noise is caused. Thanks to the ability to quickly and fully learn boundary information in small samples, the extension neural network-type 2 algorithm (ENN-2) has the potential in imbalanced data clustering and has been gradually applied in fault diagnosis. Therefore, in order to improve the unstable clustering performance of ENN-2 caused by its heavy dependence on input order of samples, a novel algorithm called linked extension neural network (LENN) is developed by redesigning the correlation function and its iterative method, which greatly reduces the clustering iteration epochs of the algorithm. In addition, an evaluation index of clustering quality for this novel algorithm, extension density, is also proposed. After that, a bearing fault diagnosis model of variational mode decomposition (VMD) based denoising and LENN is proposed. Firstly, VMD is used to get intrinsic mode functions (IMFs), and the correlation coefficients of IMFs are calculated for signal denoising. Secondly, the features are extracted from denoised signals and selected by PCA algorithm, and the fault diagnosis is finally completed by LENN. Compared with ENN-2, K-means, FCM, and DBSCAN based models, the proposed model identifies the faults with different severities more accurately and achieves superior diagnostic ability on different imbalance degrees of datasets, which can further lay a foundation for clustering fault diagnosis based on vibration signals.

1. Introduction

Bearing is one of the most common connecting parts in rotating machinery, which is more likely to break down because of wear, fatigue, corrosion, or overload. Therefore, diagnosis timely and accurately of bearing conditions is of great significance to ensure the mechanical operation steady and reliable. Much study in recent years has focused on bearing fault diagnosis based on vibration signals, including signal acquisition and noise reduction, feature extraction and selection, and fault recognition. However, in industry, diagnostic data is often derived from monitoring signals, bringing great difficulties to record the machinery conditions by frequent downtime checking or manual labeling, which is time-consuming and laborious and resulting in insufficient labeled data for fault diagnosis [1]. Moreover, the number of obtained fault samples is always far less than that

of normal samples from monitoring signals, generating the diagnostic problem of imbalanced data.

Clustering analysis is especially suitable for fault recognition when there is no sufficient labeled data. Because of the nonlinear and unstable characteristics of bearing vibration signals, scholars preserve in their attempts to construct clustering diagnosis models with stronger identification ability. For example, after processing the data by ensemble empirical mode decomposition (EEMD) and linear discriminant analysis (LDA), Hou et al. [2] used Gath-Geva clustering algorithm (GG) to identify the faults of rolling bearing and got a satisfactory clustering result with better intraclass compactness. Chang et al.[3] achieved 96% accuracy of permanent magnet synchronous motors demagnetization fault diagnosis by auto-encoder and K-means algorithm. In addition, Li et al. [4] integrated K-means in the neural network architecture for unsupervised learning and

proposed a deep representation clustering-based diagnosis model to address the data sparsity issue in data-driven machinery fault diagnosis. Also, K-means was utilized together with K-nearest neighbor algorithm (KNN) to identify a transformer's fault category by cumulative votes [5]. On the other hand, for the algorithms which are unnecessary to set the number of fault categories before clustering, the study of Li et al. [6] describes a method to generate clustering template of rolling bearing so as to reduce the effect of noise on diagnostic accuracy using density-based spatial clustering of applications with noise (DBSCAN). This algorithm was also widely used in wind turbine condition monitoring [7] and diagnosis [8], photovoltaic power station fault detection [9], bolts with mission pins on transmission lines detection [10], and thermal runaway diagnosis of battery systems [11]. Moreover, Wei et al.[12] adopted affinity propagation clustering algorithm (AP) and a novel adaptive feature selection technique to identify different fault categories and severities of bearings successfully, and another bearing fault diagnosis model based on expectation maximization algorithm (EM) and wavelet packet was proposed by Zhang et al. [13] for coal cutter. Other clustering algorithms, including spectral clustering [14], fuzzy C-means (FCM) [15], clustering by fast search and find of density peaks algorithm (CFSFDP) [16], and extension neural network-type 2 (ENN-2) algorithm [17–19] were also applied to diagnosis. In conclusion, the clustering algorithms represented by K-means need to know the number of fault categories before clustering, which is contrary to the fact that clustering analysis does not require prior knowledge; however, the clustering algorithms represented by DBSCAN do not need to know the number of fault categories, but suffer a complex parameter adjustment process during training. Therefore, there remains a need for an efficient clustering method with less prior knowledge, simple parameter tuning process, and stable performance.

At the same time, considering the vibration signals used for fault diagnosis not only contain the running state signals of bearings but also contain a lot of aliasing signals with noises, signal denoising methods have generated considerable recent research interest. The commonly used denoising methods mainly include wavelet threshold denoising method, empirical mode decomposition (EMD), ensemble empirical mode decomposition (EEMD), and local mean decomposition (LMD). For example, Komaty et al. [20] introduced a signal-filtering method of EMD and a similarity measure. In their studies, white Gaussian and colored noises were almost removed from the signals by selecting the decomposed modes according to the similarity between the estimation of the probability density function (pdf) of the input signal and that of each mode, and combined EEMD with grey theory, Jia et al. [21] removed the noise of signals by evaluating noise levels of decomposed components of signals by grey relational analysis and selecting the noise-dominant components by grey model. Yang et al. [22] proposed an adaptive signal denoising method based on LMD. However, these decomposition methods have end-effect and modal aliasing phenomena and are more sensitive to sampling frequency, resulting in pretty large decomposition error. To overcome the defects above, Dragomiretskiy and Zosso [23] in 2014 have proposed variational mode decomposition (VMD), which is a new time-frequency analysis method with adaptive signal. Based on VMD, some research combined this method with other algorithms for signal denoising, such as singular value decomposition (SVD) [24], data-driven time-frequency analysis (DDTFA) [25], and wavelet threshold noise reduction [26], and there were also many studies that selected the decomposed modes in some evaluation methods and reconstructed the signal after VMD for noise reduction, such as kurtosis criterion [27], Bhattacharyya distance [28], and a novel parameter called signal clarity proposed by Li et al. [29]. In addition, Wang et al. [30] used VMD innovatively to eliminate outliers and noise points in features extracted from signals so as to achieve the purpose of signal-filtering and denoising.

However, few researchers have addressed the problem of bearing clustering fault diagnosis on imbalanced data with noise at the same time. Thus, in this paper, close attention is paid to develop an effective clustering algorithm on imbalanced data and construct a bearing fault diagnosis model dealing with the insufficient data contained noise. In our study, an improved clustering algorithm of ENN-2, called linked extension neural network (LENN), is proposed firstly, and based on this algorithm and VMD-based denoising method, a novel bearing fault diagnosis model is presented and applied to analyze the fault conditions and severities of bearings. To validate the effectiveness of the proposed algorithm and the model, three comparative experiments are designed and conducted on commonly used artificial clustering datasets and real bearing fault signals. The results manifest that the proposed model yields higher identification accuracy of minority fault clusters on imbalanced data with noise comparing with the models based on ENN-2, K-means, fuzzy C-means (FCM), and DBSCAN. Our study provides a promising method for machinery fault diagnosis based on insufficient labeled signals with imbalance, permitting an easier parameter adjustment process with less prior knowledge.

The rest of this paper starts with the novel LENN algorithm in Section 2. Section 3 provides a brief description of the proposed model, and the proposed algorithm and model are experimentally verified in Section 4. In Section 5, the concluding remarks are drawn.

2. Linked Extension Neural Network

Extension neural network-type 2 algorithm (ENN-2) is a new clustering algorithm based on extension theory [31]. With no need to set the number of clusters manually in advance, ENN-2 shows good clustering ability and fast convergence speed in simple construction. But in fact, the performance of ENN-2 relies heavily on the initial points and correct input order of the samples. To overcome these deficiencies, we develop a novel clustering algorithm called linked extension neural network (LENN).

2.1. Network Structure. Following the form of ENN-2, the structure of LENN contains only two layers, which is shown in Figure 1. The number of input layer nodes depends on the feature dimension of data, and the number of output layer
FIGURE 1: Structure of linked extension neural network (LENN).

FIGURE 2: Image of correlation function ED in ENN-2.

nodes is determined by the number of clusters. Between the two layers, the upper and lower bounds of the clusters connect the neurons as the connection weights, and output neurons are successively constructed in the process of iteration (represented by color shades in Figure 1), with only one node activated at a time to indicate the clustering result.

2.2. Improved Correlation Function

2.2.1. Correlation Function in ENN-2.
In ENN-2, the correlation function ED based on the extension distance is used to measure the distance between a sample and a target cluster. The extension distance in extension theory describes the distance between a point x and an interval $V = \langle a, b \rangle$ quantitatively, which is defined as

$$\rho(x, V) = \left| x - \frac{a+b}{2} \right| - \frac{a-b}{2}, \tag{1}$$

where a and b are the lower and the upper bounds of V, respectively.

Given the center of the kth cluster is $Z_k = [z_{k1}, z_{k2}, \cdots, z_{kn}]$, the boundary of the kth cluster can be represented by introducing a hyperparameter to measure the distance between the center and the ideal boundary as

$$\begin{aligned} W_k &= [\langle a_{k1}, b_{k1} \rangle, \langle a_{k2}, b_{k2} \rangle, \ldots, \langle a_{kn}, b_{kn} \rangle] \\ &= [\langle z_{k1} - \lambda, z_{k1} + \lambda \rangle, \langle z_{k2} - \lambda, z_{k2} + \lambda \rangle, \ldots, \langle z_{kn} - \lambda, z_{kn} + \lambda \rangle], \end{aligned} \tag{2}$$

Also, based on the definition of extension distance, the correlation function ED between a sample $X = [x_1, x_2, \cdots, x_n]$ and the boundary W_k of the kth cluster is defined as

$$ED_k = \sum_{j=1}^{n} \left[\frac{|x_{ij} - z_{kj}| - (b_{kj} - a_{kj})/2}{|b_{kj} - a_{kj}|/2} \right], \quad k = 1, 2, \ldots, K. \tag{3}$$

As shown in Figure 2, ED measures the extension relationship between a feature and its boundary. From

Figure 2, it can be seen that, for the jth dimension of the kth cluster, when $x_j \in \langle a_{kj}, b_{kj} \rangle$, $ED_{kj} \le 1$.

For a sample $X = [x_1, x_2, \cdots, x_n]$ with n-dimensional features, the sample X could be classified into the kth cluster if

$$ED_k \le n, \quad k = 1, 2, \ldots, K. \tag{4}$$

Thanks to this property of ED, the algorithm can estimate a sample belongs to which cluster and update the boundary and the center of the corresponding cluster to revise its information for iteration. Therefore, ENN-2 does not require the number of clusters K before learning and can obtain better clustering results by only adjusting the unique hyperparameter λ.

However, since the input order of samples determines the updating direction of clusters' boundaries and centers in the iteration process, ENN-2 is greatly affected by the initial point selection and the input order of samples and shows unstable clustering performances. Therefore, it is necessary to improve this algorithm.

2.2.2. Improved Correlation Function in LENN.
Different from ENN-2, each sample could be considered as a center during iteration in LENN. Take $X = [x_{11}, x_{12}, \cdots, x_{1n}]$ for example, its boundary W_{X1} can be represented as (4) with the hyperparameter λ:

$$\begin{aligned} W_{X_1} &= \left[\langle a_{x_11}, b_{x_11} \rangle, \langle a_{x_12}, b_{x_12} \rangle, \ldots, \langle a_{x_1n}, b_{x_1n} \rangle \right] \\ &= \left[\langle x_1 - \lambda, x_1 + \lambda \rangle, \langle x_2 - \lambda, x_2 + \lambda \rangle, \ldots, \langle x_n - \lambda, x_n + \lambda \rangle \right]. \end{aligned} \tag{5}$$

In order to measure the correlation distance between the sample $X = [x_{21}, x_{22}, \ldots, x_{2n}]$ and W_{X1}, the new correlation function is defined as

$$\begin{aligned} ED_{X_1, X_2} &= \sum_{j=1}^{n} \left[\frac{|x_{2j} - x_{1j}| - (b_{x_1j} - a_{x_1j})/2}{(b_{x_1j} - a_{x_1j})/2} + 1 \right] \\ &= \sum_{j=1}^{n} \left[\frac{\left| \|x_{2j} - x_{1j}\| \right|}{\lambda} \right]. \end{aligned} \tag{6}$$

The new correlation function is plotted in Figure 3. For the jth feature of the two samples, when $X_{2j} \in \langle a_{X_1j}, b_{X_1j} \rangle$, $ED_{X_1j, X_2j} \le 1$, and taking all features into account, the sample X_2 could be considered to belong to the same cluster as sample X_1 if
FIGURE 3: Image of new correlation function ED in LENN.

$$ED_{X_1, X_2} \leq n. \tag{7}$$

2.3. Learning Algorithm of LENN.

The learning process of LENN is an unsupervised learning. It takes a dataset $X = [x_1, x_2, \cdots, x_m]$ with samples as the input, and after calculating the correlation distances between samples level by level, the clustering results of the dataset are finally output in just one epoch. The specific learning steps are as follows:

(1) Set an optimal hyperparameter λ in $(0 \sqrt{\max(x_{ij})}]$.

(2) Input a sample $X_i = [x_{i1}, x_{i2}, \cdots, x_{im}]$ randomly and mark the cluster which belongs to as $k = 0$. Calculate the improved correlation function ED between X_i and all the other unmarked samples according to equation (5) and mark the samples which meet the requirements of $ED \leq n$ as $k = 0$. (3) For all the qualified samples in step (2), each sample is taken as the center to traverse, and EDs between this sample and all the remaining unmarked samples are calculated. Similarly, the samples that meet the condition of $ED \leq n$ are also marked as $k = 0$ until no qualified samples left. (4) A sample is randomly generated from the remaining unmarked samples for input to create a new cluster $k = k + 1$. Repeat steps (2) and (3).

(5) The learning process is finished until all samples are marked.

At the end of the iteration, if a cluster contains too few samples, it can be regarded as noise.

The iterative approaches of ENN-2 and LENN are both graphically presented in Figure 4. During the iteration, ENN-2 needs to update the central coordinates each time (represented by the orange dots), and the updating direction is significantly affected by the input order of the samples. Ideally, the input order of the samples should be sorted according to the distance between samples from small to large, which is pretty difficult to ensure for the unpretreated messy datasets. As can be seen from Figure 4(a) clearly, sample 6 is closer to the center

corresponding to sample 4 than sample 5. If sample 6 is input for calculation first according to (3), the result meets the requirement of (4), indicating sample 6 and samples 1~4 belong to the same cluster, and then the final clustering results of the whole dataset contain 2 clusters. But, if input sample 5 first for calculation, the result of (3) does not satisfy (4) because of the distant relationship of sample 5 and the current center, and then a new cluster is created for iteration, resulting in the final results of 3 clusters. However, in Figure 4(b) of LENN, one specific sample is regarded as the center each time, and all the qualified samples which satisfy (7) with the sample are found and marked in this iteration. Taking two-dimensional eigenspace as an example, the learning essence of LENN is to find the samples consecutively which fall in the square constructed by the initial center sample with 2λ as the side length. All the qualified samples are classified into the same cluster with their center. And then, the next iteration begins with a subsample of the cluster. Finally, all qualified samples of the same cluster are found by this iterative linkage method. Therefore, in Figure 5, samples 1, 4, 6, 5, and 10 are successively taken as the centers for iteration, and the final clustering result contains only 2 clusters with samples 1~9 belonging to the same cluster.

According to the learning process of the algorithm, LENN has the following remarkable advantages:

(1) Based on extension distance, LENN defines a new approach to categorization by distance calculation.

(2) There is no need to preset the number of clusters as in ENN-2; in addition, it is not necessary to initialize clustering center.

(3) The improved algorithm only needs one epoch to complete the clustering process and converges faster.

(4) LENN is not sensitive to the initial center and the input order of the samples and preserves more stable clustering ability than ENN-2.

Nevertheless, LENN is very sensitive to the hyperparameter λ, so it is necessary to select the optimal λ before learning.

2.4. Parameter Selection Method.

In LENN, the selection of the hyperparameter λ seriously affects the final number of clusters and the accuracy of clustering results. As shown in Figure 5, for a smaller λ (such as $\lambda = 7.2$ in Figure 5(a)), the constructed squares will be smaller with fewer qualified samples contained, resulting in more clusters in the end, and for a bigger λ (such as $\lambda = 8.7$ in Figure 5(b)), the constructed squares will be likewise bigger with more qualified samples contained, and fewer clusters are produced finally.

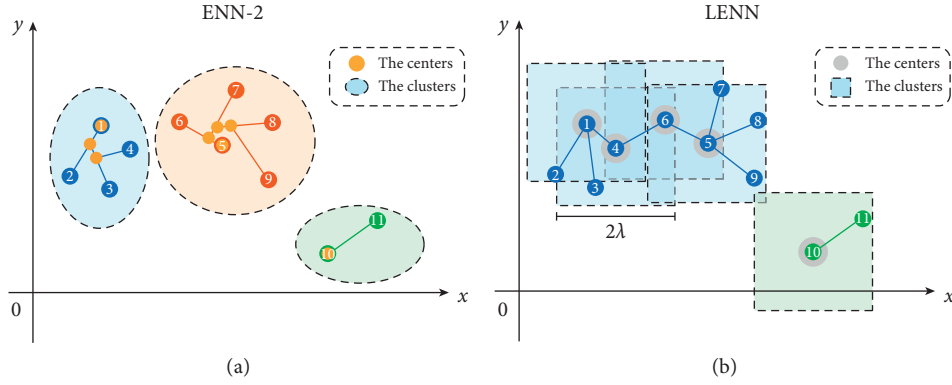
For clustering algorithms, silhouette coefficient is often used for evaluation with no real labels. However, this index is more suitable to analyze the clustering effectiveness of balanced data [32]. Considering this paper is primarily concerned with imbalanced data clustering problem, a novel evaluation index extension density EDe is developed to tune the hyperparameter λ based on extension distance, which is defined as


FIGURE 4: Iterative approaches: (a) ENN-2 and (b) LENN.
FIGURE 5: The influence of hyperparameter λ on LENN clustering process: (a) a smaller λ and (b) a bigger λ.

$$E\,De = \sum_{k=1}^{C} \frac{\sum_{x_i \in M_k, j=1}^{n} |x_{ij} - z_{kj}| - b_{kj} - a_{kj}/2}{m_k}, \qquad (8)$$

where m_k is the number of samples in the kth cluster, Z_{kj} is the center of the jth feature, and a_{kj} and b_{kj} represent the lower and upper bounds of the kth cluster respectively, a_{kj}, b_{kj} and can be computed by

$$a_{kj} = \min_{x_i \in M_k}(x_j),$$

$$b_{kj} = \min_{x_i \in M_k}(x_j), \qquad (9)$$

$$z_{kj} = \frac{b_{kj} - a_{kj}}{2}.$$

Typically, EDe declines with the increasing λ, and the optimal λ lies in the turning point of the curve.

3. Proposed Bearing Fault Diagnosis Model

3.1. Signal Denoising. Bearing vibration signals tend to present nonlinear and nonstationary characteristics with noise inevitably. Without signal denoising, the outliers in raw data will be transferred into the feature space through feature extraction and affecting the diagnostic results of the model. Compared with empirical mode decomposition (EMD) and ensemble empirical mode decomposition

(EEMD), variational mode decomposition (VMD) can effectively extract each frequency component of the signal and solve the problems of mode mixing and white noise. Therefore, VMD-based method is used for noise reduction in this paper.

3.1.1. The Principle of VMD. VMD is a variational problem solving process based on classical Wiener filter, Hilbert transform, and mixing, which can be written as the following constrained optimization form:

$$\min_{\{u_k\},\{\omega_k\}} \left\{ \sum_k \left\| \partial_t \left[\left(\delta(t) + \frac{j}{\pi t} \right) * u_k(t) \right] e^{-j\omega_k t} \right\|_2^2 \right\}$$

$$\text{s.t.} \sum_{k=1}^{K} u_k = f, \qquad (10)$$

where K is the number of modes to be decomposed, $\delta(t)$ represents Dirac function, *means the convolution operator, and $\{u_k\}$ and $\{\omega_k\}$ stand for the kth intrinsic mode function (IMF) and center frequency after decomposition.

The solution process of this problem is as follows:

(1) Transform the constrained variational problem to a nonconstrained variational problem by introducing the quadratic penalty factor α and Lagrange multiplier $\lambda(t)$:

$$L(\{u_k\},\{\omega_k\},\lambda) = \alpha \sum_k \left\| \partial_t \left[\left(\partial(t) + \frac{j}{\pi t} \right) * u_k(t) \right] \right\|_2^2 + \left\| f(t) - \sum_k u_k(t) \right\|_2^2 + \left\langle \lambda(t), f(t) - \sum_k u_k(t) \right\rangle. \tag{11}$$

(2) Solving the minimization problem of equation (12), alternating direction method of multipliers (ADMM) is adopted to seek the saddle point of the

augmented Lagrange expression by alternatively updating u_k^{n+1}, ω_k^{n+1}, and λ^{n+1}, and u_k^{n+1} can be obtained by

$$u_k^{n+1} = \underset{u_k \in X}{\arg\min} \left\{ \alpha \left\| \partial_t \left[\left(\delta(t) + \frac{j}{\pi t} \right) * u_k(t) \right] e^{-j\omega_k t} \right\|_2^2 + \left\| f(t) - \sum_i u_i(t) + \frac{\lambda(t)}{2} \right\|_2^2 \right\}, \tag{12}$$

where ω_k equals to ω_k^{n+1}, and $\sum_i u_i(t)$ equals to $\sum_{i\neq k} u_i(t)^{n+1}$.

Next, transform to frequency domain by Parseval/Plancherel Fourier isometric transform:

$$\hat{u}_k^{n+1} = \underset{\hat{u}_k, u_k \in X}{\arg\min} \left\{ \alpha \left\| j\omega \left[(1 + \operatorname{sgn}(\omega + \omega_k)) \hat{u}_k(\omega + \omega_k) \right] \right\|_2^2 + \left\| \hat{f}(\omega) - \sum_i \hat{u}_i(\omega) + \frac{\hat{\lambda}(\omega)}{2} \right\|_2^2 \right\}. \tag{13}$$

Replace ω in (13) with $\omega - \omega_k$ and then we can get

$$\hat{u}_k^{n+1} = \underset{\hat{u}_k, u_k \in X}{\arg\min} \left\{ \alpha \left\| j(\omega - \omega_k) \left[(1 + \operatorname{sgn}(\omega + \omega_k)) \hat{u}_k(\omega) \right] \right\|_2^2 + \left\| \hat{f}(\omega) - \sum_i \hat{u}_i(\omega) + \frac{\hat{\lambda}(\omega)}{2} \right\|_2^2 \right\}. \tag{14}$$

(14) is then converted to the form of nonnegative frequency interval integral:

$$\hat{u}_k^{n+1} = \arg\min \left\{ \int_0^\infty 4\alpha(\omega - \omega_k)^2 \left| \hat{u}_k(\omega) \right|^2 + 2 \left| \hat{f}(\omega) - \sum_i \hat{u}_i(\omega) + \frac{\hat{\lambda}(\omega)}{2} \right|^2 d\omega \right\}, \tag{15}$$

and set the first item in (15) to zero to obtain the quadratic optimization problem:

$$\hat{u}_k^{n+1}(\omega) = \frac{\hat{f}(\omega) - \sum_{i\neq k}\hat{u}_i(\omega) + \hat{\lambda}(\omega)/2}{1 + 2\alpha(\omega - \omega_k)^2}. \tag{16}$$

Similarly, the minimization problem of the center frequency can be obtained by converting the center frequency updating problem to frequency domain:

$$\omega_k^{n+1} = \frac{\int_0^\infty \omega \left| \hat{u}_k^{n+1}(\omega) \right|^2 d\omega}{\int_0^\infty \left| \hat{u}_k^{n+1}(\omega) \right|^2 d\omega}, \tag{17}$$

where $\hat{u}_k^{n+1}(\omega)$ is the Wiener filtering of $\hat{f}(\omega) - \sum_{i\neq k}\hat{u}_i(\omega)$, and ω_k^{n+1} represents the center of power spectrum.

Also, the learning process of VMD is as follows:

(1) Initialize $\left\{ \hat{u}_k^1 \right\}$, $\{\omega_k^1\}$, $\left\{ \hat{\lambda}^1 \right\}$ and n.

(2) Update u_k and $\overset{k}{\omega}$ according to equations (16) and (17).

(3) Update λ by

$$\hat{\lambda}^{n+1}(\omega) \leftarrow \hat{\lambda}^n(\omega) + \tau \left[\hat{f}(\omega) - \sum_k \hat{u}^{n+1}(\omega) \right]. \tag{18}$$

(4) For a given discriminant accuracy of $\varepsilon > 0$, if $\sum_k \|\hat{u}_k^{n+1}\| \sum_k \|\hat{u}_k^{n+1} - \hat{u}_k^n\|_2^2 / \|\hat{u}_k^n\|_2^2 < \varepsilon$, stop iteration, otherwise return to step (2).

3.1.2. VMD-Based Denoising Method. The VMD-based denoising method comprises two steps: (a) decompose the

vibration signal by VMD. (b) Calculate correlation coefficients of IMFs obtained by VMD for noise filtering and reconstruct the denoised signal. The parameters α, $\lambda(t)$, and K of VMD should be set before decomposition, which may affect the results noticeably.

Correlation coefficient is to describe the correlation degree between the original signal Y and its IMFs $X(i)$, which is defined as

$$\rho_i = \frac{COV(X(i), Y)}{\sqrt{D(X(i))}\sqrt{D(Y)}}. \tag{19}$$

The correlation coefficient also offers a means of measuring the degree of noise contained in IMFs. Thus, by selecting the sensitive IMFs according to (20) below [33], we are able to obtain the reconstructed denoised signal:

$$\mu_i = \frac{\max(\rho_i)}{10^* \max(\rho_i) - 3}, \tag{20}$$

where μ_i is the threshold of the ith IMF. Retain the IMFs of $\rho_i < \mu_i$ as sensitive IMFs for signal reconstruction, and remove the unqualified IMFs directly.

3.2. Feature Extraction and Selection

3.2.1. Bearing Fault Features. In feature extraction, to reflect the operation conditions of bearings accurately, objectively, and simply, statistical features are extracted from the denoised signals in this study, including 11 time domain statistical features $F_1 \sim F_{11}$ and 12 frequency domain statistical features $F_{12} \sim F_{23}$ shown in Table 1 [34]. For time domain statistical features extracted from raw signals, F_1 and $F_3 \sim F_5$ reflect the amplitude and energy of vibration in time domain; F_1 and $F_6 \sim F_{11}$ present the distribution of the signal in time series. For frequency domain statistical features extracted from FFT spectrums, F_{12} shows the vibration energy in frequency domain; $F_{13} \sim F_{15}$, F_{17}, and $F_{21} \sim F_{23}$ stand for the dispersion and concentration degree of the spectrum; F_{16} and $F_{18} \sim F_{20}$ represent the position variation of the main frequency band.

Here, $x(n)$ is a signal series in time domain, $n = 1, 2, \ldots, N$; N is the number of data points. $s(k)$ is a frequency spectrum of signal $x(n)$, $k = 1, 2, \ldots, K$, K is the number of spectrum lines, and f_k is the frequency value of the kth spectrum line.

3.2.2. Feature Selection Based on PCA. Although the multidomain features obtained above better describe the signals than using time domain or frequency domain features only, there may be feature redundancy, which will affect the diagnostic performance of the model. Considering the lack of labels of samples in clustering fault diagnosis, a commonly used unsupervised feature reduction algorithms principal component analysis (PCA) is adopted in the diagnosis model. The specific steps of PCA are as follows:

Let the multidomain characteristic matrix obtained above be $X_{n \times m} = [X_1, X_2, \cdots, X_m]$, where the number of

Table 1: Statistical features of time domain and frequency domain.

No.	Equation
Time domain features	
F_1	$\sum_1^N x(n)/N$
F_2	$\sqrt{\sum_1^N (x(n) - F_1)/N - 1}$
F_3	$(\sum_1^N \sqrt{|x(n)|}/N)^2$
F_4	$\sqrt{\sum_1^N (x(n))^2/N}$
F_5	$\max|x(n)|$
F_6	$\sum_1^N (x(n) - F_1)^3/(N-1)F_2^3$
F_7	$\sum_1^N (x(n) - F_1)^4/(N-1)F_2^4$
F_8	F_5/F_4
F_9	F_5/F_3
F_{10}	$F_4/1/N \sum_1^N |x(n)|$
F_{11}	$F_5/1/N \sum_1^N |x(n)|$
Frequency domain features	
F_{12}	$\sum_1^K s(k)/K$
F_{13}	$\sum_1^K (s(k) - F_{12})^2/K - 1$
F_{14}	$\sum_1^K (s(k) - F_{12})^4/KF_{13}^2$
F_{15}	$\sum_1^K (s(k) - F_{12})^3/K(\sqrt{F_{13}})^3$
F_{16}	$\sum_1^K f_k s(k)/\sum_1^K s(k)$
F_{17}	$\sqrt{\sum_1^K (f_k - F_{16})^2 s(k)/K}$
F_{18}	$\sqrt{\sum_1^K f_k^2 s(k)/\sum_1^K s(k)}$
F_{19}	$\sqrt{\sum_1^K f_k^4 s(k)/\sum_1^K f_k^2 s(k)}$
F_{20}	$\sum_1^K f_k^2 s(k)/\sqrt{\sum_1^K s(k)\sum_1^K f_k^4 s(k)}$
F_{21}	F_{17}/F_{16}
F_{22}	$\sum_1^K (f_k - F_{16})^3 s(k)/KF_{17}^3$
F_{23}	$\sum_1^K (f_k - F_{16})^4 s(k)/KF_{17}^4$

samples is m, and the dimension of features is n, then its covariance matrix C can be obtained by

$$C = \frac{1}{m}(X - \overline{X})(X - \overline{X})^T, \tag{21}$$

where $\overline{X}$ is a $n \times m$ matrix composed of row vectors of X, $\overline{X}_i = 1/m \sum_{j=1}^m x_{ij}, i = 1, 2, \cdots n$.

After that, the eigenvalues and the eigenvectors of the covariance matrix C are calculated by

$$|C - \lambda I_n| = 0, \tag{22}$$

where $\lambda_1, \lambda_2, \cdots, \lambda_n$ are the eigenvalues of C, and $P_1, P_2, \cdots, P_n$ are the corresponding eigenvectors of the eigenvalues.

Arrange the eigenvectors according to the magnitude of the corresponding eigenvalues, take the front k rows of eigenvectors to form the matrix P, and obtain the k-dimensional data Y by

$$Y = PX. \tag{23}$$

3.3. Bearing Fault Diagnosis Model of VMD-Based Denoising and LENN. Based on the above techniques, a bearing fault diagnosis model of VMD-based denoising and LENN is proposed in this paper, including three stages: (a) signal

denoising based on VMD and correlation coefficient calculation of IMFs; (b) feature extraction and selection by PCA; (c) clustering fault diagnosis on LENN. The specific diagnostic steps are as follows, which are shown in Figure 6.

(1) After signal acquisition, divide the raw signals into some segments of 2048 data points.

(2) For the sake of noise reduction, decompose each signal and calculate correlation coefficients and thresholds of IMFs according to equations (19)~(20). Reconstruct the signals by retaining the sensitive IMFs and removing the IMFs of $\rho_i \geq \mu_i$.

(3) Based on the denoised signals, 11 time domain statistical features are extracted from the signals and 12 frequency domain statistical features are extracted from their FFT spectrums according to Table 1.

(4) In order to avoid the influence of redundant features on the diagnosis results and improve the diagnostic speed of the model, PCA algorithm is used to obtain low-dimensional fault features for diagnosis.

(5) Finally, the proposed LENN algorithm will identify bearing fault conditions by clustering the obtained low-dimensional feature matrix into different clusters and achieve fault diagnosis.

4. Experimental Verification

4.1. Experiment of LENN Algorithm on Artificial Datasets. In order to verify the clustering effectiveness and stability of the proposed LENN algorithm on imbalanced data, LENN, ENN-2, and three commonly used clustering algorithms, namely, K-means, fuzzy C-means (FCM), and DBSCAN were experimented on three artificial datasets commonly used for clustering testing, which were Flame, Jain and Aggregation. These three datasets are all in two dimensions with different degrees of imbalance, which are summarized in Table 2. From Figure 7 of the real distributions of the datasets, it can be seen that Flame consists of a circle and a semiring, Jain contains two semirings, and Aggregation is composed of many rounded or crescent clusters with two clusters connected, which increase the difficulty of clustering.

Adopt Rand Index to evaluate the clustering results of the algorithms here, which is defined as

$$\mathrm{RI} = \frac{a+b}{a+b+h+g},\tag{24}$$

where a denotes the number of data pairs (x_i, x_j) whose clustering results and real labels are in the same category; b represents the number of data pairs (x_i, x_j) whose clustering results and real labels fall in the different categories; h denotes the number of data pairs (x_i, x_j) whose clustering results are of the same category while real labels are of different categories; and g represents the number of data pairs (x_i, x_j) whose clustering results turn to be of different categories while real labels turn to be of the same category.

In the experimental process of LENN, the optimal value range of λ was narrowed in each round of the experiment based on $(0, \sqrt{\max(x_{ij})}]$ to obtain the optimal λ, and the optimal λ

selection processes of LENN on three datasets are shown in Figure 8. As can be seen from the figure, RI reaches a peak at the inflection point of the EDe drop-down curve, and the corresponding value of λ is just the desired λ, and for ENN-2, the optimal λ was determined in the same way based on (0, 1]. The parameter K of K-means was set according to the real number of categories of each experimental dataset, and the parameter setting of FCM was the same as above. In the training process of DBSCAN, the optimal combination of the radius parameter ε and the field density threshold MinPts was searched for several times with the initial range of ε set as (0, 2] and the initial range of MinPts set as [2, 10]. In order to eliminate the influence of the sample input order on the experimental results, each experiment was conducted for ten times by disrupting the sample input order randomly to obtain RI score of the five algorithms, which are depicted in boxplots in Figure 9 and summarized in Table 3. Figure 10 presents the clustering performances of LENN graphically on three datasets.

In general, LENN achieved better performances in higher accuracy and stability on the three different datasets. Comparing Figure 9 and Table 3, it can be observed that, in terms of clustering accuracies, LENN and DBSCAN were not affected by the shape of data distribution, showing higher RI scores overall; while ENN-2, K-means, and FCM were highly affected by the shape of data distribution, all of them performed worse on semiorbicular clusters than rounded clusters, among which ENN-2 scored lowest on Flame and FCM scored lowest on Jain; in terms of clustering stability, which was visible in Figure 9, LENN showed extremely stable clustering performances on different input orders of samples, and there were small fluctuations in clustering stability of DBSCAN, K-means, and FCM, while ENN-2 showed the worst stability with the largest range of RI reaching 0.2436 on Flame. In particular, LENN scored highest on both Flame and Jain with nearly no impact of imbalanced data distribution on clustering, while scored slightly lower than that of DBSCAN on Aggregation. That was because, for Flame and Jain in Figure 10, all misclassified points of LENN, which were considered as noise, were individuals far away from their surrounding points; while for Aggregation, two clusters were closely connected distinctly by several data points, resulting in the algorithm which classified the two connected clusters as one cluster because of LENN's iterative distinguish mechanism; in spite of this, LENN could still fully identify the other minority clusters in Aggregation. As for ENN-2, only a small number of cases showed higher clustering accuracies on Aggregation, indicating that ENN-2 is better at processing rounded clusters, but still relies heavily on an appropriate sample input order. It could be concluded that the proposed LENN algorithm could deal with the clustering problem on imbalanced data in terms of higher accuracy and stability, addressing the limitations of dependency on input order of samples.

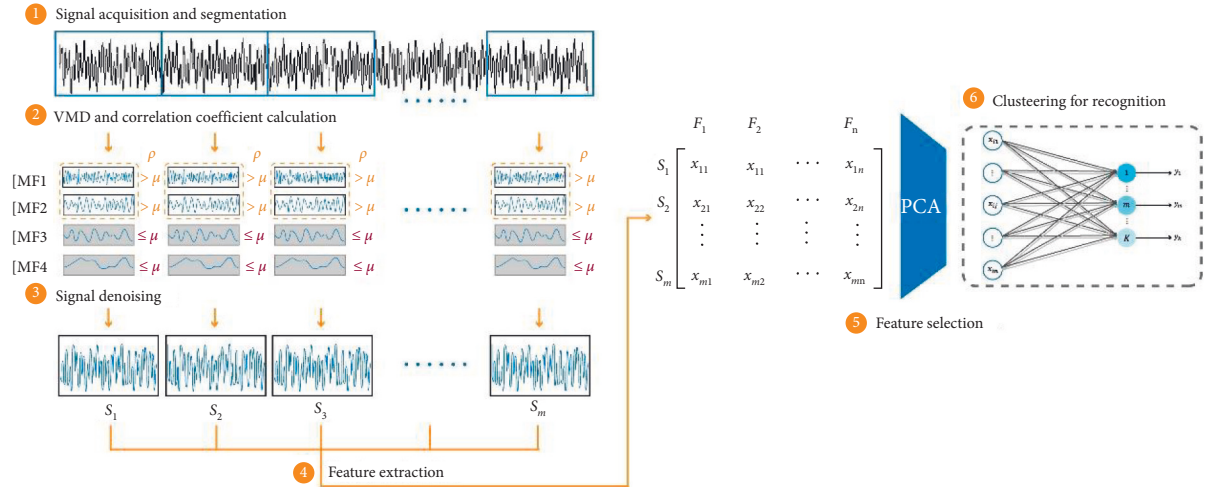
4.2. Bearing Fault Diagnosis Process of Proposed Model. The main purpose of this work was to establish an effective bearing fault diagnosis model on imbalance data with noise, so in this part, experiments were carried out based on


FIGURE 6: Flowchart of the proposed bearing fault diagnosis model.

TABLE 2: Description of the artificial datasets.

No.	Dataset	Degrees of imbalance	Feature dimensions	Number of categories	Number of samples
1	Flame	147 : 93	2	2	240
2	Jain	276 : 97	2	2	373
3	Aggregation	272 : 170 : 127 : 105 : 45 : 35 : 34	2	7	788

bearing fault data from Case Western Reserve University [35, 36] to test the performance of the proposed VMD-based denoising and LENN model by comparing with the ENN-2-based model.

4.2.1. Experimental Data. The test rig for data acquisition is shown in Figure 11, which consists of a motor driving a shaft, a force meter, a torque transducer, and an electrical control device. In this part, we selected the data of a 6205-2RS deep-groove ball bearing from SKF Company, which were grouped into five categories, including normal, minor inner race fault (with the fault size of 0.1778 mm), serious inner race fault (with the fault size of 0.5334 mm), minor ball fault (with the fault size of 0.1778 mm), and serious ball fault (with the fault size of 0.5334 mm). After dividing the raw

signals into segments of 2048 data points, five datasets above comprised the whole data of this experiment with the imbalance degree of 2 : 1:1 : 1:1, which are listed in Table 4.

4.2.2. Signal Denoising and Feature Extraction and Selection. Firstly, VMD was carried out on the segmented fault samples. Here, set $\alpha = 2000$, $\lambda(t) = 1.5$, and the initial distribution of center frequency was uniform. Considering improper selection of the number of decomposition K will lead to excessive or insufficient decomposition, therefore, K was determined according to the change of the center frequency of each mode in this paper. Taking VMD results of minor inner race fault (MIF) for example, as shown in Table 5, there were similar center frequencies appearing when $K = 5$, which may be attributed to mode mixing and

Table 3: RI scores of the five algorithms.

Algorithm	Target	Flame	Jain	Aggregation
LENN	Mean	0.9284	0.9971	0.8061
	Range	0	0	0
ENN-2	Mean	0.3547	0.4941	0.8033
	Range	0.2436	0.0998	0.1240
K-means	Mean	0.4311	0.3217	0.7663
	Range	0	0.0060	0.0024
FCM	Mean	0.4422	0.3004	0.7005
	Range	0	0	0.1276
DBSCAN	Mean	0.9028	0.9584	0.8934
	Range	0.0273	0	0.0003

excessive decomposition. Thus, K was set as four. Similarly, the number of decomposition K of other datasets was determined to be four, and the VMD results of a sample of five conditions are shown in Figure 12.

Then, the correlation coefficients and thresholds corresponding respectively to IMFs and the original signal were calculated according to equations (19)~(20). The obtained

results of all samples are graphically presented in Figure 13. Retain the corresponding IMFs whose correlation coefficient is above the red line and get the reconstructed signals.

Next, after signal denoising, extract the 23-dimensional features of each sample from both time and frequency domain according to Table 1, and PCA was used for feature selection and dimension reduction. By comparing the
Figure 10: Clustering performances of LENN on three datasets. (a) Flame. (b) Jain. (c) Aggregation.
Figure 11: CWRU bearing test rig35.

Table 4: Description of bearing fault data.

Fault type	Motor speed (rpm)	Motor load (hp)	Sample frequency (kHz)	Fault size (mm)	Number of samples
Normal (N)	1797	0	12	-	119
Minor inner race fault (MIF)	1797	0	12	0.1778	59
Serious inner race fault (SIF)	1797	0	12	0.5334	59
Minor ball fault (MBF)	1797	0	12	0.1778	59
Serious ball fault (SBF)	1797	0	12	0.5334	59

dimensionality reduction results in two and three dimensions in Figure 14, it is visible that, in two dimensions, the cluster of normal is far away from others, while the other four clusters are pretty closer; moreover, the clusters of the same parts with different severities are very close to each other, with connected and overlapped points appearing in the clusters of minor and serious inner race fault, which is not conducive to fault diagnosis. In three dimensions, all the clusters could be well separated, and for the clusters of the same parts with different severities, there seem to be no overlaps among the clusters. Therefore, the feature matrix of three dimensions was selected and finally input into the proposed LENN and ENN-2 algorithms.

4.2.3. Fault Diagnosis Results and Analysis. At the end, the obtained matrix was input into LENN and ENN-2 using RI in (24) for comparison. Similarly, for the sake of eliminating the influence of sample input order on experimental results, each diagnosis experiment was conducted for 10 times by randomly shuffling the input order of samples. Two of the diagnosis results of ENN-2 and LENN-based models are depicted in Figure 15, with the detailed results summarized in Table 6.

It is particularly evident from the results that overall, there was a marked increase in the performance of LENN-based model than that of ENN-2-based model in terms of clustering accuracy and stability. As can be seen from Figure 15, both of

TABLE 5: Center frequencies corresponding to different values of K of minor inner race fault.

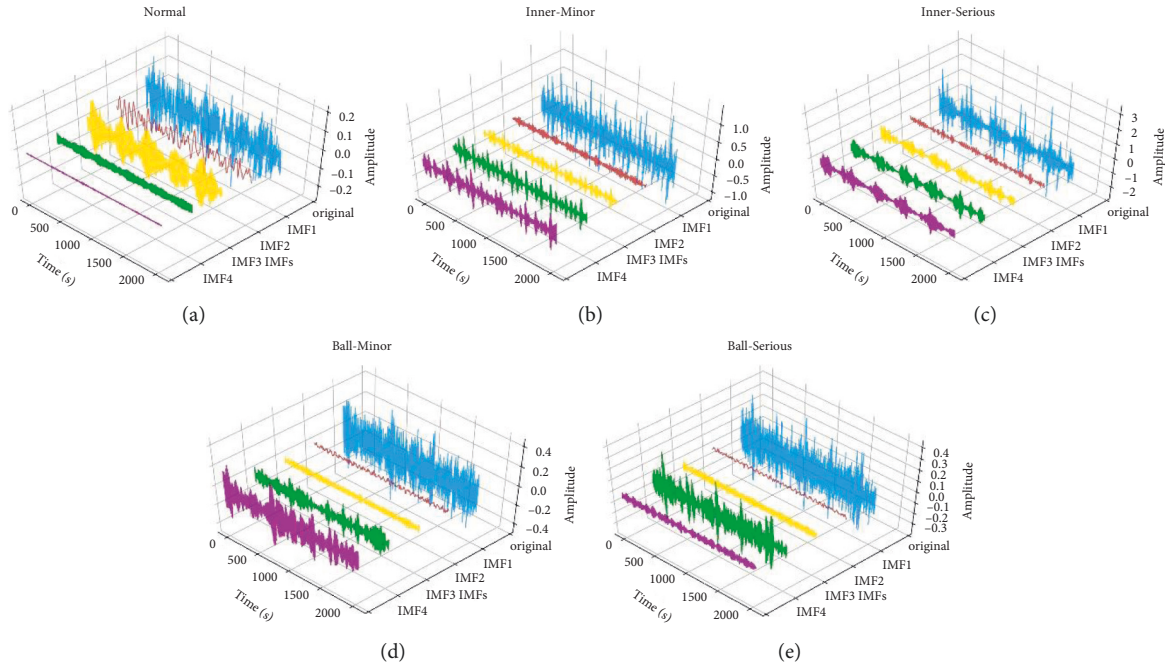
K	Center frequency (Hz)				
2	693	2776			
3	685	2740	3578		
4	615	1301	2745	3579	
5	615	1300	2729	3345	3616


FIGURE 12: VMD results of a sample of five conditions: (a) normal, (b) minor inner race fault, (c) serious inner race fault, (d) minor ball fault, and (e) serious ball fault.
FIGURE 13: Results of correlation coefficient and threshold calculation.

the two models performed well on the data of MIF, SIF, MBF, and SBF because of the compact data distribution and good differentiation, with only three SIF points misclassified into MIF in ENN-2-based model. However, for the cluster in normal condition, its distribution was relatively loose, resulting

in ENN-2-based model which could not identify the whole cluster correctly and generated multiple clusters and noise points in the results, while LENN-based model only marked very few points at the edge of the cluster as noise which were far from their near points, and from Table 6, it can be observed that
Figure 14: Dimensionality reduction results of bearing fault data: (a) in two dimensions and (b) in three dimensions.
Figure 15: Diagnosis results of the models: (a) ENN-2-based model and (b) LENN-based model.

Table 6: Detailed results of ENN-2- and LENN-based models.

Model	Average epochs	Average score	Max score	Min score	Range
ENN-2	2	0.5835	0.6833	0.4520	0.2313
LENN	1	0.9754	0.9754	0.9754	0

ENN-2-based model needed an average iteration of two epochs to converge, while LENN-based model converged in only one epoch, and a significant improvement of RI score was obtained in LENN-based model (0.9754) than ENN-2-based model (0.5835). In addition, the clustering results of ENN-2-based model changed greatly with different sample input orders, while the performances of LENN-based model were very stable. All the results strongly confirm the proposed model preserves higher clustering accuracy and more stable performances.

4.3. Impact of Imbalance Degree of Datasets on Diagnostic Models. As outlined in the introduction, the problem of imbalanced data fault diagnosis in real industrial production increases the difficulty of clustering fault diagnosis. Thus, the impact of different imbalance degrees of datasets on diagnostic models was investigated experimentally. The bearing

fault data used in Section 4.2 was still adopted in this experiment, and based on the signal denoising and feature extraction and selection method proposed in this paper, four diagnostic models commonly used in clustering diagnosis were constructed and compared on datasets in different imbalance degrees selected randomly by certain proportions (shown in Table 7), which were models on LENN, K-means, FCM, and DBSCAN. The specific parameter settings of the models were in line with the settings in Section 4.1. To evaluate the performances and measure the ability of the models to deal with the clustering problem on imbalanced data, RI, macro-recall, and macro-F score were adopted in this experiment, and by conducting each experiment randomly for 10 times, we were able to get the average scores of each model.

Macro-recall measures the clustering performance of each class, especially the minority classes, which can be computed by

$$\text{macro} - R = \frac{1}{n} \sum_{i=1}^{n} \text{Recall} = \frac{1}{n} \sum_{i=1}^{n} \frac{\text{TP}_i}{\text{TP}_i + \text{FN}_i}, \quad (25)$$

where TP_i and FN_i represent the number of correctly and incorrectly predicted samples of the ith class, respectively.

Macro-F score is a comprehensive evaluation of the precision and recall of clustering results, which is defined as

TABLE 7: Imbalance degrees of experimental data.

No.	The number of samples in each condition (N : MIF : SIF : MBF : SBF)	Imbalance degree
Dataset 1	100 : 50 : 50 : 50 : 50	2 : 1 : 1 : 1 : 1
Dataset 2	100 : 30 : 30 : 30 : 30	3 : 1 : 1 : 1 : 1

	Macro-F1	0.9487	0.4827	0.4827	0.9052
	RI	0.9250	0.4522	0.4376	0.6839
Dataset 3	Macro-R	0.9322	0.4950	0.4950	0.8130
	Macro-F1	0.9367	0.4827	0.4827	0.8486
	RI	0.8920	0.3822	0.2024	0.4329
Dataset 4	Macro-R	0.9100	0.4940	0.4860	0.7500
	Macro-F1	0.9357	0.4786	0.4500	0.8929

$$\text{macro} - F1 = \frac{\left(1 + \beta^2\right) \times \text{macro} - R \times \text{macro} - P}{\beta^2 \times (\text{macro} - R + \text{macro} - p)}, \quad (26)$$

where β denotes the relative importance of macro-R and macro-P, which is usually set as one, and macro-P can be obtained by

$$\text{macro} - P = \frac{1}{n} \sum_{i=1}^{n} \text{Precision} = \frac{1}{n} \sum_{i=1}^{n} \frac{\text{TP}_i}{\text{TP}_i + \text{FP}_i}, \quad (27)$$

where FP_i represents the number of samples which are misclassified into the ith class but do not belong to that class actually.

Table 8 collects the scores of the models on four datasets in different imbalance degrees. Two extreme cases with data imbalance degrees of $2 : 1 : 1 : 1 : 1$ and $10 : 1 : 1 : 1 : 1$ are taken to draw confusion matrices of the clustering results, which are shown in Figure 16.

It is apparent that, with the increase of data imbalance degrees, the clustering scores of all models showed a downward trend to varying imbalance degrees on the whole, among which LENN-based model performed noticeably best in all cases, while the configurations of K-means and FCM-based models were far from optimal. Comparing Table 8 and Figure 16, it can be observed that, the proposed model achieved considerably higher scores than other three models on all the datasets. Even on dataset 4 of the most extreme imbalance degree of $10 : 1 : 1 : 1 : 1$, LENN-based model also recognized four minority clusters precisely, with ten samples of minor inner race fault, nine samples of serious inner race fault, eight samples of minor

ball fault, and nine samples of serious ball fault identified correctly, DBSCAN-based model identified relatively few samples of these minor clusters; while K-means-based model regarded the samples of the same position but different severities as one cluster, failing to further subdivide the severities of samples, and FCM-based model directly identified all the four minority clusters as the same cluster, which scored lowest among the models. In addition, in the training process of LENN-based model on datasets with different imbalance degrees, the value of optimal λ grew gradually with the increase of data imbalance degree (shown in Figure 17). This was because, as the samples became more and more sparse, the distances between the samples increased, which required a larger λ to construct an extension correlation relationship between the samples, and this also indicated that the value of optimal λ was related to the final clustering results. In other words, the smaller of λ, the more precise the constructed extension relationship between samples would be, and the higher the accuracy of the proposed model could be obtained.

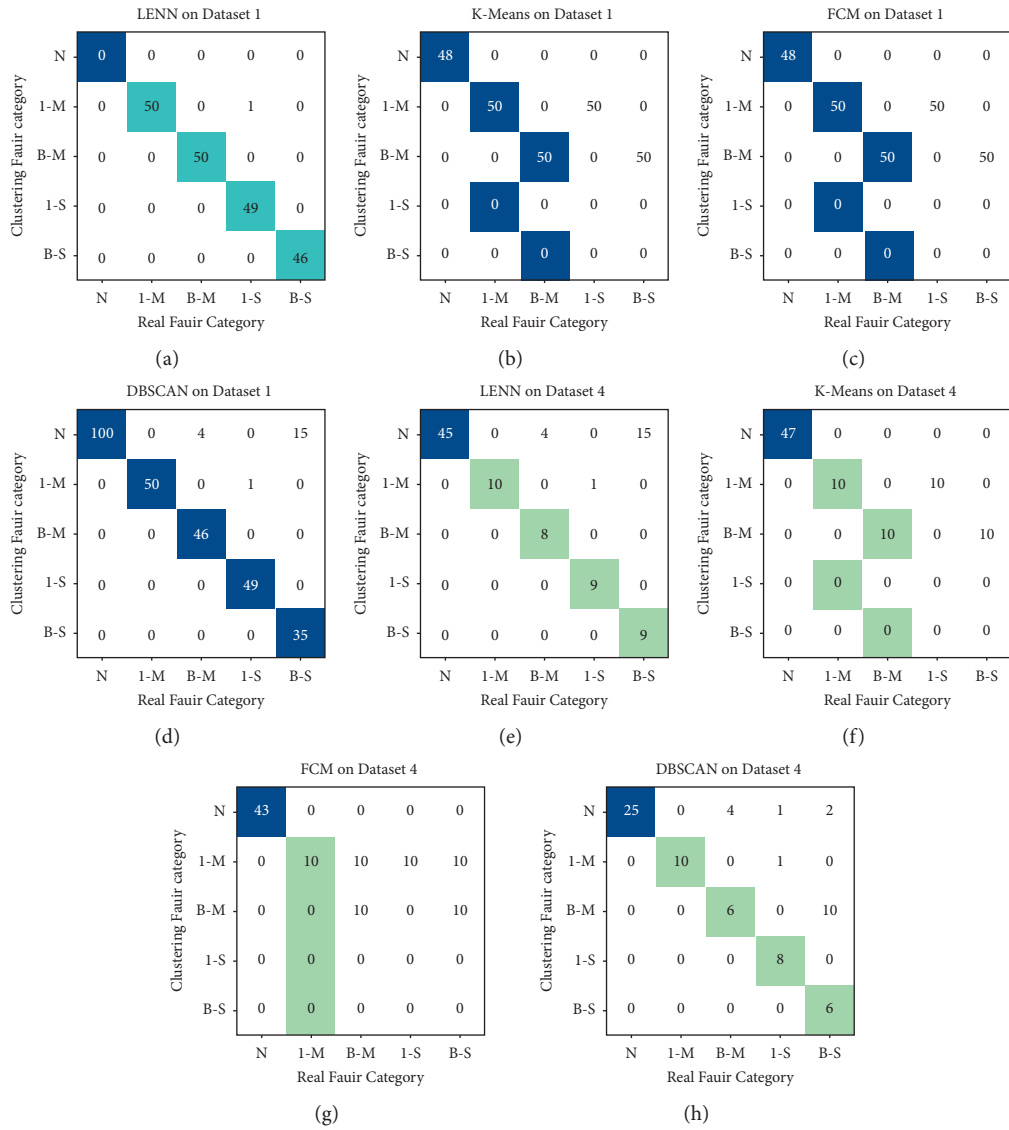
In conclusion, the imbalance degree of datasets increases the difficulty of fault diagnosis, especially for clustering algorithms relying on the selection of initial center points, and the appearances of minority clusters make it difficult for these algorithms to identify the fault categories correctly by distance calculation. At the same time, surprising outcomes of the experiments manifest that, by expressing the information of minority clusters more precisely through the constructed extension correlation function, the proposed LENN-based model shows good efficiency in identifying the minority clusters on imbalanced data.


Figure 16: Confusion matrices of the results on two imbalance degrees of the datasets (2 : 1 : 1 : 1 : 1 and 10 : 1 : 1 : 1 : 1): (a) LENN on Dataset 1, (b) K-means on Dataset 1, (c) FCM on Dataset 1, (d) DBSCAN on Dataset 1, (e) LENN on Dataset 4, (f) K-means on Dataset 4, (g) FCM on Dataset 4, and (h) DBSCAN on Dataset 4.
Figure 17: RI and optimal λ of LENN-based model on data with different imbalance degrees.

5. Conclusions

(1) A novel clustering algorithm called linked extension neural network (LENN) is developed based on extension neural network-type 2 (ENN-2), which is far less sensitive to initial point selection and sample input order by improved correlation function and new iterative method. Furthermore, to evaluate the clustering performance, extension density is proposed as an evaluation target for this algorithm.

(2) With the intention of improving the bearing fault diagnosis ability on imbalanced data with noise, a clustering fault diagnosis model of VMD-based denoising and LENN is constructed. The experimental results provide compelling evidence that the proposed model preserves powerful identification ability of minority fault clusters and achieves better diagnosis performance on imbalanced data with noise.

Knowledge sharing among teachers is one of the important ways to improve their teaching and research ability. From the perspectives of teachers' knowledge sharing willingness, knowledge sharing ability, knowledge sharing environment, knowledge sharing technology support, knowledge sharing effect, and so forth, this paper constructs a teacher knowledge sharing behavior evaluation model, develops a knowledge sharing behavior evaluation index system, and proposes a comprehensive teacher's knowledge sharing behavior evaluation method based on the improved entropy-TOPSIS method. This is a comprehensive evaluation method combining subjective and objective weights, which avoids the subjectivity of traditional expert evaluation methods and other multilevel and multi-index weight determination methods and makes the evaluation results more objective, accurate, and more realistic. Finally, by taking the example of evaluating knowledge sharing behavior of teachers in a university of Chongqing, China, this paper verifies the feasibility and practicability of the proposed comprehensive teachers' knowledge sharing behavior evaluation system and method.

1. Introduction

With the advent of the knowledge economy era, knowledge resources and knowledge management ability have become an important source of core competitiveness of organizations and individuals [1, 2]. As practitioners in education, teachers are innovators and disseminators of professional knowledge, accumulating and creating knowledge in specific educational and teaching contexts through "cognition in action" and "reflection in action," which play important roles in the development of knowledge economy. With the continuous differentiation and depth of knowledge, teachers also need to constantly learn and supplement new knowledge to guarantee the competitiveness and value of their knowledge resources. Teachers' knowledge sharing not only helps to excavate and reveal teachers' individual knowledge and improve teachers' individual ability but also helps to realize the transformation of teachers' individual knowledge into group public knowledge and further enrich the practical knowledge base of the teacher community, thus providing important knowledge resources for the development of school organizations, which is of great significance to individual teachers, teacher groups, and school organizations [3, 4].

With the in-depth development of specialized subject, knowledge increasingly embodies the characteristics of complexity, intersection, and synthesis. Meanwhile, there are large knowledge gaps among teachers due to differences in educational background, knowledge stock, learning ability, thinking patterns, academic expertise, and personality traits [5]. Knowledge sharing among teachers is an important way to help teachers quickly understand, comprehend, and master knowledge, and, whether as individuals or as teacher community, its essence is the process of teachers transferring, communicating, and sharing knowledge [6]. However, compared with the attention paid to teachers' knowledge sharing, teachers' knowledge sharing behavior has encountered dilemmas such as absence, low

end, and ineffectiveness in real practice. Teachers are constrained by factors such as egoism and altruism, subjective sharing desire and objective conditions, self-worth of knowledge, and lack of resource facilitation, which hinder university teachers' willingness and action to share knowledge, thus leading to a lack of effective knowledge exchange and cooperation [7, 8]. Therefore, stimulating internal drive of teachers to participate in knowledge sharing and mobilizing their willingness to participate in knowledge sharing behavior can promote the effective realization of teachers' knowledge sharing, thus promoting their personal development and the improvement of school knowledge management capability. Among them, how to effectively and accurately evaluate teachers' knowledge sharing behavior is the key link to improve the level of knowledge sharing among teachers. While exploring various strategies to improve knowledge level of teachers, schools must first understand the development status of teachers' knowledge sharing behavior and take the current situation of teachers' knowledge sharing behavior as the focus of improving teachers' knowledge level, which requires clarifying the methods for monitoring and evaluating the behavior of teachers' knowledge sharing. Therefore, this paper focuses on the issue of evaluation of teachers' knowledge sharing behavior to clarify the current situation of teachers' professional knowledge, so as to improve the quality of teachers' development.

The results of literature retrieval show that although there are some achievements on knowledge sharing behavior evaluation, teachers' knowledge management performance evaluation, and teachers' knowledge sharing influencing factors, there are still few achievements of in-depth research on tacit knowledge sharing behavior evaluation of teachers. In addition, current research on teachers' knowledge sharing behavior is dominated by theoretical studies and less by quantitative empirical studies. Accordingly, based on the systematic study of the influencing factors and evaluation indicators of teachers' knowledge sharing behavior, this paper constructs an evaluation model of knowledge sharing behavior and implements empirical analysis using the entropy weight method and the TOPSIS method. This work is beneficial for managers to provide effective incentives and management measures for teachers' knowledge sharing behavior in the school, which can provide theoretical guidance for improving teachers' knowledge sharing ability.

The structure of this paper is organized as follows: Section 2 reviews the related works about evaluation of teachers' knowledge sharing behavior. Then, the indicator system of teachers' knowledge sharing behavior evaluation is developed in Section 3. In Section 4, the evaluation model of teachers' knowledge sharing behavior is proposed. Section 5 presents a real case to show the feasibility and effectiveness of the proposed evaluation method. Finally, Section 6 presents the conclusion and future work.

2. Literature Review

The issue of knowledge management in education has received increasing attention from the society and academia, and the researches related to teachers' knowledge sharing have become a research hotspot. In terms of knowledge sharing behavior and its influencing mechanisms, Cummings and Teng [9] argued through empirical studies that the degree to which knowledge can be expressed through words or graphics determines the difficulty and ease of knowledge sharing; that is, the easier it is to express, the more favorable it is to share. Hu and Liu [10] used the complete information game approach to find the subgame perfect Nash equilibrium solution for the game between each participant in the knowledge alliance. Tseng and Kuo [8] found that the knowledge sharing behavior of teacher groups in online communities was significantly influenced by social relationships and community affiliation management. Liu et al. [11] established a single-group and multigroup dynamic game model of knowledge sharing and analyzed the evolutionary stabilization strategy of this model. Caskova and Chudy [12] explored the effects of the school culture on teachers' career at the beginning of their teaching and pedagogical knowledge sharing. Wu et al. [13] established the sharing behavior model and shared utility function, based on which experimental simulations of the model were conducted to summarize and analyze the knowledge sharing and motivation rules of organizational individuals. Mollazehi and Karimi [14] identified and validated the factors affecting teacher's knowledge sharing through information and communication technology (ICT).

For the study on teachers' knowledge sharing behavior evaluation, Sun et al. [15] clarified the connotation and composition of tacit knowledge sharing ability of university teachers based on two levels of process and elements and thus constructed an index system for tacit knowledge sharing ability evaluation of university teachers. Zhang et al. [16] conducted a specific study on the knowledge sharing ability of teacher scientific research teams from a holistic network perspective, including network stickiness measurement, centrality measurement, core-edge measurement, cohesive subgroups, and structural hole measurement. McChesney and Aldridge [17] described the development and validation of a new instrument to assess teachers' perceptions of the impact of professional knowledge sharing. Zhao and Wang [18] constructed a tacit knowledge sharing model for university teachers based on their knowledge sharing intention, sharing ability, sharing atmosphere, and sharing effect and then used AHP method to measure and analyze the weights of the index system. Asghar and Naveed [19] evaluated the psychometric properties of the Knowledge Sharing Behavior Scale (KSBS) in an academic context, and the results indicated that KSBS is not a valid instrument for measuring knowledge sharing behavior within an academic environment. Li and Qin [20] provided a model framework for teachers to promote students' entrepreneurial motivation through knowledge sharing. Kularajasingam and Subramaniam [21] stated that university academics' knowledge sharing behavior and social intelligence are significant in improving their performance through their grasp of competencies, and they applied a mediation model among university teachers to investigate the impact of knowledge sharing behavior and social intelligence of university academics on their performance. Wang et al. [22]

examined factors explaining rural teachers' sharing behavior regarding digital educational resources, both within and outside school, as posited by combining motivation theory and the integrative model of behavior prediction.

The above research provides a very valuable reference for the evaluation of teachers' knowledge sharing behavior. However, due to the professional and tacit characteristics of teachers' knowledge, the evaluation of teachers' knowledge sharing behavior has multiobjective attribute, and it is usually difficult to balance between different goals; that is, it is difficult to have one evaluation scheme whose indicators are better than others [15]. Therefore, the evaluation of teachers' knowledge sharing ability needs a quantitative comprehensive evaluation method to improve the validity of the evaluation process and reduce subjectivity. Thus, this paper constructs an evaluation indicator system of teachers' knowledge sharing behavior and proposes a comprehensive evaluation method based on entropy weight method and TOPSIS method and then verifies the feasibility and effectiveness of this evaluation system and evaluation method through practical cases.

3. The Indicator System of Teachers' Knowledge Sharing Behavior Evaluation

The evaluation system of teachers' knowledge sharing efficiency is a complex evaluation system, and it is unrealistic to describe the essence and rule of the whole process of teachers' knowledge sharing to control it to reach the predetermined goals of individual teachers and school organizations, which requires the establishment of a massive index system [18]. One index can only reflect a certain attribute of the knowledge sharing behavior evaluation system. Therefore, a reasonable evaluation indicator system can only be formed by selecting the main indicators in a reasonable way to comprehensively evaluate the knowledge sharing behavior of teachers within a reasonable cost range.

Although the performance of knowledge sharing behavior is related to the contribution of individual teacher, knowledge sharing among individual teachers is more influenced by some difficult-to-quantify factors of interactions among members, and the results of knowledge sharing are not immediately apparent, showing a certain lag phenomenon [23, 24]. When evaluating knowledge sharing behavior, it is necessary to consider the impact of difficult-to-quantify interrelationships among teachers and their roles in the overall knowledge sharing process. Therefore, for teachers' knowledge sharing, outcome-based indicators can only reflect part of the final results of knowledge sharing behavior but less consider the process. In fact, the more important aspect of knowledge sharing behavior is the behavioral activities and the interactive coordination between individuals, which is extremely crucial. In addition, from the practice of teachers' knowledge sharing behavior, the cognitive gap between individual teachers and the knowledge sharing environment are objective factors that affect knowledge sharing behavior; thus the evaluation of teachers' knowledge sharing behavior should consider the above factors [25, 26].

Based on the above considerations, this paper comprehensively evaluates teachers' knowledge sharing behavior from five dimensions, namely, knowledge sharing willingness, knowledge sharing ability, knowledge sharing environment, knowledge sharing technology support, and knowledge sharing effect. The logical process of this index system is as follows: First, before the beginning of knowledge sharing, teachers' knowledge sharing willingness is the determining factor for their decision to implement knowledge sharing behavior. Second, in the process of knowledge sharing, teachers' individual knowledge sharing ability, external knowledge sharing environment, and knowledge sharing technology support are the key subjective and objective factors affecting knowledge sharing behavior. Third, all these subjective and objective factors are ultimately reflected in the effect of knowledge sharing behavior. When the knowledge sharing has produced certain effects, the knowledge sharing behavior of teachers can be reflected in its entirety. Further, through analyzing the characteristics and connotations of the five dimensions and following the principles of systemic, scientific, operability, and comparability of the evaluation indicator system, the evaluation indicator system of teachers' knowledge sharing behavior is constructed, as shown in Table 1.

4. Evaluation Model of Teachers' Knowledge Sharing Behavior

Teachers' knowledge sharing behavior is a complex systematic process, and the whole process involves various theories such as transaction cost theory, cognitive psychology, and organizational behavior [27]. Teachers' knowledge sharing behavior evaluation should realize the promoting function of the evaluation process and results on the knowledge exchange behavior among teachers and then improve teachers' individual knowledge ability and school knowledge management level through knowledge sharing behavior evaluation, which shows that teachers' knowledge sharing behavior evaluation is a multiobjective evaluation problem. Many multiobjective evaluation methods have been proposed [28, 29], and when teachers' knowledge sharing is used as the evaluation object, the evaluation conclusions obtained by various methods often differ largely since the rubric used is often subjective and ambiguous, which undoubtedly brings great difficulties to the evaluation of teachers' knowledge sharing behavior.

After the evaluation indicator system of teachers' knowledge sharing behavior is determined, its evaluation results mainly depend on two factors: one is the determination of evaluation index weights, and the other is the choice of comprehensive evaluation methods. Traditional knowledge sharing behavior evaluation methods often rely on the subjective judgments of organizers and experts to determine the weights of each index, and due to the great differences in professional personal experience and mastering information, which are subjective, the weight scores given by different individuals for the same evaluation index often differ greatly, resulting in great distortions of evaluation results and even wrong decisions [18]. Based on the

TABLE 1: The evaluation indicator system of teachers' knowledge sharing behavior.

Evaluation objects	Level 1 indicators	Level 2 indicators
Teachers' knowledge sharing behavior evaluation	Knowledge sharing willingness	Self-efficiency u11
		Interpersonal relationships u12
		Gaining respect u13
		Knowledge sharing recognition u14
		Position in the organization u15
	Knowledge sharing ability	Knowledge recognition ability u21
		Knowledge transfer ability u22
		Knowledge receiving ability u23
		Knowledge innovation ability u24
	Knowledge sharing environment	Knowledge exchange atmosphere u31
		Knowledge sharing incentive policy u32
		Knowledge sharing culture u33
		Trust among teachers u34
		Intellectual property policy u35
	Knowledge sharing technology support	Knowledge sharing platform u41
		Knowledge exchange medium u42

		Knowledge base u44
	Knowledge sharing effect	Gaining valuable knowledge u51
		Knowledge sharing satisfaction u52
		Personal capability enhancement u53
		Colleague's approval u54
		Organizational performance improvement u55

above considerations, this paper combines the subjective judgment of experts with the objective situation of teachers' knowledge sharing behavior, determines the weights of the evaluation indexes of enterprise culture implementation by entropy weight method, and adjusts the subjective deviation of expert judgment by scientific weight coefficients and then adopts the improved ideal point (TOPSIS) as the comprehensive evaluation method to derive the final ideal evaluation results.

4.1. Entropy Weight Method and TOPSIS Method.

The concept of entropy originated from thermodynamics and was later introduced into information theory by Shannon. According to the definition and principle of entropy, the entropy value can be used as a measure of the amount of effective information provided by the system, representing the degree of disorder of the system. Entropy weight method is an evaluation method combining qualitative and quantitative analysis, which is an objective weighting method [30, 31]. The entropy weight method determines the indicator weights according to the amount of information conveyed to the decision-maker by each index. For an index, the entropy value can be used to judge the degree of dispersion of an index. If an index's information entropy value is smaller, the dispersion degree of the index is greater, and the influence of the index on the comprehensive evaluation is greater. If the values of an index are all equal, the index does not work in the comprehensive evaluation. For the evaluation problem, suppose that there are m evaluation objects and n evaluation indicators, and the initial evaluation matrix $R = (r_{ij})_{m \times n}$ is obtained, and r_{ij} denotes the value of the j evaluation indicator of the i

evaluation object; then the entropy value e_j of an indicator r_j is

$$e_j = -\frac{1}{\ln m} \sum_{i=1}^{m} \delta_{ij} \ln \delta_{ij}, \tag{1}$$

where $\delta_{ij} = r_{ij} / \sum_{i=1}^{m} r_{ij}$ and δ_{ij} denotes the proportion of the i participant to the indicator under the j indicator. According to the definition and principle of entropy weight method, when the entropy value of an index is larger, it means that the less effective information provided by the index, the smaller the role in the comprehensive evaluation, and its weight is smaller; conversely, the larger the entropy value, the more effective information provided by the index and the larger the role in the comprehensive evaluation, and its weight is larger [31]. Therefore, it is scientific and credible to use the entropy weight method to assign index weight during the analysis of multiple index evaluation problems.

TOPSIS method is a common method in system engineering, mainly for multiobjective evaluation and decision analysis of finite solutions, and it has many advantages, such as no requirement for sample content, no requirement for sample data distribution, simple calculation process, and intuitive and easy analysis of results, which makes TOPSIS method widely and effectively used in many fields, such as economy, management, and engineering technology. [28, 32, 33]. For the evaluation of teachers' knowledge sharing behavior, the TOPSIS method has no strict restrictions on data distribution and sample content indicators. It is suitable for small sample data and large-scale system data with multiple evaluation units and multiple indicators, which has the advantage of being real, intuitive, and reliable. The core idea and procedure of TOPSIS are as

follows: Firstly, the initial data is dimensionless processed to make the data objectively and truly reflect the gap between the evaluation objects; then, the positive and negative ideal values are determined according to the size of the standardized data of each index; next, the weighted Euclidean Distance between the evaluation objects and the positive and negative ideal values is calculated, from which the closeness of each evaluation object to the best state is derived; finally, the ranking of each evaluation object is measured. In this paper, when applying TOPSIS method for comprehensive evaluation, to address the problem of cumbersome calculation of Euclidean Distance from evaluation objects to the positive and negative ideal point, the decision matrix of TOPSIS method is normalized to simplify the calculation of the positive and negative ideal solution; meanwhile, the concept of relative closeness between the index value and ideal solution of each evaluation object is introduced, and each evaluation object is ranked according to the size of its relative closeness.

4.2. Comprehensive Evaluation Process of Entropy Weight-TOPSIS Method. The evaluation steps of the improved entropy weight-TOPSIS method are as follows:

For the evaluation problem with m teachers to be evaluated and n evaluation indicators, there is the initial data matrix $R = (r_{ij})_{m \times n}$.

(1) The normative matrix $Q = (q_{ij})_{m \times n}$ is obtained by dimensionless treatment of the R matrix; that is,

$$q_{ij} = \frac{r_{ij}}{\sqrt{\sum_{i=1}^{m} r_{ij}^2}}, \quad i = 1, 2, 3..., m, \ j = 1, 2, 3..., n. \quad (2)$$

(2) Calculate δ_{ij}, which is the weight of the j indicator of the i participant.

$$\delta_{ij} = \frac{q_{ij}}{\sum_{i=1}^{m} q_{ij}}. \quad (3)$$

(3) Calculate the entropy value e_j of the j indicator.

$$e_j = -\frac{1}{\ln m} \sum_{i=1}^{m} \delta_{ij} \ln \delta_{ij}, \quad (j = 1, 2, 3..., n), \quad (4)$$

where $0 \le e_j \le 1$.

(4) Calculate the difference coefficient e_j for the j indicator.

$$g_j = 1 - e_j. \quad (5)$$

For the j indicator, the larger the difference coefficient χ_j, the greater the role of the indicator in the program evaluation; conversely, the smaller χ_j is, the smaller the role of the indicator in the program evaluation is.

(5) Calculate the weight w_j of the j indicator.

$$w_j = \frac{g_j}{\sum_{j=1}^{n} g_j}. \quad (6)$$

(6) Construct the weighted data matrix $Z = (z_{ij})_{m \times n}$, where element z_{ij} is defined as follows:

$$z_{ij} = w_j q_{ij}. \quad (7)$$

(7) Determine the positive ideal value R^+ and the negative ideal value R^- of the index. The traditional TOPSIS method of the positive and negative ideals is more complex due to the values, which makes it difficult to calculate the Euclidean Distance of each evaluation scheme to the positive and negative ideals. For this reason, without affecting the evaluation problem to derive the final evaluation results, this paper makes improvements to the TOPSIS method to simplify the calculation. The value of q_{ij} in the normative matrix Q is taken as [0, 1]. Here we specify that the highest preferred target attribute value $q_{ij} = 1$ and the lowest preferred target attribute value $q_{ij} = 0$. Thus, it can be known that $z_j^* = w_j$ and $z_j^- = 0$; then the positive and negative ideal solutions are as follows:

$$\begin{aligned} Z^- &= \left(z_1^-, z_2^- ..., z_j^-\right) = (0, 0..., 0), \\ Z^* &= \left(z_1^*, z_2^* ..., z_j^*\right) = \left(w_1, w_2..., w_j\right). \end{aligned} \quad (8)$$

(8) Calculate the Euclidean Distance of each evaluation object to the positive and negative ideal points, and the distance formula uses Euclidean formula.

$$\begin{aligned} D_i^- &= \sqrt{\sum_{j=1}^{n} \left(z_{ij} - z_j^-\right)^2} = \sqrt{\sum_{j=1}^{n} w_{ij}^2 \left(q_{ij} - 0\right)^2}, \\ D_i^* &= \sqrt{\sum_{j=1}^{n} \left(z_{ij} - z_j^*\right)^2} = \sqrt{\sum_{j=1}^{n} w_{ij}^2 \left(q_{ij} - 1\right)^2}, \quad i = 1, 2, 3..., m, \ j = 1, 2, 3..., n. \end{aligned} \quad (9)$$

(9) Calculate the relative closeness between the index value and the ideal solution of each evaluation object ψ_i.

$$\psi_i = \frac{D_i^{-}}{D_i^{*} + D_i^{-}}. \qquad (10)$$

(10) The schemes are ranked by the magnitude of relative closeness, and the greater the relative closeness ψ_i, the higher the level of knowledge sharing of the evaluated teachers; the greater ψ_i is, the lower the level of knowledge sharing of the evaluated teachers is.

5. Case Study

This paper selects a well-known university in Chongqing, China, as an example of teacher knowledge sharing evaluation work and illustrates the evaluation process of the teacher knowledge sharing evaluation model and method. This university is a multidisciplinary university with distinct engineering characteristics, and it focuses on cultivating application-oriented compound high-quality professionals with innovative spirit and practical ability. This university has more than 2300 teachers and staffs, and it strongly focuses on and supports knowledge sharing behaviors among teachers to improve individual teachers and the university's overall knowledge management. In the process of evaluating the knowledge sharing behavior of teachers in this university, the above evaluation system is used to comprehensively evaluate the knowledge sharing level of four teachers, A, B, C, and D, and then give the ranking of each teacher's knowledge sharing behavior.

In this paper, an expert panel is formed by several experts in higher education systems and knowledge management, and the expert panel scores each teacher individually according to the evaluation indicator system proposed in this paper. The range of scores is $1 - 5$, where higher scores indicate a higher level of knowledge sharing behavior of a teacher on an indicator. The final combined scores of the expert are obtained in Table 2.

(1) Since the scores in the expert rating scale are all dimensionless data, there is no need for dimensionless processing here.

(2) According to equation (3), the weight δ_{ij} of the i participating teacher in the j indicator is calculated to obtain Table 3.

(3) According to equations (4)–(6), the entropy value, variation coefficient, and weight of each evaluation index are obtained, and the results are shown in Table 4.

(4) As shown in Table 5, the weighted normalized data matrix is obtained from equation (7).

(5) As shown in Table 6, the relative closeness and its ranking table can be obtained from equations (8)–(10).

The ranking result of the relative closeness c_i shows that the four university teachers' knowledge sharing behavior level is B〉D〉A〉C in turn, which is consistent with the intuitive judgment of experts and school colleagues about the four teachers. Meanwhile, the results are consistent with those of the unsimplified traditional TOPSIS method, so the evaluation process of the improved TOPSIS method is more concise and efficient, and the evaluation results have higher credibility and practicality.

Table 5: Weighted normalized data matrix.

6. Conclusions

Knowledge sharing behavior evaluation can help schools and teachers to understand their knowledge sharing levels and thus provide decision-making input for better policy formulation, environment optimization, organization construction, and incentive behavior. Teachers' knowledge sharing behavior evaluation has become a hot focus of attention in education and academia at home and abroad, yet there is little research on the quantitative evaluation of teachers' knowledge sharing behavior. From a systematic perspective of combining process and result, this paper constructs an evaluation indicator system of teachers' knowledge sharing behavior containing five dimensions of knowledge sharing willingness, knowledge sharing ability, knowledge sharing environment, knowledge sharing technology support, and knowledge sharing effect, which is proved in practice to be able to evaluate teachers' knowledge sharing level scientifically, systematically, and comprehensively. The entropy weight method is used to revise experts' experience scoring results and determine the weights of knowledge sharing behavior evaluation index, which avoids the subjectivity of the traditional expert evaluation method and other multilevel and multi-index weight determination methods and makes the evaluation results more objective, accurate, and more in line with reality. Compared with the traditional TOPSIS method, the improved TOPSIS method has a more streamlined, efficient, and well-organized calculation process. In summary, the evaluation system and evaluation method of teachers' knowledge sharing behavior established in this paper are reasonable and practical, which can not only judge the comprehensive level of teachers' knowledge sharing ability but also analyze the strengths and weaknesses factors of each teacher's knowledge sharing, to provide a basis for decision-making to improve teachers' knowledge sharing level. Of course, the empirical research in this paper still has its limitations, such as insufficient sample sources and insufficient sample size. In the future work, the empirical analysis is needed to further verify the advantages of the evaluation model and method in this paper.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding the publication of this paper.

Human action recognition is an important field in computer vision that has attracted remarkable attention from researchers. This survey aims to provide a comprehensive overview of recent human action recognition approaches based on deep learning using RGB video data. Our work divides recent deep learning-based methods into five different categories to provide a comprehensive overview for researchers who are interested in this field of computer vision. Moreover, a pure-transformer architecture (convolution-free) has outperformed its convolutional counterparts in many fields of computer vision recently. Our work also provides recent convolution-free-based methods which replaced convolution networks with the transformer networks that achieved state-of-the-art results on many human action recognition datasets. Firstly, we discuss proposed methods based on a 2D convolutional neural network. Then, methods based on a recurrent neural network which is used to capture motion information are discussed. 3D convolutional neural network-based methods are used in many recent approaches to capture both spatial and temporal information in videos. However, with long action videos, multistream approaches with different streams to encode different features are reviewed. We also compare the performance of recently proposed methods on four popular benchmark datasets. We review 26 benchmark datasets for human action recognition. Some potential research directions are discussed to conclude this survey.

1. Introduction

Human action recognition is one of the most crucial tasks in video understanding. This field has a wide range of applications, such as video retrieval, entertainment, human-computer interaction, behavior analysis, security, video surveillance, and home monitoring. In detail, we want to find handshake events in a movie or offside decisions in a football match and the results are returned automatically. The goal of human action recognition is to recognize automatically the nature of an action from unknown video sequences.

There are some challenges in human action recognition. The view invariance is one of the reasons that make human action recognition more complex. There are some simple datasets having a fixed viewpoint [1, 2] while most of the recent datasets have many viewpoints. In addition, each person has their size and shape as well as posture. They can

appear with various clothes and accessories. An action which is performed in an indoor environment with a uniform or static background is easy to recognize than an action that is recorded in a cluttered or dynamic background. In addition, lighting conditions or viewpoints contribute to increase or decrease of the accuracy of recognition. The next problem is intraclass and interclass variations. A human action recognition method must be able to generalize an action over variations within a class and distinguish between actions of different classes. For examples, people have different speeds when they run or walk. The occlusion problem is a hard issue in action recognition because some body parts of humans are disappeared temporarily. For example, some body parts cover other parts or a subject, or a person is hidden behind another person. Temporal variations are also an important challenge because actions are happening for a long time.

Deep learning methods have achieved state-of-the-art results on various problems of computer vision, especially

human action recognition. Convolutional neural networks (CNNs) [3] are the neural network that uses convolutional operator in their layers. Convolutional network is used for computing a grid of values such as images while recurrent neural networks (RNNs) [4] are a type of neural network for processing sequential data, such as text and video. In this survey, we focus on proposed methods for human action recognition using deep learning techniques.

1.1. Review of Related Survey Articles. Since human action recognition is an attractive problem, many surveys have been done over the last few years. The most popular survey of human action recognition is the work in [5]. Firstly, the authors discussed the local representation and global representation-based methods. Then, three types of action classification approaches were discussed, including direct classification, temporal state-space models, and action detection. However, this study have been conducted over ten years ago, and this survey reviewed methods using hand-crafted features.

Zhang et al. [6] provided an overview of human action recognition, interaction recognition, and human action detection methods. The whole part of the survey discussed human action feature representation methods. First, the authors discussed handcrafted action features for RGB, depth, and skeleton data. Then, they reviewed some deep learning-based methods. However, they focused on two-stream networks and long short-term memory methods.

A review of Singh and Vishwakarma [7] focused on human action datasets in the past two decades. They classified these datasets into two classes, namely RGB (Red-Green-Blue) and RGB-D (depth) datasets. They discussed 26 RGB and 22 RGB-D datasets. Two categories of existing methods (handcrafted and learned feature representations) were discussed; however, the main contribution of this work is dataset analysis.

RGB-D data plays a vital role in human action recognition because this data provide color, depth and skeleton data. The performance of human action recognition systems is improved significantly when they exploit depth and skeleton data. With a special focus on RGB-D data, Liu et al. [8] reviewed human action recognition and human interaction recognition based on hand-crafted features. Then, their survey discussed human activity recognition based on deep learning in the next part.

Zhu et al. [9] reviewed over 200 papers about human action recognition. Their survey focused on three different approaches for human action recognition. Firstly, two-stream networks were reviewed. The two-stream methods tried to exploit the temporal relationship between frames because motion information plays a vital role in human action recognition in video. The first stream encodes the spatial information and the second one encodes the optical flow. In this review, the authors focused on recurrent neural networks which were used as a part of a two-stream network while our work discusses RNNs-based methods for human action recognition. Next, 3D CNN-based methods were discussed. 3D CNNs exploit both spatial and temporal information by using a 3D tensor with two spatial and one temporal dimension. The two-stream networks require huge resources to compute, and the 3D CNNs are hard to train. Therefore, they reviewed efficient video modeling which try to reduce computational intensity.

Beddiar et al. [11] reported a survey which discussed human activity recognition approaches in the last ten years. The authors classified human activity recognition approaches into various categories. The first category is the feature extraction process. Both hand-crafted features and feature learning were discussed. Then, they discussed three stages of human activity recognition approaches, including detection, tracking, and recognition. Next, unimodel and multimodel approaches were surveyed. They classify human activity recognition methods into three classes of learning supervision, namely supervised, unsupervised, and semi-supervised methods. The review also provided different types of activities. However, the recent deep learning techniques for human activities recognition were not highlighted clearly.

In order to review many different challenges, Jegham et al. [10] reviewed methods which aimed to solve these challenges in human action recognition. Many challenges were discussed such as anthropometric variation, multiview variation, cluttered and dynamic background, interclass similarity, intraclass variability, low-quality videos, occlusion, illumination variation, shadow and scale variation, camera motion, and poor weather conditions. In the second part, the authors reviewed recent action classification methods and popular datasets. They focused on three types of methods, including template-based methods, generative model-based methods, and discriminative model-based methods.

A different survey [12] discussed human pose estimation and the role of it in human action recognition application. Firstly, the survey discussed various types of human pose estimation such as single person, multiperson, 3D human pose estimation, and human pose estimation in videos and depth images. In the remained part, they discussed human pose estimation for action recognition.

A review of single vision and multivision modalities was provided by Majumder and Kehtarnavaz [13]. In the single vision modality section, the authors discussed the approaches which used video data for action recognition. In the next section, the methods using RGB + Depth data were reviewed in multivision modality section. In each modality, both conventional and deep learning approaches were reviewed.

Table 1 provides a summary of recent related surveys. Moreover, some main contributions of this work are discussed.

1.2. Contributions of This Survey Article. Human action recognition has a wide range of applications; therefore, many approaches have been proposed using deep learning techniques. We aim to provide a comprehensive survey of recent deep learning techniques for human action recognition. In summary, our main contributions are listed here:

TABLE 1: Summary of the related survey articles.

(i) We discuss the most recent deep learning techniques for human action recognition.

(ii) We provide the first review of convolution-free approaches in the human action recognition field.

(iii) We survey the most popular benchmark datasets for human action recognition

(iv) We provide a comprehensive analysis of proposed methods.

1.3. Roadmap of the Survey. As in Figure 1, the rest of the survey is organized as follows. In Section 2, we discuss the most recent deep learning techniques for anomaly detection. Then, we provide two accuracy comparisons of some popular datasets in Section 3. Section 4 reviews many popular benchmark datasets in the human action recognition field. Finally, we discuss some open research problems and give the conclusion of this survey.

2. Recent Deep Learning-Based Methods in Human Action Recognition

In this section, we review recent deep learning-based methods for human action recognition. With the development of large-scale datasets and deep learning, this leads a remarkable growth of models based on deep learning for human action recognition. There are four trends and a new trend has attracted some researchers recently. The first trend is 2D Networks which uses 2D convolutional neural networks in their models, such as TSM [14], TRN [15], and GSM [16]. The second trend is action recognition based on RNN, such as in [17–19]. The third trend is 3D Single Stream Network which uses 3D convolutional kernels in the networks, such as CSN [20] and TSN [21, 22]. The fourth trend is 3D Two-Stream Network which includes a spatial and a temporal stream to encode both structure and optical flow information, such as in [23–26]. Finally, convolution-free approaches based on attention mechanism are a new trend in human action recognition with efficient computation and performance, such as in [27–29] and TimeSformer [30].

2.1. Methods Based on 2D CNN. In this part, we will discuss the proposed methods that are based on 2D CNNs. One of the advantages of 2D CNNs is that the computation is cheap [14]. However, 2D CNNs often cannot exploit well the temporal information. Therefore, many approaches try to capture both spatial and temporal information [16, 31, 32]. Optical flow information plays a vital role in action recognition, but the computation cost is expensive. Therefore, in [33–35], the authors tried to compute optical flow with low cost and efficiency.

Two-stream networks are often trained individually with high computational cost. Jiang et al. [31] proposed an efficient method to exploit both spatiotemporal and motion features in a 2D framework, namely STM block. The STM block includes a channel-wise spatiotemporal module (CSTM) and a channel-wise motion module (CMN). The CSTM is used to extract spatiotemporal information. The input feature map $F \in \mathbb{R}^{N \times T \times C \times H \times W}$ is reshaped into $F^* \in \mathbb{R}^{NHW \times C \times T}$. Then, a channel-wise 1D convolution is applied on input feature maps. A 3D convolutional network can encode local spatial and temporal features. However, they cannot encode ordered temporal information of all clips. A channel-independent directional convolution (CIDC) [32] was introduced to solve this issue. Given input feature map with C channels, CIDC convolve each channel of input feature map with T' filter. The output feature map including spatial and temporal information is obtained by concatenating $C \times T'$ feature map. Another strategy in action recognition is frame selection. Gowda et al. [36] proposed a smart frame selection method that improved over many state-of-the-art models. The method includes two branches. The first computes a score δ_i for each frame, and the second computes a score γ_i of a pair of frames. Given n frames, top m frames are chosen using a final score which is multiplied both score δ_i and γ_i. Finally, a classifier is used for the final prediction. The authors used the Something-Something-V2 dataset [37] for ablation study. They also experienced on Kinetics [38], UCF101 [39], and HMDB51 [40].

According to the observation, movement variations at motion boundaries are very important in human action recognition. Zhang et al. proposed persistence of appearance

(PA) [33] to obtain a map that encodes small motion variations at boundaries. The difference between the optical flow and PA is that PA captures the motion variation without encoding the direction of the movement. Given two frames, eight 7×7 convolutions are applied to obtain low-level feature maps F_1, F_2. The i-th PA component is computed as $PA_i(p, \Delta t) = F_i(p, t + \Delta t) - F_i(p, t)$, where F_i is the i-th feature map. All PA_i are aggregated to a channel PA. The PA maps the appearance to the dynamic motion because it maps from three-dimensional to two-dimensional tensor. To exploit motion information, Piergiovanni and Ryoo [34] proposed a convolutional layer to capture the flow of any channel for action recognition without computing optical flow. The proposed fully differentiable convolutional layer has learned parameters that enhance the performance of action recognition systems. Optical flow is an expensive method. Xu et al. [35] proposed a fast network to improve the extraction of optical flow. The optical flow is generated by MotionNet [41] which is an end-to-end trainable network. Moreover, OFF [42] is added to the network to get better optical flow features. The optical flow is computed directly from RGB frames without precalculation or storage. Therefore, both spatial and temporal information are learned by one network.

One of the most popular modules in human action recognition is temporal shift module (TSM) [14]. TSM has the complexity of a 2D CNN but obtains the performance of 3D CNN. In addition, this module can insert into a 2D CNN without extracomputation and parameters. Given a tensor with C channels and T frames. A part of the channels is shifted by -1, and another part is shifted by $+1$. The rest of the tensor is unshifted. The TSM can be inserted before convolutional layer or residual block, but the spatial features may be harmed because the information is lost. To deal with this problem, the TSM is inserted into a residual branch in a residual block. To exploit the temporal relations between frames in video, Zhou et al. [15] proposed a temporal relation network (TRN) which predict human-object interactions in the Something-Something dataset accurately. Their paper show that the TRN outperformed two-stream network as well as 3D convolution networks. The pairwise temporal relation is computed as $T_2(V) = h_\phi(\sum_{i<j} g_\theta(f_i, f_j))$, where $V = \{f_1, f_2, \ldots, f_n\}$ is the video with n frames. The functions h_ϕ and g_θ is used to fuse the frame features. Moreover, The function captured frames relations at different scale is described as $MT_N(V) = T_2(V) + T_3(V) + \cdots + T_N(V)$, where T_d is temporal relationship of d frames. A 2D convolution neural network (CNN) has smaller parameters and fast computation than a 3D CNN. However, a 2D CNN usually captures spatial information. Sudhakaran et al. proposed a gate shift module (GSM) [16] which is an 2D CNN to capture spatial and temporal features. The input is applied a spatial convolution. Then, a grouped spatial gating is computed. The 2D convolution ouput is split into group-gated features and residual. The gated features are group-shifted and fused with the residual. The spatial and temporal information is exploited by a learning spatial gating.

In a different approach to abovementioned methods, Zhang et al. [43] applied video super-resolution to human action recognition by introducing two video super-resolution (SR) modules, namely spatial-oriented SR (SoSR) and temporal-oriented SR (ToSR). The low-resolution input video is enhanced by two proposed modules. The input of the recognition network includes the output of the SoSR and the optical flow computed from the output of the ToSR module.

2.2. Methods Based on RNN.

CNNs are popular models for image representation. They are also used to learn action representation in videos [14–16]. However, they often work well with short videos [33, 34], since only spatial features are captured and motion information of action are not encoded. To encode longer motion in video, some approaches have used RNNs, and long-short term memory (LSTM), such as in [17–19]. RNN is widely used in sequence data like video, and text. LSTM is a special version of RNN with the capability of learning long-term information. In addition, LSTM is combined with an attention mechanism [44] or is used in a three-stream network [45, 46] for action recognition.

With video data, RNNs and LSTM requires high memory storage and computation cost. A compact LSTM model (TR-LSTM) [17] was proposed to solve this issue. The TR-LSTM use the tensor ring decomposition to reconstruct the input-to-hidden layer of the recurrent network. In the tensor ring decomposition, the first and last tensors are connected circularly and constructed in a ring-like structure. A densely-connected bi-directional LSTM (DB-LSTM) network [18] is used to represent the spatial and temporal information of human actions. The goal of DB-LSTM is to capture the spatial, short-term, and long-term patterns. The spatial and short-term patterns are extracted by a sample representation learner module, and the long-term patterns are exploited by a sampling stack. Another work, named correlational convolutional LSTM (C^2 LSTM) [19] aims to exploit both spatial and temporal information of human action video. The basic spatial features are extracted by two parallel convolutional networks, and then, these features are used as input for the C^2 LSTM module. The C^2 LSTM extracts the spatial and temporal information as well as the time relation by using cross-correlation inside the LSTM.

A three streams network was proposed by Liu et al. [45] for human action recognition. The network includes a spatial stream, a temporal stream, and a spatial-temporal saliency stream. These streams are used to extract appearance information of RGB frames, motion information of optical flow frames, and spatiotemporal foreground information of objects from spatiotemporal saliency maps. In addition, they proposed three attention-aware LSTMs to exploit the relationship between frames. Another three-stream network [46] processes different frame rates for human activity recognition. The first stream operates at a single frame rate and the second stream processes at low frame rates. Both streams are used to capture spatial features. The third stream processes at high frame rates to capture temporal features.

The output of the previous step is fed into two LSTM layers. This makes the proposed model deeper. Instead of using the LSTM layer, the authors use an attention mechanism to capture temporal information.

To extract the salient features of human action videos, Ge et al. [44] introduces an attention mechanism and convolutional LSTM. A convolutional network is used to extract features of the input video. Then, a combination of LSTM and a spatial transformer network extracts salient features. The final classification is obtained by a convolutional LSTM. The proposed combination can select salient localities effectively while getting higher accuracy than soft attention and using less calculation than hard attention.

2.3. Methods Based on 3D Single-Stream Network.

In this part, we will discuss 3D convolution-based models. These methods obtain good results since 3D CNN extracts spatial and temporal information from action video directly. Figure 2 is an example of single-stream network architecture. The input frames are fed into a 3D single-stream network to extract both spatial and temporal features.

Tran et al. [20] proposed a channel separated convolutional network (CSN) which employs 3D group convolution. The CSN is defined as 3D CNNs; however, only $1 \times 1 \times 1$ conventional convolutions or $k \times k \times k$ depthwise convolutions are used. In detail, the conventional convolutions are used for channel interaction and depthwise convolutions are used for local spatiotemporal interactions. In their work, a $3 \times 3 \times 3$ convolution from the bottleneck block by a pair of a $1 \times 1 \times 1$ convolution and a $3 \times 3 \times 3$ depthwise convolution to get a interaction-preserved channel-separated bottleneck block. Moreover, the $1 \times 1 \times 1$ convolution in the previous pair convolutions is removed to obtain interaction-reduced channel-separated bottleneck block. The authors also applied group convolution to ResNet blocks. Two $3 \times 3 \times 3$ convolutional layers of simple ResNet block are replaced by two $3 \times 3 \times 3$ grouped convolutions or a set of one $1 \times 1 \times 1$ convolution and two depthwise convolutions. 3D convolutional neural networks have high training complexity and huge memory cost. In order to resolve this problem, Zhou et al. [47] proposed a combination of 2D and 3D convolution, namely mixed convolutional tube (MiCT). The deep MiCT is an end-to-end network which receives RGB video sequences as inputs. The whole network includes four MiCTs and a global pooling in the last layer of the network. This pooling allows the network to accept any length videos as inputs. Each MiCT block receives an 3D signal. The input process by a 3D convolution to extract spatial-temporal feature maps. The extracted features are passed through a 2D convolution to compute the final feature maps. The MiCT-Net uses fewer 3D convolution, but it obtains deeper feature maps. Instead of combining 2D and 3D convolution, a new spatiotemporal architecture fused 2D and 3D architectures to improve spatiotemporal representation. Diba et al. proposed holistic appearance and temporal network (HATNet) [48] which exploits semantic information at different levels. HATNet uses 2D convolutional blocks to encode the appearance
FIGURE 2: 3D single-stream network.

information of individual frames in a video clip. In addition, the 3D convolutions extract temporal information in a batch of frames. ResNet18 and ResNet50 was used in HATNet for 3D and 2D modules, respectively. The output feature maps of each 2D and 3D block are merged; then, a $1 \times 1 \times 1$ convolution is applied to reduce the channel of features. With prestraining on HVU dataset [48], the HATNet obtained 97.8% and 76.5% on UCF101 [39] and HMDB51 datasets [40], respectively.

The video usually has repeating information, and the temporal squeeze network [21] can map the movement information from a long video into a set of few frames. Given a video X with K frames, a frame-wize z is obtained by applying the squeeze operation. The output of squeeze operation is fed into a excitation operation. Global average pooling is used to implement the squeeze operation while the excitation operation is implement by two fully connected layers and two activation functions. The shorter sequence frames Y' is obtained by projecting the flattened vector of X onto the hyperplane $\mathbf{A}$, where $\mathbf{A}$ is computed from the output of the excitation operation. To reduce the computational cost of motion feature, a FASTER-GRU network [49] aggregates the temporal information. The FASTER framework uses an expensive model and a lightweight model to exploit the information of the action and scene, respectively. The FAST-GRU aims to learn the features from multiple models. This network maintains the resolution of feature maps to exploit more spatial-temporal information. A fully connected layer is replaced by a 3D $1 \times 1 \times 1$ convolution. The proposed method was evaluated on Kinetics [38], UCF101 [39], and HMDB51 datasets [40]. A combination of 3D convolution neural network and long-short term memory [50] is used to capture low-level spatial-temporal feature and high level temporal feature. The proposed network used Inception 3D CNN [38] to extract spatial features and low-level motion features from a sequence of frames. Then, the output of the I3D model is fed into a LSTM network to exploit high-level spatial features. Temporal information plays a vital role in human action recognition; however, this information still has challenging problems. A temporal difference network (TDN) [51] was

proposed to capture multiscale temporal information. In addition, TDN in an end-to-end model that captures both short-term and long-term motion information. Given T frames $I = [I_1, \ldots, I_T]$, a 2D CNN is used to extract features $F = [F_1, \ldots, F_T]$. A short-term and long-term TDM is applied to exploit short-term and long-term motion. To capture the short-term motion, a stacked RGB difference of frame I_i is downsampled using an average pooling, then extracted motion information with a 2D network. The feature is upsampled to match the size of RGB features. In the long-term TDM, the aligned temporal difference is computed, and then fed into a multiscale module to extract long-range motion information. Features are enhanced by a bidirectional cross-segment temporal difference. The TDN framework with ResNet backbone [52] was evaluated on Kinetics-400 [38] and Something-Something-V1-V2 [37]. Instead of computing the optical flow frame-by-frame, the proposed MotionSqueeze module [53] learned motion features by a light-weight learning technique. The module contains three parts, namely correlation computation, displacement estimation, and feature transformation. The correlation score is defined as $s(x, p, t) = F_x^{(t)} \cdot F_{x+p}^{(t+1)}$, where $F^{(t)}$ and $F^{(t+1)}$ are two input feature maps. Then, motion information is estimated in the displacement estimation module and a confidence map of correlation is obtained from the correlation. The concatenation of displacement map and the confidence map is used as the input of the feature transformation. The feature transformation converts the input into an effective motion feature. The MotionSqueeze module is inserted into ResNet and evaluated on Something-Something-V1, Something-Something-V2 [37], Kinetics [54], and HMDB51 datasets [40].

Kalfaoglu et al. [22] proposed a method which obtained highest accuracy on both HMDB51 [40] and UCF101 [39] datasets with 85.10% and 98.69%. The most important thing in this study is that the authors replace the conventional temporal global average pooling (TGAP) layer by the bidirectional encoder representations from transformers (BERT) layer. This replacement utilize the temporal information with BERT's attention mechanism. They declared that TGAP ignores the order of the temporal features, and

BERT can focus on the important temporal features. The proposed network removed temporal global average pooling at the end of the proposed 3D CNN architecture. A learned positional encoding was added to the extracted features to maintain the positional information. The two last parts of the architecture is multihead attention a classification. Then, they also proposed some features reduction blocks. Attention is a useful tool in many fields of computer vision. A novel W3 (what-where-when) video attention module [55] including a channel-temporal attention M^c and a spatio-temporal attention M^s was proposed for the action recognition problem. An average-pooling and a max-pooling are used to aggregate global spatial information. The output is fed into a shared MLP network to exploit the interchannel relationship. To model the temporal dynamics of objects, a channel temporal attention with two layers of 1D convolutions is computed. With spatiotemporal attention, an average-pooling and max-pooling are used as in channel-temporal attention to exploit spatial feature maps. The features are concatenated and fed into a 2D convolution to obtain frame-level spatial attention. To obtain the temporal attention, two 3D convolutional layers is applied with the frame spatial attention of previous step. The W3 attention module was integrated the ResNet50-based TSM [14].

The backbone CNN network plays a vital role in many recent action recognition systems. Martinez et al. [56] changes the last layers of the backbone network to improve the representation capacity. The important information is maintained in global feature branch. The global feature branch consists a global average pooling and a linear classifier. The average pooling aggregates the spatial and temporal information of the video. In the discriminative filter bank, the filters are includes 1×1 or $\times 1 \times 1 \times 1$ convolutions and global max pooling to compute the highest activation value. The third branch is local detail preserving feature branch. A bilinear upsampling operation are applied to double the resolution of the features. A skip connection is add from the features of stage 4. Two backbone networks (2D TSN [57] and inflated 3D [38]) were used to evaluate the proposed module with Something-Something-V1 [58] and Kinetics-400 [38]. The temporal modeling methods based on 3D CNN requires a large number of parameters and computations. Lee et al. [59] proposed VoV3D which is an 3D network with an effective temporal modeling module for temporal modeling. The module names temporal one-shot aggregation (T-OSA). The T-OSA use many 3D convolutions with different receptive fields. All the output features are concatenated and reduced dimension by a $1 \times 1 \times 1$ convolution. In addition, the authors proposed a depthwise spatial-temporal module which decomposes a 3D depthwise convolution into a spatial depthwise convolution and a temporal depthwise convolution for making a more light-weight and efficient network. Something-Something-V1, Something-Something-V2 [58], and Kinetics-400 [38] was used to evaluate.

Zhao and Snoek [60] proposed a single two-in-one stream network to reduce the complex computation of two stream network. The network processes both RGB and optical flow in a single stream. The most important contribution in this work is motion condition layer and motion modulation layer. The motion condition layer maps flow inputs to motion condition Ψ. Then, the motion condition Ψ is fed into the motion modulation to learn two affine transformation parameters (β, γ). These parameters are used to influence the appearance network as below formula $\mathcal{M}^2 (F^{rgb}) = \beta \odot F^{rgb} + \gamma$, where F^{rgb} is the RGB feature maps and $\odot$ is an element-wise multiplication operation. Instead of using deeply stacking convolution layers, Huang and Bors [61] proposed region-based nonlocal (RNL) to exploit long-range dependencies. The RNL operation is used to compute the relation between two positions based on their features and the neighboring features. The feature of each position is computed from all neighboring positions. The RNL operator is embed into a residual block as $z = yW_z + x$. In addition, the RNL block is combined with SE [62] block to exploit spatiotemporal attention and channel attention. Two backbone networks are used to implement the proposed RNL, including ResNet-50 [52] and temporal shift modules (TSM) [14]. The network was evaluated on Something-Something-V1 [37] and Kinetics-400 [38]. Furthermore, OmniSource [63] trains video recognition model using web data, such as images, short videos, and long videos. The methods train a 2D teacher network and a 3D teacher network to filter the the web data that have lo confidence scores. Hua et al. proposed a dilated silhouette convolutional network (SCN) [64] for human action recognition in video. The silhouette boundary curves of the moving subject are extracted, and then, the silhouette curves are stacked as a 3D curve volume. The curve volume is resampled to a 3D point cloud to represent the spatial and temporal information of actions.

2.4. Methods Based on 3D Multistream Network.
Multistream networks can exploit different types of features in human action recognition. Spatiotemporal and motion information are two important features of human action recognition. A two-branch network has two branches, including the RGB branch and flow branch. The RGB branch exploits the visual structure of scenes and objects, while the flow branch exploits the motion of objects. Many recent proposed methods use a 3D CNN to exploit spatiotemporal information and a flow stream to exploit motion information [24, 26, 38]. The two-stream network obtains state-of-the-art accuracy by using RGB and flow images as input. However, each stream is usually trained individually and the optical flow requires a heavy computation. Therefore, some approaches try to construct a two-stream network more efficiently [23, 65]. Figure 3 shows a two-stream network architecture that are used in many recent approaches.

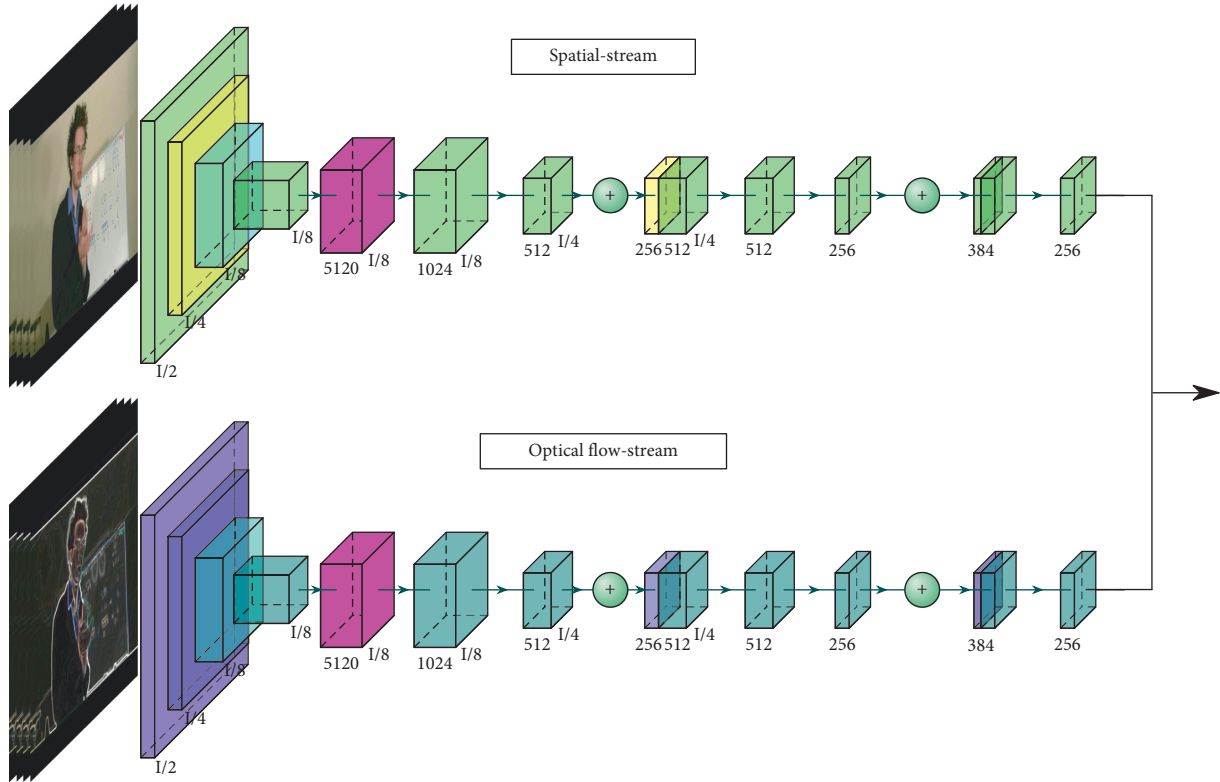
To pay different types of attention, a two-stream attention [26] was proposed using the visual attention mechanism. The network contains two streams. The first stream is the temporal feature stream which inputs an optical flow image sequence. An LSTM and a temporal attention are used to aggregate the information of the optical flow image. The second stream is a spatial-temporal feature stream. This stream uses an LSTM architecture to encode the


FIGURE 3: 3D two-stream network.

temporal relationship. The spatial features are extracted by some convolutions. Then, the spatial attention assigns an important location for the next step of feature generation and the temporal attention is used to focus the temporal frames. The method was evaluated on UCF11 [66], UCF Sports [67], and jHMDB [68]. An approach convert 2D classification networks into 3D ConvNets. The network is named as Two-Stream Inflated 3D ConvNets (I3D) [38]. They inflated all the filers and pooling kernels of the 2D architecture by enlarging a temporal dimension. To pretrain the 3D model on the ImageNet dataset, the authors converted an image into a video by copying it many times. The network has two streams. The first stream uses RGB inputs and the second one use flow inputs. The two networks are trained separately and the results are averaged. A two-pathway convolutional neural network [24] was proposed by Huang et al., namely Fine and Coarse. In the fine branch, motion information of raw input is extracted by a motion band-pass module. The extracted motion is fed into a backbone CNN [69] to learn the fine-grained motion features. On the other hand, the coarse branch is used to learn coarse-grained information. The raw frames are down-sampled and fed into a backbone CNN to exploit coarse-grained features. In order to merge the features from two branches, a lateral connection module was established. The proposed method was evaluated on Something-Something-V1 [37], Kinetics-400 [38], UCF101 [39], and HMDB51 dataset [40]. A combination of RGB, flow, pose, and pairwise stream [70] was proposed to improve the performance of the action recognition system. The network includes two branches. The first branch uses CD3 [71] and I3D [38] as backbone networks to extract spatial and temporal information. In the second branch, a pairwise stream learns the spatial relationship between the subject who perform the action and the surrounding objects. In addition, a pose stream inputs keypoint images. Keypoint images provide the connected key body parts of a person. The predicted results are obtained by using the late fusion method. The network was evaluated on UCF101 [39] and HMDB51 datasets [40].

Optical flow requires high computing. A proposed approach [23] mimics the motion stream using a standard 3D CNN. They introduced two learning strategies, namely Motion Emulating RGB Stream (MERS) and Motion-Augmented RGB Stream (MARS). In the first strategy, a flow network is trained to classify actions using optical flow clips. Then the MERS is trained to mimic the flow stream using only RGB frames. The last layer of MERS is trained by using the imitative flow features. In the second strategy, a flow stream (teacher) uses optical flow clips to train. Next, the teacher network is frozen its weight and MARS (student) is trained with RGB frames as input. Since only RGB frames are used as input in the testing phase, the network avoids the high computation of optical flow. The optical flow requires a high computation cost. Stroud et al. [65] introduced Distilled 3D Network (D3D) which obtained high performance without optical flow computation during inference. The D3D combines motion information in the temporal stream into the spatial stream. This leads the spatial to behave like the temporal stream. D3D trains two networks, including a teacher network and a student network. The teacher network

is a learned temporal stream of a two-stream network and the student network is a spatial stream. The knowledge of the teacher network is distilled into the student network during the training phase.

One of the problems of a two-stream network is to exploit the complementary information between two streams [25]. To solve this issue, Zhang et al. proposed a cross-stream network [25]. Two similar backbone networks are used to extract structure and motion features. Then, a cross-stream connection block is used to compute the correlation between the appearance and motion features. The classification scores are obtained by a classifier which inputs the extracted features of previous blocks. The cross-stream network is evaluated on UCF101 [39] and HMDB51 datasets [40] and Something-Something-V2 [58]. The most popular multimodality method fused its stream at the last stage of the model. A cross-modality [72] exchanges information between modalities in a more effective way. The proposed network has two branches. Instead of averaging the scores of the two branches, several cross modality attention (CMA) blocks are added after some stage of the network. The CMA matches a query of the first modality with key-value pairs of the second modality.

A very deep network [73] uses residual learning to encode spatial-temporal information human action recognition videos. The network, residual spatial-temporal attention network (R-STAN), includes two streams. Since the computation of optical flow has high cost, RGB Difference images are used to extract motion information. The RGB Difference images are computed by applying a element-wise subtraction operation between two frames. The network is constructed of many residual spatial-temporal attention blocks, including a residual block and a temporal and a spatial attention module. A feature map is processed as $M'(x) = M \odot A_T \odot A_S$, where M and M' are the input and output feature maps and A_T and A_S are the temporal and spatial attention, respectively. Two standard datasets (UCF101 [39] and HMDB51 [40]) was used to evaluate the proposed method. A proposed neural network [74] computed the local and global representations parallel. Therefore, the feature maps are processed in local path and global path. In the first path, the local features x_l are updated from x_{l-1} and global vector g_{l-1}. In the second one, the global vector is updated with local feature x_l. Next, they proposed a local and global combination classifier to make the final prediction by combining the local and global representations. Finally, they proposed two different local and global diffusion networks, namely LGD-2D and LGD-3D. The difference between the LGD-2D and LGD-3D is that the input of the first one is T noncontinuous frames while the input of the second is T consecutive frames. In addition, LGD-2D and LGD-3D use 2D convolution and 3D convolution, respectively. They evaluated on two datasets, namely Kinetics-400 [38] and Kinetics-600 [75]. They also experienced on two of the most popular video action recognition datasets UCF101 [39] and HMDB51 [40].

Instead of training different networks separately, Zhou et al. [76] constructed a probability space from which a spatial-temporal fusion strategy can be derived. The authors introduced spatial-temporal fusion strategies that obtained high performance on poplar datasets. To exploit the mutual correlations in the video, an attention mechanism [77] is used in the 3D convolutional network. The authors proposed a temporal and spatial attention submodule and then used these attentions to construct the temporal and spatial deformable 3D convolutional network. Both 3D convolutional networks can learn temporal and spatial information as well as static appearance. A proposed model [78] used pose information to predict actions. First, they used the PoseNet approach with ResNet backbone to obtain estimated pose keypoints for each human in a frame. The backbone network used is ResNet50 with a 3D version. They added a feature gating module and did not apply temporal downsampling in any layer of the backbone network to improve the performance. The authors tried to avoid training three models separately since the input included RGB, flow, and pose data. They proposed a multiteacher framework in which its input can be RGB, flow, or pose. They evaluated on three benchmark datasets, including Kinetics-600 [38], UCF101 [39], and HMDB51 [40],

2.5. Convolution-Free Approaches. The 2D network is very successful in capturing the spatial features. However, the motion information is still missed. 3D convolution network is used to encode spatial-temporal information in videos but it requires a high computation cost. Transformer was proposed for natural language processing and then adopted for computer vision. It does not require heavily stacked convolutions to encode information, such as in [27–30].

A convolution-free model [27] that requires a smaller number of frames for inference. The model is based on a self-attention mechanism for capturing both spatial and temporal information. The authors separate the spatial attention and the temporal attention to reduce the computation and exploit temporal information better. Each input frame ($H \times W$) of the network is split into nonoverlapping patches $N = HW/P^2$, where the size of each path is $P \times P$. Then, each patch representation is converted to query, key, and value vectors. To avoid expensive computation, spatial attention is applied between patches of the same image. The output representations of the spatial attention are applied to temporal attention. The proposed method was evaluated on Kinetics-400 [38]. They also reported the result on UCF101 [39].

To solve the heavy memory usage of the vanilla video transformer, a video transformer [28] was introduced to reduce the memory cost. The issue is solved by applying a spatial and temporal multihead separable-attention (MSA) sequentially $MSA(S) = MSA_s(MSA_t(S))$. Moreover, the authors solved the redundant information problem of the temporal dimension. Instead of using temporal average pooling or 1D convolutions with stride 2, they proposed a topK pooling which selects topK based highest standard deviation. They evaluated on 6 different datasets (Kinetics-400 [38], Kinetics-700 [79], Something-Something-V2 dataset [37], Charades [80], UCF101 [39], and HMDB51 [40]).

A convolution-free model is faster than 3D convolutional networks, namely, TimeSformer [30]. Each input

frame is split into N nonoverlapping patches same as in [27]. The spatiotemporal position of each patch is encoded by a learnable positional embedding $e_{(s)}^{pos} \in \mathbb{R}^D$. Each patch $X_{p,t}$ is mapped into an embedding vector $z_{(p,t)}^{(0)}$. The TimeSformer has L blocks and a set of query, key, and value vectors is computed from $\mathbf{z}_{(p,t)}^{(l-1)}$ for each block. In this study, the authors proposed a more efficient spatiotemporal attention. A temporal attention is applied, then, the output is fed into a spatial attention. The TimeSformer was evaluated on Kinetics-400 [38], Kinetics-600 [81], Something-Something-V2 datasets [37], and Diving48 [82].

Akbari et al. [29] introduced a convolution-free Transformer architecture, namely Video-Audio-Text Transformer (VATT). The input video clip is split into a sequence of $\lceil T/t \rceil \cdot \lceil H/t \rceil \cdot \lceil W/t \rceil$ patches. The position of each location (i, j, k) is encoded as $e_{i,j,k} = e_{\text{Temporal}_i} + e_{\text{Horizontal}_j} + V_{\text{ertical}_k}$, and Multi-Head-Attention applies the self attention on the input. Multilayer perceptron includes two dense linear projections with a GeLU activation. The common space projection contains a linear projection, and a two-layer projection with ReLU activation functions in between. The proposed method was evaluated on UCF101 [39], HMDB51 [40], Kinetics-400 [38], Kinetics-600 [75], and Moments in Time [83].

3. A Comparison of Methods

First, we compare recent methods on two benchmark datasets, including UCF101 [39] and HMDB51 [40]. These are the two most popular human action datasets that have been used to evaluate the performance of the proposed methods as shown in Table 2. We group the proposed methods by year. In 2019, the local and global diffusion network achieved the best result with 98.20% and 80.50% on UCF101 and HMDB51, respectively. Their network tried to learn local and global feature in parallel, and these features are diffused effectively. In 2020, Kalfaoglu et al. [22] obtained impressive results with 98.69% and 85.10% on UCF101 and HMDB51, respectively. The replacement of the conventional temporal global average pooling layer with the bidirectional encoder representations from the Transformers layer increase the performance of 3D convolutional neural networks. In 2021, a three-stream network obtained 99.00% on the UCF101 dataset. In this year, many approaches introduced a new model for human action recognition with a convolution-free architecture, such as VATT [29], VidTr [28], STAM [27], and TimeSformer [30].

Table 3 compares recent approaches on Something-Something-V1 and Something-Something-V2. TSM [84] is one of the most effective methods which obtains both high efficiency and high performance because it obtains the performance of a 3D network with the complexity of a 2D network. TSM uses a simple temporal shift module to exploit a temporal relationship with zero extra computation and zero extra parameters. It obtains 52.60% and 66.00% top-1 accuracy on Something-Something-V1 and Something-Something-V2, respectively. Another method TDN [51] obtained state of the art on the Something-Something-V1 and Something-Something-V2 with 56.80% and 68.20%.

TDN focus on capturing local and global motion for action recognition.

4. Benchmark Datasets

Benchmark datasets play a vital role in estimating the performance of proposed methods. The scope of the problem as well as a fairly comparison are provided by the dataset. For human action recognition, there is a wide range of benchmark datasets in common use. We briefly review the most well-known datasets and their information (size, average duration, action classes, and resolution) for human action recognition. These datasets are grouped into three categories such as simple, clip-level, and video-level. Table 4 provides a summary of these datasets.

4.1. Simple Datasets.
The two popular datasets which are most used with traditional methods are KTH [1] and Weizmann [2]. However, these datasets obtained absolute accuracy [102, 103] because the background is static and simple and one person performs an action in each video. Then, some more realistic datasets were proposed such as Hollywood [90] and Hollywood2 [91].

KTH [1] is a video dataset including 2391 videos. The dataset was performed by 25 different people in four different scenarios. The whole dataset (https://www.csc.kth.se/cvap/actions/) includes six human actions: walk, jog, run, box, hand-wave, and hand clap.

Weizmann [2] is a video dataset which was performed with nine people. Each participant performs 10 actions such as run, walk, jump, skip, jack, jump-forward, jump-in-place, side, wave-two-hand, and wave-one-hand. This dataset (http://www.wisdom.weizmann.ac.il/%20vision/SpaceTimeActions.html) includes 90 videos.

Hollywood [90] is a human action dataset taken from 32 movies. This dataset (https://www.di.ens.fr/%20laptev/download.html) has eight action classes with 233 training video samples and 211 testing video samples.

Hollywood2 [91] is a human action dataset with 3669 video clips. This dataset (https://www.di.ens.fr/%20laptev/actions/hollywood2/) includes 12 classes of actions and 10 classes of scenes with approximately 20.1 hours of video which is taken from 69 different movies.

4.2. Clip-Level Datasets.
The number of actions of previous datasets is small, and the actions are simple. Therefore, some datasets such as UCF101 [39], HMDB51 [40], and J-HMDB [68] were introduced to provide a higher variety of actions. However, the samples are short clips, and a single action is captured. Then, some large-scale datasets, such as Charades [80], Something-Something [37], Kinetics [54], Kinetics-600 [75], Kinetics-700 [79], Diving48 [82], Moments in time [83], HACS [93], HVU [48], and AViD [94], have been introduced. These datasets allow to train a deep convolutional neural network from scratch.

UCF101 [39] has 101 action classes and has split into five categories: human-object interaction, body-motion only, human-human Interaction, playing musical instruments,

Table 2: Accuracy of different methods on UCF101 and HMDB datasets.

Method	Year	Method	UCF101	HMDB
Carreira and Zisserman [38]	2017	Two-stream I3D	98.00	80.90
Zhou et al. [47]	2018	Mixed 3D CNNs, 2D CNNs	94.70	70.50

	AVA-kinetics [101]	2020	624,430	—	60	—

and sports. It includes 13320 clips and 1600 minutes of video data. All videos (https://www.crcv.ucf.edu/data/UCF101.php) are downloaded from YouTube and have a fixed resolution of 320 × 240.

HMDB51 [40] has 51 action categories with 6,766 video clips (https://serre-lab.clps.brown.edu/resource/hmdb-a-large-human-motion-database/) which are extracted from different sources. There are five types of action, including general facial actions, facial actions with object manipulation, general body movements, body movements with object interaction, and body movements for human interaction. The height of all the frames is 240 pixels. To maintain the original aspect ratio of the video, the width was scaled accordingly to the height.

J-HMDB [68] is extracted from the HMD51 dataset [40]. Not only a dataset for human action recognition but also the J-HMDB is provided for pose estimation and human detection. The dataset (http://jhmdb.is.tue.mpg.de/) contains 21 classes with 31,838 annotated frames. Each action has 36–55 video clips, and each clip includes 15–40 frames.

MPII Cooking [92] is a dataset of cooking activities. The dataset (https://www.mpi-inf.mpg.de/departments/computer-vision-and-machine-learning/research/human-activity-recognition/mpii-cooking-2-dataset) contains 65 different cooking activities which are performed by 12 participants. In total, the dataset has 44 videos with 9 hours in length.

Charades [80] is a dataset of casual everyday activities of 267 people in their homes. The dataset has 9,848 videos with an average length of 30 seconds. It includes 157 action

classes and is split into 7,985 videos for training and 1,863 videos for testing (https://prior.allenai.org/projects/charades).

Something-Something [37] includes 108,499 videos (https://20bn.com/datasets/something-something/v1) in V1 and 220,847 videos (https://20bn.com/datasets/something-something) in V2. Both versions have 170 action classes. The duration of a video is from 2 to 6 seconds. The dataset is divided into three parts, including training, validation, and testing set.

Kinetics [54] (Kinetics-400 [38]) has 400 human action classes, and each class has at least 400 video clips. All clips were taken from YouTube. The actions in the dataset are the human-object interactions or human-human interactions. The dataset (https://deepmind.com/research/open-source/kinetics) has 306,245 videos and is split into three parts for training, validation, and testing.

Kinetics-600 [75] is a large-scale, high-quality dataset. The dataset (https://deepmind.com/research/open-source/kinetics) was taken from YouTube with 500K video clips. It has 600 human action classes with at least 600 video clips for each class. The length of each clip is about 10 seconds.

Diving48 [82] has 48 classes of 48 different diving actions. The dataset (http://www.svcl.ucsd.edu/projects/resound/dataset.html) has 18,404 video clips which contain 16,067 clips for training and 2,337 clips for testing. All clips were taken without background objects and the scenes contain a board, a pool, and a spectator in the background.

Kinetics-700 [79] is an extension of the human action dataset Kinetics-600 [75]. The extended dataset (https://deepmind.com/research/open-source/kinetics) has 700 classes and was taken from YouTube. Each class of dataset has at least 600 video clips which have a variable resolution as well as frame rate.

Moments in time [83] is a human-annotated dataset with 339 different classes. This is a large-scale dataset with one million videos, and each video corresponds with an event occurring in three seconds. The dataset (http://moments.csail.mit.edu/) is split into 802,264, 33,900 and 67,800 videos for training, validation, and testing, respectively.

HACS [93] is a large-scale dataset for human action recognition. It contains 1.5M clips which are sampled from 504K untrimmed videos. All clips (http://hacs.csail.mit.edu/) in this dataset have a two-second duration with 200 action categories.

HVU [48] is a multilabel and multitask video dataset which aims to describe the whole content of a video. The dataset includes approximately 572K videos with real-world scenarios. This dataset (https://holistic-video-understanding.github.io/) is split into 481K videos for training, 31K for validation, and 65M for testing.

AViD [94] is a video dataset for human action recognition. The main difference of this dataset is that it is collected from many different countries. This dataset (https://github.com/piergiaj/AViD) contains 410K training clips and 40K test clips. The duration of each clip is from 3 to 15 seconds.

4.3. Video-Level Datasets. With the development of deep models, some large-scale datasets were introduced such as Sport1M [95]. However, this dataset only focuses on Sports actions. Recently, other action datasets have been introduced with larger samples and temporal duration such as ActivityNet [96], AVA [100], AVA-Kinetics [101], DALY [97], EPIC-Kitchens [99], MPII Cooking [92], and YouTube-8M [98].

Sport1M [95] includes 1 million YouTube videos. The dataset (https://cs.stanford.edu/people/karpathy/deepvideo/) contains 487 classes of sports. There are 1000–3000 videos in each class.

ActivityNet [96] is a benchmark dataset for human activity understanding. The dataset (http://activity-net.org/index.html) contains human activities in their daily living. With 849 video hours, ActivityNet provides 200 activity classes. Each class has an average of 137 untrimmed videos. Most of the videos have a duration between 5 and 10 minutes and a half of the video has a resolution of 1280×720.

DALY [97] is a dataset for action localization in space and time. The dataset (http://thoth.inrialpes.fr/daly/) lasts about 31 hours of YouTube videos with 10 everyday human actions.

YouTube-8M [98] is a multilabel video classification dataset. The dataset (http://research.google.com/youtube8m/) includes 8,264,650 videos. With 500,000 hours of video, YouTube-8M contains over 1.9 billion video frames and 4,800 classes.

EPIC-Kitchens [99] was recorded by 32 participants in their kitchens. The participants comes from 10 different countries. The dataset (https://epic-kitchens.github.io/2020-55.html) has 55 hours of videos which include 11.5M frames. The videos have a resolution of 1920×1080; however, there are 1% of the dataset was recorded at 1280×720 and 0.5% at 1920×1440.

AVA [100] is a video dataset in which theactions are assigned in space and time. In addition, each person in the video is annotated with multiple labels. This dataset (https://research.google.com/ava/) contains 437 different videos of realistic scenes and action complexities. Each video is taken from the 15th to 30th minute time and has 900 frames. It is divided into 239 videos for training, 64 videos for validation, and 134 videos for testing, roughly a $55 : 15 : 30$ split.

AVA-Kinetics [101] is an extension of the AVA dataset [100] with new videos from the Kinetics-700 [79] annotated with the AVA action classes. The AVA-Kinetics (https://research.google.com/ava/) has 238,906 videos which is split into 142,475 videos for training, 32,529 videos for validation, and 64,902 videos for testing.

5. Open Research Problems

In the previous sections, we discuss the recent proposed methods and benchmark datasets for human action recognition with RGB data video. In this section, we will introduce some of the potential research problems in this field.

Data for human action recognition RGB videos are widely used in most methods for action recognition because these data are very popular and acquired with a low cost. However, other types of data provide more information for action recognition, such as skeleton, depth, infrared sequence, and point cloud. Skeleton data provide the trajectories of human body joints. Depth and point cloud data capture 3D structure and distance information. Infrared data provide data in a dark environment. Therefore, we cannot exploit color or texture in infrared data.

Pose estimation detects the location of human body joints in images. The skeleton data provide the body structure and pose of the object; therefore, we have more information for human action recognition. The skeleton data are obtained by using pose estimation on RGB videos or depth data.

Combination of different data types, such as RGB data with depth data or skeleton data with depth data, provides rich information for learning models. The RGB video data provide spatiotemporal features while depth data provide the 3D structure and depth information. We also combine different features of different models to get better performance.

6. Conclusions

In this survey, we provided a review of recent deep learning-based methods for human action recognition with RGB video data. We categorized recent approaches into five different groups, including 2D CNN-based methods, RNN-based methods, 3D single-stream network-based methods, 3D multistream network-based methods and convolution-free-based methods. More recently, a pure vision transformer with a convolution-free network has shown to be effective for human action recognition and various fields of computer vision. Therefore, we discussed recent transformer-based methods. We compared the accuracy of recent methods on four popular datasets, including UCF101, HDMB51, Something-Something-V1, and Something-Something-V2. We also discussed a wide range of benchmark datasets for human action recognition that are used in recently proposed methods. Lastly, we provide some potential research directions for human action recognition.

Data Availability

The datasets generated during and/or analysed during the current study are available from the corresponding author on reasonable request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

As a market means to control nongreen behaviors of firms, the most expected incentive effect of the carbon emission trading system (CETS) is to achieve the dual economic and environmental effects. As a typical developing country, whether China's CETS has a positive incentive effect is significant to controlling greenhouse gas. Based on the quasinatural experiment of China's pilot policy on CETS in 2013, this study investigates its emission reduction and economic benefits using the difference-in-difference (DID) method. Then, the realization mechanism of CETS's incentive benefits is reversely studied with the idea that goals generate behavior. The results show that the following: (a) China's CETS has produced positive incentive effects of promoting both economic and emission reduction benefits. Furthermore, the results are still valid after using the instrumental variable to overcome the endogenous problem, placebo tests to eliminate sampling bias, and a series of robustness tests. (b) Further analysis shows that firms can choose to improve technology innovation and energy efficiency to get the positive incentive effects of CETS. (c) The incentive effects of CETS also have regional heterogeneity. The emission reduction and economic benefits are greater in provinces with deficient resource endowments and strict environmental law enforcement.

1. Introduction

Since the 21st century, climate warming has become a major obstacle to global sustainable development. Therefore, the United Nations proposed the carbon emission trading system (CETS) to regulate greenhouse gas emissions and alleviate the contradiction between ecological protection and economic development. According to "*Kyoto Protocol*," this market-oriented environmental regulation (ER) was first applied in developed countries. Since European Union (EU) launched the world's largest CETS in 2005, CETS has been widely recognized for its role in curbing greenhouse gas emissions and promoting economic development [1–3]. However, some scholars argued that CETS could fail to bring out its best incentive benefits due to the imperfect trading and management systems [4–6]. Therefore, current research still focuses on whether CETS can produce positive incentive

effects, especially how to produce and get the best incentive effects. Apart from developed countries, developing countries like China and India also need to reduce greenhouse gas emissions. After four decades of rapid economic growth, China became the world's second-largest economy in 2010. However, the rapid economic growth has also caused serious environmental problems. According to Carbon Brief, China emitted 10. 1 bn tons of CO_2 in 2018, the highest in the world, and 1.2 bn tons more than the sum of the US (5.4 bn tons) and the EU (3.5 bn tons). It can be seen that China plays a vital role in the world's economic and environmental problems. Studying the incentive benefits of China's CETS can provide substantial evidence for carbon reduction.

The research ideas of this article are as follows: Firstly, this study verifies whether China's CETS have positive incentive effects under the guidance of the new behavior theory. Secondly, the realization path is explored to obtain

positive incentive effects. Finally, the heterogeneity of incentive effects is analyzed to provide more accurate information for the effective implementation of CETS. The specific methods are as follows: Firstly, China's pilot policy on CETS in 2013 is used as a quasinatural experiment to analyze its emission reduction and economic benefits using the DID method. CO_2 emissions and total factor productivity (TFP) are used to represent the emission reduction benefits and economic benefits, respectively. Dynamic benefits analysis, instrumental variables, counterfactual test, placebo test, and other methods are used to test the robustness of the constructed econometric model. That is, to test whether the emission reduction benefits and economic benefits of the pilot policy on CETS are still significant after overcoming endogeneity, policy implementation time, and selection bias of pilot areas. Secondly, the mediation model is used to examine whether CETS's positive incentive effects can be achieved through technological innovation and energy efficiency. Finally, grouping regression is adopted to investigate CETS's incentive effects heterogeneity.

The marginal contributions of this study are as follows: (a) This study applies behavior theory to the research of ER. The role of China's market regulation is investigated from the perspective of the incentive effect. The realization path of incentive effect is discussed with the idea that goals generate behavior. This study provides a new vision for the formulation and implementation of ER. (b) This study includes emission reduction and economic benefits in a unified research framework. In the context of China, a more comprehensive evaluation of CETS's policy benefits is made. The ability of CETS to balance the environment and economy in developing regions is tested, which provides evidence for the decrease of greenhouse gas. (c) The empirical analysis based on the quasinatural experiment and DID avoid endogenous problems such as missing variables to a certain extent. However, it still could not eliminate the interference of regional characteristics that changed over time. Therefore, this paper further tests the robustness of the empirical results through instrumental variables, counterfactual test, and placebo test. It provides scientific evidence for studying emission reduction benefits and economic benefits of CETS.

The article is organized as follows. Section 2 presents the literature review. Section 3 analyzes the institutional background and theory. Section 4 discusses the results of the empirical research. Section 5 presents the results of the mechanism analysis. Section 6 presents highlights conclusions and the scope of future work.

2. Literature Review

2.1. Research on the Benefits of ER.
The relationship between ER and economics is controversial in academia. The neoclassical economic theory supports the view that ER internalizes pollution as cost and transfers resources from production to environmental protection [7, 8]. Therefore, the firms' production efficiency may regress in the short term [9]. However, economists represented by Porter raised objections. Porter and van der Linder [10] proposed the Porter hypothesis, which elaborates that strict and

appropriate ER can generate higher productivity through innovation. The hypothesis has been widely discussed. Lanoie et al. [11] and Peuckert [12] believed that the positive effects of ER through environmental technology could offset the short-term cost and ultimately benefit production efficiency. Testa et al. [13] found that more flexible ER significantly increased R&D investment and eventually improved firms' production efficiency. Using the steel industry data, Liu et al. [14] proved that economic incentives significantly boosted firms' profitability. Using panel data of 17 manufacturing industries, Rubashkina et al. [15] found that productivity increased only in industries under ER. With the increasing international status of China, scholars pay more attention to the environmental and economic benefits of ER in the context of China. Li et al. [16] found that the promotion effects of China's ER on production efficiency is only significant in the eastern provinces. Li and Chen [17] studied the promotion effects of China's air pollution prevention and control law on TFP by DID model. Wang and Liu [18] proved an inverted N relationship between China's ER and TFP.

2.2. Research on CETS.
Research on CETS focus on policy effects. They generally use developed countries as data sources. Scholars believed that CETS has positive policy effects. Anderson et al. [19] confirmed the emission reduction effects of EU's CETS in the manufacturing industry and firms participating in CETS are more likely to implement green technology innovation. However, some scholars believe that the policy effects of CETS are limited. Hoffmann [20] compared the emission reduction effects of the 2008 economic crisis and the CETS, and the results showed the former were far greater than the latter. Borghesi et al. [21] conducted an empirical study based on Italy's manufacturing industry and found that overly loose allocation of carbon quota limited the policy effects of the EU CETS. While China's CETS has a short running time, its emission reduction and economic benefits are unclear. Findings of the emission reduction benefits are inconsistent. Li and Zhang [22] proved that China's pilot policy on CETS significantly suppressed carbon emissions using industrial data. However, affected by the heterogeneity of objects, carbon quota, carbon price, and regional policies, the emission reduction benefits of CETS are not always significant [23, 24]. Findings of the economic benefits are also controversial. The empirical results from Liao et al. [25] suggested that the CETS generated green economic benefits by stimulating green innovation. Wang and Wang [26] found that China's CETS did not significantly affect the economic benefits measured by per capita GDP.

3. Institutional Background and Theoretical Analysis

3.1. Institutional Background.
CETS can be traced back to the "*Kyoto Protocol*" in December 1997. The protocol proposed a market-based approach to greenhouse gases, known as CETS. It also advocated that all signatories should reduce

emissions, but developed countries are greater than developing countries. Since then, developed countries, such as the UK, Germany, the EU, and Australia, have successively launched CETS, which means that CETS has changed from concept to practice. The EU CETS is the largest CETS in the world, who completed 80% of the global carbon trading volume. Furthermore, California and Tokyo have also established regional CETS. The existing CETS control local greenhouse gases and provide experience for the global CETS.

China needs to reduce emissions without harming the economy as a developing country. Therefore, the Chinese government has been committed to CETS in recent years. In October 2011, the Chinese government announced that CETS would pilot in seven regions, including Guangdong Province, Hubei Province, Beijing, Shanghai, Tianjin, Shenzhen, and Chongqing. From June 2013 to April 2014, the CETS was launched in seven pilot regions. Since then, the regional governments have continuously improved the supporting facilities of CETS, such as incentives and punishment system, cross-regional trading system, and offset system. At the same time, policies such as carbon mortgage, carbon finance, carbon funds, and carbon bonds have continuously strengthened the capital attributes of carbon emission rights. In December 2017, China began planning the national CETS. On July 16, 2021, the national CETS officially launched online trading. On the first day, the trading volume reached 4.1 million tons, with a turnover of 210.2 million yuan. So far, China's CETS has completed the spread from pilots to the entire nation. Although the national CETS only covers the power industry, it will radiate to electrolytic aluminum, cement, steel, petrochemical, chemical, papermaking, aviation, and other sectors in the future. At that time, the national CETS is expected to become the largest CETS in the world.

3.2. Theoretical Analysis. CETS is a market-based ER used to control nongreen behaviors of firms. New behaviorism theory holds that behavior depends not only on the perception of stimuli but also on behavior results. Similarly, whether firms can participate in CETS more actively depends on whether CETS has positive incentive effects. The Coase theorem emphasizes the property and market rules. The former makes public resources commodities, and the latter restrains participants' economic behavior [27]. CETS exerts incentive effects through the financial means of carbon emission trading. High-carbon firms can purchase carbon quotas to waive penalties for nonviolations. Low-carbon firms can sell carbon quotas to get additional economic benefits. In the end, a high level of emission reduction benefits can be achieved at a low economic cost. Moreover, Porter hypothesis argues that strict and flexible ER can promote economic growth while controlling pollution [10]. As an essential market-based regulatory tool, CETS uses market prices as a signal to enable firms to have higher flexibility [28]. Firms with more flexibility are more likely to increase productivity to alleviate and offset the additional costs of ER. Therefore, this article believes that CETS

ultimately produces positive incentive effects. That is, CETS has significant emission reduction benefits and economic benefits.

According to behaviorism theory, to achieve the dual effects of economy and emission reduction, the behavior adopted by firms must be conducive to both economy and environment, namely, green behaviors. This article analyzes the path of CETS to achieve positive incentive effects from two common green behaviors, as shown in Figure 1.

(1) CETS achieves economic and emission reduction benefits by promoting technological innovation. Because innovation has the characteristics of a long cycle, considerable investment, and high risk [29], whether a firm innovates depends on the external incentives it receives [21]. The analysis of CETS's policy benefits through technological innovation is as follows. (a) The surplus carbon quotas can be sold or used to offset the cost of violations. At this time, CETS provides firms with continuous and dynamic economic incentives. (b) CETS provides firms with market information about technological improvement, thereby reducing the uncertainty of technological innovation [30]. (c) CETS could increase firms' environmental and production costs as a legal pressure. As the pursuer of profit, firms' motivation to reduce cost by improving production technology will increase. Therefore, CETS can promote technological innovation and ultimately achieve economic and emission reduction benefits.

(2) CETS achieves emission reduction and economic benefits by improving energy efficiency. China's pilot policy on CETS adopts means of total control. First, the total quotas of national carbon emissions are determined, and then, certain carbon quotas are allocated to specific firms. If firms emit more than their quotas, they need to buy quotas from the carbon market or face default penalties. (a) Carbon emissions mainly come from the combustion of energy. The most direct means of emission reduction is to reduce energy consumption [31]. Nevertheless, this crude means greatly damage the economy [32]. Improving energy efficiency means using less energy with the same output, reducing carbon emissions without sacrificing the economy. (b) CETS make carbon quotas rare commodities. It makes capital flow to energy-saving industries, conducive to improving energy utilization efficiency [33]. Therefore, CETS is conducive to energy efficiency and ultimately to reduce CO_2 emissions and improve TFP.

4. Variables and Models

4.1. Variables

(1) CETS. China's pilot policy on CETS is an independent variable, represented by the dummy variable *TIME × TREAT. TIME* is a time dummy variable bounded by 2013 when the pilot policy started. The value is 0 from 2008 to 2012 and 1 from 2013 to 2017.
Figure 1: Theory frame.

Treat is a grouped dummy variable assigned to 1 if the province belongs to the pilot area and 0 otherwise. Among the seven pilot areas of CETS (Guangdong, Hubei, Beijing, Shanghai, Tianjin, Chongqing, and Shenzhen), Shenzhen is a city in Guangdong Province with a different administrative level from the other pilot areas, and its various data are a part of the Guangdong data. In addition, this article takes 30 provinces as samples for research. Therefore, the pilot areas mentioned in the subsequent study are Guangdong, Hubei, Beijing, Shanghai, Tianjin, and Chongqing.

(2) Emission reduction benefits. The emission reduction benefits measured by CO_2 emissions is a dependent variable, and the data come from the author's calculation. CO_2 mainly comes from the combustion of fossil energy. Therefore, the calculation of CO_2 emissions usually uses energy consumption data, as shown in formula (1). Carbon emission factor provided by IPCC (as shown in Table 1).

$$CO_2 = \sum_{j=1}^{7} E_j \times NCV_j \times CEF_j, \qquad (1)$$

where, CO_2 represents CO_2 emissions, and j represents seven kinds of energy: coal, coke, gasoline, kerosene, diesel, fuel oil, and natural gas. E is energy consumption, NCV represents net calorific value, CEF represents carbon emission factor.

(3) Economic benefits. Economic efficiency measured by TFP is another dependent variable. DEA-Malmquist calculates this index based on provincial data. (a) Capital input. "Permanent inventory" is used to estimate capital stock. Firstly, according to Zhang et al. [34], the total fixed capital formation is selected as the investment indicator for the current year. Then, the actual investment with

the constant price in 2000 is calculated through the investment product price index. Finally, the capital stock in 2008 is calculated according to Wang and Yan [35]. It can be referred to Wang et al. [36] to select the depreciation rate of each province. (b) Labor input. The number of employees is adopted as the labor input. (c) Energy input. Energy consumption is used to measure energy input. (d) Output. The real GDP with 2000 as the base period is selected as output.

(4) Control variables. Referring to Timothy et al. [2] and Akhmat et al. [31], the following variables are selected as control variables: the level of the service industry, optimization of industrial structure, level of foreign capital utilization, level of opening up, and level of education. The specific content is shown in Table 2.

4.2. Econometric Model. In order to test the emission reduction and economic effects of CETS, this paper constructs the DID model shown in formula (2).

$$Y_{it} = \alpha_0 + \alpha_1 \left(TIME_t \times TREAT_i \right) + \beta X + \gamma_t + \mu_i + \varepsilon_{it}, \qquad (2)$$

where, i is the province, and t is the year. Y represents dependent variables, i.e., CO_2 emissions and TFP. $TIME \times TREAT$ is the dummy variable representing China's pilot policy on CETS. The coefficient α_1 is the emission reduction and economic benefits of CETS concerned in this article. X is the vector of control variables. γ is the time fixed effects, which controls the common time factors of all samples, such as business cycle, monetary policy, macroeconomic shock, and fiscal policy. μ is the individual fixed effects that control the characteristics of each sample that do not change with time, such as geographical characteristics, climate, and resource endowment. ε is the random error term.

TABLE 1: Carbon emission factors of IPCC.

Energy types	Coal	Coke	Gasoline	Kerosene	Diesel	Fuel oil	Natural gas
NCV (kj/kg)	20908	28435	43070	43070	42652	43070	38931
CEF (kg/tj)	95333	107000	70000	71500	74100	77400	56100

TABLE 2: Variable design and description.

Variable types	Variable name	Code	Measure index
Independent variable	CETS	TIME × TREAT	China's pilot policy on CETS since 2013
Dependent variable	Emission reduction benefits	CO_2	CO_2 emissions
	Economic benefits	TFP	Total factor productivity
Control variable	Level of service industry	SI	Value-added service industry/GDP
	Optimization of industrial structure	OIS	Value-added tertiary industry/value-added secondary industry
	Level of foreign capital utilization	FDI	Actual utilization of FDI/GDP
	Level of opening up	OPEN	Total export/GDP
	Level of education	EDU	Total population of high school and above/total population at year end
Mediator variable	Technology innovation	TI	Turnover in the technology market
	Energy efficiency	EE	Total energy consumption/GDP

Note: the original data came from China Statistical Yearbook and China Environmental Statistical Yearbook. The data of TFP and EE were calculated by the authors.

5. Results and Discussions

5.1. Parallel Trend Analysis. The trends diagram of CO_2 emissions and TFP in pilot and nonpilot provinces are plotted in Figure 2. The emission reduction and economic benefits of pilot policy on CETS can be elementarily judged from the diagram. (a) CO_2 emissions in nonpilot provinces are higher than that in pilot provinces. In 2008–2012, CO_2 emissions in pilot and nonpilot areas showed an upward trend. After 2012, CO_2 emissions in nonpilot areas changed slightly but remained on the rise, while CO_2 emissions in pilot provinces showed a clear downward trend. (b) TFP in pilot provinces is higher than that in nonpilot areas. Before 2013, TPF in pilot and nonpilot provinces showed an upward trend. After 2013, the TFP growth of pilot provinces has increased, while nonpilot areas have shown a downward trend. Therefore, this article preliminarily speculated that compared with nonpilot areas, the decrease of CO_2 emissions, and the increase of TFP in pilot provinces might be caused by the pilot policy on CETS in 2013.

5.2. Results of Benchmark Regression. The results of CETS's emission reduction and economic benefits are shown in Table 3. The coefficients of CETS's emission reduction and economic benefits are −0.189 and 0.346, respectively, significant at 1%. After adding control variables, columns (3) and (4) are the results. The regression results change slightly, but the sign and significance remain the same, which shows that the regression results are stable. The above results indicate that China's pilot policy on CETS has produced significant emission reduction and economic benefits. This study refutes the view of foreign scholars such as Allen et al. [37] that all marketization mechanisms in China are invalid.

It is conducive to dispel the skepticism about China's marketization reform. As the central government's environmental and economic reform, CETS has political advantages in government guidance and market leadership. CETS provides an important direction for China to achieve green development through market-oriented means, under the dual pressure of environmental and economic.

5.3. Analysis of Dynamic Effects. The results of the benchmark regression only reflect the average emission reduction and average economic benefits of the pilot policy. In order to achieve the dynamic effects in CETS's emission reduction and economic benefits, a measurement model with reference to Jacobson et al. [38] is shown in formula (3), where φ represents a series of estimates for 2013–2017. $TIME_{2013}$ is assigned as 1 in 2013 and 0 in other years. Similarly, $TIME_{2014}$, $TIME_{2015}$, $TIME_{2016}$, and $TIME_{2017}$ take 1 in 2014, 2015, 2016, and 2017, respectively, and 0 in other years. Other variables are defined following formula (2).

$$Y_{it} = \varphi_0 + \sum_{t=2013}^{2017} \varphi_t \left(TIME_t \times TREAT_i \right) + \phi X + \gamma_t + \mu_i + \varepsilon_{it}. \tag{3}$$

Table 4 reports the results of dynamic analysis. It can be found that the absolute value and significance of $TIME \times TREAT$ gradually increase after the implementation of the pilot policy. It shows that the emission reduction and economic benefits of China's pilot policy on CETS increase with time. The possible reasons are as follows. CETS converts firms' emission reduction achievements into economic benefits through the carbon market. The longer the policy is

implemented, the more complete the market construction will be, and the more emission reduction and economic benefits will be produced.

5.4. Results of Instrumental Variable.
DID can subtly overcome the endogeneity by comparing treat and control groups, but this requires that the pilot areas be chosen randomly. However, this is not the case. The pilot work is not easy because the pilot policy is of great significance, and there are specific requirements for carbon trading technology and supporting measures. It is not completely random when the government determines pilot areas. That is to say, the estimation results of the DID may be disturbed by potential factors. Therefore, drawing on Hering and Poncet [39], the instrumental variable is used to overcome the endogeneity as much as possible.

Instrumental variables need to be related to endogenous variables and not associated with the stochastic disturbance team. CETS aims to stabilize temperature by reducing carbon emissions. Temperature is affected by region and climate and is an exogenous factor. Therefore, referring to the practice of Hu and Ding [40], the annual average temperature is taken as an instrumental variable of the pilot policy on CETS. Temperature data comes from each province's statistical yearbook and China meteorological yearbook. The two-stage least square is used for regression.

After adding the instrumental variable, the results are shown in Table 5, where *IV* represents the instrumental variables. In the regression results of the first stage, the coefficient of $TIME \times IV$, the cross product of the instrumental variable and the time grouping variable, is significantly positive. It shows that the higher the temperature, the stricter the CETS is. The results of the weak instrumental variable show that the F value is 24.110, much higher than 10, rejecting the hypothesis of weak instrumental variables. In the regression results of the second stage, $TIME \times TREAT$, the pilot policy on CETS, still has significant inhibition effects on CO_2 emissions and significant promotion effects on TFP. The results indicate that the pilot policy on CETS still shows significant emission reduction and economic benefits after eliminating endogenous problems. That is, the results of the DID model are not caused by the bias in sample selection.

5.5. Results of Robustness Tests

(1) To replace the dependent variable, CO_2 emissions and TFP are replaced by pollutant emissions (*PE*) and GDP per capita (*PGDP*), respectively. Pollutant emissions are represented by the normalized indexes of total wastewater, exhaust gas, and general industrial solid waste production. Formula (2) is used for regression, and the results are shown in Table 6. The coefficient of pollutant emissions is still significantly negative, and the coefficient of economic benefit is still significantly positive. It suggests that the emission reduction and economic benefits of CETS do not depend on measures of dependent variables.

(2) To change the regression method, tobit method is adopted to conduct regression analysis on formula (2) again, and the results are shown in Table 7. The pilot policy on CETS has a significantly negative impact on CO_2 emissions and a significantly positive impact on TFP, consistent with the research results above. It shows that the regression method will not affect the estimation results. This result supports the robustness of the econometric model.

(3) Dynamic window test. The dynamic effects of CTES's emission reduction and economic benefits have been analyzed above. However, it only focused on changes after policy implementation and could not compare the differences before and after implementation. Therefore, dynamic window tests are carried out based on Shi and Li [41]. In addition to dynamically analyzing benefits gaps, this test can also test whether the DID model is affected by time horizons. Specifically, with 2013 as the time node of the policy introduction. One year, two years, three years, and four years are selected as the time window width to re-regress formula (2). The test results are shown in Table 8. The effects direction of CETS on CO_2 emissions and TFP does not change with the change of time window width. As the width of the time

window increases, the significance of the coefficients of emission reduction and economic benefits keeps improving. It is consistent with the results of dynamic effects analysis.

(4) Counterfactual test. The premise of DID is that the treatment and control groups are comparable. A year before the implementation of CTES is taken as the assumed impact point. If the assumed impact point coefficient is significant, there are significant differences between the experimental and control groups before implementing CETS. That is, the empirical model constructed in this article is not robust. On the contrary, if the coefficient is not significant, there is no significant difference between the experimental and control groups before implementing CETS. The difference between the two in the benchmark regression is caused by implementing CETS. The DID model constructed in this article is robust. In order to test this premise, referring to Hung et al. [42], the policy starting time of 2009, 2010, and 2011 is assumed as respectively, and formula (2) is used for regression. The results are shown in Table 9. The coefficient of $TIME \times TREAT$ is not significant when the start time is advanced to 2009, 2010, and 2011, respectively. It indicates that before the base year, the pilot policy of CETS cannot produce emission reduction and economic benefits. In other words, the actual policy year can indeed significantly reduce CO_2 emissions and improve TFP. Therefore, the previous conclusion has strong robustness.

(5) Placebo test. To further exclude the influence of unknown factors on the selection of pilot provinces and to ensure that the conclusions in this study are caused by the pilot policy on CETS, a placebo test is performed by randomly assigning pilot provinces [43]. In this article, 6 provinces are randomly selected as pilot areas of CETS from 30 provinces, and the other provinces are nonpilot areas. The placebo test should ensure that $TIME \times TREAT$, the independent variable, has no impact on CO_2 emissions and TFP. In other words, any significant findings will show that the results of this article are biased. 1000 random samples are taken using formula (2). The distribution of 1000 coefficients, and their *P* values are plotted in Figure 3. It can be seen that the distribution is mostly concentrated near the zero point, and the *P* value of most coefficients is bigger than 0.1. Therefore, the conclusions obtained in this article can pass the placebo test. The emission reduction and economic benefits of the pilot policy on CETS have no relationship with other unknown factors.

(6) To exclude the impact of other policies. In 2007, the Chinese government launched a pilot policy on emissions trading systems in 11 provinces, including Tianjin, Hebei, Shanxi, Inner Mongolia, Jiangsu, Zhejiang, Henan, Hubei, Hunan, Chongqing, and Shaanxi. Studies have shown that the policy also

contributes to the reduction of pollutant emissions and the improvement of TFP. In order to identify the effects of CETS accurately, it is necessary to exclude the interference of similar policies. In addition, reward and punishment policies related to energy-saving technologies are also important factors affecting economic and environmental benefits. China's Ministry of Finance stated in document No.7 in 2016 that the central finance would continue to allocate funds to reward new energy technology-related issues from 2016 to 2020. Therefore, formula (2) is used for re-regression after removing policy cross-region and cross-time samples. The results in

Table 10 show that the coefficients of the two interaction terms are significant at the 1% level, and the influence direction of the CETS on these two dependent variables does not change. It indicates that the results are still robust after excluding the interference of other policies.

6. Further Analysis

6.1. Analysis of Mechanism. The above results show that China's pilot policy on CETS has positive incentive benefits. However, what behaviors should firms take under the stimulation of CETS to get positive incentive results? In

order to verify the role of technological innovation and energy efficiency, the mediation model as shown in formulas (4) and (5) is constructed. The significance of the interaction terms' coefficient in formula (4) and the mediating variables' coefficient in formula (5) are the focus, where, *MEDIATOR* represents the mediating variable, namely, energy efficiency (*EE*) and technological innovation (*TI*). Other variables are defined as formula (2).

$$MEDIATOR_{it} = \theta_0 + \theta_1 \left(TIME_t \times TREAT_i\right) + \lambda X \\ + \gamma_t + \mu_i + \varepsilon_{it}, \quad (4)$$

$$Y_{it} = \delta_0 + \delta_1 \left(TIME_t \times TREAT_i\right) \\ + \delta_2 MEDIATOR_{it} + \eta X + \gamma_t + \mu_i + \varepsilon_{it}. \quad (5)$$

The three-step method is used to test whether the mediating effects are significant. Firstly, the impact of CETS on CO_2 emissions is significantly negative, and the impact on TFP is significantly positive (Table 3). Secondly, the effects of CETS on the mediating variable are tested. The results are significantly positive, as shown in columns (1) and (4) of Table 11. Finally, the effects of mediating variables on CO_2 emissions and TFP are tested, respectively. As shown in Table 11, technological innovation and energy efficiency have a significantly negative impact on CO_2 emissions and a significantly positive impact on TFP. Therefore, it can be concluded that CETS can stimulate firms to improve technological innovation and energy efficiency to obtain positive incentive effects.

6.2. Analysis of Heterogeneity

(1) Resource endowment. According to the resource curse hypothesis, regions with abundant resources have greater cost advantages. Therefore, they are not sensitive to the compliance cost pressure and the economic

incentives of CETS. Conversely, firms in poor resource endowment areas face higher illegal costs. They are more likely to gain additional economic benefits through carbon trading to cover environmental costs. A comprehensive index of the stock of 16 mineral resources, such as oil, natural gas, and coal, is used to measure the resource endowments of each province. The sample is divided according to the resource stock in 2012, one year before implementing the pilot policy on CETS. The provinces with resource stock higher than the average are defined as resource-rich provinces. The provinces with resource stock lower than or equal to the average are defined as resource-deficient provinces. In order to test the heterogeneity of the incentive effects of CETS under different resource endowments, formula (2) is used to regress the two samples separately. As shown in Table 12, CETS's emission reduction and economic benefits are greater in resource-deficient provinces than in resource-rich provinces. It suggests that the policy effects of CETS are also affected by the resource curse.

(2) Environmental law enforcement. The implementation of CETS needs a solid legal system, such as collecting carbon emission information and the punishment of noncompliance with trading rules. In order to protect local interests, some local officials allow polluters to discharge carbon emissions illegally, which leads to the failure of carbon emission trading. Tu and Chen [44] argued that strict environmental enforcement is necessary for China's market-oriented ER to achieve Porter's benefits. In theory, the greater the intensity of environmental law enforcement is, the higher the illegal cost is. There will be fewer violations, such as leakage and nonperformance. Also, firms are more likely to follow CETS. The sample was divided by the number of environmental administrative penalty cases in each

province in 2012 (the year before the policy was implemented). Provinces with lower than the mean are defined as lax provinces, while those with higher or equal to the mean are defined as strict provinces. In order to test the heterogeneity of the incentive benefits of CETS under different environmental law enforcement, formula (2) is used to regress the two samples separately. The results in Table 13 show that the positive incentive effects of CETS are greater in provinces with strict environmental law enforcement. It indicates that the effective enforcement of China's CETS needs the support of local governments, especially environmental law enforcement departments.

7. Conclusion

Taking China's pilot policy on CETS in 2013 as a natural experiment, a DID model was constructed to control the potential endogenous problems. Under the guidance of

behavioral theory, a comprehensive study was conducted on the emission reduction benefits and economic benefits of China's CETS. The conclusions are as follows. (a) China's pilot CETS has produced significant emission reduction benefits and economic benefits. The results persisted after a series of robustness tests, including instrumental variable test, dynamic window test, counterfactual test, and placebo test of random sampling. (b) China's CETS can reduce CO_2 emissions and improve TFP through technological innovation and energy efficiency. (c) The results of heterogeneity analysis show that resource-deficient provinces and provinces with strict environmental law enforcement are more sensitive to CETS and have greater emission reduction and economic benefits.

Future research could focus on the following aspects. (a) Future research can investigate the impact of CETS on energy efficiency, industrial structure, and firm strategy to explore the firm's other responding behaviors to CETS. (b) Consumers are part of greenhouse gas emitters, and the following researchers can include them when formulating a more comprehensive carbon reduction policy system.

By taking the 16 cities in Anhui Province for evaluation, the main influencing factors and indicator system for integrated urban-rural development in the new era were explored, to build the BCC model, cross-efficiency model, and game cross-efficiency model of DEA. The above models were applied for empirical analysis and comparative study on the rural revitalization and urban-rural integration efficiency in Anhui Province, to summarize the conclusions efficiency and give suggestions based on the above calculations.

1. Introduction

City and countryside serve as two important constituents in social life, and the whole society's prosperity and development rest upon the sustainable development of these two parts. Rural revitalization and urban-rural integration supplement each other, so the study on their intrinsic logical relation shall be aimed at the complexity and dynamics of urban-rural regional system and exploring the construction plan, mode, and scientific method for eliminating urban-rural gap [1].

In September 2018, the issuance of the Plan for the Rural Revitalization Strategy (2018–2022) marked that rural revitalization stepped into the specific implementation stage and became the focus of attention of domestic scholars. Chinese government provides its scholars with the research direction of rural revitalization through land reform, socialism market system reform, and development of the beautiful village and modern agriculture [2]. Rural revitalization aims at establishing the system and mechanism for integrated urban-rural development and constructing the comprehensive development system for rural area, including the reformation, reconstruction, and innovation according to the requirements of thriving enterprises, pleasant living environment, convenance, civilized and effective governance, and prosperity.

Therefore, the urgent problem for rural revitalization is to objectively recognize the differences between urban living quality and rural living quality and identify the urban-rural integration degree, which is of important guiding significance to improving the living quality in urban and rural areas and promoting the formulation of the policies for integrated urban-rural development [3].

2. Current Situations of Domestic and Overseas Research

Along with the development of globalization and urbanization, different countries and regions are all faced with various problems and conflicts. Foreign countries mainly took the following policies for rural revitalization:

New Countryside Movement in South Korea, Comprehensive Village and Town Construction Demonstration Project in Japan, European Common Agricultural Policy (2014–2020), Japan's agricultural support policy and the study on rural economic development in Italy.

Rural-urban fringe zone refers to the transitional area combining the factors. As the border of urban expansion and the reserved land in rural area, rural-urban fringe zone has to solve the problem of urban-rural land use, which results in traffic jam, environmental pollution, and living quality degradation. Therefore, in order to effectively present the microdynamic development of the marginal area between city and countryside, it is necessary to guide the effective use of land. In Herberholz's opinion, urban-rural relationship is fundamental in the social development of human beings and also important to be solved in regional development [4]. Lysgard believes that theoretically, there are three main trends in the development of rural-urban relations: urban orientation, urban-rural interaction, and rural orientation [5]. Schmidt and Piloyan considered that the land element in the transitional area is one of the key points of the research by foreign scholars [6, 7]. Hachem successively proposed the concept of mixed community, which was strongly recommended and applied in the construction of modern integrated urban-rural development. It is used to promote the local economy by encouraging unity, supporting network, enhancing safety, and creating job opportunities [8].

The urban-rural dual structure gives priority to urban development, and labor force, resources, and capital are input for urban construction, resulting in a series of problems, such as village hollowing, environmental pollution, weakening of agriculture. Urban and rural areas are an interactive organism, and they are contradictory, coordinated, integrated, and equivalent, so rural revitalization is the only road for urban-rural integration.

Zheng et al. believe that pluralities of fields are covered for implementing rural revitalization strategy, including social governance, industrial development, and rural civilization, and all stakeholders shall develop top-level policy design for the rural revitalization strategy. We can really promote the integrated urban-rural development only by changing the development concept, allocating production factors efficiently, and optimizing the economic structure [9]. Li and Bo consider that it is necessary to put forward the overall plan for "development in five areas," seeking the inherent thought train for realizing the urban-rural integration [10]. Zhang and Zhao elaborate the basic frame of urban-rural integration from the consistency among objectives, essence, and space of rural revitalization strategy and integrated urban-rural development and put forth the result-based common development [11]. Li believes that the key to rural revitalization lies in urban-rural integration which is the objective law and also the effect form coping with risks and crises. Either-or thinking is not applicable to rural revitalization and urbanization; overall planning must be made for development in the process of promoting the rural revitalization strategy to realize integrated urban-rural development [12].

3. Research Methods, Data Source, and Index Construction

3.1. Research Methods. It analyzes the process and effect of rural revitalization and integrated urban-rural development by comprehensively applying the theory and method of system science and management. It analyzes indexes systemically with methods of statistics and operational research and builds scientific evaluation models and path selection models with data mining and mathematical modeling to provide a theoretical basis for path selection of rural revitalization and integrated urban-rural development.

3.2. Data Source and Index Construction. In this paper, the data are mainly from Anhui Statistical Yearbook, and the urban-rural integration is comprehensive and analyzed from the spatial arrangement, industry configuration, income gap, public service, and ecological environment. It makes crossover analysis on rural revitalization and urban-rural integration and finds their intersection combining with the statistical index of Anhui Statistical Yearbook. The analysis is detailed in the following Table 1.

In the table, $X1$ indicates the ratio between nonagricultural workers and agricultural workers, $X2$ refers to the ratio between nonagricultural production value and agricultural production value, $X3$ means the ratio of hospital bed, $X4$ refers to the ratio of the number of days with the air quality of and above Level II between urban and rural areas, $X5$ refers to the ratio of subsistence allowances amount per capita, $X6$ indicates the ratio of the number of students enrolled in middle schools, $X7$ means the green coverage ratio in built-up areas, $X8$ refers to the sewage treatment rate, and $X9$ refers to the ratio of disposable income. Moreover, $Y1$ is the variable and is expressed by the urbanization rate of residents [13].

4. Construction of Game Cross-Efficiency Model

First, it finds out the major influencing factors by factor analysis and carries out factor analysis for the original variables by data mining [14]. Second, it evaluates the efficiency by inputting three kinds of models of data envelopment analysis.

4.1. Principal Component Analysis. It means to classify variables based on the relevance of variables in systems and take the classified variables as the principal component to show the main system information with less principal component. n decision bodies and p evaluation indexes are provided, and the original data are

$$X = \begin{pmatrix} x_{11} & x_{12} & \dots & x_{1p} \\ x_{21} & x_{22} & \dots & x_{2p} \\ \dots & \dots & \dots & \dots \\ x_{n1} & x_{n2} & \dots & x_{np} \end{pmatrix}. \quad (1)$$

The correlation factor matrix is calculated as

TABLE 1: Index system of crossover analysis.

	Thriving business	Pleasant living environment	Rural civilization	Effective governance	Living in abundance
Spatial layout	X1	—	—	—	—
Industry configuration	X2	—	—	X3	—
Public service	X4	X5	X6	X7	—
Ecological environment	—	X7	—	X8	—
Income gap	—	—	—	—	X9

$$R = \begin{pmatrix} r_{11} & r_{12} & \cdots & r_{1p} \\ r_{21} & r_{22} & \cdots & r_{2p} \\ \cdots & \cdots & \cdots & \cdots \\ r_{n1} & r_{n2} & \cdots & r_{np} \end{pmatrix}, \tag{2}$$

where r_{ij} $(i, j = 1, 2, \ldots, p)$ is the correlation factor between the i th and the j th evaluation indexes.

$$r_{ij} = \frac{\sum_{k=1}^{n} (x_{ki} - \bar{x}_i)(x_{kj} - \bar{x}_j)}{\sqrt{\sum_{k=1}^{n} (x_{ki} - \bar{x}_i)^2 \sum_{k=1}^{n} (x_{kj} - \bar{x}_j)^2}}, \tag{3}$$

where

$$\bar{x}_i = \frac{1}{n} \sum_{k=1}^{n} x_{ki}, $$

$$\bar{x}_j = \frac{1}{n} \sum_{k=1}^{n} x_{kj}. \tag{4}$$

The eigenvalue and eigenvector of R are calculated. The equation $|\lambda I - R| = 0$ is solved to work out the eigenvalue λ_i, the eigenvalue λ_i in order of size $\lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_p \geq 0$ is arranged, the corresponding eigenvector $\vec{e}_i$ $(i = 1, 2, \ldots, p)$ is calculated; $\sum_{j=1}^{p} e_{ij}^2 = 1$, e_{ij} is the j th component of vector $\vec{e}_i$.

The contribution rate is

$$\frac{\lambda_i}{\sum_{k=1}^{p} \lambda_p} \ (i = 1, 2, \ldots, p). \tag{5}$$

The accumulative contribution rate is

$$\frac{\sum_{k=1}^{i} \lambda_k}{\sum_{k=1}^{p} \lambda_p} \ (i = 1, 2, \ldots, p). \tag{6}$$

Generally, the eigenvalue of the principal component with the accumulative contribution rate of 85%–95% is used; $\lambda_1, \lambda_2, \ldots, \lambda_m$ are, respectively, the 1st, 2nd, and $\ldots$, the $m(m \leq p)$th principal component.

The principal component load is calculated as follows:

$$l_{kij} = p(z_k, x_{ij}) = \sqrt{\lambda_i} e_{kij}, \tag{7}$$

where $k = 1, 2, \ldots, n$; $i, j = 1, 2, \ldots, p$.

Principle component is extracted, the load l_{kij}, $(k = 1, 2, \ldots, n; i, j = 1, 2, \ldots, p)$ of original variables x_{kj} $(k = 1, 2, \ldots, n; i, j = 1, 2, \ldots, p)$ on principle component z_k $(k = 1, 2, \ldots, n)$ is determined, and the representation of principle component of original data is

$$Z = \begin{pmatrix} z_{11} & z_{12} & \cdots & z_{1m} \\ r_{21} & r_{22} & \cdots & r_{2m} \\ \cdots & \cdots & \cdots & \cdots \\ x_{n1} & x_{n2} & \cdots & x_{nm} \end{pmatrix}, \tag{8}$$

where

$$z_{i1} = l_{1i_1} x_{i_1} + l_{1i_2} x_{i_2} + \ldots + l_{1i_p} x_{i_p}$$

$$z_{i2} = l_{2i_1} x_{i_1} + l_{2i_2} x_{i_2} + \ldots + l_{2i_p} x_{i_p}$$

$$\cdots \tag{9}$$

$$z_{im} = l_{mi_1} x_{i_1} + l_{mi_2} x_{i_2} + \ldots + l_{mi_p} x_{i_p}.$$

4.2. Envelopment Analysis Model. When the scale benefit is changeable, Banker, Charnes, and Cooper propose to evaluate the BCC model for decision-making unit U_0, and the oriented model is input in the type of

$$\min\left(\theta - \varepsilon\left(e^T s^- + e^T s^+\right)\right)$$

$$\text{s.t.} \sum_{i=1}^{n} (x_{ij} \lambda_i) + s^- = \theta x_{0j}, \quad j = 1, 2, \ldots, m,$$

$$\sum_{i=1}^{n} (y_{ir} \lambda_j) + s^+ = \theta y_{0r}, \quad r = 1, 2, \ldots, s, \tag{10}$$

$$\sum_{i=1}^{n} \lambda_i = 1,$$

$$\lambda_j \geq 0, s^+ \geq 0, s^- \geq 0.$$

x_{ij} and y_{ir} are the input and output factors, respectively, and θ is the effective value of U_0.

If $\theta = 1$, $s^+ = s^- = 1$, U_0 means DEA is effective; if $\theta = 1$, $s^+ \neq 1$ or $s^- \neq 1$, U_0 means weak DEA is effective; if $\theta < 1$, U_0 refers to non-DEA is effective.

4.3. Cross-Efficiency Evaluation. The linear programing (LP) type is as follows:

$$\max \sum_{r=1}^{s} u_r y_{rd} = \theta_d$$

$$\text{s.t.} \sum_{i=1}^{m} \omega_i x_{ij} - \sum_{r=1}^{s} u_r y_{rd} \geq 0, \quad j = 1, 2, \ldots, n,$$

$$\sum_{i=1}^{m} \omega_i x_{id} = 1. \tag{11}$$

$$\omega_i \geq 0, \quad i = 1, 2, \ldots, m,$$

$$u_r \geq 0, \quad r = 1, 2, \ldots, s,$$

We get a group of optimal weight value (multiplier) $\omega_{1\,d}^*, \ldots, \omega_{m\,d}^*, \mu_{1\,d}^*, \ldots, \mu_{s\,d}^*$ for each $DM\ U_d\,(d = 1, 2, \ldots, n)$ evaluation. The cross-efficiency of any $DM\ U_j\,(j = 1, 2, \ldots, n)$ can be expressed and calculated below with the weight chosen by DMU.

$$E_{dj} = \frac{\sum_{r=1}^{s} u_{rd}^* y_{rj}}{\sum_{i=1}^{m} \omega_{id}^* x_{ij}}, \quad d, j = 1, 2, \ldots, n. \tag{12}$$

As shown in Table 2, when we move along the line d in the cross-efficiency matrix E, each factor E_{dj} is the cross-efficiency of $DM\ U_d$ and $DM\ U_j$, and the main diagonal thereof is a special case for DMU self-evaluation [15].

Then, everyone averages the column of the cross-efficiency matrix in Table 1. The average value of all $E_{dj}\,(j = 1, 2, \ldots, n)$ for $DM\ U_j\,(j = 1, 2, \ldots, n)$, is $\overline{E_{dj}}$, namely, $\overline{E_{dj}} = 1/n(E_{1j} + E_{2j} + \ldots + E_{nj})$.

4.4. Game Cross-Efficiency.
During the calculation of game cross-efficiency, the efficiency of U_d is set as α_d; the optimal weight on the premise of ensuring no reduced α_d to maximize the self-efficiency [16] is obtained. The game cross-efficiency is

$$\alpha_{dj} = \frac{\sum_{r=1}^{s} u_{rjd} y_{rj}}{\sum_{i=1}^{m} v_{ijd} x_{ij}}. \quad d = 1, 2, \ldots, n \tag{13}$$

The corresponding model is

$$\max \sum_{r=1}^{s} u_{rjd} y_{rj},$$

$$\text{s.t.} \sum_{r=1}^{s} u_{rjd} y_{rj} - \sum_{i=1}^{m} v_{ijd} x_{ij} \leq 0,$$

$$\sum_{i=1}^{m} v_{ijd} x_{ij} = 1, \tag{14}$$

$$\alpha_d \sum_{i=1}^{m} \left(v_{ijd} x_{id} \right) - \sum_{r=1}^{s} \left(u_{rjd} y_{rd} \right) \leq 0,$$

$$u_{rjd}, v_{ijd} \geq 0.$$

5. Empirical Analysis on Game Cross-Efficiency

5.1. Principal Component Analysis (PCA) of Influencing Factors of Rural Revitalization and Urban-Rural Integration.

The influencing factors were analyzed with SPSS software. The results of the corresponding total variance explained are shown in Table 3.

The analysis results of the component scoring system matrix for the influencing factors are shown in the following Table 4.

Therefore, its corresponding regression equation is

$Z1 = 0.174 * X1 + 0.228 * X2 + 0.200 * X3 - 0.105 * X4 - 0.170 * X5 - 0.115 * X6 + 0.200 * X7 + 0.084 * X8 - 80.131 * X9$

$Z2 = -0.303 * X1 - 0.096 * X2 - 0.029 * X3 - 0.343 * X4 - 0.256 * X5 + 0.080 * X6 + 0.114 * X7 + 0.501 * X8 + 0.421 * X9$

$Z3 = 0.345 * X1 + 0.077 * X2 + 0.115 * X3 + 0.579 * X4 + 0.236 * X5 - 0.187 * X6 - 0.010 * X7 + 0.429 * X8 + 0.417 * X9.$

By the regression variance, we can calculate the results of three principal components of the influencing factors in 16 cities of Anhui Province. The specific condition is shown in Table 5.

5.2. Data Envelopment Model Analysis of Influencing Factors of Rural Revitalization and Urban-Rural Integration.
The MaxDEA software is used to calculate the above three efficiency values, and the calculation results are shown in Table 6.

By the above calculation results, we can derive a trend chart of efficiency indicators, as shown in Figure 1.

5.3. Result Analysis

5.3.1. Regional Development Is Unbalanced, and Echelon Distribution Is Significant.
From the efficiency results of 16 cities in Anhui Province, it can be seen that Hefei and Tongling belong to the first echelon; Ma'anshan, Huaibei, Huainan, and Wuhu belong to the second echelon; Bengbu, Xuancheng, Chuzhou, Chizhou, Anqing, and Huangshan belong to the third echelon; and Fuyang, Lu'an, Suzhou, and Bozhou belong to the fourth echelon.

5.3.2. The Results of BCC Efficiency and Cross-Efficiency Are Similar, but There Are Slight Differences.
From the comparison of the BCC efficiency and cross-efficiency results of 16 cities in Anhui Province, it can be seen that the ranking of efficiency values that are calculated by the two calculation methods has not almost changed. However, there are slight differences between the two groups of cities: Ma'anshan and Huaibei, and Anqing and Huangshan.

We can learn from the analysis that one of the main reasons for the above situation is that BCC efficiency and cross-efficiency are similar. The BCC efficiency in data envelopment analysis is mainly determined by the way that is most beneficial to the evaluated DMUs, while the cross-efficiency model evaluates all DMUs with each group of weights. In addition, the input and output indexes of Ma'anshan and Huaibei, Anqing and Huangshan are similar,

TABLE 2: General cross-efficiency matrix.

Evaluated units	1	2	3	. . .	n

FIGURE 1: Trend chart of efficiency indicators.

so this is how the above analysis results are similar but slightly different.

5.3.3. Combined with the Analysis of Game Cross-Efficiency, the Differences among Cities in Anhui Province Are Obvious.

By combining with the analysis, it is found that the game cross-efficiency of Hefei, Xuancheng, and Huangshan fluctuates with BCC efficiency and cross-efficiency. From the comparison results of 16 cities in Anhui Province, it is found that the efficiency of urban-rural integration in Hefei in the first echelon declines significantly, while that in Huangshan and Xuancheng, the third echelon sees a rising trend, and especially, the rising extent of Huangshan is significant.

It is found from the above analysis that Hefei's attraction to the country is relatively insufficient. Tongling has done a good job in the urban-rural integration, because it is small, with little difference between city and country, and it has fewer difficulties than other cities [17]. Huangshan and Xuancheng have relatively strong competitiveness in potential and attractiveness in the future.

6. Conclusion and Suggestions

6.1. Strategic Direction of Building an Urban-Rural Integration System.

In order to implement the rural revitalization strategy, we should, by taking cities and countries as organic systems, build a coupling model and innovation system that integrates "human," "land" with "industry" in rural areas to promote gather of capital, talents, and other elements in rural areas, gradually break the urban-rural functional division pattern, and realize urban and rural areas support each other, integrate with each other and make progress simultaneously.

6.2. Overall Design of Urban and Rural Functional Planning.

A convenient and smooth transportation network system from the market to the field can be formed through the implementation of construction projects. The consolidation and upgrading project of urban and rural basic infrastructure can be implemented to improve and build an efficient network [18]. We should implement the overall design of functional planning, implement informatization construction projects, develop a safe and efficient information and communication network with reasonable urban and rural layout, balanced development and perfect functions, implement the digital rural strategy, and comprehensively promote the "Internet+."

6.3. Promote Cobuilding and Sharing of Urban and Rural Infrastructure.

The government should vigorously promote the network infrastructure construction that fits the demands of agriculture, rural areas, and farmers, adhere to overall planning, urban-rural integration, focus on weakness and break major problems, accelerate the upgrading of urban and rural infrastructure, and build a safe, efficient, and connective infrastructure network system [19]. According to local conditions, the government should implement a demonstration pilot project of integrated urban-rural development, promote upgrading and transformation of urban and rural infrastructure to realize joint construction and

sharing, and calmly realize the overall goal of building space that is suitable for both living and industry development and picturesque ecological scenery.

In order to improve the effect of animal husbandry economic analysis, this article studies the animal husbandry economy based on system dynamics and studies how to define total factor productivity and its measurement method. Moreover, this article compares and analyzes the production function method, data envelopment analysis, and index method for measuring total factor productivity, selects decision-making units, and determines and processes input-output data. In addition, this article combines the system dynamics model to explore the causal relationship of the animal husbandry economy and builds an intelligent model to intelligently analyze the animal husbandry economy. Finally, this article analyzes the economy and performance of animal husbandry based on simulation experiments. The simulation test results show that the system dynamics model proposed in this article has a good performance in the economic analysis of animal husbandry.

1. Introduction

The living standards of residents are constantly improving, the consumption structure is constantly improving, and health awareness is also increasing. Therefore, people's demand for all kinds of healthy and nutritious animal products is growing rapidly, especially the demand for high-quality meat, eggs, and milk products. These shifts in food demand are also adding impetus to the development of animal husbandry. The national economy is a general term for various social production sectors and other labor sectors, including material production sectors such as industry and agriculture and nonmaterial production sectors such as transportation, finance, and commerce. These departments are both interrelated and independent, and together they form an organic whole of the national economy. However, the status of each sector in the national economy is not the same. Among them, agriculture, as the primary industry, plays a fundamental role in the national economy.

In human history, animal husbandry came into being before planting, and the emergence of nomadism separated animal husbandry from agriculture, realizing the first great division of labor in human history, which is a sign of the progress of human civilization. With the development of the times, animal husbandry is showing its important status and significance more and more. Planting and animal husbandry are two extremely important parts of agriculture, and they are interrelated and mutually reinforcing. On the one hand, planting provides essential fodder for the development of animal husbandry. Without the development of animal husbandry, planting is the basis for the development of animal husbandry; on the other hand, the development of animal husbandry provides the fertilizer, power, and funds needed for production, which in turn will promote the development of the planting industry. It can be seen that agriculture is the foundation of the national economy, embodied by both planting and animal husbandry. Both planting and animal husbandry are the basis for human survival and social development.

With the development of society and economy, the status of animal husbandry has become increasingly important, and

it is more closely related to the lives of the people. In the food consumption structure of many developed countries, animal products have become the theme of improving people's food structure and nutrition. The proportion of agricultural output value has exceeded that of the traditional planting industry, accounting for about 60%–80%. Driven by consumer demand, the labor force produced by the planting industry has begun to transfer to animal husbandry, which has promoted the industrialization and urbanization of rural areas. The development of animal husbandry has also greatly increased the demand for feed, changed the traditional planting structure, and transformed the traditional dual planting structure based on "grain-economic crops" into "grain-economic crops-feed crops" ternary planting structure has optimized the agricultural industry structure. It is undeniable that animal husbandry has many irreplaceable characteristics of other sectors, such as planting, and its correlation with other industries within agriculture is particularly high. Therefore, the development level of modern animal husbandry has become a measure of whether a country or a region's agricultural industry structure is reasonable. An important sign is the development of agricultural modernization that increasingly requires the support of strong animal husbandry.

This article studies the animal husbandry economy based on system dynamics and constructs an intelligent model to intelligently analyze the animal husbandry economy so as to improve the subsequent development effect of the animal husbandry economy.

2. Related Work

Literature [1] believed that due to the development of economic level and the continuous improvement of science and technology, the development of animal husbandry has been greatly impacted, and the traditional development mode of animal husbandry will face the elimination of the market. The application of science and technology to animal husbandry production can improve productivity and reduce costs, improve the ability of animal husbandry to respond to natural disasters or market changes, and promote the sustainable development of animal husbandry. Literature [2] pointed out that animal husbandry is a pillar industry of agriculture, which plays an important role in promoting the level of economic development and improving the comprehensive national strength. Developers should pay attention to the development of animal husbandry, which has an irreplaceable role in the development of the country. Therefore, the production and development of animal husbandry must be rationally arranged, and the construction of animal husbandry infrastructure must be strengthened. Attention must also be paid to fund support and policy guarantees. The sustainable development of animal husbandry is a challenge and an opportunity. Literature [3] found that poultry farms have been affected by the large-scale development of animal husbandry and suggested changing the development model of animal husbandry in order to realize the development of animal husbandry. The scale, standardization, and industrialization of the

development model need to meet the needs of the national residents for livestock products and to promote the development of agriculture and rural areas. Literature [4] pointed out that with the adjustment of the production structure of animal husbandry in the early days of the United Kingdom, the production of animal husbandry in the United Kingdom had undergone great changes and analyzed the importance of adjusting the production structure of animal husbandry. Literature [5] pointed out that the education level of the practitioners plays a very important role in the development of animal husbandry.

Literature [6] analyzed the output value and location quotient of modern grassland animal husbandry, studied the industrial advantages and scale, and proposed that the development of animal husbandry should follow the ecological priority, scientific ethics concept, modern pasture system, product differentiation design, synchronization, and the road to related industries. Literature [7] put forward suggestions for improving the development of animal husbandry by studying the coordination of grain production and animal husbandry development, aiming at different problems that arise, such as changing the development model, increasing grain output, and improving feed utilization. Reference [8] used the grey relational method to analyze the relevant data, and concluded that the factor with the highest correlation is the number of Internet users, and finally put forward countermeasures and suggestions to promote the development of animal husbandry. Literature [9] analyzed the output of animal husbandry, the output of animal products, and the number of slaughters and inventories, summarized the problems existing in the development of animal husbandry, and put forward development suggestions such as improving the efficiency of livestock and poultry breeding, improving the breeding system, and strengthening the control of livestock and poultry pollution. Literature [10], based on the analysis of animal husbandry market share, resource endowment coefficient, and product cost, summed up the road of combining agriculture and animal husbandry and industrial clusters, improving the competitiveness of animal husbandry, and promoting the development of animal husbandry. Reference [11] described the specific status of animal husbandry, analyzed the problems that restrict the development of animal husbandry, and put forward suggestions for sustainable development, including sustainable recycling mechanisms, the transformation of development models, and utilization of manure resources. For the development route, in [12], four suggestions for the sustainable development of the animal husbandry economy have been proposed, which are to increase the ideological emphasis on sustainable development of the ecological economy, improve the relevant policy support system for development, and expand the animal product market.

Reference [13] used the production layout index to illustrate the layout of the main production areas of raw milk and used empirical analysis to conclude that the factors affecting the layout change are resources, economy, non-agricultural employment, and the market. Reference [14] put forward suggestions for increasing or decreasing the

aquaculture scale in different regions. Reference [15] used the resource endowment index method and the comprehensive comparative advantage index method and used the principle of comparative advantage to research and analyze animal products. Literature [16] compiled and analyzed the relevant data on animal husbandry in the past 30 years, established the livestock and poultry breed structure index, and obtained the evolution process and characteristics of the breed structure index at different stages in the six major production areas of animal husbandry. The dominant varieties in the region are put forward, and countermeasures and suggestions for optimizing the production layout are put forward. Reference [17] used PIL to analyze the evolution process of changes in animal husbandry areas, combined with the principle of comparative advantage, and obtained the direction of layout changes and the advantageous breeding areas. Reference [18] used different indicators to calculate the industrial concentration based on the relevant production data of three years and finally identified the advantageous production areas.

3. Economic Calculation Model

DEA method is the most commonly used method in nonparametric frontier efficiency analysis. Farrell first proposed the DEA method, and then Charns further improved the CCR model. With the development of time, many scholars have improved the DEA method to make it more scientific and rational. Now, the DEA method has been relatively mature, and it has become a research method to study input-output efficiency with equal emphasis on traditional econometric methods.

The DEA method is used to scientifically evaluate the decision-making unit and measure the relative efficiency of the measurement unit according to the model. Decision-making unit (DMU) is a specific title; it can be the army, police station, prosecutor's office, or the same entity unit as a supermarket or coffee shop. Moreover, each decision-making unit has the same input and output indicators. DEA calculates input-output data to obtain quantitative indicators of decision-making units and comprehensive efficiency. According to this result, the decision-making units are sorted, the decision-making unit with the largest relative efficiency value is determined, and then the reasons and levels of the ineffectiveness of other decision-making units are analyzed. Finally, it provides suggestions for improvement and development direction of the decision-making unit system. The DEA method can also judge the scale return of each decision-making unit and put forward a scientific suggestion for a decision-making unit to adjust the industrial scale. Compared with other research methods, the DEA method has huge advantages in the research and analysis of multi-input-output systems, which are mainly manifested in the following:

(1) It is not necessary to determine the choice of the mathematical form of the production function before the research so as to avoid getting the wrong conclusion because of the wrong function selection;

(2) DEA research method does not have to collect price information of input products;

(3) In the study of complex systems, the DEA method does not need to sort out the relationship of each subsystem and also does not need to establish the comparability between the indicators;

(4) The DEA method does not need to determine the weight of the system and its input and output in advance, excludes the influence of subjective factors, and has the characteristics of simple and objective;

(5) DEA sorts out the data from an overall macro perspective to avoid the one-sidedness of the treatment of scattered indicators.

DEA has two models: the CCR model with constant returns to scale and the VRS model with variable returns to scale. CCR is used to calculate comprehensive technical efficiency (STE), including scale efficiency, and VRS is used to calculate technical efficiency (TE) without the effect of scale efficiency.

The CCR model assumes that there are N DMUn ($1 \leq n \leq N$), and each DMU has a kind of input and b kind of output, then the DMUn vector is expressed as follows:

$$X_j = \left(x_{1j}, x_{2j}, \ldots, x_{aj}\right)^T > 0, \quad j = 1, 2, \ldots, N,$$
$$Y_j = \left(y_{1j}, y_{2j}, \ldots, y_{bj}\right)^T > 0, \quad j = 1, 2, \ldots, N. \quad (1)$$

According to the above assumptions, the CCR model formula is as follows:

$$s.t. \begin{cases} \sum_{j=1}^{a} X_j \lambda_j \leq \theta x, \sum_{j=1}^{a} Y_j \lambda_j \leq Y_n, \lambda_j \geq 0, \quad j = 1, 2, \ldots, a. \quad (2) \end{cases}$$

In this system of equations, the economic meaning of DEA is that DMUn is valid for DEA if and only if $\theta = 1$ and all inequalities have equal signs. That is, in this system composed of N decision-making units, the output obtained by the current input level has reached the optimum. When $\theta = 1$ and the inequalities of formula (2) are all inequality signs, DMUn is weakly effective; that is, reducing the current input in this system can keep the output level unchanged or increase the output level under the current input level. When $\theta < 1$, DEA is invalid; that is, in this system composed of N decision-making units, the current output level can be maintained when the current input is reduced by θ times.

The CCR model calculates the overall efficiency under the premise that the scale benefit remains unchanged. This assumes that the decision-making unit can increase the output proportionally by increasing the input ratio. This situation is difficult to achieve in actual production, so scholars further study it. By adding a convexity assumption $\sum_n \lambda_j = 1$ to the CCR model, it becomes the aforementioned BBC model for calculating the removal of returns to scale, as shown in the following formula:

$$s.t. \left\{ \sum_{j=1}^{a} X_j \lambda_j \le \theta x_n, \sum_{j=1}^{a} Y_j \lambda_j \ge Y_n, \lambda_j \ge 0, \quad j = 1, 2, \ldots, a, \lambda_j \ge 0, \quad j = 1, 2, \ldots, a. \tag{3}\right.$$

By solving the BEC model, we can also obtain the technical efficiency θ of each decision-making unit. When $\theta = 1$, the decision-making unit technology is effective, and formula (3) is used to solve each decision-making unit, and the technical efficiency values of all DMUs are obtained.

Through the CCR and BCC models, we obtained the scale efficiency and technical efficiency of the object under investigation. Next, we will briefly introduce how to calculate pure technical efficiency (PTE). This calculation mainly uses the DEA model with crowded elements:

$$s.t. \left\{ \sum_{j=1}^{a} X_j \lambda_j \le \theta x_{j0}, \sum_{j=1}^{a} Y_j \lambda_j \ge \frac{1}{\theta} Y_{j0}, \sum_{j=1}^{a} \lambda_j = 1 \, (0 \le \theta \le 1). \tag{4}\right.$$

θ obtained in formula (4) is the pure technical efficiency we require. With regard to the introduction of the DEA model, we obtain the technical efficiency, pure technical efficiency, and scale efficiency of the decision-making unit. Lei Ming (1996) stated that management efficiency (ME) can be expressed by the following formula:

$$ME = PTE \cdot CE \cdot SE \cdot AE. \tag{5}$$

If TP is technological progress, then total factor productivity can be derived from the following formula :

$$\frac{\Delta TEP}{TFP} = \frac{\Delta TP}{TP} + \frac{\Delta ME}{ME}. \tag{6}$$

In traditional economics research, it is usually assumed that the cost is minimized to study the change of total input or that the profit is maximized to study the change of total output. Behind these assumptions, there is a perfectly competitive market, which is very demanding and difficult to achieve in empirical research. The emergence of the distance function perfectly solves the above problems. The distance function is a tool to study multiple input and output without making any assumptions about the production activities of the observer. How Farr et al. utilized the distance function will be described in detail below.

We assume that the vector X_j is the input vector of the DMU and Y_j is the output of the DMU. Because the minimum value of the distance function cannot be determined in the context of multiple outputs, the "inferior bound" is taken as the research object, and the distance function of the output angle is defined as $Do(X, Y) = \inf\{\theta: (X, Y|\theta) \in P(X)\}$. P(X) represents all feasible production combinations; that is, input X'' can

produce Y, and $\theta \in [0, 1]$ represents production efficiency. When $\theta = 1$, the resource allocation is reasonable, and when $\theta < 1$, it means that the research object is in a state of input redundancy. Under the premise of constant returns to scale, the distance function is single output (Figure 1(a)) or dual-output (Figure 1(b)), as shown in the figure below.

We assume that there is no efficiency loss in production, and the output point should be located at two points AC, but the actual situation may be located at two points BD. Under the premise of constant input, the object at BD two points can increase the output to AC two points; that is to say, from the perspective of output, the distance function represents the limit expansion of output to the production frontier.

The functions mentioned above do not take the time factor into account, so we consider the time factor as an independent variable. We assume that the input-output vectors in period t and period $t+1$ are (X_t, Y_t) and (X_{t+1}, Y_{t+1}), and the distance function diagram of single input and single output is shown in Figure 2. Then the Malmquist exponent with reference to time t is as follows:

$$M_t = \frac{D_t(X_{t+1}, Y_{t+1})}{D_t(X_t, Y_t)}$$
$$= \frac{l_{od}/l_{oe}}{l_{oa}/l_{ob}}. \tag{7}$$

The Manquist exponent expressed with reference to period $t+1$ is as follows:

$$M_{t+1} = \frac{D_{t+1}(X_{t+1}, Y_{t+1})}{D_{t+1}(X_t, Y_t)}$$
$$= \frac{l_{od}/l_{of}}{l_{oa}/l_{oc}}. \tag{8}$$

By borrowing Fisher's method of constructing the ideal index, we take the average of the above two formulas, and we get the Manquist productivity index as follows:

$$M_{t,t+1} = \left(\frac{D_t(X_{t+1}, Y_{t+1})}{D_t(X_t, Y_t)} \times \frac{D_{t+1}(X_{t+1}, Y_{t+1})}{D_{t+1}(X_{t+1}, Y_{t+1})} \right)^{1/2}. \tag{9}$$

By deforming formula (9), it can be seen that the total factor productivity change is composed of two parts, the technical efficiency change (EC) and the technical change (TC), that is, the following formula.

$$M_{t,t+1} = \underbrace{\left(\frac{D_t(X_{t+1}, Y_{t+1})}{D_t(X_t, Y_t)} \times \frac{D_{t+1}(X_{t+1}, Y_{t+1})}{D_{t+1}(X_{t+1}, Y_{t+1})} \right)^{1/2}}_{BC} \cdot \underbrace{\frac{D_{t+1}(X_{t+1}, Y_{t+1})}{D_t(X_t, Y_t)}}_{TC}. \tag{10}$$
FIGURE 1: Distance function output. (a) Distance function for a single output. (b) Distance function for double output.
FIGURE 2: Manquist productivity index from an output perspective.

When $TC > 1$, it means technological progress; when $TC < 1$, it means technological regression; when $EC > 1$, it means that technical efficiency has improved, and when $EC < 1$, it means that technical efficiency has declined. The technical efficiency change is composed of pure technical efficiency change (PC) and scale efficiency change (SC); namely, $EC = PC \times SC$, so that $TFPch = TC \times PC \times Sc$ can be obtained.

4. Economic Analysis of Animal Husbandry Based on System Dynamics

System management is divided into classification management, membership management, and basic information management. Its main function is to set up the basic information, membership level, and different resource data categories of the entire platform in advance. At the same time, it has the functions of adding, modifying, and deleting, which is convenient for the future function expansion of the platform and the docking with other systems. Data management is mainly divided into animal husbandry economic statistical data management, scientific and technological achievements and literature resource management, and

member authority review management. The specific structure of the platform is shown in Figure 3.

The ecological economic system of animal husbandry cannot escape the influence of human beings. It is a complex system composed of customers, manufacturers, government, and other stakeholders, and it is reflected in the interrelationship of different subjects. In the era of a self-sufficient natural economy, the production mode of animal husbandry is mainly characterized by the natural regrowth of animals, and it drives the continuation and development of life according to the basic characteristics of the food chain and relies more on natural ecological laws for regulation. The conceptual structure of the animal husbandry ecological economic system is shown in Figure 4.

Residents' consumption behavior of livestock and poultry products constitutes the consumption subsystem of the animal husbandry ecological economic system, as shown in Figure 5(a). Residents' demand for livestock products depends on the population and per capita disposable income. The larger the population, the greater the demand for livestock products, and the higher the per capita disposable income, the higher the residents' demand for livestock products. When the supply is in short supply, the price of livestock products will rise, which will in turn affect residents' purchases of livestock products.

Under the current economic conditions, consumers cannot fully accept ecological livestock products but make a balanced choice between general livestock products and ecological livestock products. Therefore, in the consumption subsystem of the animal husbandry ecological economic development system, it includes both the consumption of general livestock products and the consumption of ecological livestock products (as shown in Figure 5(b)), and the two are substitute products for each other.

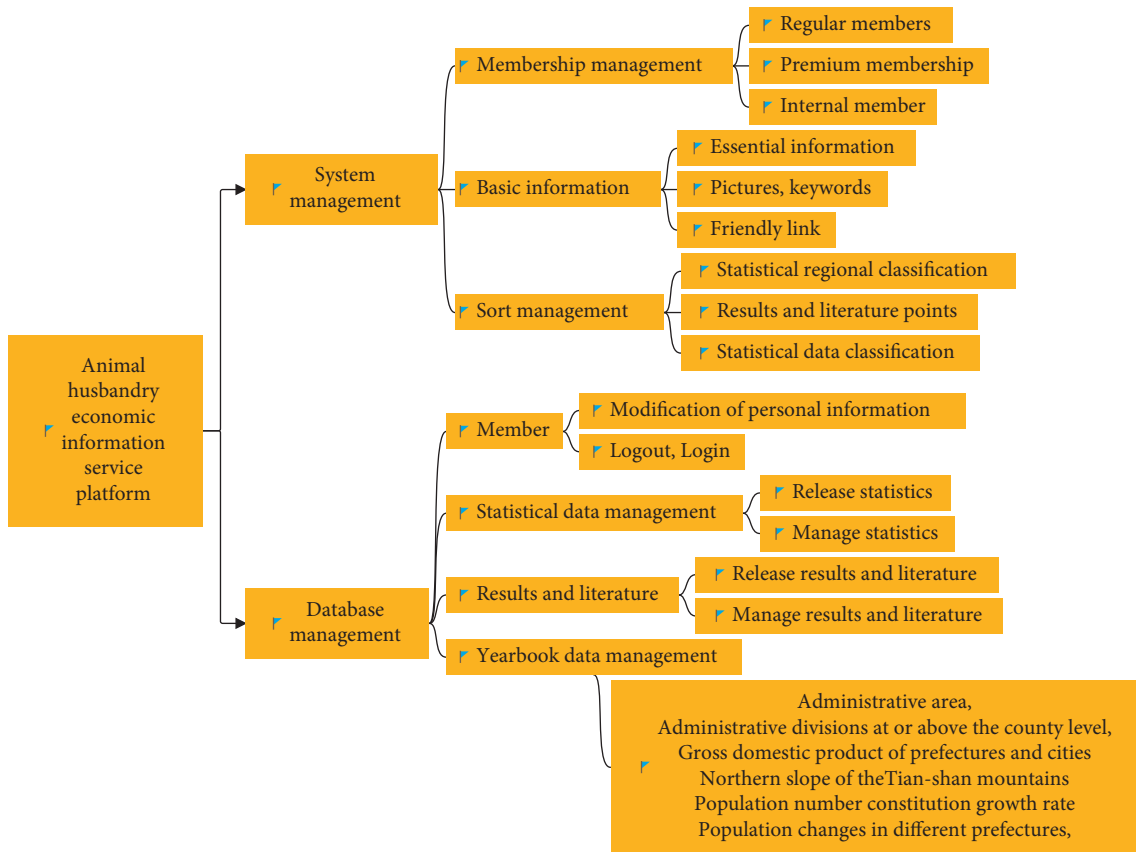
From an economic point of view (as shown in Figure 5(c)), residents' demand for animal husbandry products prompts animal husbandry enterprises to produce more animal husbandry products to meet the needs of customers. Animal husbandry enterprises can obtain more profits and require more raw materials for production, thus driving the development of raw material enterprises, thereby driving the development of the entire animal husbandry and other related industries, and promoting the GDP of the


Figure 3: Platform structure diagram.
Figure 4: Conceptual structure diagram of animal husbandry ecological economic system.

entire country. At the same time, due to the increase in corporate assets, reinvestment is made to expand production.

With the development of the industry, the pressure from the natural environment continues to increase. The pressure from the natural environment is mainly manifested in the

(a)

(b)

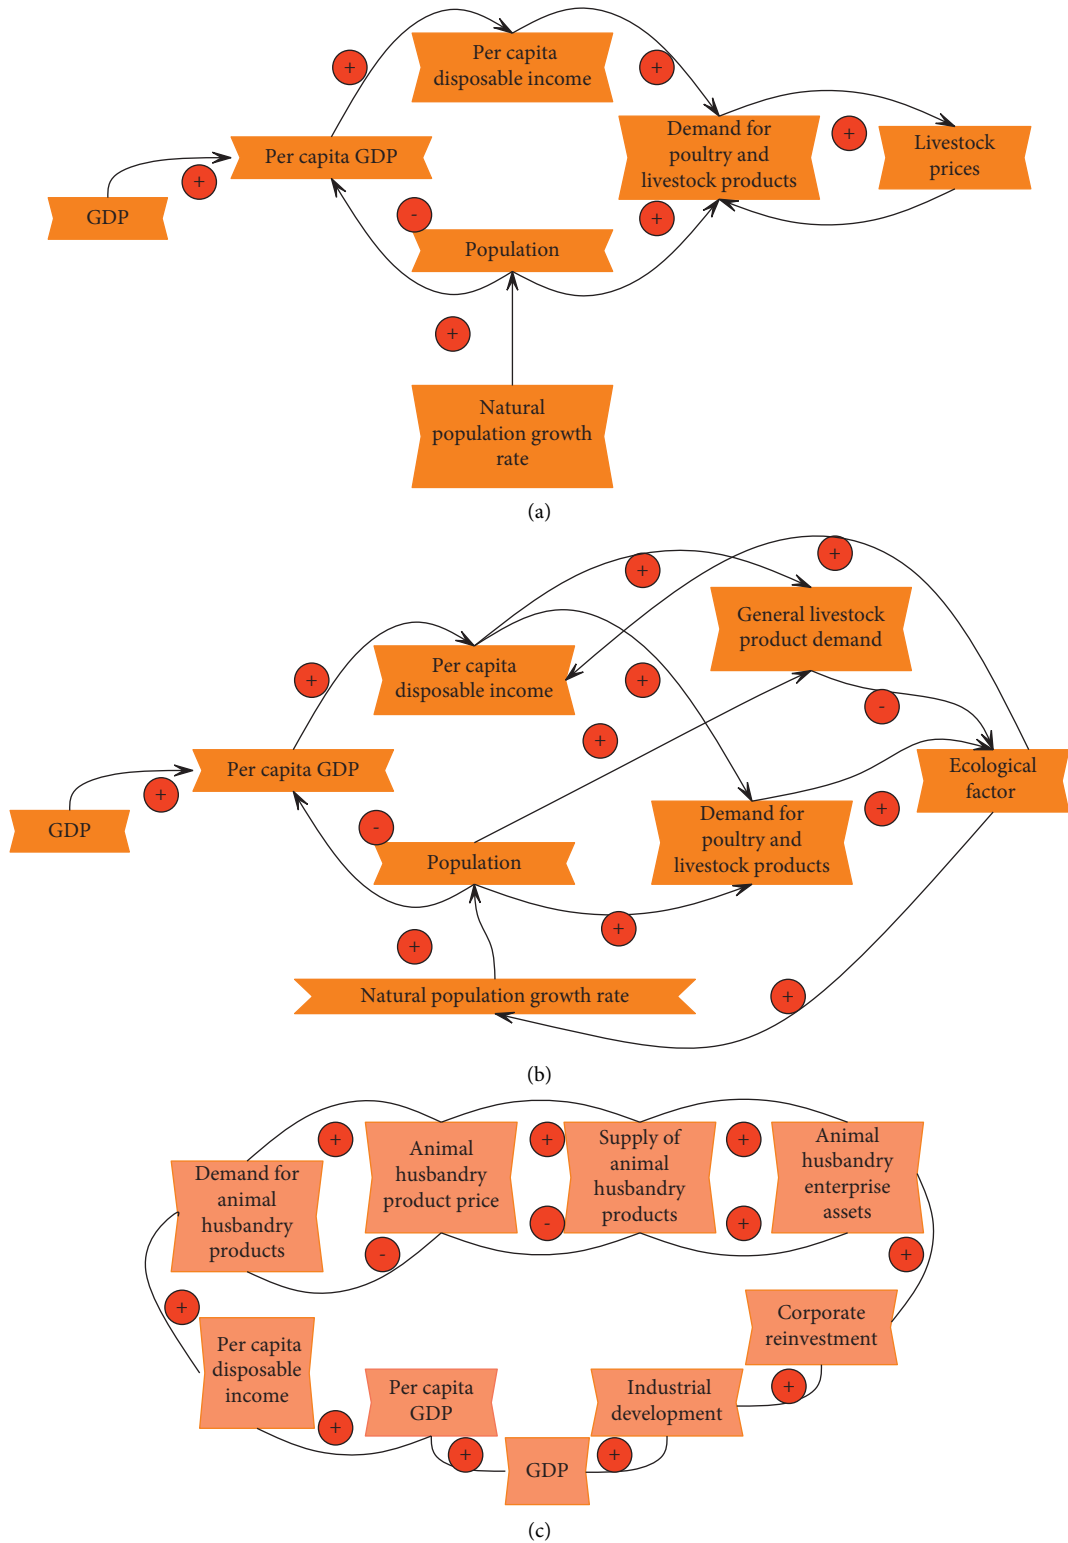
(c)


Figure 5: Continued.

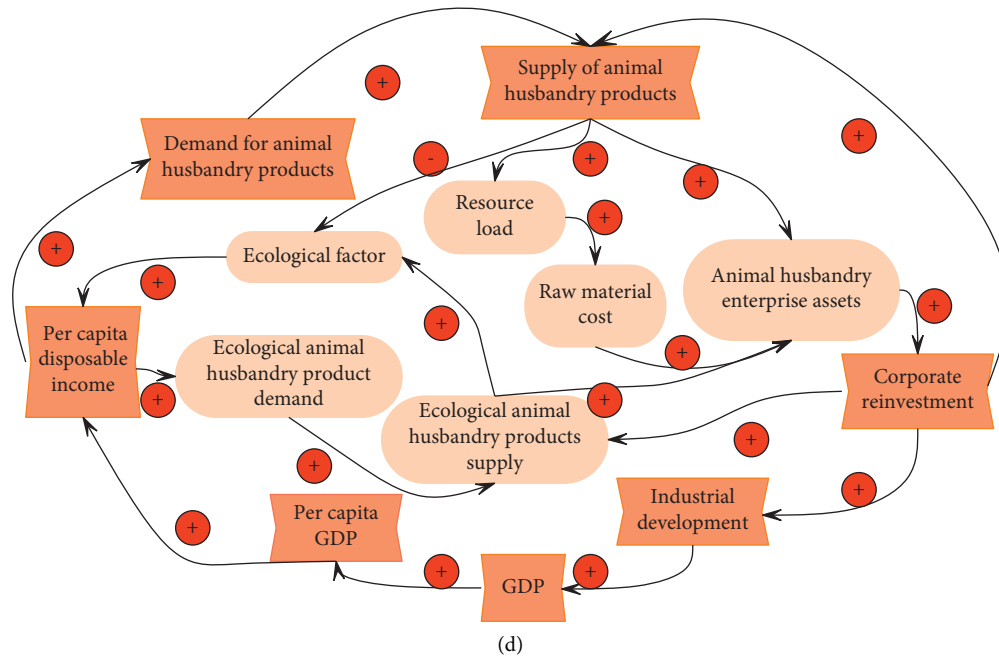
(d)


Figure 5: The causal relationship diagram of the animal husbandry economic system. (a) The causal relationship diagram of the demand subsystem from the economic point of view. (c) The causal relationship diagram of the production subsystem from the economic point of view. (d) The causal relationship diagram of the ecological and economic production subsystem of animal husbandry.

overuse and waste of raw materials and the pollution of the environment by excrement. In order to alleviate the pressure on the environment, it is necessary to invest more balancing funds, which causes the cost to rise, product prices to rise, and consequently the decline of the funds available for the industry to expand and reproduce, thus inhibiting the development of the industry (Figure 5(d)).

As shown in Figure 6(a), the ecological economic technology subsystem of animal husbandry is mainly reflected in three aspects of the consumption subsystem and economic subsystem of animal husbandry ecological economy. First, scientific and technological progress improves the spiritual and material life of human beings, and the increased disposable income of human beings can lead to more consumption of ecological animal husbandry products, which forms positive feedback. The second is the improvement of educational technology and the improvement of residents' educational level brought about by investment in science and technology. Humans realize the significance of ecological animal husbandry products for their own development, which can change consumption awareness and behavior, increase the consumption of ecological animal husbandry products, and form positive feedback. Third, the investment in science and technology has greatly improved the production technology of existing enterprises, improved the production efficiency of enterprises and the utilization rate of resources, and can produce ecological animal husbandry products at a lower cost, forming positive feedback. Conversely, if the technical orientation is wrong, it will exacerbate the negative feedback effect (as shown in Figure 6(b)). For example, the concentration of science and technology on the production and consumption of

nonecological products will inevitably increase the capital load and environmental degradation and make the system continue to deteriorate.

As shown in Figure 7(a), for nonecological economic behaviors, the government sets a higher threshold for customers and producers through economic penalties and direct supervision by regulatory authorities and turns to the production and consumption of ecological livestock products. For example, the government environmental monitoring department sets punitive consumption policies or thresholds according to environmental conditions, which increases the cost of general livestock products and reduces per capita disposable income.

Under the ecological economic behavior (as shown in Figure 7(b)), the government adopts more incentive policies to attract producers, consumers, and technology developers to switch from general animal husbandry products to ecological animal husbandry products, thereby promoting ecological animal husbandry products for nonprofit replacement of ecological livestock products and promoting a virtuous circle of positive feedback.

In order to further understand the operation law of the animal husbandry ecosystem, we combine nonecological economic products and ecological economic products together. Moreover, this article uses the proportion of ecological animal husbandry products in total animal husbandry products (the ratio of ecological animal husbandry products) to specifically express the choice of consumers, producers, and other subjects for ecological animal husbandry products and ecological behaviors. The SD causal relationship diagram of the whole animal husbandry ecological and economic development system is obtained as shown in Figure 8(a).

(a)

(b)
FIGURE 6: Causal diagram of technical subsystems. (a) The causal relationship diagram of the ecological economic technology subsystem of animal husbandry. (b) Negative feedback relationship diagram of technical subsystem.

Figure 8(b) shows the causal relationship diagram of the coordinated development of the ecological economic system of livestock and forestry. On the one hand, the development of animal husbandry requires forestry to provide more raw materials, so forestry enterprises increase the supply and can obtain more for their own expansion and reproduction. However, due to the constraints of the natural environment, the supply of forestry has a certain load limit, and if the load exceeds the load, it will have a negative impact on human beings and the environment. On the other hand, the development of forestry requires more organic fertilizers, which drives the development

of ecological animal husbandry enterprises, while investing in and expanding reproduction. Therefore, the development of forestry also drives the development of the ecological economy of animal husbandry.

Figure 8(c) shows the causal relationship diagram of the coordinated development of the ecological economic system of animal husbandry and crop farming. The relationship between the animal husbandry ecosystem and agriculture basically includes two aspects of coordinated development with forestry. However, unlike forestry, the products of planting not only meet the needs of ecological
FIGURE 7: Relationship diagram of the management subsystem. (a) The causal relationship diagram of management subsystems under non-ecological economic behavior. (b) Relationship diagram of management subsystems under ecological economic behavior.

animal husbandry for raw materials but also meet the needs of people for food. Therefore, human needs aggravate the resource load of the planting industry, so that the ecological and economical operation of animal husbandry is more necessary to balance the needs of human and animal husbandry for the planting industry so as to alleviate and solve the resource load of the planting industry.

On the basis of the above research, the system dynamics model proposed in this article is simulated by the simulation software, and the analysis effect of the system dynamics model on the development of the animal husbandry economy is calculated. The effects in the ecological analysis of animal husbandry economy and the analysis of economic development effects are verified, and the results shown in Tables 1 and 2 are obtained.

It can be seen from the above research that the system dynamics model proposed in this article has a good performance in the economic analysis of animal husbandry and can provide a reference for the development of the animal husbandry economy.

5. Conclusion

There are many industries associated with animal husbandry, which influence each other to promote development, and animal husbandry integrates supply, production, and marketing. Among them, the planting industry is responsible for providing raw material feed, livestock and poultry use the feed for growth, and the produced manure is processed into organic fertilizer, which is recycled to the fields for use in the planting industry. The processing industry plays a key role in ensuring the quality of animal products and is an indispensable intermediate link in the output of animal husbandry. The logistics industry ensures the normal transportation and circulation of animal

products, and the service industry is indispensable in the process of animal product sales. This article studies the animal husbandry economy based on system dynamics and conducts an intelligent analysis of the animal husbandry economy by constructing an intelligent model. The simulation test study shows that the system dynamics model proposed in this article has a good performance in the economic analysis of animal husbandry and can provide a reference for the development of animal husbandry economy.

With China's attention to the requirements of brand illustration innovative design, under the background of Industry 4.0, the advantages of applying 3D modeling method in the field of traditional illustration design are becoming more and more prominent. Based on this, this paper studies the modeling method of brand illustration innovative design based on Industry 4.0 and constructs a 3D analysis model of illustration design based on cattle cooperative hybrid algorithm. This paper innovates the innovative design method of brand illustration under the background of Industry 4.0 from the three aspects of illustration structure, illustration style, and illustration creation method, uses the cattle cooperative hybrid algorithm to quantify its innovation, and realizes the intelligent evaluation of its innovation and the quantitative representation of modeling method based on the illustration database. The experimental results show that the illustration innovative design analysis model based on cattle collaborative hybrid algorithm can effectively combine the industrial 4.0 background, realize the modeling innovation at the three-dimensional level, and significantly improve its innovative design efficiency and modeling success rate.

1. Introduction

Industry 4.0 is a division based on different stages of industrial development. According to the consensus, Industry 1.0 is the era of steam engine, Industry 2.0 is the era of electrification, Industry 3.0 is the era of information, and Industry 4.0 is the era of using information technology to promote industrial change, that is, the era of intelligence. In order to improve the core competitiveness of Germany's industrial revolution, the new concept of occupation machine appeared in Germany's Industrial Expo in 2013. In recent years, most illustration design masters have made many achievements in modeling the innovative design of brand illustration. Among them, the illustration design of traditional cultural style is the main, supplemented by the illustration design style of local and national characteristics [1]. Under the background of industry 4.0, new designers gradually began to combine illustration innovative design with industrial elements, such as illustration and advanced manufacturing technology, intelligent manufacturing

technology, robot technology, micro nano sensing technology, and other elements, so as to realize the innovative expression of their illustration [2]. On the other hand, with the emergence of a variety of modern 3D modeling methods, different types of brand illustration innovative design methods have gradually developed in a blowout way. The emergence of modern illustration design styles such as online illustration design scheme, multidimensional collaborative design, and two-dimensional and three-dimensional collaborative design provides a new direction for promoting "brand illustration innovative design" on a large scale [3]. Therefore, how to create more and better brand illustration works under the background of industry 4.0 has become an important feature of illustration design in China [4]. At present, although the existing illustration graphic design modeling method group provides a large number of reference design schemes, in terms of practical application, it is difficult to create more and more aesthetic illustration works in combination with the existing business characteristics of the actual brand company [5]. Under this

background, combined with the background of Industry 4.0, this paper proposes a modeling method of brand illustration innovative design based on cattle collaborative hybrid algorithm and studies the application of different types of 3D modeling and data analysis methods in the field of intelligent illustration 3D design.

This paper studies the modeling method of brand illustration innovative design based on Industry 4.0 and constructs an intelligent illustration design modeling strategy analysis model based on cattle cooperative hybrid algorithm. Compared with the traditional illustration design method with cultural elements as the main creative style, the innovation of this paper is to apply the cattle cooperative hybrid algorithm to the innovative design of brand illustration. On this basis, make full use of different types of 3D modeling data and collaborative multidimensional data analysis methods. Taking industry 4.0 as the background, combined with brand characteristics, realize the optimal and innovative design of illustrations, and use a variety of 3D modeling methods to represent different types of illustration works. Combined with the current illustration innovation analysis system, intelligent design and performance of different types of brand illustration works are carried out.

This paper studies the application of industrial 4.0 background in brand illustration innovation design modeling, which is mainly divided into four chapters. Chapter 1 briefly describes the background and necessity of this study. Chapter 2 discusses the brand illustration design method and existing research results on the application of cattle cooperative hybrid algorithm (domestic and foreign) analysis and summary. Chapter 3 constructs the analysis model of brand illustration innovative design based on cattle collaborative hybrid algorithm and uses the Laplace factor analysis method to create a 3D structure design method based on collaborative innovation and multidimensional analysis. Chapter 4 evaluates the optimization analysis model of brand illustration innovative design and the innovation of illustration constructed in this paper. Test the price index, analyze the test data, and draw a conclusion.

2. Related Work

At present, there are many problems in promoting the innovation of modeling methods in the field of intelligent illustration 3D design, especially in the brand elements of illustration design scheme, intelligent digital combination method, and collaborative design [6]. Chang and other scholars found that the current process of brand illustration design mainly takes the cultural value of the brand as the core and rarely reflects the industrial 4.0 background as the characteristic elements. Therefore, they proposed a free design method of illustration design based on the brand value communication method [7]. Hummel and other scholars proposed that attention should be paid to the development of three-dimensional illustration design methods. Through the use of 3D animation table technique based on modern style, it reflects the more affinity and appeal in the process of illustration design. By combining virtual and real works, it reflects the value circle

communication effect reflected by the brand through illustration [8]. According to the collaborative innovative design theory in illustration design, Qarariyah and other scholars put forward a new brand illustration innovative design system and intelligent integrated design scheme, analyzed the relationship between the traditional illustration design field and the integrated scheme of intelligent modern picture design, and realized its innovative and prominent design in the main features [9]. Aiming at the problem of slow modeling speed in illustration design, Ekman and Feng proposed an efficient illustration modeling method combined with intelligent collaborative hybrid algorithm based on illustration design theory. Through the analysis of illustration design effect, aesthetic requirements, and brand communication in different illustration design field schemes, multidimensional design is carried out according to its internal relevance. It realizes the efficient design of illustration at different levels [10]. Wang and other scholars put forward an illustration design module analysis method based on cloud comprehensive and unified distribution by analyzing the advertising illustration contents of multiple brands, combined with the actual illustration design methods, and aiming at the design commonalities of their internal correlation schemes. This method can effectively solve the low efficiency of illustration design, but it has limited-application scope and low data utilization [11]. Xu and other scholars combined with the illustration design culture and experience of local brands and used the deformed illustration design method to comprehensively analyze the traditional intelligent illustration design method. The results show that the illustration design field system has a good overall coordination effect and can be applied to different brand illustration designs and unconventional brand illustration innovative designs. It can effectively solve the problem of poor universality of illustration design methods [12]. Based on the traditional illustration design theory and illustration aesthetic structure design method, Li and other scholars proposed a panoramic brand illustration innovative design strategy. The results show that the strategy based on intelligent distribution of data flow can effectively reduce its comprehensive errors in the illustration design system and improve the overall illustration design effect. Later, it is optimized by combining Fourier function algorithm. The results show that the optimized method effectively reduces the differentiation problem in the process of illustration design [13]. In order to solve the problems of low efficiency of multi-illustration design cooperation and slow speed of multivariate analysis in the brand illustration innovation design system, Zhao and other scholars proposed an automatic design method of illustration design scheme based on genetic algorithm and particle swarm optimization algorithm. Experiments show that the automatic design method can effectively improve the innovative effect in the process of intelligent illustration design [14]. Aiming at the problem of low efficiency in traditional brand design methods, Deng and other scholars proposed a 3D modeling illustration design method combined with massive data information. This method can realize the innovative evaluation basis of brand illustration innovative design system

by simulating the three-dimensional structure diagram in illustration design, but it has the problem of low efficiency [15].

To sum up, it can be seen that the current research on brand illustration innovative design still focuses on the traditional illustration style design and the method based on low-dimensional data analysis strategy, mainly on the brand elements, intelligent digital combination method, and collaborative design of illustration design scheme, and rarely on the effective combination of intelligent algorithm and industrial 4.0 background [16–18]. On the other hand, in the modeling and optimization of illustration design style, most illustration design modeling and analysis models need to summarize the modeling data in different ranges first and then conduct unified analysis and processing, which leads to the overall illustration design efficiency becoming very low. And there is no research on optimization design and construction of relevant models for illustration design modeling [19–22]. Therefore, the research on the modeling method of brand illustration innovative design based on industry 4.0 has important practical significance.

3. Methodology

3.1. Application of Cattle Cooperative Hybrid Algorithm in Brand Illustration Innovative Design Analysis Model. In this study, in order to better quantify the data level of the intelligent illustration design process, a cattle cooperative hybrid algorithm based on color recognition strategy is adopted [23]. When studying the laws of different types of multidimensional information data, cattle collaborative mixing algorithm is a more commonly used one. Cattle collaborative mixing, also known as multilinear collaborative regression analysis, is a dynamic research model for comprehensive analysis based on the correlation between data and data, which is often used in big data analysis, cloud model verification, and so on [24]. In essence, collaborative hybrid algorithm belongs to two classification problems. Generally speaking, it is to carry out different degrees of classification process according to different types of problems, take the minimum error as the solution standard, and finally realize the optimal solution of the results [25]. Collaborative hybrid operation is also a basic method of self-learning and updating at the data level. In the process of data updating and analysis, through the accumulation of the characteristics of different types of data, it can realize the high relevance and coupling verification so as to solve the unknown complex multidimensional operation problem.

In this study, in order to build the brand illustration innovation design modeling and analysis model, the cattle cooperative hybrid algorithm is the core key point for the data information required for processing, and its corresponding data processing type is also obtained by multidimensional analysis and corresponding matrix operation. The data analysis and three-dimensional simulation operation process of its intelligent illustration innovative design is shown in Figure 1.

3.2. Establishment Process of Performance Analysis Model of Intelligent Illustration 3D Design Based on Cattle Cooperative Hybrid Algorithm. This intelligent illustration 3D design model based on cattle collaborative innovation algorithm combines the industrial 4.0 background and brand influence analysis mechanism to simplify the processing of complex data in intelligent illustration 3D information. Therefore, the intelligent 3D design performance analysis model needs to analyze many factors of illustration innovation so as to judge whether there are closely related factors in a variety of data. Therefore, this method can not only use the three-dimensional data required in the process of illustration design as the reference standard, but also use these comprehensive average indicators with closely related factors for data analysis or represent the modeling and analysis factors existing in intelligent illustration design through one of them. In addition, the information carried by these multidata (three-dimensional images) to be processed cannot be seriously distorted. The data analysis process of the intelligent three-dimensional description model of brand illustration is shown in Figure 2.

In the process of brand design of illustration, there is a data object to be processed (illustration innovative design modeling feature information). This process is called modeling the illustration model. In three-dimensional space, the position sequence expression in the illustration innovative design model is

$$
\begin{aligned}
Z_2 &= \frac{(z_2(1), z_2(2), \ldots, z_2(n))}{2n^2 + 3n - 1}, \\
Z_1 &= \frac{(z_1(1), z_1(2), \ldots, z_1(n))}{n^2 + n - 1}, \\
Y_2 &= \frac{(y_2(1), y_2(2), \ldots, y_2(n))}{2n^2 + 3n - 1}, \\
Y_1 &= \frac{(y_1(1), y_1(2), \ldots, y_1(n))}{n^2 + n - 1}, \\
X_2 &= \frac{(x_2(1), x_2(2), \ldots, x_2(n))}{2n^2 + 3n - 1}, \\
X_1 &= \frac{(x_1(1), x_1(2), \ldots, x_1(n))}{n^2 + n - 1}.
\end{aligned}
\tag{1}
$$

In the above formula, x, y, z refer to the three-dimensional coordinate information, X, Y, Z in the process of brand illustration innovative design refers to the design change position of brand illustration in the three-dimensional space, and n refers to the stacking product of feature points of different brand illustration innovative design. In this stage, in the processing of data groups with different dimensions, the simulation results of the three-dimensional space design change position with the cattle cooperative hybrid algorithm and the three-dimensional space change position without the cattle cooperative hybrid algorithm are shown in Figures 3 and 4, respectively.
FIGURE 1: Data analysis and 3D simulation operation process of intelligent illustration creative design.
FIGURE 2: The data analysis process of the intelligent 3D description model of the brand illustration.

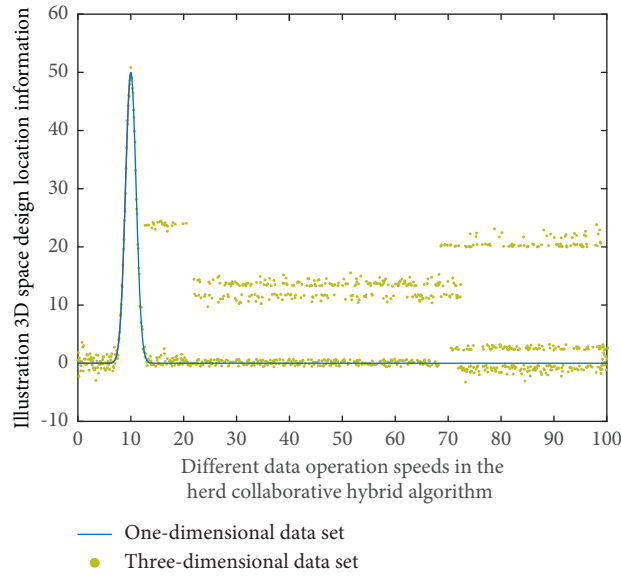
It can be seen from Figures 3 and 4 that under the cattle cooperative hybrid algorithm, with the increase of data operation speed, the difference between the data operation efficiency corresponding to the illustration design style and the internal correlation of the illustration three-dimensional spatial design position information is very obvious, because with the increase of the number of cattle cooperative operations, different types of illustration modeling impact graph indicators also show the same change law, which gradually decreases, and when the threshold is smaller, the impact


FIGURE 3: The spatial position change of the illustration design at different speeds without using the herd collaborative hybrid algorithm.
FIGURE 4: The spatial position change of the illustration design at different speeds using the herd collaborative hybrid algorithm.

indicator is smaller, because the smaller the threshold is, the weaker the impact degree is, and the better the corresponding stability is. Therefore, this means that the cattle collaborative hybrid method proposed in this study can effectively improve the modeling efficiency of illustration innovative design.

After combining the cattle cooperative mixed variable function $K(x, y, z)$ and the reinforcement machine learning mechanism rule function $L(x, y, z)$, the position expression of the corresponding illustration background 3D design modeling is

$$Z_2' = \frac{3n+5}{5n^2+7n-1} \frac{(z_2(1), z_2(2), \ldots, z_2(n))}{(n+1)^2 K(x,y,z) + (n+2)L(x,y,z)},$$

$$Z_1' = \frac{n+2}{n^2+n-1} \frac{(z_1(1), z_1(2), \ldots, z_1(n))}{n^2 K(x,y,z) + (n+1)L(x,y,z)},$$

$$Y_2' = \frac{3n+5}{3n^2+2n-1} \frac{(y_2(1), y_2(2), \ldots, y_2(n))}{K(x,y,z) + n^2 L(x,y,z)},$$

$$Y_1' = \frac{n+2}{n^2+n-1} \frac{(y_1(1), y_1(2), \ldots, y_1(n))}{K(x,y,z) + nL(x,y,z)},$$

$$X_2' = \frac{3n+5}{3n^2+2n-1} \frac{(x_2(1), x_2(2), \ldots, x_2(n))}{K(x,y,z) + 2L(x,y,z)},$$

$$X_1' = \frac{n+2}{n^2+n-1} \frac{(x_1(1), x_1(2), \ldots, x_1(n))}{K(x,y,z) + L(x,y,z)}.$$

$$(2)$$

The expressions of cattle cooperative mixed variable function $K(x,y,z)$ and reinforcement machine learning mechanism rule function $L(x,y,z)$ are, respectively,

$$L(x,y,z) = \frac{3x^4 - 3y^2 - 7z^3}{5x^2 + 7y^2 + 2z^3} \frac{zy^2 x^3 + xy^3 + x^{-1}y^{-1}z^3}{x^2 + y^2 + z^{-1}},$$

$$K(x,y,z) = \frac{x^4 - y^2 - z^3}{x^2 + y^2 + z^3} \frac{yx^2 + xy^2 + xyz^2}{x + y + z}.$$

$$(3)$$

X, Y, Z are the motion position function of brand illustration in three-dimensional space, n is the total number of feature points of different brand illustration innovative design schemes, and x, y, z are the spatial trajectory coordinate information of illustration three-dimensional design. When the set signal is different from the coordinate signal in the innovative design of illustration, combined with the analysis of signals by the function of reinforcement machine learning algorithm, the integral expression $Q(t)$ of the correlation comparison results between different types of data is as follows:

$$Q(t) = \frac{k_p \left[e(t) + 1/T_1 \int_0^t e(t)dt + T_D de(t)/dt \right]}{x^2 + y^2 + z^3},$$

$$(4)$$

where x, y, z are the three-dimensional coordinate information in the process of brand illustration innovative design, $e(t)$ represents the deviation, k_p represents the error increase of illustration three-dimensional design, and T represents the conventional modeling constant.

3.3. Application of Brand Illustration Innovation Analysis Model in Intelligent Illustration 3D Design.
Before completing the first draft of different types of brand illustration schemes, in the process of illustration design for different types of brands, after optimizing the innovative design methods of illustration, it is necessary to select different innovative countermeasures and methods of illustration design in combination with the characteristics of innovative design of brand illustration. In this process, by adopting the technical methods involved in different types of industrial 4.0 brands, taking the design brand illustration innovative design scheme and illustration design field as the core modeling goal, the process of the involved illustration design field will be comprehensively evaluated and analyzed to obtain the optimal illustration modeling design scheme. In this process, the internal relevance of different types of data will be analyzed through the 3D modeling method of the brand illustration innovation design system.

Secondly, the intelligent illustration 3D design method is to mine the collected illustration data types. For unknown cattle cooperative mixed data target (innovative design styles of different types of brand illustration), carry out fuzzy search and screening to realize data mining and feature analysis of the overall process of illustration design modeling, and transform the information of different types of intelligent illustration design schemes into data information that can be recognized by the system through a certain pattern. Data mining of different brands will produce different effects. The speed simulation results of the modeling method of innovative illustration design in the traditional illustration 3D design method and intelligent illustration 3D design method are shown in Figures 5 and 6, respectively.

Finally, after completing the above links, it is necessary to accumulate and stack the data generated by modeling under the cattle cooperative hybrid algorithm; that is, it is also necessary to estimate the error degree through the computer database information and the preset automatic innovative judgment program of illustration and then deeply mine and analyze some information in the field of illustration design so as to realize the secondary analysis and error analysis of the data after the initial linear analysis. The results of the illustration modeling simulation analysis method under different disturbing factors in this process are shown in Figure 7.

As can be seen from Figures 5–7, with the increase of illustration modeling and simulation times, its internal relevance is very obvious, especially in the aspects of modeling efficiency and illustration innovation. Moreover, under different thresholds, the change trends in modeling spatiotemporal differences are relatively similar, which are gradually increasing or decreasing, but the increase ranges are different, which shows that the cattle collaborative innovation method can well reduce the differences in illustration design methods. This is because the cattle cooperative hybrid algorithm has an inevitable correlation between data decision-making and state transition in illustration design, so its difference will be very small.

4. Result Analysis and Discussion

4.1. Experimental Results of Intelligent Illustration Modeling and Design Method Based on Cattle Collaborative Hybrid Innovation Model.
After constructing the performance analysis model of brand illustration innovative design, we need to evaluate its practical application effect in intelligent
Figure 5: Simulation results of traditional illustration 3D design methods.

Figure 8: Preliminary analysis results of experiments under the cooperative hybrid algorithm of cattle herd.

illustration 3D design. When evaluating the data acquisition and analysis model of illustration innovative design based on Industry 4.0, it needs to be evaluated from many aspects. According to the needs of innovative illustration design of different brands, this study proposes several indicators to evaluate micro nano flexible sensors. This paper analyzes the application effect and quality of intelligent illustration in three-dimensional design in the process of illustration design. Therefore, it is necessary to analyze the data corresponding to multiple indicators of the three groups of experiments. The preliminary analysis results are shown in Figure 8, in which the horizontal axis is the number of multidimensional data. The vertical axis is the innovative and beautiful effect of illustration.

As can be seen from Figure 8, in the process of this experiment, in the verification process of intelligent illustration 3D modeling design experiment, in this study, the

above indicators can be properly classified, linear analysis and logistic regression through the observation results of known experimental object data. By deleting some unnecessary (i.e., less influential) impact indicators in the illustration design field. With the increase of the number of cycles of the conduction mechanism in the experiment, there are also great differences in the spatiotemporal delay accuracy of the illustration design structure under the corresponding collaborative innovation hybrid strategy, and the accuracy of the spatiotemporal difference of the experimental data of the three-dimensional financial structure will be higher. This is because the brand illustration innovation design analysis model of degree learning algorithm is optimized and classified according to the individual differences between different modeling 3D structures and technological innovation. Through the use of big data analysis and

intelligent fusion technology, the whole process monitoring of illustration innovation models of different brands in the illustration design process is realized, and the process is represented by data. Through the big data analysis system, the source data is transmitted to the system terminal, and then through the intelligent data depth mining technology and optimal analysis scheme based on cattle cooperative hybrid algorithm, a one-to-one analysis scheme is provided for the heterogeneity influence link of illustration innovative design modeling method. The above is the construction idea of brand illustration innovative design intelligent model.

4.2. Experimental Results and Analysis. Among the multiple data indicators used in this experiment to evaluate the three-dimensional design of intelligent illustration, some or several indicators do have correlation or mixed relationship. In order to analyze the experimental data more conveniently, the six comprehensive evaluation indexes involved in the experimental process and the correlation coefficient between the indexes are analyzed. Through the impact evaluation and application of the results of the experimental analysis of the known 9 different types of intelligent illustration design methods and the corresponding indicators in the illustration design, the performance optimization design and fiber flexibility effect of intelligent illustration modeling are realized. The corresponding image analysis is shown in Figure 9. The horizontal axis is the number of experiments and the vertical axis is the impact evaluation factor.

According to the result analysis in Figure 9, the correlation degree between the first index and the second index is 0.97; that is, the coupling relationship between the illustration design effect and the illustration style selected by the modeling method in the illustration design is very high because there is also a positive correlation between the design style and the 3D modeling method in the corresponding brand illustration innovation design system. There is also a positive correlation between design style and 3D modeling method. The relevant test results of six different types of evaluation indicators are passed in the corresponding brand illustration innovation design system. It can well reflect the effectiveness and timeliness of illustration design modeling and analysis model based on cattle cooperative hybrid algorithm. On the other hand, the experimental results show that the correlation degree between the second index and the third index is 0.96, which is very close to 0.9, which also shows that the aesthetics and symmetry in the field of illustration design are also very relevant, and its correlation value is more in line with the current practical experience, which also shows that there is a strong correlation between the two. It can be explained that the innovative modeling of illustration design and brand is also a strong correlation of positive synergy.

Therefore, the results of this study show that the intelligent illustration 3D design method based on big data analysis strategy and cattle collaborative hybrid algorithm can realize the efficient analysis of the internal information and external correlation degree between the data generated by different brands in the illustration design process. In
FIGURE 9: Analysis of experimental results under the synergistic hybrid algorithm of cattle.

addition, the relationship between brand illustration innovative design effect and external aesthetics can also be quantified and compared through the design modeling analysis model proposed in this study, and the degree of correlation is very small or even negligible, which is also in line with our life experience—under the background of Industry 4.0, the relationship between brand illustration design effect and external aesthetics is not large. This also shows the accuracy and objectivity of the results of this study in the application of brand illustration innovative design Industry 4.0 based on cattle collaborative innovation algorithm in innovative design.

5. Conclusion

In recent years, with the vigorous promotion of Industrial 4.0 technology, the application prospect of traditional illustration design in brand 3D modeling is becoming more and more obvious. Based on this, this paper studies the modeling method of brand illustration innovative design based on Industry 4.0 and constructs an intelligent illustration design and modeling strategy analysis model based on cattle cooperative hybrid algorithm. The collection of data and information in the process of brand illustration innovative design is realized from six aspects. The cattle cooperative hybrid algorithm is used to realize its data fusion. Combined with the quantitative evaluation method of multidimensional data, the illustration intelligent analysis model can comprehensively analyze and evaluate the data of different types of models. According to the relevant requirements in the field of illustration design and the general rules of modeling design method, the efficient modeling method in the process of brand illustration design is improved. Finally, relevant experiments are designed for verification. The experimental results show that the

intelligent illustration design modeling model based on cattle cooperative hybrid algorithm has the advantages of quantifiable evaluation and good stability. It can improve the efficiency of illustration three-dimensional design and strengthen the intelligence of brand illustration innovation design system. However, this study only analyzes the impact and relevance of modeling methods in intelligent illustration design and does not take other potential influencing factors in the implementation of intelligent illustration design methods into account. Therefore, the impact of other factors on the modeling effect of brand illustration innovative design needs to be further studied.

In order to realize accurate marketing by analyzing customer individual demand, a new quantitative Kano model method is put forward, and it is helpful to provide customized products for heterogeneous customer classification groups. By improving the traditional Kano model, the customer satisfaction and the importance degree of products are defined, and the quantitative Kano demand model is established. Customers are classified as the price preference group, the brand preference group, and the service priority group, and decision-making of product attribute quality improvement for customer classification is realized. Lastly, electric vehicles (EVs) are selected as a study case, and their various demands for different classifications of customers are discussed by questionnaire survey and calculation of satisfaction and the importance degree. Furthermore, different customer group demands are classified as attractive demands, expected demands, nondifferential demands, or essential demands, and the important product attribute acquisition process for various customers is discussed to improve enterprise market competitiveness.

1. Introduction

With the continuous improvement of people's consumption levels and the diversification of product forms, more and more consumers no longer simply pay for the premium of the product brand but expect to achieve consumption upgrading on the basis of the price, which also brings huge opportunities and challenges for enterprises to design and customization of products and services. Many manufacturing enterprises have also been user-centered, driven by the demand side, and depicted the user portrait on the basis of big data mining and analysis, so as to realize personalized customized services to users. As early as 1998, Yeh and Pearlson proposed the concept of customer customization, providing the corresponding personalized design, production, and delivery of customer products or services according to their personalized needs [1, 2]. Foreign IKEA and BMW-Mini have launched user customization in product customization, while Amazon, Haier, and other websites have made personalized recommendations for use

[3]. Domestic red collar and WeiShang fully reflect the personalized personalization in the product application [4]. Enterprises can segment the market, regard the same type of users as a market segment, and provide them with the corresponding customized services to meet the personalized needs of users [5]. Personalized needs are to let products or services reflect their own unique needs and personality, not different needs from others. Therefore, while all users have common needs, the types of users can be distinguished through the personalized needs of users, and the products and services can be customized for different users' needs, which is of great significance to improving the competitiveness of enterprises in the same industry and the formation of precise marketing for customers.

At present, there is a certain vague uncertainty in the expression of user demand for products and services. How to maximize the personalized needs of users is the key to enterprise customization. There are two main ways to obtain information about users' needs: one is the data collection based on the Internet with the help of marketers. In [6], they

proposed a method of product personalized customization with a case-based reasoning theory to solve the problem of low matching between user requirements and product modules in the process of product personalized customization. A new method for KANO model classification was created in [7]. By collecting customer reviews and rating scores, the author builds a regression model between the score and the degree to which product attributes meet user needs according to their text expression. However, the cost of one-to-one communication with customers is high, and the expression of product demands in the process of independent selection is vague. Besides, the existing options and parameters are difficult to meet the needs of customers. In [8], they researched the user's personalized needs of smart health preserving pot based on the Kano model to guide the interaction design and make the interaction of smart health preserving pot more fit the user's real needs. In [9], they focused on investigating traditional garment enterprises' transformation from mass production to mass customization, and it probed deeply into the ways for the garment manufacturing industry to realize Internet-based mass customization and key problems to be solved. An approach of integration of the Kano model into QFD to examine customer satisfaction based on aesthetic sentiments was proposed in [10], and a sport utility vehicle has been selected for the study. The aesthetic attributes have been selected with the help of QFD and their importance and classification have been calculated using both the fuzzy Kano and the traditional Kano models. [11]aimed to examine consumer perspectives about service satisfaction in the domestic medical industry using Kano's two-dimensional model and employed the importance-satisfaction model to determine service items that need improvement. In [12], they estimated customer preference based on conjoint analysis and categorized service quality elements by the IPA-Kano model. A methodology that integrates the Kano model (KM), analytic hierarchy process (AHP), and quality function deployment (QFD) methods with intuitionistic fuzzy set (IFS) to solve decision-making problems in new product development and design was proposed in [13]. By the new method, the web crawler technology was first applied to e-commerce web sites to collect raw data, and the representative CRs were extracted through combining the LDA model with the Apriori algorithm. Second, the intuitionistic fuzzy Kano model (IFKM) is proposed to evaluate the adjustment coefficient of CRs and Kano categories via customer preference membership functions. In [14], they proposed the product feature KANO analysis method based on the emotional distribution of product features, and Kano analysis of product characteristics by using product review data can provide valuable reference information for companies to improve their products. Literature [15] classified the product functions mentioned in social media. In [16], they divided the design demands information of personal protective mask into several attributes initially and obtained the final Kano required attributes by the better-worse coefficient analysis method. In [17], they used the Kano model to identify and screen demand and built the quality demand hierarchy model of high-quality housing to calculate the importance

degree of each demand item. In the study [18], they defined the user requirements in the Kano model and classified user requirement hierarchies using the rough analysis hierarchy process method to calculate requirement weight. In [19], a hybrid Kano model with tools of SII and DDI was proposed.

Most of the existing customer demand determination methods are to calculate the importance degree of a customer's personalized demands and then determine the priority of the customer's demands, ignoring the existence of product satisfaction. Product satisfaction is an important and influencing factor of product upgrading, and it can realize product accuracy in marketing if the demands of customers are quantified with feedback on product importance and satisfaction. Therefore, this paper acquires the customer preferences for different types of demands by through a quantified Kano model classification according to the importance degree of customer demands. Furthermore, the satisfaction and importance evaluation of customer demands are combined to determine which types of demand items should be emphasized in the later update and upgrading of products so as to provide user groups with products that meet customer scenarios and actual demands in the future.

2. Related Work

The Kano model was formally proposed by Japanese scholar Yoshino. According to the subjective performance of the product and the customer subjective perception [11], the quality characteristics of the product were classified and screened. Among them, the customer's demand for products is divided into five categories, namely, necessity, expectation, charm, no difference, and reverse [20]. Must-be requirement refers to the basic requirements that the product should have. If the attribute is sufficient, the user will not be delighted, but if the point is absent, the user will be very dissatisfied. Attractive requirement, also known as excited demand, is a characteristic that can surprise or surprise customers. When it is sufficient, it can improve customer satisfaction to a large extent, but it will not cause dissatisfaction when it is insufficient. One-dimensional requirement is an essential factor for enterprises to evaluate competitiveness, which makes customers satisfied when the product has enough characteristics and causes dissatisfaction when it is not sufficient. Indifferent requirement, customers ignore factors, and whether it is satisfied does affect users' satisfaction with products. Reverse requirement, when product attributes are satisfied, customers are not satisfied, and when product attributes are not satisfied, customers are more satisfied. According to the objective performance of the product and customer satisfaction, the Kano model diagram is shown in Figure 1.

The Kano model requirement classification evaluation table designs the product attributes as positive and negative aspects and obtains the demand classification of product attributes by analyzing the Kano questionnaire filled by users. Among them, M represents the necessary demand, O represents the expected demand, A represents the charming demand, I represents the nondifference demand, R
Figure 1: Kano model schematic.

Table 1: Kano model demand classification evaluation table.

Positive problem	Reverse problem				
	Like	Naturally	Never mind	Passable	Dislike
Like	Q	A	A	A	O
Naturally	R	I	I	I	M
Never mind	R	I	I	I	M
Passable	R	I	I	I	M
Dislike	R	R	R	R	Q

represents the reverse demand, and Q represents the problem demand (Table 1).

The traditional Kano model is essentially a qualitative analysis method, and its classification method is subjective. The preference of product characteristics is classified by the degree of selection of positive and negative problems in the Kano model demand classification evaluation table, which lacks quantitative standards. Therefore, it is of great significance to quantitatively improve the traditional Kano model and divide the user's demand preference after quantification, so as to realize the precise marketing of users.

3. Quantitative Kano Model Method
