This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Few-shot learning is a method to acquire learning ability in a small amount of sample data scenarios. This paper aims to study an online and offline interaction model applied to international Chinese education and teaching based on the few-shot learning method. It first expounds an overview of international Chinese education, including the connotation and characteristics of the hybrid mode of online teaching and offline teaching in international Chinese education, then designs an online and offline interactive model, and finally compares it with a baseline model and a traditional single teaching model. The experimental data shows that the accuracy and recall rate of the international Chinese education online and offline interaction model based on few-shot learning both reach 70%, which verifies its effectiveness.

1. Introduction

Language is not only one of the important media for the transmission of culture, but also an indispensable part of the expression of human thoughts and ideas. With the diversified development of world culture and the rapid increase of China's economic and technological strength, Chinese has become another popular language after English. The charm and connotation of Chinese are more and more appreciated and valued by many countries. According to research data released by the Ministry of Education, more than 70 countries around the world have incorporated Chinese language education into their educational systems and structures. The number of people studying Chinese overseas has also exceeded 20 million, and the number of overseas Chinese education institutions is also increasing every year, as shown in Figure 1. International Chinese education has entered a period of vigorous development. However, with the outbreak of the new crown epidemic, traditional offline education has been hit. International Chinese education has transformed from offline to online development. However, due to the particularity of Chinese teaching, and because online education is still in the early stage of exploration, there are still many limitations in the current international Chinese education. For example, online classroom learning is full of difficulties, low flexibility, and the interactive experience between students and teachers, which has brought many negative effects [1].

The Chinese interpretation of few-shot learning is small sample learning. As the name implies, it is to master the ability of learning and generalization in a small number of samples. Learning in this way can enable humans to obtain an initial target set for learning in a very small number of individual categories. Humans can not only learn object permanence through this target set, but also generalize and apply it to other objects based on this target set. This type of method often plays its own role in task scenarios where data or supervision information is difficult to obtain. It can not only find suitable models for scarce sample tasks, but also assist in data- and computing-intensive data collection, such as image retrieval, object tracking and language modeling, and one-shot architecture search.

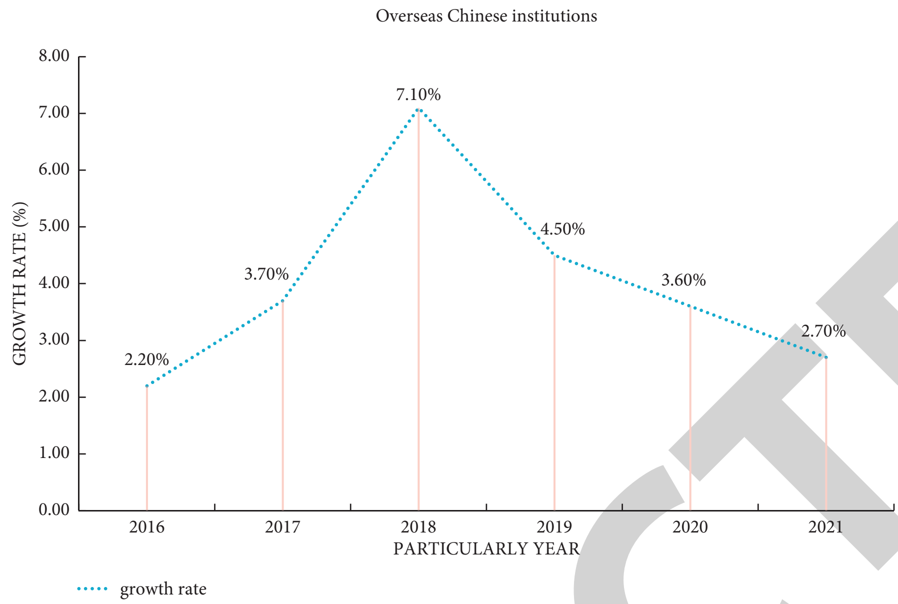

Figure 1: Growth and changes of overseas Chinese education institutions.

Many academics have studied the subject of more-shot training in recent years. Shi Y proposed a self-determination training-based multishot modeling algorithm. The algorithm has a large number of resources and a simple network design. Finally, simulation results show that this algorithm can improve model recognition by 5% to 10%. Chen M proposed a novel diversity transfer network generation framework to address the lack of diversity in few-shot learning. He also confirmed that the generation framework has state-of-the-art results in the few-shot learning method based on feature generation [2] through experimental results. Lv Q proposes the new more-shot learning method in conjunction with programming observation and replaces the mean square error loss function with L1Loss and BCEloss. The test's final results show that the method has an average accuracy of 97.25 percent in the data set, indicating that it is effective [3]. In manipulated microbot systems, Zhang D proposed a data-driven approach to stability and depth analysis. It also demonstrates the method's generality by adapting to microrobots of various shapes using a multishot learning curve [4]. Aharchaou M gives an example of machine learning in action. This example is based on recent advancements in deep learning systems, as well as Siamese networks' few-shot learning capability, which has been shown to generalize well to new datasets [5]. Deng S used meta-learning and unsupervised language models to solve the problem of negating common language features implicit across tasks in few-shot tasks and confirmed that pretraining is a promising solution in many few-shot tasks [6]. Few-shot learning was proposed by Wang Y to address the problem of machine learning being hindered in applications with small datasets. He also looks into the setting, technical, applied, and theoretical aspects of the few-shot learning problem in order to give researchers ideas for future research [7]. Silver T proposes a powerful but general prior and a learning algorithm that, when combined, can learn interesting policies from few shots and shows that this method is a good fit for tasks with sparse training data [8]. In the field of civil aviation emergency management, Hong W proposed a few-shot learning method. Finally, experiments show that the method can solve the problem of automatic updating of concepts and relationships in large-scale domain ontologies while also providing good data support, and using few-shot machine learning [9–11] to train general neural network models in cell lines also has many advantages for high-throughput screening of individual patients. To summarize, many scholars have studied the few-shot learning method and application in depth after several years of research. However, there are few studies that integrate it with the international Chinese education model of online and offline interaction, and previous studies still have some flaws, as shown in Table 1.

Therefore, this paper incorporates the few-shot learning method to establish an online and offline interaction model in order to further promote the long-term development of international Chinese education. It also investigates the current state of international education and teaching, as well as problems and practical teaching strategies. It proposes a novel educational interaction research direction that can effectively improve the quality of Chinese education and teaching, offer suggestions for improvement and improvement for international Chinese communication, and generate new ideas for Chinese education and teaching research.

2. International Chinese Education Based on Few-Shot Learning

2.1. Overview of International Chinese Education. On the basis of the first Chinese international education, international Chinese education is being developed. It is primarily written in the form of a second language for foreigners and foreign Canadians who do not speak English as their first

Table 1: Weaknesses of previous studies.

Sequence	Insufficiency	Influence
1	More qualitative discussions, less quantitative research	Not objective enough
2	More micro research, less macro research	Not comprehensive enough
3	More experience summaries, less theoretical discussions	Not deep enough

language. Although international Chinese education and teaching have an offline component, traditional offline education cannot be adapted in the face of the new epidemic. Traditional education should keep up with the times, build digital and networking, and develop online teaching and learning, as shown in Figure 2, in order to promote the healthy and sustainable development of international Chinese education. Of course, this does not imply that international education and teaching in Canada will replace traditional schooling, nor that offline education will become the predominant teaching method. Modern technology and techniques will not completely replace traditional face-to-face instruction, but they are more likely to introduce a variety of teaching positions in various combinations and sizes. It is believed that it will be able to fully benefit from Chinese online education and that online education can be used as an aid and complement to offline education if the level of international online education in Canada is raised and the quality of education is improved.

2.1.1. The Connotation of the Mixed Mode of Online Teaching and Offline Teaching. The hybrid teaching mode that combines online and offline is an organic combination of online teaching and traditional face-to-face classroom teaching, which integrates multiple elements (teacher, student, classroom, environment, etc.). It is through the transformation of modern information technology means and teaching methods. On the basis of conforming to the laws of language communication, the complementarity between online learning and offline classroom teaching can be realized, so as to achieve the best learning effect. Pure online teaching or offline teaching can no longer fully meet the current Chinese learning needs. Compared with traditional face-to-face classroom teaching and fully online teaching, the online-offline hybrid teaching mode has a deeper meaning. This teaching model neither unilaterally emphasizes the dominant position of students and ignores the dominant position of teachers, nor unilaterally emphasizes online teaching and ignores the emotional communication between teachers and students in traditional face-to-face classrooms. The blended teaching combining online and offline may become a normalized teaching mode in the postepidemic era.

2.1.2. Characteristics of the Hybrid Mode of Online Teaching and Offline Teaching

(1) Multichannel Teaching. At present, the online and offline teaching modes of international Chinese education and teaching are still not closely connected, and the two have not been organically combined. The hybrid teaching mode that combines online and offline teaching cannot simply separate the two, and online Chinese teaching can not only be used as an auxiliary to offline teaching, but must be a necessary teaching link. The offline Chinese teaching in the blended teaching should not just copy the teaching activities in the traditional face-to-face classroom teaching, but should further develop the teaching activities based on the previous results of online Chinese teaching.

(2) Complete Teaching Links. The first stage of the learner's learning process is mainly information transmission, and the second stage is mainly the absorption and internalization of the teaching content. The blended teaching mode of Chinese online teaching optimizes the classroom structure and promotes the rationalization of teaching content distribution. The flipped classroom teaching mode adopts the teaching form of "learning knowledge before class—consolidation and practice in class", and learners can conduct autonomous learning of target knowledge by watching videos online. Practical language practice is carried out in the offline classroom, and the target knowledge is applied in practice.

(3) Targeted Teaching. The online Chinese teaching in the online and offline hybrid teaching can make up for the lack of offline classroom teaching time to a certain extent. However, due to the lack of deep participation of teachers, the effect of learners will be difficult to guarantee; teachers should pay attention to the design of teaching content and target language environment in offline Chinese classroom teaching. By recording the learner's Chinese learning situation, the teacher supervises the learner's learning progress, which is helpful for the teacher to better grasp the teaching progress of the offline classroom and make the teaching activities more targeted.

(4) Interactive Teaching. Training Canada online and offline can not only affect the quality of teachers, but also reflect the high position of students. Teachers teach relevant target knowledge online and complete information transfer; offline practice is a specific exercise of language points. By strengthening the interaction between teachers and students in the classroom, learners can complete the absorption and internalization of knowledge, so that online teaching can better serve offline teaching. At the same time, offline education can be better adapted to online education, in order to achieve a positive attitude and improve the quality of teaching and learning.

2.2. Design of Online and Offline Interactive Model Based on Few-Shot Learning. Few-shot learning is used in this paper to identify the features of intent classification and semantic

Figure 2: Online and offline teaching of international Chinese education.

understanding in international Chinese education, and the two models are combined with algorithms to create a complete online and offline interaction model. The sample input model of the support set and query set must first be encoded, and the data must then be converted into a sample semantic vector that contains semantic information and is more conducive to model learning for the task of intent classification. The class vector of each class in the support set is then obtained by extracting some intentional category features from the semantic vector of the support set sample. Finally, they calculate the loss function and finish the backpropagation by comparing the class vector with the query set sample semantic vector. The few-shot intent recognition model is divided into three parts based on these three basic steps, as shown in Figure 3: encoding module, induction module, and relation module.

The main task of the encoding module is to receive the sample input of support set and query set and encode them into sample semantic vectors. In this study, a bidirectional long-term and short-term memory network with self-attention mechanism was used to form the encoder. Given a set of input text $x = (x_1, x_2, \ldots, x_T)$ represented by a sequence of word embedding, use $Bi - \text{LSTM}$ to process this set of text:

$$\begin{aligned} \overrightarrow{h_t} &= \overrightarrow{\text{LSTM}}(x_t, h_{t-1}), \\ \overleftarrow{h_t} &= \overleftarrow{\text{LSTM}}(x_t, h_{t+1}). \end{aligned} \tag{1}$$

Connect $\overrightarrow{h_t}$ and $\overleftarrow{h_t}$ to obtain a hidden state h_t, and record all T hidden states as $H = (h_1, h_2, \ldots, h_T)$. The length of each text sample is different, and we need to encode it as a fixed-size embedding, which can be achieved by choosing a linear combination of T latent vectors LSTM in H [12]. Computing the linear combination requires a self-attention mechanism that takes the entire hidden state H of LSTM as input and outputs a weight to a:

$$a = \text{soft max}\left(W_{a2}\tanh\left(W_{a1}H^T\right)\right). \tag{2}$$

The definitions of all parameters in (2) are shown in Table 2.

From this, the semantic vector e of an input sample is finally expressed as the weighted sum of H for the self-attention weight a:

$$e = \sum_{t=1}^{T} a_t \cdot h_t. \tag{3}$$

The sample semantic vector of all samples in the support set and query set can be obtained through the encoding module. Among them, the sample semantic vector e^s of the support set needs to be input into the induction module, while the sample semantic vector e^q of the query set is directly input to the relation module [13]. The induction module needs to summarize some essential characteristics of the intent category according to the K samples of each class in the support set, that is, according to the sample semantic vector of the support set, abstract a class vector c of each class, so this part is called the induction module:

$$\left\{e_{ij}^s \in R^{2u}\right\}_{i=1,\ldots,C,\, j=1,K} \leftrightarrow \left\{C_i \in R^{2u}\right\}_{i=1,\ldots,C}. \tag{4}$$

In previous studies, there have been some computational methods, for example, directly adding the semantic vectors of each sample, or taking the average value of the semantic vectors of the samples as a class vector to obtain abstract class vectors. But in few-shot learning, because the number of samples is too small, it is not enough to cover a wider and general situation. This kind of simple algorithm will bring great chance, and the noise brought by each sample is huge, and the capsule network can solve this problem very well [14]. The capsule network adopts an idea of inverse rendering, which can predict the overall features of the high-level from the local features of the bottom layer, so that the model has better generalization, as shown in Figure 4.

In the task of intent classification, the sample semantic vector can be regarded as a local feature, while the class vector that needs to be abstracted can be regarded as the overall feature. Through the dynamic routing algorithm, the coupling coefficient between the sample vector and the same kind of vector is increased, and the coupling coefficient with other class vectors is reduced, so as to obtain a class vector that can dynamically change according to the sample vector and has better generalization. According to the dynamic routing algorithm, it is first necessary to multiply the sample vector by a transformation matrix to obtain the prediction vector:

$$\widehat{e}_{ij}^s = W_s e_{ij}^s. \tag{5}$$

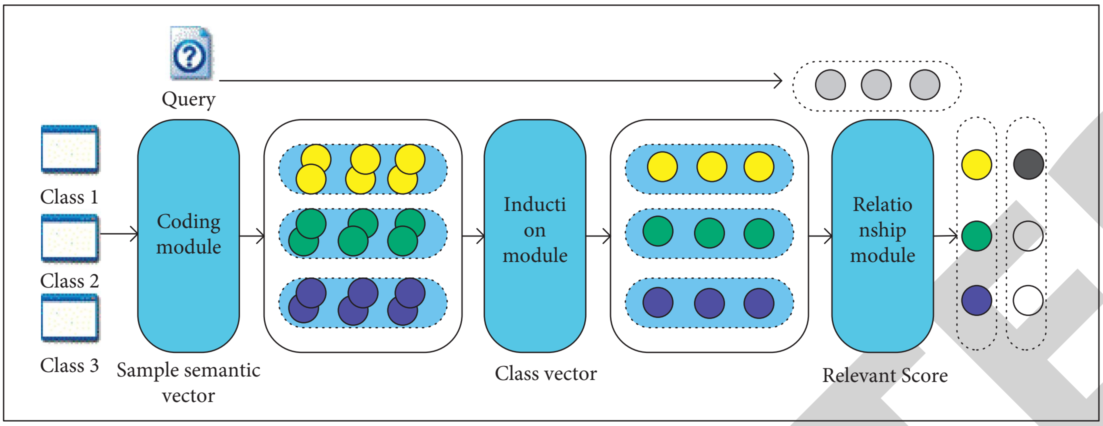

Figure 3: Few-shot intent recognition model structure.

Table 2: Definition of formula parameters.

Sequence	Parameter	Paraphrase
1	$W_{a1} \in R^{d_a \times 2u}$	Weight matrix
2	$W_{a2} \in R^{d_a}$	Weight matrix
3	d_a	Hyperparameters
4	u	The size of the hidden state vector for each one-way LSTM

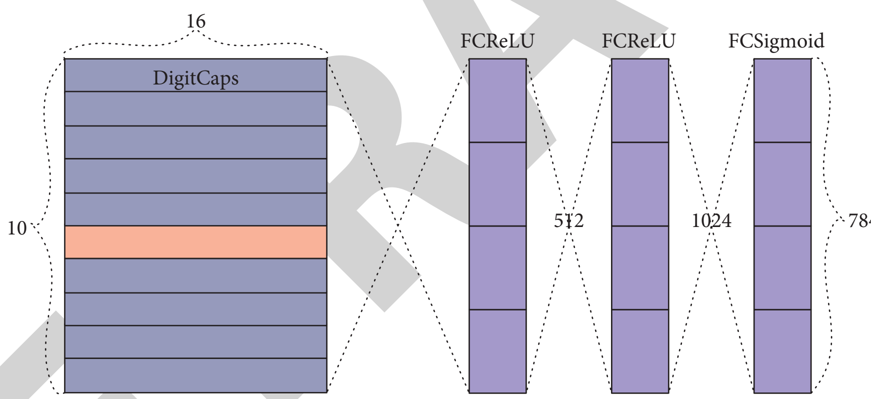

Figure 4: Capsule network structure diagram.

Here is a slight change to the original dynamic routing algorithm: In order to be able to support sets of various sizes (that is, C and K can take any value), let all sample semantic vectors in the support set share a transformation matrix $W_s \in R^{2u\times 2u}$, instead of setting a W_{ij} for each sample. This transformation matrix W_s can encode important spatial and other relations between low-level features (sample semantics) and high-level features (intent categories), and it is also learned to update through backpropagation.

Next, the coupling coefficient d needs to be learned, which is used to represent the probability that each sample semantic vector is routed to each class. And the size of d will be automatically corrected in multiple iterations of the dynamic routing algorithm, and the sum of the coupling coefficients for each class of sample vectors is guaranteed to always be 1 by the softmax function:

$$d_i = \text{soft max}\left(b_i\right), \tag{6}$$

where b_i is the logarithm of the coupling coefficient, initialized to 0 in the first iteration.

A weighted sum is performed on all the predicted vectors obtained in each class, so that the predicted class vector is obtained:

$$\hat{c}_i = \sum_j d_{ij} \cdot \hat{e}^s_{ij}. \tag{7}$$

The modulus of $\hat{c}_i$ represents the probability of the existence of the class it represents, so the nonlinear function squash is used in the capsule network to replace the activation function relu in the traditional neural network, as shown in Figure 5.

It is ensured that short vectors can be compressed to lengths close to 0 and long vectors to lengths close to 1, and the direction of the vectors remains unchanged [15].

$$\text{squash}\left(x\right) = \frac{\|x\|^2}{1 + \|x\|^2}\frac{x}{\|x\|}. \tag{8}$$

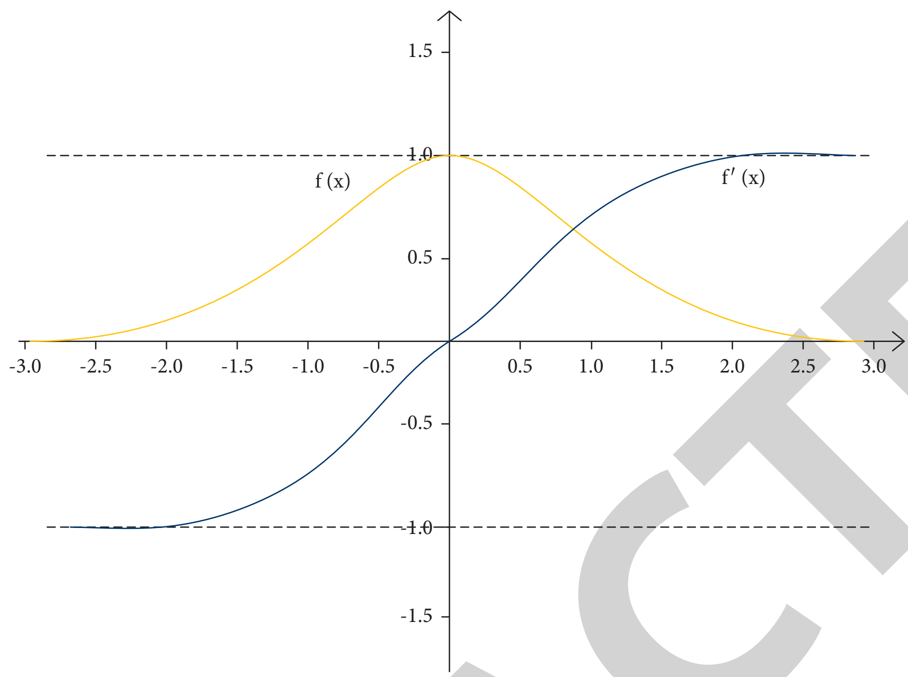

Figure 5: Activation function distribution map.

Finally get the class vector c_i:

$$c_i = \text{squash}(\hat{c}_i). \quad (9)$$

The final step of each iteration of the dynamic routing algorithm is to update the logarithm of the coupling coefficient of b. If the dot product of c_i and b_{ij} is large, there is a top-down feedback, which increases the coupling coefficient of this sample and decreases the coupling coefficient of other samples. Each b_{ij} is updated by

$$b_{ij} = b_{ij} + \hat{e}_{ij}^{s} \cdot c_i. \quad (10)$$

To sum up, the entire algorithm process is shown in Table 3, where r is a hyperparameter representing the number of iterations of the algorithm. The algorithm finally outputs a class vector c_i for each class.

The relation module measures the correlation between each sample semantic vector e_i^q in the query set and each class vector c_j output by the induction module, and it outputs a scalar between 0 and 1 to represent this correlation score. The calculation formula of the scoring function is as follows:

$$r_{ij} = \text{sigmoid}\left(\text{SIM}\left(e_i^q, c_j\right)\right). \quad (11)$$

Among them, SIM is a similarity function, which can choose cosine similarity, dot product similarity, and so on. Cosine similarity measures the similarity of two vectors by calculating the cosine value of the angle between the two vectors and pays more attention to the similarity in direction, while the dot product similarity directly calculates the dot product of the two vectors, which can directly measure the similarity of the length and direction of the two vectors. The higher the similarity of two vectors, the larger their dot product. Moreover, compared with the calculation steps of cosine similarity, dot product similarity is simpler to implement, and it is the simplest similarity measurement method, which can improve the efficiency of the model. For the above two reasons, this paper uses the dot product similarity to calculate the similarity of two vectors, namely:

$$\text{SIM}\left(e_i^q, c_j\right) = e_i^q, c_j. \quad (12)$$

In this paper, the mean square error (MSE) is used as the loss function. For matching query set samples (x_q, y_q) and intent categories, the closer the correlation score r_{iq} is to 1, the better it will be, while for unmatched samples and categories, the closer r_{iq} to 0, the better. In episode, for the input support set S_{support} and query set S_{quiry}, the loss function of C classes is defined as

$$L\left(S_{\text{support}}, S_{\text{quiry}}\right) = \sum_{j=1}^{C}\sum_{i=1}^{n}\left(r_{ij} - 1 \cdot \left(y_i == j\right)\right)^2. \quad (13)$$

The loss function is derived and backpropagated, and all parameters in the above three modules are updated until the best parameters are learned.

The few-shot semantic understanding joint model is improved on the basis of the structure of the few-shot intent recognition model. The overall structure is also divided into three parts: cocoding module, separate induction module, and fusion scoring module. Figure 6 is the basic structure of the joint model of few-shot semantic understanding.

The coencoding module is one of them, and it is used to coencode the input model's support and query set samples not only to get the sample semantic vector, but also to get the sample sequence vector for the semantic slot filling task. The class vectors for the intent and semantic slots are inducted separately using a separate

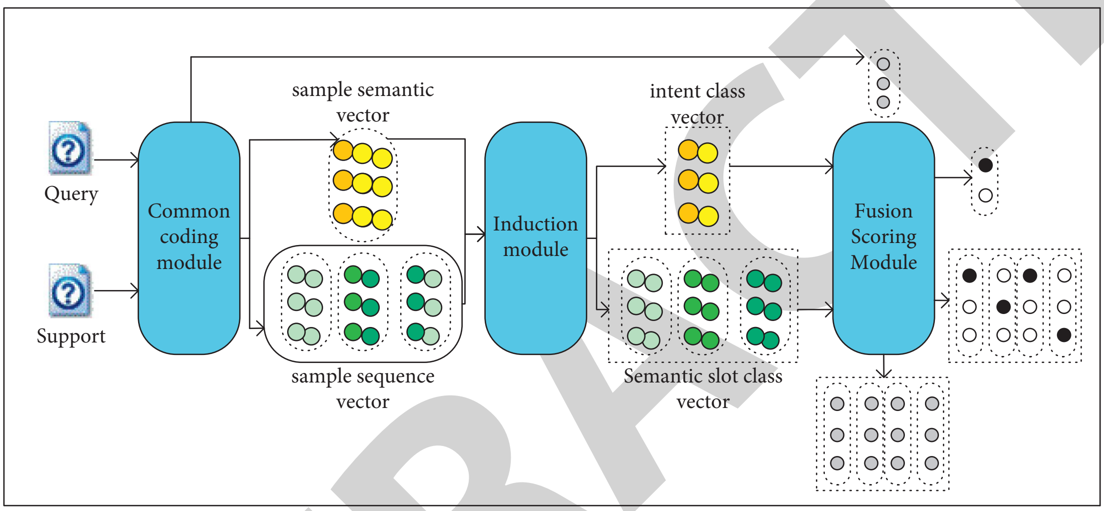

Figure 6: Few-shot semantically understands the basic structure of the federated model.

induction module. The fusion scoring module scores the intent and semantic slot matching based on the similarity between the sample vector and the class vector, but the semantic slot scoring is not done separately, but rather combines the results of the intent classification, so that the sample intent category provides some support for semantic slot annotation. Finally, the backpropagation loss is reduced by combining the loss functions of the two tasks. The coencoding module's primary function is to receive support and query set sample input. For semantic slot prediction and intent classification, they are encoded to produce a sample sequence vector and a sample semantic vector for each sample. The sample semantic vector is an attention-based vector obtained by weighting and calculating the sample sequence vector, which can better focus on the important information in the sample, and the sample sequence vector incorporates the context information of the entire sample during the encoding process.

Given a set of input text $x = (x_1, x_2, \ldots, x_T)$ represented by a sequence of word embedding, first process this set of text using $Bi-\mathrm{LSTM}$:

$$\begin{aligned} \overrightarrow{h_t} &= \overrightarrow{\mathrm{LSTM}}(x_t, h_{t-1}), \\ \overleftarrow{h_t} &= \overleftarrow{\mathrm{LSTM}}(x_t, h_{t+1}). \end{aligned} \tag{14}$$

Connect $\overrightarrow{h_t}$ and $\overleftarrow{h_t}$ to obtain a hidden state h_t, and record all T hidden states as $H = (h_1, h_2, \ldots, h_T)$. Among them, each h_T is a word vector representation that obtains the information before and after the current word, and H is used as the sample sequence vector e^s of this input sample, namely:

$$e^s = H = (h_1, h_2, \ldots, h_T). \tag{15}$$

The attention calculation is performed on H, and the calculation method is the same as that of the few-shot intent recognition model, and the sample semantic vector e^I of each sample is obtained:

$$e^I = \sum_{t=1}^{T} a_t \cdot h_t. \tag{16}$$

Finally, the sample sequence vector e^{S_S} and the sample semantic vector e^{S_I} of each sample of the support set and the sample sequence vector e^{Q_S} and the sample semantic vector e^{Q_I} of each sample of the query set are output to the common coding module.

Input e^{S_I} and e^{S_S} of the support set samples output by the coencoding module into the induction module, which are used to calculate the class prototype representation c^I for each intent category and the semantic slot label class vector c^S for each semantic slot label category:

$$\begin{aligned}\left\{e_i^{S_I} \in R^{2u}\right\}_{i=1,\ldots,s} &\longrightarrow \left\{c_j^{I} \in R^{2u}\right\}_{j=1,\ldots,C_I},\\ \left\{e_i^{S_S} \in R^{2u}\right\}_{i=1,\ldots,s} &\longrightarrow \left\{c_j^{S} \in R^{2u}\right\}_{j=1,\ldots,C_S}.\end{aligned} \tag{17}$$

Among them, the class prototype vector is still obtained by the dynamic routing algorithm, and the semantic slot label class vector is obtained by TapNet.

3. Online and Offline Interactive Model Test

This paper evaluates and tests the online and offline interaction model of international Chinese education based on few-shot learning. Then it is used in teaching practice to verify the validity of the model from the aspects of teaching quality and learning effect, students' experience, and acceptance.

3.1. Evaluation Test. The online and offline interactive model evaluation test of international Chinese education based on few-shot learning uses the FewJoint dataset as the experimental dataset. The parameters it uses in the process of building the model and training the model are shown in Table 4

Table 4: Experimental parameter settings.

Serial number	Parameter name	Parameter value
1	Batch size	4
2	Learning rate	L $e-5$
3	Balance parameters α	0.7

The performance evaluation index of the interactive model adopts the internationally common PRF evaluation index, namely, the precision rate (Precision, P), the recall rate (Recall, R) and the F value. In order to verify the effect of the model, this experiment uses the prototype network as the baseline model and conducts training tests in the six fields of idiomsDic, drama, timesTable, length, story, and constellation of the dataset, and the test results are shown in Figures 7 and 8.

Figure 7(a) shows the accuracy test results of the model proposed in this paper.

Figure 7(b) shows the accuracy test results of the prototype network model.

It can be seen from Figure 7 that the model proposed in this paper has an overall training accuracy of 71.31% in the six fields of the dataset: idiomsDic, drama, timesTable, length, story, and constellation; the training accuracy of the prototype network in the six fields of idiomsDic, drama, timesTable, length, story, and constellation of the dataset is 60.03%.

Figure 8(a) shows the recall test results of the model proposed in this paper.

Figure 8(b) shows the recall test results of the prototype network model.

It can be seen from Figure 8 that the model proposed in this paper has an overall training recall rate of 70.15% in the six fields of idiomsDic, drama, timesTable, length, story, and constellation of the dataset; the recall rate of the prototype network training in the six domains of idiomsDic, drama, timesTable, length, story, and constellation of the dataset is 57.99%.

3.2. Teaching Practice. This experiment takes foreign students majoring in international Chinese education in a university as the experimental object, with a sample size of 50 people, who are divided into two classes. Class A adopts the online and offline interactive teaching mode proposed in this paper for Chinese learning, and class B adopts a single online mode for Chinese learning. The students of the two classes have basically the same level of Chinese proficiency and related theoretical knowledge and are at the same starting point. Through a semester of teaching practice, the test data of the teaching quality and learning effect, students' experience, and acceptance of the four key stages of teaching were compared and analyzed. The analysis results are shown in Figures 9 and 10.

Figure 9(a) shows the test of teaching quality and learning effect under the online and offline interactive teaching mode.

Figure 9(b) shows the test of teaching quality and learning effect under a single online teaching mode.

It can be seen from Figure 9 that, under the online and offline interactive teaching mode, the overall average of the teaching quality of the four key teaching stages reached 86.28 points, and the overall average of the learning effect reached 82.85 points; under the single online teaching mode, the overall mean of teaching quality in the four key stages of teaching is 78.65 points, and the overall mean of learning effect is 73.68 points.

Figure 10(a) is the test of students' experience and acceptance under the online and offline interactive teaching mode.

Figure 10(b) is a test of students' experience and acceptance under a single online teaching mode.

As can be seen from Figure 10, under the online and offline interactive teaching mode, the overall average score of students' experience in the four key stages of teaching reached 86.23 points, and the overall average score of students' acceptance reached 90.38 points; under the single online teaching mode, the overall average score of students' experience in the four key stages of teaching is 80.75 points, and the overall average score of students' acceptance is 76.70 points.

4. Discussion

Through the evaluation test data of the online and offline interaction model based on few-shot learning and the prototype network baseline model, the following conclusions can be drawn:

(1) In terms of the accuracy of the model, the overall mean of the online and offline interactive model based on few-shot learning in the training and testing of the dataset is 11.28% higher than the overall mean of the prototype network baseline model in the training and testing of the dataset, which shows that the online-

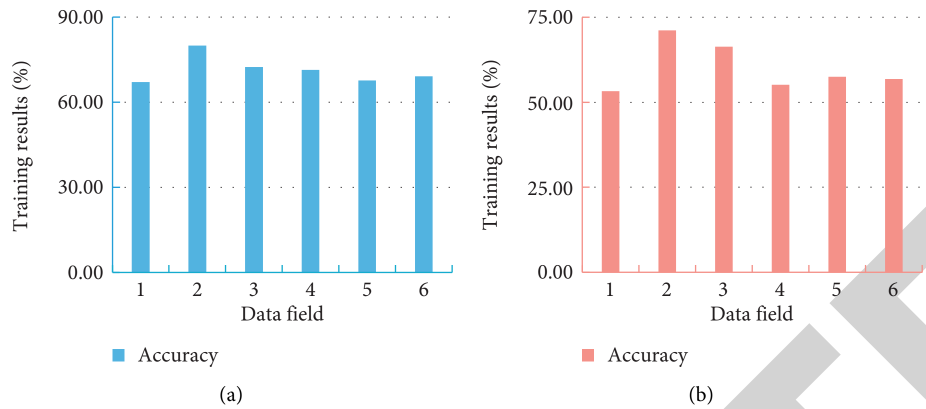

Figure 7: Model accuracy evaluation test.

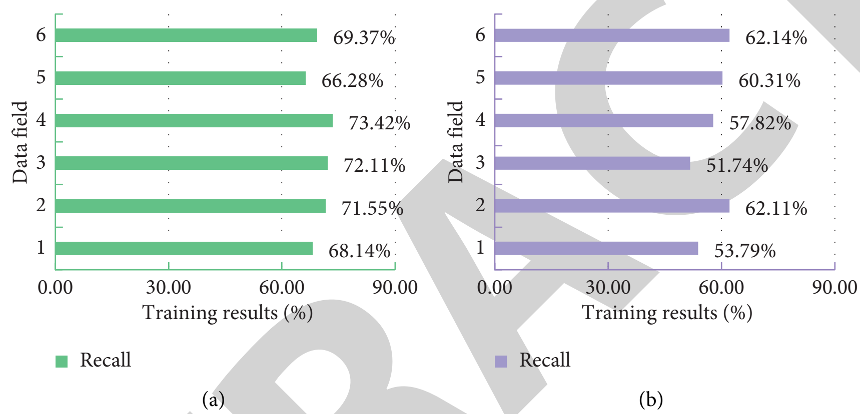

Figure 8: Model recall evaluation test.

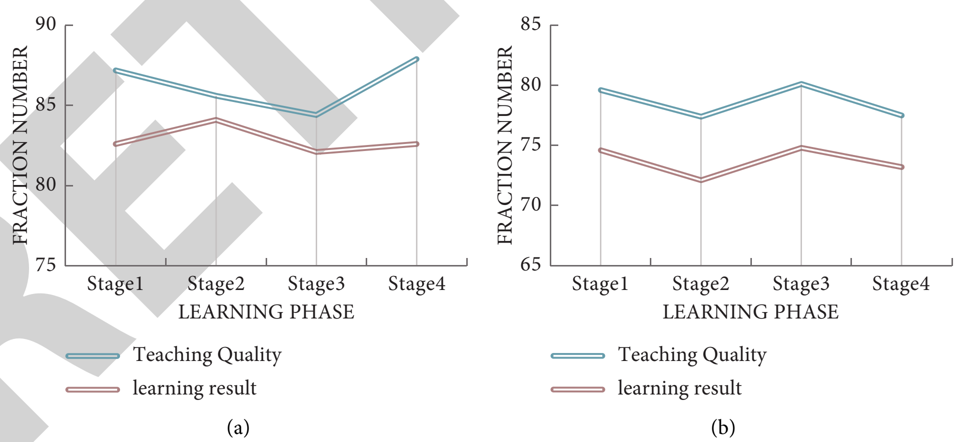

Figure 9: Teaching quality and learning effectiveness test.

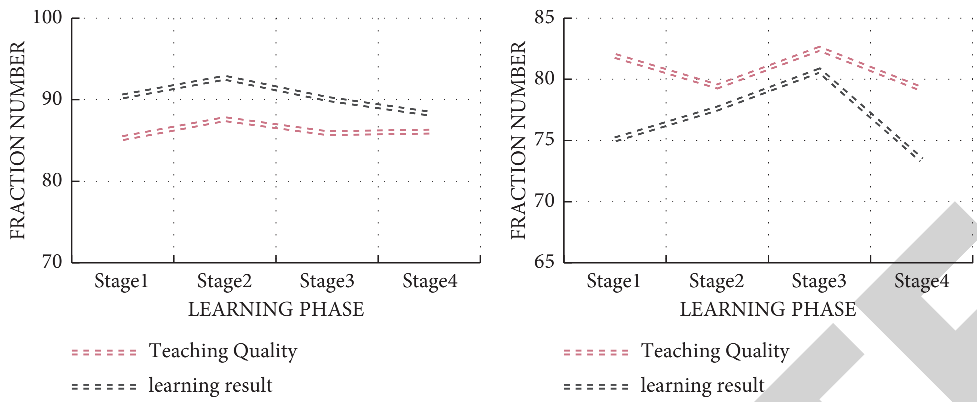
offline interaction model based on few-shot learning has superior accuracy.

(2) At the model recall level, the overall mean of the online and offline interaction model based on few-shot learning in the training and testing of the dataset is 12.16% higher than the overall mean of the prototype network baseline model in the training and testing of the dataset, which shows that the online-offline interactive model based on few-shot learning is also superior in retrieval performance.

(i) Through the teaching practice data of the online and offline interactive teaching mode based on few-shot learning and the traditional single online teaching mode, the teaching quality and learning effect, students' experience, and acceptance, the following conclusions can be drawn.



(a) (b)

Figure 10: Student experience and acceptance test.

(3) In terms of teaching quality and learning effect, the overall mean of teaching quality under the online and offline interactive model teaching mode based on few-shot learning is 7.63 points higher than the overall mean of teaching quality under the single online teaching mode; the overall mean of the learning effect is 9.17 points higher than the overall mean of the learning effect under the single online teaching mode.

(4) In terms of student experience and acceptance, the overall mean of students' experience under the online and offline interactive model teaching mode based on few-shot learning is 5.48 points higher than the overall mean of students' experience under the single online teaching mode; the overall mean of student acceptance is 13.68 points higher than the overall mean of student acceptance under the single online teaching mode; and the overall mean of student acceptance is 13.68 points higher than the overall mean of student acceptance under the single online teaching mode.

The entire comparative experimental data shows that when all other experimental conditions are held constant, the online and offline interactive model test data based on few-shot learning performs better in terms of model accuracy and teaching practice results after model scoring and teaching practice test. It demonstrates that the few-shot learning-based online and offline interaction model can improve the level and quality of international Chinese education and teaching, thereby promoting the development of international Chinese education.

5. Conclusion

The continuous updating and development of information technology have promoted the modernization of international Chinese education. A new round of Chinese teaching has begun to change, and online and offline Chinese teaching will become an important development direction for international Chinese education. The combination of few-shot learning method and international Chinese education and teaching is beneficial not only to its own diversified development, but also to international Chinese education to solve the teaching restrictions caused by the epidemic and improve the level of intelligent teaching.

There are still many deficiencies in the research of this paper. The depth and breadth of the research in this paper are not enough, without taking into account some interfering factors involved in the teaching practice process, and the evaluation of the teaching mode is also restricted by many factors. And our academic level research is also limited; the research on the online and offline interaction model of few-shot is still in the preliminary stage. In the future work, the model performance will be improved from more angles based on the existing technology and level, and the teaching methods of international Chinese education will be continuously optimized.

Academic Editor: Xin Ning

Scientific and accurate prediction of high-tech industries is of great practical significance for government departments to grasp the future economic operation and formulate development strategies. In this paper, aiming at some shortcomings of neural network (NN) applied in economic forecasting, GANN was introduced to construct the economic forecasting model of high-tech industry. Genetic algorithm (GA) has simple calculation and strong robustness and can generally ensure convergence to the global optimum, which effectively overcomes the shortcomings of NN using gradient descent method. In order to verify the feasibility of the economic forecasting model in this paper, the comparative experiments of different models are carried out in this paper. Experimental results show that the proposed algorithm has faster convergence speed and greater generalization ability, and the average error rate is reduced to about 1%. The prediction accuracy of this model reached 95.14%, which was about 11.93% higher than the previous model. Applying the economic forecasting model in this paper to the economic forecasting of high-tech industries can provide the means and reference value for the government to formulate regional future economic development plans, forecast, and control the economic growth and development direction.

1. Introduction

With the rapid development of information technology, the pace of economic development is also accelerating [1]. The rise and growth of high-tech industry has become an important industry to promote economic growth in today's world, which has a great influence on the position and role of a country or region in the world pattern in economic, political, military, and other aspects [2]. In the era of the "knowledge economy," high-tech industry is at the heart of all industries, the most important motivator for a country or region to gain a long-term competitive advantage, and the engine of social economy development. The advancement of high-tech industry is not only an important tool for optimizing and upgrading industrial structure but it is also a critical factor in achieving economic multiplication [3]. As a result, in countries and regions all over the world, the development of high-tech industries has become a strategic focus of economic and social development. One of the topics that the Chinese government and economists are paying increasing attention to is how to accurately and reasonably predict the industrial economic situation based on relevant industrial economic indicators [4]. Prediction is a study that compares the results of things that will happen with reality, and it is an estimate and speculation of things that have not yet happened and are not clear at this time. Economic forecasting, as an important branch of forecasting, has gotten a lot of attention in the economic field [5]. For government departments to grasp the future economic operation and formulate development strategies, scientific and accurate predictions of high-tech industries are critical.

The economic forecast of high-tech industry plays a vital guiding role in implementing effective economic macro-control by national departments at all levels and making specific production and delivery by various enterprises under the market economy. Although traditional economic forecasting and early warning methods have their own advantages, with the complication of economic management problems, these traditional methods are increasingly unsuitable for scientific management and precise management. Therefore, it is particularly important to find a more general and accurate economic forecasting model. Neural network (NN) [6–8] is an important Artificial intelligence (AI) technology [9–11]. NN is also one of the fastest-growing research achievements in AI field recently. It has been successfully used in scientific calculation and automatic control. In recent years, domestic and foreign scholars have carried out a lot of applied research on NN in economic fields such as economic prosperity analysis, economic time-series prediction, portfolio optimization and stock prediction, and achieved good application results. The most widely used NN in the economic field is BPNN (back-propagation neural network). As it is essentially a gradient descent method, and the objective function to be minimized is complex, it has some shortcomings. For example: (1) The learning process converges slowly. (2) It is easy to fall into local minima and the algorithm is incomplete. (3) Poor robustness and poor network performance. Therefore, this paper introduces genetic algorithm (GA). GA is a computational model developed in recent years, which opens up a new way to solve complex problems. GA is an algorithm model to simulate the evolution process or evolution process in nature. It simulates the evolution process of species from low level to high level, adopts the natural law of survival of the fittest to select individuals, generates the next-generation population through mating and mutation and evolves from generation to generation until individuals who meet the conditions are produced [12]. GA is based on strict theory. It has strong adaptability and robustness and is especially suitable for searching for optimal solutions in high-dimensional, multipole, nondifferentiable, continuous, or discrete space. In this paper, based on genetic algorithm neural network (GANN), the economic prediction model of high-tech industry is constructed, and its innovations are as follows:

(1) In this paper, GANN is introduced to overcome some shortcomings of NN in economic forecasting. Combining the two methods, GA, with its unique characteristics, effectively overcomes the shortcomings brought by NN using gradient-descent method. In this paper, GANN is applied to the economic forecast of high-tech industries and good results are obtained.

(2) In view of the large scale of modern industrial economy and the uncertainties such as nonlinearity and time-varying brought about by globalization, this paper puts forward the research assumption of intelligent modeling and prediction. Combining structural self-organizing genetic optimization NN with reinforcement learning theory and method, the economic prediction model of high-tech industry is studied. The growth rate data and time-window series data of economic indicators are introduced into the constructed NN input layer unit, which improves the generalization ability of the established NN model.

The research content and structure of this paper are mainly divided into five chapters:

The introduction is the first chapter. This section introduces the paper's research background, significance, contents, and methods. The second chapter primarily summarizes and examines related literature from both within and outside the United States. Based on these documents, the second chapter introduces the innovation and research methods in general. The third chapter focuses on related theoretical high-tech industry development research and the development of a genetic optimization economic forecasting model. Section 3.1, for example, examines the concept connotation of high-tech industry and summarizes the basic theories relating to its development. In addition, the contents of artificial neural network (ANN) and GA were introduced. The construction method and implementation of the GANN model are discussed in Section 3.2. The experimental analysis section is covered in the fourth chapter. The actual test is carried out in this section, and the test results are obtained, based on the relevant data. The model's performance is evaluated in comparison to the experimental results of other models. The fifth chapter concludes with a prognosis. This section primarily reviews the main contents and findings of economic forecasting model research, summarizes the findings, and suggests future research directions.

2. Related Work

The scope of China's high-tech industries and their products was determined by Zeng et al., who also analyzed the characteristics of high-tech industries, as well as the conditions and methods of developing high-tech industries and outlined the basic theories related to high-tech industry development [13]. Kuo et al. proposed a construction scheme for a stock price forecasting system based on the vector error correction model [14] based on previous research in the field of economic forecasting and early warning. Liu et al. proposed a rolling grey model economic forecasting algorithm based on particle swarm optimization [15] to address the uncertain subjective factors in economic forecasting and control. To predict the industrial economy, Yuan et al. developed a GA-based BPNN model and compared it to a regression analysis model [16]. Claveria et al. used special processing methods to create a general economic forecasting model by combining the characteristics of economic time series. And then use this model to forecast economic data [17]. For the control and prediction of regional macroeconomics, Rossi et al. developed a prediction model based on the intelligent NN algorithm. Modeling and predictive control methods are proposed to be improved [18]. The NN model is used for multivariate time-series forecasting, according to Zhao et al., and its accuracy and trend are better than traditional statistical methods. The experimental results show that the method is feasible and that it has a higher prediction accuracy than one-shot modeling [19]. The use of NN for multivariate time-series forecasting and multivalue forecasting was investigated by Qiu et al., who discussed the modeling mechanism and multivalue forecasting of this method, as well as its application in stock price forecasting [20]. Ince et al. discussed the NN-based time-series prediction model's establishment mechanism, then proposed adaptive time-series modeling and prediction based on a combination of the time difference method and the BPNN method and experimented with the foreign exchange rate problem as an example [21]. According to Fameliti et al., there is currently little systematic evidence that NN methods are better than traditional time-series forecasting methods in some areas. As a result, before using NN for prediction, it must be rigorously compared to traditional statistical methods to demonstrate that NN is indeed superior and then it is a wise decision to use it [22]. Shang et al. investigated the economic forecasting method, classification, and forecasting accuracy evaluation index, as well as developing a forecasting model for key macroeconomic indicators [23]. Talaat et al. proposed a new load-forecasting algorithm, the GANN optimization forecasting method [24], by combining GA and ANN. Using corporate financial data, Ding et al. developed a new discrete grey multivariate model to predict the output value of China's high-tech industries [25].

In this paper, some opinions and ideas are presented based on the predecessors' research on NN and economic forecasting models, and a high-tech industry economic forecasting model based on GANN is established. The structure and weights of GANN are used in this paper, and the NN learning algorithm is used to iterate several steps, with the network average error after iteration being used to calculate individual fitness values. Near this point, the NN learning algorithm is in charge of some quick local searches, and GA is in charge of global searches. The competition mechanism is used to adjust the structure of NN automatically. The distribution and adjustment of weights are further optimized while adjusting the structure, demonstrating more intelligence and better self-organization, self-adaptation, and self-learning ability. It not only eliminates the large approximation error caused by the fixed network model structure, but it also improves control and prediction. In this paper, GA is used to combine NN models, which overcomes the problem that NN models are prone to local minima. The simulation results show that this model's economic forecasting of the high-tech industry has a high predictive effect.

3. Methodology

3.1. High-Tech Industry and GANN Algorithm. High-tech industry refers to an industry with high knowledge and technology density, rapid industrial development, high added value and high benefit, and a certain market scale and great influence on related industries. High-tech industry is the core of all industries in the era of "knowledge economy", the most important motive force for a country or region to gain long-term competitive advantage, and the driver of sustainable development of social economy. High-tech industry is the crystallization of the highest scientific wisdom and technology of mankind, reflecting the highest level of human production activities and management [26]. At present, the high-tech industry is developing well, and it has become an important force for mode change, structure adjustment, and steady growth. There are usually two ways to develop high-tech industries: first, based on high-tech, develop the high-tech products and form new high-tech industries. The second is to transform traditional industries with high technology. At present, we should give full play to the leading role of high-tech industries in stabilizing growth and restructuring and promote the rapid and healthy development of high-tech industries. Therefore, scientific and accurate prediction of high-tech industries is of great practical significance for government departments to grasp the future economic operation and formulate development strategies.

With the development of high-tech industries and the constant changes of society, how to establish a scientific economic forecasting system for high-tech industries, improve forecasting efficiency and accurately predict the possible development trend of industrial economy in the future has become the main goal of current research [27]. As a nonlinear calculation model, ANN expands the concept and approach of "calculating" the possibility of nonlinear systems. Its basic principle of simulating human brain and its high dimension, distributed storage and processing of neurons, self-organization, self-adaptation, and learning ability are especially suitable for economic information processing in complex modern social and economic systems [28]. The basic structural unit of ANN is neuron, which is also called node. It simulates the structure and function of biological neuron. According to the different connection modes of neurons, NN with various structures can be formed. ANN has four basic characteristics: (1) Parallel distributed processing, (2) learn through training, (3) nonlinear mapping, and (4) adaptation and integration.

Economic forecasting is essentially the forecasting of economic time series, which is a collection of unique data. The previous number will have an influence on the latter number in this set of data, and this influence can be expressed as a certain trend change or periodic change, for example. The influence relationship is usually nonlinear, and establishing a quantitative and fixed mathematical relationship is difficult. ANN is a nonlinear science. It has parallel processing, fault tolerance, and self-learning capabilities, which distinguishes it from traditional statistical methods and allows it to effectively solve such problems. This paper introduces GA as a solution to NN's shortcomings. GA refers to a collection of random search heuristic parallel algorithms [29]. The GA algorithm selects several search points at random and then conducts parallel searches from each of these search points, with the goal of obtaining points with higher-objective function values. Only the fitness guides and executes the search process repeatedly. The search points have high fitness and are close to the optimal solution after many times or generations of evolution. In NN, feed-forward NN is a common hierarchical structure. NN with various functional characteristics can be formed using various neuron transfer functions, hidden layers, and weight adjustment rules. An input layer, an output layer, and a hidden layer between the input and output layers comprise the BPNN [30]. Only one hidden layer exists in the most common NN. The goal of applying GA to BPNN is to improve learning accuracy and iteration speed, as well as to better match biological systems. Figure 1 depicts the flow of the GANN algorithm.

By learning and training the samples, NN can constantly change the connection weights and topology of the network, ensuring that the network's output is close to the expected output. The forward NN algorithm has good local searching and climbing abilities, but it is easy to converge to the local minimum, so it is necessary to improve global convergence. To find a solution that can jump out of the local extremum and converge to the global optimal solution, the GA crossover operator and mutation operator are used. In this paper, we combine GA and NN to create an algorithm that converges quickly and finds the global optimal solution. Encoding is the process of mapping the representation of a search space solution to the representation of a genetic space solution in GA; decoding is the process of mapping the representation of a search space solution to the representation of a genetic space solution. Individuals or chromosomes are the solutions of genetic space, and multiple individuals form a group. In GA, there are several key parameters to consider, including population capacity, replacement ratio, and crossover operator. We must adjust the parameter values for different problems because the optimal values of these parameters vary from problem to problem and cannot be obtained using fixed rules.

3.2. Construction of Economic Forecast Model of High-Tech Industry. The system applied in this paper is nonlinear, and the selection of initial weights follows the following principles: take random values and ensure that the weights are relatively small, and the output value of each neuron after initial weighting is close to zero, which can ensure that the weights of each neuron can be adjusted where their S-shaped activation function changes the most. The system is time-varying and time-delayed, so each data sample should have a different weight. For economic forecasting, the data close to the year to be forecasted should have a greater weight. In the concrete implementation, GA is used to learn the weights and offsets between layers of feed-forward network. Arrange the weights and offset values in order and generate chromosomes according to certain coding rules. In addition to the change of the connection coefficient with other neurons, the number of neurons in the middle layer can also be randomly adjusted within a certain range according to the specific situation. Once the prediction NN is preliminarily determined, its input layer and output layer will not change. GANN-based economic forecasting system and its subsystems are shown in Figure 2.

The learning rate adaptive gradient-descent method with additional momentum term is used to train the network. For each NN and its training data, there is a suitable learning rate. However, different learning rates may be required in different parts of the error surface for complex network models. When there is a large prediction error and the network needs to be corrected, the middle hidden layer is the first thing to adjust and change. A sufficient data supply is required for the establishment of multilayer forward NN. The data are primarily used to train the network and determine weights, but it is also used to check and verify the network's correctness. As a result, the information provided must be divided into two sections: training and experiment. After the decoded weights and offset values of chromosomes are substituted into the network, the fitness function is defined as the difference between the actual output and the expected output. Through GA, a new generation of people will be created on a regular basis, while those who are not fit will be weeded out. The inheritance is terminated if a specific termination condition is met. The weight and offset corresponding to the chromosome with the best fitness are currently the network's optimal solution.

Let the number of neurons in the input layer be n, the output layer be m, and the hidden layer be p. Then the output formula of the hidden layer is as follows:

$$x_i^1 = f\left(\sum_{j=1}^{n} w_{ij}^0 x_j + w_{i0}^0\right), \quad i = 1, 2, \ldots, p. \tag{1}$$

Among them, x_i^1 is the output of neurons in the hidden layer, and $\sum_{j=1}^{n} w_{ij}^0 x_j + w_{i0}^0$ is the weighted sum of all neurons in the input layer. w_{ij}^0 is the weight coefficient of input neuron j to i. w_{i0}^0 is the threshold of neuronal i. f is a nonlinear excitation function. The calculation formula of the neuron output value of the output layer is as follows:

$$y^k = f\left(\sum_{j=1}^{p} w_{jk}^1 x_j^1 + w_{k0}^0\right), \quad k = 1, 2, \ldots, m. \tag{2}$$

In addition, the output layer neuron error function is as follows:

$$E = \frac{1}{2} \sum_k \left(d^k - y^k\right). \tag{3}$$

Among them, d^k is the target value. After calculating the error value of each node by layer-by-layer back-propagation error, the error is corrected. The weighted correction formula is as follows:

$$\Delta w_{ij}^m = \eta \delta_j^m y_j^{m-1}. \tag{4}$$

Among them, w_{ij}^m is the weight coefficient; y_j^{m-1} is the output value of the neuron, η is the learning rate, and δ_j^m is the error signal. Define the error function E_p as the sum of squares of errors between the expected output d_{pi} and the actual output y_{pi}:

$$\begin{aligned} E_p &= \frac{1}{2} \sum_{i=1}^{N_{L+1}} \varepsilon_{pi}^2 \\ &= \frac{1}{2} \sum_{i=1}^{N_{L+1}} \left(d_{pi} - y_{pi}\right)^2. \end{aligned} \tag{5}$$

It is hoped that E_p can be reduced as much as possible, so that the actual output value can be as close to the expected

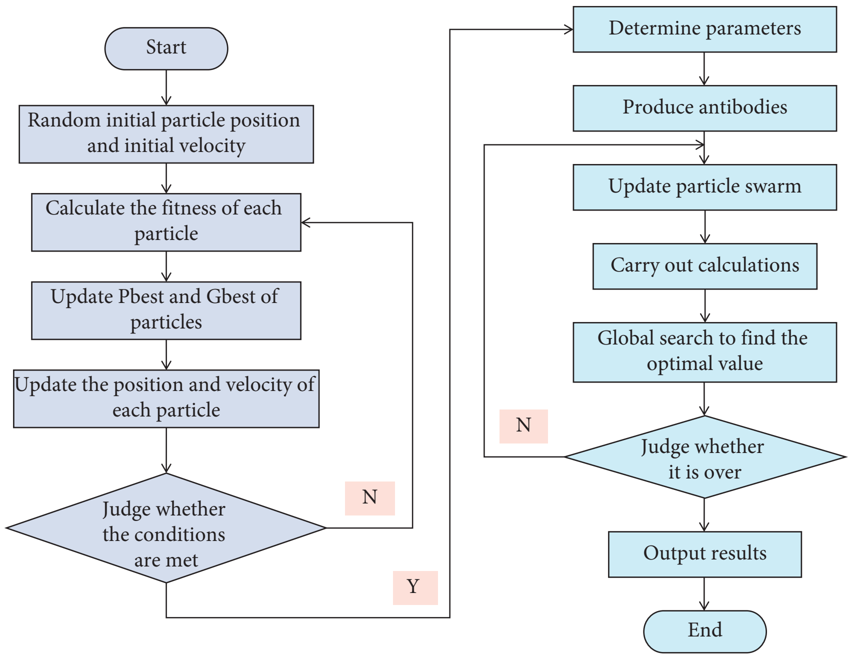

Figure 1: GANN algorithm flow.

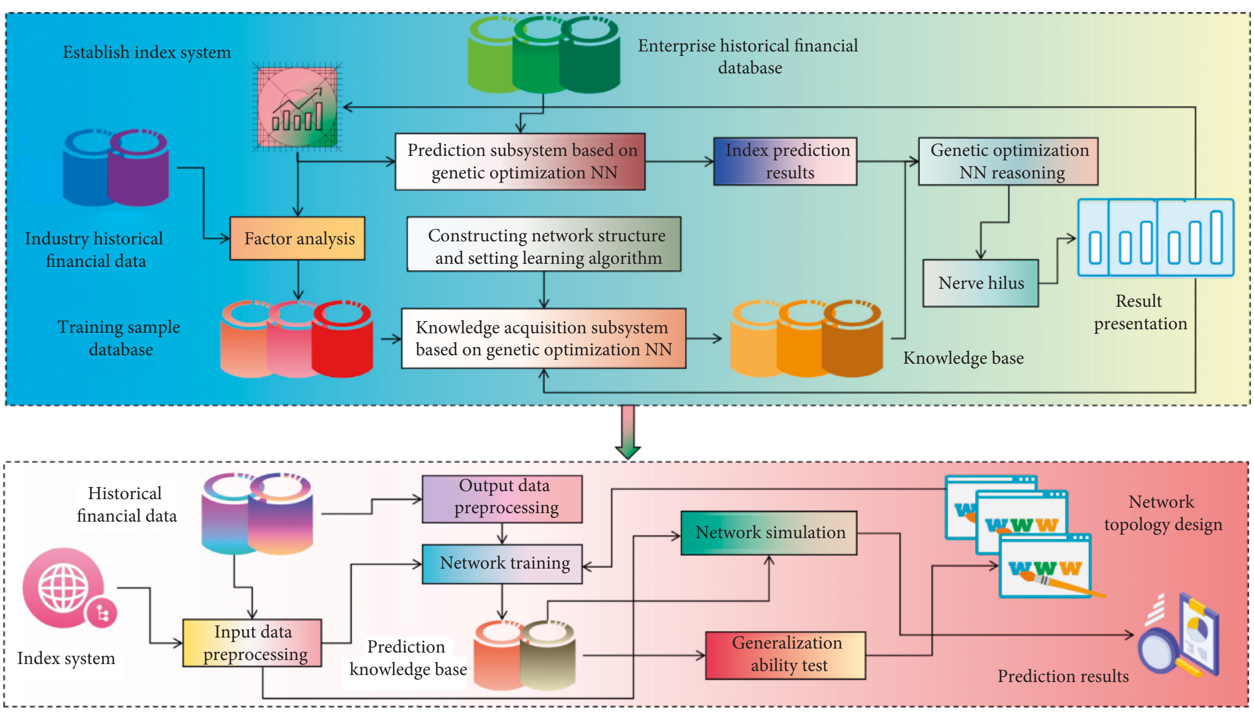

Figure 2: The composition of the GANN-based economic forecasting system and its subsystems.

output value as possible. This is actually the problem of finding the minimum value of the error function, and the steepest descent algorithm can be used to make the weight coefficients change along the negative-gradient direction of the error function. The adjustment amount of the weight coefficient $W_{ij}^{(l)}$ can be calculated as follows:

$$\Delta_p W_{ij}^{(l)} = -a \frac{\partial E_p}{\partial W_{ij}^{(l)}}, \quad a > 0, \tag{6}$$

In the formula, a is the learning stride, which changes with the learning process. $l = 1, 2, \ldots, L$; $i = 1, 2, \ldots, N_{l+1}$; $j = 1, 2, \ldots, N_{l+1}$.

The test data are used to determine the prediction error of the established network, and the training data are used to establish the network. The middle layer should be adjusted if the error exceeds the allowable range. When correcting the network's weight, the additional momentum method takes into account not only the effect of error on the gradient but also the influence of changing trend on the error surface. The network may fall into shallow local minima without additional momentum, but it is possible to slip through these minima with additional momentum. At the same time, making the middle layer dynamic is critical for accurate economic time-series prediction. Unlike when using NN in scientific calculations, the prediction point of NN prediction is always outside the training data, making it difficult to control the error. Furthermore, some economic fields, such as stock market fluctuations, change at a rapid pace, necessitating dynamic models to keep up.

When calculating the fitness of genetic algorithm, the reciprocal of neural network error is used to evaluate the fitness of the network, namely,

$$\begin{aligned} \text{fitness} &= \frac{1}{S_{se}}, \\ S_{se} &= \frac{1}{2}\sum_{i=1}^{k}\sum_{j=1}^{n}\left(d_{ij} - o_{ij}\right)^2, \end{aligned} \tag{7}$$

where d is the standard output, o is the actual output, k is the number of input patterns contained in the training set, and n is the number of neurons in the output layer.

Establish an initial group. The number of individuals in the population is between 45 and 65, and the length of individuals is the product of the sum of weights and offsets of NN and the number of digits occupied by a code, and the genes of individuals are randomly selected within a predefined range. The information provided by an input neuron is not enough to establish an accurate network model to simulate complex nonlinear relationships. At the same time, the input values should show the curve characteristics of fluctuation. Therefore, in addition to expanding the one-dimensional time series, the input data should be preprocessed. On the contrary, the goal of prediction determines the single output characteristic of the network. If the total input of neurons is too far from the threshold, the modification of weights will be very small, which will not only slow the learning speed, but also make it difficult for the network to converge. At the same time, small numerical information may be overwhelmed by large numerical information. Therefore, before NN prediction, in order to avoid network paralysis caused by too large raw data, the raw data should be normalized. For the predicted value, it is not suitable to be directly used as the output of NN because of the large change range. GA algorithm is used to optimize the combination of weights and parameters of ANN model repeatedly. The goal is to set a small load error, with the hybridization rate of 0.4 and the variation rate of 0.005. According to the value range of the parameter set and the set number of individuals, the initial population is randomly generated, and the fitness value of each individual is calculated. Through systematic cluster analysis, the population is divided into several populations, and the average fitness of each population is calculated, and some individuals with the best fitness value are selected as the representatives of the population to breed the next generation.

For the same forecast project, the size of the mean square error can be used to measure the quality of different forecasting methods. For different forecast items, due to their different actual values, only comparing the size of the mean square error cannot explain the problem. At this time, $E(|e|/x)$ should be used as the comparison standard, which is called the predicted mean absolute percent error (MAPE). It is estimated by retrospective forecasting, and its estimator is as follows:

$$\text{MAPE} = \frac{1}{n}\sum_{i=1}^{n}\frac{|e_i|}{x_i}. \tag{8}$$

In the NN model, in order to prevent the situation that the fitting of the learned data is good and the fitting of the nonlearned data is not good, rolling learning and prediction are adopted, and the minimum sum of the error of learning and prediction is the evaluation mark of the success of the model. Generally, the quality of prediction results is measured by MAPE. Table 1 gives the prediction accuracy range of MAPE.

Select the individual with the best fitness value in each population to continue the genetic operation until the fitness of the solution is no longer significantly increased. At this time, the decoded parameter combination is close to the best combination that meets the application needs. On this basis, the BP algorithm of ANN is used to further accurately optimize the network parameters obtained above, until the optimal network parameters are found, and then the precise optimal parameter combination can be obtained. Owing to the singularity in NN training, the results of each training will be slightly different. This also means that the prediction result of NN will be a range value, so it is necessary to evaluate the prediction result, and get the reliability and risk degree of the prediction. As GA replaces the initial optimization of NN, the network only optimizes the parameters on the basis of approaching the optimal solution, thus effectively improving the optimization speed and accuracy of the network. GA-based NN model is used in prediction. That is, the model prediction result is used as input and the actual value is used as output, and a mapping relationship is established between the model prediction result and the actual value. After continuous learning and testing, the network is applied to the economic forecast of high-tech industry to get the final forecast result.

4. Result Analysis and Discussion

Through theoretical analysis, the economic factors related to the GDP of high-tech industries are: labor input and capital input. Based on the GDP data of high-tech industries in a province from 2010 to 2020, this paper establishes a prediction model. MATLAB software has powerful functions of numerical calculation, data visualization, graphic drawing,

Table 1: Prediction evaluation based on MAPE.

Scope of MAPE	Prediction and evaluation
MAPE ≤ 8%	High precision prediction
8% ≤ MAPE ≤ 25%	Good prediction
25% ≤ MAPE ≤ 55%	Feasible prediction
MAPE ≥ 55%	Misprediction

and so on, which brings great convenience to users. In this paper, the NN toolbox based on MATLAB is implemented in full software. The network training involves the generalization ability of the network. The so-called generalization ability refers to the ability of NN to correctly reflect the new sample data other than the training samples. In this paper, the available samples of the training set are randomly divided into two parts: one part as the training set and the other part as the test set. Taking eight samples from 2010 to 2017 as training samples and three samples from 2017 to 2020 as test samples, the established prediction model is tested.

The fitness function is used to evaluate the superiority and inferiority of individual solutions, so as to breed or select individuals. The fitness function is not bound by continuously differentiable condition, and the domain of the function can be any set. The only requirement for the fitness function is that the input can be compared with the output. For time-series prediction, the number of input nodes can be obtained by the following methods: changing the number of input nodes from small to large, and training and testing its accuracy. When the error does not decrease further with the increase of the number of input nodes, the critical value of the change of the number of input nodes is the numerical value to be adopted. We use various forecasting methods, such as Arima model, Stepar model, and Winters model, to forecast the economy, respectively. These prediction methods are compared with this GANN prediction method, and the results are shown in Table 2.

Draw representative MAPE results into line charts, as shown in Figure 3.

As a result, this algorithm outperforms the others. Dynamic NNs are those that have feedback, whether local or global. The weights and thresholds of the network can be changed, and the structure of the network, that is, the number of nodes in the input layer, hidden layer, and output layer, can be changed, so that the network is not only dynamic, but also the retained system information is more complete. After the BPNN has been generated and initialized, the network can be trained using the existing "input-output" sample vector data. The train function completes the BP network training, and the network training parameters are properly set prior to training. The train function is used to train the BP network after the training parameters have been set. The network training will alternate between training and testing, with the mean square error of each training recorded. The network weight will then be left unchanged, and the network simulation will be run forward with the test data, with the test mean square error recorded once. The curves of two kinds of mean square errors with training times can be drawn using the two types of data, as shown in Figure 4.

From the error curve, it can be seen that before a certain number of training times, with the increase of training times, the two curves decrease simultaneously. When this number of training times is exceeded, the training error continues to decrease, while the test error begins to rise. This training number is the best training number.

Mutation operation refers to the change between 0 and 1 in some bits when an individual generates the next generation. It plays the role of local search in GA, which increases the ability of GA to search the optimal solution. Appropriate mutation strategy can improve the diversity of individuals in the population, thus preventing GA from falling into local solution and terminating evolution. The preprocessing of input data is the key step to effectively train NN, which directly affects the performance of the trained network. In this paper, the mean and variance of the sample set data are standardized so that the mean is zero and the variance is 1. When there is new data input, we think it has the same distribution as the training sample data, so we can convert it according to the aforementioned formula. In this paper, some measures are taken to improve NN from the learning rate adaptive network learning with additional momentum term, the principle of minimizing empirical risk and the principle of minimizing structural risk, and so on, so as to make the NN model closer to the actual economic operation. Figure 5 shows the comparison result of recall rate of the algorithm.

It can be seen from Figure 5 that the recall rate of the algorithm in this paper is higher than that of the other two algorithms, and the recall rate of the algorithm in this paper is better. Research and analyze the factors that affect the industrial technical and economic indicators, and determine some important factors as the input elements of the network. Analyze and determine some main technical and economic indicators of the enterprise as the output elements of the network, that is, the indicators that need to be predicted. Taking the influencing factors of the industry to be predicted as the input elements of the grid, input them into the model for pattern matching inference, and finally output the expected predicted value of technical and economic indicators. According to various typical rules for modifying network weights and the network training process, various network design and training subroutines are written in MATLAB language. We can call the NN design and training in the toolbox according to our own needs. Program, so that you can free yourself from tedious programming and concentrate on thinking and solving problems, thereby improving efficiency and the quality of problem solving. We compare the economic forecast results using our model with the actual values, and the results are shown in Figure 6.

In order to ensure the generalization ability of the network, the error accuracy cannot be improved only by the number of training, and the test of the test data error is appropriately added in the training process, which can stop the network training in advance and prevent over-training. Although this method sometimes cannot achieve the preset error accuracy, it ensures the good generalization ability of the network, thus making the prediction more effective.

Table 2: Comparison of different methods.

Method	Square sum error	Mean absolute error	Mean square deviation	Average percentage error	Mean square percentage error
Arima model	2216.8	4.59	0.54	3.11	0.53
Stepar model	2119.6	3.78	0.29	3.63	0.55
Winters model	1987.2	3.96	0.37	2.26	0.42
GANN model	214.9	2.13	0.21	1.01	0.31

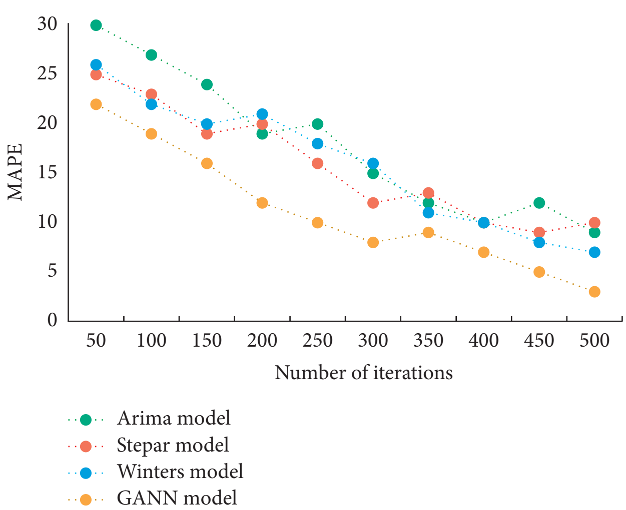

Figure 3: Comparison of MAPE results of different algorithms.

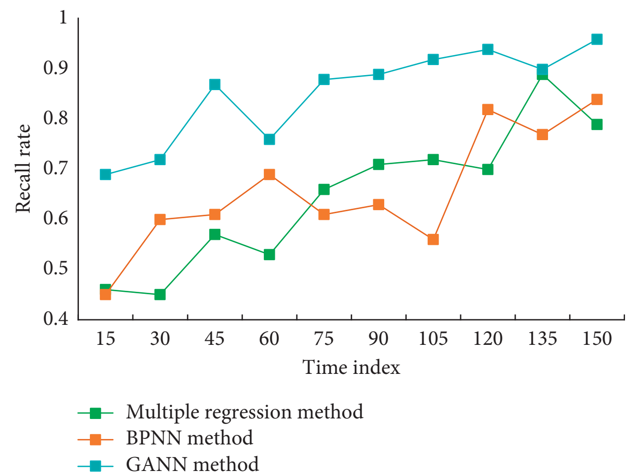

Figure 5: Comparison of recall rates of algorithms.

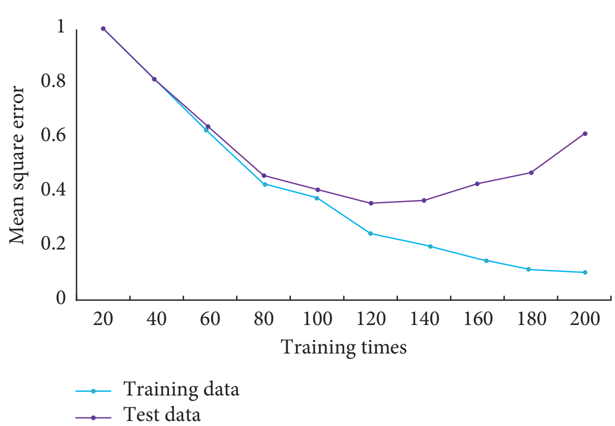

Figure 4: Network output error change diagram.

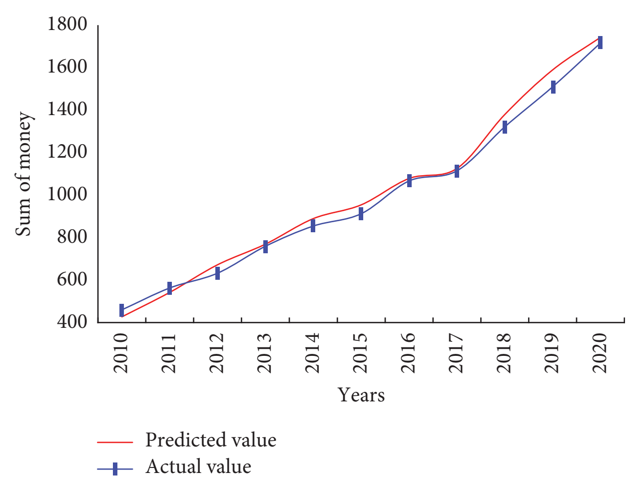

Figure 6: Comparison of predicted and actual values.

Owing to the increasing trend of economic system index data year by year, it is easy to fall into the blind spot of prediction using historical data values to train network models and applying the trained models for prediction. Therefore, we introduce an economic indicator growth rate input node in the network input unit to improve the generalization ability of the NN. As long as the input data of the validation sample set is predicted, it can ensure that the nerve does not fall into the training blind spot. The multiple regression method, BPNN method, and GANN method are used to compare the economic forecasts of high-tech industries. The results are shown in Figure 7.

The comparative analysis of the prediction results shows that the prediction accuracy of the multiple regression method is low, and the highest is only 83.21%. The prediction accuracy of BPNN method is better, the highest is 89.17%. The GANN method proposed in this paper has the best prediction accuracy, up to 95.14%. This result further verifies the feasibility and practicability of the method in this paper. From the comparison of system modeling and prediction results, it can be seen that after using GANN, expanding the sample set, and introducing time-series data input units, the NN model meets the requirements of economic system

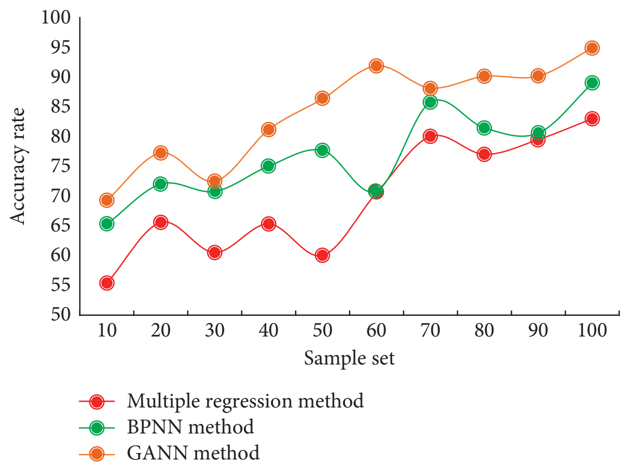

Figure 7: Economic forecast results of different models.

modeling and prediction. The generalization ability of the GANN constructed in this paper has been greatly enhanced, and the system time-varying delay problem has been solved. The experimental results show that the prediction accuracy of the model in this paper reaches 95.14%, and a satisfactory prediction effect is achieved.

5. Conclusion

At present, the development of high-tech industry has become an important indicator to measure the comprehensive national strength, economic strength, and scientific and technological strength of a country or region. Therefore, scientific and accurate prediction of high-tech industries is of great practical significance for government departments to grasp the future economic operation and formulate development strategies. This paper adopts NN modeling method to study the establishment of economic forecasting model of high-tech industry, introduces GA to optimize NN and gives specific implementation steps. The construction scheme of this paper fully reflects the advantages of combining GA and NN technology in economic forecasting and has strong normative and operability. In order to verify the performance of the model, through simulations, predictions are made for the instances. The results show that the algorithm in this paper has faster convergence speed and greater generalization ability, and the average error rate is reduced to about 1%. The algorithm improves the learning and prediction accuracy of NN, and its accuracy reaches 95.14%. At the same time, the good flexibility makes it well suited to many economic forecasting fields. The research of this paper provides a certain basis for the economic forecast of the high-tech industry and the government's regulation of economic growth and has certain practical significance. The construction idea of this paper has certain reference value for most enterprises to construct their own economic forecasting system. However, due to the limitation of knowledge level, time and energy, there are still some problems in this paper. For example, the entire economic forecasting system is based on the authenticity of the data. If the original data are not true, the final forecast result will not have a reference. Value; since the network is dynamic, the number of neuron nodes and the number of hidden layers are adjusted during the training process, which also makes it difficult to prove the stability of the network. These problems need to be expanded and further researched to solve.

Retracted: An Entity Relationship Extraction Model Based on BERT-BLSTM-CRF for Food Safety Domain

Computational Intelligence and Neuroscience

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Dealing with food safety issues in time through online public opinion incidents can reduce the impact of incidents and protect human health effectively. Therefore, by the smart technology of extracting the entity relationship of public opinion events in the food field, the knowledge graph of the food safety field is constructed to discover the relationship between food safety issues. To solve the problem of multi-entity relationships in food safety incident sentences for few-shot learning, this paper adopts the pipeline-type extraction method. Entity relationship is extracted from Bidirectional Encoder Representation from Transformers (BERTs) joined Bidirectional Long Short-Term Memory (BLSTM), namely, the BERT-BLSTM network model. Based on the entity relationship types extracted from the BERT-BLSTM model and the introduction of Chinese character features, an entity pair extraction model based on the BERT-BLSTM-conditional random field (CRF) is established. In this paper, several common deep neural network models are compared with the BERT-BLSTM-CRF model with a food public opinion events dataset. Experimental results show that the precision of the entity relationship extraction model based on BERT-BLSTM-CRF is 3.29%~23.25% higher than that of other models in the food public opinion events dataset, which verifies the validity and rationality of the model proposed in this paper.

1. Introduction

Food is the paramount necessity of the people and the material basis for human survival. Food safety is closely related to human health and has always been a concern of the society. With the development of the Internet and the wide application of computers, the Internet has penetrated into people's daily life. People have been accustomed to expressing their opinions on the Internet, so online public opinion has become an important channel to reflect social problems. Especially in recent years, food safety issues, such as dyed steamed buns, expired meat, poisoned bean sprouts, and other incidents have aroused high public concern. Some food safety incidents were not noticed until they were exposed on the Internet and finally solved. It can be seen that online public opinion is particularly important for the governance of food safety issues.

With the progress of society and the awakening of people's health consciousness, people's demand for improving medical technology and enhancing health is more urgent. In the actual industrial development, China's smart healthcare is still in its infancy [1]. Smart health management is the application of artificial intelligence technology to specific scenarios of health management [2–6]. In terms of risk identification, through the acquisition of information and the use of artificial intelligence technology for analysis, we identify the risk of disease occurrence and provide risk reduction measures. In addition, virtual nurses can collect personal habit information about patients, such as eating habits, exercise cycles, and medication habits, and use artificial intelligence technology to analyze data and evaluate patients' overall status to help plan their daily life.

Therefore, by constructing the knowledge graph of public opinion events in the field of food safety, we can find food safety problems, prompt public opinion problems and give risk warnings, to make the connection between diseases clearer, and patients can receive treatment before complications occur, thus improving the health of patients. Extraction of public opinion events in the field of food safety is one of the important basic tasks in the construction of a knowledge graph in the field of food safety. Tao et al. [7] proposed crowdsourcing and machine learning approaches for extracting entities indicating potential food-borne outbreaks from social media using the dual-task BERTweet model. Mitra et al. [8] adopted a multiview deep neural network model for chemical-disease relation extraction from imbalanced datasets.

However, due to the diversity and universality of diseases caused by food safety incidents, there is a lack of a large number of available corpus in the field of food safety. Therefore, few-shot learning has become an effective method for information extraction. Gao et al. [9] proposed a multitask graph neural network based on few-shot learning for disease similarity measurement. Lu et al. [10] built a few-shot learning-based classifier by limiting training samples for food recognition. Sainz et al. [11] proposed a method of label verbalization and entailment for effective zero and few-shot relation extraction.

Extraction of public opinion events in the field of food safety is one of the important basic tasks in the construction of a knowledge graph in the food safety domain. The purpose is to extract semantic relationships between entities marked in sentences. Entity relationship extraction is mainly used to transform text unstructured data into structured data. The complexity of the entity relationship extraction task and the small sample of corpus lead to the difficulty to complete the task with few-shot learning. For the supervised deep learning model, the model is prone to underfitting due to the small sample corpus. On the other hand, the model is easy to fall into the local optimal solution, resulting in the poor actual effect of the model.

This paper mainly studies an entity relationship extraction method based on BERT-BLSTM-CRF for the food safety domain. Based on few-shot learning, the whole model adopts the pipeline-type extraction method, which is divided into two tasks: entity relationship extraction and entity pair extraction. In the entity relationship extraction network model, the BLSTM network joined the BERT network trains on Chinese corpora, preprocessed to complete the entity relationship extraction task. In the entity pair extraction network model, to add feature information in the BLSTM network, this model puts the entity relationship extracted from the entity relationship extraction model to both ends of the character vector to reinforce the semantic features and obtain the radical feature to join the character vector. The model can not only handle entity overlap well but also effectively use the information of Chinese characteristics.

The rest of the article is organized as follows: Section 2 describes the related work. Section 3 introduces the algorithm proposed in this paper. Section 4 describes the environment we used to validate the algorithm as well as the experimental results and analysis. Finally, Section 5 summarizes this paper.

2. Related Work

The pipeline relationship extraction method [12–15] is popular in entity relationship extraction methods based on deep learning. In recent years, the problem of extracting multi-entity relationships in sentences has attracted the attention of researchers.

Bai et al. [16] proposed to extract local semantic features through word embedding and designed a new fragment attention mechanism based on CNN (convolutional neural network). Compared with the CNN model, the RNN (recurrent neural network) model can deal with distant patterns, so it is particularly suitable for learning relationships in longer contexts. Socher et al. [17] applied the matrix-recursive neural network model (MV-RNN) to natural language processing for the first time, which effectively solved the problem that the word vector model could not capture the constituent meaning of long phrases or sentences.

The long short-term memory (LSTM) network model [18] has the same general framework as the RNN model, which has both forward pathways to transmit information and a self-feeding pathway to process information. However, LSTM allows each neural unit to forget or retain information. To some extent, the problem of vanishing or explosion gradient of RNN is solved. Zhang et al. [19] proposed a location-aware attention mechanism based on the LSTM sequence, which is combined with a kind of entity location-aware attention, to achieve better performance of relationship extraction. Huang et al. [20] proposed a new Chunk Graph LSTM network to learn the representation of solid blocks and infer the relationship between them. Chen and Hu [21] transformed the BLSTM-CRF deep learning model and improved sequence labeling rules.

In the latest research on natural language processing, the BERT model is a kind of network model which performs well in the present research stage. Instead of the traditional one-way language model or the method of shallow splicing of two one-way language models for pretraining, the algorithm adopts the new marked language model, which can generate deep two-way language representation and fine-tune specific downstream tasks [22]. At present, BERT has played an essential role in the research field of natural language processing, such as entity relationship extraction, text emotion analysis, and text classification [23]. Gao et al. [24] proposed a medical relationship extraction model based on BERT, which combined the whole sentence information obtained from the pretrained language model with the corresponding information of two medical entities to complete the relationship extraction task. Qiao et al. [25] proposed an agricultural entity relationship extraction model based on BERT-BLSTM-LSTM, which can effectively extract the relationship between agricultural entities.

In terms of the improvement of the model, Zhang et al. [26] proposed a new multi-label relationship extraction method based on a capsule network, which performed better than existing convolutional networks or cyclic networks in identifying highly overlapping relationships in a single sentence. Hang et al. [27] proposed an end-to-end neural network model for joint extraction of entity and overlap relations. Li et al. [28] proposed a new lightweight neural network framework to solve the problem of remote supervised relationship extraction. Xu et al. [29] proposed a new DocRE code-classifier-reconstruction model to extract document-level relationships and give more attention on the related entity pairs and path reconstruction. Sun and Wu [30] studied joint entity relationship extraction under remote supervision and developed a new adaptive algorithm that could deliver high-quality but heterogeneous entity relationship annotations robustly and consistently.

However, in the papers mentioned above, most studies on entity relationship extraction are based on a large-scale corpus, while in the field of food safety, there is a lack of a large corpus. Moreover, in the literature given above, word vectors are used to represent semantic features of sentences, but unlike the foreign corpus, Chinese entities are usually grouped together in the form of characters. Furthermore, the radical feature of Chinese characters, which can reflect the semantics to some extent, has not been well used.

3. Methods

In Section 3.1, how to carry out manual annotation is introduced. Section 3.2 describes how to construct the radical feature. In Section 3.3, the structure of the BERT-BLSTM-CRF model is introduced and the operating mechanism of the model is shown. In Section 3.4, this paper explains the detail of the extraction process of relationships of Chinese food public opinion event sentences. Section 3.5 introduces the entities extraction model of food public opinion events sentences.

3.1. Manual Annotation. Firstly, entity relationship triples in sentences are extracted as shown in Figure 1, and then, sentences are processed into sequence labels as shown in Figure 2.

Sequence label in single relationship entity extraction consists of three parts, namely, entity boundary, entity relation, and entity role label. The entity boundary label is used by BIO to represent the location information of the element in the entity, where B indicates that the element is at the beginning of the entity, I indicates that the element is in the middle or end of the entity, and O indicates that the element is not an entity. Entity relationship labels in the corpus are shown in Table 1 in Section 4.1. The entity role tag represents the role of the entity in the triple, denoted by 1, 2, 1 for the subject and 2 for the object, for example, (metronidazole in edible duck egg exceeding bid, adverse reaction, nausea).

3.2. Construction of the Radical Feature. At first, Chinese sentences are divided into character units and then converted to radicals according to the correspondence defined

Input sentence: Metronidazoleinedible duck egg exceedingbid can cause nausea.

↓

Extracting result: (Metronidazole in edible duck egg exceeding bid, adverse reaction, nausea)

Figure 1: Manual annotation instance.

in "Specification for Identifying Indexing Components of GB 13000.1 Chinese Characters Set," as shown in Figure 3. For the problem that the simplified radicals are not defined in the word list of the pretrained model during the experiment, some of the simplified radicals are converted into normal Chinese characters by referring to the work of "Specification for Identifying Indexing Components of GB 13000.1 Chinese Characters Set" and the study by Chen and Hu [31].

Formally, each Chinese character f in the sentence is added to Cr. And then, according to the rule of the radical decomposition, the radicals of the input sentence are generated and the radical f_{iv} of each character in the input sentence is added to Cr_v.

$$\begin{aligned} Cr &= [f_1, f_2, f_3, \ldots, f_n], \\ Cr_v &= [f_{1v}, f_{2v}, f_{3v}, \ldots, f_{nv}]. \end{aligned} \tag{1}$$

Then, the vector representation G_r corresponding to the input Cr_v can be obtained through the one-hot method. Finally, we get the radical feature G_r of the input sentence.

$$\begin{aligned} G_r &= \left[g_v^1, g_v^2, g_v^3, \ldots, g_v^n\right] \\ &= \text{one} - \text{hot encoder}\left(Cr_v\right). \end{aligned} \tag{2}$$

3.3. Framework of the BERT-BLSTM-CRF Model. Figure 4 shows the structure of the BERT-BLSTM-CRF network model. The model is divided into left and right parts. Among them, the left half part of the figure shows the relationship extraction process of Chinese food public opinion events sentences. The right half part of the figure shows the extraction process of the entity pair of food public opinion events sentences.

In the relationship extraction model, as shown in the left half of Figure 4, after the sentence is put through the BERT, the character vector is obtained. Then, the BLSTM model which receives the character vector as input outputs the hidden layer vector, and finally, under the activation function of the sigmoid, the multirelationships can be obtained. The implementation details of the model are explained in Section 3.4.

In the entity pair extraction model, as shown in the right half of Figure 4, firstly, we obtain Chinese radicals in the field of Chinese food public opinion events and then get the Chinese radical feature representation by the one-hot method. In the BLSTM model, the character vector participates with the Chinese radical feature representation in the calculation of the intermediate hidden layer, and the entity relationships extracted by the model in left

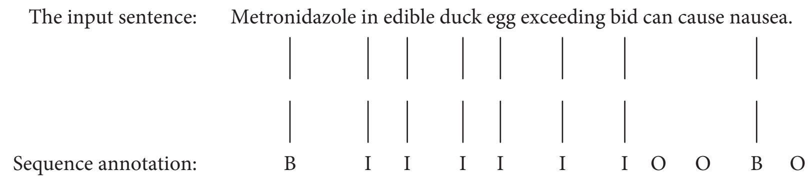

Figure 2: Sequence annotation instance.

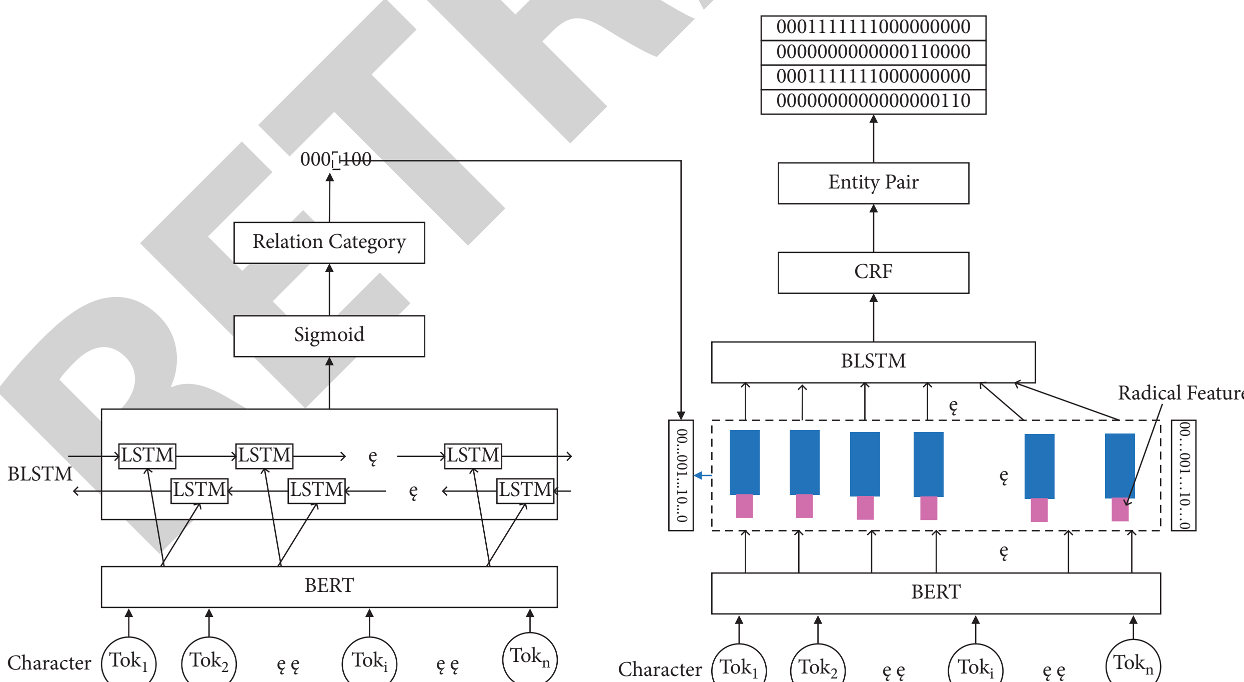

Figure 4: Structure diagram of the BERT-BLSTM-CRF model.

half part are added to the front and end of the hybrid character vector. After the BLSTM model outputs the hidden layer vector, the entity pairs are finally labeled under the function of the CRF method. Section 3.5 will explain the specific implementation process of the model in detail.

3.4. Structure of the Relationship Extraction Model. The internal structure of the relationship extraction model is shown in Figure 5.

In order to strengthen the semantic features of Chinese, this paper chooses the way of character annotation, that is, the character is input as the basic unit.

BERT is a language model trained by using a large number of unmarked texts in an unsupervised way. The encoder part based on the transformer carries out bidirectional coding. By constructing a marking language model, BERT can randomly cover or replace any word in a sentence, so that the model can predict the part that is randomly covered by the context and get the distributed context representation of the word. In addition, BERT performed the next sentence prediction task at the same time in the pretraining stage to make the model understand the relationship between the two sentences. Therefore, in order to enhance contextual semantic relevance, the BERT model is adopted in this paper. In the model of relational extraction, firstly, in the BERT, the characters loop through the Token Embedding layer, the Segment Embedding layer, and the Position Embedding layer. In the Token Embedding layer, [CLS] is put at the beginning of the sentence as the mark to be used for follow-on tasks to determine the kind of relationship.

The BLSTM receives the character vector generated by the BERT as input. In the BLSTM network, the character vector propagates forward and backward and the output layer outputs the final hidden layer vector. Finally, the sigmoid function is used to predict the multirelationship types, as shown in (3). The threshold value is trained by the neural network. When the value of the activation function is greater than the threshold value, it is judged to have a correlation and marked as 1; otherwise, it is judged to have no correlation and marked as 0. Finally, we get the relationship types.

$$\text{Sigmoid} = \frac{1}{1 + e^{x}}. \tag{3}$$

In this paper, we labeled seven types of relationships. We adopt seven bits to indicate whether there is a relevant correlation, where 1 represents correlation and 0 represents no correlation.

3.5. Structure of the Entity Extraction Model. The internal structure of the entity pair extraction model is shown in Figure 6.

To enhance the accuracy of entity recognition, entity semantics in statements need to be enforced. Firstly, the identified relationships are added to the hybrid vector to highlight the entities that need to be recognized. Secondly, Chinese characters have their own characteristics and radical features can represent a certain degree of Chinese meaning. Therefore, for the BLSTM model, the hybrid vector input is adopted.

At the input end of the BLSTM model, there are three kinds of inputs. The first one is the character vector generated by the BERT, and the second one is the Chinese radical feature representation. And then, one of the relationships extracted from the relational extraction model is constructed as the vector as long as the character vector which joins the Chinese radical feature and is added to the front and end of the hybrid character vector.

The Chinese radical features of character have been obtained according to formula (2) as in Section 3.2. The character vectors are generated when Chinese characters pass through the BERT model, as shown in the following formula:

$$\begin{aligned} T &= \left[t_r^1, t_r^2, t_r^3, \ldots, t_r^N\right] \\ &= \text{BERT encoder}\,(Cr). \end{aligned} \tag{4}$$

Then, the character vectors are spliced with the radical features, as shown in the following formula:

$$R = \left[G_r \odot T\right]. \tag{5}$$

Next, we take one of the relations obtained in Section 3.4 and construct a relation vector $H(i)$ as long as the splicing vector R, as shown in formula (6). Then, we divide the relation vectors into t parts, which are the kinds of relationship types, and the length of each part can be obtained by dividing the length of the splicing vectors by the kinds of relationship types. At last, we get the vector of the i^{th} relationship: the vector of the i^{th} segments are 1_i^k, and the vector of the other segments are 0_i^k.

$$H(i) = \left[0_1^k, 0_{2,}^k \ldots 1_i^k, \ldots, 0_t^k\right]. \tag{6}$$

Finally, the hybrid vector K is constructed by integrating G_r, T, and $H(i)$, as shown in the following formula:

$$K = \left[\left[G_r \odot T\right], H(i)\right]. \tag{7}$$

After the sentence passes through the BERT and BLSTM models, only the relationship between the text sequence and tags can be obtained and the relationship between tags cannot be considered, so there will be many invalid predictive tags. Through the CRF layer, the obtained prediction tags are constrained to reduce the number of invalid prediction tags and obtain the global optimal tag sequence.

There are two types of scores in the CRF layer; one type is the tag probability P obtained through the BLSTM layer and the size of the matrix P is n*m. N is the number of sentences, m is the type of tags, and $P_{i,j}$ is the probability of the label of the word in the sentence. And, the other type is the transition matrix T, and $T_{i,j}$ represents the transition probability from tag i to tag j. The sentence sequence $x = \{x_1, x_2, \ldots, x_n\}$ corresponding to the tag sequence $y = \{y_1, y_2, \ldots, y_n\}$ shown in the following equation:

$$s(x, y) = \sum_{i=1}^{n} \left(W_{yi-1,yi} + P_{i,yi}\right). \tag{8}$$

The loss function of CRF consists of the real path score and the total score of all possible paths, as shown in the following equation:

$$\text{loss function} = \frac{e^{s(x,y)}}{\sum_{\tilde{y} \in Y_x} e^{s(x,\tilde{y})}}. \tag{9}$$

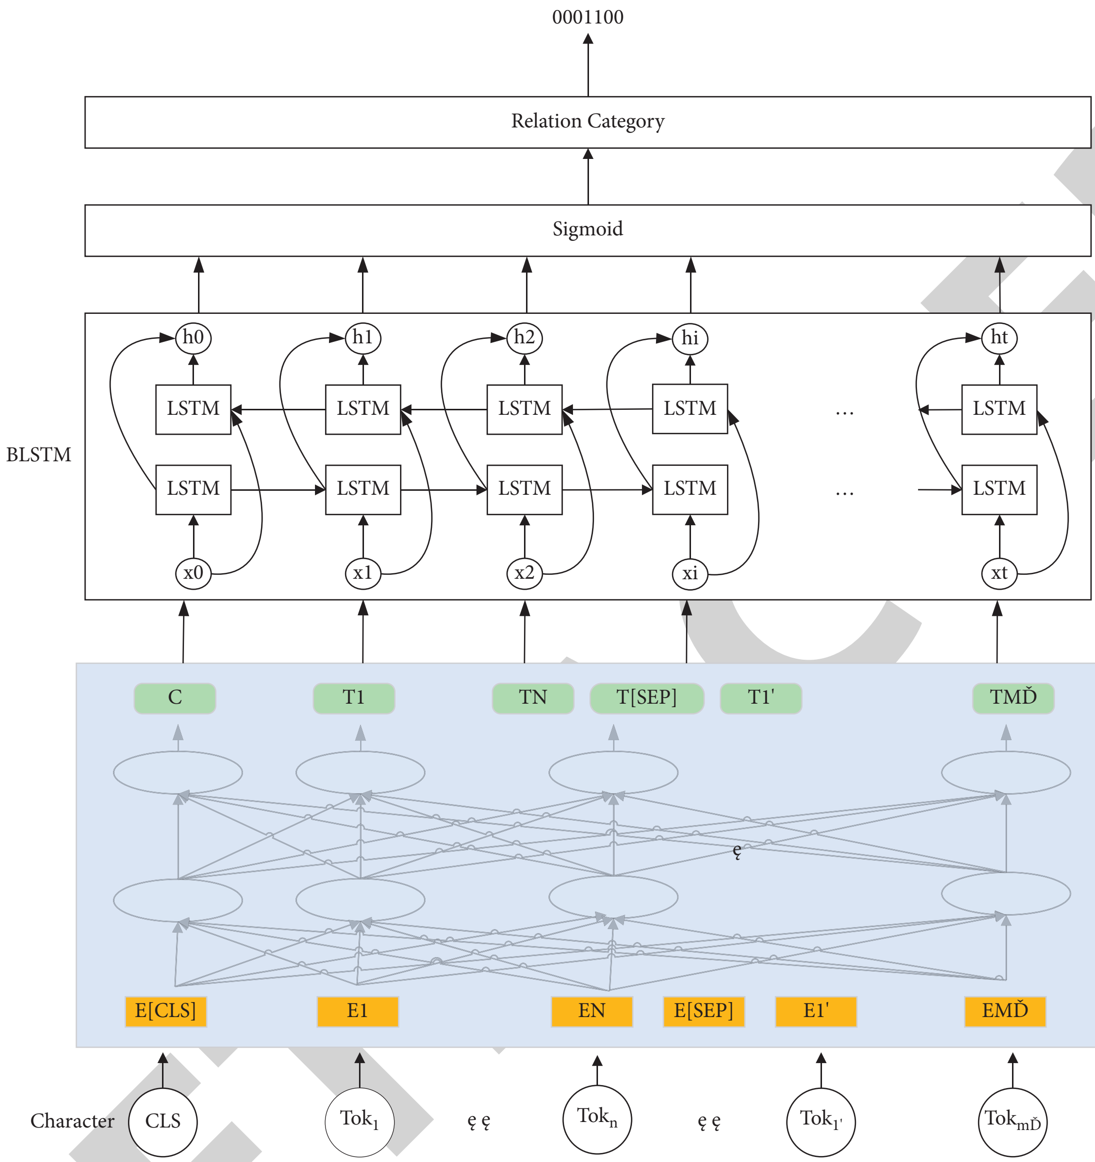

Figure 5: The framework of the relationship extraction model.

After the label probability and transfer probability in the CRF layer are obtained, the Viterbi algorithm is used to find the shortest path and the prediction label of each word in the sentence is obtained. The final hidden layer vector as the input passes through the conditional random field layer to mark whether the character is a subject or an object.

The outputs of the BERT-BLSTM-CRF network model consist of four layers of output vectors. Two layers are the output vectors of subject labels in entity annotation, and the other two layers are the output vectors of object labels in entity annotation. Vector labels have no order and depend on input.

4. Results and Discussion

In Section 4, we introduce our experimental environment and parameter settings and compare the experimental results of entity relationship extraction with different models.

4.1. Experimental Dataset. In this paper, a field dataset (BBC) of food public opinion events in China is constructed as an experimental dataset. The corpus of the experimental dataset is from authoritative and professional websites in the field of food safety (such as China Quality News Network and Baidu Information about Food-Borne Diseases and Food Safety Events). In addition, another open (OP) dataset is used for comparison experiments to ensure the fairness of the experimental results. Among them, the corpus contains seven kinds of relationships. Table 1 lists the seven relationship types, as well as their names and abbreviations.

The experimental dataset and open-source dataset are divided into three parts: training set, validation set, and test set. The data volume size of each subset is shown in Table 2, and the details of the experimental dataset are given in Figure 7

In addition, to evaluate the effectiveness of BERT-BLSTM-CRF in different entity overlap scenarios, sentences

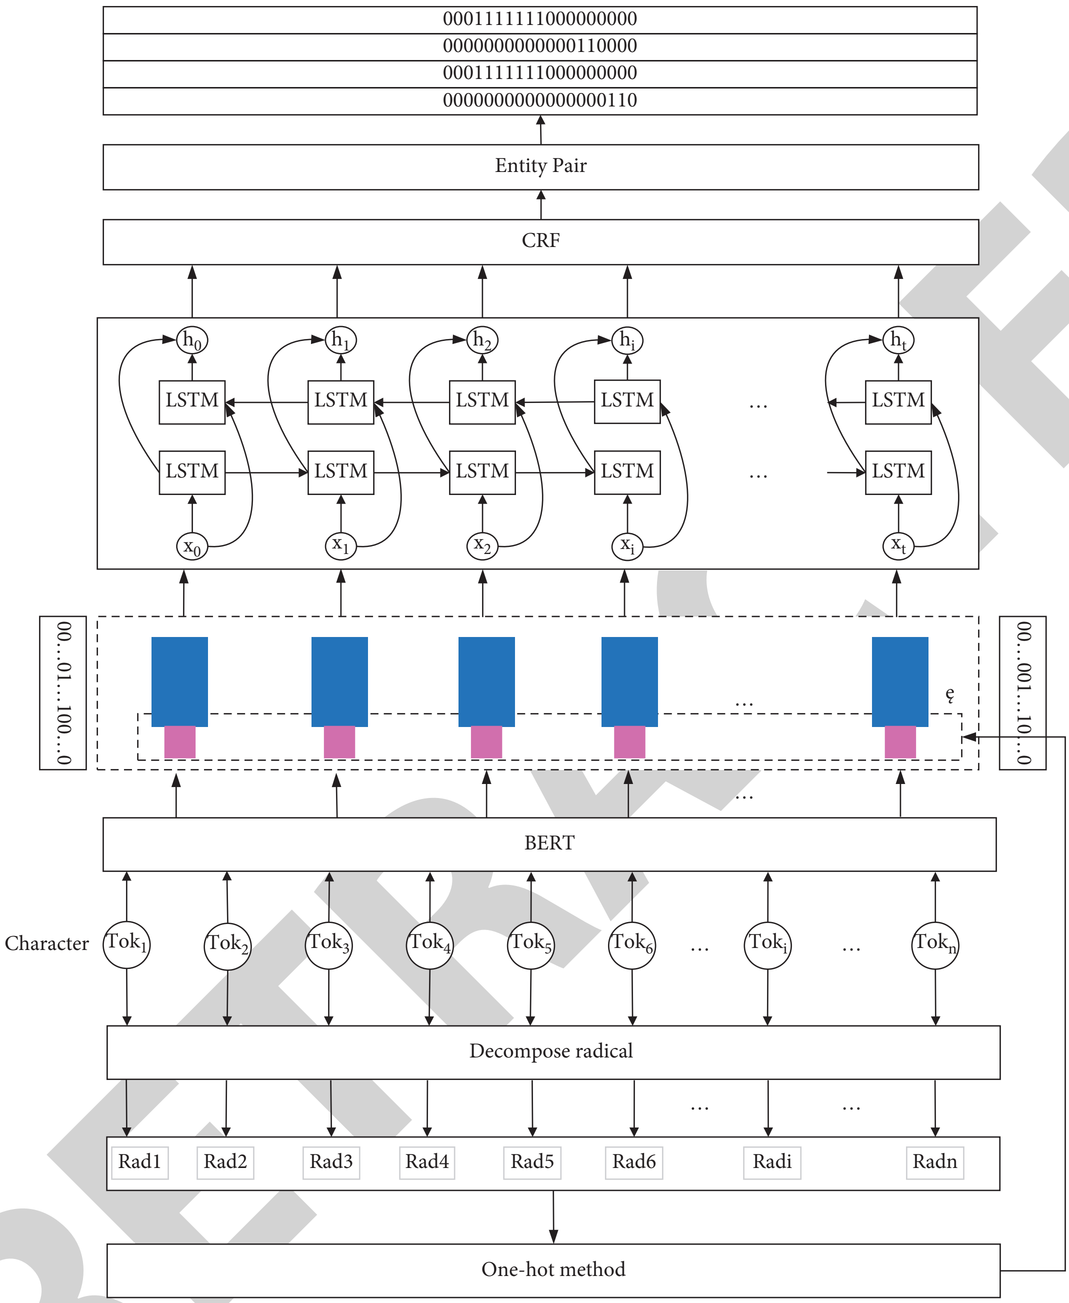

Figure 6: Entity extraction model structure diagram.

Table 2: Experimental dataset.

Dataset	Training	Validation	Test	Label
BBC-DATA	1500	300	400	7
OP-DATA	180000	50000	50000	35

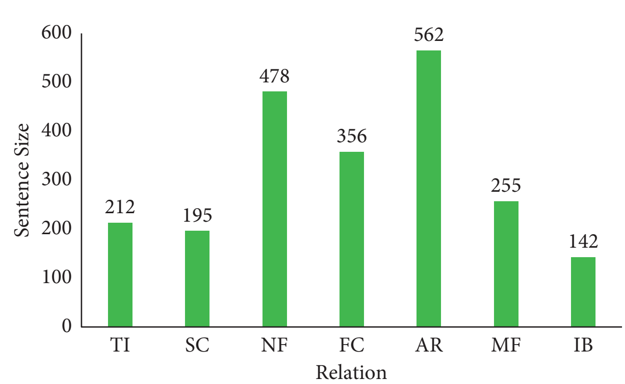

Figure 7: Details of the BBC experimental dataset.

in the BBC dataset are divided into normal (normal), entity pair overlap (EPO), and single entity overlap (SEO) according to different overlap types of relational triple, as shown in Figure 8. The normal class contains only one triple. In the SEO scene, only a single entity is shared at both ends of the relationship, such as the entity “excessive drug residues in turbot” in the sentence related to the entities

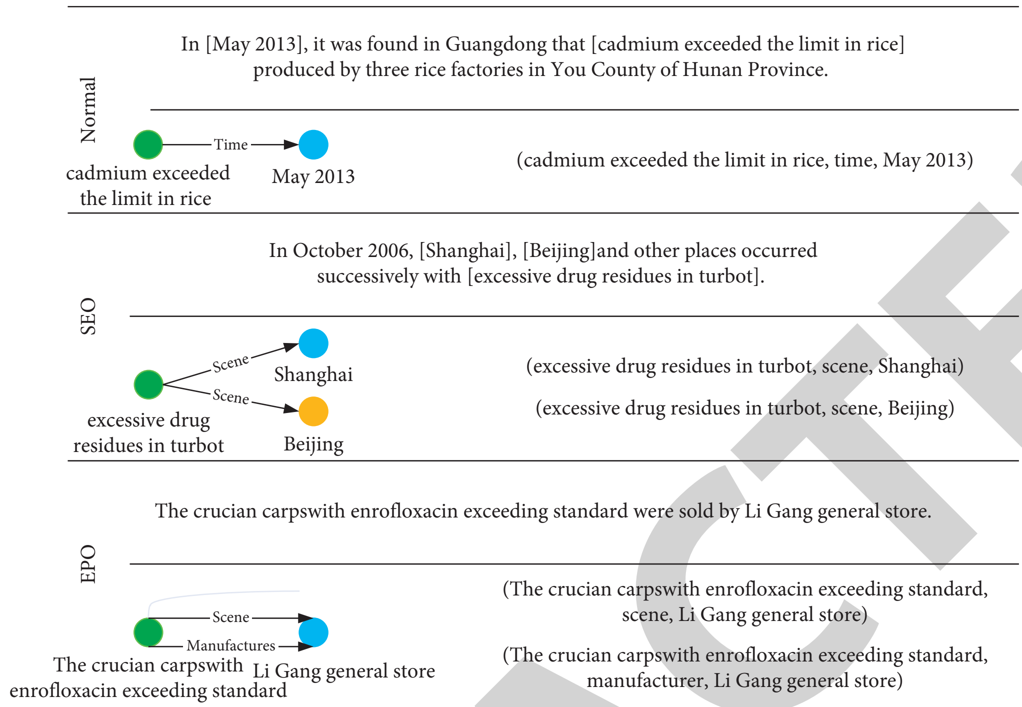

Figure 8: Different overlap types of relational triple.

Shanghai and Beijing. In the EPO scenario, the entities at both ends of the relationship are consistent, such as the entities in the triple < the crucian carps with enrofloxacin exceeding standard, Li Gang general store > overlapping. Table 3 describes BBC experimental dataset division for different entity overlap scenarios.

Table 3: BBC experimental dataset division for different entity overlap scenarios.

Dataset	Training	Validation	Test
Normal	573	96	143
EPO	281	35	79
SEO	646	169	178

4.2. Evaluation Standard Setting. In this paper, three experimental results of precision, recall rate, and $F1$ value are used as performance measurement standards. The calculation formulas are shown as follows:

$$P_i = \frac{TP_i}{TP_i + FP_i}. \tag{10}$$

In precision calculation formula (10), the precision as shown previously is referred to as P. TP_i represents the number of positive classes predicted by the model correctly and FP_i represents the number of positive classes predicted by the model from negative classes.

$$R_i = \frac{TP_i}{TP_i + FN_i}. \tag{11}$$

In recall calculation formula (11), the recall as shown previously is referred to as R. TP_i is as the same as the above-mentioned formula and FN_i represents the number of negative classes predicted by the model from positive classes.

$$F1 = \frac{P * R * 2}{P + R}. \tag{12}$$

The dataset of BBC-DATA constructed in this paper is a balanced dataset. Since precision and recall are a pair of contradictory indicators, to evaluate the performance of the classifier better, the harmonic mean $F1$ score of precision and recall rate is adopted as the evaluation standard to evaluate the comprehensive performance of the model.

4.3. Experimental Parameter Settings. In terms of experimental parameter setting, the main parameter information of the model in this experiment is determined by training the model and adjusting the parameters constantly. Among them, the BERT model's hidden layer has 12 layers, the vector has 768 dimensions, and the BLSTM model's hidden layer has 256 dimensions. An open-source deep learning framework based on PyTorch (https://pytorch.org/) is used to construct a deep learning model for experimental platform development. The main parameter information of the model proposed in the experiment is shown in Table 4 The hyperparameters in the experiment are determined by experiment and corpus, in which the dimension of character embedding is based on the experiment, the pad size is based on the maximum length of the sentence, and the learning rate is adjusted by the experiment.

4.4. Experimental Results and Analysis. In this paper, the proposed BERT-BLSTM-CRF model is experimentally compared with several other classical neural network models

Table 4: Experimental parameter setting.

Model	Parameters	Value
BERT	Layer	12
	Dimensions	768
	Learning rate	$5e-5$
	Pad size	128
	Function	Tan$h$
BLSTM	Layer	2-Layer
	Dimensions	256
	Learning rate	$1e-3$
	Pad size	128
	Function	ReLu Tan$h$

and models with an added attention mechanism. As shown in Table 5, the BERT-BLSTM-ATT model was proposed in [15]. In this experiment, seven annotated relationships are selected to conduct comparative experiments on independently constructed datasets and open datasets. The experimental results of each model relationship identification, including precision, recall rate, and $F1$ score, are shown in Table 5.

The experimental results in Table 5 show that in the food public opinion events corpus and the open-source dataset, the precision of the BLSTM-ATT model is better than that of the CNN-ATT model, but CNN-ATT is better than BLSTM-ATT in recall rate and the overall effect of BLSTM-ATT is better. It can be seen from experiments 1, 2, 3, and 4 that the extraction precision of the neural network model is greatly improved after the attention mechanism is added. In the latest research on relation extraction, BERT learned a better text feature through the deep learning model, which further improved the overall performance of the model. In experiment 4, the BERT model is introduced into the BLSTM-ATT model and its accuracy is significantly higher than in the original model, which further verifies this point. The BERT-BLSTM-CRF model with no attention mechanism proposed in this paper adopts the BLSTM network model and the BERT network model. It is shown that the relational extraction precision and recall rate of the BERT-BLSTM-CRF model adopted in this paper have been greatly improved in the small sample dataset of the food public opinion events corpus and open-source dataset of large-scale corpus. Furthermore, its $F1$ value is the best.

After extracting the relationship, to test the effectiveness of entity pair extraction of the model proposed in this paper in the field of entity recognition of food public opinion events in China, this paper uses the same neural network model mentioned above for comparative experiments. The specific experimental results are shown in Table 6.

After extracting multiple relationships, the BLSTM model is only used to extract entity pairs. Experiments showed that the BERT-BLSTM-CRF model performs better with datasets. BERT-BLSTM-CRF offers significant improvements in precision and recall rate, and F1 also offers the best performance. For entity recognition, the BERT-BLSTM-CRF network model makes use of extracted relationships and Chinese radical features to reinforce the semantics of entities in sentences and enhance the entity recognition ability of the whole network. It is worth noting that the BERT-BLSTM-CRF network model constructed in this paper has good performance in both precision and recall rate, because not only BLSTM in the model can deal with the long-distance dependency problem in time series modelling but also BERT can introduce a deep learning model to learn a better text feature.

This paper also verifies the BERT-BLSTM-CRF model's ability to extract relational triples from sentences with different numbers of triples. The sentences in the dataset are divided into five categories according to the number of different triples in the sentence, and the number of triples in the sentences is denoted by N. Figure 9 shows the results of each model with different numbers of triples. It is obvious that the performance of the baseline model, including precision, recall rate, and $F1$ score, decreases with the increase of the number of triples included in sentences. Here, precision, recall rate, and $F1$ score are calculated according to the number of correctly extracted triples. Although the BERT-BLSTM-CRF model also showed a downward trend, it achieved excellent performance in all five classes. Compared with the baseline models, the model in this paper is least affected by the increasing complexity of input sentences, which also proves that the BERT-BLSTM-CRF model has achieved considerable improvement. At the same time, the biggest improvement of the BERT-BLSTM-CRF model in the BBC dataset comes from the most difficult cases ($N \geq 5$), which also indicates that the model in this paper is more suitable for complex scenarios than the baseline model.

To further investigate the ability of the BERT-BLSTM-CRF model to extract overlapping triples, experiments are carried out on different types of sentences and the performance is compared with that of the baseline model. Figure 10 shows the detailed experimental results of three different sentence types. It can be seen that the performance of all models in normal, EPO, and SEO sentence classification shows a decreasing trend, which also reflects that with the increase in sentence complexity, the difficulty of extracting relational triples from these three overlapping patterns is increasing. In other words, among the three overlapping cases, the normal class is the easiest sentence form to extract, while the EPO class and SEO class are relatively difficult cases to extract. In contrast, the BERT-BLSTM-CRF model achieves better performance in the extraction of three

Table 5: Experimental results of relationship extraction.

Model	BBC-DATA			OP-DATA		
	P%	*R*%	*F*1%	*P*%	*R*%	*F*1%

BLSTM-ATT	77.85	71.87	74.74	75.25	70.37	72.72
BERT-BLSTM-ATT	89.19	86.78	87.97	84.22	83.37	83.79
BERT-BLSTM-CRF	92.48	91.82	92.15	93.15	92.42	92.78

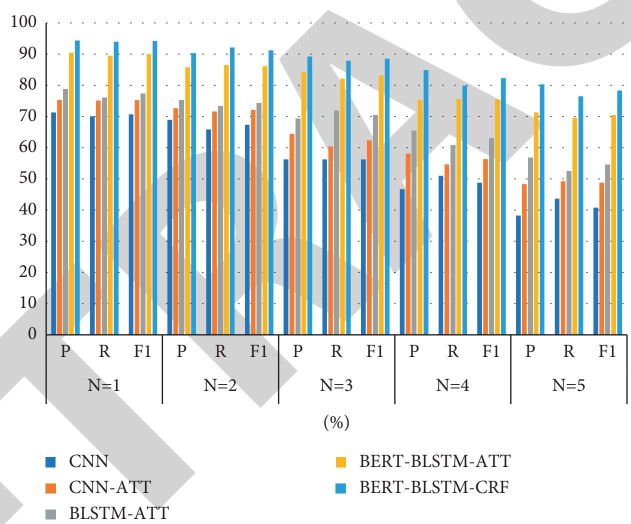

Figure 9: Precision, recall rate, and *F*1 scores for different number of triples.

sentence types. It is worth noting that the experimental effect of the EPO scenario is better than the effect of the SEO scenario on the BERT-BLSTM-CRF model. The reason is that the model adopts the pipeline-type extraction method, which extracts the relationship first and then the entity. Therefore, the improvement of the relationship extraction can improve the extraction effect of the entity to a certain extent and thus improve the extraction effect of the triplet.

The decreasing trend of the loss function of the BERT-BLSTM-CRF model proposed in this paper is shown in Figure 11. At the beginning of model training, many

Figure 10: Precision, recall rate, and *F*1 scores of relational triples in different overlapping patterns.

parameters of BERT have just been initialized and have not been adjusted for many iterations, so BERT does not have a good effect and the loss function has a large value. However, as the number of iterations of model training increases and the parameters are adjusted to a better state, the performance of the BERT-BLSTM-CRF network is gradually improved and the value of the loss function is gradually reduced.

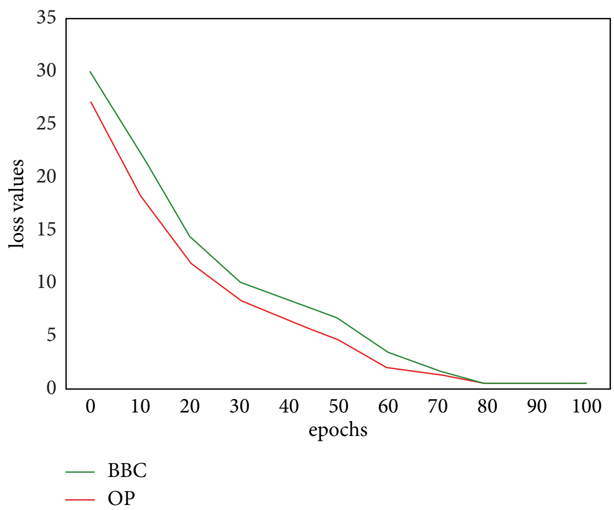

Figure 11: The loss function trending graph.

5. Conclusions

This paper proposes a BERT-BLSTM-CRF relationship entity extraction model based on the corpus of food public opinion events in China. This model adopts the BLSTM model, BERT model, and CRF algorithm and performs training on a small sample corpus to complete the entity relation extraction task of transforming unstructured data into structured data. By constructing the BERT network model and the BLSTM network model, we predict the multirelationship in one sentence. Then, the splicing character vector is constructed by the character vector generated by the BERT joining the Chinese radical feature in the field of food safety events. One of the multirelationships is put on the front and the end of the splicing character vector of the sentence. Finally, CRF is used to mark the entity pair. The comparison experiment results show that the model proposed in this paper performs better than the previous deep neural network model.

The BERT-BLSTM-CRF model can solve the problem of entity relationship in the field of food safety by few-shot learning, which provides the basis for smart healthcare and security guarantees for human health. The model in this paper can not only have a good performance for multirelationship and multi-entity extraction problems but also handle entity overlap well. However, it has a limit for the number of entity pairs. Therefore, we will further explore how to solve more entity problems in Chinese entity relation extraction, such as the improvement of annotation methods, and transfer the proposed method to other application fields such as agricultural image recognition, greenhouse environmental time-series prediction, food safety risk assessment, and image recognition [32–40].

Establishing resilient transport infrastructure is an effective way for cities to deal with external disturbances and uncertainties during rapid urbanization. However, human society is presently facing a series of sustainable development obstacles, where the energy shortage and environmental pollution are catching significant concerns. Hence, it is imperative to investigate the carbon emission of the growing number of resilient transportation infrastructure (RTI) projects. Through extracting the carbon emission factor (CEF), this study built the carbon emission measurement model (CEMM) to evaluate the carbon emission of 26 resilient high-speed railway construction projects in China. The results indicated that the carbon emissions of the entire high-speed railway infrastructure projects in China show regional and social environmental differences. Meanwhile, there are potential correlations and positive relationships between the resilience of the high-speed railway infrastructure projects and their carbon emission. Suggestions and recommendations for governments and construction enterprises are put forward to further improve the resilient and low-carbon development of transportation infrastructure in China.

1. Introduction

In the past decade, China is undergoing a rapid urbanization process with a high increasing rate of 1.46%. Under this background, a large number of people have poured into the megacities and the capitals of the provinces of China, such as Beijing, Shanghai, Guangzhou, and so on. To effectively alleviate the pressures on the urban caused by the concentration of the large populations, these cities are promoting and improving infrastructure construction. However, the construction projects of urban transport infrastructure, which are served as the lifeline, are challenged by a series of natural or man-made disasters, such as the natural hazards of hurricanes, fires, earthquakes, public security problems, and so on. These disasters act as the most significant uncertainties and disturbances that bring severe damage to the infrastructure, which thus will result in huge economic and social losses for the urban residents [1].

The concept of "resilience," which owns the unique advantages of the traditional disaster management framework, is one of the efforts made to overcome the challenges [2]. A resilient transport infrastructure with the characteristic of absorption, adaptation, recovery, and upgrading can withstand the external uncertainties and disturbances and maintain the basic function and performance, which finally guarantee the lives and property safety of the residents.

However, the urban transport infrastructure that required huge investments is of both high energy and resource consumption. Can the resilient transport infrastructure meet the current requirements for low-carbon emission? In 2018, global carbon emissions reached the historic high record of 33 billion tons, an increase of 1.7% over the last year [3]. At the same time, China's carbon emissions reached 9.5 billion tons, an increase of 2.5%, accounting for about 28% of the world [4]. China became the country with the largest carbon dioxide emissions in the world, and it is the key area for carbon emission reduction and low-carbon development. Thereafter, China has implemented a series of national strategies to actively respond to climate change achieve low-carbon and sustainable development and promote carbon emission reduction in infrastructure construction [5]. At the end of 2019, China's carbon emissions have been reduced by about 48.1% compared with 2015, reversing the rapid growth of carbon dioxide emissions. In 2021, China aims to "strive to achieve carbon peaks by 2030 and carbon neutrality by 2060." The "14th Five-Year Plan" has also made comprehensive arrangements for achieving carbon peaking, carbon neutrality, and addressing climate change [6, 7].

On these bases, the resilient transport infrastructure and the low carbon emission share the crucial strategic goals that both are expected to enhance the performance of the city, maintain the steady of the city system, reduce losses bring benefits, and improve the life quality of the residents. Hence, when the transport infrastructure is designed to be resilient, it must also be planned to meet the needs of low carbon emissions.

However, scarce prior studies have investigated the connections between resilient transport infrastructure and low carbon emission. The existed literature focused on making an independent discussion of the resilient transport infrastructure and the low carbon emission separately. Hence, this study aims to investigate the relationship between resilient transport infrastructure and low carbon emissions from this perspective. The tasks of this study are as follows.

2. Literature Review

2.1. Transport Infrastructure Resilience. The infrastructure is acknowledged as the most critical lifeline of the cities [8–10] which is of great significance for the flow of commerce, city residents, goods and information, and even the daily activities of society [11]. Infrastructure can be considered to include everything from the physical infrastructure of roads, bridges, airports, rail, water supply, telecommunications, and energy services to the social infrastructure of health care, education, banking, and financial services, emergency services, and the justice system [12–15].

The main responsibility of the department of traffic management is to give priority to ensuring that the physical engineering of the transportation infrastructure is intact and that the social services provided by the transportation infrastructure can operate continuously, stably, and safely [16–19]. Compared with traditional risk defensive measures, this demand for the transportation infrastructure system level will attract special attention from the decision-makers and the researchers [20, 21]. Therefore, the resilience proposal helps define, measure, and improve the traditional paradigm in the entire transportation system [22, 23].

From the perspective of the function of the transportation infrastructure construction project, the social and urban producing activities depend on the availability of the transportation network [24–27]. When the transportation infrastructure project operates under uncertain conditions and disturbances and the ability to quickly restore an acceptable level of service after a disruptive event occurs, it is the basis for the survival of the whole city [28, 29].

2.2. Carbon Emission

2.2.1. Greenhouse Gas and Environmental Problems. With the progress of human civilization, production activities have become increasingly frequent. Large-scale industrialization activities require the consumption of a large number of fossil fuels, resulting in a large number of cumulative emissions of carbon dioxide [30]. The global accumulation of large amounts of carbon dioxide emissions will cause the concentration of greenhouse gases in the Earth's atmosphere to increase rapidly and significantly, eventually causing a series of environmental problems such as global warming and rising sea levels [31, 32].

These environmental problems will have a significant negative impact on the global natural ecosystem. In addition to global temperature rise and sea-level rise, extreme climate events are also typical climate disaster events, posing a huge threat to human survival and development [33].

The generally accepted view in theoretical circles is that carbon dioxide (CO_2) is the main greenhouse gas (GHG). If carbon dioxide emissions cannot be controlled and active and effective actions are taken, a series of environmental problems caused by the global climate will bring huge losses to the global economy (about 5% of global GDP each year). Therefore, achieving carbon emission reduction should be the consensus and top priority of everyone.

2.2.2. Carbon Emissions. Carbon emissions refer to the average greenhouse gas emissions produced by byproducts during the life cycle of production, transportation, use, and recycling [34, 35]. In actual research, the total amount of carbon emissions in a certain area can be measured in a certain period. Carbon footprint is usually used to measure the total amount of greenhouse gases released by an organization or product each year. Carbon efficiency is used to quantify carbon footprint efficiency. It is the ratio of carbon dioxide emissions to the company's annual revenue [36, 37].

2.2.3. Carbon Emissions Factor. Carbon emission factor (CEF) refers to the number of carbon emissions produced per unit of energy during combustion or use. The IPCC believes that the carbon emission factor of a certain energy source is fixed. But, every year, the Chinese government announces the carbon emission factors for the six major regions of China.

2.2.4. Carbon Emission Intensity. Carbon emission intensity (CEI) aims to reveal the internal relationship between the level of economic development and carbon emissions in different countries and regions. Its calculation formula is the ratio of carbon emissions to GDP, that is, carbon emission intensity is inversely proportional to GDP. High carbon emission intensity indicates carbon emissions in the region. High energy consumption or low GDP value and low carbon emission intensity indicate that the region's energy use efficiency is high. Per capita, carbon emission is the ratio of the total carbon emissions of a country or region to the population of the region. Per capita, carbon emission can generally measure the level of development of a country or region.

2.2.5. Carbon Emission Measurement Method. Based on applicable objects and measurement scales, carbon emission measurement methods can be divided into four types: field measurement method, carbon emission coefficient method, input-output method, and material balance algorithm [38].

The site measurement method is the most accurate carbon emission measurement method, and its measurement objects are specific and specific carbon emission units [39]. The site measurement method requires the use of specific professional equipment to monitor the emission flow rate and speed of the research gas and then calculate the output carbon emissions. The site measurement method is generally applied to the carbon emission measurement of the ecosystem, and the industrial carbon emission measurement is less used.

The carbon emission coefficient method, also known as the IPCC inventory method, was first proposed by the IPCC (United Nations Intergovernmental Panel on Climate Change). It refers to the establishment of a carbon emission factor database containing all emission units, combing the carbon emission inventory, and obtaining the carbon emission units of activities or products [40]. Multiply the carbon emission unit data on the carbon emission inventory with the corresponding carbon emission factor to obtain the carbon emission of the emission unit and sum them up to obtain the total carbon emission of the research object. This method is similar to the domestic railway engineering quantity inventory pricing method, and the key to its use is to accurately calibrate the carbon emission factor. Many experts and scholars worldwide have calculated and analyzed the carbon emission coefficients of various energy and materials and constructed a rich database of carbon emission factors. Due to the simple calculation logic, strong operability, and relatively easy acquisition of carbon emission data, the carbon emission coefficient method has become the most widely used carbon emission measurement method [41].

The material balance algorithm, also known as the material balance method or the mass balance method, is a method of measuring the material consumption of the research object according to the law of conservation of mass [42]. Material balance refers to the principle of conservation of quality or "four-pillar inventory" in the system per unit time, that is, the original amount of material + the amount of new material = the amount of material consumption + the remaining amount of material. In the actual industrial production process, the use of this method requires first determining the process flow, to obtain the internal connection between the raw materials and the product [43, 44]. The products include the final product, the semi-finished product that has not been processed, and the byproducts produced together with the main product. It is necessary to comprehensively control the material consumption, physical and chemical reactions, and the impact of the environment on the production of products in each production stage and finally analyze and calculate carbon emissions. Because this method needs to master the physical and chemical reactions and energy consumption in each production stage, the calculation logic is complicated and involves a lot of content, and the measurement workload is relatively large.

The input-output method is different from the first three measurement methods. It uses the macro input-output table data to build a model; analyzes the internal connections between different industries, different economic sectors, and macroeconomic data; and combines them to reflect the characteristics of the industry [45]. The environmental impact data of the company estimate the environmental impact of a product. The input-output method has low requirements on the data accuracy and data range of the research object. Using the input-output method does not need to spend a lot of time and energy sorting out the carbon emission inventory. As long as the macro input-output table data are used, the environmental impact of a product can be determined for quick evaluation [46]. In summary, the input-output method is a macroevaluation method that analyzes the overall environmental impact of a certain industry or department and cannot accurately measure the carbon emissions of specific products or objects [47].

2.2.6. Carbon Emission Factor Calibration Method. The key to using the carbon emission coefficient method is to accurately calibrate the carbon emission factor. There are currently the following three mainstream carbon emission factor calibration methods:

(1) The carbon emission factor is calibrated based on the equivalent carbon dioxide value produced per unit of energy. This law applies to the calibration of energy carbon emission factors. For example, the carbon emission factors of fossil energy and electricity can be calibrated with the amount of fossil energy consumed per unit mass (volume) and the carbon dioxide emissions produced by consuming 1 kWh of electricity;

(2) The carbon emission factor is calibrated based on the equivalent carbon dioxide value produced by the production unit product. This method is applicable to the calibration of carbon emission factors of materials and construction machinery. According to the production process, the carbon dioxide emissions produced by the production unit materials and equipment are measured to achieve the purpose of carbon emission factor calibration;

(3) The carbon emission factor is calibrated based on the equivalent carbon dioxide value produced by the direct carbon source consumed. This method is suitable for direct carbon source carbon emission factor calibration. For example, coal can be used to measure the amount of carbon dioxide, nitrogen oxide, and other gases produced after full combustion based on the element composition to achieve carbon emission factor calibration.

This study uses the first two methods to calibrate the carbon emission factor.

3. Methodology

As mentioned above, there are many carbon emission measurement methods, and multiple methods are used for accurate measurement in many studies. Since the carbon emission coefficient method has obvious advantages in carbon emission measurement in the fields of construction and engineering, this study chooses the carbon emission coefficient method as the carbon emission measurement method. The carbon emission coefficient method is adapted in this study as the carbon emission measurement method.

3.1. Defining the Boundary of Carbon Emission Measurement. The determination of the carbon emission measurement boundary is the first step in the construction of the carbon emission measurement model. The definition of the measurement boundary is subjective, and its breadth and depth directly determine the accuracy and difficulty of carbon emission measurement.

Railway engineering can generally be divided into eight subsystems of bridges and culverts, tunnels, subgrades, tracks, traction power supply, electricity, signal, and communication (the latter four systems are generally collectively referred to as the four-electric system). This paper takes all subsystems into the carbon emission measurement. Meanwhile, we select the "bid section Y of railway X" as the studied cases. However, due to the large amount of railway construction projects and many majors involved, it is difficult to consider all aspects. Therefore, this article only measures the carbon emissions of major energy sources, materials, machinery, and equipment. The carbon emissions of energy, materials, and machinery that do not account for a large proportion are no longer considered. The specific selection criteria are as follows:

(1) Quality standards: Classify all building materials consumed in railway construction and sort all types of materials from large to small according to their quality. Materials whose cumulative mass exceeds 80% of the total mass of the materials are included in the measurement range.

(2) Cost standard: Classify all materials consumed in railway construction and sort all kinds of materials according to cost from largest to smallest. Building materials whose cumulative cost exceeds 80% of the total material cost are included in the measurement range.

(3) Carbon emission standards: Classify all machinery and equipment used in railway construction and sort all types of machinery according to carbon emissions from largest to smallest. Machinery and equipment with cumulative carbon emissions exceeding 80% of the total carbon emissions are included in the measurement scope.

3.2. Source of Data. The railway construction process involves a large amount of energy consumption, the use of materials and construction equipment, and a large amount of relevant data is generated, which causes the railway construction carbon emission measurement to rely heavily on data, and the accuracy of the data directly affects the accuracy of the carbon emission measurement results. This study divides the carbon emission measurement data into two major categories: railway engineering quantity data and carbon emission factor data, and explains their data sources and selection methods.

3.2.1. Railway Engineering Volume. Railway engineering volume data is the basis of railway construction carbon emission measurement. Railway engineering volume data mainly includes two parts.

(1) Railway construction materials and construction equipment data

Railway construction materials and construction equipment data include the types and consumption of construction materials, the types of construction equipment and the number of mechanical shifts, and the energy consumption per mechanical shift. As a large amount of data is involved in the process of railway construction, data accuracy and data availability are considered comprehensively when selecting.

The data sources of materials and construction equipment include railway project budget documents, cost software such as Glodon, and engineering drawings. Budget documents generally refer to construction quotas or budget quotas; the built-in quota data in the cost software depend on the productivity levels of different regions, and there may be differences in consumption of the same equipment or process.

(2) Railway construction material transportation data

The carbon emission generated by the energy consumption during the transportation of a large number of building materials is an important part of the carbon emission of railway construction. The transportation objects in the transportation stage include the building materials, prefabricated components that constitute the railway engineering entity, and turnover materials used in amortization during the construction stage. In the construction material transportation stage, carbon emission measurement should collect data such as the transportation distance, transportation weight, and transportation method of the building materials.

It is generally believed that the transportation process includes three parts: one is the raw material mining place to the raw material processing place. The carbon emission factor for building materials calibrated in this paper considers the transportation process of raw materials from the mining place to the processing place, so it is no longer considered in the transportation data. The second is the construction material production site (raw material processing site) to the construction site. This transportation process includes the transportation of turnover materials and prefabricated components used in railway construction. The third is the waste from the construction site to the landfill. The railway construction phase involves the transportation of a large number of wastes such as tunnel slag and abandoned formwork.

In summary, the transportation data in this study need to consider the transportation process of building materials production site (raw material processing site) to a construction site and waste from the construction site to the landfill.

3.2.2. Identification of the Carbon Emission Factor. Carbon emission factor calibration is the core part of carbon emission measurement using the carbon emission coefficient method. Accurate carbon emission factors are the key to achieving accurate carbon emission measurement. The carbon emission factors are identified from the literature (Table 1).

3.3. Calibration of the Carbon Emission Factor. Carbon emission factor calibration is the core part of carbon emission measurement using the carbon emission coefficient method. Accurate carbon emission factors are the key to achieving accurate carbon emission measurement. This research sorts out the carbon emission factors of energy, transportation, building materials, and construction machinery and establishes a reliable carbon emission factor database.

3.3.1. Energy CEF. In the railway construction stage, direct consumption of energy or indirect consumption of energy through machinery produces a large number of carbon emissions. Energy carbon emission factors are the basis for the calculation of carbon emission factors for building materials and machinery, so it needs to be clarified first. This article divides energy into fossil energy, electricity, and water.

(1) Fossil energy CEF

Regarding the hot issue of carbon emissions, many institutions actively participate in the research and calculate and publish carbon emission factor data. Among them, the IPCC (United Nations Intergovernmental Panel on Climate Change), as a climate change assessment agency with international influence, published assessment reports five times in 1990, 1995, 2001, 2007, and 2013 and issued research systems, computing science, and comprehensive energy carbon emission factor data. However, since the IPCC's latest assessment report was released in 2013 (IPCC WGI Fifth Assessment Report), the timeliness is poor, and the energy carbon emission factor in the IPCC assessment report is determined based on international data, which is different from China's carbon emission data. Therefore, this cultural stone energy carbon emission factor data does not directly quote the relevant data in the IPCC assessment report but draws on the calculation method of the IPCC energy carbon emission factor and calculates it by China's national conditions. Since the carbon emissions of fossil energy mainly come from the use (consumption) stage and the carbon emissions in the production and transportation stage are difficult to measure, this article only measures the carbon emissions generated during the use (consumption) stage.

According to the benchmark method published in the energy section of the 2006 IPCC National Greenhouse Gas Inventory Guidelines 2019 Revised Edition, the calculation formula for the carbon emission factor of this cultural stone energy (combustion) is

$$\begin{aligned} \text{Fossil energy CEF} &= \text{default net calorific value} \times \\ &\quad \text{default carbon content} \times \text{default carbon oxide factor} \\ &\quad \times \text{molar conversion coefficient of carbon and carbon dioxide}. \end{aligned} \tag{1}$$

In the formula, the default net calorific value is derived from the "China Energy Statistical Yearbook 2018"; the default carbon content is quoted from the "2006 IPCC National Greenhouse Gas Inventory Guidelines 2019 Revised Edition"; the default carbon oxidation factor is 100% (the degree of carbon oxide combustion does not affect its carbon content); the molar conversion coefficient of carbon and carbon dioxide is 44/12. The calculation results of fossil energy carbon emission factors are shown in Table 2.

(2) Electricity CEF

As clean energy, electricity does not directly produce carbon emissions during its use but consumes energy to produce carbon emissions during its production process. Therefore, the carbon emission factor of electricity is affected by the energy structure of power generation. The Climate Change Department of the National Development and Reform Commission has clarified two types of marginal emission factors, OM (marginal emission factor for electricity) and BM (marginal emission factor for capacity) in the "2019 China Regional Grid Baseline Emission Factors," and unifies the grid boundaries. It is divided into regional power grids in North China, Northeast China, Northwest China, East China, Central China, and South China, excluding Tibet Autonomous Region, Taiwan Province, Hong Kong, and Macau Special Administrative Regions. The carbon

emission factors of power in each region are shown in Table 3.

(3) Water CEF

Water does not contain carbon elements, so water is not a direct carbon emission unit but indirectly produces carbon emissions during its production and transportation. Therefore, its carbon emission factor refers to the energy consumption per unit volume (mass) of water production and transportation. Carbon emissions are generated. This study quotes the value of 0.91 kg CO_2/m^3 in the literature. Since the density of water is 1,000 kg/m^3, the water carbon emission factor can be converted to 0.00091 kg CO_2/kg.

3.3.2. Materials CEF

(1) Silicon-Containing Materials. Sand and gravel are indispensable building materials for railway construction, but there are relatively few studies on carbon emissions during sand and gravel mining and processing. As the carbon emission measurement process for production and mining without sand and gravel in the reference, assuming that the measurement range is the same as this article, it can be

Table 2: Fossil energy CEF.

Fossil energy	Net calorific value	Carbon content	Carbon dioxide factor (%)	Unit	CEF
Raw coal	20,908	25.8	100	kg	1.978
Washed coal	26,344	25.8	100	kg	2.492
Coke	28,435	29.2	100	kg	3.044
Crude	41,816	20.0	100	kg	3.067

Table 4: Silicon-containing materials CEF.

Silicon-containing materials	Bulk density (kg/m^3)	CEF ($kg\ CO_2/m^3$)	CEF ($kg\ CO_2/kg$)
Stone	1,560	31.2	0.02
Sand	1,450	72.5	0.05

directly quoted. The specific numerical calculations are shown in Table 4.

(2) Blended Materials. Since there is no carbon emission measurement process for bentonite, mineral powder, and fly ash in the references, assuming that the measurement range is the same as this article, it can be directly quoted, then the carbon of bentonite, mineral powder, and fly ash. The emission factors are 0.041 kg CO_2/kg, 0.05692 kg CO_2/kg, and 0.0015 kg CO_2/kg.

(3) Cement Materials. The total carbon emission factor of cement can be obtained by summing the carbon emission factors of the raw material production stage, raw material transportation stage, and cement production and processing, as shown in Tables 3–8, that is, the cement carbon emission factors of PS32.5, PO42.5, and PI52.5 are, respectively, 802.259 kg CO_2/t, 1,103.707 kg CO_2/t, and 1,254.874 kg CO_2/t.

(4) Concrete Materials. The production amount and processing energy consumption of different strength concrete raw materials are used to calculate the CEF in this study, namely C20, C25, C30, C35, C40, C50, and C60.

In the raw material production stage, five strength grades of concrete (C20, C25, C30, C35, and C40) use 42.5# cement, and two strength grades (C50 and C60) use 52.5# cement. The consumption of raw materials for concrete production is shown in Table 6.

The carbon emission factors of raw materials consumed in concrete production are shown in Table 7.

The carbon emission factors of the raw material production stage, the raw material transportation stage, and the concrete processing production stage are added together to obtain the concrete carbon emission factor, as shown in Table 8, that is, the carbon emission factors of the seven strength grades of concrete (C20–C60) are 306.192 kg CO_2. /m^3, 336.680 kg CO_2/m^3, 371.654 kg CO_2/m^3, 389.568 kg CO_2/m^3, 419.599 kg CO_2/m^3, 502.819 kg CO_2/m^3, and 549.342 kg CO_2/m^3.

(5) Mortar Materials. The carbon emission factor of cement mortar is obtained by adding the carbon emission factors of the raw material production phase, the raw material transportation phase, and the cement mortar processing production phase. As shown in Table 9, the carbon emission factors of the four different ratios of cement mortar are 829.388 kg CO_2/m^3, 636.038 kg CO_2/m^3, 581.347 kg CO_2/m^3, and 532.518 kg CO_2/m^3.

(5) Steel Materials. A large amount of steel is used in the railway construction stage, and the steel production stage consumes a lot of resources and energy to generate carbon emissions. Steel materials can be classified according to processes and uses, and there are large differences in the carbon emission factors of steel products of different uses and processes. Steel materials can be divided into screw steel, angle steel, section steel, round steel, and so on according to

Table 5: Cement materials CEF.

CEF	Raw material production stage	Raw material transportation stage	Cement production and processing stage	Total
P.S.32.5	517.100	40.498	244.661	802.259
P.O.42.5	729.200	44.211	330.296	1,103.707
P.I.52.5	835.550	46.092	373.232	1,254.874

the purpose. As is presented in Table 10, the classification of steel in this study is that the four types of steel are large steel, medium and small steel, hot-rolled steel, and cold-rolled steel.

(6) Wood Materials. Timber is a commonly used turnover material for railway construction, such as wooden formwork, wooden support, and so on. This article believes that turnover wood is difficult to regenerate, that is, the turnover rate of turnover wood is 0. According to the above formula of turnover material carbon emission factor calculation formula, the turnover wood carbon emission factor can be obtained as 120.924 kg CO_2/m^3. Turnover timber amortization frequency is taken as 10 times, and its amortization uses CEF = 120.924/10 = 12.092 kg CO_2/m^3. Table 11 presented the CEF of wood material.

The construction materials CEF of railway engineering are shown in Table 12.

3.3.3. Facility CEF. The CEF of commonly used construction equipment for railway construction is shown in Table 13.

3.4. Measuring Model of the Carbon Emission. The carbon emissions from railway construction should include three aspects: carbon emissions from the transportation of building materials, carbon emissions from the use of building materials, and carbon emissions from construction. However, the use of construction machinery to assemble building materials does not directly generate carbon emissions. Carbon emissions related to building materials occur in the process of production, that is, carbon emissions from railway construction are "transferable."

In this study, the production of building materials is listed separately before the construction phase, that is, it is divided into the building material production phase, the building material transportation phase, and the construction and construction phase. Based on the carbon emission measurement boundary, this research clarifies the content of carbon emission measurement at each stage and combs the carbon emission calculation formula.

(1) The calculation model of CEs during the production stage of building materials is shown in the following formula:

$$C_{sc} = \sum_{i=1}^{n} m_i \times (1 + \mathscr{U}_i) \times C_i, \tag{2}$$

where C_{sc} represents the carbon emissions during the production phase of building materials, m_i represents the consumption of building materials, $\mathscr{U}_i$ denotes the building material loss rate, c_i represents the CEF of the building material production stage, and n represents the types of the building materials.

(2) The calculation model of CEs during the building materials transportation stage is shown in the following formula:.

$$C_{ys} = \sum_{i=1}^{n} \sum_{j=1}^{k} m_{ij} \times (1 + \mathscr{U}_i) \times d_{ij} \times C_i, \tag{3}$$

where C_{ys} represents the carbon emissions during the building materials transportation stage, d_{ij} denotes the average transportation distance of type j for construction materials (waste) i,m_i represents the consumption of building materials (amount of waste engineering), $\mathscr{U}_i$ denotes the building material loss rate, and c_i represents the CEF of the building material production stage.

(3) The calculation model of CEs during the construction stage is shown in formula (4).

During the construction phase, carbon emissions are composed of two parts: the operation of construction machinery consumes energy (gasoline, diesel, electricity, etc.) to produce carbon emissions, the amortization of revolving materials produces carbon emissions, and the direct consumption of energy produces carbon emissions.

$$C_{js} = C_{js1} + C_{js2}, \tag{4}$$

where C_{js} represents the carbon emissions during the construction phase, C_{js1} denotes the construction machinery carbon emissions, C_{js2} represents the energy carbon emissions, $\mathscr{U}_i$ denotes the building material loss rate, and c_i represents the CEF of the building material production stage.

The C_{js1} and C_{js2} can be obtained through the following equations:

$$C_{is1} = \sum_{l=1}^{a} h_l \times c_l = \sum_{m=1}^{b} r_m \times c_m, \tag{5}$$

$$C_{is2} = \sum_{t=1}^{f} r_t \times c_t. \tag{6}$$

Table 6: Consumption of raw materials for concrete production.

Materials	C20	C25	C30	C35	C40	C50	C60
Cement	135	170	210	235	270	320	370

4. Determining the Samples Implementing the MCDM

We collected 188 high-speed railway infrastructure construction projects in China using the average sampling method to complete the empirical research. These samples are China's important high-speed railway infrastructure construction projects. The Delphi method was used to determine whether these samples are resilient. MCDM selection techniques were used to determine the suitable MCDM methodology tailored to the decision process [79, 80]. The techniques adapted totally 9 alternatives for determining the required abilities from a set of 78 MCDM databases where the specific descriptors for the properties of the decision process are presented. For instance, qualitative, quantitative, and relative are regarded as the general standards for the alternative type of weights [81–83]. Finally, 26 samples are identified as resilient high-speed railway infrastructure construction projects.

The proposed measuring model was implemented to calculate the carbon emissions of the selected 26 projects.

5. Results and Discussions

We separately calculated the carbon emissions of these 26 resilient high-speed rail projects. Taking section A of the Huaihua-Hengyang (HH) high-speed railway project in China as an example, the measurement for the sample is adapted as follows.

The length of section A of the HH high-speed railway project is 66.95 km, including 44.36 km of tunnels, 9.65 km of bridges, and 12.94 km of roadbeds and stations; the proportion of bridges and tunnels is 80.7%; and the contract period is 60 months. The main project quantities are shown in Table 14.

(1) The value of carbon emissions

The total carbon emission is calculated from the two dimensions of the construction stage and carbon emission source. The total carbon emission of materials is 1,253,677.42 t, of which the carbon emission in the production stage is 1,124,700.91 t and the carbon emission in the transportation stage is 128,976.52 t. The total carbon emission of construction equipment is 158,279.70 t. The total energy carbon emission is 7,167.56 t.

(2) Comprehensive assessment of the carbon emissions

The results presented that the material production stage is the largest source of carbon emissions in the case of railway construction, accounting for 79%; the construction stage carbon emissions account for 12%; and the construction stage carbon emissions are the least, accounting for 9%. Moreover, the carbon emission contribution of materials is 88%; the carbon emission contribution of construction equipment is 11%; and the carbon emission of direct energy use only accounts for 1%. A comprehensive analysis of the data showed that reducing carbon emissions during material production is of great significance for controlling carbon emissions in high-speed railway construction.

The carbon emissions of cement and stone materials are higher than those of other building materials in the material production stage and material transportation stage. The high-speed railway construction in this study uses ready-mixed concrete. Cement, as the main building material for concrete production, consumes a huge amount of carbon, accounting for 54.38% and 25.83% of carbon emissions in production and transportation, respectively. As an important building material for concrete production, sand and gravel account for 16.80% of carbon emissions, second only to cement carbon emissions. The consumption of stone is smaller than that of cement, so the proportion of carbon emissions in the production process is lower than that of cement. However, due to the high density, a large amount of carbon emissions is generated in the transportation process. In summary, reducing carbon emissions from cement and sand production and transportation is the key to controlling carbon emissions from building materials.

Among the construction equipment, the top four contributors to carbon emissions are power machinery; transportation machinery; earth-rock machinery; foundation and pump machinery, with carbon emissions accounting for 37%, 26%, 17%, and 9%, respectively; hoisting machinery; and paving machinery. The carbon emissions from

Table 8: Concrete material CEF.

CEF	C20	C25	C30	C35	C40	C50	C60
Raw material production	184.051	213.396	247.016	266.137	295.257	375.593	422.704
Raw material transportation stage	119.431	120.574	121.928	120.721	121.632	124.516	123.928
Concrete production and processing stage	2.710154	2.710154	2.710154	2.710154	2.710154	2.710154	2.710154
Total	306.192	336.680	371.654	389.568	419.599	502.819	549.342

machinery, processing, and other machinery are relatively small. From this, it can be seen that the carbon emission reduction of construction equipment such as power machinery and transportation machinery with a large carbon emission contribution is the focus of carbon emission control of construction equipment.

Among the direct energy carbon emissions, electricity carbon emissions account for up to 73%, and water carbon emissions account for 26%. Direct consumption of fossil energy produces the least carbon emissions, accounting for only about 1%. Therefore, the energy and carbon emission reduction of construction sites can start by saving electricity and water resources.

After obtaining the carbon emissions of 26 resilient high-speed rail projects, we investigated the relationship between the resilience of the high-speed railway projects and the low-carbon emission. The results of the statistical analysis revealed that the resilience of the high-speed railway projects has a significant positive influence on low-carbon emissions.

6. Suggestions and Recommendations

6.1. Carbon Emission Control Strategy for the Government. Some scholars have called the climate change caused by excess carbon emissions, “the most serious and wide-ranging market failure in history,” and pointed out that only the coordinated efforts of the government and enterprises can avoid the irreversible consequences of excess carbon emissions. According to externality theory, effective government regulation can compensate for market failures. As a typical market failure, carbon emission requires effective government control to achieve its externality internalization. Based on literature research and domestic and foreign practice, it is concluded that carbon emission control strategies widely recognized at home and abroad mainly include carbon auditing, carbon tax collection, and carbon emission trading.

Railway construction carbon auditing refers to tracking and measuring the carbon emissions generated in the process of railway construction, reviewing the management of carbon emissions in the process of railway construction, and achieving the purpose of external intervention in carbon emissions. Carbon audit not only can realize the supervision of carbon emission reduction activities and promote the rational allocation of resources but also can contribute to the coordinated development of the economy and environment.

The participants in the carbon audit process of railway construction include the audit client, the carbon audit subject, and the carbon audit object. Among them, the principal-agent relationship between the audit client and the carbon audit object is the fundamental reason for carbon audit activities, and the audit content is the carbon emissions generated in the process of railway construction. The main body of carbon audit plays an important role in audit activities and can be divided into three categories: government audit subject, social audit subject, and internal audit. In the early stage of the development of carbon auditing in railway construction, China lacked relevant practical experience in carbon auditing in railway construction, and the audit risk was relatively high. Government auditing mainly assumed the main role of carbon auditing. Moreover, the government audit is highly authoritative, which is conducive to promoting the carbon audit of railway construction on the right track. With the gradual improvement of the carbon emission trading market, the participation of social audit subjects has gradually increased, which can play an important role in the carbon audit of railway construction. When the carbon emission trading market is relatively complete, the carbon emission audit of railway construction will become a routine audit business. At this time, the main body of internal audit was derived, and the role of carbon emission management in the process of railway construction was brought into full play.

Since it is currently impossible to implement mandatory carbon audits for all railway construction processes, this paper proposes the implementation framework of railway construction carbon audits concerning the “Kyoto Protocol.” Railway projects can be divided into three categories according to the priority of railway construction. The first category is the railway projects with mandatory carbon audit. The second category is the railway projects that are ready to implement carbon audit, and the third category is all the remaining railway projects. Then carbon audits are carried out for these three types of railway projects in three steps. Under the condition of gradual improvement, the implementation of carbon audits for the second type of railway projects has been promoted, and the construction of related systems such as carbon tax has been promoted. Furthermore, the carbon audit system is promoted in the construction process of all railway projects to achieve energy saving and emission reduction in the process of railway construction.

Based on the relevant economic theories, the negative external effects of carbon emissions originate from the coupling effect of government failure and market failure. To solve this problem, we must make full use of market instruments, which leads to carbon emission trading, a carbon emission response measure widely recognized and used by all countries in the world. The carbon audit of railway projects and the carbon emissions trading system promote and complement each other and can work together to help reduce carbon emissions. The attestation role of carbon audit

can regulate market transactions and provide a basis of trust for both parties to the transaction. At the same time, carbon emission trading will also promote the development of carbon auditing, and the economic benefits brought by carbon emission trading will attract more carbon emission entities to participate. Finally, the market means to guide the construction unit's carbon audit activities.

To ensure the sustainable, long-term, and healthy development of the carbon audit system for railway projects, we should also build a friendly audit environment for carbon audit of railway projects from the perspectives of politics, economy, law, and social environment.

The economic principle of carbon emission trading involves three classic theories of resource scarcity, externality, and property rights. The theory of resource scarcity reveals the deep root of carbon emissions trading. The negative externality of carbon emissions is the direct cause of emissions trading, and the definition and trading of carbon emissions provide solutions for the internalization of negative externalities of carbon emissions. According to economic theory, carbon emission behaviors enter the market without clear property rights, resulting in significant negative external effects. Economists believe that based on the initial allocation of carbon emissions within the quota, carbon emission rights can be regarded as a tradable commodity and allowed to circulate freely, to achieve the purpose of controlling carbon emissions and achieving economic benefits. In the exploration of carbon emission rights trading in the past 10 years, China has laid a solid foundation for the construction of a unified national carbon emission rights trading market and has also contributed to the early establishment of a carbon emission rights trading system. This study explores key regimes for rail carbon emissions trading.

Government regulation can be divided into two stages: carbon emission reduction regulation and carbon emissions trading regulation, which are implemented through the following mechanisms. The first is the quota allocation supervision mechanism. Whether the allocation of carbon emission allowances is fair and effective is directly related to the normal operation of the carbon emission trading market. The competent department of carbon emission allowance allocation should set up a reasonable and effective supervision system and take measures such as introducing a notary public for supervision and implementing allowance allocation through an online carbon emission allowance allocation system to ensure fair distribution. The second is the regulatory mechanism for trading market behavior. The government should supervise the carbon emission trading process strongly to ensure the trading order. On the one hand, qualification checks can be set up. The carbon emission rights exchange should conduct qualification examinations on carbon emission rights trading entities and set membership criteria. Only those who meet the standards can join the membership. On the other hand, transaction monitoring is possible. Exchanges can establish a transaction monitoring platform to monitor transaction information in real time. The third is the performance offset supervision mechanism. Carbon emission compliance and write-off directly affect the emission reduction results of railway projects, so they must be taken seriously. The carbon emission rights trading authority should formulate a time scale for compliance and urge emission reduction units to submit carbon emission quotas promptly. Competent authorities should also focus on carbon emissions trading volumes in carbon emissions trading and conduct data verification. After the implementation of the contract, the competent department should cancel the quota that has been implemented in time to lay the foundation for the next round of carbon emission reduction implementation.

In addition to supervision, the carbon emission rights trading of railway projects should also set up a penalty mechanism to achieve constraints on emission reduction units. The punishment mechanism should not only punish those who fail to meet the emission reduction targets but also cannot affect the enthusiasm of carbon emission entities to participate in carbon emission trading. In practice, a combination of various punishment methods can be considered.

The first is to set up a mechanism for the disclosure of energy efficiency of railway projects. The key to carbon emission trading of railway projects is the lack of accurate energy consumption and carbon emission data. At present, the energy consumption data of railway projects are not

Table 11: Wood material CEF.

Production process	Log harvesting	Log transportation	Timber processing
Energy	Gasoline	Diesel fuel	Electricity
Number	16.487 (kg/m^3)	4.844 (kg/m^3)	70.142 (kWh/m^3)
CEF (kg/CO_2)	2.985	3.159	0.8042
CEF (m^3/CO_2)	49.214	15.302	56.408

public, which is not conducive to the promotion of carbon emission reduction of railway projects. China can learn from the practical experience of developed countries, set up a special carbon emission information disclosure agency, and require enterprises to include emission reduction information in their annual reports to facilitate supervision by the competent authorities. The second is to set up an overquota price increase mechanism. For small projects, when the carbon emission exceeds the allocated carbon emission quota, the overquota price increase system can be adopted concerning the electricity price. This kind of pricing utilizes a progressive price lever, which is conducive to guiding emission reduction entities to conduct spontaneous emission reductions. In the specific implementation process, relevant departments need to coordinate and cooperate to jointly determine the data such as the price increase rate.

The incentive system is the opposite of the penalty system, and positive incentives are used to promote the development of the carbon emissions trading market. In the early stage of the establishment of the market, the relevant system is not perfect, and the participants are limited. The role of the incentive system should be brought into full play to encourage carbon emission entities to actively participate in carbon emission trading so that the role of the carbon emission trading market can be brought into full play.

On the one hand, it can make full use of market adjustment funds. In the early stage of the establishment of the carbon emission rights market, a unified national normative system has not yet been established, and the participation of carbon emission entities is less, resulting in a shortage of demand. The government should play a role at this time to stimulate the demand for carbon emissions trading, allocate funds to set up special funds, and stimulate market vitality. When the market develops gradually, the government can buy or sell the carbon emission allowances it holds according to the actual market conditions, to achieve the purpose of market regulation. After the market matures, it is no longer necessary for the government to fully invest in the establishment of special funds, which can be composed of various sources such as fines for violations and social donations, to achieve the sustainability of funds. On the other hand, support should be provided for railway energy-saving technologies. The carbon emission of railways is relatively large, and the realization of carbon emission reduction requires long-term continuous promotion, and the key to realizing carbon emission reduction is the research and development and promotion of energy-saving technologies. The government should fully support the technical needs of emission reduction entities, carry out research on energy conservation and emission reduction in relevant national or

local research centers, increase financial support, and vigorously promote low-carbon railway technology research and railway low-carbon equipment upgrades.

6.2. Carbon Emission Control Strategies of Construction Enterprises. The carbon emission control strategies of construction enterprises focus on low-carbon materials, environmental protection construction techniques, and clean energy. The carbon emission information integrated management platform and various information tools can effectively help reduce carbon emissions. As an important participant in railway engineering construction and the main promoter of carbon emission reduction in railway construction, the construction unit should implement the concept of low-carbon construction and optimize on-site management; it can also make full use of information tools

such as BIM to achieve integrated management of railway carbon emissions information.

Due to the huge volume of railway projects, carbon emission measurement needs to call a large amount of engineering data. Manually exporting engineering quantities and then performing carbon emission measurement is time-consuming and inefficient, and carbon emission measurement cannot be correlated with information such as construction progress and cost. BIM technology can meet the above requirements at the same time. Therefore, a BIM model of railway engineering construction should be constructed to integrate various information such as railway construction project quantity, progress, cost, and carbon emissions to provide information technology support for railway carbon emissions management.

The integrated management of carbon emission information in railway engineering construction refers to the combination of low-carbon information in the railway engineering construction stage and the BIM model to build a low-carbon information database in the railway engineering construction stage and at the same time integrate construction data (construction progress, railway cost, etc.) with low-carbon information, realize the real-time measurement of carbon emissions in the construction phase of railway projects, and analyze the influencing factors of carbon emissions accordingly. Its essence is to add progress information, cost information, and carbon emission information based on the 3D BIM model to build a 6D BIM model. The carbon emission information integrated management model can realize the carbon emission management in the construction process. By monitoring the progress, cost, carbon emission, and other data displayed in the model in real-time, the influencing factors of carbon emission in the construction process can be analyzed, which can provide a reference for the selection of schemes and promote railway construction carbon emission management.

The implementation steps of the railway carbon emission integrated management model are as follows: first, collect carbon emission data. Carbon emission data are the prerequisites for the integrated management of carbon emission information in the construction phase of railway projects, including railway engineering volume data and carbon emission factor data. The railway engineering quantity data can be obtained directly from the railway BIM model, and the carbon emission factor can be queried in the authoritative carbon emission factor database. Second, integrate schedule data, cost data, and carbon emissions data in the BIM model. The construction progress plan is imported into the BIM model as construction progress information, and the on-site construction progress of the railway construction stage is controlled in real-time; the price information of different regions has been included in the BIM software, and the bill of quantities can be coded to summarize the railway construction cost data. The carbon emission data of the BIM model is added to the BIM model as a resource, and the carbon emission generation process is regarded as the resource consumption process, and the resource consumption curve diagram of the construction schedule is obtained.

7. Conclusion

We collected 188 high-speed railway infrastructure construction projects in China using the average sampling method to complete the empirical research. These samples are China's important high-speed railway infrastructure construction projects. The Delphi method was used to determine whether these samples are resilient. Finally, 26 samples are identified as resilient high-speed railway infrastructure construction projects.

The proposed measuring model was implemented to calculate the carbon emissions of the selected 26 projects. Achieving a resilient transport infrastructure is imperative to building a modern society. At the same time, the resilient transport infrastructure requires a combination and investment of multiple resources that have caused concern about the carbon emissions of resilient transportation infrastructure. Therefore, from this perspective, this study developed a carbon emission measurement framework for evaluating the carbon emission of several selected resilient transport infrastructure projects. Twenty-six samples are finally identified as resilient high-speed railway infrastructure construction projects. The results revealed a relatively high carbon emission in these resilient high-speed railway infrastructure construction projects. Resilient transport infrastructure with lower carbon emissions is located in remote cities.

The findings could help investigate the carbon emission of resilient transport infrastructure projects. The correlation between resilience and carbon emission is useful for policy-makers to conduct an effective plan for the cities.

Data Availability

All data sets generated for this study are included in the article.

Disclosure

Zheng He and Genda Wang are the co-first authors.

Conflicts of Interest

The authors declare that there are no conflicts of interest.

Acknowledgments

The study was funded by the Natural Science Foundation of Hunan Province (2021JJ30861). The authors are very grateful for the time the reviewers voluntarily spent reviewing the manuscript. The authors would like to thank the constructive comments and suggestions, which have helped them improve the manuscript.

Academic Editor: Xin Ning

The idea of EAE (Ecological Aesthetic Education) is put forward on the basis of the mature development of ecological aesthetics and AE theory. Starting with EAE, establishing people's aesthetic attitude and improving people's spiritual realm will help to reverse people's hostile attitude towards nature and rebuild the harmonious relationship between man and nature. This paper studies the application optimization of AE (aesthetic education) resources in universities based on ML (machine learning) from the perspective of resource development. The recommendation algorithm based on ML is the main idea of the classification of AE resources, and the classification model of AE resources is constructed. Through deep learning, we can learn the effective features of items from the content data in advance and then transform the learned features into CF (Collaborative Filtering) target learning task. Optimize the voting mechanism of the algorithm, and compare the RF_VM (random forest with optimized voting mechanism) algorithm with the traditional RF (random forest) algorithm. Experiments show that the algorithm proposed in this paper can effectively classify texts and has high feasibility.

1. Introduction

The core of basic education reform is curriculum reform, and AE is an aspect that cannot be ignored in curriculum reform. The development and utilization of AE curriculum resources is an important part of AE. The essence of EAE (Ecological Aesthetic Education) is AE with vivid ecological beauty, which exerts a subtle influence on college students, which is unmatched by other ecological education and AE forms [1]. It should be emphasized that the implementation of EAE is mainly realized through art education. That is to say, art education in our school must also examine its own value and function from the perspective of EAE. The effective implementation of EAE will help young people enjoy the fun of life no matter what stage they are in, and they will not give up easily no matter what adversity they face in the future [2]. School living resources are the foundation and premise of school EAE, and the development and utilization level of school EAE resources determines the effectiveness of school EAE.

The smooth implementation of education requires a well-designed school curriculum. Process is a means and tool for achieving educational and teaching objectives, as well as an important link in determining educational quality [3]. AE (Aesthetic education) is frequently based on theoretical research or individuals in terms of a comprehensive and systematic analysis of history, current situation, tasks, and in these papers [4–7], but there is still a lack of research on how to systematically and comprehensively apply AE elements. The content and quality inspection of the scientific AE process is the key to the development of college AE [8–10], while rationality is the issue that college AE does not play its role. This is a crucial reason, and more in-depth and systematic research and discussion on the use of AE resources in universities is required.

Generally speaking, the university AE started later than other education, so we have some knowledge of university AE, but there is still a big gap compared with other education. Although some university leaders attach importance to AE and care about building AE, not all university leaders attach importance to it and there is no general consensus. EAE development aids in the cultivation of people's ecological awareness, the realization of harmonious coexistence between man and nature, the improvement of people's spiritual world, and the realization of people's poetic existence. The active development of EAE is a key component of current AE. The goal of this study is to more objectively analyze and evaluate the selection, organization, and implementation of university AE resource support by looking into the current status of AE resources in universities and identifying problems with the support. Recognize the current state of AE resources in universities and propose countermeasures and suggestions that are appropriate for the goal.

Innovation:

(1) Taking resource development as a breakthrough, this study makes theoretical thinking on the main topic of youth education-school EAE. In the study of school EAE, we should focus on resource development, explore the elements of EAE resources, choose an effective implementation path of school EAE, and develop and construct AE resources ecologically.

(2) Personalized recommendation is very common on commercial websites, but it is rarely used in university AE resources. In this paper, the similarity of course and user attributes is calculated, specific algorithms are designed, and personalized recommendations are made so as to put forward reasonable suggestions for the application optimization of AE resources in universities.

The organizational structure of the paper is as follows:

The first chapter introduces the research background and significance before moving on to the paper's main work. The second chapter focuses on the technologies associated with university AE resource application optimization. The research's specific methods and implementation are presented in the third chapter. The fourth chapter verifies the research model's superiority and feasibility. The fifth chapter is a synopsis and preview of the entire text.

2. Related Work

2.1. Present Situation of AE Research in Universities. The fundamental goal of higher education is to promote the high-level development of college students, and the ultimate goal is the all-round development of morality, intelligence, physique, beauty, and labor. Among them, AE is not only one of the important goals of quality education, but also one of the important contents of school education. With the continuous promotion of quality education strategy in China, more and more scholars begin to pay attention to and study the AE in universities.

Aesthetic course research must be grounded in AE theory research. All students, regardless of their background or talent, should have the resources and conditions to learn art and exercise their right to art education, according to Leanne and others [11]. According to AFBY and others, professional art education in universities has advanced to unprecedented levels in the new era, with universities establishing art departments, offering art courses, organizing art activities in schools, and promoting a positive artistic environment in schools [12]. Many universities have not included AE in their education plans, but AE still exists, according to Jianlin et al. and this has had an impact on the development of AE practice [13]. Because of its own characteristics, Lvdn and others believe that AE, as one of the methods for achieving quality education, has an inherent and inevitable connection with moral education, intellectual education, and physical education and pervades all education, games, and people's spiritual worlds, and plays a significant role in comprehensive influence. Freedom, communication, experience, honesty, and extensiveness, according to Krainer and others, are the operating principles of modern AE. Yan and colleagues looked at teaching aesthetics from three perspectives: language, posture, and rhythm.

Although the research on the basic theory of AE has achieved fruitful results, the existing research on AE in universities has little penetration into the new achievements of AE theory and lacks the support for college students' AE theory.

2.2. Research Status of ML. ML (machine learning) [14–17] is the core of artificial intelligence and the fundamental way to make computers intelligent. Using effective artificial intelligence technology to obtain abstract information from big data and turn it into useful knowledge is one of the main challenges facing big data analysis today [18]. In the era of big data, how to effectively analyze complex data, reflect its value, and make rational use of it is an urgent task to be solved and considered.

Stein et al. conducted a study to eliminate heterogeneous influence by removing sensitive attributes from the decision-making process and adding fairness constraints to avoid heterogeneous processing. Observe that the standard fairness constraint is nonconvex; then use covariance to turn the nonconvex problem into a convex problem. Finally, measure the output results and sensitive attributes of parameters to investigate the sensitive attributes of multiple classification and analysis. Some scholars looked at the fairness metrics of a variety of algorithms to see how they correlated with different definitions and discovered that they were very closely related. The transformed data retains most of the characteristic signals of insensitive attributes, intersection-sensitive attributes are proposed, and the effects of two sensitive attributes do not overlap [19]. Nguyen et al. modified each attribute so that the marginal distribution of a given subset of sensitive attributes is the same, and this change will not affect other variables, and the transformed data retains most of the characteristic signals of insensitive attributes and intersection-sensitive attributes are proposed, and the effects of two sensitive attributes do. To control identification, limit the degree of distortion of a single data sample, and maintain utility, Nguyen et al. proposed a convex optimization for learning data conversion [20]. Nguyen et al. improved the logistic regression and support vector machine algorithms without bias based on historical data and provided a flexible balance between fairness and accuracy according to various false alarm rates. When sensitive attribute information is unavailable, this method works well [21]. In social networks, Wang et al. proposed a random walk push model. In the trust relationship, this model uses the traditional CF (Collaborative Filtering) method, which can define and measure the reliability of recommendations [22]. Lang et al. experimented with a number of online recommendation systems [23] and found that when both online systems and friends recommended them, users preferred the latter. The difference between content-based and user-based recommendations demonstrates that users prefer the latter. However, their model's goal is to predict users' and items' scores rather than personalized preference ranking, so the goal does not align with the recommendation system's ultimate goal, resulting in low recommendation accuracy.

3. Methodology

3.1. Analysis of the Application of AE Resources in Universities. Ecological problems are closely related to people, and ecological imbalance is the deviation of people's ideas and consciousness. To solve ecological problems, we must first solve the problem of people's ideology, which is actually a problem of people's education. AE aims to establish people's aesthetic attitude and create aesthetic living conditions, as an education to improve people's living standards. Starting with AE, it is of great significance to establish people's aesthetic attitude for solving ecological problems and improving people's living conditions, and EAE is still a new field of AE in China.

EAE's mission is to educate and infect people through art and various forms of EAE so that they can achieve true enlightenment, good education, and emotional edification in a pleasant spirit and gradually develop people's ecological aesthetic sensibility and consciousness. Realize the survival of ecology and aesthetics and perform a one-of-a-kind and irreplaceable role. On the one hand, we should focus on infecting and educating people about the aesthetic method of perceptual freedom so that they can consciously educate beauty or "give freedom with freedom." On the other hand, understanding the natural laws of the ecosystem should be a priority in the implementation of EAE so that people can correctly apply the natural laws and realize the harmonious unity between man and nature. EAE imbues educated people with a sense of beauty and encourages them to pursue and yearn for ecological beauty. Colorful ecological landscapes, endless back and forth, and endless phenomena make people feel a new rhythm of life, ideal living conditions, and a stirring sense of life, which makes them indulge and miss. Ecological beauty education will have a positive impact if we can make conscious use of these resources and educate people about ecological beauty.

The difference of EAE resources in schools is caused by the imbalance of social economy, the difference of management system and supply mode, and the information asymmetry of social demand for talents. The difference of school EAE resources constitutes the difference of school EAE process and effect. The diversity and complexity of school EAE resources determine the instability of education resources, among them are human factors, material factors, policy orientation, development and changes of social and economic conditions, and other factors. Its mobility is mainly manifested in the flow of teachers' resources and students' resources and funds.

The aesthetic course of university is mainly realized through aesthetic activities, so the appreciation and creation of various kinds of beauty is an important part of the course content. If you want to appreciate various forms of beauty, you must know and understand the basic knowledge of various forms of beauty. Through the study of various meanings, features, forms, elements, and other knowledge of beauty, we can accumulate certain theoretical knowledge and become the basis of aesthetic practice. The forms of beauty can be divided into natural beauty, social beauty, and artistic beauty, and the aesthetic practice part of the application of university AE resources is also selected from these four parts. It can be concluded that the basic framework of university AE resource application is shown in Figure 1.

The frame diagram only shows what the AE courses in universities should have, which can be emphasized or supplemented in the implementation of specific courses. For example, in the part of aesthetic practice, you can appreciate and create natural beauty, artistic beauty, and social beauty at the same time, or you can choose one kind of beauty as the main part of the course and another form. Even in the part of basic theory, theoretical study can be appropriately increased or decreased according to class time, students' aesthetic quality, classroom content arrangement, and so on.

3.2. University AE Resources Application Optimization

3.2.1. Hybrid Recommendation System. Social ecological beauty is the beauty reflected in the social ecosystem, which widely exists in all fields of people's production and life, is reflected in the harmonious and orderly social life, and embodies people's ecological aesthetic ideal. Therefore, we can cultivate people's sensibility and ecological aesthetic consciousness through various social and ecological aesthetic forms. In the implementation of EAE in schools, the development of material resources such as educational environment resources should reflect the spirit of the times, and the architectural style should fully reflect the characteristics of vitality and simplicity. At the same time, we should also pay attention to the nationalized and localized material resources, which contain our precious culture and fine traditions, and embody the harmonious unity between man and nature, tradition and modernity, and ideas and modernity.

The world, including humans, is an interconnected life ecosystem that appears as an organic whole. The concept of ecological science highlights the inseparable relationship between man and nature, breaking the existing concept of separation and opposition between man and nature. Everything in this place is connected. Life and life, life and

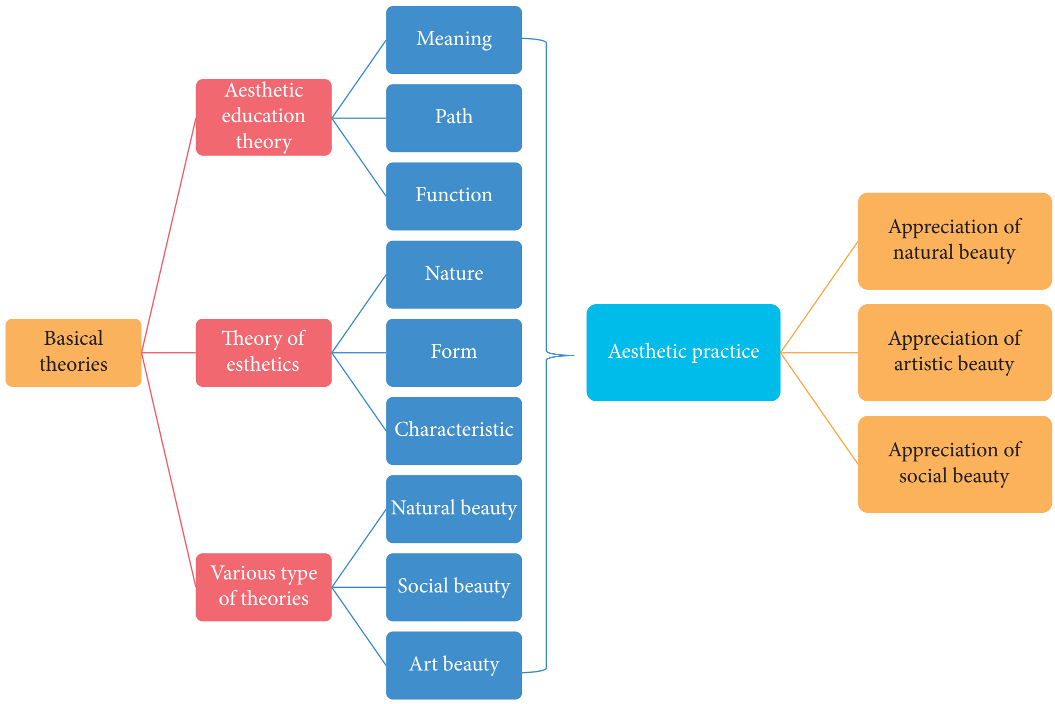

FIGURE 1: Basic framework of AE resource application in universities.

environment, life and environment, and life and environment, communicate and coordinate with one another, cooperate with one another, displaying a beautiful form. The use of a recommendation system [24] is one of the most important and effective ways to reduce information overload, and it is crucial to the success of various Internet application platforms. Most existing recommendation algorithms are based on the CF algorithm, which analyzes historical interactive information, such as scoring, browsing, and collecting, to provide products that users are most likely to be interested in. The evaluation matrix, on the other hand, is very sparse in the face of very sparse real-world data, and the CF-based model frequently fails to provide reliable recommendations. To reduce data sparseness, cold start, and scale, the HHR_L (Learning-based Hash Hybrid Recommendation) model constructs a loss function aimed at predicting ranking and learns the effective hash codes of users and projects by adding individual constraints to users and projects.

The HHR_L model is proposed to solve the data sparseness, cold start, and scalability problems in recommendation system. HHR_L constructs a recommendation algorithm based on hash, which enables the recommendation system to handle large-scale data recommendation, improves the recommendation efficiency, and provides an effective method for scalable recommendation. The model framework as an example of HHR_L is shown in Figure 2.

At first, we initialize the hidden layer feature representation of the project by DAE (Denoising Autoencoder); then we fine-tune the DAE network by combining the paired sorting objective function based on CF, and finally get the hash codes and items of users, and the top-k suggestions are given by Hamming distance sorting.

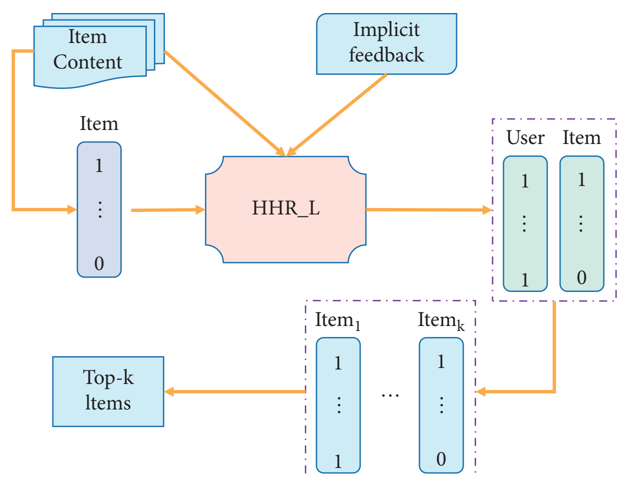

FIGURE 2: Framework diagram of HHR_L model.

The basic idea of hashing algorithm is to compress input data of arbitrary length and map it to data output of fixed length. A key skill is dimension reduction. For test samples, if the information from adjacent samples and related markers is known, the maximum posterior criterion is used to predict a group of markers in the test samples.

Then, through the maximum posterior probability criterion, it can be shown that the ith mark of sample x is

$$y_x(i) = \underset{b\in\{0,1\}}{\arg\max}\, P\left(H_i^b|x\right), \quad i \in Y. \tag{1}$$

Among them, $y_x(i)$ represents the posterior probability of the label corresponding to sample x. Because the posterior probability is difficult to be directly calculated, it can be converted into prior probability and conditional probability according to Bayesian theorem. Therefore, if the label of the sample is unknown, the labeled sample can be expressed as

$$y_x(i) = \underset{b\in\{0,1\}}{\arg\max}\, P\left(H_i^b\right)P\left(x|H_i^b\right), \tag{2}$$

$P(H_i^b)$ represents the prior probability of H_i^b, $P(x\,|\,H_i^b)$ represents the conditional probability that the tag belongs to sample x when H_i^b is known, and $P(H_i^b)$ and $P(x\,|\,H_i^b)$ can be obtained from a given data set.

And change the distribution of hashed points on the machine by selecting a specific hash function. First, given the parameter $D > 0$, the hash function $R^k \longrightarrow Z$ satisfies the formula

$$G(v) = \left[\frac{\alpha \cdot v + \beta}{D}\right], \tag{3}$$

$\alpha \in R^k$ represents a K-dimensional feature vector that obeys $N(0,1)$ standard normal distribution, $\beta \in R$ represents a feature vector randomly selected from the range of $[0, D]$, and D represents the width of the bucket.

From the above steps, we can get the quantization result from k groups $s = \{s_1, \cdots, s_k\}$. For example, the ith group will have a cluster center point μ_i. We distinguish data points based on the median points of two neighboring groups, and the median plane between them is hyperplane. The definition of the vertical plane is as follows:

$$\left(x - \frac{\mu_i + \mu_j}{2}\right)^T \left(\mu_i - \mu_j\right) = 0. \tag{4}$$

Given B, D, Y, Θ, when the intermediate variable X is updated, the items unrelated to X in formula equation (4) are eliminated, and the objective function becomes the following subobjective about X:

$$\begin{aligned} &\max_{X\in R^{d\times n}} tr\left(B^T X\right),\\ &\text{s.t}\, X1_n = 0,\ XX^T = nI_d. \end{aligned} \tag{5}$$

The above model can be optimized by SVD (Singular Value Decomposition). In particular, the update rules of X are as follows:

$$X = \sqrt{n}\left[U_b, \widehat{U}_b\right]\left[V_b, \widehat{V}_b\right]^T. \tag{6}$$

U_b, V_b is a stack of left singular vector and right singular vector of matrix $\overline{B} : \overline{b}_{ui} = b_{ui} - 1/n\sum_{u=1}^{n} b_{ui}$ centered on row mean, respectively. $\widehat{U}_b$ is a matrix of zero singular vector stack, and $\widehat{V}_b$ represents Gram–Schmidt orthogonal complement of V_b, which can be determined by $[V_b, 1]^T \widehat{V}_b = 0$.

3.2.2. Text Classification. A collection of natural languages is referred to as a document set. To classify and organize the document set, all that is required is to extract elements from the document set that can express the content of each document. Because "word" is a fully expressible semantic object in Chinese documents, it is frequently chosen as the metadata of text features. The metadata of text features must first be extracted before text mining can begin. Currently, all types of text representation methods suffer from the same issue. There are many dimensions that can be used to represent a document, and many documents that are not useful for text clustering. As a result, text features must be extracted twice. After the text feature vectors have been dimension reduced, they can be clustered, and the clustering results can be analyzed in light of the current situation.

"Thesaurus," or machine dictionary, has as many entries as possible. Word segmentation based on Thesaurus is the most commonly used, the simplest operation method and the most effective method. Match the item to be processed with Thesaurus, and if the match is successful, display the item string as a word. If they appear more at the same time, they are most likely to form a word. Therefore, the confidence of two adjacent words can usually be obtained by calculating their co-occurrence frequency. The mutual information M is

$$M(X,Y) = \log \frac{P(X,Y)}{P(X)P(Y)}, \tag{7}$$

where $P(X,Y)$ is the adjacent co-occurrence probability of X, Y, and X, Y represent two Chinese characters. $P(X), P(Y)$ are the probability of X, Y appearing separately in the text. This can indicate the tightness between Chinese characters. When the value of M is greater than a certain threshold, it can be considered that X, Y can form a word.

CI (Conceptual index) is a simple and effective dimension reduction method. For supervised learning, CI constructs CI subspaces, takes the cyclic vector composed of these CI subspaces as the base vector, and projects the text cyclic vector onto this subspace.

Classified prototype vector: assuming that the prototype vector of the ith classification is Center_i, its calculation method is as follows:

$$\text{Center}_i = \frac{1}{N}\sum_{j=1}^{N_i} \text{Doc}_{ij}, \tag{8}$$

where N_i is the number of texts in category C_i and Doc_{ij} represents the j prototype vector in category C_i.

PCA (principal component analysis) is a widely used method of pattern recognition and signal processing, which is especially effective for data compression and feature extraction. In this paper, we apply PCA method to text classification, hoping to obtain low-dimensional representation of text vectors.

Assuming that there are M categories in the training set sample, the following is how to calculate the covariance matrix of each internal document category separately:

$$X_i = E\left[(x-\mu)(x-\mu)^T\right]. \tag{9}$$

Among them, X_i is the covariance matrix of the internal document classification in the ith classification, x is the text vector in the ith classification, and μ_i represents the prototype vector in the ith classification.

The essence of PCA method is that you can always get the best linear mapping from M-dimensional space to

D-dimensional space. This is because the sum of error squares of the data obtained by the algorithm can always be kept to a minimum. At the same time, the mutual information between the original vector x and the mapping vector y is the largest.

When dealing with multiclassifier combinations in classification problems, the voting mechanism is frequently used in machine learning. In the above rules, the relative majority voting rule, which selects the class with the highest output among all machine classification algorithms, is a commonly used voting rule. The RF (random forest) algorithm must aggregate the classification results of each DT in the forest and vote on classification categories when determining the classification results. The DT (decision tree) model's similarity can be calculated from two perspectives: DT semantics and DT structure. The concrete implementation idea for improving the voting mechanism is to combine the DT classification effect with the weighted voting method of class probability to improve the RF voting mechanism. The accuracy of data classification outside the bag reflects the classification effect of DT. The DT classification effect improves as classification accuracy improves.

Before making the classification decision, it is necessary to calculate the accuracy rate of each DT's out-of-bag data. If the total number of samples is X and the number of correctly classified samples is X^{correct}, then the accuracy rate of DT's out-of-bag data is the ratio of the two. The accuracy of DT data outside the bag is used to weight DT, and the weight of DT in RF algorithm is

$$W_i = \frac{X^{\text{correct}}(i)}{X}. \tag{10}$$

Remember that the probability that DT outputs that the sample belongs to each class is P_i, the probability that the sample belongs to class y is $P_i(y)$, the weight of DT is w_i, and the number of DTs in RF is k. The weighted value $z(y)$ of the sample belonging to class y is obtained by the formula

$$z(y) = \sum_{i=1}^{k} w_i * P_i(y). \tag{11}$$

The probability that the sample belongs to each class is calculated by the above method, and the class with the largest weighted value is selected as the classification result.

The RF_VM (Random Forest Classification Using Optimized Voting Mechanism) model can be divided into three modules: learning module, weight calculation module, and decision module. The algorithm flow is shown in Figure 3.

First, we implement a training module, which is almost the same as the traditional RF algorithm. Next, the weight calculation module calculates the weight of each DT according to formula (10). Finally, the decision-making module uses the DT set obtained by the learning module and the DT weight obtained by the weight calculation module to classify the samples and calculates the probability weight that the samples belong to a specific category as formula (11). Compare the probabilities of all classes, and get the classification results by weighted values.

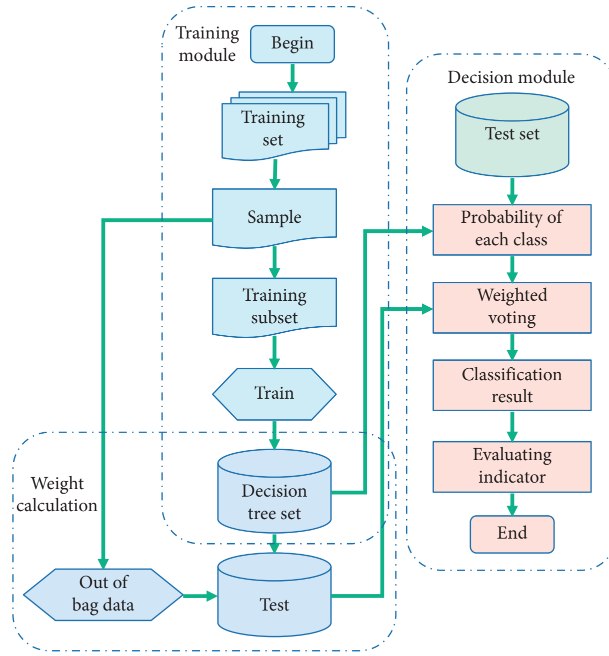

Figure 3: RF algorithm for optimizing voting mechanism.

4. Experiment and Results

4.1. Experimental Environment Setting. The computer used in the experiment is running Microsoft Windows 10. In this article, we choose Python as the development language of our experiment. Try PyCharm software to make Python language development more efficient.

As an excellent Python integrated development software, PyCharm can provide intelligent Python support through intelligent code completion, code inspection, and navigation. PyCharm supports project and file management and various scientific packages, such as Anaconda, matplotlib, and NumPy. Table 1 shows the main hardware configuration of the computer used in this experiment.

In order to verify the effectiveness of the proposed algorithm in cold start and sparse scenarios, we choose to experiment on two public datasets (Amazon dataset and Yelp 9th round dataset), and the sparsity is as high as 99.9%. For content data, first, delete punctuation marks and numbers. And words with stop words and length less than 2 usually have no clear meaning, so the remaining words are processed by English word segmentation.

4.2. Result Analysis. In this paper, Accuracy and MRR (Mean Reciprocal Rank) are used to evaluate the recommendation performance of HHR_L in cold start environment. The experimental results are shown in Table 2 and Figure 4.

It can be seen that the recommendation accuracy of HHR_L is higher than that of comparison method. This is because [18] and [20] are hash recommendation algorithms based on CF, and no project content data is used for modeling. However, in a highly sparse environment, the recommendation accuracy of [18] and [20] will be reduced

Table 1: Use the main hardware configuration of the experimental computer.

Project	Deploy
CPU	Intel Core i5 2.5 GHz
Internal storage capacity	8 GB
Hard disc capacity	300 GB

Table 2: Comparison of recommended accuracy at sparsity of 20% and 30%, respectively.

Method	Amazon		Yelp	
	20%	30%	20%	30%
Ref [18]	0.0123	0.0169	0.0196	0.0341
Ref [20]	0.0114	0.0102	0.0192	0.1162
Ref [21]	0.0463	0.0266	0.0154	0.0128
HHR_L	0.0452	0.0511	0.0288	0.0286

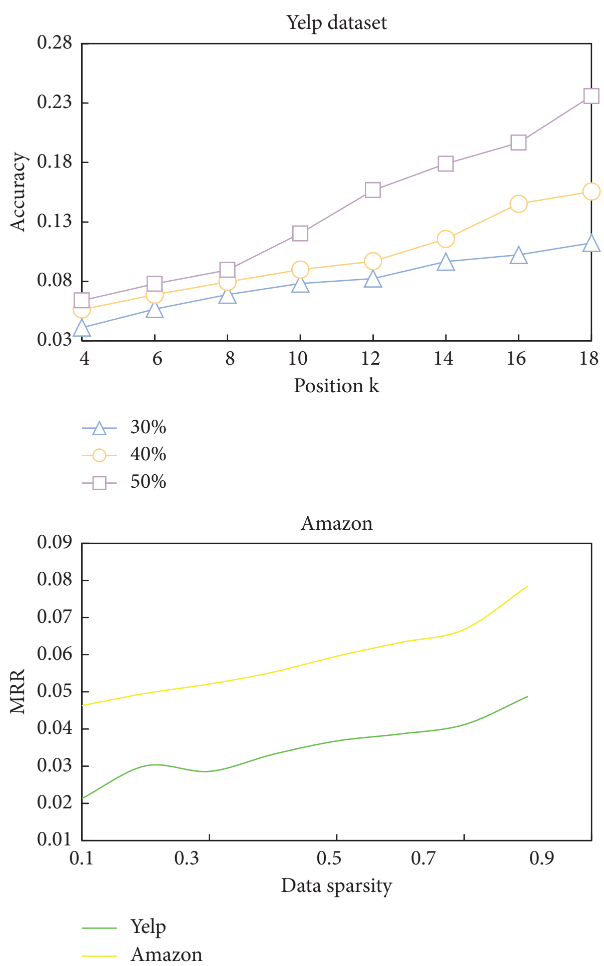

Figure 4: The recommendation accuracy of HHR_L in sparse environment varies with data sparsity.

because the content data plays a key role in improving the recommendation accuracy.

In addition, although the recommendation accuracy of HHR_L increases steadily with the increase of data density, the performance of [21] is unstable, because [21] is based on score prediction rather than ranking. Because the prediction goal is consistent with the ultimate goal of the recommendation system, the recommendation performance is more reliable.

Keep more commonly used words in text documents to improve classification accuracy. CI_PCA and DF (Document frequency) are compared in dimension reduction effect, so KNN (*K*-Nearest Neighbors) algorithm is used for classification, where $K = 10$ is shown in Figure 5.

In Figure 5, except for the 0 dimension, we can see that the accuracy of CI_PCA proposed in this paper is much higher than that of the conventional DF method. When the last 110 dimensions are reached, the accuracy of the algorithm is as high as 80%, and the accuracy of DF method is only 70%. Increasing the dimension to 5 significantly improves the accuracy of the text frequency method.

Another problem in this example is how to choose the appropriate K value when using KNN algorithm for classification. The choice of K value has a great influence on the classification effect. If the K value is too small, the similarity vector may be ignored. If the K value is too large, a large number of noise vectors will seriously affect the classification result. The results are shown in Figure 6.

The experimental results show that the small K value is better than the large K value, and the accuracy rate can reach 81% when $K = 10$ is 110. That is to say, after the CI_PCA process, we prove that similar documents are closer in subspace, prototype vector can weaken the negative influence of synonyms and semantics, and projection of original text vector can partially filter "document vector."

In this paper, the existing RF classification algorithm and RF_VM algorithm are used for the comparative experiment of text classification. Different DT numbers are selected for text classification. In the experiment, the number of DT trees is selected as 20, 50, 60, 90, 150, 220, and 300, and other hyperparameters are used as default values for comparative experiments. The time for performing text classification is shown in Figure 7.

It can be seen from Figure 7 that the number of DTs in RF classification algorithm has a certain influence on the text classification time of both algorithms. Most of the text classifications using these two algorithms will increase accordingly. Although the RF_VM algorithm in this paper is more complicated than the existing RF algorithm in voting, each DT is given a constant weight according to the prediction accuracy of the trained out-of-pocket data. However, the probability that the output samples belong to each category does not significantly increase in the required time resources. Figure 8 shows the prediction accuracy of the existing RF classification algorithm and the RF_VM algorithm in this paper for text classification experiments.

It can be seen that the number of DTs in the algorithm has a great influence on the accuracy of the algorithm. Generally speaking, the higher the number of DTs, the higher the prediction accuracy of the algorithm. For other DT trees, the prediction accuracy of RF_VM algorithm in this paper is improved compared with the existing RF algorithm. The RF_VM algorithm in this paper improves the prediction accuracy of text classification based on the

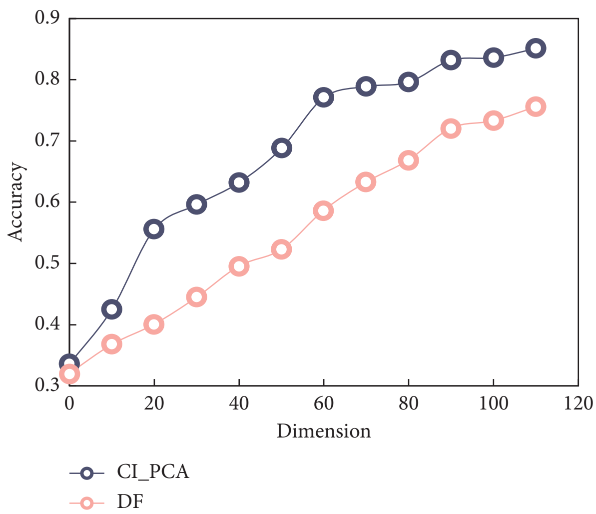

Figure 5: Comparison of dimension reduction effects.

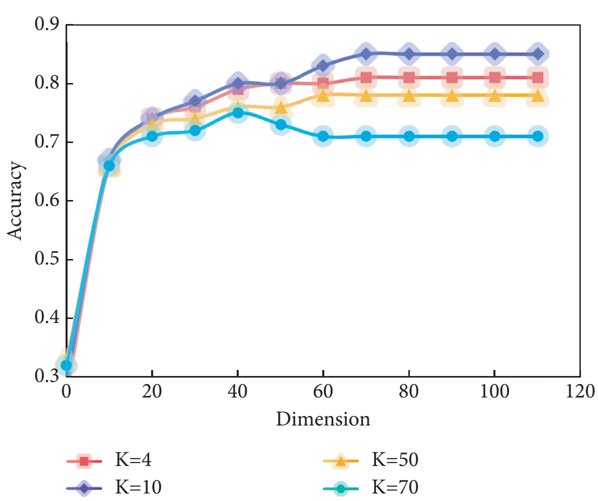

Figure 6: Influence of K value on accuracy.

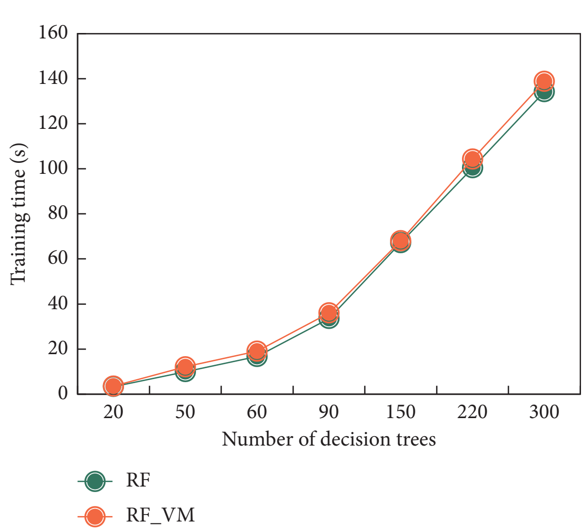

Figure 7: Algorithm time comparison.

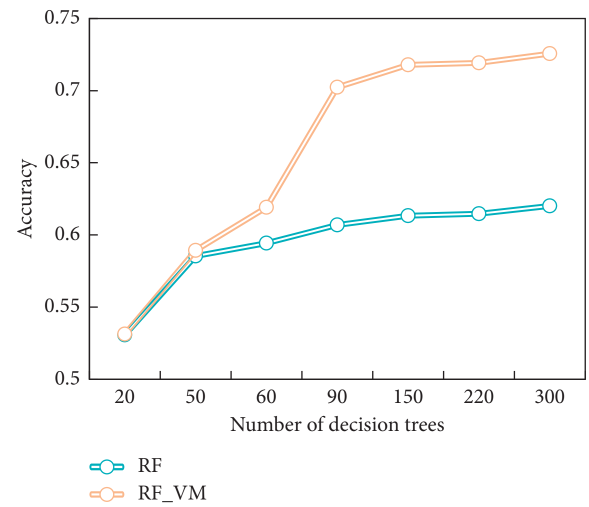

Figure 8: Comparison of prediction accuracy of algorithms.

characteristics of less increase of time resources and better performance than existing RF algorithms. In addition, the prediction accuracy of the two algorithms failed to reach a high level, which was related to the use of default values (excluding DT number) for the superparameters of the algorithms, which also proved the importance of value optimization.

5. Conclusions

EAE is extremely important for environmental protection and improving human living conditions. The EAE educational method should focus on aesthetics, psychological discipline, and infection, and its practical implementation should be integrated with all aspects of school operations. Teachers' human resources are the main body, curriculum resources are the foundation, and material resources are the carrier in the development of school EAE resources, in order to create a humanized environment, build an information platform, and carry out various activities. When designing an ML algorithm, try to avoid data sparsity and a cold start. Data scarcity is not a big deal because of the curriculum limitations, so we pay attention to the new curriculum. By projecting the high-dimensional prototype text onto a low-dimensional subspace and then reducing the dimension according to the classification covariance matrix, the CI PCA algorithm significantly reduces the classification cost. When the proposed RF algorithm is combined with the optimized voting mechanism, the algorithm's classification ability can be greatly improved.

Shadow detection and removal play an important role in the field of computer vision and pattern recognition. Shadow will cause some loss and interference to the information of moving objects, resulting in the performance degradation of subsequent computer vision tasks such as moving object detection or image segmentation. In this paper, each image is regarded as a small sample, and then a method based on material matching of intelligent computing between image regions is proposed to detect and remove image shadows. In shadow detection, the proposed method can be directly used for detection without training and ensures the consistency of similar regions to a certain extent. In shadow removal, the proposed method can minimize the influence of shadow removal operation on other features in the shadow region. The experiments on the benchmark dataset demonstrate that the proposed approach achieves a promising performance, and its improvement is more than 6% in comparison with several advanced shadow detection methods.

1. Introduction

Although the shadow in the image is a kind of image information, it often interferes with object recognition, image segmentation, and other image processing work. Therefore, the detection and removal of shadow have been widely concerned. The difficulty of shadow detection lies in the complexity of background and light in the image, as well as the interference of dark objects in the image. The difficulty of shadow removal is to ensure that only the shadow is removed without changing other image features in the shadow region.

Inspired by the relevant articles on shadow detection and removal through region matching and other methods [1, 2], this paper proposes a shadow detection and removal method based on interarea material matching without training. This method can accurately detect the shadow region and minimize the impact of shadow removal on other features in the shadow region.

The contributions of this paper are as follows. (1) In shadow detection, based on the mutual restriction between image region features and matching region, this method can detect directly without training. (2) In shadow removal, the shadow region is restored according to the region matching. The calculation time is very short. Other features in the shadow region can be kept unchanged to a great extent, and only the shadow is restored.

The remainder of this paper is organized as follows. Section 2 introduces the related works of our proposed approach. In Section 3, we present the processes of shadow detection and removal. The experiments and experimental results' analysis are described in Section 4, and finally, this paper is briefly summarized in Section 5.

2. Related Works

At present, the commonly used shadow detection and removal methods are divided into three directions: the method based on a physical model, the method based on basic image features, and the method based on machine learning. At the same time, there are many ways to combine these directions.

2.1. Shadow Detection

2.1.1. Shadow Feature. At present, shadow detection based on image features is widely studied, mainly to extract some changing and invariant features in shadow. Zhu et al. [3] proposed a variety of features that change and remain unchanged under the shadow in the gray image, including the features of distinguishing dark objects from shadow regions. Lalonde et al. [4] emphasized the local features of the image and determined the shadow boundary quickly by comparing the features of adjacent regions. Chung et al. [5] proposed a single feature threshold method for directly distinguishing shadow regions. Dong et al. [6] proposed the characteristics of brightness and change rate. Some color-related features were mentioned in [1, 7] to distinguish shadow regions.

2.1.2. Machine Learning Method. Currently, a lot of works combined the direct distinction of original features with machine learning algorithms to train classifiers to distinguish shadow regions under the premise of data-driven [1, 3, 4, 8]. At the same time, for the models that distinguish each pixel separately, most of the works used CRF, MRF, and other similar models to maintain regional consistency [3, 9–11]. With the development of deep learning algorithms in recent years, deep learning models have also been applied to shadow detection [9, 10, 12]. Deep learning models make the original feature engineering no longer necessary, but these algorithms are often based on a large amount of data and need a long time for model training.

2.2. Shadow Removal. User assistance shadow removal can be completed under two conditions: automatic image shadow detection and input of some image information with user assistance. Different from the earlier user assistance that requires users to clearly input various complex information such as shadow contour [13–15], at present, some user assistance methods only need to input a small amount of information to obtain good results [16–18].

2.2.1. Shadow Removal Algorithm. At present, many shadow removal algorithms are based on shadow matting [1, 9], that is, to decompose the image into the form of some parameters acting on the original unshaded image, and then remove the shadow by calculating these parameters. On the basis of shadow detection, shadow boundary and image reorganization with shadow can be used to remove shadow [19–21]. Vicente and Samaras [2] proposed a method to restore the shadow by using the adjacent region of the shadow region, but this method required the shadow region to have the same material as its adjacent region. At the same time, some recent machine learning algorithms and deep learning methods also have good performance in shadow removal [9, 12, 22].

3. The Proposed Method

The proposed method in this paper is based on image region matching and image optical features. Firstly, the Meanshift [23] algorithm is used to segment the image into a total of n regions. Each region is recorded as S_i, and the center is C_i. Then, match the region with the closest material for each region (see Section 3.1). Shadow detection (see Section 3.2) and shadow removal (see Section 3.3) are realized according to region matching. The overall pipeline is shown in Figure 1.

3.1. Region Matching Calculation. Since the color, saturation, and other features will change in the shadow region and the target is looking for the region with the most similar materials, the features used in region matching are the two shadow-invariant features mentioned in reference [3]: gradient feature and texture feature.

3.1.1. Gradient Feature. The gradient change of the image region is hardly affected by shadow. The gradient similarity between regions with similar materials is stronger. In order to extract this feature, a histogram is calculated using the gradient value of each region in the image, and the similarity between regions is measured through the Euclidean distance of the histograms between two regions.

3.1.2. Texture Feature. Image surface texture features are almost independent of shadows. Specifically, the method in reference [24] is used to extract texture features. Similarly, the similarity between regions is measured by calculating the Euclidean distance of the histograms of two regions.

3.1.3. Distance between Regions. In order to ensure the local consistency, the distance between the central points of the two regions is added as the factor to judge the regional similarity. The calculation of similarity between regions is shown in the following equation:

$$D_{i,j} = D_{\text{gradient}_{i,j}} + D_{\text{texture}_{i,j}} + D_{\text{distance}_{i,j}}, \tag{1}$$

where $D_{\text{gradient}_{i,j}}$, $D_{\text{texture}_{i,j}}$, and $D_{\text{distance}_{i,j}}$, respectively, represent gradient feature similarity, texture feature similarity between regions i, j, and distance between center points of regions i, j.

3.2. Shadow Detection. In shadow detection, on the one hand, the shadow is judged by the shadow features; on the other hand, the shadow is judged by the mutual restriction between regions.

3.2.1. Feature Selection. In color images, color tone is a powerful descriptor that simplifies and dominates feature identification and extraction in visual pattern recognition applications. Shadow detection and removal require separate chrominance and luminance information. Since the image represented by the RGB color space is a mixture of

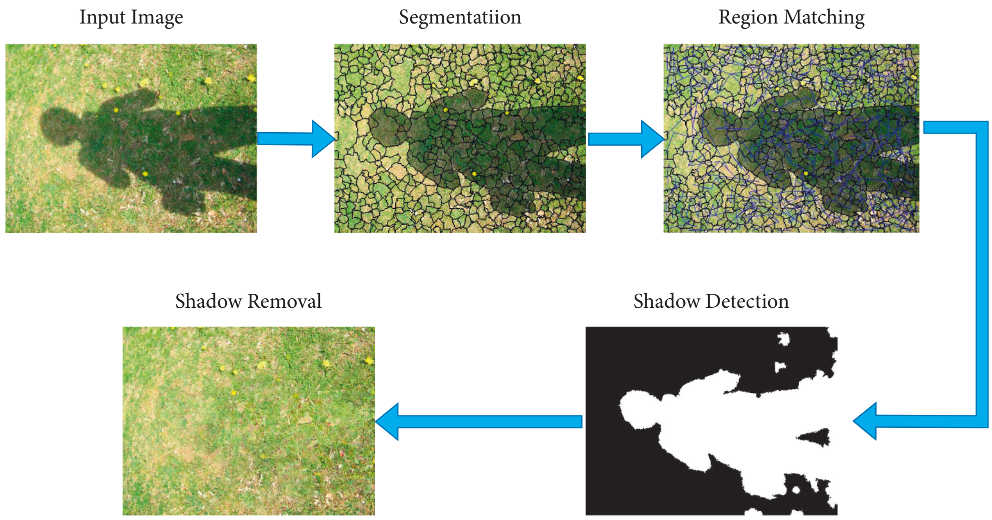

Figure 1: Pipeline of the proposed method.

chrominance and luminance information into the three components of R, G, and B, we need some other color models to handle shadow. There are five invariant color models, HSI model, HSV model, HCV model, YIQ model, and YCbCr model. All of the models consist of independent chromaticity and luminance. We select three common color space models to detect and remove shadows.

(1) Y-channel information in YCbCr color space: convert the original image from RGB color space to YCbCr color space. According to the method mentioned in reference [25], when the value of a pixel on the Y-channel in YCbCr space is less than 60% of the average value of the Y-channel of the whole image, it can be directly considered that the pixel is in shadow. In the algorithm introduced in Section 3.2.2, when the average value of the Y-channel of a region is less than 60% of the average value of the Y-channel of the whole image, this region is considered in the shadow. Take the average value from the region S_i and record the feature as Y_i.

(2) HSI color space information: convert the original image from RGB space to HSI space and then normalize the values on H and I channels to the [0, 1] interval to obtain H_e and I_e. According to the method in reference [5], the value in equation (2) is extracted for each pixel as another feature of the image. Take the average value from the region S_i and record the feature as R_i.

$$R(x, y) = \frac{H_e(x, y) + 1}{I_e(x, y) + 1}. \tag{2}$$

$R(x, y)$, $H_e(x, y)$, and $I_e(x, y)$ represent pixel at position (x, y) in R, image H_e, and image I_e, respectively.

(3) HSV color space information: convert the original image from RGB space to HSV color space. We utilize the chrominance channel H as the other feature. Take the average value from the region S_i and record the feature as H_i.

3.2.2. The Proposed Algorithm. Figure 2 shows the flowchart of the shadow detection approach.

The specific implementation steps of the proposed shadow detection method are as follows.

Variable Preparation.

(1) Segment image with Meanshift algorithm and then obtain n regions; each region is remarked as S_i. The center of each region is C_i.

(2) Compute the disparity between S_i and S_j and get the corresponding region with the highest similarity for a given region which is denoted as Near_i. At the same time, record the information label_i of whether the region i is in shadow and initialize label_i to 255. The similarity of regions i and j is computed as equation (1).

(3) For all R_i, $1 < i < n$, use K-means algorithm to calculate two centers C_{shadow} and C_{lit} which, respectively, represent whether it is the feature center of the shadow region. Suppose R follows a normal distribution; the standard deviations $\text{Std}_{\text{shadow}}$ and Std_{lit} are calculated, which correspond to C_{shadow} and C_{lit}, respectively. Then, for every R_i, F_{shadow} and F_{lit} corresponding to C_{shadow} and C_{lit} are computed.

(4) For each region S_i, Refuse_i represents whether S_i is forbidden to be a shadow region because of other regions, and Refuse_i is initialized to 0.

Steps.

(1) Extract features Y_i and R_i and prepare relevant variables.

(2) If $Y_i < 60\% * \text{mean}(Y_{\text{image}})$, $\text{label}_i = \text{shadow}$.

(3) Select the region S_i with the greatest F_{shadow} and $\text{Refuse}_i = 0$, and set $\text{label}_i = \text{shadow}$.

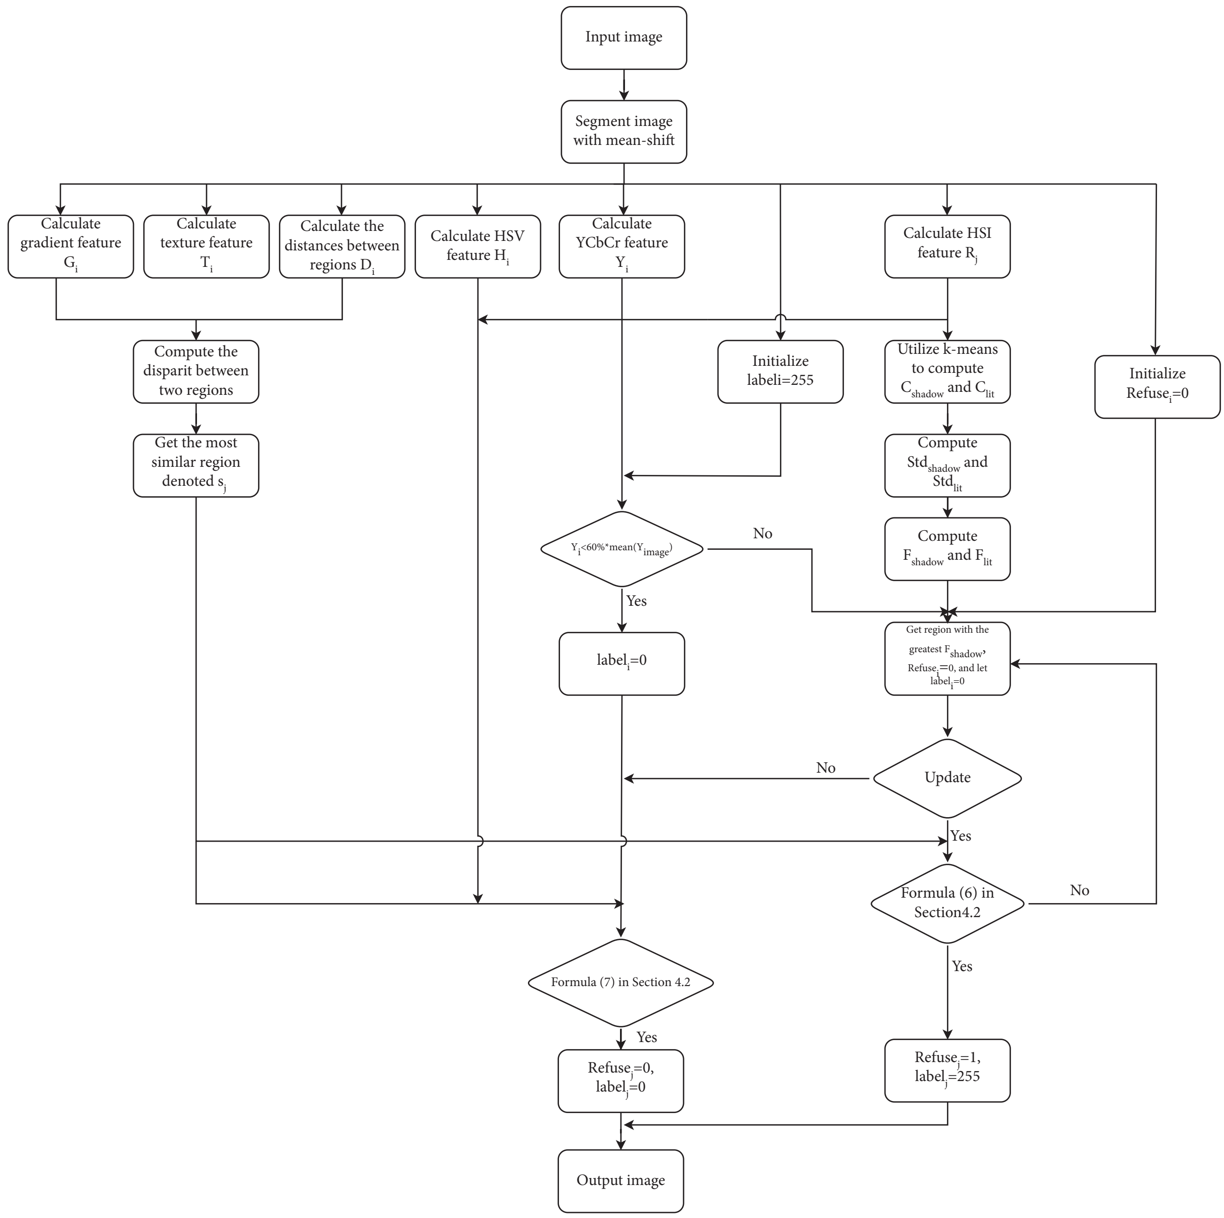

Figure 2: The flowchart of the shadow detection.

(4) Denote the nearest region Near_i of S_i as S_j. Check whether S_i and S_j are brightness opposite regions by comparing R_i and R_j, and if so, then judge $\text{Refuse}_j = 1$.

(5) Iteratively execute steps (3) and (4) until no update.

(6) For the region S_i of label_i = shadow, if the brightness of S_i is similar to S_j and $\text{Refuse}_j = 0$ by comparing Y_i, Y_j, R_i, R_j, set $\text{label}_j = 0$.

3.3. Shadow Removal. Shadow removal is mainly carried out in HSV color space. The overall idea is to find the corresponding region S_j for the shadow region S_i to meet $\text{label}_j = 1$ and minimize $D_{i,j}$. Therefore, S_j is the most similar non-shaded region of S_i. Consider using S_j to adjust the brightness of S_i, remove the shadow on the S_i through the histogram matching algorithm, and minimize the impact of the operation on other features. The flowchart of shadow removal is shown in Figure 3.

3.3.1. Histogram Matching. Supposing the feature of region S_i as Feature_i, given template histogram Hist_T, the purpose of histogram matching is to ensure that the overall offset conforms to the distribution of the template T under the condition of ensuring the minimum change of mutual distributions between Feature_i. The specific methods are as follows.

(1) Calculate the histogram Hist_i of Feature_i with the number of bins equal to T.

(2) The cumulative histograms Acc_i and Acc_T are calculated for Hist_i and Hist_T, respectively.

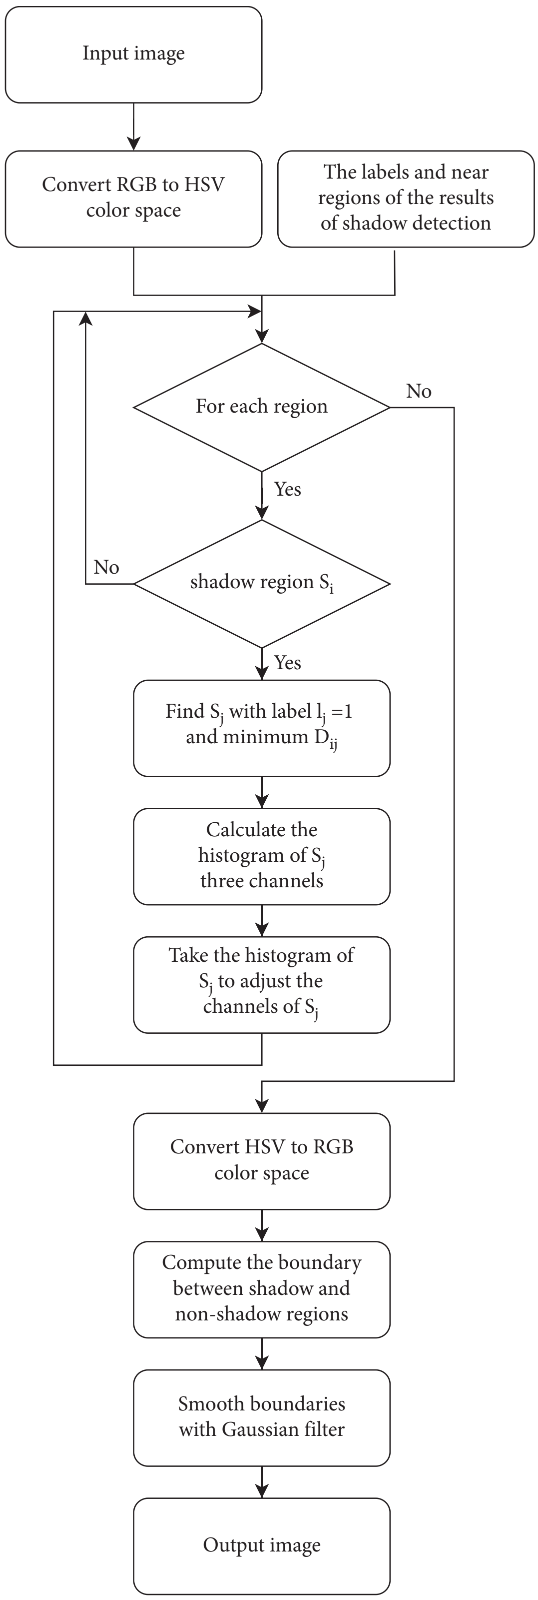

Figure 3: The flowchart of the shadow removal.

(3) For each stripe p in Acc_i, calculate the bin number q with the smallest interpolation among Acc_i.

(4) Move each bin p to the position q.

3.3.2. The Proposed Algorithm. The specific implementation steps of the proposed shadow removal method are as follows.

(1) Calculate the shadow detection result label and convert the image to HSV space at the same time.

(2) Repeat steps (3)–(5) for each shadow region S_i.

(3) For region S_i, find S_j with label$_j$ = 1 and minimum $D_{i,j}$, and use S_j to relight S_i.

(4) In the HSV color space, compute the histograms $\text{Hist}_{H,j}$, $\text{Hist}_{S,j}$ and $\text{Hist}_{V,j}$ of S_j in the three channels H, S, and V, respectively..

(5) Take $\text{Hist}_{H,j}$, $\text{Hist}_{S,j}$, $\text{Hist}_{V,j}$ as the template of histogram matching and adjust the three features of S_i, so that the feature distribution is close to the template.

(6) Convert the image to RGB space.

(7) Calculate the intersection boundary of all shadow regions and non-shaded regions in the image and then smooth all boundaries using a Gaussian filter.

4. Experiments

Experiments are conducted on the shadow dataset SBU [26]. SBU dataset is a large shadow detection dataset, which contains 4727 images, and each image has a ground truth based on pixel markers. In order to quantitatively evaluate the effectiveness of the proposed method and comparative methods, the commonly used indexes such as recall, specificity, and balanced error rate (BER) are used as the evaluation indexes, which are defined as follows:

$$\begin{aligned} \text{recall} &= \frac{\text{TP}}{\text{TP} + \text{FN}}, \\ \text{specificity} &= \frac{\text{TN}}{\text{TN} + \text{FP}}, \\ \text{BER} &= 1 - 0.5 * (\text{recall} + \text{specificity}), \end{aligned} \tag{3}$$

where *TP* indicates that the real shadow is correctly classified, *FN* indicates that the real shadow is incorrectly classified as non-shaded, *TN* indicates that the non-shaded pixels are correctly classified, and *FP* indicates that the non-shaded pixels are incorrectly classified as shadow pixels. The higher the recall is, the more the shadow pixels are found. The higher the specificity is, the more the non-shaded pixels are recalled. Recall and specificity are considered a pair of contradictions. The comprehensive performance of the algorithm is tested by BER. The smaller the BER, the better the shadow detection performance.

4.1. Region Matching. Region matching is shown in Figure 4. The blue line in the figure connects the center of each pair of matching regions. It can be seen that when the image segmentation is more accurate, the nearest region matching is also more accurate.

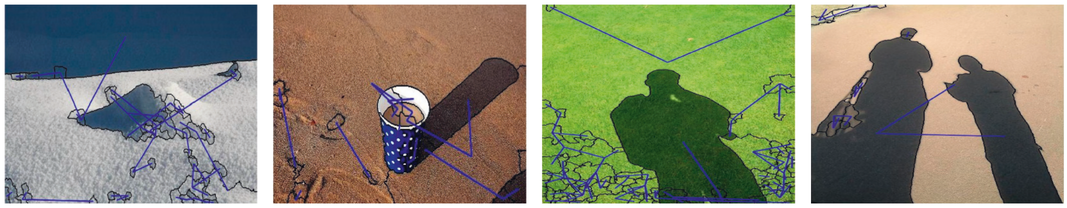

FIGURE 4: Most similar region matching.

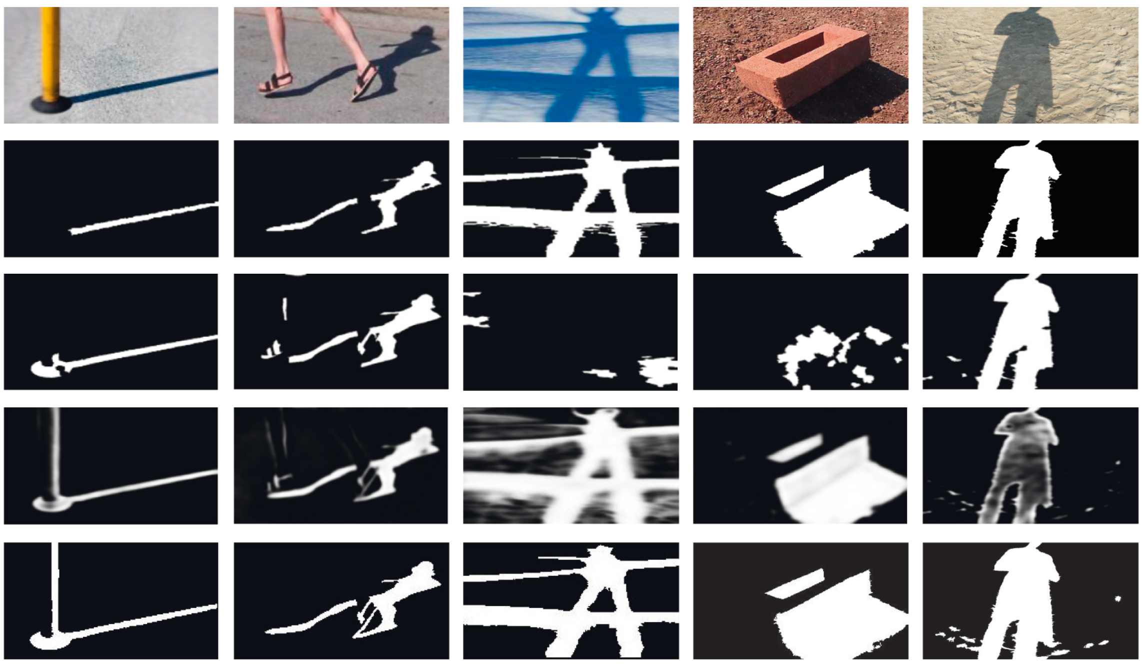

FIGURE 5: Qualitative comparison of the proposed method with other methods. Rows from top to bottom: input images, ground truths, results of the Unary-Pairwise method, results of the Stacked-CNN method, and results of the proposed method.

4.2. Shadow Detection. The parameter setting of shadow detection is mainly in steps (4) and (6) of Section 3.2.2.

In step (4), when equation (4) is satisfied between S_i and S_j, it is considered that the label properties of R_i and R_j are opposite, and set $\text{Refuse}_j = 1$.

$$\frac{R_i - C_{\text{shadow}}}{\text{Std}_{\text{shadow}}} - \frac{R_j - C_{\text{shadow}}}{\text{Std}_{\text{shadow}}} > 3, \tag{4}$$

where R_i and R_j are the features of shadow detection in the region S_i and S_j. The value of R_i ado R_j can be computed by equation (2). C_{shadow} is the feature center of the shadow areas, and $\text{Std}_{\text{shadow}}$ is the standard deviation corresponding to the C_{shadow}. Step (3) of Section 3.2.2 describes the details.

In step (6), when equation (5) is satisfied between S_i and S_j, it is considered that the label properties of S_i and S_j are the same, and set $\text{label}_j = 0$.

$$\frac{\min\left(H_i, H_j\right)}{\max\left(H_i, H_j\right)} + \frac{\min\left(Y_i, Y_j\right)}{\max\left(\left(Y_i, Y_j\right)\right.} + \frac{\min\left(R_i, R_j\right)}{\max\left(R_i, R_j\right)} > 2.5, \tag{5}$$

where H_i, Y_i, R_i, H_j, Y_j, and R_j are the shadow detection features of regions S_i and S_j, respectively.

TABLE 1: Evaluation of shadow detection methods on SBU dataset.

Method	Recall	Specificity	BER
Unary-Pairwise	0.5636	0.9357	0.2504
Stacked-CNN	**0.8609**	0.9059	0.1166
Our method	0.8460	**0.9361**	**0.1090**

The bold entries indicate the best result in a given column.

TABLE 2: Time complexity of shadow detection methods on the SBU dataset.

Method	Testing (hours)	Testing (sec/image)	Training (hours)
Unary-Pairwise	9.13	51.56	~
Stacked-CNN	25.08	141.56	9.4
Our method	**3.08**	**17.40**	~

The bold entries indicate the best result in a given column.

3 and 2.5 are empirical constants. Tuning of the parameters is outside the scope of the current work.

The performance of the proposed shadow detection method is evaluated by comparing it with two commonly used methods: Unary-Pairwise [27] and Stacked-CNN [26].

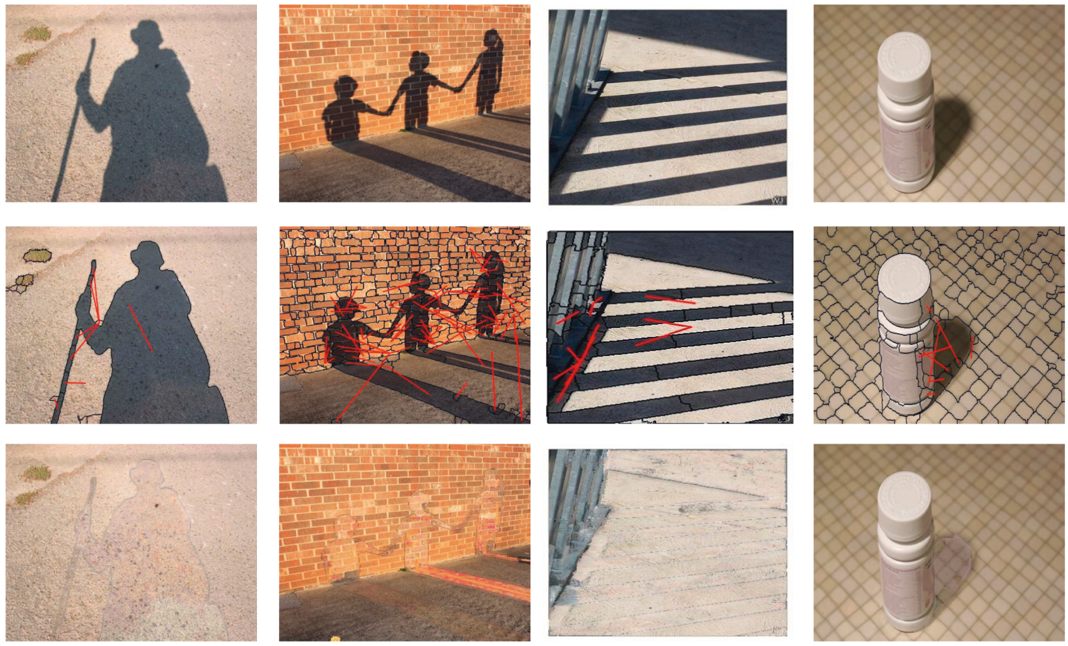

Figure 6: Qualitative analysis results of the proposed shadow removal method on the SBU dataset. Rows from top to bottom: input images, shadow removal matching regions, and shadow removal images.

Figure 7: Failed images for shadow removal on the dataset.

The Unary-Pairwise method is one of the best statistical methods to detect shadows from a single image. The Stacked-CNN method is a shadow detection method based on the deep learning framework using shadow prior map.

4.2.1. Qualitative Analysis. Figure 5 shows the shadow detection results of some images in the SBU dataset.

It can be seen from the third line of Figure 5 that the Unary-Pairwise method has good shadow detection results in some images, but almost no shadow is detected in columns 3 and 4. The fourth line of Figure 5 shows the shadow detection results of the Stacked-CNN method, which can detect all correct shadows, but the visual effects of some results are blurred.

As can be seen from the last line of Figure 5, the proposed method has relatively small error in image shadow detection, but the detection is basically correct. The consistency of shadow regions is ensured by region matching. It should be noted that in the images in column 1, the black base of the pole is detected as a shadow, which is caused by the similar color features between the black base and the shadow. Objects with color features similar to shadow will reduce the precision of shadow detection.

4.2.2. Quantitative Analysis. Table 1 shows the results of quantitative analysis on the SBU dataset. The proposed method can improve the detection rate of shadow and non-shaded regions. Obviously, recall and specificity are considered a pair of contradictions. Considering the performance of shadow detection, the BER metric is used, and the proposed method effectively reduces the BER.

The Stacked-CNN method can detect most shadow pixels in the dataset, but it also causes pixels in non-shaded areas to be insufficiently recalled. Some non-shaded pixels are wrongly classified as shadow pixels, resulting in blurred shadow detection images, which is consistent with the results of qualitative analysis. The Unary-Pairwise method has the lowest recall of shadow pixels on a large-scale shadow detection dataset. This is because of the false pairing between regions due to the loose constraints. Although the recall of the proposed method is lower than that of the Stacked-CNN method, the precision is higher. On average with BER, the improvement made by the proposed method is more than 6% which is impressive.

In Table 2, we show the execution time of testing phases of the proposed approach. Our method does not need training, and it works faster than the statistical method and one order of magnitude faster than the deep learning method.

4.3. Shadow Removal. The parameters of shadow removal are set in step (7) of Section 3.3.2, in which Gaussian blur is applied to the points whose distance from the edge pixel is less than or equal to 2, and the parameters of Gaussian blur are set to $h$size = 15, $\sigma = 15$.

The second line of Figure 6 shows the shadow removal process of some images in SBU dataset, in which the red lines connect and match the corresponding shadow region S_i and non-shaded region S_j. Use S_j to relight S_i through the algorithm in Section 3.3.2.

The third line of Figure 6 shows the shadow removal results of the images. It can be seen that the regions after removing shadow through region matching maintain the original texture features, but the brightness changes. The image after removing shadow has an obvious boundary around the original shadow region, but the edge effect is significantly weakened after Gaussian smoothing.

Through experiments, it is found that not all the shadows of the image can be removed correctly. Two failed shadow removal scenarios are shown in Figure 7. In the first image, the shadow occupies most of the image, and the shadow is evenly distributed in the image, which will lead to the uniform distribution of image feature histogram, and the non-shaded region is not enough to remove the shadow region. In the second image, the shadows of multiple objects are complex, and the fire hydrant is almost completely in shadow, resulting in the wrong shadow removal matching, so the shadows cannot be removed correctly.

In this work, the experiments are run on a PC with a 3.6 GHz CPU and 8G RAM in the Matlab 2018b environment under Windows 10.

5. Conclusion

Experiments show that the shadow detection and removal algorithm based on region matching is effective. In the aspect of shadow detection, the consistency of images can be guaranteed to a certain extent through the mutual restriction of regions with the same material; in the aspect of shadow removal, the method of brightening the shadow by the region with similar material can minimize the impact of shadow removal on the non-shaded features in the shadow region.

The limitation of the method proposed in this paper is that it is difficult to ensure the accuracy of region matching for complex images. Therefore, in shadow detection and shadow removal, it will bring wrong constraints due to wrong matching or restore the region to the wrong material. At the same time, this algorithm is based on Meanshift image segmentation technology, which is difficult to segment accurately in complex images.

The further improvement mainly lies in the calculation of the material matching region. First, using more and more datasets, the matching region is given by training classifiers and other methods. Second, adding more shadow-invariant features to improve the accuracy of region matching in complex images will be taken into account.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

Wireless sensor network is an ad hoc network with sensing capability. Usually, a large number of sensor nodes are randomly deployed in an unreachable environment or complex area for data collection and transmission, which can realize the perception and monitoring of the target area or specific objects and transmit the obtained data to the remote end of the system. Human health activity recognition algorithm is a hot topic in the field of computer. Based on the small sample problem and the linear indivisibility of real samples encountered in metric learning, this paper proposes a human activity recognition algorithm for wireless sensor networks. Human activity recognition algorithm for wireless sensor networks uses human activity recognition algorithm to solve the singularity of intraclass divergence matrix, so as to reduce the impact of small sample problem. The algorithm maps two different feature spaces to the high-dimensional linearly separable kernel space through the corresponding kernel function, calculates the distance between samples in the two projected feature subspaces to obtain two distance measurement functions, and finally linearly combines them with weights to obtain the final distance measurement function.

1. Introduction

The recognition of human health activities is a hot topic in the computer field. Human activities, like language, play an important role in human communication. With the rapid development of mobile terminals, as well as the intelligent development of mobile terminals, today's mobile phones, tablets, and other devices can accurately judge simple human activities using gyroscopes and gravity sensors and send them to opposite target terminals via the network [1]. A wireless sensor network [2, 3] is a distributed network system in which a series of microsensor nodes collect and transmit data using wireless communication. Because of the characteristics and viability of this technology, this paper develops a set of human activity recognition algorithms for mobile terminals and employs wireless sensor networks to implement a series of complex commands for controlling computer terminals from mobile terminals. A wireless sensor network is a sensor-capable ad hoc network. Typically, a large number of sensor nodes are randomly deployed in environments or complex areas that are inaccessible to humans to collect and transmit data, realize perception and monitoring of target areas or specific objects, and transmit the acquired data to the system's remote end [4, 5]. For the elderly living alone, using the behavior recognition technology based on wireless sensor network to build an intelligent monitoring system indoors can not only send alarm signals in time to prevent accidents of the elderly, but also make intelligent decision-making and behavior recommendation by monitoring their daily activities [6]. For example, we can monitor the user's behavior of boiling water and then use the previous life records to find out from the data that the user has the behavior of boiling water from 8 : 00 to 9 : 00 every morning. According to this rule, we can set the electric water heater to work at 8 : 00 a.m. [7, 8].

Based on the small sample problem encountered in metric learning and the linear indivisibility of real samples, a human activity recognition algorithm for wireless sensor networks is proposed [9]. Human activity recognition algorithm for wireless sensor networks uses human activity recognition algorithm to solve the singularity of intraclass divergence matrix, so as to reduce the impact of small sample problem. The human activity recognition algorithm maps the samples from the linear nonseparable original feature space to the linearly separable high-dimensional feature space through the chi-square kernel function, then constructs the divergence matrix describing the proximity relationship between samples in the high-dimensional space, and finally obtains the projection matrix from high-dimensional to low-dimensional space by regularized linear discriminant analysis, so that the samples can still maintain the separability of high-dimensional space in low-dimensional shadow space, so as to improve the classification effect. The purpose of the method based on metric learning is to design a representation model of human activity recognition algorithm with wireless sensor networks [10, 11]. The extracted features should be robust to changes such as illumination and viewing angle and can distinguish different human activities. The most commonly used features in human activity re-recognition are color features and texture features [12, 13].

The essence of human activity recognition algorithm in wireless sensor networks based on metric learning is to learn a distance metric function through training samples, which can effectively classify samples, and make the distance between similar samples as small as possible and the distance between different samples as large as possible. Considering the difference of descriptive ability of different features, a pedestrian re-recognition algorithm based on kernel regularization linear discriminant analysis is proposed by using the idea of multifeature subspace [14]. In this algorithm, two different feature spaces are mapped to the high-dimensional linearly separable kernel space through the corresponding kernel functions, and then the projection matrices of the two feature spaces are obtained by performing regularized linear discriminant analysis in the kernel space, and the distances between samples are calculated in the two projection feature subspaces to obtain two distance measurement functions, and finally the final distance measurement function is obtained by linearly combining them with weights [15]. However, in actual research, the human activity recognition algorithm is complicated and its accuracy is low, and the effect will be even worse when processing a large amount of data, so improving recognition accuracy has become the most important task of human activity recognition at the moment. This paper focuses on a metric learning-based algorithm for human activity recognition, with the goal of learning the relationship between data using this method, making the relationship more beneficial to the recognition task, and thus improving the accuracy of human activity recognition.

2. Related Work

Binary sensors and motion sensors, according to [16], are used to identify ADL in the elderly. Human behavior recognition research can be divided into two categories: the first is image vision recognition, which uses image equipment to generate pictures or videos and monitor user behavior. Reference [17] employs a convolutional neural network to learn behavior data automatically using a big data analysis method to select the best features. A feature fusion method is proposed in light of the overfitting phenomenon of data labels in the learning process, which strengthens the ability of feature learning and improves the discrimination of behavior features. Although this method solves the problem of data label overfitting, it adds to the data complexity and slows down the process. Taking the video data provided by the image equipment as input, [18] proposes a moving human body segmentation algorithm based on interframe difference and an improved C-V model. The algorithm can solve the problem of recognizing moving human body behavior in complex situations and provide real-time alarms for security and monitoring systems. According to [19], wireless sensor networks have a solid business foundation as well as theoretical research significance, whether in astronomy, basic people's livelihood, or human activities. Many applications requiring the location of nodes in wireless sensor networks on a large scale, such as animal survival ecology monitoring, activity range monitoring, and so on, must solve the problem of obtaining the location of nodes in the network. Literature [20] through the big data analysis method and wireless sensor networks, with their ad hoc characteristics, further expands human vision, enables people to obtain information more safely and conveniently, enables people to explore areas unsuitable for human activities or inaccessible to human beings, and directly and efficiently obtains the information needed by human beings. The research in [21] shows that the hidden Markov model is used to segment the user's daily behavior sequence. According to the characteristics of continuity of actual actions and multisensor data fusion, a dynamic segmentation method of continuous action sequence based on hidden Markov model is proposed, and the result directly affects the accuracy of action recognition. Finally, the average recognition accuracy is 89%. This method only carries out time sequence segmentation for continuous actions and does not take into account discontinuous action sequences. Literature [22] suggests that the process of monitoring by sensors is completely transparent to users and will not affect the daily life and work of the monitored person. Sensor data is collected through a computer network and stored in a database for pattern recognition and prediction. Literature [23] proposes a design framework for data transmission scheduling and a data aggregation scheduling strategy in the network, with the goal of reducing energy consumption and data transmission delay in wireless sensor networks using big data analysis. According to [24], a wireless sensor network can transmit relevant information from the battlefield to a remote terminal without causing a network footprint due to the loss or failure of some nodes in the network, ensuring information acquisition continuity. The method of improving user behavior characteristics is presented in [25]. It proposes an algorithm for enhancing sensor data characteristics and uses the feature enhancement coefficient to express the feature recognition ability of behaviors, addressing issues such as behavior concurrency and peer diversity. Time series features are added to behavior characteristics to highlight features in the data, and the physical meaning of behavior data is improved to make it easier to understand. Although this method solves the behavior concurrency problem, it ignores the behavior similarity problem.

Based on metric learning, this paper studies the human activity recognition algorithm in wireless sensor networks. In this case, the divided time slice is used to represent the activities that occupy most of the time. However, the result is that the situation after the discretization is different from the actual situation. In order to express the difference, the discretization accuracy is introduced. When there is a rejection task, the difficulty of recognition will be increased, because it limits a part of the samples, which will make the training model unstable. Human activity recognition algorithm module is the preprocessing module of this system, which is mainly used to complete the function of human activities. It can disassemble the relationship between specific points, lines, and surfaces of human activities according to specific algorithms, and transmit these data to the calculation module.

3. Human Activity Recognition Algorithm Based on Metric Learning in Wireless Sensor Networks

Measurement Learning: By training and learning the wireless sensor network, we can get the appropriate Markov matrix M, treat the characteristics of different emotional contributions in the wireless sensor network data samples differently, and then measure the similarity of the wireless sensor network data samples more accurately, and finally achieve the goal of improving the accuracy of emotional recognition. The discretization accuracy based on metric learning indicates the percentage of correct labels in the discretized data set, and the data after discretization is used to calculate the performance metric of the model. In this paper, 1 s discrete data is used as the comparison data to evaluate the performance of the model. The algorithm of human activity recognition in wireless sensor networks based on metric learning is based on the solution set of a problem, which is called population, and there are individuals with certain gene coding properties in the solution set, and the individuals can also be considered as chromosomes. Individual chromosomes contain important information, which is expressed by a human activity recognition algorithm through gene combination. Human hair color features, for example, are determined by a gene combination of this feature. If it is to be applied to real-world problems, the first step must be coding, or expressing the characteristics of things through gene coding. A global optimization can be achieved using a human activity recognition algorithm. It differs from a general optimization algorithm in that it starts with the problem's solution set rather than a single solution at the beginning of the search. The search range is initially broad, which can serve as a good foundation for the subsequent steps and make finding the best solution easier. Metric learning is a projective space-friendly non-Euclidean metric. By finding a human activity recognition algorithm in wireless sensor networks, metric learning can reflect the fractional linear transformation of spatial structure information or semantic information of samples and model the potential relationship of training samples; it can improve discrimination. The structure of human activity recognition algorithm is given as shown in Figure 1.

The metric learning algorithm of human activity recognition algorithm draws lessons from the idea of maximum interval of SVM and learns the Markov matrix with the goal that the same sample points are as close as possible, and the different sample points are away from and maintain a large interval. It optimizes the K target nearest neighbors and intrusion samples of the target sample, so that the new feature space and space obtained from the original sample features are mapped. The K samples closest to the target sample belong to the same class, while they maintain a large interval distance from heterogeneous samples. In the process of evaluating individuals, human activity recognition algorithm only needs to calculate the fitness function value without other information. The form of fitness function can also be set for different problems, which increases the application scope of human activity recognition algorithm. In terms of recognition, clustering, and retrieval performance, although the Mahalanobis metric obtained by metric learning is better than Euclidean metric or original Mahalanobis metric, the limitations of the transformation of human activity recognition algorithm make it unable to describe the potential nonlinear relationship of training samples, which limits its application in practice. Because the expression form of the potential Riemannian manifold of the training sample is not known in advance, and the type of nonlinear transformation is also unknown, the Riemannian metric can only be approximately calculated by Euclidean metric on the training data, and the calculation efficiency is very low. In practical applications, Riemannian metric learning is not always better than Markov metric learning in recognition, clustering, and retrieval. As far as we know, there is no important breakthrough research progress in Riemannian metric learning. The framework of human activity recognition is shown in Figure 2.

The pedestrian re-recognition method based on metric learning mainly includes three stages: feature extraction, distance metric learning, and re-recognition. These advantages of human activity recognition algorithm make it widely used in parameter optimization. But its problems can not be ignored, such as nonstandard population coding, premature convergence, local optimum, and so on. In this paper, the distance measurement learning stage is studied, and the algorithm of human activity recognition is proposed. The kernel method is used to map the training samples to the linearly separable feature space, in which the divergence matrix describing the neighborhood relationship between samples is constructed, and finally a projection matrix is obtained. The flowchart analysis of human activity

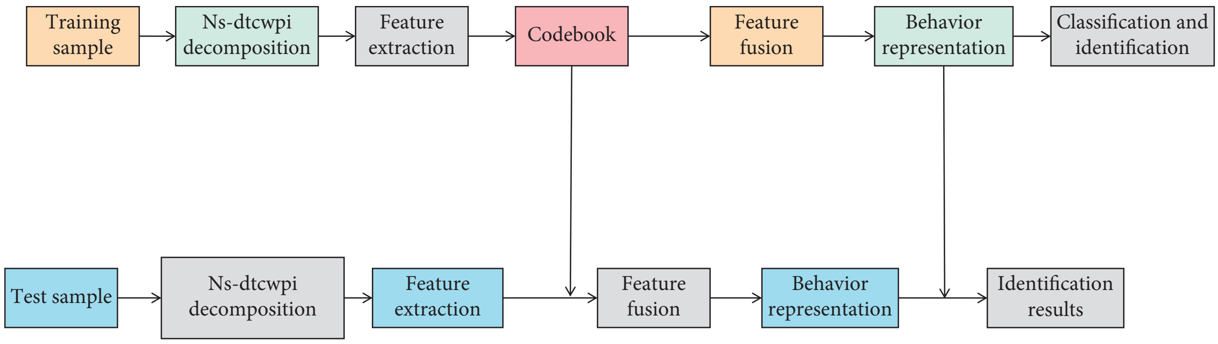

Figure 1: Structure diagram of human activity recognition algorithm.

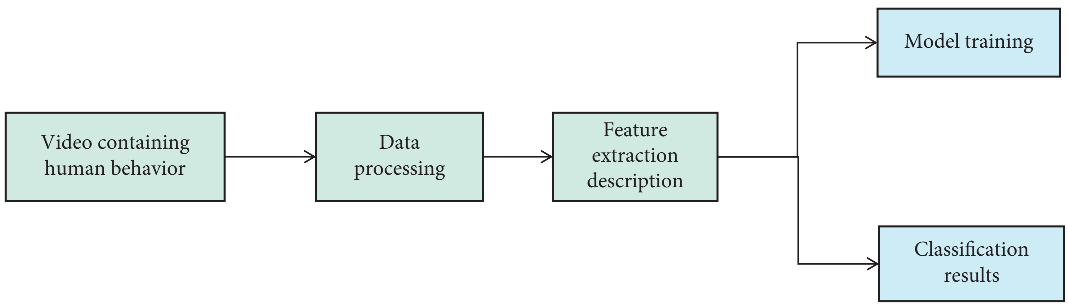

Figure 2: Framework diagram of human activity recognition.

recognition algorithm in wireless sensor networks based on metric learning is shown in Figure 3.

The process of human activity recognition can be divided into two subprocesses: one is to extract human behavior features and fully express human behavior through feature data; the other is to construct recognition algorithm or recognition model according to the obtained features. Although the human activity recognition algorithms based on metric learning proposed in this paper have high recognition rate, in each data set with very little human activity knowledge, the kernel regularized linear discriminant analysis can not well reflect the intraclass and interclass changes of samples due to the very small number of samples in each human activity knowledge during training. Thus, the performance of the algorithm is greatly affected. Distance measurement plays a very important role in many application tasks in the field of wireless sensor network understanding and pattern recognition. The most widely used is Euclidean metric, which regards the input sample space as isotropic, so instinct has been well used.

Given a reversible symmetric matrix $\Psi \in R^{(n+1)\times(n+1)}$, its bilinear form can be represented by $\psi(x, y)$.

$$\psi(x,y) = \left(x^T, 1\right)\Psi\begin{pmatrix} y \\ 1 \end{pmatrix}, \forall x, y \in R^n. \tag{1}$$

If the matrix Ψ is positive semidefinite, let $E^n = \{x \in R^n\colon \psi_{xx} > 0\}$ define

$$\rho_E(x,y) = \frac{k}{2_i}\log\left(\frac{\psi_{xy} + \sqrt{\psi_{xy}^2 - \psi_{xx}\psi_{yy}}}{\psi_{xy} - \sqrt{\psi_{xy}^2 - \psi_{xx}\psi_{yy}}}\right)(k > 0). \tag{2}$$

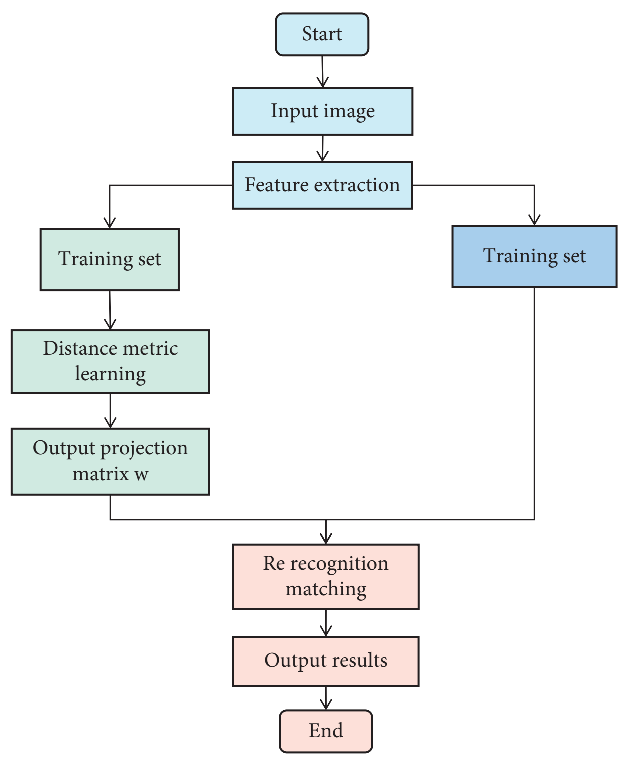

Figure 3: Flowchart of human activity recognition algorithm in wireless sensor networks based on metric learning.

If the matrix Ψ is indefinite, let $B^n = \{x \in R^n | \psi_{xx} < 0\}$ define

$$\rho_H(x,y) = -\frac{k}{2}\log\left(\frac{\psi_{xy} + \sqrt{\psi_{xy}^2 - \psi_{xx}\psi_{yy}}}{\psi_{xy} - \sqrt{\psi_{xy}^2 - \psi_{xx}\psi_{yy}}}\right)(k > 0). \tag{3}$$

On En and Bn, $\rho_E(x,y)$ and $\rho_H(x,y)$ forces both satisfy the metric axiom, so they are metrics on En and Hn. (R^n, ρ_E) is called elliptic geometry space, (B^n, ρ_H) is called hyperbolic geometry space, k is a constant related to CC, $1/k$ is the curvature of elliptic geometry space, and $-1/k$ is the curvature of hyperbolic geometry space. They are all special Riemann geometry, collectively called Kelley Klein metric geometry and can be unified into

$$\rho(x,y) = \frac{k}{2}\left|\log\left(\frac{\psi_{xy} + \sqrt{\psi_{xy}^2 - \psi_{xx}\psi_{yy}}}{\psi_{xy} - \sqrt{\psi_{xy}^2 - \psi_{xx}\psi_{yy}}}\right)\right|(k > 0). \tag{4}$$

The abovementioned Kelley Klein metric only depends on the symmetric matrix Ψ; that is, given a symmetric matrix, there can be a specific Kelley Klein metric.

Given a symmetric positive definite matrix G, its bilinear form in Kelley Klein metric can be expressed as

$$\sigma(x_i, x_j) = (x_i^T, 1)G\begin{pmatrix} x_j \\ 1 \end{pmatrix} \stackrel{\Delta}{=} \sigma_{ij}. \tag{5}$$

Ellipse Kelley Klein measures as follows:

$$d_{ck}(x_i, x_j) = \frac{k}{2i}\log\left(\frac{\sigma_{ij} + \sqrt{\sigma_{ij}^2 - \sigma_{ij}\sigma_{ij}}}{\sigma_{ij} - \sqrt{\sigma_{ij}^2 - \sigma_{ij}\sigma_{ij}}}\right)(k > 0). \tag{6}$$

The V support vector machine method is used as a reference in this chapter to make the Cayley-Klein metric between data points of the same class smaller and the Cayley-Klein metric between data points of different classes larger, and the following Cayley-Klein metric learning optimization model is given:

$$\begin{aligned}
&\min \quad \sum_{i,j \longrightarrow i}\left(d_{CK}(x_i, x_j) - \nu\beta + \mu\sum_i \zeta_{ijl}\right),\\
&s.t. \quad (a)d_{CK}(x_i, x_l) - d_{CK}(x_i, x_j) \geq \beta - \zeta_{ijl},\\
&(b)\zeta_{ijl} \geq 0, \beta \geq 0,\\
&(c)G > 0,
\end{aligned} \tag{7}$$

where the symbol $j \longrightarrow i$ represents X_j and X_i, which are data points belonging to the same category. The first term of the objective function punishes the large distance between the input sample and its samples of the same category, the V in the second term controls the proportion of misclassified sample points, the third term punishes the small distance between heterogeneous samples, and μ is the equilibrium constant.

With the mark $C_{ij} = (x_i^T, 1)^T \ (x_j^T, 1)$, there is

$$\sigma(x_i, x_j) = tr(C_{ij}G) = tr(C_{ij}(L^T L)). \tag{8}$$

In order to improve the iterative efficiency, this chapter uses small batch random gradient descent algorithm to solve the above optimization problems. Assume that the total number of samples is that, at each iteration, only B samples are selected to update the gradient value, where B is far less than the total number of samples N. The pedestrian re-recognition method based on metric learning needs labeled sample data in the training process to learn a metric model with good discrimination and generalization ability. However, in practical application, the cost of labeling samples is relatively high, which leads to the lack of enough training samples in metric learning and the problem of small samples.

4. Research on Human Activity Recognition Algorithm in Wireless Sensor Networks

4.1. Human Activity Recognition Algorithm for Wireless Sensor Networks Based on Metric Learning. Metric learning can be traced back to some early research. Metric learning, on the other hand, first appeared in Xing et al's 2002 proposal for the first Markov distance measurement method. It uses the nonregularized convex formula to maximize the sum of distances between points while keeping the distance between similar examples as small as possible. Some existing studies have introduced mobility into wireless sensor networks in order to maximize the network life cycle and reduce the delay in wireless sensor networks. Because rejection processing is required after measurement learning, we must manually select the rejection radius in order to achieve the same accuracy in discrimination and rejection tasks. To achieve the expected trade-off between identification and rejection tasks, the rejection radius can be selected using the cross validation method. Mobility in wireless sensor networks has a number of benefits, including improved connectivity, lower deployment costs, higher reliability, and lower energy consumption. However, using the human activity recognition algorithm, the average recognition accuracy of the human activity process is 97.42, which is 2.58 higher than the decision tree algorithm. Sensors and activity tags both use the same discrete time length, so two or more activities can happen at the same time. For example, one activity could be stopped in the middle of the time period while the other could begin right away.

Human activity recognition in wireless sensor networks based on metric learning can be divided into visual activity recognition and nonvisual activity recognition. Vision-based human activity recognition focuses on the field of computer vision, using imaging devices such as cameras and video cameras to collect information, and tracking, identifying, analyzing, and understanding activities through related processing technologies of graphics and images. Non-vision-based activity recognition mainly obtains human information through sensors such as gyroscope, gravity accelerator, and GPS. However, the feature extraction of the above methods is mostly carried out in time domain, and it is not robust compared with feature extraction in frequency domain. Another important point is that the above methods are basically based on SVM to classify different group behaviors. Human health activity recognition in wireless sensor networks can be divided into four aspects according to the complexity of the research object: posture, individual behavior, interactive behavior, and group behavior, in which interactive behavior is an action completed by two or more people, and group behavior refers to an action completed by a group of people. Measuring group behavior is influenced by complex semantics and environment, and there are relatively few studies, most of which focus on posture and individual behavior. All nodes in this architecture are static, and the receiver is mobile here. Once the receiver reaches a given sensor node and the sensor detects the existence of the receiver, data collection is completed. This architecture is beneficial to better connect to WSNs deployed in the area of interest. The process of learning human activity recognition algorithm in wireless sensor networks can usually be simplified to the classification of time-varying data; that is, the test sequence is matched with the reference sequence of typical behaviors calibrated in advance. At present, the algorithms of human behavior recognition in wireless sensor networks based on metric learning mainly include template matching method and state space method. Frame-to-frame matching method, fusion frame matching method, and key frame matching method all belong to template matching method.

4.2. Experimental Results and Analysis. The following is the experimental results of the measurement learning-based wireless sensor network human activity recognition algorithm model implemented in MATLAB language on the data set. This experiment adopts four algorithms, namely, decision tree algorithm, data mining algorithm, machine learning algorithm, and human activity recognition algorithm in this paper. Three experiments are carried out, as shown in Figures 4–6.

On three data sets, the recognition accuracy of the fast nearest neighbor component analysis algorithm is clearly improved when compared to the 1NN and NB algorithms, according to the experimental results. On the Weizmann data set, the average recognition accuracy of decision tree and data mining algorithms is 92.86 and 94.61, respectively, which is higher than decision tree algorithm. However, using the human activity recognition algorithm, the average recognition accuracy of the human activity process is 97.42, which is 2.58 higher than the decision tree algorithm. Sensors and activity tags both use the same discrete time length, so two or more activities can happen at the same time. For example, one activity could be stopped in the middle of the time period while the other could begin right away. The divided time slice is used to represent the activities that take up the majority of the time in this case. However, as a result of the discretization, the situation afterward differs from the actual situation. The discretization accuracy is introduced to express the difference. When a rejection task is used, the difficulty of recognition is increased because a portion of the samples is limited, making the training model unstable. In this case, however, the average recognition accuracy of the machine learning algorithm is 83.68, while the average recognition accuracy of the human activity recognition algorithm is 89.63, which is 5.45 higher than the

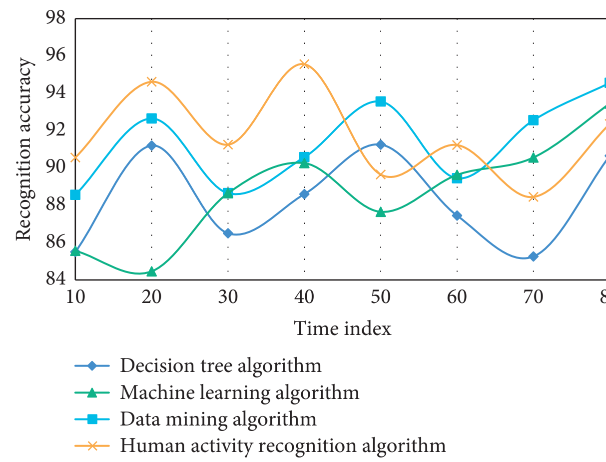

Figure 4: Data results of different algorithms in wireless sensor networks based on metric learning.

no rejection task. Individual behavior recognition research results can be fully utilized in group behavior recognition based on individual behavior recognition. However, feature extraction in the above methods is primarily done in the time domain, which is less robust than feature extraction in the frequency domain. Another important point to note is that the methods described above use SVM to classify various group behaviors. Because SVM is difficult to apply to large samples and sensitive to missing data, metric learning is used to classify different group behaviors due to its advantages.

In this experiment, in order to evaluate the advantages and disadvantages of the human activity recognition algorithm of wireless sensor networks based on metric learning proposed in this chapter, two types of group behaviors are mainly considered, each of which is completed by individuals. The wireless sensor networks are selected, in which six segments are used as training samples and two segments are used as test samples, including frames of group target images. The group behavior corresponding to each frame is manually calibrated as a reference value. The recognition rate obtained by this method is low. The main reason is that the background is complex and the interference to recognition is large. On the other hand, only hog features are relatively single and the ability to describe behavior is limited. In general, the human activity recognition algorithm based on metric learning in wireless sensor networks has a high recognition accuracy. This experiment adopts four algorithms, namely, decision tree algorithm, data mining algorithm, machine learning algorithm, and human activity recognition algorithm in this paper. Four experiments are carried out, as shown in Figures 7–10.

The experimental results show that these methods are all based on the feature extraction of human activity recognition in wireless sensor networks based on metric learning. They need to be processed accurately in the early stage, and complex models need to be built in the later stage, which makes the whole algorithm less robust. In this paper, feature extraction in complex frequency domain can effectively suppress the influence of noise, and the whole model is

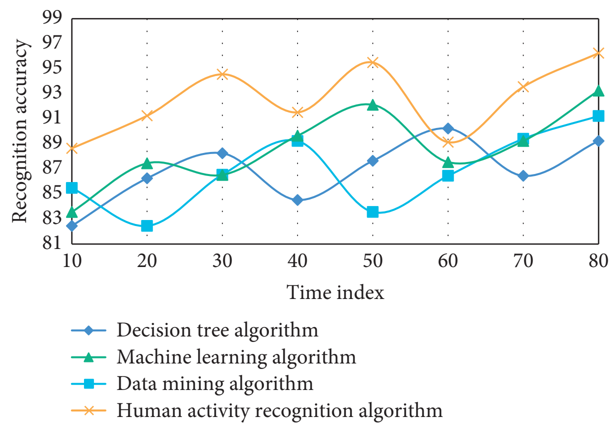

FIGURE 5: Data results of different algorithms in wireless sensor networks based on metric learning.

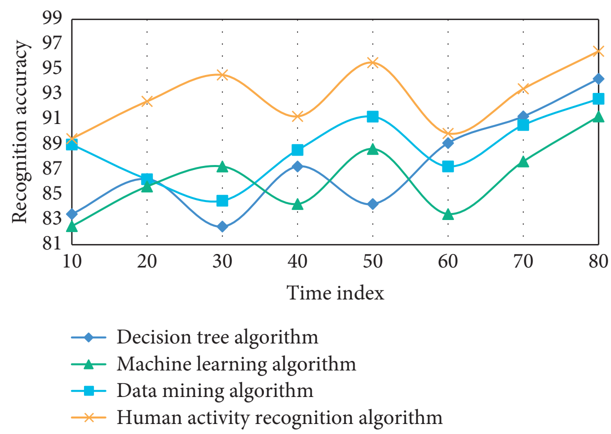

FIGURE 6: Data results of different algorithms in wireless sensor networks based on metric learning.

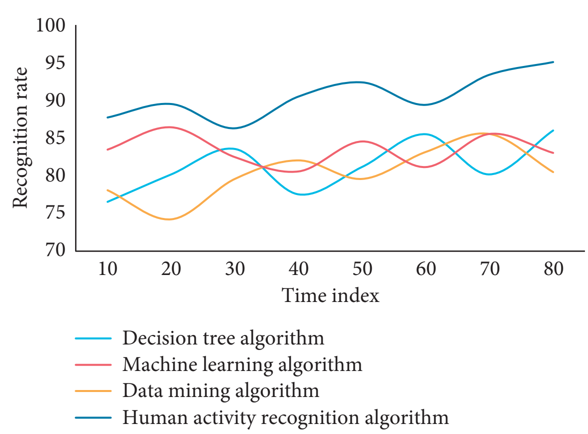

FIGURE 7: Recognition rate of different algorithms in wireless sensor networks.

simple and robust. In addition, on the sum video set, using basic methods to identify group behaviors, the recognition rates can reach 64.58% and 56.87%, respectively. Human activity recognition method based on metric learning uses linear method to classify human activity recognition samples. However, the real pedestrian sample data is often nonlinear, so it is obviously inappropriate to use linear method to solve nonlinear problems. Finally, most of the human activity recognition algorithms based on distance metric learning encounter the problem of small samples due to the lack of enough training samples. However, in this case, the average recognition accuracy of machine learning algorithm is 83.68, and that of human activity recognition algorithm is 89.63, which is 5.45 higher than that of no

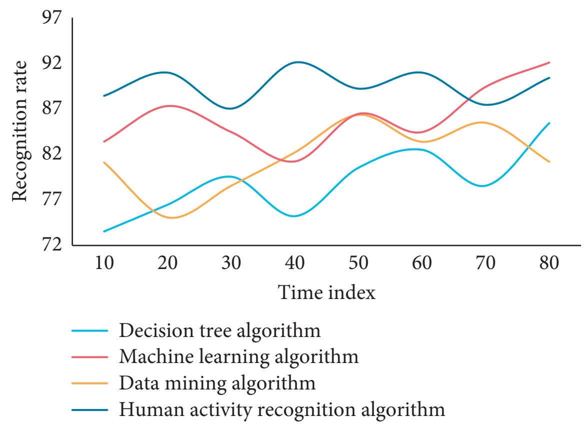

Figure 8: Recognition rate of different algorithms in wireless sensor networks.

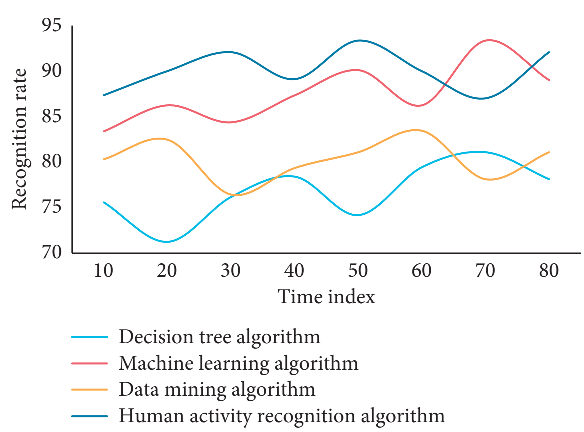

Figure 10: Recognition rate of different algorithms in wireless sensor networks.

rejection task. Group behavior recognition based on individual behavior recognition can make full use of the existing research results of individual behavior recognition.

5. Conclusions

Measurement: Some existing research has introduced mobility into wireless sensor networks in order to maximize the network life cycle and reduce the delay. Because we must deal with rejection after metric learning, we must manually select the rejection radius to achieve the same accuracy in task identification and rejection. Wireless sensor networks have become increasingly popular in recent years because they are nonintrusive, private, and simple to set up. Contact switches, for example, are used to monitor how well doors and cupboards open and close. Mercury contacts are for measuring the movement of objects or the switch state of drawers. Passive infrared sensor is for detecting the movement of specific areas. The status of the flushing device is measured by a floating sensor. The human activity recognition algorithm of wireless sensor networks based on metric learning, on the other hand, uses the chi-square kernel function to map samples from the linearly indivisible original feature space to the linearly separable high-dimensional feature space, then constructs the divergence matrix describing the neighborhood relationship between samples in the high-dimensional space, and finally obtains the projection matrix from the high-dimensional space to the low-dimensional space.

Intracranial aneurysms are local dilations of the cerebral blood vessels; people with intracranial aneurysms have a high risk to cause bleeding in the brain, which is related to high mortality and morbidity rates. Accurate detection and segmentation of intracranial aneurysms from Magnetic Resonance Angiography (MRA) images are essential in the clinical routine. Manual annotations used to assess the intracranial aneurysms on MRA images are substantial interobserver variability for both aneurysm detection and assessment of aneurysm size and growth. Many prior automated segmentation works have focused their efforts on tackling the problem, but there is still room for performance improvement due to the significant variability of lesions in the location, size, structure, and morphological appearance. To address these challenges, we propose a novel One-Two-One Fully Convolutional Networks (OTO-Net) for intracranial aneurysms automated segmentation in MRA images. The OTO-Net uses full convolution to achieve intracranial aneurysms automated segmentation through the combination of downsampling, upsampling, and skip connection. In addition, loss ensemble is used as the objective function to steadily improve the backpropagation efficiency of the network structure during the training process. We evaluated the proposed OTO-Net on one public benchmark dataset and one private dataset. Our proposed model can achieve the automated segmentation accuracy with 98.37% and 97.86%, average surface distances with 1.081 and 0.753, dice similarity coefficients with 0.9721 and 0.9813, and Hausdorff distance with 0.578 and 0.642 on these two datasets, respectively.

1. Introduction

Intracranial aneurysms are abnormal projections that occur on the walls of cerebral arteries. Such hemorrhage is common among relatively young people, with a higher mortality and incidence rate and about 3% in healthy adults [1]. The main threat comes from subarachnoid hemorrhage (SAH) caused by the rupture of an intracranial aneurysm [2], which accounts for more than 85% [3, 4]. According to the survey, SAH is a catastrophic event, with a mortality rate as high as 25%–60% after rupture [5]. Therefore, accurate measurement and evaluation of the shape of intracranial aneurysms are crucial in daily clinical work so that we can monitor and analyze the growth and rupture risks of aneurysms, making it easier to intervene or treat early [6, 7].

According to the current form of technological development, combined with the actual clinical situation, we found that the inspection methods for intracranial aneurysms include invasive and noninvasive. Compared with invasive Digital Subtraction Angiography (DSA), Computed Tomography Angiography (CTA), magnetic resonance angiography (MRA), and Transcranial Doppler (TCD) have been advocated as the best detection methods for intracranial aneurysms [8]. MRA is a noninvasive angiographic method that does not require radiation exposure. With the introduction of new technologies such as 3D imaging, contrast enhancement, and 3T magnetic field, its sensitivity can reach the detection of aneurysms less than 3 mm [9]. Therefore, based on the simple operation and accurate imaging characteristics of MRA technology, radiologists usually use it to perform 3D visualization and quantitative analysis of small intracranial aneurysms [10]. However, the MRA image of a particular part usually contains part of normal tissue, and it may have a relatively large proportion. Therefore, currently in clinical practice, experts often use manual segmentation to separate the tumor tissue regions. In this context, the segmentation results are greatly affected by the subjective experience of experts, and the repetition rate is low and time-consuming. With the development of emerging technologies such as deep learning, some automated segmentation algorithms have gradually emerged, which have initially solved the problem of manual segmentation. However, the accuracy of these algorithms is still to be discussed.

Under the background of the current era of big data, driven by artificial intelligence, it automatically recognizes complex pattern features in image data and provides quantitative data evaluation results [11]. In particular, the application of Convolutional Neural Network (CNN) [12] in deep learning has shown superior performance in a series of image recognition tasks [13], including medical image processing [14–17]. At present, the research on intracranial aneurysms is not in-depth, but some researchers have made courageous attempts. Park et al. developed and applied a neural network segmentation model called the HeadXNet model, which can generate accurate voxel prediction of intracranial aneurysms on head CTA images [18]. Wang et al. presented a multilevel segmentation method based on the lattice Boltzmann method (LBM) and level set with ellipse for accurate segmentation of intracranial aneurysms, making it potential for clinical assessment of the volume and aspect ratio of the intracranial aneurysms [19]. However, these studies focused on unruptured intracranial aneurysms (UIAs) and did not include patients with Aneurysmal subarachnoid hemorrhage (aSAH). Hence, it remains unclear how deep learning model (DLM) algorithms perform on patients with acutely ruptured intracranial aneurysms (RIAs) and whether the extent of hemorrhage impedes detection sensitivity. Moreover, there still has room for performance improvement due to the significant variability of lesions in the location, size, structure, and morphological appearance.

Based on this, we propose a novel automated MRA image segmentation network for intracranial aneurysms, which can quickly locate intracranial aneurysms and accurately segment its three 3D shapes to help radiologists quantitatively evaluate MRA examinations. The contributions are as follows:

(1) A novel 3D image preprocessing scheme is designed to correlate the structural information between data blocks through overlap and partition operations. If the Graphic Processing Unit (GPU) is large enough, the kind of processing is not necessary;

(2) A new One-Two-One Fully Convolutional Network (OTO-Net) for intracranial aneurysms automated segmentation in MRA images is proposed, which is based on the idea of fully convolutional networks with three consecutive encoding and decoding structures to detect and segment intracranial aneurysms more efficiently and accurately;

(3) Aiming at the severe imbalance of categories caused by small intracranial aneurysms, a loss ensembles objective function is proposed, which improves the segmentation accuracy and dramatically enhances the stability of the backpropagation of the network structure.

After reviewing the state-of-the-art in the field of traditional machine learning-based segmentation methods, deep learning-based methods, and the current intracranial aneurysms segmentation methods in Section 2, we introduce in detail the structure and method of our proposed model in Section 3. Then, we describe the details and results of the experiment in Section 4. Finally, we present a discussion in Section 5 and draw the conclusions in Section 6.

2. Related Work

2.1. Traditional Machine Learning-Based Segmentation Methods. For a long time in the past, traditional machine learning algorithms have occupied a significant position in image segmentation. Traditional machine learning algorithms include decision tree, random forest, extra tree, ridge classifier, logistic regression, K-Nearest Neighbor [20], Naive Bayes (Gaussian) [21], and Kernel Support Vector Machine (polynomial, Gaussian) [22], and other algorithms. Yang et al. used the random forest method to build a predictive model of cardiovascular disease and achieved significant results, referencing cardiovascular disease prediction and treatment [23]. In addition, Bender used regression models to analyze epidemiological statistics so that an adjusted effect estimate can be obtained that takes into account the impact of potential confounding factors [24]. On the other hand, as the advancement of high-throughput technology had resulted in the generation of a large amount of genomic and epigenome data, the classification features of support vector machines were expanding their applications in cancer genomics, leading to the development of new biomarkers and new drug targets [25].

2.2. Deep Learning-Based Segmentation Methods. With the application of image segmentation in biomedical image processing, relevant characteristics of this field are also exposed, such as small sample dataset, high segmentation accuracy, and fast segmentation speed. In order to solve this series of problems, new algorithms such as deep learning were born. However, because CNN loses image details in convolution and pooling, the size of the feature map gradually decreases. It does not provide a good indication of the precise contour of the target body. To solve this problem, Shelhamer et al. proposed a Fully Convolutional Network

(FCN) [26], which became the basic framework for semantic segmentation tasks. Most of the subsequent networks are improved on this basis. In 2015, Ronneberger et al. proposed the U-Net structure [27], which has the advantages of supporting a small number of data samples, classifying each pixel and high image segmentation efficiency. In 2016, the V-Net structure was introduced [28], a volume segmentation algorithm based on FCN. Due to its 3D convolution, the introduction of Dice objective function, novel data expansion method, and residual learning, this model showed superior performance in the prostate MRI segmentation task. Especially in recent years, image segmentation has been widely used in medical image processing [29].

2.3. Intracranial Aneurysms Segmentation Methods. With the development of modern medical imaging technology, it is possible to understand further the structure, size, and other characteristics of the diseased tissue in a noninvasive way to diagnose the progress of the disease. In 1895, the German physicist Wilhelm Konrad Rontgen discovered X-rays [28, 30], which had opened the door to medical imaging. Medical imaging methods commonly used in clinical practice include X-ray imaging, X-ray computed tomography (CT), emission computed tomography (ECT), magnetic resonance imaging (MRI), etc., and various medical imaging equipment are widely used in hospitals [31]. Based on literature reading and clinical experience, MRA is a relatively good imaging method for diagnosing intracranial aneurysms. We learned that relevant scholars had explored the intracranial aneurysms' automatic segmentation and analysis. However, the accuracy of its segmentation and other indicators cannot be fully guaranteed. This means that aneurysm detection proves to be challenging and time-consuming.

Shahzad et al. [32] developed and evaluated a Deep Learning Model (DLM) to automatically detect and segment aneurysms in patients with aneurysmal subarachnoid hemorrhage (aSAH) on computed tomography angiography. The results prove that this method is highly sensitive and can potentially assist treating physicians in aSAH by providing automated detection and segmentation of aneurysms. Law et al. [33] proposed a novel intensity-based algorithm to segment intracranial vessels and the attached aneurysms, which can handle the low-contrast aneurysmal regions affected by turbulent flows. It is grounded on multirange filters and local variances to extract intensity-based image features. Prior to this, the team also designed a new method based on multirange filters and local variance to segment blood vessels and intracranial aneurysms on PCMRA images that achieves an excellent segmentation effect [34]. Even though there are related research results in this field, there is still no systematic system to solve this problem. This shows that in order to achieve the effect of accurately and efficiently segmenting the tumor area, new methods are being explored continuously.

2.4. Our Work. Facing the vast challenge of precise segmentation, how to segment the intracranial aneurysm structure from the complex brain tissue structure has become an urgent problem that we need to overcome. Aiming at the characteristics of the existing technology, we proposed a novel model for intracranial aneurysms segmentation in MRA images. We used datasets from the First Affiliated Hospital of Gannan Medical University (GMU) and Aneurysm Detection and segMentation Challenge 2020 (Adam2020, https://adam.isi.uu.nl/). The specific process of our method is as follows: first, the original MRA images of desensitized intracranial aneurysm patients were pretreated. Next, an OTO-Net for intracranial aneurysms automated segmentation in MRA images was proposed. Then, the OTO-Net model was trained on the preprocessed datasets. Finally, the generalization ability of the OTO-Net model is validated by model testing and evaluation indexes. The flow chart of this experimental research is shown in Figure 1.

3. Methodology

The purpose of this paper is to realize the accurate and automated segmentation of intracranial aneurysms in MRA images. Therefore, we designed a novel OTO-Net model, which was based on the idea of fully convolutional networks with three consecutive encoding and decoding structures. The process of data preprocessing, OTO-Net network structure, and loss function used were introduced in this section.

3.1. Data Preprocessing. MRA image is a 3D data structure, and the 2D network-based segmentation model needs to slice it. The sliced data is 2D data, making the model unable to learn the structural relationship between layers in the data, leading to insufficient network model learning. Therefore, to preserve the spatial expression of intracranial aneurysms, we decided to use 3D data as the model's input. For radiologists' observation and analysis of images, 3D data has significant value in clinical diagnosis and treatment. Below we will elaborate on the 3D image preprocessing method.

3.1.1. Overlapping Blocks. Due to the limitation of GPU memory resources, MRA images cannot be input into the original size network, so the 3D MRA images must be processed in blocks. The paper introduces two chunking methods, namely nonoverlapping block and overlapping block, the structure of which is shown in Figure 2.

The dimension size of the input data of the network structure we designed is $128 \times 128 \times 64$. Here, an MRA image with a size of $512 \times 512 \times 128$ in the dataset is taken as an example. If the same nonoverlapping partitioning processes the original image and the label image, then the step size of each partitioning operation in the X and Y directions is equal to 128. Furthermore, there is no overlap between the data blocks, so the X and Y directions are divided into four blocks, respectively. Similarly, if the Z step equals 64, it is split into two pieces.

Although 3D data as input solves the structural relationship between the layers of the learning model, nonoverlapping block processing contains up to 64 layers of image information, and the data blocks are still disconnected

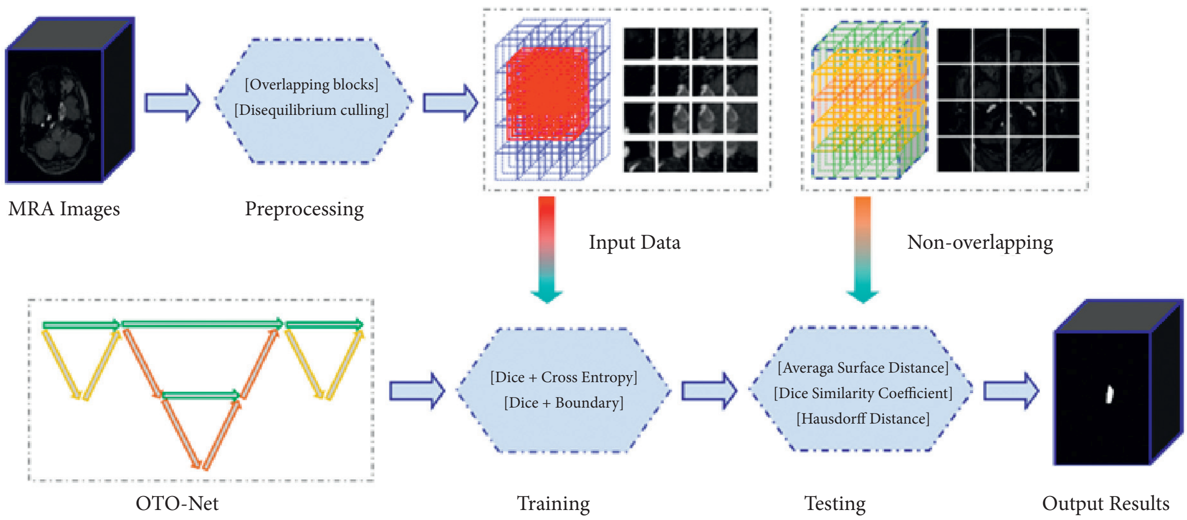

Figure 1: Procedures of our OTO-Net for intracranial aneurysms automated segmentation in MRA images.

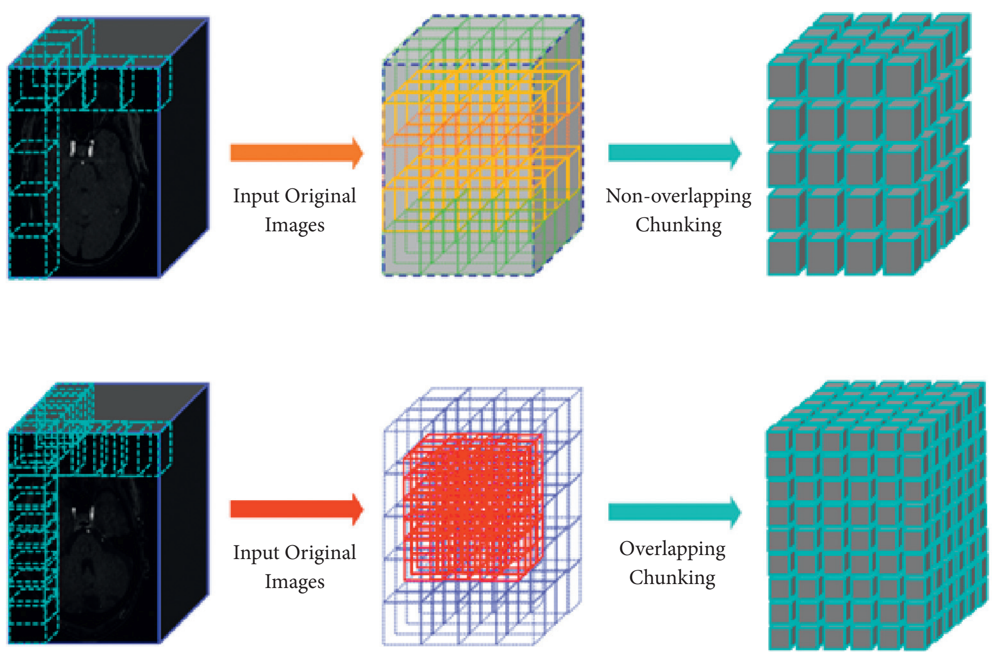

Figure 2: Nonoverlapping chunking and overlapping chunking.

from each other, making the complete structure unable to be learned. It is similar to the slice image input from the 2D network model. Therefore, we propose an overlapping division method to alleviate this problem. The size of the block remains the same. The step size of the original image and the label image that move simultaneously in the X, Y, and Z directions is smaller than the block size. Although it increases the number of blocks, the advantage is that there is absolute information correlation between blocks.

3.1.2. Disequilibrium Culling. After the block processing, a 3D original image and label image are cut into many $128 \times 128 \times 64$ data blocks. Since the lesion area only occupies a small part of the brain, the block processing partnership will contain the nonlesion blocks. If these data blocks are used together as input data for the model, the class imbalance will be caused, and the model's learning process will be troubled.

Therefore, to mitigate category imbalance in this study, the label image data block is further screened after the chunking process. If there is no data more significant than 0 in the data block, the lesion area is not included, the original image and label image data block would be discarded.

3.2. Model Design. The OTO-Net is a model based on 3D fully convolutional networks. Its main structure takes advantage of the encoder-decoder proposed by Hinton et al. [35] in 2006. The most significant feature of the OTO-Net

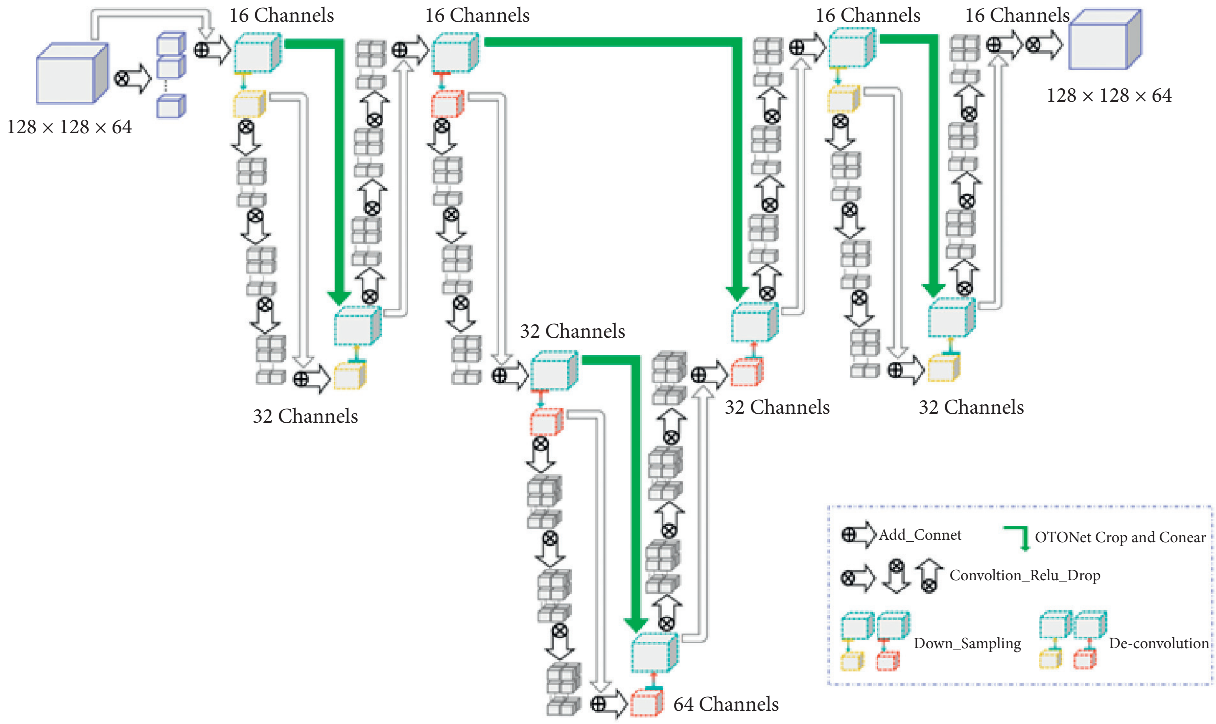

Figure 3: Overall architecture of our proposed OTO-Net.

structure is the continuous use of three complete encoding and decoding structures to achieve the purpose of accurate detection and segmentation of intracranial aneurysms. The whole network still presents an entirely symmetrical design. The schematic diagram of OTO-Net is shown in Figure 3.

In the OTO-Net structure designed by us, the convolution kernel uses $3 \times 3 \times 3$ voxels, assigns 'SAME' mode to supplement data, and selects ReLU as the activation function. The three complete encoding and decoding structures in OTO-Net are used in downsampling, upsampling, and skip connection. First, the input data of $64 \times 128 \times 128 \times 1$ was received. And then, the convolution check with $3 \times 3 \times 3$ voxels with the convolution step of [1] was performed for two convolution operations. Finally, Layer 1 was obtained by adding the first and second convolution layers.

After being downsampled with a convolution kernel step size of [1, 2], the network structure of Layer1 changes from 16 channels to 32, and then, perform three successive convolution operations and add the downsampled layer and the third convolutional layer to get Layer2. Subsequently, deconvolve Layer2. Moreover, the convolution kernel size was still [1, 2], so the channels changed from 32 to 16. After skip connection between the deconvolution layer and Layer1 stack operation, three consecutive convolution operations and the deconvolution layer are added to obtain Layer3, whose size is the same as Layer1. At this point, the first complete encoding and decoding structure is completed.

Except for the second encoding and decoding structure is different from the first structure, two consecutive downsampling and then two successive upsampling are used, while the third is the same as the first structure. When the OTO-Net structure enters Layer 9, the layer's size is the same as that of Layer1 again. Finally, it passes through the output layer's convolution operation and uses the Sigmoid activation function to map out the prediction result of the size of $64 \times 128 \times 128 \times 1$. The theoretical calculation of network parameters of the OTO-Net structure is shown in Table 1.

Table 1: Parameter details of the proposed OTO-Net.

Layer	Input size	Kernel
O^{I}-Stage1	128	$3 \times 3 \times 3 \times 16 \times 16$
O^{I}-Stage2	64	$3 \times 3 \times 3 \times 32 \times 32$
T-Stage1	128	$3 \times 3 \times 3 \times 16 \times 16$
T-Stage2	64	$3 \times 3 \times 3 \times 32 \times 32$
T-Stage3	32	$3 \times 3 \times 3 \times 64 \times 64$
T-Stage4	64	$3 \times 3 \times 3 \times 32 \times 32$
T-Stage5	128	$3 \times 3 \times 3 \times 16 \times 16$
O^{II}-Stage1	64	$3 \times 3 \times 3 \times 32 \times 32$
O^{II}-Stage2	128	$3 \times 3 \times 3 \times 16 \times 16$

3.3. Loss Ensembles. The loss function, also known as the objective function, solves and evaluates the model by minimizing it, so it is crucial for model construction. Medical images usually have a characteristic that the target area to be segmented is unbalanced with the background area. To solve this problem, Milletari et al. proposed a new objective function in the V-Net structure, which had an immediate effect because the Dice coefficient was cited [36]. Since then, Dice loss has become one of the most critical evaluation indexes of medical image segmentation.

Nevertheless, as Figure 4 shows, intracranial aneurysms account for a tiny proportion of the entire brain, and the

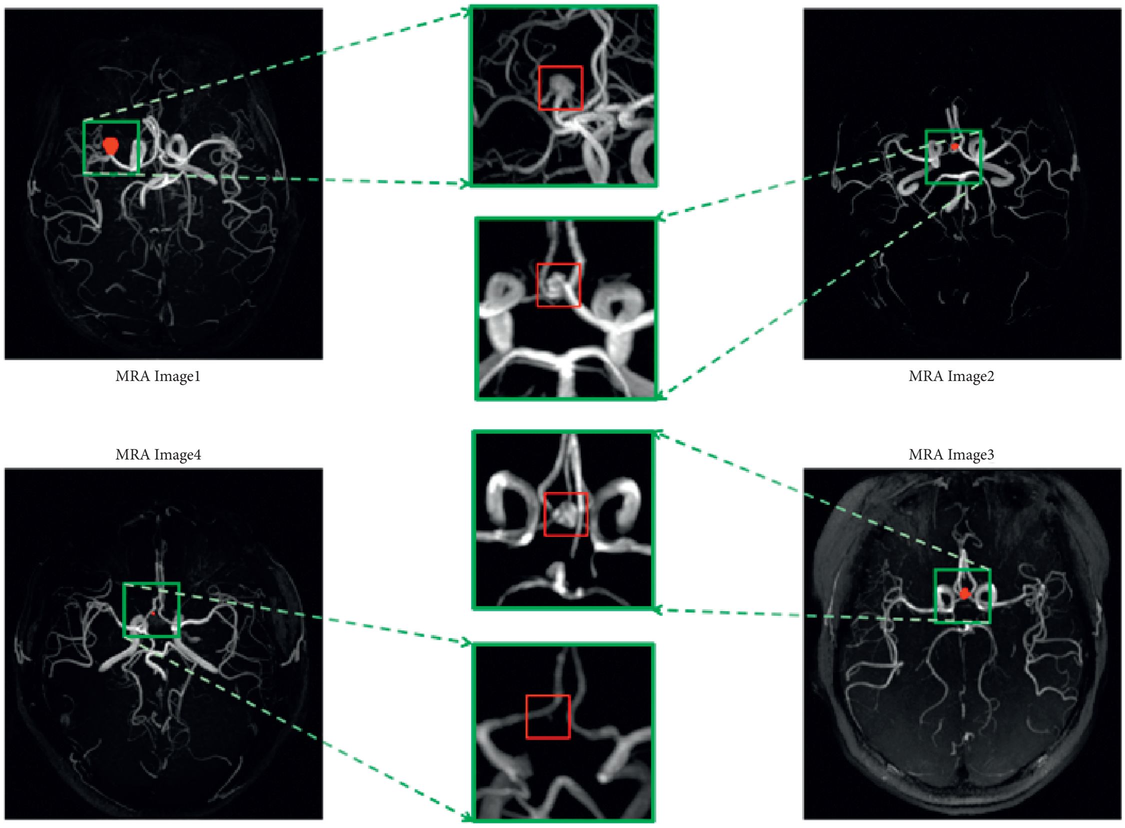

Figure 4: Morphology of intracranial aneurysm at high magnification.

foreground and the background are highly imbalanced. Therefore, we propose an objective function optimization for loss ensembles, including the comparative experiment between Dice loss + Cross-Entropy loss and Dice loss + Boundary loss. The principles of each are described in detail in the following sections.

3.3.1. Dice Loss. Dice coefficient is a set similarity measurement function, which is usually used to calculate the similarity between two samples, and its value ranges between [0, 1]. The formula is as follows:

$$s = \frac{2|\mathbf{A} \cap \mathbf{B}|}{|\mathbf{A}| + |\mathbf{B}|}, \tag{1}$$

where $|\mathbf{A} \cap \mathbf{B}|$ represents the intersection of set $\mathbf{A}$ and set $\mathbf{B}$, $|\mathbf{A}|$ and $|\mathbf{B}|$ represents the number of elements of set $\mathbf{A}$ and set $\mathbf{B}$, respectively. And the coefficient 2 in the numerator is to eliminate the common component of double calculation in the denominator. For semantic segmentation, p represents the predicted image and g represents the label image. Thus, Dice loss can be expressed as follows:

$$L_{dice} = 1 - \frac{\left(2\sum_{i=1}^{N} p_i g_i\right) + w}{\left(\sum_{i=1}^{N} p_i^2 + \sum_{i=1}^{N} g_i^2\right) + w}, \tag{2}$$

where w is known as the smoothing coefficient, a minimal number. And it is used to prevent the denominator from being 0. Although Dice loss has a good performance in the scenario where there is a severe imbalance between positive and negative samples and focuses more on the mining of foreground area in the training process, it also has disadvantages. Loss is prone to be unstable, especially in small targets, which will lead to gradient saturation in extreme cases. Therefore, we propose a loss ensembles optimization method to solve these problems.

3.3.2. Cross-Entropy Loss. Suppose two different probability distributions, $P(x)$ and $Q(x)$, for the same random variable X. In that case, we can use relative entropy (KL divergence) [37] to measure the difference between these two probability distributions. The formula is expressed as follows:

$$D_{KL}(PQ) = \sum_{i=1}^{N} P(x_i)\log\left(\frac{P(x_i)}{Q(x_i)}\right), \tag{3}$$

$$D_{KL}(PQ) = -H(P(x)) + \left[-\sum_{i=1}^{N} P(x_i)\log(Q(x_i))\right]. \tag{4}$$

KL divergence formula (4) can be obtained by further deformation from (3), where the former represents information entropy and the latter represents cross-entropy, that is, KL divergence = cross-entropy − information entropy.

In the model training process, since the input data and labels have been determined, and the true probability distribution $P(x)$ has also been determined, the information entropy is constant. In addition, since the value of KL

Ex11	1613	0.001	0.5	150	2
Ex12	1613	0.001	0.5	150	2

divergence represents the difference between the true probability distribution $P(x)$ and the predicted probability distribution $Q(x)$, the smaller the value, the better the prediction result. Therefore, it is necessary to minimize the KL divergence to obtain the best results. It is easier to calculate using the cross-entropy loss function as the objective function. Replace $P(x)$ with $g(x)$ and $Q(x)$ with $Q(x)$. The formula of cross-entropy loss can be expressed as follows:

$$L_{ce} = -\sum_{i=1}^{N} g(x_i)\log(p(x_i)), \tag{5}$$

where the former represents the KL divergence, and the latter is a constant.

3.3.3. Boundary Loss. Boundary loss is an objective function proposed by Kervadec et al. to solve the difficulty of highly unbalanced segmentation [38]. The core of the method is to calculate the distance between the predicted image and the boundary of the marked image through calculus. The calculation formulas are as shown in (6) and (7), respectively:

$$\mathrm{Dist}(\partial G, \partial S) = \int_{\partial G} \left\| y_{\partial S}(p) - p \right\|^2 \mathrm{d}p, \tag{6}$$

$$\mathrm{Dist}(\partial G, \partial S) \approx 2\int_{\Delta s} D_G(q)\mathrm{d}p. \tag{7}$$

Since the distance differential expression (6) cannot be used as a loss function, the integral expression (7) is adopted. The crucial region $\triangle S$ is divided into S and G, and the binary indicators function $s(q)$ and $g(q)$ about segmentation and ground truth are introduced so that the integral region extends from S and G to the entire image domain.

$$\Delta S = \left(\frac{S}{G}\right) \cup \left(\frac{G}{S}\right), \tag{8}$$

$$\begin{aligned}\frac{1}{2}\mathrm{Dist}(\partial G, \partial S) &= \int_S \phi G(q)dq - \int_G \phi G(q)dq \\ &= \int_\Omega \phi G(q)s(q)dq - \int_\Omega \phi G(q)g(q)dq.\end{aligned} \tag{9}$$

Then we replaced $s(q)$ in formula (9) with $S(q)$, which established a connection with the softmax output of the network. At this point, we can obtain the Boundary loss function expression (11):

$$\min_\theta Di\ st(\partial G, \partial S_\theta) \approx \int_\Omega \phi G(q)S_\theta(q)dq - \int_\Omega \phi G(q)g(q)dq, \tag{10}$$

$$L_B(\theta) = \int_\Omega \phi G(q)S_\theta(q)dq. \tag{11}$$

4. Experiments

4.1. Datasets. In the study, we evaluated the proposed OTO-Net on one public benchmark dataset and one private dataset used to train, evaluate and objectively compare the performance of standardized intracranial aneurysm MRA data segmentation algorithms. First, we use the Adam2020 dataset. A set of 255 representative intracranial aneurysm MRA data is shared on the challenge website (https://adam.isi.uu.nl/) [2]. Adam2020 dataset includes 113 training data and 142 test data, and about 32 epochs are needed for training the model. In addition, the second in-house private dataset is provided by the First Affiliated Hospital of Gannan Medical University (GMU dataset). In total, 65 clinical intracranial aneurysm MRA data are provided with manual segmentation labels to verify the model, including 30 training data and 35 test data. It takes about 27 epochs to train the proposed OTO-Net with GMU dataset.

4.2. Evaluation Metrics. In order to have a more systematic evaluation of the effect of segmentation, we have stipulated the following indicators as the evaluation metric. The Average Surface Distance (ASD) refers to the average surface distance of all points in the 3D data block. It is a commonly used evaluation index in medical image segmentation tasks, and its mathematical definition can be expressed by the following formula:

Table 4: Evaluation index and a comprehensive score of each experimental model.

Experiment	Time (h)	ASD	DSC	95% HD	Comprehensive ranking
Ex1	11.5	3.562 ± 0.77	0.9391 ± 0.023	7.332 ± 2.31	12/12 + 11/12 + 12/12 = 2.91
Ex2	11.7	2.409 ± 0.26	0.9502 ± 0.032	3.053 ± 1.11	9/12 + 10/12 + 8/12 = 2.25
Ex3	12.1	**0.706 ± 0.05**	0.9672 ± 0.020	2.751 ± 1.29	1/12 + 7/12 + 7/12 = 1.25

Ex11	40.1	0.905 ± 0.11	0.9761 ± 0.007	1.041 ± 0.31	3/12 + 2/12 + 4/12 = 0.75
Ex12	40.6	0.753 ± 0.03	**0.9813 ± 0.008**	0.642 ± 0.17	**2/12 + 1/12 + 2/12 = 0.33**

$$ASD = \frac{\sum_{a\in S(A)} \min_{b\in S(B)} \|a-b\| + \sum_{b\in S(B)} \min_{a\in S(A)} \|b-a\|}{|S(A)| + |S(B)|}. \quad (12)$$

Next, since Dice Similarity Coefficient (DSC) is equivalent to equation (1), and the sum of Dice loss and DSC is 1. Based on the above conditions, DSC can be expressed as follows by the following formula:

$$\mathrm{DSC} = \frac{2\sum_{i=1}^{N} p_i g_i}{\sum_{i=1}^{N} p_i^2 + \sum_{i=1}^{N} g_i^2}. \quad (13)$$

If DSC is sensitive to internal filling, Hausdorff distance (HD) focuses on calculating segmentation boundaries. Hausdorff distance is a maximum function describing set A to set B. And the general definition can be expressed by the following formula:

$$\mathrm{HD}(C,D) = \max\{h(C,D), h(D,C)\}, \quad (14)$$

where $h(C,D)$ is called the directed Hausdorff distance and given by $h(C,D) = \max_{a\in C}\min_{b\in D}\|a-b\|$, where $\|a-b\|$ is some norm. In all HD calculations, the maximum distance quantile is set to 95%. The purpose is to eliminate the little distance caused by some outliers to ensure the overall value's stability.

4.3. Experimental Details. We use the V-Net model and the OTO-Net model for comparative experiments. As mentioned in the previous article, we used the comprehensive objective function of Dice loss + Cross-entropy loss and Dice loss + Boundary loss in the training process. The intracranial aneurysm segmentation study provided two datasets, so we designed Table 2 that shows the experimental protocol.

4.4. Training Process. As shown in Table 3, to meet the experimental conditions of the control group without limiting the optimal performance of the model, we reasonably set the training parameters of each group of experiments, such as learning rate, dropout, epoch, and batch size.

In this study, we used the python-based PyCharm framework to implement the preprocessing and our proposed OTO-Net model, including the software packages such as 1.19.2 NumPy, 3.1.1 Nibabel, 2.0.0 SimpleITK, 1.1.2 Pandas, 4.4.0 OpenCV, and the GPU version of 1.13.1 TensorFlow. The workstation is installed with the Window10 system, equipped with two Intel(R) Xeon(R) Silver 4210 CPU @2.20 GHz, one NVIDIA TITAN RTX 24 GB GPUs, and 128G running memory. All different modes were tested under the same GPU and environment.

5. Results and Discussion

5.1. Results. After completing the model's training process, we tested its segmentation detection performance. Evaluation indicators can be considered as the most intuitive manifestation of results. As shown in Table 4, we used the ASD, DSC, and HD three indicators introduced in the previous article to compare and evaluate the effects of all experimental groups. The last column of the table—comprehensive ranking is the cumulative sum of the scales of each group in the three indicators. It can be implied by its definition that the smaller the value, the higher the overall performance of the corresponding model.

By observing and comparing the experimental data, it can be concluded that Ex3, Ex5, and Ex12 rank first in the three indicators of ASD, HD, and DSC, respectively, and Ex12 is the best in the overall ranking. Combined with the experimental model design, they use all OTO-Net. Therefore, we have reason to believe that O's segmentation effect on V has been further improved. In addition, for another experimental variable loss function, we found that the overall rankings of Ex1, Ex4, Ex7, and Ex10 that only use the dice objective function are relatively low, and the loss ensembles play a critical role in improving the segmentation performance.

We comprehensively analyze and calculate the results of 6 sets of experiments and finally conclude that the accuracy of the OTO-Net model on the GMU and Adam2020 datasets is 98.37% and 97.86%, respectively. The accuracy is the ratio of the correct prediction area to the target area. Ex5 ranked first in the GMU dataset, with ASD reaching 1.989, DSC reaching 0.9721, and HD reaching 0.578 mm; Ex12 ranked first on the Adam2020 dataset with ASD of 0.753, DSC of 0.9813, and HD of 0.642 mm. We have noticed that this model performs better on the Adam2020 dataset and believe

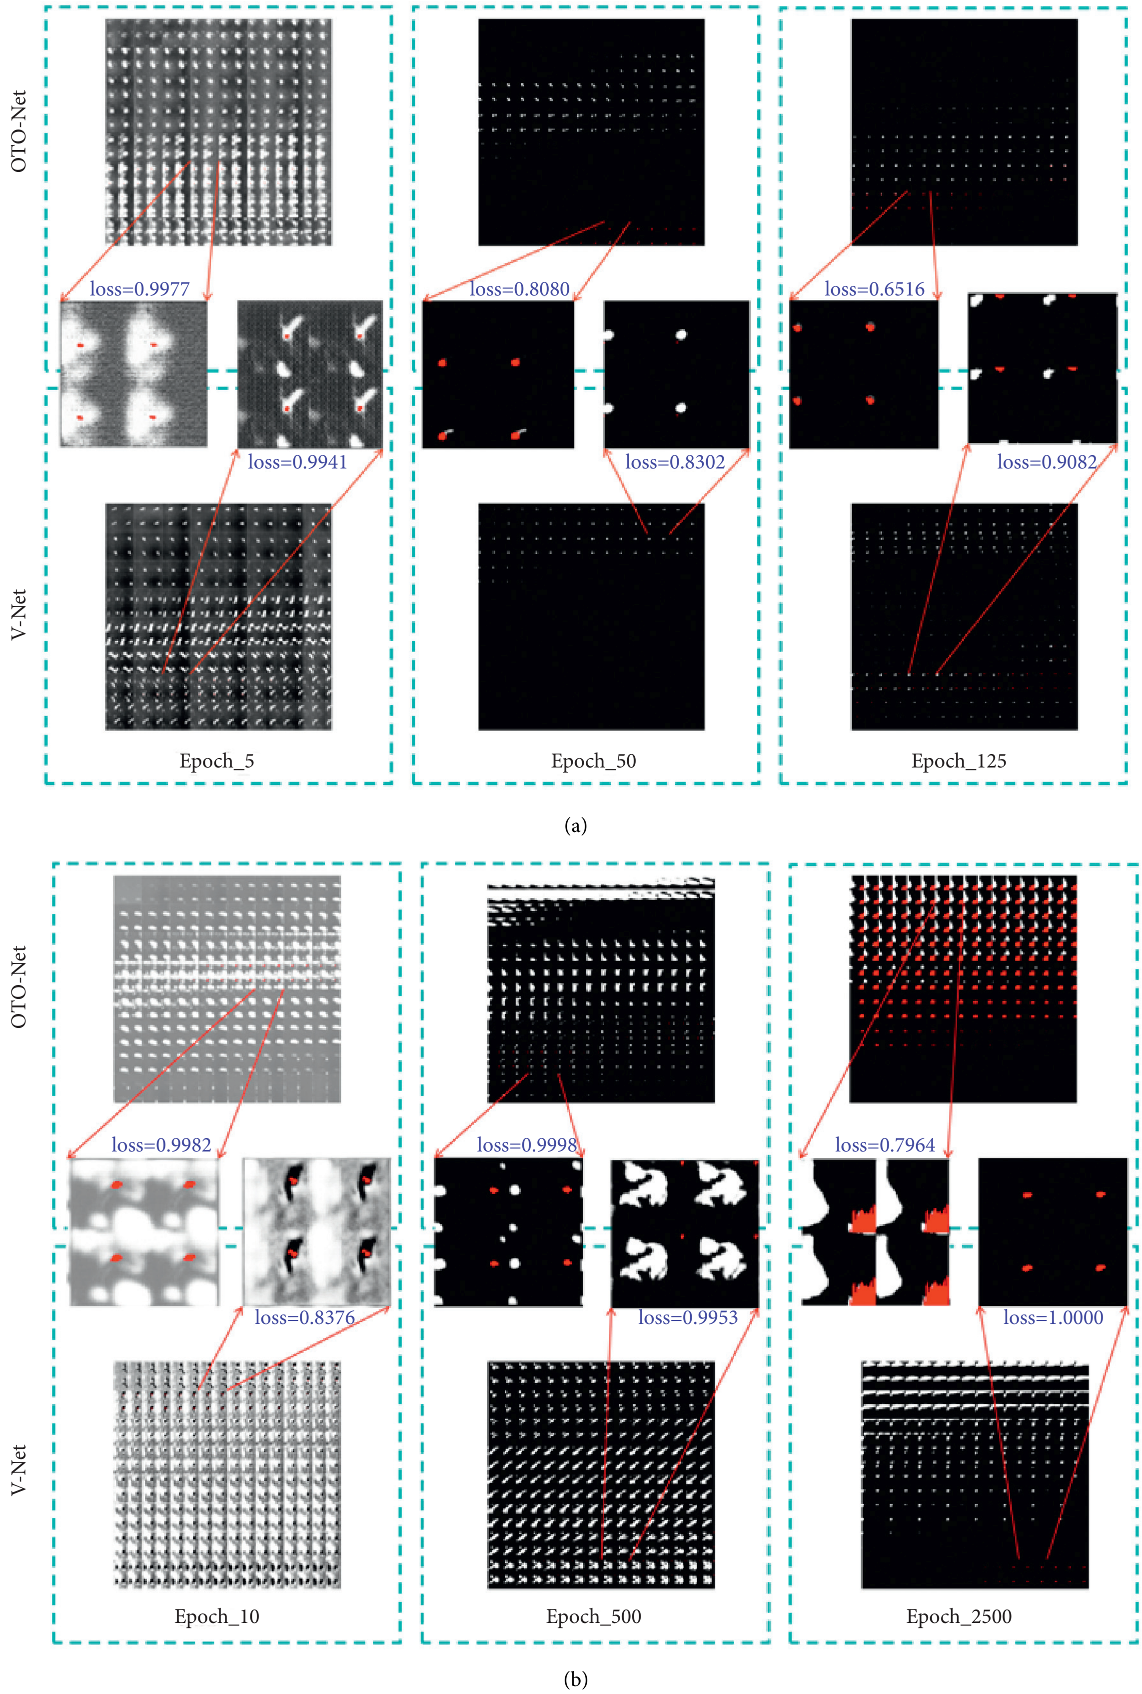

Figure 5: Prediction results comparison between the OTO-Net and V-Net: (a) GMU dataset, (b) Adam2020 dataset.

Table 5: RSS calculation results for each loss curve.

	Ex1/Ex7	Ex2/Ex8	Ex3/Ex9	Ex4/Ex10	Ex5/Ex11	Ex6/Ex12
Residual sum of squares (RSS)	17.7597	17.0351	18.1124	15.9172	**15.1319**	17.0053
	19.8024	19.0271	21.9512	16.3814	18.7011	**16.1217**

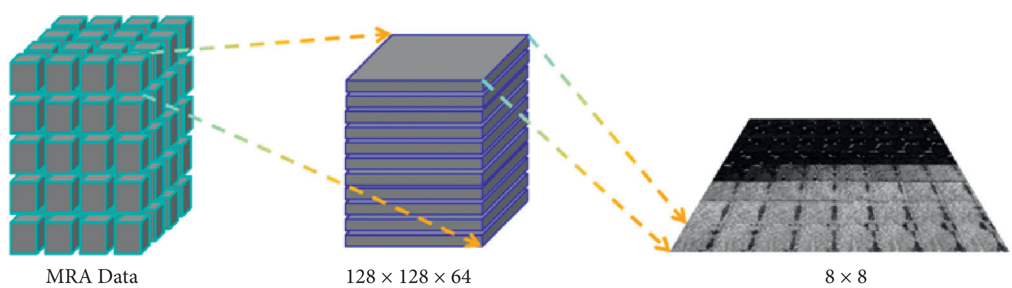

Figure 7: Test set nonoverlapping block processing.

that the reason is that the data contained in it is more standardized.

For the clinician's diagnosis, the most intuitive and effective way of presentation is the visualization of the segmentation results. Both OTO-Net and V-Net mentioned in this article have end-to-end characteristics, so the output data size is still $128 \times 128 \times 64$. To preserve the predicted results in the model training process, we converted the $128 \times 128 \times 64$ 3D data blocks into 64 128×128 2D images and then merged them into 8×8 images. The smaller the inference cycle of the model is, the faster the inference speed is, and the stronger the model's performance is. When the reasoning cycles are the same, the reasoning cycles' size can be evaluated by comparing the value of dice loss, and then the performance of the model can be judged.

As shown in Figure 5(a), (a) is the comparison between the prediction results of OTO-Net and V-Net on the GMU dataset in the 5th, 50th, and 125th rounds of the inference period and the standard; (b) is the comparison between the prediction results of OTO-Net and V-Net on the Adam2020 dataset in the 10th, 500$^{\text{th}}$, and 2500th rounds of the inference period and the standard. By comparing the four groups of data, it can be found that the dice loss values of Ex5 and Ex12 are significantly smaller, indicating that their predicted results are more similar to the standard. Therefore, the model structure of Ex5 and Ex12 is superior.

On this basis, to observe the loss values of each group of experiments in the training process, Figures 6(a) and 6(b) recorded and described the dynamic change curves of training loss of 12 groups of experiments GMU and Adam2020 datasets, respectively. The volatility of the loss curve is one of the important indexes to measure the model's stability. As shown in Table 5, by calculating the residual sum of squares (RSS) of each loss curve, the volatility of the loss's discrete value was characterized by a quantity that measured

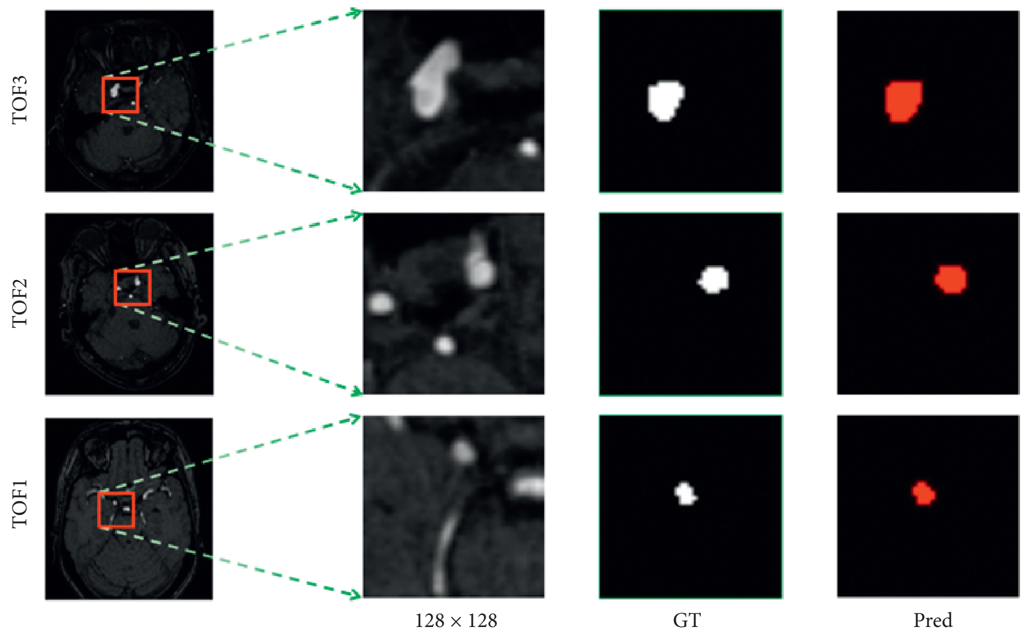

Figure 8: Visualization results of the intracranial aneurysms segmentation using the proposed OTO-Net on GMU dataset.

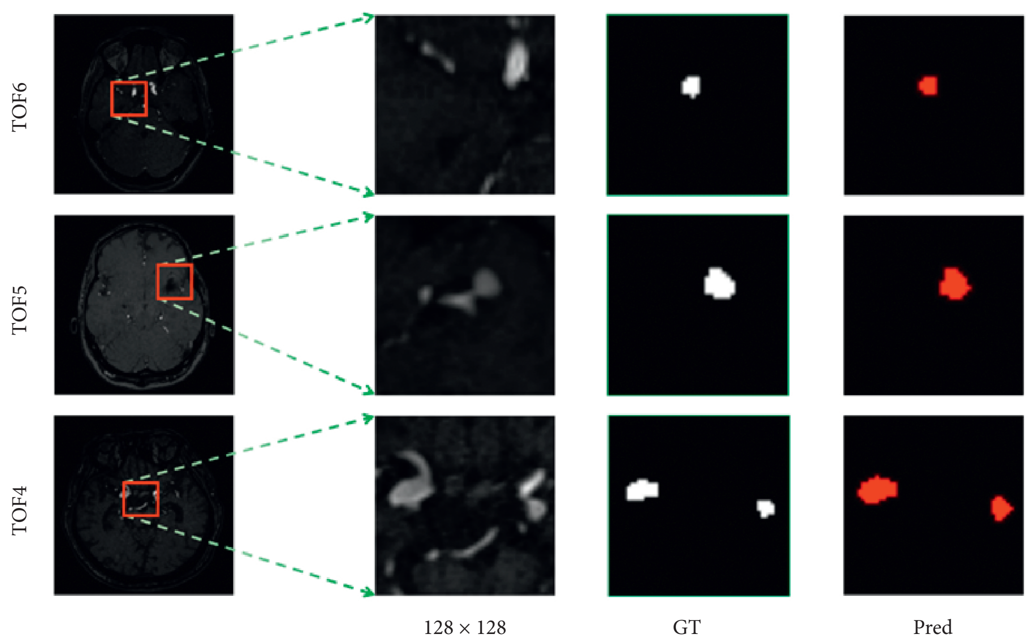

Figure 9: Visualization results of the intracranial aneurysms segmentation using the proposed OTO-Net on Adam2020 dataset.

Table 6: Evaluation indexes of six MRA image test sets.

Test	Dataset	ASD	DSC	95% HD
TOF1	GMU	0.982	0.9604	0.812
TOF2	GMU	**0.699**	0.9711	0.640
TOF3	GMU	0.704	0.9622	**0.506**
TOF4	ADAM2020	1.105	0.9730	0.618
TOF5	ADAM2020	0.786	**0.9803**	0.574
TOF5	ADAM2020	1.032	0.9705	0.713

the degree of model fit in the linear model. The smaller the matter is, the smaller the fluctuation is, which means that the model tends to be more stable. By comparing the data in the table, it can be seen that the RSS values of Ex4~6 and Ex10~12 are small, so the model structure is more stable.

To sum up, all the experimental data, respectively, reflect the excellent effects of training stability, segmentation accuracy, and generalization ability, which effectively verify the advancement of the OTO-Net structure and loss ensembles proposed by us.

5.2. Discussion. After introducing the process and results of this experiment, it can be seen that OTO-Net with loss ensembles shows high overall accuracy and robustness in the segmentation of highly unbalanced intracranial aneurysms. As shown in Figure 7, the test samples divided in advance by GMU and Adam2020 datasets were first processed by nonoverlapping block processing, respectively, to obtain multiple test datasets with the size of $128 \times 128 \times 64$, and then input them into OTO-Net, respectively, for prediction.

Figures 8 and 9 respectively, show the three groups of MRA image results predicted by the OTO-Net model on the GMU dataset and the Adam2020 dataset. Because the intracranial aneurysm was too small, we enlarged and clipped the target region to have a precise observation of each result. Observation of the predicted results shows that OTO-Net can still achieve pixel-level segmentation requirements, but for tiny intracranial aneurysms, it is difficult for OTO-Net to achieve absolute precision segmentation in some marginal areas. In order to quantitatively discuss the prediction results, three indicators of ASD, DSC, and HD of the six groups of test data were counted, respectively. As shown in Table 6, ASD of TOF2 reached 0.699 and HD of TOF3 reached 0.506 mm, both of which were higher than the maximum values of the training results. The maximum value of DSC is 0.9803, which is slightly inferior to the maximum value of training.

In order to increase the persuasiveness of the results of the article, we must effectively compare it with the results of previous studies. However, by reading a large number of documents, we can see that few studies overlap entirely with the research field of this article, which fully proves that the idea of the article is quite innovative. The model proposed by Sichtermann et al. has a system with a maximum overall accuracy of 90% for detecting intracranial aneurysms and an accuracy of 96% for aneurysms with a diameter of 3–7 mm, which is lower than the segmentation result obtained by this model [39].

Therefore, it can be seen from the whole that the current research results show that OTO-Net has a high level of segmentation accuracy for large, medium, and small regions and multiregions. OTO-Net is fully competent to assist radiologists in quantitative analysis and evaluation of MRA examination in patients with intracranial aneurysms. Accuracy is the most important index in the field of medical image processing. There is no upper limit to this index, so our current research needs to be more in-depth and detailed.

6. Conclusion

This study proposed the OTO-Net model for intracranial aneurysms automated segmentation in MRA images and performed experiments on the Adam2020 dataset and GMU dataset, respectively. We designed a novel 3D image preprocessing scheme to correlate the structural information between data blocks through overlap and partition operations. At the same time, we proposed the OTO-Net for intracranial aneurysms automated segmentation in MRA images. The OTO-Net uses full convolution to achieve intracranial aneurysms automated segmentation through the combination of downsampling, upsampling, and skip connection. In addition, loss ensemble is used as the objective function to steadily improve the backpropagation efficiency of the network structure during the training process. We evaluated the proposed OTO-Net on one public benchmark dataset and one private dataset. Our proposed model can achieve the automated segmentation accuracy with 98.37% and 97.86%, average surface distances with 1.081 and 0.753, dice similarity coefficients with 0.9721 and 0.9813, and Hausdorff distance with 0.578 and 0.642 on these two datasets, respectively. Therefore, our proposed OTO-Net plays an essential role in radiologists' assisted discovery and diagnosis of intracranial aneurysms and brings substantial value to intelligent medicine's advancement and development. The next research direction is to better use the transformer and 3D information to segment intracranial aneurysms in MRA images.

Data Availability

The raw/processed data required to reproduce these findings cannot be shared at this time as the data also forms part of an ongoing study.

Ethical Approval

The studies involving human participants were reviewed and approved by Institutional Review Board (IRB), Gannan Medical University.

Consent

The patients/participants provided their written informed consent to participate in this study.

Conflicts of Interest

No conflicts of interests, financial or otherwise, are declared by the authors.

Authors' Contributions

This paper discusses the development of new hardware and software for protecting access to HMI/SCADA systems via Unprotected Internet Networks (UPN), mainly when working remotely with confidential information. Based on the analysis carried out, it is shown that the existing vulnerabilities can be exploited by cybercriminals to steal passwords and user authentication logins. Modern protection technologies based on the OTP method have been investigated. Moreover, a new concept of information security for user authentication in UPNs when working with information remotely is proposed. The structure of the electronic key and the connection diagram based on the selected hardware modules have been developed. In addition, the two-level user identification algorithms and the firmware program code for the ATmega32U4 microcontroller are considered. Finally, to show the reliability and stability of the of the developed electronic user authentication key against any unexpected software hacking, a number of experiments have been performed.

1. Introduction

Industry 4.0 is a new vision in production associated with the introduction of modern digital technologies, such as Industrial Internet of Things (IIoT), Machine-to-Machine (M2M), Operation 4.0 (Ops 4.0), Big Data (BD), Cloud Computing (CC), and integration of Robotic Process Automation (RPA) with Artificial Intelligence (AI) [1]; these technologies facilitate the achieving of implementing new models for managing the production processes. One of the current ideas about modern production has found its reflection in the concept of Smart Manufacturing (SM). SM is a production concept that implements computer integration, and a high level of adaptability and a rapid change in production levels, which depends on the demand and the required tasks to solve [2]. Moreover, [2] showed that for the usage of digital information techniques that can be implemented for more flexible multiscale dynamic production systems, a single end-to-end industrial network based on IIoT is required. Indeed, the single end-to-end industrial network provides the access to the global Internet network, which supports the connection to all information control actions, besides the interaction with all constituent elements of the SM. However, implementing end-to-end systems may worsen the vulnerability of the MS systems, as a result of the information loss risk and distortion that carried out by the cyberattacks from the Internet uncontrolled sources, which could cause high economic losses and even man-made disasters. Therefore, when applying the end-to-end systems, protecting production information from the cyberattacks becomes a priority; as an example, the Stuxnet worm affected the access to the information from industrial systems Simatic WinCC SCADA [3]. Another example is the Bushehr nuclear power plant in Iran, where a worm disabled a large number of uranium enrichment centrifuges controlled by the Variable-Frequency Drive (VFD). Similarly, [4] presented the theft of IIoT production files from a Korean nuclear power plant in 2014. Indeed, the examples in [3, 4] show the urgent need to protect the access to the production SCADA/HMI information from external unprotected IoT networks during far-distance work of enterprise employees.

The work of Ali Süzen indicates that a threat of cyberattack is always present as long as there is available digital data [5]; consequently, the need for high level of cyber security is increasing. Moreover, [5] conducts valuable research into the threat of the cyberattacks sources in the Industry 4.0 ecosystem, which are listed below:

(i) Unsecured device connections in the control system protocols.
(ii) The lack of regular penetration tests.
(iii) The lack of ability to effectively manage network devices, mainly by untrained personnel, resulting in the shortage of complete prevention of the cyberattacks in the Industry 4.0 ecosystem [5].

Pang et al. proposed a new two-stream structure of SM includes specifications, organizational architecture, security, user access, databases, and hardware and software requirements [6]. However, [6] indicated that the standard solutions are left for enterprise cyber security.

The authors Efe and Isik in their publications classify the types of vulnerabilities that need to be considered and resolved in an enterprise to counter cyberattacks and increase cybersecurity [7]. However, the authors consider solutions to SM cyber security issues, only on the basis of case studies, which are not specific, but generalized in nature.

Mullet et al. evaluate methodologies and technical solutions from classic countermeasures to cyberattacks to innovative ones, for example, based on decoys and digital twins [8]. As a result, the authors have given recommendations on the cyber protection of SM, which are of a general nature without a specific solution.

The proposed new methodology for the semantic expansion and improvement of cyber security models is presented in the work of Laković et al. [9], which allows quantifying the level of existing cyber security SM, through adapted methods. At the same time, the authors do not consider security issues at the SCADA/HMI, MES, and ERP levels.

In Ferencz et al.'s article, the authors conduct MS research from a security perspective, focusing on the integration of IoT devices, and propose a theoretical architecture for the integration of SOC and IoT [10].

On the other hand, Sharma introduces the vulnerabilities and defines a cyber-defense strategy for corporate and end users, who are instructed to simultaneously implement preventive protection measures [11].

Naanani and Humayun in their work carried out a detailed review of possible cyberattacks targeting each level of Industry 4.0, as well as the consequences of these attacks and the corresponding countermeasures [12]. In addition, a multilayered framework is presented that can provide end-to-end protection against cyberattacks; however, this structure has a minimum level of protection on the Application Layer, against theft of usernames and passwords using the Phishing and Social Engineering methods to access the SCADA/HMI, MES, and ERP levels [13, 14], besides the ability to cyberattack the PLC, SCADA/HMI levels, which can lead to disruption of physical production processes.

In the work of Gómez et al., the issues of PLC, SCADA/HMI protection are considered by finding anomalies in control networks [15].

Based on the analysis of [15], it can be seen that they are aimed at tracking the possibility of a cyberattack within the IIoT network, while not paying attention to the issue of protecting the username and password from theft when logging into the SCADA/HMI system. So if the username and password are stolen, the system will consider that the user is identified with certain access parameters, resulting in making the system to be insecure and vulnerable to industrial espionage and cyberattacks.

Based on the above, in order to prevent the above commented-on errors and take into account possible other errors, the proposed work in this paper is directed to the following guidelines:

(i) Analyzing modern methods and technologies for user authentications; taking into account the positive aspects and identifying flaws; and developing a new concept of protecting user authentication information using modern software and hardware.
(ii) Considering the possibility of minimizing the influence of the human factor on the loss and disclosure of the username and password content and conducting researches to resist the hacking.

2. General Concept of Information Protection Using Electronic Keys for User Authentication

Cracking a password is one of the most common types of attacks on any information system that uses password or username-password pair authentication. The essence of the attack boils down to the seizure of the password of the user who has the right to enter the system. In this case, the following approaches can be used [16]:

(i) Direct search: Enumeration of all possible combinations of characters allowed in the password.
(ii) Selection by dictionary: The method is based on the assumption that existing words of any language or their combinations are used in the password.
(iii) Method of social engineering: Based on the assumption that the user used personal information as a password, such as the first or last name, date of birth, and so on.

The attackers' goal is to obtain the password to guarantee granting all the rights that the original user holds. At the same time, logging in under an existing account that does not arouse suspicion among system administrators and enterprise security systems.

Therefore, the reliability of the authentication using a password or a "username-password" pair is determined by the following criteria:

(i) Length (the number of characters that the password contains).

(ii) Complexity (the usage of the combinations: letters, symbols, and numbers).

(iii) Unpredictability (the usage of the publicly available data, nicknames, dates, or any information available on social networks).

The most common cracking methods of an authentication password or username-password pair are presented in Table 1.

The presented methods of cracking an authentication password or a "username-password" pair are implemented in the following software tools; some of the most common are presented in Table 2.

By analyzing the methods of cracking the password for authentication or username/password pairs, it can be seen that reusable passwords can be compromised. As a consequence, for the safety of working with industrial information via remote SCADA/HMI, it is necessary to consider alternative security methods, which are presented in Table 3.

Let's analyze alternative authentication methods from the point of view of their application for access to industrial SCADA/HMI in unsecured networks:

(i) Biometrics Method: in 2017, it was proved that it is possible to recreate a fingerprint pattern from photographs taken with a digital camera from a distance of three meters [36]. In 2014, the fingerprints of the Minister of Defense of Germany were shown, which recreated from official high-resolution photographs from open sources [37]. Thus, the use of biometrics methods to implement access to industrial SCADA/HMI can be considered irrelevant and easily vulnerable.

(ii) The Single Sign-On (SSO) method is based on setting up a trust relationship between an application known as a service provider and an access control system. The software snippet assumes local installation. This allows implementing a password store, where a single username and a single password are allowed; however, they must be entered every time to access a new application or a new site. Such a system simply stores the credentials for other applications and enters them when needed. Within the framework of these studies, this method is not suitable, since access to industrial data via SCADA/HMI is carried out through a trust relationship, and they are possible only within the industrial IIoT. Therefore, this method is not suitable for the proposed work in this paper.

(iii) The OpenID Connect method allows Internet resources to verify the identity of the user based on the authentication performed by the authorization server. For work, the RESTful API described in the specification is used. Also, OpenID Connect defines additional mechanisms for strong encryption and digital signatures. But at the same time, some researchers believe that the OpenID protocol is vulnerable to phishing attacks, when, instead of the provider, attackers direct the end user to a site with a similar design. If the user does not notice the substitution, then he enters the authentication data (login, password). As a result, attackers can present themselves to Internet resources as a given user and gain access to the information stored on these resources. Phishing attacks are also possible when a site that supports OpenID authorization is forged in order to obtain information about the user from the provider. Using the "hidden redirect" vulnerability, attackers can create the illusion for the user that the information is being requested by this site [38].

(iv) One-Time Password (OTP) is a one-time password method valid for only one authentication session. The one-time password can also be limited to a certain period of time. The advantage of a one-time password over a static password is that the password cannot be reused [39]. However, in some cases, the use of one-time passwords increases the risk of compromising the data of the entire system, since when an attacker accesses the OTP authentication server all system components will trust this server. However, this may increase the risk of transferring one-time passwords to attackers if the token is lost. It is worth mentioning here that often in the application, in addition to a one-time password, a reusable password should be entered, but it can also be compromised in the same way as a regular password. Finally, when OTP does not function correctly, the security of the system becomes vulnerable, such as increasing the validity period of a one-time password, which increases the possibility to guess the password, which what happened at the Banks of Sweden in 2005, and Citibank (USA) in 2006, where one-time passwords were obtained as a result of phishing attack [40].

The resynchronization of OTP tokens and authentication servers in time, as a result of which, at a certain moment, the server may have several "correct" one-time passwords. Suppose, for example, that the approximate desync time is 5 minutes and the OTP changeover period is 30 seconds. In such a situation, up to 10 "correct" passwords can exist simultaneously, which increases the likelihood of unauthorized access.

Table 1: Methods for cracking the authentication password or username-password pair.

Method	Description
Dictionary attack [17]	The method involves using a list of words to compare with user passwords.
Brute force attack [18]	The method uses algorithms that combine alphanumeric characters and symbols to come up with passwords for the attack. For example, a password with the value "password" can also be used like the word p @ $$ using a brute force attack.
Rainbow attack [19]	The method uses precomputed hashes (md5), a ready-made database of hashes is generated or bought, and then it is compared with the hashes to be cracked.
Guessing [20]	The method assumes guessing the most common passwords (qwerty, password, and admin). Usually used or set as default passwords. If they have not been changed or the user is careless when choosing passwords, then they can be easily compromised.
Spidering [21]	The method of social engineering. Most organizations use passwords that contain company information. This information can be found on company websites and social networks, such as Facebook, Twitter, and so on. Spidering collects information from these sources to compile word lists. The wordlist is then used to carry out dictionary and brute force attacks.

Table 2: Software tools for cracking authentication passwords.

Name of the tool	Description
John the Ripper [22, 23]	Uses command line to crack passwords. This makes it suitable for advanced users who are comfortable working with teams. It uses a wordlist to crack passwords. The program is free, but the wordlist is not.
Cain and Abel [24, 25]	Used for password cracking methods: dictionary attack, brute force, and cryptanalysis. Unlike John the Ripper, Cain and Abel uses a graphical user interface.
Ophcrack [25–27]	Is a cross-platform, Windows password cracker that uses rainbow tables to crack passwords. It works on Windows, Linux, and Mac OS. It also has a module for brute force attack attacks among other features.

Table 3: Alternative authentication methods.

Method	Description
Biometrics [28, 29]	These are unique biological and physiological characteristics that make it possible to establish a person's identity. There are five most common types of biometrics: fingerprint, facial, voice, eye iris, and palm and finger vein patterns.
Single sign-on (SSO) [30, 31]	An authentication method that allows users to securely authenticate to multiple applications and sites at once using a single set of credentials.
OpenID Connect (OIDC) [32, 33]	Describes a metadata document RFC that contains most of the information needed for any application to sign in. This includes information such as the used URLs and the location of the service signing public keys.
One-time password (OTP) [34, 35]	It is a password that is valid for only one authentication session. The one-time password can also be limited to a certain period of time. The advantage of a one-time password over a static password is that the password cannot be reused. Thus, an attacker who intercepted data from a successful authentication session cannot use the copied password to gain access to the protected information system.

3. The Proposed Mythology and the Hardware

Based on the analysis of alternative authentication methods presented in Table 3, this paper proposes to modify the OTP method by using new concepts of protecting the access to the production information through unprotected networks, which are as follows:

(i) Implementing access in such a way that the user does not know the password and identification login.

(ii) Complicating the password and not associating it with specific dates or associative concepts of the user (i.e., automatic generation of the username and password).

(iii) Changing of the username and the password once a week automatically or more often without notifying the user. The period of changing the username and the password depends on the required protection level of the information and the level of security of the internal IIoT networks.

(iv) Providing information for automatic login without using the keyboard, thus avoiding the use of key-loggers and similar spyware.

(v) Automatically checking of the URL, which the user visits for the protection against phishing attacks.

(vi) Implementing two-factor user authentication.

(vii) Providing connections to the HMI, HMI/SCADA terminal via modern USB/Tape-C/OTG interfaces, and so on, considering the protection against malicious Trojan viruses transmitted via INF/Autorun.

The structural diagram and the components' selection for the implementation of the proposed electronic key to improve the user authentication through unsecured Internet networks is illustrated in Figure 1, which shows how to implement the concept of information protection during user authentications to access HMI and HMI/SCADA systems via unprotected Internet networks.

During the development of the structural diagram, an analysis was also carried out of modern interfaces that can be used to connect to PCs, laptops, tablets, mobile phones, or external and internal terminals, through which a physical connection could be applied to ensure the authentication of user access rights to the production HMI and HMI/SCADA systems [41].

The proposed work in this paper suggests implementing the most common USB (Universal Serial Bus) 1.0–3.0 interface and its compatible Type-C and OTG counterparts. Serial interface for connecting peripherals is divided into USB 1.x (average speed 12 Mb/s); USB 2.x (average speed 25–480 Mb/s); USB 3.x (average speed 2.5 Gb/s); and Type-C or USB 3.1. All listed serial interfaces are used on 98% of industrial control systems and PCs, laptops, and modern mobile phones (except for Apple corporation). To combine these serial interfaces, adapters are used, which are free for sale and which allow you to connect the developed electronic dongle even to a hardware device of Apple corporation.

As a consequence, it is necessary to use a microcontroller with built-in extended USB functions to provide universal access to all kinds of devices, resulting in the developing of the access key that consists of three main elements: a control board, based on the ATmega32U4 microcontroller [42], was chosen due to the peculiarities of its CPU architecture, inside which, on a chip, a usb <> uart converter is implemented. Thanks to this, no drivers are required when connecting to a PC. And the computer itself recognizes the Arduino Pro Micro ATmega32U4 as a Human Interface Device (HID) device, an LCD display for displaying the necessary information [43], and a push-button control unit [44]. Analyzing the modern element base and the characteristics to solve the assigned tasks, the following hardware components of the electronic key were selected, which are shown in Figure 2.

The main characteristics of the selected hardware items are taken from the Datasheet: Arduino Pro Micro (ATmega32U4) where the Micro has built-in USB communication, eliminating the need of a secondary processor, operating voltage 5 V microUSB, Flash ROM-4Kb with dimensions of 18×33 mm [42], and 0.91 OLED display module with I2C connection interface; the viewing angle is more than 160°; the operating voltage is 3.3-6V with dimensions of $12 * 12 * 38$ mm [43] and Clock button model A24 with number of contacts 4, with dimensions of $12 * 12 * 7.3$ mm [44].

Based on the selected hardware modules, the following wiring diagram has been developed, which is shown in Figure 3.

To connect the 0.91 OLED display module, the I2C connection interface is used that requires connecting the SCL c D3 and SDA c D2 connectors to the Arduino Pro Micro. This display module was chosen because of its support for the I2C interface, which allows data transmission over two connectors (SCL, SDA) and two power supplies (5V, GND), as opposed to the Serial Peripheral Bus (SPI) interface, which uses four connectors (MISO, SCK, SS, and MOSI) for data transmission and two for power supply (5 V, GND). The 5 V power supply for the display can be taken from the VCC and GND connectors on the Arduino Pro Micro and connected to the corresponding connectors on the display. Based on the proposed structural diagram, the A24 clock model buttons is connected through a common ground, to the digital connectors (D6, D7, and D8). Accordingly, the "<<" button for menu control is connected to the D6 connector, the selection confirmation button "OK" to the D7 connector, and the menu control button ">>" to the D8 connector.

To assemble an experimental dummy of the electronic authentication key, the size form factor of a USB flash drive was chosen. The placement of all hardware modules is done on a breadboard with dimensions of $30 \times 40 \times 20$ mm (WxDxH). When designing the topology of the printed circuit board of the electronic key, the authentication was carried out using modern CAD systems EDA Altium Designer, which reduces the overall dimensions. The obtained result of assembled prototype of the proposed electronic authentication key is shown in Figure 4.

The next step is to develop an algorithm for two-factor authentication of access to SCADA/HMI. To simplify perception, the proposed algorithm was divided to several levels.

At the first level, user authentication is performed to provide the access to the main menu of the electronic key, where a 4-digit digital access pin must be entered. Depending on the security requirements and the level of user access to the production HMI or HMI/SCADA, the minimum number of attempts in the Attempt counter, can be equal to one attempt. If pin is entered incorrectly, the electronic key is blocked for in the interval of 30 seconds before the new firmware by the security administrator is created. The algorithm of the first level of the electronic key user authentication is shown in Figure 5.

The second level of user authentication is automatic, where the electronic key management menu (Main Menu) of the user offers the name of the domains needed to perform the necessary actions. In this case, the name of the domains can be any name that is convenient for the user's association. After choosing the HMI/SCADA domain name, the electronic key copies the address line in the Web browser for verification and compares it with the domain name stored in the memory of the electronic key; if they do not match, the site is considered as "fake," and hence the work stops, and the user receives a warning about the danger. If the domain addresses are the same, then the user puts italics on the login field and clicks the "OK" button on the key. This allows the user of the electronic key not to remember the login and password for accessing Cloud Storage of the enterprise. After automatic filling of the authentication fields, the user performs the standard action to enter in the form of clicking the "Sign in" button. Further, the received data is transferred to the enterprise's Cloud Storage server, where the user's level

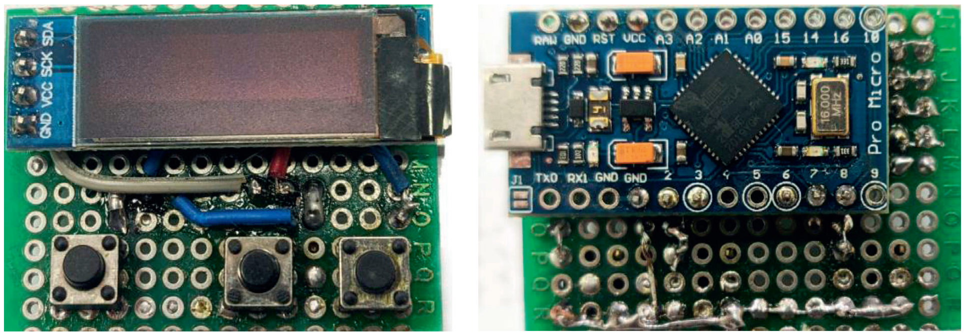
of the access to the information is checked on the server. If the user is defined on the server, then in accordance with his priorities and permissions, the access to information is given that is displayed in the Web browser window. The algorithm of the second level of automatic user authentication is shown in Figure 6.

The next step in the development of the HMI/SCADA user authentication electronic key is the development of software for the ATmega32U4 microcontroller. To be able to understand the required software, it is necessary to analyze the existing software development environments for microcontrollers of the whole family, which considers the following development environments: AVRStudio [45], MPLAB [46], and Arduino IDE [47]. All of the above development environments, a C ++ language or a subset of it, can be implemented. However, it is worth noting that for software development in Atmel Studio, it is necessary to additionally install the Atmel Toolchain [48]. At the same time, there is no confusion when compiling software, due to the fact that for different versions of Atmel Studio two types of compiler Atmel Toolchain and WinAVR are used [49], which complicates the perception of the compilation process. Therefore, the Arduino IDE to develop the HMI/SCADA user authentication electronic key software is chosen. The selection was based on the following factors:



(a) (b)

Figure 4: Assembled prototype of the electronic authentication key. (a) Top view. (b) Bottom view.

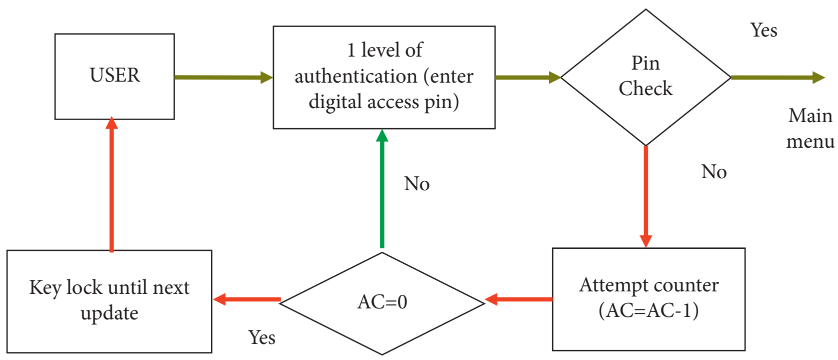


Figure 5: Algorithm of the first level of user authentication with an electronic key.

simplicity and ease of software development, ease of library integration, support from official Arduino developers, and a Freeware license. The enlarged logic of the firmware for the electronic key in the form of an algorithm is shown in Figure 7.

At the first stage of program development, it is necessary to connect the libraries necessary and sufficient to implement the specified functions and work with hardware modules, such as 0.91 OLED display modules 128×32 or tact button model A24.

In the form of constants, the password of the first level of authentication of the electronic key user to implement the algorithm (Figure 5) is set, where a 4-digit numeric password from 0 to 9 is required:

const int pas_1 = 0;

const int pas_2 = 0;

const int pas_3 = 0;

const int pas_4 = 0.

In later steps, flashing electronic access keys in secure IIoT and hence generating a random new password for the first level of electronic key automatically is required, and automatically sent to the user's phone or mail, with information about the time of its validations in the system.

The pins for connecting the clock buttons is inserted into the navigation menu for controlling the electronic key of the Arduino Pro Micro, in accordance with the connection diagram (Figure 3):

const int pin_OK = 8;

const int pin_UP = 6;

const int pin_DOWN = 7.

A limit on the number of HMI/SCADA access accounts used (the maximum can be 25) is created:

int max_account_number = 5;

A function that allows dividing the key's array into columns, in the record format: site—username—login—password, is created.

typedef struct {char* site; char* name; char* login; char* password;} State;

An array in accordance with the division suggested above is created.

The flags "menu" and work with Electrically Erasable Programmable Read-Only Memory EEPROM (EEPROM) is set, where EEPROM is a type of memory that allows writing and reading data from a program, while it is not possible to clear it by rebooting the electronic key. Accordingly, implementing the storage of settings that changes "from the menu" of the device, without flashing is required, as well as a counter of attempts to maintain the first level of authentication and a counter of the timer for blocking the electronic key:

int pas_ST_1 = 0, pas_ST_2 = 0, pas_ST_3 = 0, pas_ST_4 = 0, flag_menu = 60, flag_RES_DISP = 0, msecs = 300;

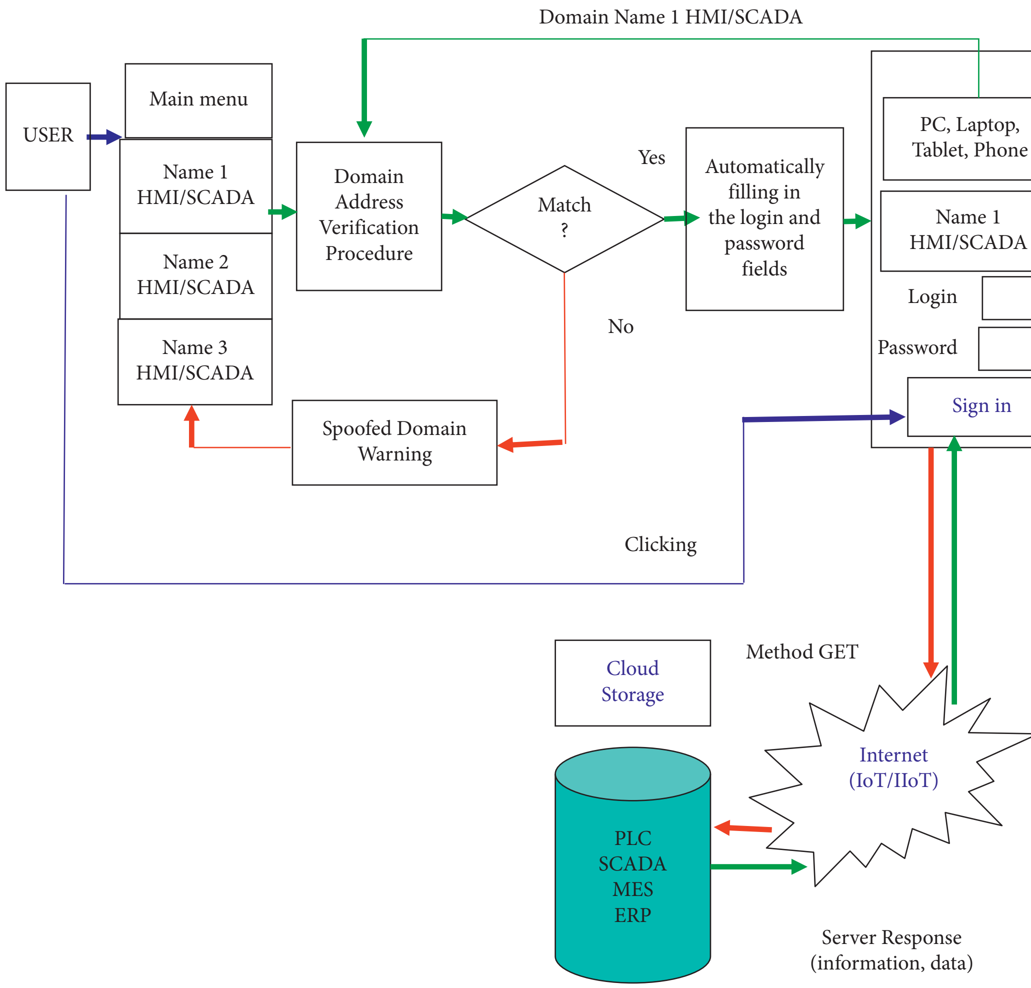

FIGURE 6: Algorithm of the second level of automatic user authentication with an electronic key to access information in HMI/SCADA IV. Development of the software for the functioning of the proposed electronic key.

```
int pin_OK_st = 0, pin_UP_st = 0, pin_DOWN_st = 0, account_number = 0, flag_RES_ACC = 0, timer = 0;
int address_FLAG = 1, flag_EEPROM = 125, seconds = 0;
int seconds1 = 10, seconds2 = 20;
```

To enter the 4-digit password of the first level of user authentication of the electronic key on the OLED display, the following function is implemented.

The function of scanning tact buttons on an electronic key is implemented by the following function:

```
void scan_buttons(){
  pin_OK_st = digitalRead(pin_OK);
  pin_UP_st = digitalRead(pin_UP);
  pin_DOWN_st = digitalRead(pin_DOWN);
}
```

Using the void setup () function, the settings for the electronic authentication key is described.

The main program for the operation of the electronic key using the void loop () cyclic function is implemented.

To flash the layout of the electronic key for user authentication in HMI/SCADA, configuration of the following Arduino IDE settings is required to work with the ATmega32U4 microcontroller (Arduino Pro Micro). In the Tools menu, in the Board section, select “Arduino Micro” and specify the Com port number, as shown in Figure 8.

After the configuration, the firmware with an ATmega32U4 microcontroller (Arduino Pro Micro) is carried out. When the electronic key is turned on for the first time, the user of the electronic key must enter a 4-digit pin to enter the main menu, as shown in Figure 9(a), and the implementation of the selection menu is shown in Figure 9(b).

The developed prototype of the electronic key for user authentication in HMI/SCADA has the following characteristics:

(i) The ability to memorize up to 25 pairs “username-password,” while the user is not obliged to know the “pair” username and does not know the “password,” which avoids the leakage of the disclosure of access data to HMI/SCADA, in contrast to software protection: Google Authenticator, SafeNet Trusted Access (STA), Microsoft MFA, and GateKeeper Enterprise, which displays the token number on the

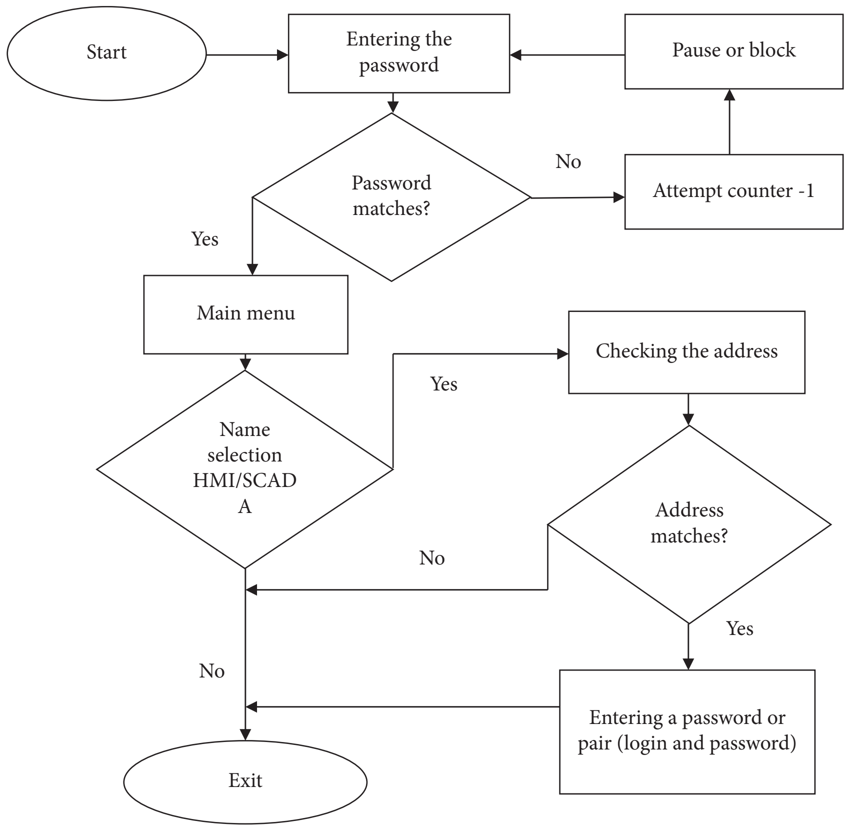

Figure 7: Enlarged algorithm of the electronic key firmware operation.

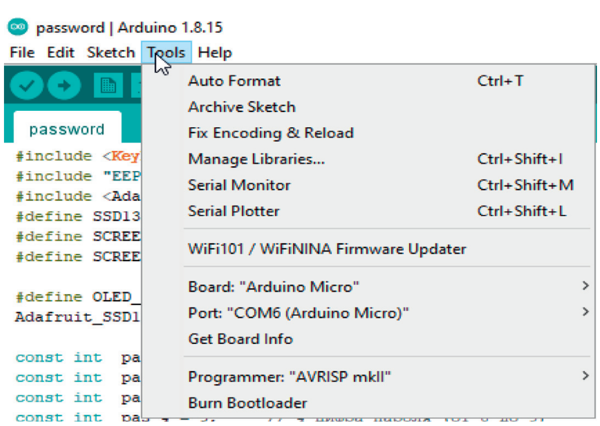

Figure 8: Arduino IDE settings for flashing user authentication electronic key in HMI/SCADA.

smartphone display, hardware protection: RSA token, SafeNet OTP from Thales, which displays the token number on the key display, and the visual access data, which is vulnerable.

(ii) The implemented access concepts in the developed electronic key for user authentication in HMI/SCADA, in contrast to OTP technologies, avoid the desynchronization of OTP tokens and authentication servers in time; as a result of which at a certain moment, there can be several "correct" one-time passwords on the server. For example, suppose the approximate desync time is 5 minutes and the OTP changeover period is 30 seconds; in such a situation, up to 10 "correct" passwords can exist simultaneously, which increases the likelihood of unauthorized access.

(iii) Input of information about the "username-password" pair, on public devices, occurs without using data input devices (keyboards), the data is filled in automatically, and the user simply sends them for verification to the server. This solution avoids the theft of information for a username-password pair using keyloggers, which record the sequence of typing data from the keyboard.

(iv) In case of loss and theft of the user electronic key authentication in HMI/SCADA, a "rigid system" of regulations has been developed according to the following steps:

(1) The action of the key and passwords is limited in time, depending on the security requirements, the change of the "username-password" pair occurs automatically on the server without human involvement, using random symbol generators, which reduces the likelihood of accidental disclosure to zero.

(2) If the notable four-code pin is entered incorrectly at the first level, the user authentication level, the authentication key is blocked for the set time by the administrator, during this time a new "username-password" pair is automatically

generated on the server, as a result of which information about access to the HMI/SCADA is deprecated. The selection of pin by the combinatorial method is 10,000 combinations; it is not possible to perform it manually and this is provided for by the key.

(v) A high degree of protection against "dumping" information is conditionally possible only in the case of the physical theft of an electronic key, and at the same time, an attacker is not very likely to receive a firmware file in a hexadecimal format, which must be disassembled.

4. Practical Experiments to Test the Burglary Resistance of the Proposed Key Security

We will conduct a number of studies to check the stability of the developed electronic key against theft of information in HMI/SCADA user authentication. When introducing the developed electronic key into mass use, it is possible to use a three-level protection for reading the firmware by known methods: protection against opening the case, hidden internal breakage of the leg used by the programmer for reading, and hidden on-chip removal of the leg control logic used for reading. The first level is a refractory polymer that is resistant to acids and solvents, which does not allow reaching the crystal. The second level makes it impossible to read the programmer without special expensive tools. The third level performs a function similar to the second, but at the same time on-chip restoration of the control logic on the inner layers is practically impossible, or it requires very expensive equipment. When introducing the developed electronic key into operation, the authors recommend using the unpackaged ATmega32U4 microcontroller. In the course of an attempt to hack the firmware of an electronic key, in laboratory conditions, the authors of the article were unable to remove the "firmware clone" through the AVRDUDE

+ not vulnerable, ± partially vulnerable, and − vulnerable.

program [50], since the firmware is copy-protected. Therefore, a situation when attackers managed to steal an electronic key and copy a firmware file from it in *.hex format will be simulated. A hex file is a hexadecimal file containing source code, configuration information, setting information, or other data. The format is commonly used in low-level programming when developing microcontrollers. A fragment of the firmware file of the electronic key in hex format is shown in Figure 10(a) and in Figure 10(b), in an attempt to disassemble it.

As an example, an attempt to disassemble the resulting fragment is presented in Figure 10(b), using the strcpy functions (the standard library of the C programming language, for copying a null-terminated string into a given buffer) for the ARM architecture. A fragment of the resulting assembly language code is shown in Figure 11.

The presented fragment contains the command for calculating registers and the processing, and then the cycle can be observed; however, from the presented fragment, it is impossible to understand the essence of the execution of commands and the purpose, which does not allow to open and understand the authentication passwords and the purpose; as a result, this gives an opportunity to make sure that the software hacking the electronic user authentication key in HMI/SCADA is a difficult task, even if the attackers have a source file in *hex format, the maximum that allowed to be viewed is the firmware code.

We can also note the strengths and weaknesses of the developed approach. This is presented in Table 4, which gives a comparative description of the developed approach and existing approaches.

5. Conclusions

In this paper, the processes of developing authenticating user access to industrial information through unsecured Internet networks were introduced in detail. Moreover, a number of vulnerabilities for cyberattacks were identified, such as phishing and social engineering, which are based on the human factor.

The authors analyzed the proposed new method for organizing user access to industrial SCADA/HMI. The analysis based on the concept of an unknown authentication parameters. Consequently, an electronic key based on ATmega32U4 microcontroller was developed as well. All the necessary information to enter the industrial SCADA/HMI is stored inside the firmware in accordance with the company's internal cyber security regulations, which allows generating a powerful automatic passwords and user logins without involving the user's information to remove the risk of accidental transmission of the authentication parameters to a third part. Accordingly, the authors developed a structure, selected electronic components, developed a connection diagram, and assembled an experimental model of an electronic key for user authentication of industrial HMI, HMI/SCADA. On the other hand, to protect the access to the main menu of the electronic key, the authors have developed an algorithm for the first level of user authentication and an algorithm for the second level of automatic user authentication with an electronic key for accessing information in HMI/SCADA. The firmware for the ATmega32U4 microcontroller has been developed as well, which can store up to 25 logins and passwords. To testify the proposed algorithm, a number of experiments were carried out to simulate the hacking of an electronic key, which showed high stability and reliability of the stored information, compared to the same parameters without applying the proposed development. The future work is planned to be directed to apply the proposed algorithm on more complicated networks where the information is transmitted in broadcast manor, such as the networks introduced in [51–55].

The authors are confident that the method proposed in the article will protect data with high reliability from hacking by social engineering. But this requires the implementation of all the recommendations in the proposed concept. This is based on the fact that the strength of the password is due to the fact that the user does not know the access passwords, which are automatically generated and remotely recorded on the electronic key. Moreover, depending on security requirements, access passwords can be changed each time the dongle is connected to a secure device (PC, etc.) in the local network without warning the user. The authors are also confident that if the developed key is stolen, the data will be protected from hacking during the first 24 hours. This is based on the fact that during this time you can change access passwords or block an account. At the same time, the authors understand that there is a possibility of physical hacking of the prototype microcontroller. But this method of hacking requires expensive equipment. Moreover, this hacking method leads to the destruction of the key.

Data Availability

The data used to support the findings of this study are included in the article.

Conflicts of Interest

The authors declare that they have no conflicts of interest to report regarding the publication of the present study.

Human activity recognition (HAR) using radar micro-Doppler has attracted the attention of researchers in the last decade. Using radar for human activity recognition has been very practical because of its unique advantages. There are several classifiers for the recognition of these activities, all of which require a rich database to produce fine output. Due to the limitations of providing and building a large database, radar micro-Doppler databases are usually limited in number. In this paper, a new method for the generation of radar micro-Doppler of the human body based on the deep convolutional generating adversarial network (DCGAN) is proposed. To generate the database, the required input is also generated by converting the existing motion database to simulated model-based radar data. The simulation results show the success of this method, even on a small amount of data.

1. Introduction

Human activity recognition (HAR) has been a popular field of study in the last decade [1–5]. This field of research has attracted the attention of data scientists since the 1980s. HAR is a technology that tries to recognize the activities or movements of the human body through a computer. The purpose of HAR is to recognize the activity of an individual using a series of observations of human behaviors and environmental conditions. In recent decades, various methods have been used to recognize human activities. The methods used can be divided into two main categories: those based on wearable sensors and those based on nonwearable sensors. Wearable sensors require some markers to be attached to a part of the human body for their functionality [6–8]. In applications such as clinical care of the elderly and disabled people, the sensor must be attached to the patient's body and cause inconvenience to them, which is their disadvantage. In contrast, nonwearable sensors such as video surveillance cameras, infrared sensors, and radars do not encounter these problems.

Among the nonwearable sensors, radar has shown its application as well. The advantages of using radar for HAR are as follows:

(1) Radar is resistant to light and weather conditions. Therefore, it can be used in environments with adverse conditions.
(2) The radar sensor maintains the visual privacy of people. Because instead of extracting the visual form of the body, it uses target-modulated return signals that contain valuable information about the range and speed of the moving target.
(3) Radar can detect humans even through walls, which makes it useful in more scenarios.
(4) Radar does not need to attach a marker to a human target for its operation. This makes it more user-friendly.

The human body is a nonrigid target. In addition to the translational motion of the whole body, the locomotion of the body parts is also significant. The instantaneous distance of the body parts to the radar changes with micromotions, and it induces the effects of micro-Doppler on the echo signal [9]. The radar micro-Doppler signature carries unique and valuable information about moving targets, which has received much attention in the classification, recognition, and identification of human targets.

An issue that has always been a major concern in machine learning-based classification problems is how to prepare a standard, large, and diverse enough database. In camera-based classification methods, the camera sensor is publicly available, many images and videos of people's daily lives and activities are recorded, and usually many databases are available for these sensors [10, 11]. However, radar is not a typical sensor and is accessible only to certain people. So, the radar databases are very limited and sometimes not available due to some security issues. Lack of sufficient volunteer humans, costly radar data recording tests, long preparation time of the test environment, and such issues make providing radar database very difficult and rather challenging. Therefore, the challenge we are dealing with is the collection of diverse and appropriate data. Attempts have been made to increase the data in a way other than direct testing.

One of the methods used in various literature is the computer simulation method. In this method, data are generated statistically from scratch using human kinematic models. The most famous kinematic model of the body is the Boulic gait model [12]. In this model, given a limited number of body parameters such as height and thigh length, the human gait model can be simulated. This method has been validated many times, including [13, 14]. It has been used as a reference for walking simulation. Although this method can generate an unlimited amount of data for deep network training, it is limited to the walking model and can also be used for running with little modification, but it is not applicable for other activities, such as crawling and sitting. In [15], a method for simulating micro-Doppler signatures of running and crawling in addition to walking activity has been proposed using virtual reality animation. However, the diversity of models is not significant.

The most widely used method is using the Kinect sensor for Microsoft's Xbox game console [16, 17]. This camera has two optical sensors and an IR sensor. By integrating the data from these three cameras, it has been able to measure the depth and instantaneous location of the joints in the human body with an accuracy of better than 1 cm. Thus, a model provides a simplified point of the human body at about 18 to 30 frames per second (depending on software and hardware conditions) in 3D space.

The locations of these body joints can be used to simulate the radar echo signal [9, 18], which is a widely used method that is close to reality. In this method, a 17-point model equivalent to the Boulic model is extracted from the joints of the test object. Each limb is then assigned a simple geometric shape. All body parts (except the head) are assigned an ellipse, and a sphere is assigned to the head. By calculating the RCS of each limb according to physical relations, the radar echo can be simulated. After that, the echo in the time domain is transformed to the time-frequency domain by a transform such as the STFT. This method has also proven its efficiency and closeness to reality. The use of the Kinect will be limited due to the very short operational range (less than 2 meters) and the missed detection of some limbs, such as the legs [17].

Another method to solve the problem of data shortages is using a method known as transfer learning. In this technique, a few network layers that have already been trained on a large database are used in the designed network. The initial database should be somewhat close to our desired task. Usually, the primary layers of the deep grid are responsible for extracting general and basic features, and therefore, a series of general features can be extracted regardless of the input contents. In contrast to deeper layers, they extract minor features. So, if we maintain the primary layers of a deep network trained with a large database and retrain and replace the deep layers with a database of related data, which is called "fine-tuning," then we will be able to achieve the required accuracy with a small amount of data. References [19–25] have used this method to improve classification with a small amount of data. However, it is often difficult to find a database close enough to the radar micro-Doppler problem. Although using heterogeneous and irrelevant databases can train the primary layers of the network, they can also take us away from our destination. Radar micro-Doppler images are composed of several lines and curves and using natural pictures to train the transferred network will produce unpromising results as they contain completely different content.

A new method that has recently been discussed to produce a realistic image [26–29] is the use of generating adversarial networks, or GAN for short. The faces in Figure 1 are simulated using the DCGAN network trained with the CelebA database [30]. This database contains more than 200,000 faces of Hollywood actors and singers around the world. The faces in Figure 1 do not exist in the real world, but they look like real faces, and that shows the power of GAN.

Due to the weakness of the mentioned methods and the novelty and power of GAN networks in making realistic images, in this paper, we have proposed a new method for generating human body radar micro-Doppler based on the deep convolutional generative adversarial network (DCGAN) using a simulated database. The structure of the paper is as follows: Section 2 describes how to generate our database. Section 3 provides an overview of GANs. Section 4 introduces the proposed GAN network. Section 5 presents the results of the simulations. Finally, Section 6 is devoted to the discussion and conclusion.

2. Database Preparation

We used the MoCap motion capture database of CMU [31] to simulate radar echo. In this relatively rich database, various activities have been performed by volunteers, and their body locomotions, have been recorded by very accurate multi-modal motion sensors. They are a combination of cameras and inertial sensors like gyroscopes and

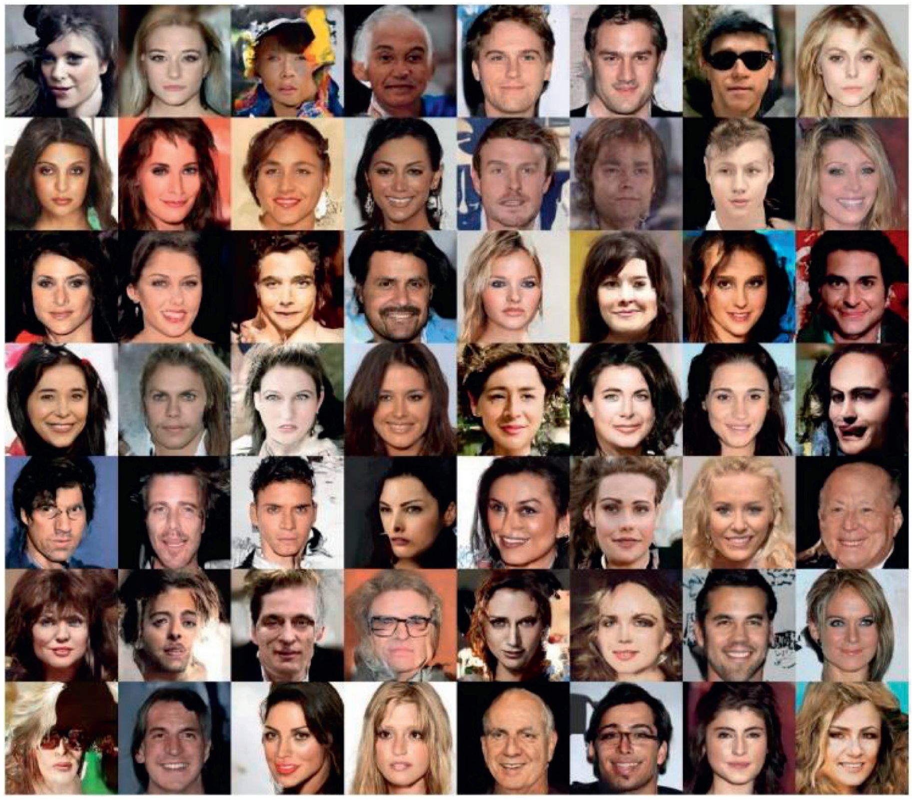

Figure 1: Simulated faces with DCGAN [29].

accelerometers. We have focused only on walking activities. The data recorded in the MoCap output related to the bodies of walking people was first extracted in the point model. The number of points is up to 40, but we used only 17 points, according to [9]. Figure 2 shows a frame of the 17-point body model extracted from the CMU database and simulated by the routine of [9].

According to this method, an ellipsoid is assigned to each limb except for the head, which is spherical. These geometric shapes move according to the instant locations of body joints. The temporal coordinates of the body parts are extracted from data provided by [32] in the form of $[x(t), y(t), z(t)]^T$. By micromotion of these shapes, radar echo data is simulated. The signal at this stage is generated in the range-time domain. Finally, the simulated echo signal is transformed into the time-frequency domain. We used the FSST transform introduced in [33], whose time-frequency resolution is better than STFT. A synchro-squeezing process is applied to the time-frequency domain to make it sharper along the frequency axis. A comparison of FSST and STFT is performed in [34] and is depicted in Figure 3. As we can see, the resolution of FSST is better than that of STFT.

After transforming into the T-F domain, the echo signal of each trial is stored as an image like Figure 3(a). In this way, the initial data were generated to enter the DCGAN.

3. Generative Adversarial Networks

The GAN network, first introduced in [26], implements the game theory method by training two different networks, one as a generator and the other as a discriminator. The generator network is represented by the G function and is parameterized by θ_g and initialized with an input noise vector z, which consists of samples of a normal distribution. (P_{noise} (z)) and its output is $\tilde{I}$.

The discriminator network is a convolutional neural network (CNN) represented by the D function and is parameterized by θ_d. Its input is a real image I or a fake image $\hat{I}$, and its output is a number between 0 and 1 that indicates the probability that the input is real or fake. Training of the GAN includes a minimax game [35] in which the generator tries to fool the discriminator so that it cannot recognize fake images from real ones. Meanwhile, the discriminator is trying to identify them correctly.

D is trained to maximize the probability of assigning the correct label to both training samples and generated samples of G. At the same time, G is trained to minimize the $\log(1-D(G(z))$, in other words, D and G play the minimax game with the value of the $V(G, D)$ as given inthe following equation:

$$\min_G \max_D V(D,G) = E_{x\sim p_{\text{data}}(x)}[\log D(x)] + E_{z\sim p_z(z)}[\log(1-D(G(z)))], \tag{1}$$

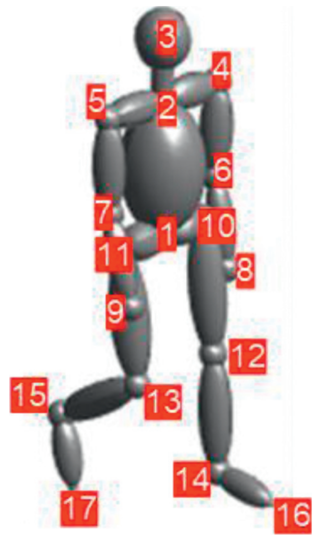

Figure 2: 17-point simulated body.

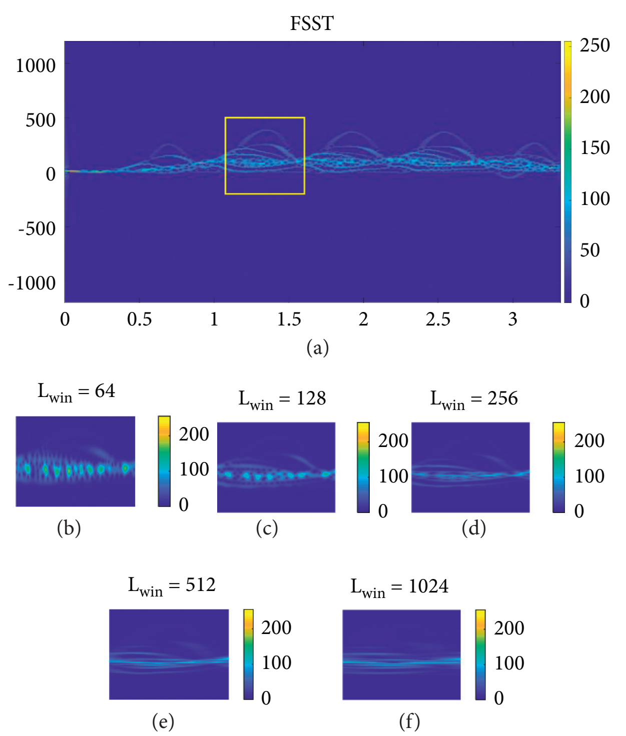

Figure 3: Comparison of (a) FSST and (b)–(f) STFT with different window lengths [32].

where P_g is the probability distribution of G on set x, $G(z, \theta_g)$ is a differentiable function with parameters θ_g, and $D\ (x;\theta_d)$ is a differentiable function with parameters θ_d.

After several training iterations, if G and D have enough training capacity, they will reach a final point in which the training error does not decrease further. At this point, $P_g = p_{data}$ and the discriminator does not have enough power to discriminate between two distributions. Now network G is ready to generate fake samples with maximum similarity to real samples and with the same statistical distribution. A basic GAN block diagram is depicted in Figure 4.

4. Proposed DCGAN Network

In [29], a kind of convolutional GAN network called DCGAN is used to produce realistic images. Due to the success of GAN networks in various studies, in this paper, we have used a kind of DCGAN to generate the micro-Doppler signal of the walking human in the T-F domain. The original DCGAN was trained on the LSUN database [36], Imagenet-1k [37], and CelebA [30]. The contents of these databases are about natural scenes, which have many details. Our proposed discriminator network structure has only four convolutional layers. The purposes for reducing the convolutional layers are as follows:

(1) The network is trained to generate the micro-Doppler signal in the time-frequency domain, which is composed of some periodic curves, and unlike natural images, it does not have much detailed information.

(2) Computational load could be reduced by the simplification of network structure.

The architecture of the generator network is shown in Figure 5 and the discriminator network in Figure 6.

The generator network is composed of five transposed convolutional layers followed by a batch normalization layer for the stability of training progress and an activation layer of type rectified linear unit (ReLU). Table 1 lists the parameters of the generator network.

The parameters of discriminator network are listed in Table 2.

These two networks are trained simultaneously on our database using the Adam optimization method. The output images from the simulated database described in Section 2 will enter into the discriminator network of Figure 5. Simultaneously, noise with a length of 100 samples enters the generator network of Figure 6. As a result of the training described previously, the statistics of the data generated by the generator network gradually approach the statistics of the samples within the database.

5. Simulation Results

In this section, we have reported the simulation results of generating curves by the proposed DCGAN network.

5.1. Simulation Platform. Training of deep neural networks usually encounters challenges. The first challenge is the high computational load, which forces us to use powerful processing platforms. In the simulations presented in this paper, due to the modifications that are performed on the network structure and the small number of input trials in the database, a CPU-based platform has been used.

5.2. Training Options. Hyperparameters of training are selected as in Table 3.

According to Table 1, the number of trials in the simulated database is only 81. However, the output is very close to reality and promising. In the simulation process, as the

5.3. Evaluation. Because the output of the DCGAN network is random, it cannot be evaluated in terms of traditional image comparison criteria such as PSNR because the ground truth could not exist. However, it is important to note that the matching of generated data statistics and database statistics is the optimization criterion of the adversarial learning process, and it converges when these statistics are matched. Thus, the adversarial network ensures that the output image statistics and the database images are the same, which can be considered a quantitative evaluation and a complement to the visual evaluation.

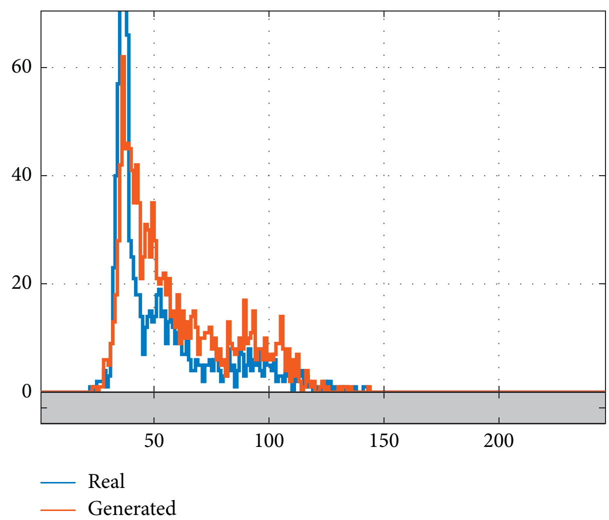

Figure 8: Comparison of the histograms of the real and generated samples.

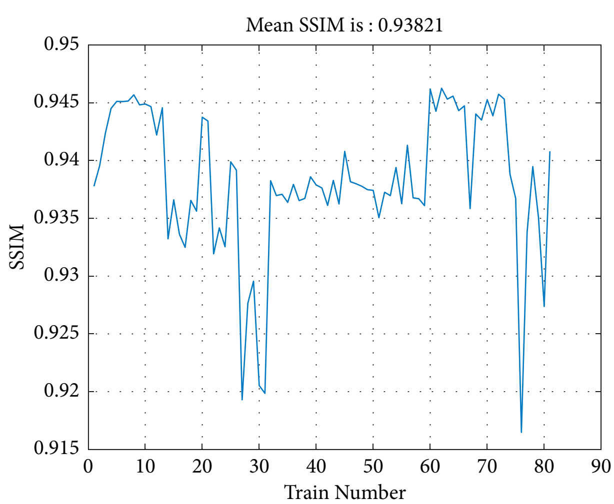

Figure 9: SSIM calculated over generated samples and real samples.

The histogram of an image is a demonstration of the intensity levels and can represent the distribution of these intensities. To show that the trained network is able to generate good fake results, we have compared the average histogram of some samples in the database with some generated samples. Figure 8, shows the results. The result demonstrates the similarity of statistics.

As a second metric for similarity measurement of the real and fake images, we used the structural similarity index measure (SSIM) [38]. SSIM is a good metric to show perception and saliency-based errors. Therefore, we can conclude that SSIM could be comparatively a better metric than mean square error (MSE) and PSNR metrics from a human visual perspective. The term structural information emphasizes pixels of the image that are strongly interdependent or pixels that are spatially interconnected. Highly dependent image pixels provide more valuable information than visual objects in the image domain [39]. The SSIM metric is an index in [0,1] with 0 indicating no similarity and one indicating maximum similarity.

For comparison, we have calculated SSIM between 100 generated images and every image in the database and averaged them, as shown in Figure 9. The consequent average value is about 0.94, which represents a very high similarity between generated images and real samples.

6. Conclusions

In this paper, a new method based on the use of the DCGAN for the production of micro-Doppler of the human body is presented. The database required for this work was generated using a computer simulation of the radar echo signal based on the 17-point body model while considering the system parameters of a typical radar. Motion data of 17 body parts and their kinematics are taken from the MoCap database of CMU University. The production database for the input of the proposed method has only 81 members, but the result is very promising. In the future, we will seek to increase the database and train this network with more diverse data. The results of this work provide a valuable tool for future research in the field of classification of human activities based on radar micro-Doppler.

Data Availability

The data we have used is given from the publicly available online Carnegie Mellon University (CMU) motion capture database [32], [online] available from https://mocap.cs.cmu.edu/.

Conflicts of Interest

The authors declare that they have no conflicts of interest with this study.

Academic Editor: Xin Ning

Players in modern basketball have a lot of physical contact, a lot of bumps, and a lot of physical struggles. The competition for the ball, whether in the air or on the ground, is fierce, putting higher demands on the players' physical abilities. Coaches frequently use plateau physical training, which is very effective in developing athletes' cardiopulmonary function, among many other training methods. The proportional length and active area of arms are obtained using the skin color model of the human body, the angle and posture information of each joint is extracted from dynamics, and the 3D posture of arms and dynamic arms is trained and recognized in this paper, which is based on Kinect. The findings revealed that mild hypoxia in the plateau significantly lowered basketball players' performance and that basketball players' maximum heart rate and 1-minute heart rate recovery in high-intensity exercise were lower than those in flat area training.

1. Introduction

Altitude training refers to a special training method that uses the double stimulation of altitude hypoxia and exercise hypoxia to deepen the stress reaction of the body and improve the various functions and sports ability of the body [1]. Basketball is a combination of walking, sports, and running at various speeds based on the anaerobic decomposition of high-energy phosphate compounds, which is characterized by the mixture of anaerobic metabolism and aerobic metabolism [2]. Athletes' physical examinations are an important part of their physical development, and they help to promote their physical development to some extent. The collection, collation, and analysis of training data have become an important link with continuous scientific training [3, 4], which is the main reason for including physical training in the basketball training plan, improving the physical fitness of basketball players to a certain level, ensuring the improvement of athletes' physical fitness, and establishing a certain physical reserve in competition to ensure the use of more effective tactics and commands [5].

With the rapid development of the intelligent industry, the application scope of robots in various industries is constantly expanding, and artificial intelligence technology [6–8] has penetrated into people's work and life. 3D gesture recognition in dynamic arm is an important way to improve the technical level of artificial intelligence, and it is also a major problem to be solved urgently in the field of intelligent technology. The use of RGB-D sensors like the Microsoft Kinect is a convenient and effective way to obtain a diverse and realistic 3D human model, but existing methods of extracting whole body point cloud information for 3D modeling are complicated in terms of operation, equipment, and subsequent processing, and the modeling effect is not suitable for 3D crowd animation [9]. With the introduction of Kinect technology, a new type of disease rehabilitation system has emerged, allowing athletes to select the appropriate exercise mode based on their current situation, allowing for more targeted and planned rehabilitation and a desire to recover as quickly as possible [10]. The new rehabilitation exercise system adds a variety of exercise methods, allowing players to customize their workouts based on their preferences and improving their real-world experience. The new system can also help doctors make more accurate and scientific exercise plans, reduce workload, improve the efficiency of doctors' diagnosis and treatment, and help athletes achieve faster health recovery.

Although the recent research on plateau training has made some achievements, due to the different characteristics of each event, there is no plateau training model suitable for all sports and athletes [11], which has great theoretical and practical value. Kinect equipment has achieved interdisciplinary and has a good development prospect and economic value. After the introduction of Kinect technology, the overall functions of the training system can become more powerful and rich. When athletes use the training system, they can choose their own training mode in a targeted way and get the best results with proper exercise. In order to scientifically explore the high-level physical training of high-level basketball players, the changes of body function and body shape before and after the plateau were deeply studied.

2. Related Work

Some basketball players have competed in terms of training quantity and intensity, and their mutual cooperation has been strained. In general, there is a negative correlation between basketball players and their training. That is, as the training amount increases, the training intensity decreases [12, 13], and as the training intensity increases, the training amount decreases as well [12, 13]. The difference between basketball and other sports, according to literature [14], is that it is the same game in which space, ground, time, and speed compete with each other around the basket in the air. Basketball is a speed-strength, confrontation-endurance-skill event aimed at fast and changeable attack and defense [15]. According to literature [16], anaerobic metabolism and anaerobic and aerobic mixed metabolism are the primary sources of energy for elite female basketball players in competition, with aerobic metabolism and aerobic metabolism as backups. According to literature [17], short-term actions in basketball games such as fast layups, jumping, shooting, dribbling, and rebounding are primarily dependent on energy conversion from ATP (adenosine triphosphate) to CP (creatine phosphate), but this energy supply is not limited to 10–15 seconds and is primarily triggered by the system during continuous attack and defense conversion. Basketball players should have tall, well-proportioned, slender limbs; big hands; and big feet [18]. Other related works' qualitative descriptions of basketball players' physical characteristics are mostly similar to those mentioned above, so I will not repeat them here.

Nowadays, Kinect technology researched and designed by Microsoft Corporation is more and more used in medical care. Reference [19], in conjunction with Kinect technology and system, proposes a system for assisting upper-limb recovery in stroke athletes that has shown to be effective. Reference [20] has conducted professional research on the rehabilitation assistant robot, focusing on the intensity control of the robot and the training scheme implementation. Literature [21] has created a new type of equipment that uses Kinect technology to obtain athletes' bone data, creates the best recovery training plan for athletes, and monitors their training results and disease recovery. The factors affecting the random error of depth data when using Kinect are discussed in [22]. Reference [23] proposes a method for reconstructing a 3D model of the human body that involves using 24 Kinect devices to collect registration and fusion of local point clouds from various parts of the body, followed by template fitting. Reference [24] proposes a method to measure human morphological parameters by using the depth information of the front and side of human body obtained by the second generation Kinect equipment and creates a new model by modifying the standard human body model. In [25], RGB-D sensor based on Kinect extracts the information of human point cloud from 6 directions, 3 pitch angles, and a total of 18 viewing angles and uses it in 3D human reconstruction method combined with improved point cloud alignment algorithm. Reference [26] proposes a 3D gesture recognition method of dynamic arm based on D-S evidence theory algorithm, which uses gesture sensor to acquire and analyze 3D gesture information from human dynamic arm. Reference [27] puts forward a 3D gesture recognition method of dynamic arm based on classification feature extraction. The background model of dynamic arm is built based on adaptive Gaussian mixture model, and the human arm region is divided by fusion background subtraction method. The limited scanning accuracy and range of Kinect equipment limit the accuracy of 3D mannequin to a certain extent. Multiple devices or multiple small scans are used to improve the scanning accuracy and reduce the scanning range. This will lead to hardware environment, operation methods, and problems. The algorithm is very complicated to implement.

Indoor strength training, aerobic endurance training on land, exercises after strength conversion, and coordination and relaxation exercises make up the majority of the regular physical education class, which lasts about 2 hours. Prior to technical training, 40–60 minutes of special preparation activities is required. According to the literature [28], the 5000 m and 10000 m swimming events are 8% lower than sea level, and the 100 m swimming events are 2–3% lower, with the decline becoming more apparent as the movement distance increases [28]. Working at a 2000 m altitude increased the heart rate by 10–20% when compared to working on the plain; according to literature [29, 30], when the altitude is 1000 meters or higher, the maximum oxygen uptake drops by 10.5 percent. The decrease in VO_2 max was linked to an increase in oxygen tolerance as altitude was increased, according to research. Blood flow and oxygen saturation are also involved. Basketball players can benefit from altitude training not only in terms of aerobic endurance, but also in terms of lactic acid energy supply. As a result, team sports like basketball require altitude physical training to enhance athletes' physical fitness during the pre-match preparation stages.

3. Research Method

3.1. Research Design

3.1.1. Research Objects. All the players took part in and completed the test. The average age of the subjects was 26.5 years, average body weight 70.4 kg, and average height 174.8 cm.

3.1.2. Literature Data Method. Through China Journal Network and National Library, a lot of literature on basketball selection, physiology, physical education, and modern training theory was retrieved and collected, basically focusing on the research and development of basketball in China. By reading and classifying various papers, relevant data were analyzed, classified, and synthesized according to the physical characteristics of basketball players.

3.1.3. Expert Interview Method. I had the opportunity to take part in the physical fitness test of Chinese basketball players in winter training and interviewed five coaches according to the prepared interview outline, so as to understand the specific situation of physical fitness training of Chinese basketball players and do more in-depth research.

3.1.4. Test Method. The complete test lasted two months and was divided into two parts. All subjects underwent elevation and routine electrocardiogram (ECG) before the experiment, and all subjects' ECGs were normal. During the whole testing process of the two sites, ECG samples of the subjects were obtained and no abnormal ECGs were found. Physical function test finger blood was collected on an empty stomach at around 7:00 a.m., and body composition test was conducted at around 7:00 a.m. to complete the tester analysis.

3.2. Physical Training Process. Fitness should be defined as the combination of various physical abilities required of athletes in order to maximize the flexibility of various organs and systems of the body, overcome fatigue, and produce exceptional performance under the stress of special training and competition. Physical and intangible physical strength are included. Physical ability is referred to as tangible physical ability, while psychological ability is referred to as intangible physical ability. Physical quality is divided into three categories: physical structure, physical function, and mental willpower. There are two types of stretching: static and dynamic. Basketball is a type of high-intensity anaerobic exercise that causes muscles to produce a lot of lactic acid. As a result, athletes should do warm-up and relaxation exercises to improve their health and performance in sports. The comprehensive principle, ladder principle, goal principle, proper subordinate principle, and recovery principle should be followed when developing a basketball plan.

Physical training at altitude is a well-thought-out method. It is a good pre-competition training method for improving athletes' performance by assembling athletes in a large enough area and conducting routine special sports training under anoxia and anoxia conditions. Altitude training helps to stimulate and unlock the body's full potential, allowing the body's absorption, transportation, and utilization of oxygen to be improved and enhanced, and thus the body's functions and athletic performance to be maximized. As a result, sports performance in training and competition will improve.

Physical training is the process of transferring athletes' physical strength from the actual state to the target state. According to the training cycle, the whole physical education process from training to retirement can be regarded as a complete process, which is linked to multiple stages, such as multiyear training courses, annual training courses, and step-by-step training. Every stage of the training process, regardless of the duration, should theoretically cover the basic knowledge: diagnosing the situation of athletes (or sports teams), determining the training objectives, making training plans, and implementing and checking the training plans. The results of the performance evaluation can be found in Figure 1.

In the training process, it can be seen that there are four key steps to effectively change the physical fitness from a relatively chaotic reality state to a relatively orderly target state, realize the effective coordination of all components of physical fitness, accurately grasp the actual situation of athletes (or sports teams), scientifically determine the training objectives, make a careful training plan, ensure the effective implementation of the training plan, and establish a perfect training process monitoring system.

For the training participants, the training goal describes the ultimate goal of the sports training process, and all training activities aid in achieving this ultimate goal. By ensuring that all links and training activities in the training process can be fully developed around the realization of the target state [12], the determination of this ultimate goal provides a basis for the formulation and implementation of training plans and competition plans in the training process. Physical fitness goals, on the other hand, are horizontally related to technical and psychological training goals, so adjustments to other training goals, such as physical fitness requirements, should be taken into account when determining physical fitness goals. Innovation in technology physical training is a subgoal that is made up of several separate goals that must all work together to achieve the desired result.

3.3. Kinect-Based Physical Training Model for Basketball Players. Kinect is one of the most popular somatosensory devices on the market. The functional design of this product is mainly to enhance the real experience of gamers in the game. Community interaction is also a key function of Kinect, allowing people to play games together and communicate with others instantly through voice and text [17]. Kinect is far beyond the traditional concept of human-computer interaction in function. It does not need to use other devices to capture the user's physical information in sight, manipulate objects in the interface, provide intelligent

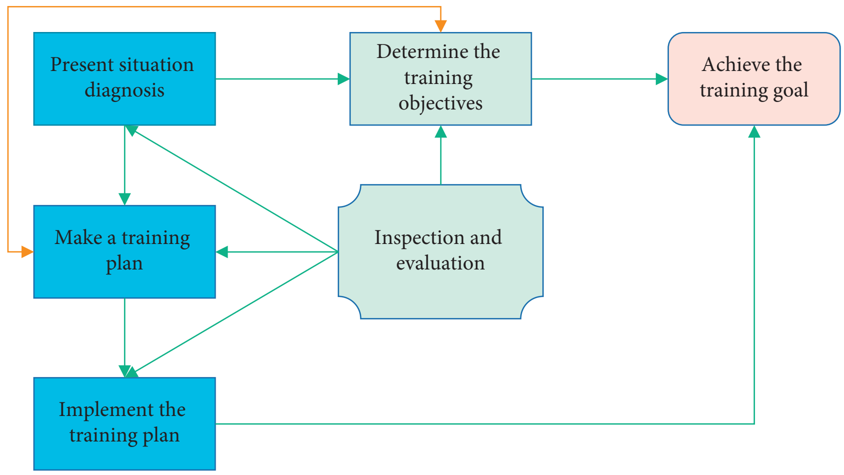

Figure 1: Basic structure of exercise training process.

and flexible human-computer interaction, realize work functions, and have strong human characteristics.

Kinect somatosensory device has many functions such as speech recognition, microphone input, and advanced sensing technology. The sensing technology of Kinect somatosensory device can fully acquire the video and audio images in the field of vision and use this information to identify the user's identity and voice information and track the bones. For users, Kinect can provide unprecedented interactive experience and achieve four goals: first, bone tracking; second, gesture recognition; third, face recognition; and fourth, voice recognition.

Practice shows that database design is software engineering, and the principles, techniques, and methods of software engineering can be applied. Compared with general software engineering, database design has a wider range and is closely related to the application environment, so database design has its own characteristics and training. The database design mainly includes some parts: demand analysis, conceptual structure design, logical structure design and physical structure design, database management, physical fitness test database system design (logical structure design and physical structure design), and database management (Figure 2).

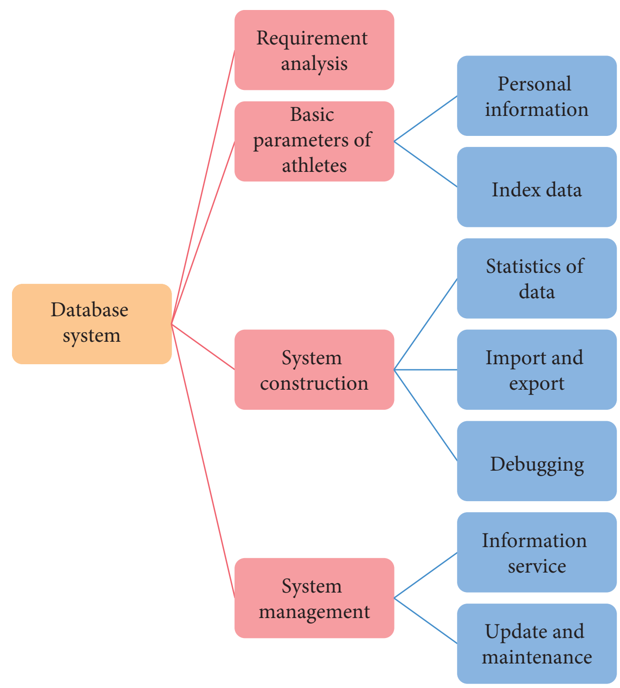

Figure 2: System design process.

The database of athletes' test data needs to include the functions of summary, input, modification, deletion, storage, download, backup, update, statistical analysis of physical test data, and system security. The system's ease of use is ensured by the integrated friendly operation interface. The DTW (dynamic time warping) method is primarily used to compare two unrelated time series. Different from other methods, when the lengths of two sequences are different or the X axis cannot judge them, this method can explain the relationship between the current two sequences by time warping function under certain conditions. In this calculation process, firstly, a matrix of m rows and n columns should be established, and the distance between points in two sequences should be stored in the matrix to observe the matrix effect. The smaller the value, the higher the similarity between the two sequences. When the calculation reaches the end point, the accumulated value reflects the similarity of the two sequences to a certain extent. The cumulative distance $\operatorname{dist}(i, j)$ can be expressed as the following formula:

$$\operatorname{dist}(i, j) = \min \begin{cases} \operatorname{dist}(i-1, j-1) + d(A(i), B(j)), \\ \operatorname{dist}(i-1, j) + d(A(i), B(j)), \\ \operatorname{dist}(i, j-1) + d(A(i), B(j)), \end{cases} \tag{1}$$

where $\operatorname{dist}(i, j)$ represents the cumulative distance, which represents the sum of the distance between data column $A(i)$ and data column (j) plus the cumulative distance of the element closest to the end point.

If each frame of motion data is regarded as a point in 16-dimensional space, then an action sequence can be regarded as a curve in this space. The similarity between two action sequences can be obtained by calculating the distance between the two sets of data, which is usually referred to as

Euclidean distance. Then, the Euclidean distance between them is as follows:

$$D(M_1, M_2) = \sqrt{\sum_{i=0}^{N-1} (G_i - G_i')^2}. \quad (2)$$

The smaller the calculation result, the closer the two groups of actions are.

In covariance probability theory and statistics, this parameter represents the total error of variables. Assuming that the two quantities have the same changing trend, they must be both greater than or less than their expected value, in which the calculated covariance is positive. For the same reason, if the two trends are opposite, the calculated covariance is negative.

$$\operatorname{cov}(X, Y) = E((X - \mu)(Y - \upsilon)). \quad (3)$$

μ represents the expectation $E(X)$ of X, and υ represents the expectation $E(Y)$ of Y.

The evaluation of rehabilitation training in this system adopts triple evaluation algorithm (DPL algorithm for short), which combines dynamic time warping algorithm, human correlation coefficient, and longest common subsequence algorithm. The data streams of patient motion applying DPL algorithm are sent to DTW algorithm, Pearson correlation coefficient evaluation, and longest common subsequence (LCS) algorithm to obtain the similarity evaluation data with the standard template.

The specific formula of DPL algorithm is as follows:

$$\begin{aligned} D = {} & \frac{C_1}{C_1 + C_2 + C_3} \times S_1 + \frac{C_2}{C_1 + C_2 + C_3} \\ & \times S_2 + \frac{C_3}{C_1 + C_2 + C_3} \times S_3. \end{aligned} \quad (4)$$

By setting three confidence variables in advance to a certain extent, the problem that the accuracy of the three fusion algorithms decreases according to the actual situation can be solved, and it can also be adjusted by professional medical staff according to the treatment experience, which is suitable for the rehabilitation of some patients.

In the process of 3D posture recognition in dynamic arm, assuming that x, y represent two joint points of the arm, first calculate the difference between the coordinates of the arm and the shoulder node, then judge whether the joint points of each arm are in approximately the same position according to the difference, and then use (5) to calculate the angle (Euclidean distance) between the connection lines of the joint points in dynamic arm:

$$d = K \tan(Hd_{\text{raw}} + L) - O. \quad (5)$$

In (5), d_{raw} represents the depth value of the three-dimensional posture image in the dynamic arm, and H, L, O represent the constants of the depth value.

According to the distance between the two joint points, calculate the angle between the two joint points of the arm and the X axis of the reference point, use the angle of the reference point on the X axis to obtain the coordinates of the specified point, and then use (6) to obtain the angular constraint conditions of the arm joint points:

$$P_A = \frac{\{P_1, P_2, \theta, \tau\}}{D(X, Y)} \times d, \quad (6)$$

where P_1 represents the reference point of the arm, θ represents the angle between the arm joint point P_2 and the X axis, and τ represents the set angle threshold.

In the process of three-dimensional posture optimization recognition in dynamic arm, the feature vector sets of angle between arm joint points with different postures are obtained by the following formula:

$$\text{Ktr} = K_i \times \frac{\{K_1, K_2, \ldots, K_n\}}{\text{Str}} \text{Str}. \quad (7)$$

Among them, $\{K_1, K_2, \ldots, K_n\}$ represents the feature vector of the angle between arm joints in different postures. Str stands for training sample set.

4. Result Analysis and Discussion

4.1. Physical Training Plan and Load Arrangement. Special preparation activities before technical training are also selected according to the content of technical training, mainly including elastic belt shoulder wrist joint maintenance, weight-bearing water bag basketball footwork practice, ball practice, and dynamic stretching. In the definition of load intensity and load quantity in this study, the load intensity is determined as the maximum of the main load indexes (bench push, squat, high pull) in the last two weeks of flat land. The relationship between load intensity and load weight during training is reflected in the percentage of each training index relative to the maximum load value and total training weight (Figure 3).

There is no restricted load applied, the load is only close to the level of flat ground, and the load strength is only about 80% of the maximum strength. A three-day break between two high-intensity strength workouts can help athletes recover completely. The men's basketball team in this study used the plateau to perform strength training, aerobic endurance training, and special skill training, with fat being one of the challenges of this plateau training. Because the waist-hip ratio has changed dramatically, this plateau training can be considered a training goal for body fat reduction.

4.2. Analysis of Physical Fitness Test of Basketball Players in Winter Training. Quantitative quality ensures the physical fitness of basketball players and is the material basis for rapidly changing skills and tactics. Modern basketball players need highly developed comprehensive strength. Comprehensive strength is the comprehensive strength of athletes who are engaged in special basketball activities due to the coordination of various sports links. It is the foundation of athletes' special abilities. Improving the overall strength in training is the development trend of modern basketball strength training. In strength training, the

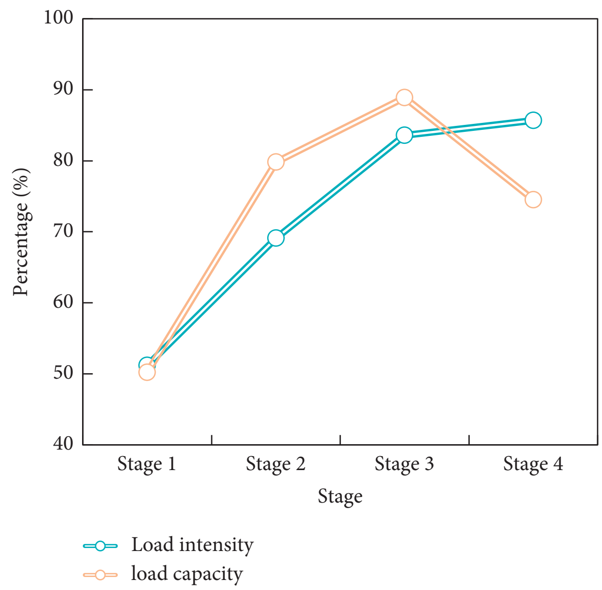

Figure 3: The relationship between altitude train load and intensity change.

training methods of adults are not completely suitable for young athletes, so the physiological characteristics of young athletes must be taken into account in training, based on moderate load, comprehensive and gradual.

Figure 4 shows the main physical indexes of young male basketball players in China. Among them, indicators 1~8, respectively, represent comprehensive running (s), in situ touching height (m), run-up touching height (m), sit-ups, standing long jump (m), 1-minute bench press, turn-back running (s) and 3,200 meters (s).

Generally speaking, the aerobic endurance of Chinese basketball players has obviously decreased, and other indexes have not improved. This shows that the physical training of Chinese youth men's basketball team is not systematic and has not produced good results. Speed endurance and aerobic endurance training can improve other physical qualities of athletes every year, laying the foundation for athletes to reach a higher level.

4.3. Comparison of HR Recovery after Exercise in Different Regions. In order to further observe the ability of basketball players to recover cardiovascular function after altitude exercise, the heart rate (HR) recovery at different times after exercise was compared, so as to understand the influence of altitude hypoxia on cardiovascular function. That is, immediately after exercise, the difference between the peak HR of warm-up activity and normal HR is 100%, and the net recovery of HR at different times after two activities in different regions is compared. As a result, the heart rate recovery in 1 minute after high-intensity 10-minute running is obviously faster than that in flat and highland areas, and there is no significant difference between the two places after 4-minute exercise.

It can be seen that, even in the 10-minute curve executed in Figures 5 and 6, the change of the individual's normal

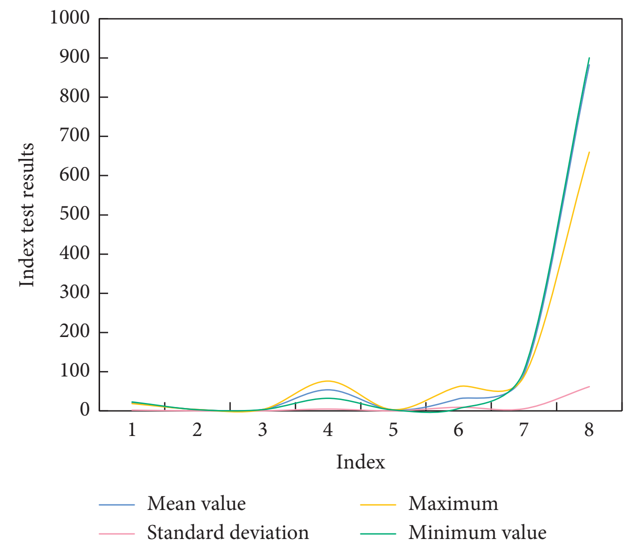

Figure 4: Test and analysis of main physical indexes of Chinese basketball players in winter training.

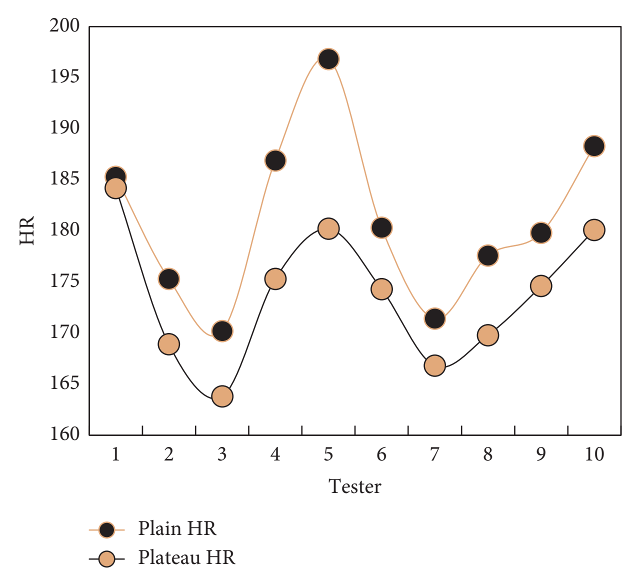

Figure 5: Comparison of HR recovery between plain and plateau immediately after 10 min running.

heart rate is relatively stable. The HR at high altitude is generally higher than normal HR, but individuals with lower HR in plain areas still keep lower HR in high altitude areas.

After running for 4 minutes and 10 minutes, HR basically returns to the HR level of the preparation activities, whether in flat or highland areas. It is found that the heart recovery ability of basketball players is not affected by the local altitude (see Figure 7).

The heart is different from other organs in human body. The nutritional system and functional system of different organs are two different systems. The heart not only performs its own functions, but also nourishes the organs themselves. Therefore, insufficient oxygen supply to myocardium is one of the reasons why the heart works at a high level for a long time. On the one hand, increased myocardial

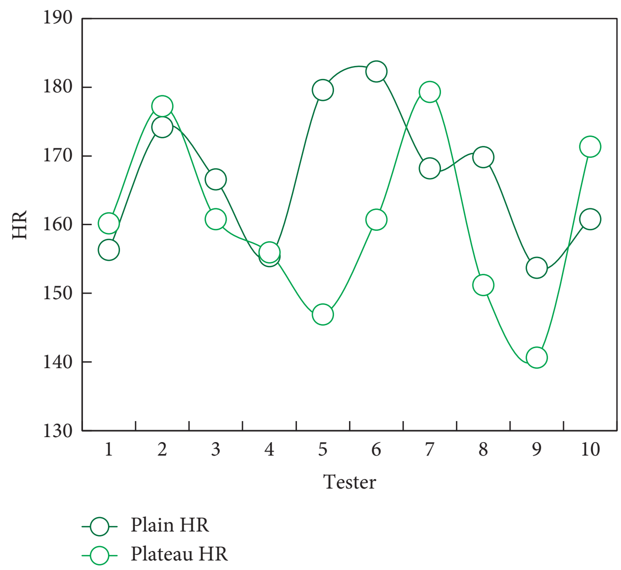

Figure 6: Comparison of 1 min HR recovery after 10 min running.

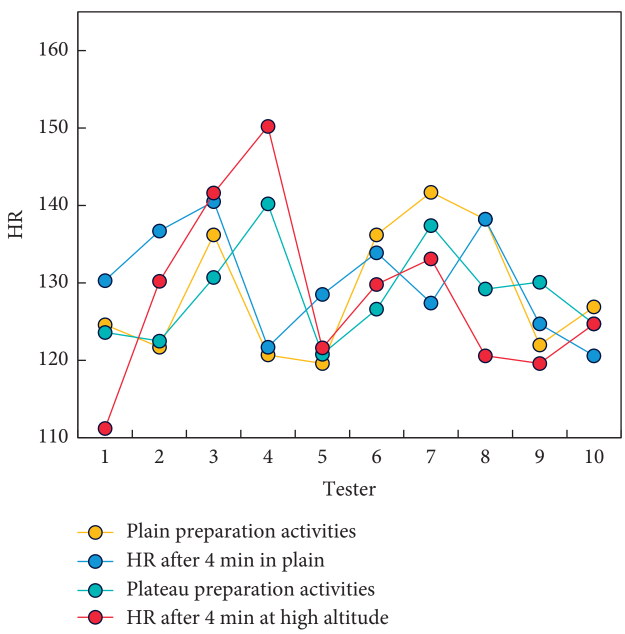

Figure 7: Comparison of 4 min HR after preparation and exercise.

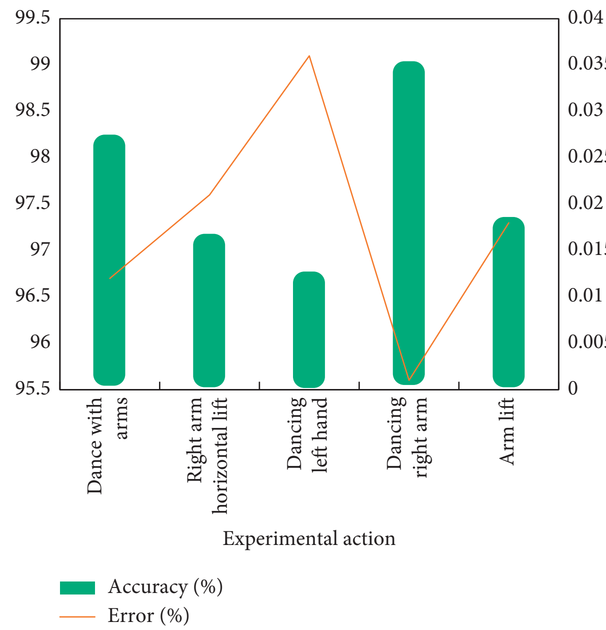

Figure 8: Improve the effectiveness of algorithm identification.

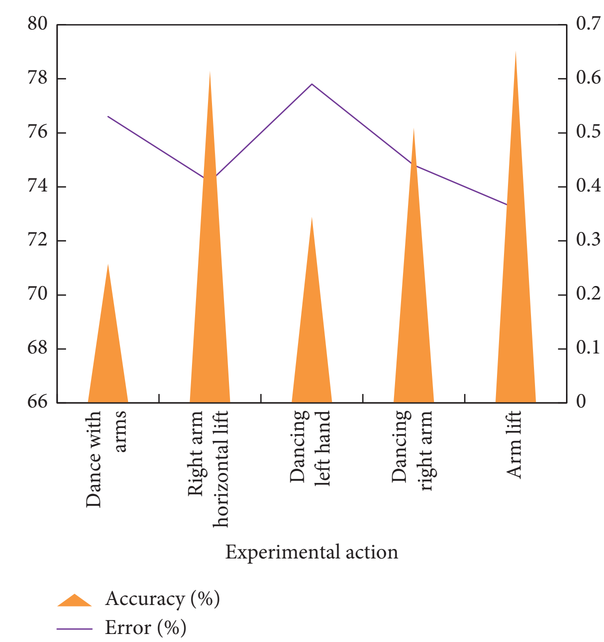

Figure 9: Effectiveness of traditional algorithm identification.

contractility raises oxygen consumption and necessitates more blood to perfuse myocardial tissue. Because myocardial tissue relies almost entirely on oxidative metabolism for energy, coronary artery oxygenation is critical [19]. On the other hand, a high HR reduces the diastolic time of the myocardium and makes the coronary artery insufficient in blood supply. Because most coronary artery branches are deeply embedded in the myocardium, the intense compression of myocardial contraction causes a sharp decrease in coronary blood flow.

HR can maintain a relatively stable change in both plain and plateau. Although the overall HR level in the plateau area is higher than that in the plain area, individuals with lower HR in the plain area still maintain a lower HR level during the plateau training period. Therefore, the heart rate can be said to be a very effective index to monitor the changes of cardiovascular function during actual exercise, and it is not affected by the altitude of the area, but only related to exercise intensity, so it can objectively reflect the status of cardiovascular system. During the exercise, the heart deformation and function of athletes of different levels adapt to the training course of specific functions.

4.4. Comparison of Algorithm Identification Effectiveness. Simulation verification is needed to prove the effectiveness of 3D gesture recognition method in boom based on Kinect.

A virtual platform for 3D gesture recognition experiment in boom is built with Windows 7 operating system, and the experimental computer is a personal computer. The number of participants in the experiment was five. Using the improved algorithm and the existing algorithm, 3D postures of dynamic arms were identified, and each person created five kinds of dynamic arm postures. The recognition accuracy and error rate of the two algorithms are compared, and the results are shown in Figures 8 and 9.

The analysis shows that the improved 3D gesture recognition algorithm of dynamic arm has higher accuracy than the existing algorithms and ensures higher accuracy and fewer recognition errors. Using the improved algorithm, in 3D gesture recognition rendering of dynamic arm, the direction, position, and some specific details of human dynamic arm can be well displayed, and the recognition effect is better than that of the existing algorithm, which can effectively meet the requirements.

5. Conclusion

Altitude physical training can help basketball players lose weight, but its effect on muscle circumference is dependent on their height, body shape, and training load. Athletes' aerobic metabolism can be improved, allowing them to tap into their full potential and better adapt to high-intensity training and competition. The DTW algorithm is used to evaluate sports, and the DTW distance is calculated as the similarity evaluation index between two sports groups. This method compensates for the traditional Euclidean distance's shortcomings in determining the similarity of nonconformal data. Simulation results show that a 3D gesture recognition method based on the Kinect boom has a high recognition accuracy and can meet intelligent technology application requirements.

Background. Chloasma is a common skin pigment disorder. Treatment of chloasma has been challenging, often unsatisfactory, and difficult to avoid recurrence. PRP is a new treatment for chloasma, but there is no consensus on its use. Lingyun Zhao's team recently reported a systematic evaluation and meta-analysis of the efficacy and safety of PRP in the treatment of chloasma, which is consistent with our ideas, but we will elaborate on the application of PRP in chloasma from a deeper and more comprehensive perspective. Before we started this study, we had registered with Prospero as CRD42021233721. *Methods*. The authors searched the public medical network, MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials, ScienceDirect, Scopus, and Science Network. The clinical trials registry ClinicalTrials.gov databases were searched for relevant publications to June 2021. The results showed the area and severity of chloasma (MASI) or revised MASI (mMASI) score. *Results*. Three RCTs, one nonrandomized controlled study, and four were prospective before and after self-controlled studies met the inclusive criteria. Intradermal PRP injections significantly improved chloasma as indicated by the significant decrease MASI (average balance -6.71, 95% CI -8.99 to -4.33) and mMASI scores (average balance -2.94, 95% CI -4.81 to -1.07). The adverse reactions were mild, and there were no significant long-term adverse events. *Conclusive*. The data can reflect the effectiveness and safety of PRP therapy for chloasma. RCTs are needed to determine effective treatment parameters, and long-term follow-up should be included to better clarify the efficacy and side effects of PRP in treating chloasma.

1. Background

Chloasma is a pigmentation disorder that mostly affects women's faces. The cheeks, forehead, chin, lips, and neck are the most common areas exposed to the sun, but other areas are not uncommon [1]. The main clinical manifestation of brown facial patches has a significant impact on the patient's appearance and quality of life [2]. It is a disfiguring dermatosis that affects a large number of people all over the world, and it is difficult to treat because the pathogenesis is still unknown [3]. Many studies have recently confirmed that contraceptive pills, ultraviolet radiation, genetic predisposition, and sex hormone levels are all strongly linked to the occurrence of chloasma. In addition, skin destruction, barrier vascular factors, and inflammatory factors all play a role in chloasma pathogenesis. Drug therapy, chemical peeling, and laser are the most commonly used treatment methods today. Despite the fact that there are numerous ways to treat chloasma, data obtained through general methods cannot reach the ideal state. Because of its recurrence, chloasma can cause complications like irritation, excessive pigmentation after inflammation, and excessive pigmentation after rebound, making it an unsolvable problem in the field of beauty [4].

The main problems to be solved in chloasma are facial pigmentation and pigmentation after drug treatment. As a new technique used in dermatology and plastic surgery, PRP has been confirmed in the latest studies in its potential role in pigmented dermatitis. PRP is an autologous blood product defined as a platelet concentrate obtained by centrifuging blood to a concentration 3 to 5 times above the basal platelet concentration [5]. As for the mechanism of PRP in the treatment of pigmentation diseases such as chloasma, the present research can be divided into three aspects [6]. On the one hand, the key elements of platelets are contained in alpha particles. Alpha-granules contain more than 30 cytokines and growth factors. These include PDGF, TGF-β1 and β2, EGF, and MGF [7]. Of these, the most important reduction in pigmentation is TGF-β1 [8]. It has already been shown to reduce melanogenesis by delaying activation of extracellular signal-regulated kinases [9]. On the other hand, some recent studies show that the key pathology needs to control melanin production by adjusting the activities of extracellular kinase and prostaglandin E2 (PGE2). In addition, it guides extracellular matrix remodeling, strengthens the expression of matrix metalloproteinases, eliminates extracellular matrix elements damaged by light, and stimulates fibroblast proliferation and collagen synthesis [1]. In summary, PRP can reduce pigmentation and brighten skin tone [10], which is also the primary need of patients with chloasma.

In recent years, PRP is a novel treatment option for chloasma and has shown significant clinical improvement. However, there is no consensus on its use [11]. The safety, efficacy, and prognosis of PRP have not been fully confirmed. Zhao et al. [12] recently reported a systematic review on PRP in the treatment of chloasma, which included studies without controlled experimental designs. We will elaborate on the application of PRP in chloasma under more stringent inclusion and exclusion criteria and bias evaluation and try to explore the evaluation of efficacy and safety by multiple factors including ethnic differences and pharmacological effects. This study was registered with PROSPERO as CRD42021233721.

2. Method

A systematic review and meta-analysis were conducted according to the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analysis) statement [13].

2.1. Search Strategy. A literature search was conducted in PubMed (1966 until acquisition time), MEDLINE (1966 until acquisition time), EMBASE (1974 to until acquisition time), ScienceDirect (until acquisition time), Scopus (until acquisition time), and Web of Science (until acquisition time). From 2000 to 2021, the clinical trial registry of ClinicalTrials.gov (http://ClinicalTrials.gov/) was searched.

The analytical strategy is to fuse the terms associated with chloasma with the terms identifying platelet rich plasma. Text and mesh term searches cover the words "platelet rich plasma," "platelet concentrate," "melanosis," "chloasma," "chloasma," "chlodue to the factma," "plaque," "spot," "chlosimilar Toma," "color," "photo," "stain," "stain," "pigment" "And word variants and similar words combined with Boolean operators" or "and."

We will review the list of documents that have been identified for similar tests or reviews to clarify the next research ideas. A complete article attachment of references reporting potential qualified tests will be obtained. If this is not possible, we will try to contact the author of the study to get some relevant information.

2.2. Sample. Inclusive criteria were as follows:

(1) Participants were diagnosed with chloasma.

(2) Intervention was any form of platelet-rich plasma, alone or as an adjunct in chloasma.

(3) Control was placebo, standard care, or alternative topical therapies.

(4) Pre- and post-treatment chloasma area and severity index (MASI) or modified MASI (mMASI) scores completed by dermatologists, as well as objective skin imaging analysis data. Other valid methods of evaluating the effects of PRP therapy include physician assessment, participants' subjective self-assessments, participant-reported outcomes, or satisfaction level. Additional outcomes included adverse effects reported during and after treatment.

(5) Study type was RCTs. Without a random trial, well-designed non-RCTs and prospective before-and-after self-control research will be regarded as a narrative embodiment of the present facts.

2.3. Study Quality and Risk of Bias Assessment. Two authors independently assessed the risk of bias of each study in the field of sequence generation using the criteria suggested in the Cochrane Handbook of Systematic Reviews of Interventions [14]: occupational concealment, blindness for healthcare professionals, participants and evaluators, incomplete outcome data, and other potential threats to outcomes and validity. For nonrandomized and before-and-after studies, risk of bias was assessed using the ROBINS-I bias tool [15]. The tool includes assessments in seven areas: bias due to obscure, bias in choice of study participants, bias in intervention classification, bias in expected interventions, missing data bias, outcome measurement bias, and reporting outcome selection bias.

2.4. Data Extraction. The data was collected and given to two reviewers to complete on their own. The discrepancy will be repaired through discussion or negotiation with the third reviewer. The following blinded and structured stratification strategy will be used by reviewers. First, the title and abstract should be filtered. Second, read the first article you chose. Third, choose research that satisfies the predetermined inclusive and exclusionary criteria. The author name, study duration, location, year of publication, journal, study design, sample, patient characteristics, dose and type of PRP used, concomitant interventions and outcomes, duration of follow-up, evidence level, and quality of research were all listed in a standard format.

2.5. Data Synthesis and Statistical Analysis. Results are combined unless diversity indicates that the combination is unreasonable. If some studies reported results as continuous measures, while others used dichotomous methods of the same structure, we would convert the previous results from continuous measures to binary. If results were reported at different times throughout the year, data from each time were aggregated and combined with data from other trials from similar times. After data collection is complete, the final analysis point is determined by consensus.

ReviewManager version 5.3 was used for meta-analyses. A meta-analysis was performed as suggested by the Cochrane Collaboration [16]. For continuous data with the same measurement unit, the weighted average difference and 95% confidence interval are used. For continuous data with different measurement units, the standardized average balance and 95% confidence interval are used. The difference is represented by 95% confidence interval. When there was no heterogeneousness ($I^2 = 0$), a fixed-effects model was used. We also used a random effects model. When heterogeneousness was high ($I^2 \geq 70\%$), except for the lowest quality studies, sensitivity analyses were performed to account for heterogeneousness and to confirm the stability of the results, with $p \leq 0.05$ considered statistically significant.

3. Results

From the database, a total of 101 records were retrieved (Figure 1). Following the deletion of 66 duplicate records, 35 articles were screened based on title and abstract. There is no other literature available from other sources. Eight studies were considered appropriate and included in the qualitative meta-analysis, while three studies were included in the quantitative meta-analysis after dragging through studies that did not meet inclusive criteria. Three RCTs, one non-randomized controlled study, and four prospective before-and-after self-controlled studies were among the studies included.

3.1. Characteristics of Included Studies. Tables 1 and 2 summarize study characteristics and patient demographics. A total of 8 articles published between 2017 and 2021 were included in this study, which included a total of 277 patients with chloasma. All of the study patients were adults, patient age-bracket from 20 to 58 years of age, and about 80 percent of them were women. Of the eight studies included, three were from Egypt, two were from Pakistan, one was from Thailand, and the remaining two were from India. All studies used the MASI or mMASI score to assess the severity of patients' chloasma conduct an initial assessment. Of the 8 studies, 3 had subjects with skin types III and VI, 1 had subjects with skin types II, III and VI, 1 had subjects with skin types IV and V, 1 had subjects with skin types III and V, and the other 2 were not mentioned. In 4 of the studies, the type of chloasma in patients was epidermal and mixed, while the remaining 4 were not mentioned. The mean follow-up time of patients was 97 days (range 14–180 days). All studies have demonstrated the significant efficacy of PRP in the treatment of chloasma. The specific quality results of RCT and non-RCT studies are shown in Figure 2 and Table 3.

4. MASI

Four of the eight included studies comparing the MASI between experimental (PRP treatment) group and control group were reviewed [1, 3, 18, 20]. The baseline MASI were comparable between experimental and control groups in all included studies ($p > 0.05$). In MASI, the random-effect model showed significant differences between the experimental group and the control group (average balance −6.71, 95% CI −8.99 to −4.33; $p < 0.05$; $I^2 = 55\%$) (Figure 3).

4.1. mMASI. Four studies comparing the mMASI between experimental (PRP treatment) group and control group were enrolled in the meta-analysis [3, 4, 18, 19]. The baseline mMASI were comparable between experimental and control groups in all included studies ($p > 0.05$). A REM yielded a significant difference in mMASI between experimental and control groups (average balance −2.94, 95% CI −4.81 to −1.07; $p < 0.05$) (Figure 4). The heterogeneousness was substantial ($p < 0.05$; $I^2 = 87$ percent). The study by Sirithanabadeekul et al. [4] was conducted in Thailand, whereas other studies were conducted in Egypt [3, 18, 19]. The racial difference may account for the heterogeneousness. The heterogeneousness decreased from 87% to 26%, and the average balance increased slightly to −3.66 (95 percent CI −4.74 to −2.57; $p < 0.05$) (Figure 5).

4.2. Degree of Improvement. A description of the extent of improvement can be found in five of the included studies [3, 17, 19, 20] (Table 4). The degree of improvement is mainly determined by referring to the decline ratio of MASI or mMASI score; among them, the most important values as dividing stages are 0%, 25%, 50%, and 75%, respectively. In most studies, the degree of improvement was rated as follows: 0: no feedback; 1: partial feedback (decrease 0%–25%); 2: good feedback (26%–50% reduction); 3: very good feedback (51%–75% reduction); 4: near perfect (75% reduction). Among the five studies, only one study chose the decrease ratio of MASI score as the evaluation criterion. Faiz and Meng [20] found that more than 60% of patients showed fair improvement, but no patient (0%) showed excellent response. Among them, 2 studies only used the decrease ratio of mMASI score as the basis for evaluating degree of Improvement. Tuknayat et al. [17] found that more than 80% of patients had mild or greater improvement, and about 40% of patients showed significant improvement. Topical tranexamic acid alone and topical tranexamic acid combined with PRP both showed some improvement in both groups, according to Gamea et al. [19]. PRP-treated patients, on the other hand, improved significantly more than the control group. MASI and mMASI were chosen as the improvement degree evaluation indexes for the remaining two groups. Hofny et al. [3] found that both the MASI and mMASI scores decreased and that more than 80% of patients improved mildly or significantly but that the difference

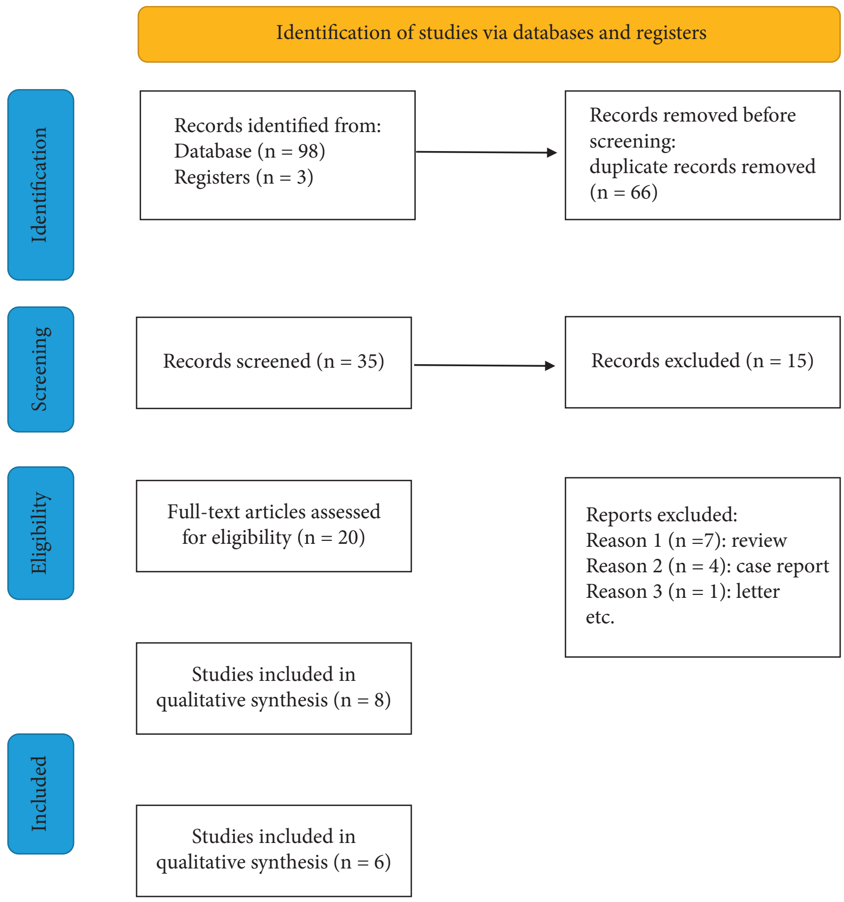

Figure 1: Flow diagram of included studies.

between two different PRP injections was insignificant. According to Adel et al. [18], clinical efficacy of PRP alone or PRP combined with IPL was improved, but there was no significant difference between the two groups.

4.3. Patient Satisfaction. A total of five studies reported patients' satisfaction after treatment. In two of the RCTs looking at PRP versus other therapies, patient satisfaction was significantly higher under PRP than in the control group [4, 19]. In the study of the effect of two different injection methods of PRP and the randomized controlled study examining the efficacy of PRP alone and in combination with PRP and IPL, there was no significant difference in satisfaction with the efficacy between the experimental group and the control group [3, 18]. And in another prospective before-and-after self-control studies, more than 90% of patients were satisfied with the efficacy of PRP [2] (Table 4).

4.4. Adverse Events. Adverse events were mentioned in 6 studies. Faiz et al. [20] found the presence of temporary transient erythema at the injection site of PRP (13% of the patients). Hofny et al. [3] noted swelling, redness, and pain at the injection site of PRP. Sirithanabadeekul et al. [4] noted bruising at the injection site of PRP (the number was not mentioned). Tuknayat et al. [2] noted xerosis and hyperpigmentation at the injection site of PRP (the number was not mentioned). Gamea et al. [19] reported hyperpigmentation (5% of the patients), erythema (50% of the patients), and pain (60% of the patients) at the injection site of PRP (Table 4). Tuknayat et al. reported xerosis (35% of the patients) and pruritus (25% of the patients) at the injection site of PRP (Table 4).

4.5. Other Outcomes. In the RCTs conducted by Sirithanabadeekul et al. [4] on the efficacy of PRP in the treatment of chloasma, not only were MASI and mMASI score used as the efficacy criteria, but also indicators such as melanin levels, skin wrinkle levels, and erythema levels were used. However, based on the disease characteristics of chloasma and the requirements of this study, only melanin level was included in the analysis. They found a significant drop in melanin levels in the skin of patients treated with PRP, but there was no significant change in melanin levels in the skin of patients injected with normal saline (Table 4).

5. Discussion

Chloasma is a common skin pigment disorder characterized by brown patches on the face, which sometimes becomes a chronic distressing condition on the patient. Chloasma is caused by a complex interplay of factors such as sunlight,

Table 1: Characteristics of included studies.

Author, year	Study design	Location	Number assigned/evaluated	Age	Control	PRP preparation	Treatment	Treatment time	Follow-up
Hofny et al. 2019 [3]	Prospective before-and-after self-control studies	Egypt	23/23	21–50	before-and-after self-control	(1) Double centrifugation (2) 10 minutes at 1600 rpm (3) 10 minutes at 4000 rpm	(1) Used PRP alone (2) Hemi-face study (3) Intradermal injections on the left side and microneedling before and after PRP application on the right side	Three sessions (four-week intervals)	1 month
Sirithanabadeekul et al. 2020 [4]	Randomized, split-face, single-blinded prospective trial	Thailand	10/10	33–58	Intradermal normal saline injection	(1) Single centrifugation 2.4 minutes at 3200 rpm	(1) Used PRP and saline (2) Hemi-face study (3) Unilateral intradermal injection of PRP and the other side was injected with saline	Four times every two weeks	1 month
Tuknayat et al. 2020 [17]	Prospective before-and-after self-control studies	India	64/65	—	before-and-after self-control	(1) Single centrifugation (2) 8 minutes at 3500 rpm	(1) Used PRP alone (2) Autologous PRP injections	Three sessions (four-weeks intervals)	3 months
Mumtaz et al. 2021 [1]	Nonrandomised controlled trial	Pakistan	64/64	20–40	Intradermal tranexamic acid	(1) Double centrifugation (2) 10 minutes at 1500 rpm (3) 10 minutes at 4000 rpm	(1) Used PRP and tranexamic acid (2) Grouping study (3) Experimental group: intradermal injection of PRP Control group: intradermal tranexamic acid	Three sessions (four-week intervals)	6 months
Adel et al. 2021 [18]	Randomized prospective split-face study	Egypt	20/20	—	Intradermal injection of PRP vs intradermal injection of PRP + IPL	—	(1) Used PRP and IPL (2) Hemi-face study (3) One side: intradermal injection of PRP The other side: intradermal injection of PRP + IPL	Four sessions (two-week intervals)	1 month
Gamea et al. 2020 [19]	Randomized controlled trial	Egypt	40/40	32–58	Topical 5% tranexamic acid	(1) Double centrifugation (2) 3 minutes at 2000 rpm (3) 5 minutes at 5000 rpm	(1)Used PRP and tranexamic acid (2)Grouping study (3) Experimental: topical tranexamic acid and intradermal injection of PRP Control group: topical tranexamic acid	Topical tranexamic acid (twice daily for 12 weeks	1 month

endocrine, hepatopathies, ovarian tumors, parasitic infestations, cosmetics, and stressful life events in a genetically predisposed individual [21–24]. However, the exact etiology of chloasma is still not well elucidated yet.

Although there are various treatments including drug therapy, chemical peeling, laser, etc., finding a cure for chloasma has always been challenging, often unsatisfactory, and hard to avoid recurrence [24].

In order to provide a reference for clinical treatment, we conducted a systematic review and meta-analysis to assess the safety and efficacy of PRP in the treatment of chloasma. The key finding of this systematic review was that intradermal PRP injections significantly improved chloasma, as evidenced by significant decreases in MASI and mMASI scores in various patient populations over a 12-week period. The systematic analysis found no serious or significant long-term negative effects. The effectiveness and safety of PRP therapy for chloasma were also demonstrated by the reported degree of improvement and patient satisfaction in enrolled studies. The following are some of the benefits of our research: (1) we focus on the efficacy and safety of intradermal PRP injection to improve chloasma, providing clear conclusions for other clinicians; (2) The conclusions are true and reliable due to rigorous and serious inclusion and exclusion by two professionals, and reasonable and standardized inclusion of relevant research and analysis; (3) the topic and possibility of the corresponding direction are analyzed and discussed based on the relevant professional knowledge of the team.

Our discovery is in line with a few previous studies. Cayırlı et al. [5] reported a case of a 27-year-old woman who accepted three PRP injections sessions with 15-day intervals for skin rejuvenation, and regression of chloasma achieved more than 80%. Farag et al. [25] reported a case with resistant chloasma. After six sessions of PRP injection, her MASI score came down from 17.7 to 7.5, and after a three-month follow-up, no relapse of chloasma was examined. In another case report, PRP was used as an adjuvant with Q-switched Nd-YAG laser and alpha arbutin therapy with hopeful lightening [26].

PRP is a high concentration of platelet plasma. Platelets are cellular fragments of megakaryocytes of the bone marrow. They are characterized by the absence of nuclei, organelles, and three types of granules in the cytoplasm: alpha, dense, and lambda [27]. Green fluorescence can regulate the biological medium of cell turnover and regeneration, exert influence on target cells and extracellular matrix, and thus realize the stimulation of repair and tissue regeneration. At present, the most widely studied green fluorescent factors include PDGF, TGF, and vascular endothelial growth factor, insulin-like growth factor, and EGF. Among them, TGFβ and PDGF play the biggest role in PRP treatment of chloasma. TGF-β1 and PDGF present in PRP could have led to chloasma reduction [15]. TGF-1 inhibits melanogenesis by downregulating the expression of the paired-box homotypic c gene of the ommatidium-associated transcription factor (MITF) promoter in a concentration-dependent manner. PDGF not only promotes collagen

PRP: platelet-rich plasma; IPL: intense pulse light; MASI: melasma area severity index; mMASI: modified melasma area severity index.

production, synthesis, and extracellular matrix formation, but also promotes angiogenesis, collagen, and hyaluronic acid synthesis. The rationale is that EGF reduces melanin production by inhibiting the expression of prostaglandin E2 and the activity of tyrosinase. They can further improve the pigmentation of the spots.

PRP treats chloasma not only through the action of platelets themselves, but also through biological stimulation at the time of injection. Biological stimulation can activate the anabolic function of fibroblasts and collagen production, thus restoring the metabolism and normal function of the skin [27], which also has a certain effect on delaying the process of chloasma.

PRP appears to be a potential new therapy with significant efficacy for chloasma, as a monotherapy as well as an adjuvant therapy. Gamea et al. [19] used PRP therapy in combination with topical 5% tranexamic acid, compared to topical 5% tranexamic acid monotherapy, which showed significantly better treatment results and patient satisfaction was detected in patients of combination therapy group. Adel et al. [18] compared PRP alone versus intense pulsed light (IPL) plus PRP, proving an obvious improvement of chloasma after PRP treatment ($p < 0.05$). However, no statistically significant difference was found between the two groups regarding mMASI score or patient satisfaction ($p > 0.05$).

The clinical stage and classification of chloasma can be divided into active stage and stable stage according to the results of slide pressure diagnosis, the number and morphology of inflammatory cells and dendritic cells under the reflection confocal microscope (RCM), and the changes of the number and morphology of blood vessels under the skin microscope and the erythema index. In addition, melasma was examined by slide pressure and wood lamp. Combined with its pathogenesis, melasma can be divided into four types: pigment type (m, melanin); vascular type (V, vessel); pigment dominant type (M > V); vascular dominant type (V > m). For typing treatment, simple type M: oral chloromethylnaphthoic acid, combined with fruit acid or Q-switched laser; Type V: to improve microcirculation, Nd: YAG/KTP can be used for treatment. M > V type and V > M type: both types are formed by both pigment and vascular factors. The treatment plan should take into account the inhibition of melanin production and the improvement of blood circulation. At present, PRP can not only inhibit the synthesis of melanin, but also have a variety of repair functions, such as its antibacterial or anti-inflammatory effect and skin vascular remodeling function, which play a role in a variety of main pathological and pathogenic mechanisms of chloasma. However, more and more data are needed to support and analyze whether the efficacy of PRP combined with the above treatment schemes is better.

What we can know is that chloasma is more common among Hispanic and Oriental people, but unfortunately we have not retrieved or understood the treatment of PRP in Indochina. However, there are exact reports on the efficacy of PRP for chloasma in the Middle East, India, East Asia, and other countries included in this study.

In terms of delivery methods, Hofny et al. [3] evaluated the efficacy of PRP treatment on chloasma via two different delivery methods. A statistically significant decrease was detected in both groups after treatment ($p < 0.05$), while no significant difference was found between two delivery methods.

6. Limitations

This review and meta-analysis established a foundation for using PRP to treat chloasma patients. It does, however, have some limitations. First, RCTs and prospective self-controlled before-and-after studies were combined, increasing the risk of choice bias. Furthermore, the current meta-analysis is constrained by a lack of high-quality studies, and biases hampered the interpretation of study findings. Furthermore, the small sample sizes and short follow-up periods in this study may have hampered the ability to detect clinically significant differences in outcome measures. Even if we use REM, the disparity in curative effect could be due to differences in research design, population, preparation technology (centrifugal/anticoagulant), treatment (volume/frequency/method), baseline patient characteristics (age, sex, skin type, or chloasma depth), and research methods.

7. Conclusion

To summarize, people are becoming more aware of and interested in PRP treatment for chloasma. In light of the findings discussed above, PRP therapy is a safe and effective treatment option for chloasma, regardless of the MASI or mMASI score, the degree of clinical improvement, or patient satisfaction. To establish optimal treatment parameters, more RCTs with an adequate control group, controlling for obscure factors, and larger sample sizes are required. Furthermore, the negative effects of PRP were not fully understood, limiting clinicians' use of PRP as a first-line treatment for chloasma. Long-term follow-up for effectiveness and side-effect profiles would be beneficial.

Teaching is defined as a relatively stable structural framework and activity process of teaching activities established under the guidance of specific teaching concepts and theories. It serves as a link between teaching theory and practice, as well as between the teaching system's static and dynamic conditions. The ITM (Inquiry-Based Teaching Model) has received a lot of attention and has been used in a lot of classrooms. Data mining (DM) is a method for discovering knowledge in databases and a technology for mining information in large data sets. It is primarily used to discover unknown relationships and patterns in related data. This paper applies DM's core technology, particularly the decision tree algorithm, to give hospital managers more comprehensive and in-depth data analysis capabilities, as well as strong technical support for hospitals in developing management plans. Furthermore, due to the scarcity of research data in the nursing profession, this paper introduces the few-shot learning technology to improve the model's analysis ability.

1. Introduction

At present, nursing students in China have low information quality, unclear information behavior, low information demand, weak learning awareness, poor literature retrieval ability, and weak information ethics awareness [1–5]. Moreover, the teaching method of nursing major is mainly classroom teaching; the teaching methods and teaching methods are relatively simple, with little contact with practice and little cultivation of students' management ability, which is not conducive to cultivating high-quality students [6]. It is an important part of nursing medicine, providing health and health services for human beings and taking the road of multicultural nursing to adapt to the changes of globalization and pluralism. Nursing education is the cornerstone of nursing career development, and how to adapt to the changes of pluralistic society is an important issue that modern nursing education should pay attention to and solve.

Data mining (DM) is an important method for discovering knowledge in databases. Data collection, processing, analysis, and interpretation are all part of the DM technology process [7, 8]. However, a study to improve the suitability and efficiency of curriculum resources is looking into how to organically combine these vast educational resources and apply them to classroom teaching according to students' interests. ITM (Inquiry Teaching Mode) emphasizes students' independent inquiry spirit, with the goal of cultivating students' innovative ability and thinking and ultimately guiding them to learn for life [9]. ITM has made significant progress in China in terms of reforming traditional teaching methods. In this case, it is decided to use DM technology to extract hidden but useful information and knowledge from these huge, incomplete, disturbing, noisy, and random data. By classifying and analyzing this potential basic information, potential problems can be identified with professional care planning and management [10, 11].

Under the guidance of modern nursing education thought, how to make full use of DM skills, integrate DM skills into subject education, and combine with the characteristics of nursing subjects to build a new education model is an important topic of education reform. In this study, DM technology is used to create a realistic scene of nursing management, provide abundant network resources, transform a single theoretical education into a rich activity experience, transform an isolated classroom space into a realistic scene of active reconstruction and closure between teachers and students, and accept open and interactive communication passively. Furthermore, because the Internet has abundant information resources and a human-computer interface that allows students to access a large amount of knowledge and information that matches their associative thinking and associative memory characteristics, students can use the Internet to generate interest in learning and encourage exploration and discovery learning [12]. Applying ITM to the course of educational research methods and exploring the innovation and practice of university teaching methods has a lot of practical implications.

2. Related Work

In the traditional teaching process, teachers pay more attention to the relevance, accuracy, emphasis, and difficulty of teaching content, and students are in a completely passive learning state [13]. Literature [14] puts forward the course of "inquiry learning" and points out that students' active participation in the process of scientific inquiry is the best way to learn scientific research. Literature [15] holds that science education should not require students to learn knowledge from textbooks but should master the process or method of scientific inquiry. Literature [16] holds that the content of textbooks should no longer emphasize students' passive knowledge learning but should involve them directly in the learning process, so as to cultivate students' inquiry ability and enable them to understand and master the inquiry process. According to [17], most nursing colleges do not provide multicultural nursing education, but only a few universities provide multicultural nursing education. Literature [18] holds that textbooks are an important carrier for spreading knowledge, and there is no development of education without textbooks. Therefore, it is particularly important to improve the compiling ability of multicultural nursing teaching materials and enable nursing students to acquire knowledge related to multicultural nursing in the process of nursing education. In [19], multiculturalism is regarded as a wide-ranging content, which has no clear connection and influence with the actual nursing practice. Therefore, only focus on professional knowledge education, ignoring the guidance of students' humanistic quality and cross-cultural ability. Literature [20] holds that foreign-related nursing talents should have competent humanistic professional knowledge, skilled operation skills, and nursing talents in medical and health institutions and community posts and have a high level of English to meet international nursing requirements. Literature [21] puts forward the "quality-oriented" training mode of foreign-related nursing talents in higher vocational colleges and constructs a nursing professional education program based on nursing professional ability and dominated by cross-cultural nursing ability.

In recent years, with the increasing amount of data and the increasing demand for data storage, management, and analysis, DM has gradually attracted the attention of academic and business circles. DM has been widely used in the fields of finance, commerce, and medicine to date, with positive results. Reference [22] is a rudimentary model for predicting and analyzing student dropout. It builds a university data warehouse and improves the ID3 decision tree algorithm by using educational administration and student information systems as data sources. Students' dropout can be predicted by factors such as major, percentage of failed subjects, and attendance records. The spectral clustering method is used in [23] to classify courses based on their degree of correlation, align existing courses, build an intuitive curriculum association system, and apply association rule mining to courses. Reference [24] proposed an algorithm to combine multiple subclusters based on connectivity, with the goal of improving the quality and accuracy of clustering results by focusing on the local optimality of the K-means algorithm and the sensitivity to the initial cluster centroid. Reference [25] proposes an algorithm for determining the number of clusters in a data set based on object stability. Reference [26] examines 11 widely used clustering validity evaluation indexes in depth, assessing their performance as well as the limitations of application scenarios in five aspects of the clustering algorithm.

3. Research Method

3.1. Application of DM Technology in the Nursing Field. Constructivism holds that the interaction between learners and the surrounding environment plays an important role in the understanding of learning content (that is, the construction of knowledge meaning). Under the teacher's organization and guidance, students discuss and communicate together, form a study group, analyze and discuss nursing management issues together, and conduct counseling discussion. This collaborative learning environment enables the whole group to share the ideas and wisdom of students and teachers.

With the development of nursing field, the nursing function is greatly expanded, and nursing is gradually developing towards specialization. DM technology from these huge, incomplete, noisy, fuzzy, and random data is used to discover the relationship between things through hidden but useful extracted information and knowledge to build a professional nursing quality management platform [1].

C4.5 algorithm is evolved from ID3 algorithm. An item called split information is introduced into the gain ratio. Split information is used to measure the width and balance of attribute split data. The formula is

$$SplitInfo(A) = -\sum_{i=1}^{w} \frac{s_i}{s} \log_2 s_i. \tag{1}$$

The formula for calculating the gain ratio is

$$GainRatio(A) = \frac{Gain(A)}{SplitInfo(A)}. \tag{2}$$

The information entropy of classification with attribute as root node is $Entroy(A)$, and its calculation formula is as follows:

$$Entroy(A) = \sum_{i=1}^{v} \frac{p_i + n_i}{p + n} Entroy(p_i, n_i). \quad (3)$$

Therefore, the formula $Gain(A)$ for calculating the information gain divided with A as the root node can be obtained as follows:

$$Gain(A) = Info(p, n) - Entroy(A). \quad (4)$$

After the calculation of the judgment criterion, that is, the information gain, a set of data can be obtained, which is the information gain of all attributes on the initial root node to divide the data set S.

The ID3 decision tree algorithm is a common decision tree learning algorithm. Its essence is to select all of the attributes of decision tree nodes based on information gain, so that all of the largest class classification nodes can have gain and the entropy of the classification data set is minimized when testing on each nonleaf. By reducing the average depth of the tree, this method effectively improves classification efficiency. To create the best decision management plan, the platform first uses a decision tree algorithm to mine and analyze these data [2]. Create a tree using this algorithm. Each node in the tree represents a single instance of a column, with the algorithm determining the node's placement, whereas each column in another instance is represented by nodes of varying depths. As a result, the algorithm is a classification form, with nodes represented as tree structures that represent additional data classification.

The implementation of decision tree can not only help nurses analyze the influencing factors of various clinical symptoms and implement targeted nursing actions according to the analysis results, but also effectively reduce patients' complications and improve nursing quality. It supports clinical decision-making by establishing predictive evaluation model, thus reducing medical cost and saving medical resources. Skilled nursing platform is a basic functional module, which is consistent with the clinical management of patient information through peripheral central venous catheter, including initiating clinical nurse consultation, checking professional nurse consultation table and writing consultation opinions, adding catheterization records for patients, arranging the next maintenance time, adding maintenance records, and adding complications, statistical reports, and other functions. The structure is shown in Figure 1.

Patient records in the data warehouse can be used to classify the prognosis of patients with various catheters at first and then analyze the indicators such as catheter consultation history, catheter maintenance, incidence of adverse events, etc., so as to improve related treatment schemes. In patients with catheterization, disease prognosis evaluation is an important means to promote medical quality control [6].

3.2. ITM Construction of Nursing Specialty Course. All teaching methods are developed by continuously verifying and fine-tuning the ideas, theoretical guidance, and teaching practice of specific teaching methods. Cognitive structuralism and constructivism are primarily at the heart of ITM's theory. The constructivist teaching theory emphasizes the fact that knowledge evolves over time. Professors cannot ignore students' prior experience because learning is active construction of knowledge based on one's own experience background. Simultaneously, the roles of teachers and students are clear: teachers serve as guides and supporters of learning, while students are active knowledge builders. As a result, constructivism theory emphasizes the importance of "situation" and "collaborative learning" in students' learning, particularly in learning environment design.

Through the mining and analysis of learning behavior data, the characteristics of students in the learning process are extracted and the learning process portrait is established. Analyze the learning time and learning quality of different students, establish a unified process description method, and make a formal description. Analyze the behavior information of students in process learning, determine the learning characteristics of the process, and set up the process portrait. Use the degree of understanding and difficulty of knowledge points embodied in learning behavior to optimize curriculum design and curriculum planning and improve existing deficiencies and improvement plans. Through the comprehensive analysis of the above two methods, data related to subject learning can be obtained, which is convenient for students to accurately get the subject learning situation and learning effect. Teachers can teach plan coordination without frequent interactive surveys and classroom tests.

By summarizing, analyzing and mining the data of various learning behaviors of the course, the learning situation of course learners can be obtained to form personalized labels. This label reflects the learner's learning ability and mastery of knowledge points in the course learning. The active time for learners to explore the course content on the information education platform can reflect the demand level for the expansion and renewal of learning resources. And dynamic and static information analysis are shown in Figure 2.

Because the classroom is the main part of classroom activities, the main component of ITM is to explore the classroom through group activities. Generally speaking, the team leader should be recommended democratically, and it is better not to be appointed by the teacher. This will allow students who are responsible and supported by students to organize and lead group activities. The team leader is responsible for coordinating within the group, supervising and inspecting the team members, and contacting the teachers during the investigation. The composition of student groups can usually be determined in the first two weeks of the new school year and will not change in the next semester or even the first year. Of course, if necessary, this will change according to the specific situation, for example, after a unit or chapter is completed.

The improved K-means algorithm designed in this paper firstly defines the sample density according to the local spatial distribution of samples. You can set a density threshold to identify outliers and temporarily delete them

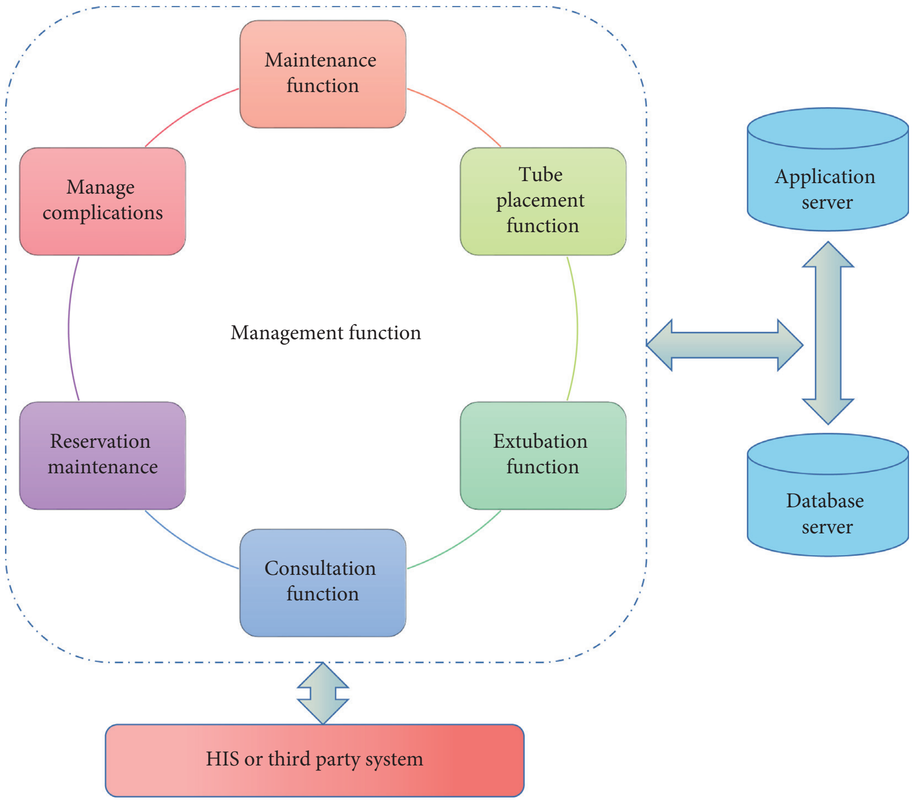

Figure 1: Platform architecture.

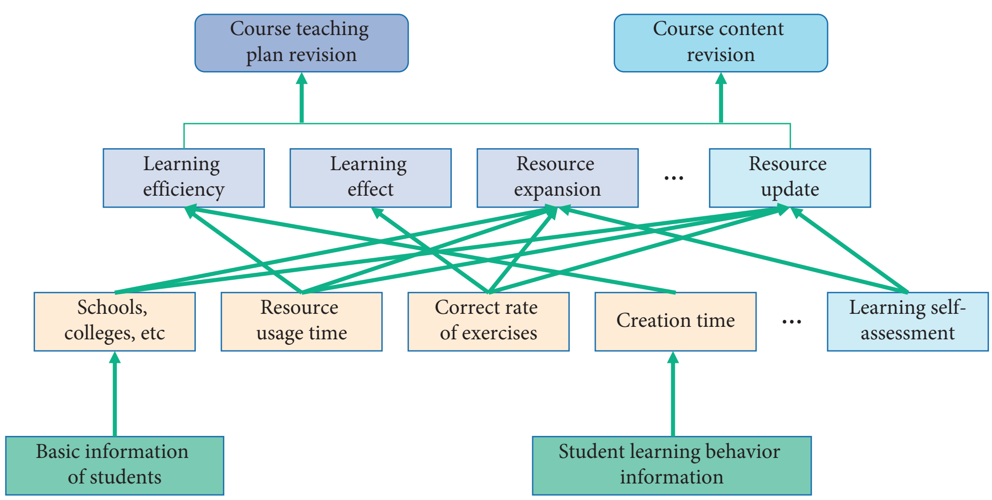

Figure 2: Dynamic and static data acquisition and analysis.

from the data set. Then it selects an initial cluster centroid according to the density of sample distribution.

The achievement data of students in a certain course and session are represented by data set $X = \{x_1, x_2, \cdots, x_n\}$, and the data object $x_i = \{i = 1, 2, \cdots, n\}$ in the data set is one-dimensional achievement data. n is the number of data points in the data set, and k is the number of clusters.

The distance between data points x_i, x_j is

$$d\left(x_i, x_j\right) = \sqrt{\left(x_i - x_j\right)^2} i = 1, 2, \cdots, n; \quad j = 1, 2, \cdots, n. \tag{5}$$

Sample distribution density of data point x_i is defined as the number of data points within the radius r around the data point:

$$density\left(x_i\right) = count\left\{x | x \in X, \left|x - x_i\right| < r\right\}. \tag{6}$$

Because there are a large number of overlapping data points in the score data, the number of overlapping data points is directly taken as the sample density value of this data point; that is, $r = 1$ is taken.

The threshold value of sample density is determined by multiplying the average value of sample density of all data points by a coefficient c:

$$threshold = c \times \frac{1}{n} \sum_{i=1}^{n} density(x_i). \tag{7}$$

Pay attention to cultivating students' innovative spirit and practical ability through examination, cultivating good psychological quality, learning interest and positive emotional experience, respecting individual differences, recognizing the uniqueness of individual development, giving positive evaluation, and giving full play to students' multiple potentials [20].

Teachers play an important role in assisting and guiding students in inquiry learning, which is centered on students' self-exploration process. Teachers should assist and guide students as needed throughout the learning process and fully reflect their leadership abilities. Students' time and homework must be carefully planned by teachers. Inquiry learning in the context of an inquiry-based teaching management platform relieves teachers' workload while also testing their professional abilities. Teachers' primary role in inquiry-based classroom instruction is to guide and inspire students, as well as to improve their learning and problem solving abilities. In a timely manner, summarize and evaluate the discussion and communication process, as well as the outcomes of the discussion and communication. Teachers and students collaborate in inquiry classroom teaching. They are clearly teachers and masters when they enter the inquiry classroom [13].

4. Results Analysis and Discussion

4.1. ITM Application Analysis. All kinds of teaching methods have relatively fixed teaching methods, and the active exploratory learning course is not static, but flexible and diverse. Let students study and discuss problems through independent thinking, group discussion and group communication, find solutions to problems, acquire relevant knowledge and resources, and combine and summarize classroom teaching applications and student feedback. Through the teaching system, abundant knowledge and information resources are provided, so that teachers and students can easily obtain the required information from the system, and at the same time, the natural and convenient navigation system can be exchanged to enable students to quickly complete self-study activities. In this way, teachers can avoid spending a lot of time and energy to master deep network computer knowledge and making educational software, so that teachers can concentrate on educational design and students will not get lost and struggle, in addition to the influence of bad information.

QQ chart and QQ residual were used to test the normality of evaluation results of nursing management knowledge and skills of nursing students. From QQ chart and QQ residual chart, the evaluation scores of nursing students obey normal distribution. Figure 3 shows the test results of the evaluation results of nursing management knowledge and skills of two groups of nursing students.

According to the evaluation scores of EG (experimental group) and CG (control group) nursing management knowledge and skills, as well as statistical tests, the total score, comprehension level, and application analysis level of EG nursing students, are higher than those of CG nursing students, with no significant difference in memory scores. Inquiry-based learning is based on the principle of interaction between two subjects, emphasizing learners' active participation, teachers' proper guidance, and students' active participation in the learning process. A learning method for gathering, organizing, and actively mining knowledge is included in the materials. Students can develop not only scientific knowledge, but also scientific thinking and attitude in this way. In general, teachers incorporate knowledge and skills into problems, allow students to learn knowledge while solving problems, and use knowledge to improve skills, all of which exemplify the concept of "hands-on learning."

Figure 4 shows the comparison between the total score of self-study ability before experimental teaching (before intervention) and scores of various dimensions of EG and CG nursing students.

According to the statistical test, there was no significant difference between the scores of self-study ability of EG nursing students and CG nursing students before the intervention. Step-by-step explanation of new knowledge points put forward by students aims at combining and discussing new knowledge points and practical teaching methods with students, instead of completely brainwashing and gradually injecting new knowledge into students' learning process. The ultimate goal of group exploration is to complete the general tasks stipulated in this chapter and require students to plan and design in various aspects after mastering the basic knowledge. They must perform a set of specific steps, such as division of labor, time planning, provision of materials, data collection, running experiments, and writing reports. The students' ability to accomplish the activity objectives is evaluated by concrete demonstration and project description.

After the intervention, the scores of self-learning ability, information ability, and cooperation ability between EG nursing students and CG nursing students were significantly different, but there was no significant difference in the scores of self-management ability (see Figure 5).

Nursing is a discipline with strong theoretical knowledge, which contains many concepts, principles, and abstract theories, which makes students feel bored. The research shows that most CG students who adopt traditional teaching methods lack interest and enthusiasm in nursing management. ITM of nursing specialty courses based on DM skills has significantly increased students' interest in learning, enhanced their learning enthusiasm and initiative, and increased the fun and intuition of education. This stimulates students' interest in learning and makes learning more active. Based on the course ITM of DM skill nursing specialty, this study makes full use of DM skill simulation to create a realistic nursing management scene, and students use the knowledge they have learned to conduct nursing

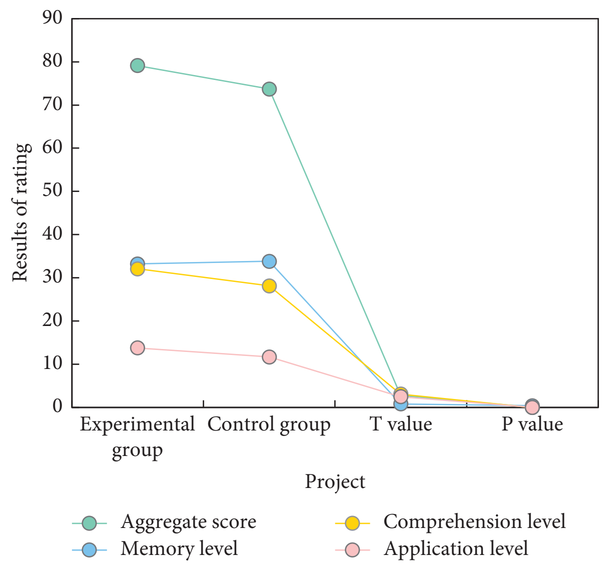

Figure 3: Examination results of nursing management knowledge and skills of nursing students.

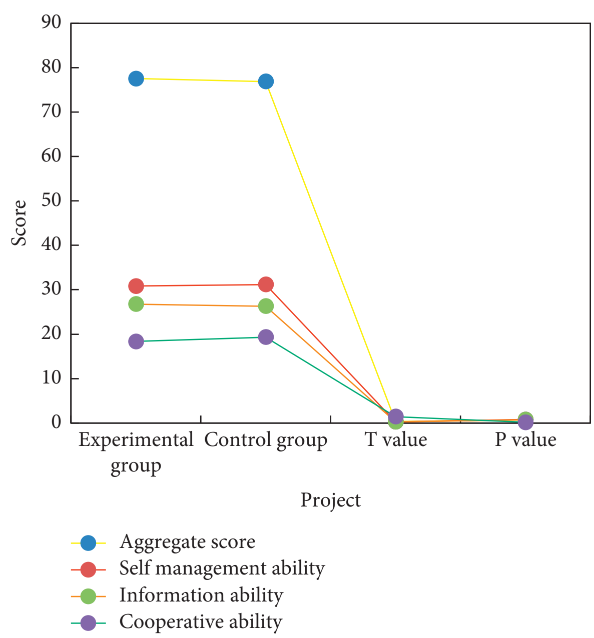

Figure 4: Comparison results of total scores and scores of all dimensions of autonomous learning ability of nursing students (before intervention).

management activities in the simulation situation, thus transforming into a single theoretical teaching, with rich experience in activities in class. Therefore, the nursing professional course ITM based on DM skills can improve students' problem analysis ability and practical problem solving ability and help to cultivate nursing management skills.

The network-based education has clear learning objectives and content, as well as related tasks and problem situations. Students are primarily responsible for learning objectives throughout the educational process, aside from

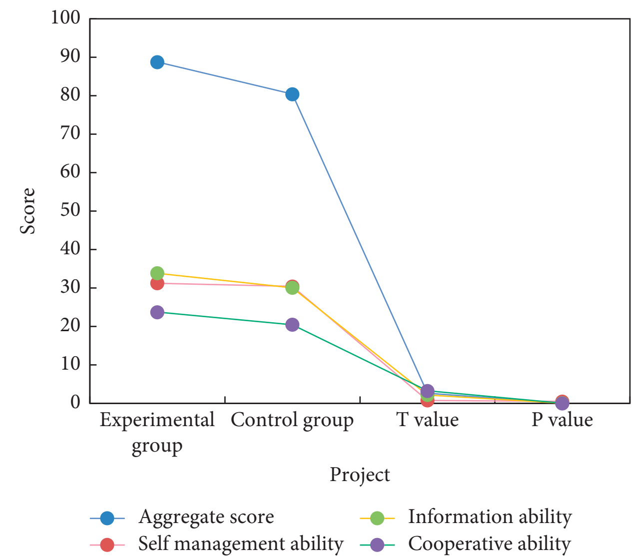

Figure 5: Comparison results of total scores and scores of each factor of independent learning ability of nursing students (after intervention).

the appropriate inspiration, guidance, and assistance from teachers. It conducts independent exploratory learning in a variety of ways, actively refers to and collects reasonable data, combines and processes it, and finally achieves the goal of solving problems and acquiring knowledge and ability, all while being guided and driven by problems or tasks. Students have a lot of freedom to study independently with this multichannel problem solving method. As a result, an ITM-based nursing professional course based on DM technology can help students improve their autonomy and discipline awareness. Consider internal medicine, which is at the heart of the nursing process. In terms of the knowledge system and curriculum requirements, ITM does not contradict nursing education [4, 5]. This model integrates the cultivation of innovative ability, clinical thinking ability, and cooperation ability into nursing education in the new era, trains innovative applied nursing talents with innovative spirit and adapting to the development of the times, promotes nursing education's innovative development, and thus produces better teaching effect for nursing students (Figure 6).

From these analysis results, the comprehensive inquiry-based teaching concept can improve the innovative thinking of undergraduates. In the interview, students thought that inquiry education provided a platform for innovation, guided scientific research, and helped innovation. This is basically consistent with many scholars' research on providing an innovation platform for college students to improve their innovation ability [6, 7].

The concept of inquiry teaching supporting nursing practice education puts forward a higher level of professional test for teachers. Teachers should organize and carefully consider all aspects of educational activities. In the whole process of maker education, teachers should learn to integrate and help students innovate and share their successful creation. This will greatly develop and improve teachers' abilities and improve the quality of comprehensive

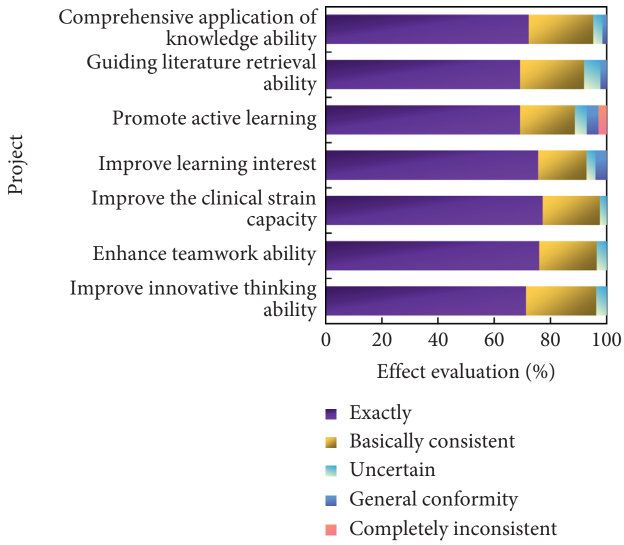

FIGURE 6: EG students' evaluation of the effect of inquiry-based teaching.

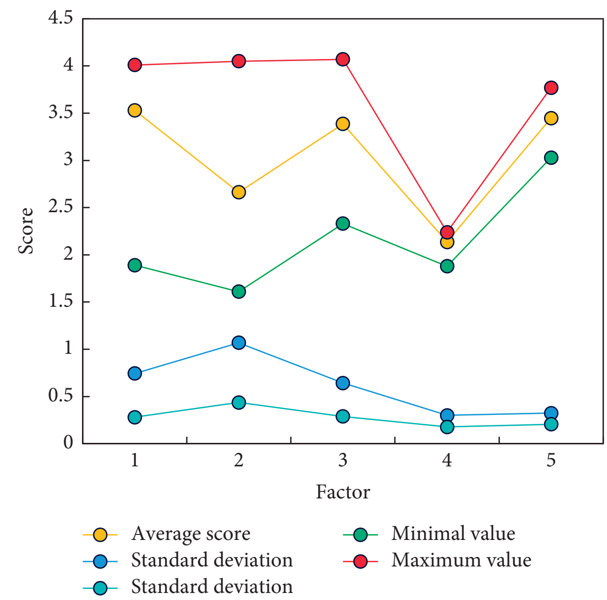

FIGURE 7: Scores of various factors in cross-cultural sensitivity scale.

education for nursing teachers. In order to analyze the poor cross-cultural sensitivity of the interviewees in more detail, the multicultural sensitivity was counted according to the factors shown. See Figure 7 for details. Among them, 1~5, respectively, represent communication participation, difference of identity, communication confidence, communication pleasure, and communication concentration.

The results show that the scores of each factor from high to low are communication participation, communication concentration, communication trust, discriminatory identity, and communication pleasure. Among them, the scores of communication participation and communication focus are relatively separated, indicating that modern nursing students are willing and able to engage in cross-cultural communication seriously. But differences in identity and communicative enjoyment were relatively poor, suggesting that, despite cross-cultural communication, students were less able to distinguish between cultural differences due to a lack of understanding of other cultural differences, affecting the pleasure of communication. Therefore, it is suggested that follow-up research work should focus on cross-cultural knowledge learning.

4.2. DM Analysis. The distribution of scoring data has the following characteristics: First, the distribution of scores in the same subject may fluctuate greatly due to changes in subject content, question types, examination difficulty, and so on. Secondly, in the case of different subjects in the same academic year, the distribution of scores may be quite different due to the great differences in subject contents and examination methods. Third, the scores of most subjects are distributed continuously, without obvious flaws, and the number of intermediate students is large. Fourth, the scores of individual students in most subjects are not good, so they are separated from the scores of most students and become outliers in the data set. Calculate the standard deviation of sample size and contour coefficient for the discretization results of the three algorithms.

Figure 8 shows the standard deviation of the result sample size of three methods of discretizing the result data of some courses according to the score value by using the K-means algorithm and the improved K-means algorithm.

As can be seen in Figure 9, the result of fractional discretization is not good in data similarity and does not meet the requirement of discretization, so as to maximize the data similarity within clusters and the data difference between clusters.

The improved K-means algorithm of data discretization can make the data similarity within segments and data differences between segments as large as possible and make the number of data points more uniform, meeting the requirements of class discretization.

It is worth noting that ITM injects a lot of color into teaching and teacher evaluation methods, as well as raising the bar for teachers, students, the educational environment, and educational conditions. Teachers' knowledge scope, classroom control, students' understanding, and instructional design skills are all put to the test in ITM. And teaching methods are not set in stone. Teachers must pay attention to course effectiveness, integrate various teaching methods based on the actual teaching situation in the classroom, and fully exploit the benefits of each teaching method. ITM, on the other hand, is time-consuming and labor-intensive, making it unsuitable for classes with a large number of students. As a result, teachers should adapt it to the situation at hand. Dynamic data differs from static data in that it can be changed. Bring course learners' learning habits into the information-based teaching platform. Compare the time spent browsing course content, the correct rate of answering course matching questions, and the knowledge point feedback scores. These data reflect students'

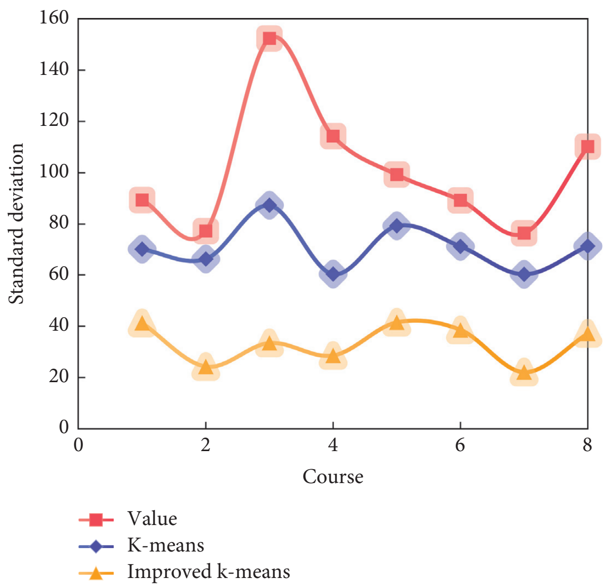

Figure 8: Standard deviation of the sample number of results of data discretization.

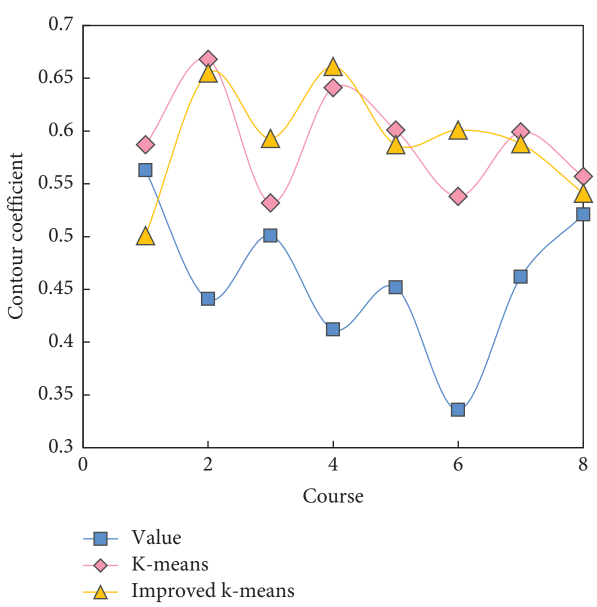

Figure 9: Contour coefficient of result of data discretization.

interest in and mastery of the course, and self-tests and other tests can be used to achieve the online learning effect. The learner's self-evaluation of the mastery degree of the learning content, such as complete mastery, basic mastery, and unclear places, is referred to as a self-test. It comes with knowledge test questions that the system evaluates based on the answers to the test questions.

The ITM course of nursing specialty constructed by researchers has achieved relatively successful results. In the inquiry teaching of nursing major courses, researchers guide students to learn independently, adopt flexible and diverse teaching methods around the teaching content, and make the teaching content more colorful, thus stimulating students' learning subjectivity and learning better and constantly deepening students' understanding of multicultural nursing, so that students can enhance their memory and absorption of multicultural nursing knowledge through multiangle and novel ways. According to the evaluation results of teaching methods, students have a high degree of recognition of the teaching methods and means adopted in this study, which has produced positive and effective results.

5. Conclusion

In the era when DM realizes personalized learning with big data, big data is influencing and changing the ecological environment of education and the operation mode of teaching. Using various related technologies of DM to deeply process the massive data of the platform can make the information system get rid of the previous mode which can only be used as electronic data entry tool, simple query function, and statistical report. Evaluation feedback in each teaching stage is used to continuously improve and perfect teaching activities, promote students to better understand and apply DM knowledge and concepts, and improve the quality of engineering education. Under DM technology, the nursing professional course ITM has changed the teaching concept, established a brand-new modern nursing education concept, effectively cultivated the nursing professional students' autonomous learning ability, auxiliary learning ability, and practical problem solving ability, laid a solid foundation for the full implementation of student-centered quality education, and provided reference for the development of inquiry teaching.

Few-Shot Learning has had a significant influence on how people live, work, and learn. Physical education is a requirement for a college diploma. Sports management systems, which focus on data collection, organization, and analysis, as well as timeliness and guidance, are one of the current challenges in the field of physical education at the country's top colleges and universities. The amount of sex in the room is minimal. Time is money when it comes to making college sports decisions, and this paper uses data from physical fitness tests to illustrate this point. Use Few-Shot Learning technology to extract relevant data from the data, allowing teachers to provide more scientific and effective guidance and suggestions to students. The design and implementation of this paper collect data from physical fitness tests in real-time using mobile edge computing, analyze the data, and display the results using machine learning technology, which mines deep features and displays analysis results, can be used to evaluate students' physical fitness. The data and information in the physical fitness analysis system are more readable and time-saving, allowing students to better understand their true level of physical fitness. Because of the results of data mining, teachers can provide more specific guidance and recommendations for each student's physical characteristics.

1. Introduction

With the deepening of the practical application and theoretical research of big data, big data has become a new growth point of the economy and society, as well as an emerging analytical tool for humanities and social science research, which has put forward innovative requirements for decision support of college sports in the era of big data [1]. The rapid development of big data and the Internet, cloud computing, and other technologies have prompted the growth of data in the information age, and the accumulation of data has become more and more massive, with the consequent generation of industry data in massive areas. Sports can improve people's physical and mental health, as well as guide them toward developing scientific and healthy lifestyles and habits and promoting their overall development. It is conducive to deepening sports reform, enabling the sports industry to be developed more systematically and comprehensively, and enhancing the vitality and momentum of the sports industry's development; it is conducive to increasing employment opportunities and raising the employed population; it is conducive to deepening sports reform, enabling the sports industry to be developed more systematically and comprehensively, and enhancing the vitality and momentum of the sports industry's development. The main shortcomings of such tools are manifested in the manual way of input work intensity; form stacking complex, inefficient, weak analysis, data readability is poor. Traditional physical education adopted statistical tools, often taking Excel office software and comprehensive class education office system. It not only adds to administrators' and teachers' daily workloads but it also makes data processing and analysis more difficult. Daily teaching activities and physical fitness tests cannot provide students with real-time and effective feedback [2]. In terms of analysis methods, the analysis methods used in the above tools are still stuck on simple variance, mean, and reliability calculations, resulting in the conclusions obtained from the analysis staying on the surface and failing to bring the full value of a large amount of data into play. However, the data and conclusions that administrators, teachers, and students care about are precisely these less easily discovered and valuable hidden information. To meet the development needs of big data analytics and to facilitate the deep integration of big data and its applications in various fields, research on big data analytics process modeling techniques is conducted to fully consider the ease of data analysis, domain complexity, and efficiency of execution of big data analytics. To improve the efficiency of big data analysis, to allow users to focus on domain business analysis logic rather than tool usage in big data analysis, to establish a domain-oriented reusable, well-structured processing framework for big data analysis processes, and to rely on the Hadoop platform with distributed storage scale and parallel computing capabilities. This aids big data analysis and value discovery in a variety of fields, and it is critical for developing scalable and user-friendly big data intelligent analysis software systems. The integration of existing resources and the development of a professional university sports decision support system can solve problems and issues encountered on the road to sports development, provide advice and strategic support for the development of sports, and accelerate the construction process of physical education in the context of globalisation and informatization [3].

In this paper, I attempt to use data mining techniques to study and analyze data on college students' physical fitness, develop a new college sports decision support system, and mine and analyze data on college physical fitness in order to uncover more valuable hidden information. This will assist students in better understanding their physical fitness status and teachers in initiating appropriate teaching activities on time. It improves the quality of university physical education by making physical education more timely, effective, and relevant; it also assists students in improving their physical fitness and developing good exercise habits.

2. Related Work

With the in-depth research of data mining technology, the application of data mining technology has been gradually extended to different fields, and some of the scholars have applied data mining technology to the education industry.

The literature [4] systematically discusses the importance of data mining techniques applied to education and teaching. The literature [5] employs crude sugar set theory and mining analysis to determine the relationship between improved student performance and active learning IM's dominant factors. There is still a lot of data in the university education system that can be mined, such as teaching evaluations, student performance, student information, and so on. However, data mining research in college education is currently primarily theoretical, and there are few shaped products that apply to data mining technology. The number of students and data managed by colleges and universities is growing year by year, and the manual processing mode in dealing with student information and student achievement can no longer meet the current needs. More scholars and researchers are applying data mining techniques to college education and physical ability analysis in this environment. Literature [6] uses the classification method of a decision tree, applies data mining technology to the student performance information, and constructs a professional ability decision tree model to help teachers gain more accurate and efficient insight into the problems that exist in the teaching process, and achieve the effect of optimizing teaching quality by using performance information. The literature [7] adopted the decision tree ID3 algorithm, and the association rules Apriori algorithm for data mining analysis based on student performance data. The ID3 algorithm was analyzed to get which factors are related to students' good grades; the association rules Apriori algorithm was analyzed to dig out the degree of influence of course excellence on other courses. The literature [8] used the FP-Growth algorithm to study the student physical fitness test data from a deeper level based on the physical fitness test data from six colleges and universities. The results showed that nearly half of the students in the six colleges were not at the standard weight and the results of the algorithm run observed that the students lacked training for lower body strength in their physical training and had significantly weaker lung capacity rating and endurance rating, suggesting that the students should strengthen their aerobic training. The literature [9] used the association rule Apriori algorithm to filter out five strong association rules about male and female students, respectively, based on the physical test data of college students in a university. The results showed that under the condition of "total score = pass," more female students failed in the test item standing long jump, and more male students failed in the test item pull-up. This identifies sports that need further attention in the future at the university to strengthen the overall physical fitness of students. The literature [10] used student data from a US university to develop an early warning system for students. The literature [11] proposes a method for predicting students' knowledge of the necessary skills for their majors by mining information from their academic performance once the students' bias in the learning process has been compensated for. Literature [12] uses the Hadoop big data platform to mine the data of informative campus applications in order to recommend campus information based on learning characteristics. The literature [13] examines the innovation of graduate physical education's deep evaluation mechanism in the era of big data from three perspectives: student-oriented value logic, practical logic with the goal of theory implementation, and problem-oriented reality logic. The literature [14] examines the general idea of reforming the evaluation method of college physical education based on big data from a theoretical perspective before delving into the specific application of big data evaluation on a practical level. The literature [15] begins with the current state of operation and growth trend of the big data platform for physical education in colleges and universities, analyses its goals and values, and investigates its architecture and characteristics in order to develop an excellent scheme to promote the construction, operation, and management of the big data platform for physical education.

It can be seen that a large number of research findings on big data have aided in the development of quantitative analysis methods in physical education. These findings seize big data's innovation opportunity and examine the innovation of quantitative analysis methods of physical education promoted by big data from multiple perspectives, based on a comprehensive analysis of big data's characteristics and mining its value; However, the majority of big data and physical education research is based on a general perspective of physical education or a more general study on the overall grasp of physical education, and the relevance of theoretical guidance, as well as the operability of the application of theoretical results, must be improved. Simultaneously, research into the integration and innovation of big data and quantitative analysis methods in physical education is primarily based on theoretical or empirical feasibility analyses, with the realistic path of how to apply it not being sufficiently explored.

3. Research and Construction of a Decision Support System for University Sports Based on Big Data Analysis Technology

3.1. Big Data Analytics Technology. In the current network era, the value of data as the core of big data does not arise out of thin air and requires the help of certain mining techniques.

Data mining usually has the following eight steps: (1) information collection: abstract the analyzed object, get the characteristic information of the analyzed object, and use reasonable information collection methods to load the characteristic information of the analyzed object into the database. (2) Data integration: the information collected from various objects is centralized to facilitate the subsequent correlation analysis work. (3) Data statute: The data volume after data integration is generally large and difficult to handle. The data set obtained can be statutorily represented, and the data volume after the statute is much smaller than the original data, but still maintains the integrity of the original data, and the data mining result after the statute is the same as a result before the statute. (4) Data cleaning: Some of the data collected in the database may be incomplete, noisy, or have conflicts, etc., so data cleansing work is needed to improve the data in the database and eliminate all kinds of illegal data. (5) Data transformation: the data in the database will be transformed into a form that is convenient for data mining, and the common ways and means are smooth aggregation, data generalization, etc. (6) Data mining: the data information stored in the data warehouse, the use of appropriate analytical tools and statistical methods, processing data, and finally getting the analysis results. (7) Pattern evaluation: Validate the data mining results from the business perspective and analyze whether the data mining results are correct. (8) Knowledge representation: presenting data mining results to users, which can use various visualization tools, reporting tools, etc.

Deep learning [16–18] is one of the key technologies for tapping the value of data at the level of big data; at the level of deep learning, the collection and use of a large amount of data has the potential to improve the accuracy of machine models. The meanings of TP and TN when classifying a class in a machine model both represent the case where the classification result is correct: TP is a positive class, and TN is a negative class. FP denotes that the incorrect category is divided into the correct, while FN denotes that the correct category is divided into the incorrect. As a result, the support of big data is required to develop machine learning, and the assistance of machine learning is required to mine the value of big data, and the two are mutually reinforcing and interdependent. The study's main algorithm is machine learning, which is a broad term for a specific type of algorithm. Machine learning algorithms [19, 20] attempt to intervene or classify a large amount of raw data in order to uncover hidden laws in the data and discover the data's value, allowing data models to be built. As shown in Figure 1, it mainly consists of three types, and this study is chosen to implement model building with supervised learning.

Concerning the machine models in this study, they are all practically similar to decision tree classification models, and all amount to a combination of multiple dichotomous classification problem models. Therefore, before proceeding to model generation, the first task is to gain a detailed understanding of the binary classification problem. The next example will be picture content discrimination: there is a picture stored in a certain computer gallery. The task of the computer at this point is to determine the specific content in the current picture. After making the relevant determination, the computer has to check whether the judgment output meets the expected effect. Therefore, a feature vector X can be set in the computer for representing the result. Then, the current computer can use the computer language $Y = 0$ or $Y = 1$ to indicate the right and wrong results of the judgment, the main formula used as shown below:

$$Y_i^{l+1} = \left[X_{i,j,c}^{l+1}\right]_{s^*s^*32}. \tag{1}$$

$$\prod_i X(\oplus| > i) = \prod_i Y(\, > i\oplus) \tag{2}$$

CRM, as a cascade regression model, usually requires first integrating the predictions of each decision tree and calculating the average as the final prediction; however, the classification problem employs a different strategy: the plural voting method, which requires counting the number of votes received for each type of label and selecting the one with the most votes. As the final prediction result, the classification labels are output. According to the previous analysis, some factors tend to influence the combined classifier's generalization ability, which is mainly related to the classification performance of individual metaclassifiers from the perspective of individual metaclassifiers; from the perspective of the set of metaclassifiers, the size of the correlation between metaclassifiers is also an important influencing factor.

The boundary function of a decision forest is described as follows:

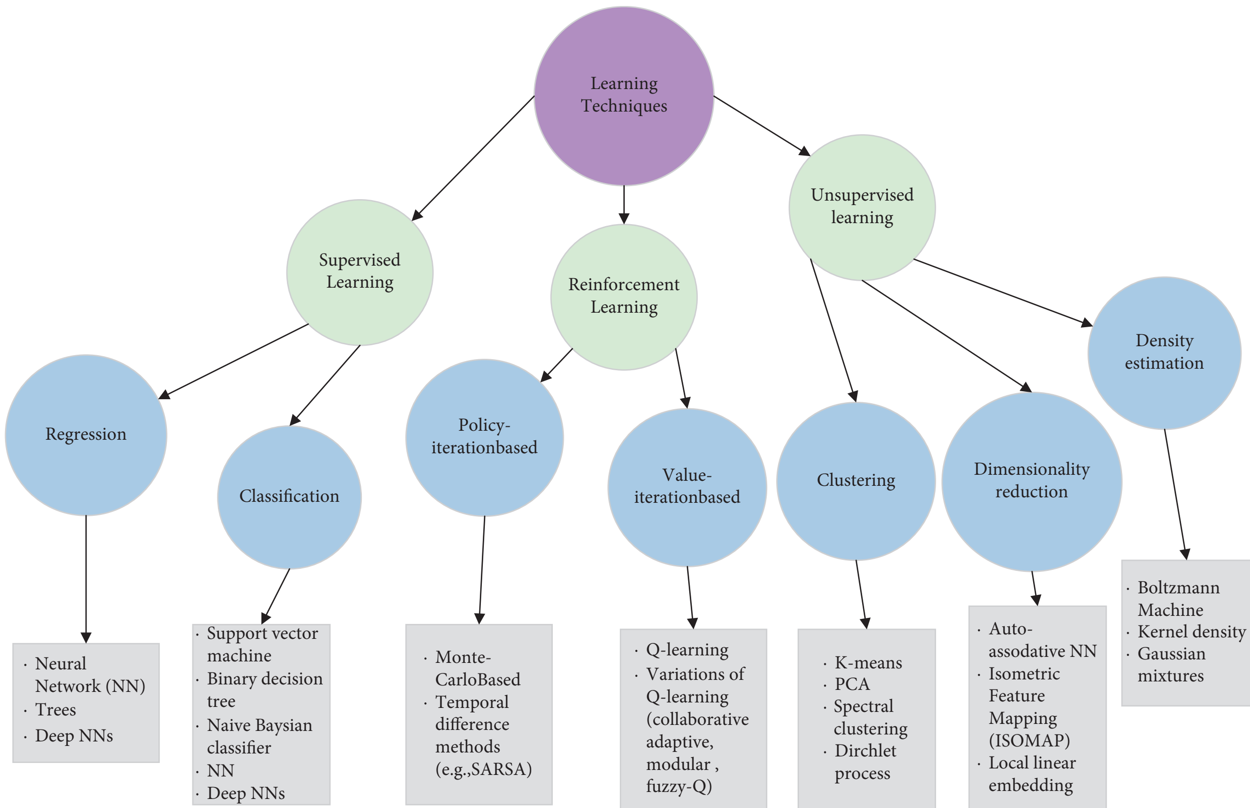

FIGURE 1: Machine learning classification graph.

$$g_{i,j,f}^{1} = \mathrm{ReLU}\left(b_1 + \sum_{a=1}^{m}\sum_{b=1}^{n} g_{i,j,f} + b\cdot t_{a,b,c}^{1}\right). \tag{3}$$

The categorical efficacy of decision forests is defined as follows:

$$r(h_i) = Nh_i(1)\left(Nh_i(1) + Nh_i(-1)\right)^{-1}. \tag{4}$$

Define the original prime function of the decision forest as $rm(\theta, x, y)$, and the boundary function as the mathematical expectation of the original prime function on $m(x, y)$, whose expression is as follows:

$$rm(\theta, x, y) = m(x, y)\cdot I(x, \theta) + k(y, \theta)\cdot j(\theta, x) \tag{5}$$

Since the mathematical expectation of the variance satisfies the following:

$$g^{\mathrm{n}}(x) = \lim_{a\longrightarrow 0}\frac{1}{a^n}\sum g(x - ak)\binom{n}{k}(-1)^k. \tag{6}$$

Therefore, it can be obtained that the generalization error of the decision forest PE^* satisfies the inequality

$$PE^* = \bigcup_{i=1}^{n} X_i\left(1 - s^{\mu}\right) + C. \tag{7}$$

The decision tree's definition and principle have been explained. The decision tree is essentially a process of growing data from the root node to the leaf nodes in a continuous split. The branching direction of nodes is currently determined in the construction of decision trees primarily based on the judgment criteria of the classified nodes, which cannot be changed once the direction has been established. Following VGGNet, 3 ∗ 3 small convolution kernels became the standard for network design. Most general neural networks start with a 7 ∗ 7 large convolution and then use 3 ∗ 3 convolution stacking (ResNet, DenseNet), whereas lightweight neural networks start with a 3 ∗ 3 convolution and then use 3 ∗ 3 convolution stacking. This method can make the network classify the best at the current node, but it cannot guarantee the best final classification result, according to the Info-Gain principle. A "probabilistic" decision tree is designed to balance the current optimum and the final classification result. This tree does not determine the split of each node but rather describes it in a probabilistic manner. Because the number of labeled samples in practical recognition tasks is usually limited, using ISM for target detection tasks has some drawbacks.

Figure 2 explains the structural framework of the decision tree algorithm, where the voting codebook is obtained by sliding windows and extracting feature channels (feature descriptions), and in the training process, a series of decision trees are formed by supervised target training and heuristic algorithms, and further formed into a decision forest; in the target detection process, the voting codebook obtains numerous target locations by weighted voting, and the greedy algorithm is used to solve for the maximum target probability to obtain the final target location.

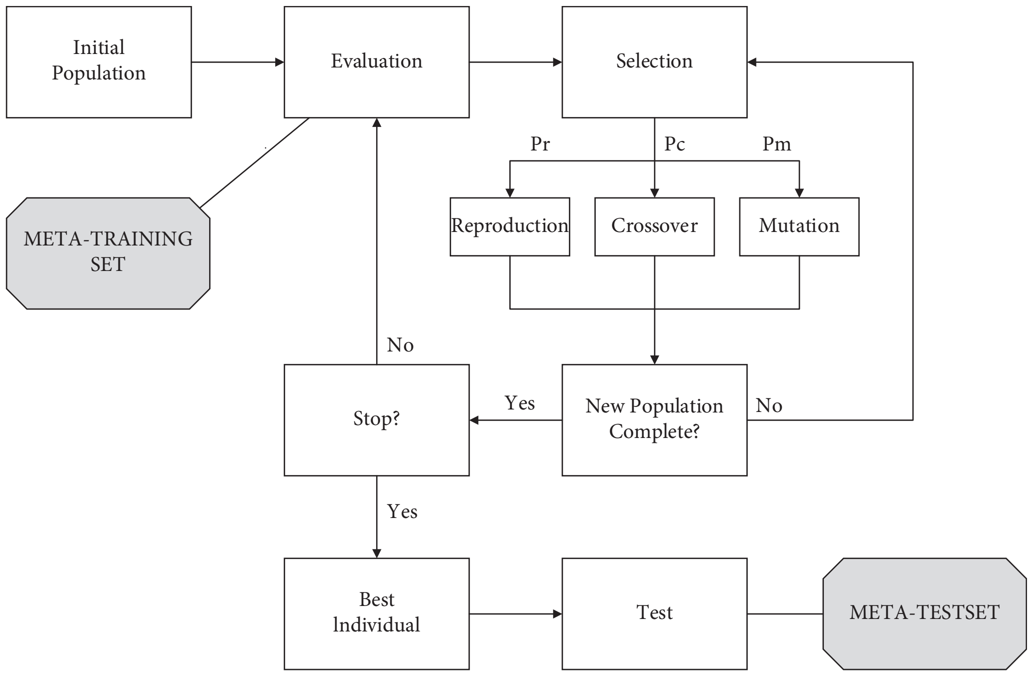

Figure 2: The structural framework of the decision tree algorithm.

3.2. Research and Construction of a Decision Support System for University Sports Based on Big Data Analysis Technology. Colleges and universities provide physical education in the form of college physical education courses for physical exercise, education, and guidance. The issue is primarily focused on the fact that physical education in China is still a teaching system centered on physical education teachers and that the quality of physical education is influenced to some extent by the disparity in physical education teacher quality. Simultaneously, the physical education system's and statistical tools' backwardness lowers the quality of teaching and learning in three ways: first, the traditional method of performance evaluation and statistics makes teachers' work tasks cumbersome and inefficient; second, the traditional method of performance evaluation and statistics makes teachers' work tasks cumbersome and inefficient. Second, the single system for evaluating physical education results and physical tests makes it difficult to apply the results to each student's problems of physical fitness and health. Third, based on the above two points, the heavy workload of teachers makes it difficult to give students effective guidance advice immediately; the single sports assessment makes it difficult to come up with professional guidance and feedback. For the above problems, data mining methods can be adapted to analyze the sports test data of college students and the whole process. After determining the content and purpose of the project, then the relevant data are collected and preprocessed, where the data preprocessing includes data selection, data cleaning, data integration, and data specification, in four steps. Finally, data mining processing is then performed on the data set using relevant data mining models to obtain data mining results. The actual content of the project is linked to getting the corresponding value knowledge. The process is shown in Figure 3.

The personal data analysis module can realize the detection and analysis of personal physical fitness test data and judge the comprehensive evaluation of individual users and fitness methods. Test indicators include three major indicators of body shape, body function, and physical quality. Morphological indicators mainly include waist circumference, scapular skinfold thickness, height, hip circumference, weight, chest circumference, abdominal skinfold thickness, and upper arm skinfold thickness; functional indicators mainly include step index, veins, systolic blood pressure, vital capacity, and diastolic blood pressure. Qualities mainly include choosing reaction time, push-ups, back strength, grip strength, sitting forward bends, sit-ups, vertical jumps, standing on one foot with eyes closed. Secondly, adults are grouped by age and gender, each group is 5 years old, and there are 16 groups of men and women in total. 10 test indicators are used to analyze individual physical fitness test results, which is convenient for the rapid processing of physical fitness test data. Potential value analyze the needs of individual users and managers, provide specific implementation methods for each module, and complete the overall design of the service application platform.

After performing machine learning, the result obtained from the learning is often an optimal decision tree, which leads to the establishment of a comprehensive evaluation model of college students' physical fitness. Next, the performance of the model needs to be evaluated using the sample data of the physical fitness test. Only when the evaluation result is good using the sample data of the physical fitness test, the comprehensive evaluation model of university students' physical fitness has the most "optimal" set of functions to solve the problem.

The personalized fitness mode recommendation service solution based on machine learning mainly includes three

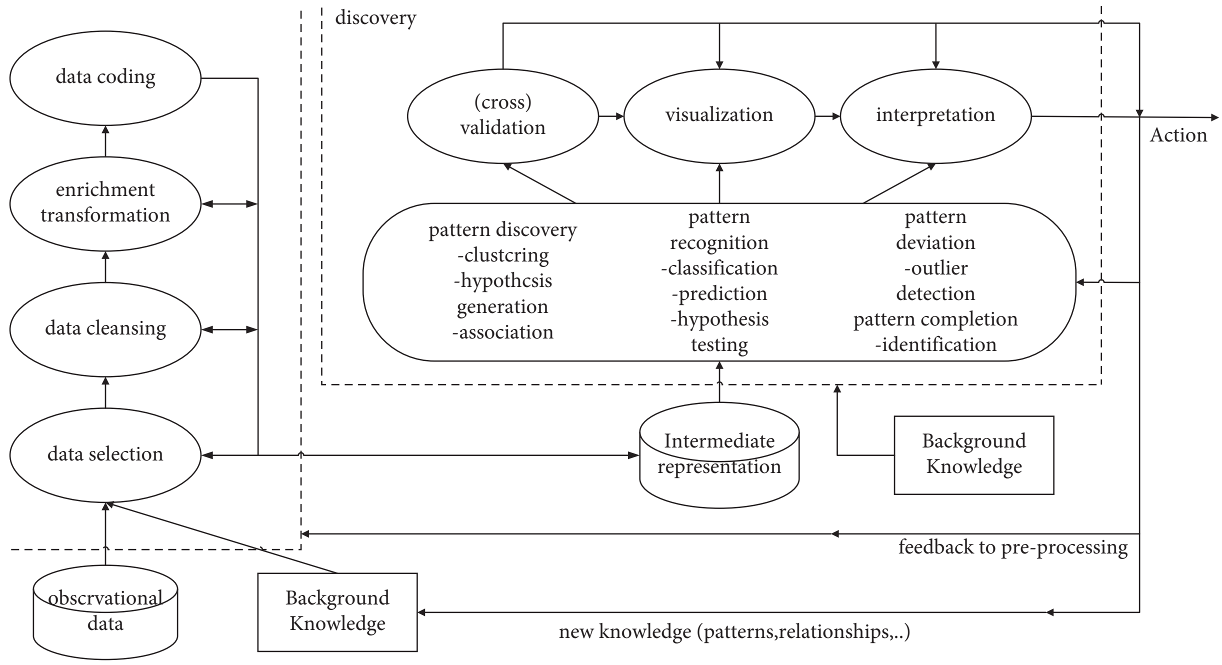

Figure 3: Data mining process for student physical tests in universities.

parts: the collection of basic user data, the discovery of fitness modes that match personal fitness test data and interest needs, and the recommendation of personalized fitness modes that match personal fitness test information and so on. For the generation of the fitness mode recommendation model based on machine learning, machine learning is then mainly applied to tap the value of personal fitness test information and carry out fitness mode recommendations suitable for individual users' fitness test information. Using the fitness test data uploaded by the administrator or the personal fitness test data stored in the database by the service application platform as input, the fitness test data is classified by the machine learning algorithm after entering the model, and the corresponding fitness mode categories are extracted from the fitness resource library, and the fitness modes of the corresponding categories are called through the Web UI module in the recommendation list and presented to the individual user through the service application platform presented to individual users.

The scale transformation mechanism makes the variable scale cluster analysis method capable of automatic execution, ensuring that the decision-maker is almost not required to participate in the method execution process, i.e., the decision-maker only needs to subjectively select the type of scale transformation strategy and deterrence. This method can directly obtain all college students' physical test results that satisfy decision preferences and their performance on the appropriate analysis level, assisting the university sports director in making the best sports training decision for the students. Because the traditional cluster analysis method can only perform cluster analysis at a single scale level, and the management business itself has multilevel characteristics, i.e., competition support groups made up of various participating students each have their own appropriate levels of decision analysis, the traditional cluster analysis method can only perform cluster analysis at a single scale level. All three scale levels have unsatisfactory classes in the single-scale clustering results. Although unsatisfactory classes are always present in the traditional cluster analysis method's clustering results, as the scale hierarchy grows, the number of unsatisfactory classes decreases significantly. This is strong evidence that scales can link decision-making activities to subjective and objective data and that scale transformation can add more valid information and knowledge to operational data, reducing decision complexity.

In addition to the basic scale hierarchy, the variable scale cluster analysis method can obtain more accurate scale characteristics of satisfaction classes than the traditional cluster analysis methods at the same level. Since the scale transformation process of variable scale cluster analysis starts from the basic scale level and takes the lowest scale level of each satisfaction class as its appropriate decision analysis level, the satisfaction class consistency theorem ensures that the clustering results are consistent among different data analysis levels so that each satisfaction class retains its most detailed scale characteristics, allowing analysts to have more accurate information and thus improve the quality of decision results [21]. For the traditional clustering analysis method, even if it can find the partial satisfaction class in the process of single-scale data analysis, it does not guarantee that the scale characteristics of the satisfaction class reach a better analysis level at this time, which leads to the problem that the result class characteristics are often not significant in solving practical problems in management.

4. Experimental Verification and Conclusions

Clustering validity can be evaluated in terms of internal validity evaluation and external validity. Since there is a scale transformation iterative transformation process in the execution of the variable scale clustering analysis method, and the set of objects (thesis domain) decreases with the increase of the number of iterations, there is a situation that the results of variable scale clustering analysis are distributed in different analysis levels. The internal validity index can only evaluate the quality of clustering results on the same analysis level, so to ensure the objectivity and fairness of the evaluation results; this paper adopts the external validity evaluation method to verify the variable scale clustering analysis method. The experiments are conducted on the premise of satisfying the methods and principles of multiscale data model construction and randomly generating multiscale data models, and the main purpose is to conduct relevant experimental analysis on the validity and parameter sensitivity of the variable-scale clustering analysis method. Since the experiments take an external validity evaluation index to test the clustering effect, data labels are added to this data model. The basic task of the experiments on the validity of the variable-scale cluster analysis method is to test the clustering effect of the variable-scale cluster analysis method compared with the traditional single-scale cluster analysis method. Because the meta-partitioning cluster analysis algorithm's initial class center selection is random, this paper first repeats the class analysis work 50 times on each of the 54 single-scale data models obtained from the multiscale data model and then takes the mean, maximum, minimum, and standard deviation of the results of these 50 experiments, as well as the maximum value, minimum value, and standard deviation to complete the full-scale spatial clustering analysis. The variable scale clustering analysis method's validity is tested by comparing its results to those of the traditional single scale clustering analysis method at the basic scale level to see if the variable scale clustering analysis method can meet the clustering results' quality requirements. The results of the clustering validity index evaluation between the variable-scale cluster analysis method and the traditional single-scale cluster analysis method at the optimal scale level are compared to see if the variable-scale cluster analysis method can improve clustering analysis efficiency. The clustering validity index evaluation results are shown in Figure 4.

Sensitivity analysis of satisfaction determination thresholds for variable scale cluster analysis methods. The basic task of the experimental analysis of satisfaction determination thresholds & sensitivity for variable scale cluster analysis methods is to test the clustering effect of variable scale cluster analysis methods under the conditions of different satisfaction determination thresholds. It is the maximum granularity deviation taken from all the basic scale clustering results that satisfy the business requirements. In this experiment, the clustering effect of the variable scale clustering analysis method under all possible values is examined by setting the experimental analysis range of the satisfaction determination threshold parameter. As can be seen from Figure 4, among the 50 clustering experiments of the variable scale cluster analysis method, the average clustering validity results of the variable scale cluster analysis method for all the above evaluation indexes are better than the average validity results achieved by the traditional single

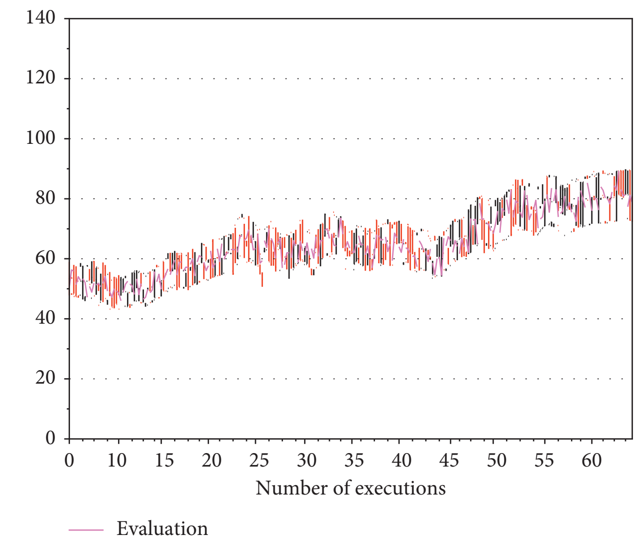

Figure 4: Results of the evaluation of clustering validity indicators.

scale cluster analysis method at the basic scale level, and the quality improvement rate of the clustering results is more than 10%, among which the quality improvement rate of the results under the NMI evaluation index reaches 1. 5. 63%. 5.63%, proving that the variable scale clustering analysis method can better meet the validity requirements of the clustering results of the traditional single scale clustering algorithm.

According to the basic task of the sensitivity experiment of the variable scale cluster analysis method's satisfaction threshold R, the experiment compares the results of the external validity evaluation indicators of the variable scale cluster analysis method under different satisfaction threshold R0 and investigates the degree of influence of the satisfaction threshold R 0on the validity of the variable scale cluster analysis method. To investigate the relationship between satisfaction determination thresholds and the effectiveness of the variable scale clustering analysis method and to compare the trends of the clustering effect of the variable scale clustering analysis method under various satisfaction determination thresholds, the satisfaction threshold R0, which was determined subjectively by the analyst, was 3.8 in the above-mentioned experiments on the effectiveness of the variable-scale cluster analysis method. The satisfaction threshold's experimental analysis range was set to a region around 3.8, which was specifically set to [3.0, 6.0] in this experiment, and the step of change was 0.1. Each satisfaction threshold was subjected to 50 runs of the variable-scale cluster analysis method. The cluster result validity evaluation indicators were averaged to perform a satisfaction determination threshold sensitivity analysis.

Figure 5 shows the results of the sensitivity analysis of the parameters of the scale cluster analysis method. By comparing the experimental results, it is found that the variable scale clustering analysis method is less affected by the satisfaction determination threshold R_0 and the results have stability, as discussed below: although the results of all evaluation indicators of the variable scale analysis method

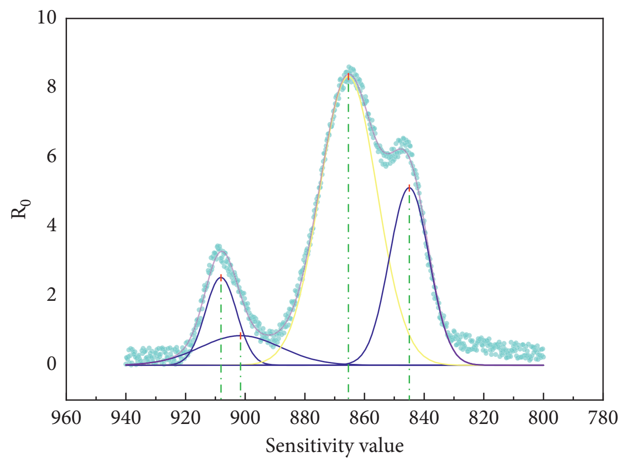

FIGURE 5: Results of sensitivity analysis of parameters of the scale cluster analysis method.

fluctuate in the range of the satisfaction determination threshold parameter, the maximum fluctuation does not exceed 1%, indicating that the validity of the clustering results of the variable scale clustering analysis method is not sensitive to the satisfaction determination threshold. The overall trend of the evaluation index results of the variable scale cluster analysis method increases slightly with the increase in the value of the satisfaction determination value parameter, indicating that the overly strict initial satisfaction constraint is not conducive to the optimal solution of the variable scale cluster analysis method.

After obtaining valuable data based on machine learning decision trees and multiscale cluster analysis methods, the data can be applied to the actual curriculum for decision support. Classroom monitoring is mainly achieved through wearable sports bracelets, which can monitor various indicators such as student exercise intensity, exercise density, heart rate curve, and heart rate warning. The sports bracelet has four colors: green, blue, orange, and red, and it can be used to guide teaching by monitoring students' heart rates. When the red logo appears, it means the student's heart rate is higher than normal, and the sports watch will sound an alarm, alerting the teacher to reduce the intensity and volume of exercise. The teacher can then use big data to analyze the movement of students through the class's background and determine whether the class has met the teaching objectives. The use of the decision support system by teachers is depicted in Figure 6.

According to the research, 94.4 percent of students believed the decision support system could achieve targeted teaching, while 5.6 percent believed it could not. This means that the majority of physical education teachers still believe that decision support systems can help them deliver more targeted instruction and learning. At the same time, the decision support system can make intelligent statistical analyses of students' learning performance, as shown in Figure 7. Based on the conversion scores of students' indicators, and statistical comparison and analysis based on items, gender, grade level, and other degrees, the system can continuously track students' physical development trends, quickly grasp students' physical and athletic qualities, and conduct targeted teaching according to students' differences, to solve the problems of students' "not being able to eat" and the problem of "not being able to eliminate." And through intelligent statistics out of the student results can not only be viewed by individual students, but also for classmates, teachers, school leaders, and other views. The percentage of teachers who often use the decision support system to push PE homework to students is 35.2%, the percentage of PE teachers who use it occasionally is 53.7%, and 11.1% of PE teachers will not use the platform to push homework to students, with teachers occasionally assigning homework accounting for the largest percentage. This indicates that physical education teachers do not frequently use the decision support system to assign physical education homework to students. Physical education is now gradually being paid attention to in junior high school teaching, recognizing that cultivating students' physical quality cannot be accomplished overnight, that a few minutes in the classroom is insufficient, and that teachers must reasonably arrange students' physical education homework to ensure that students can develop good physical exercise habits whether in classroom teaching or at home. This will help junior high school students grow in a healthy way. It is a new trend in physical education to assign "physical education homework," which will serve as a strong motivator for students to engage in physical activity. PE homework will not only encourage students to engage in physical activity after school, but it will also draw parents' attention to their children's physical development and improve their physical performance.

As can be seen in Figure 8, the use of decision support systems for learning by students grows steadily with grade level. The lowest usage rate is among the first-year students, with 24.1%. The next highest usage rate is among sophomores, with 33.2%. The highest rate of use was among third-year students, with 42.7%. The move of junior high school students to use the decision support system for learning makes it possible to deeply integrate "Internet+" with college sports. The decision support system is a manifestation of the integration of Internet+ with sports, which breaks the traditional way of learning sports. For example, the learning space has changed a lot. Physical education is traditionally taught by teachers in physical education classes, and students learn the content from the teachers. The learning space must be set up in a specific location on campus. Schools with better hardware facilities have more indoor learning space and are less affected by weather, but schools with poor hardware implementation may not be so fortunate and will be impacted by weather. When it rains, for example, physical education classes are canceled, and the physical education program in junior high schools has only one class per week, so there is not much physical education left in a semester after holidays and rainy days. Physical education teaching tasks in high schools cannot be completed on time, in a high-quality and quantity manner, and students' physical health will not improve but will deteriorate as they grow older. The advent of the decision support system allows schools to overcome

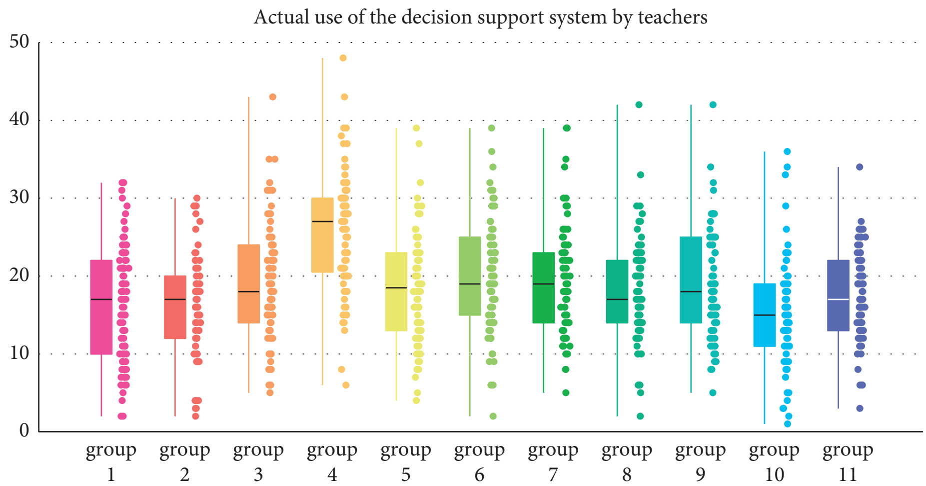

FIGURE 6: Actual use of the decision support system by teachers.

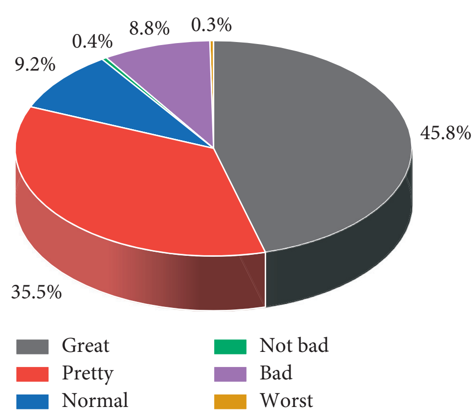

FIGURE 7: Results of intelligent analysis of learning achievement.

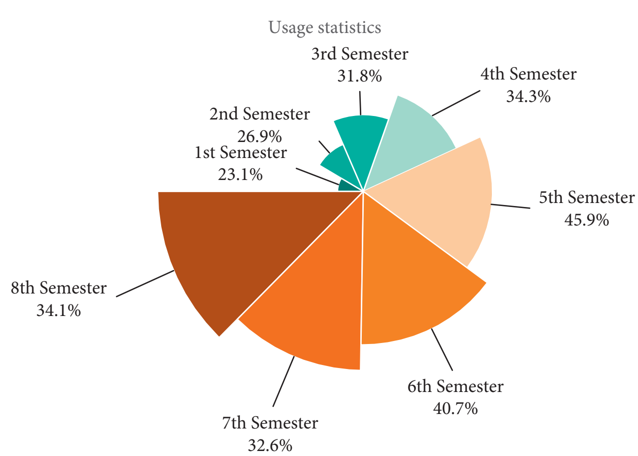

FIGURE 8: Usage statistics of the decision support system.

learning space constraints; the transformation of students' learning spaces adds color to the traditional way of physical education learning, while the decision support system also contributes to college physical education innovation.

5. Conclusions

While data mining techniques have made significant progress in a variety of fields, the use of fitness analysis in conjunction with data mining techniques is less common. The main reason for this is the limitations of physical education in colleges and universities, where major institutions have vastly different curricula and evaluation criteria. This has resulted in a physical fitness and health management system based on data collection and statistics, making guidance and educational significance difficult to achieve. With the advent of the big data era, the problem of data support for college physical education decision-making guidance has been solved, and the "online + offline" hybrid teaching model has emerged and permeated the college physical education teaching model, which is not only innovation of the college physical education teaching model, but also an important reflection of the new curriculum concept. Furthermore, the rapid development of big data has aided the development of multifunctional school teaching instruments. Teaching can benefit from a web page with a larger capacity and faster page updates, which provides richer and more specialized information resources. The research objects in this paper are physical test data and physical health self-assessment data, and the physical test data have uniform standardization and guidance but are not strong for readability and guidance. In order to achieve better physical fitness health education goals, this paper employs data mining technology and design to implement a physical fitness analysis system. The theory of data mining is discussed, as well as data mining algorithms such as the decision tree and association rule algorithms and the decision tree C4.5 algorithm and association rule algorithm. To mine the physical fitness data information, the apriori algorithm and multiscale clustering algorithm are chosen, and the results of big data analysis are also used to design, implement, and verify the physical fitness analysis system for college students.

Human posture equipment technology has advanced significantly thanks to advances in deep learning and machine vision. Even the most advanced models may not be able to predict all body joints accurately. This paper proposes an adaptive generative adversarial network to improve the human posture detection algorithm in order to address this issue. GAN is used in the algorithm to detect human posture improvement. The algorithm uses OpenPose to detect and connect keypoints and then generates heat maps in the GAN system model. During the training process, the confidence evaluation mechanism is added to the system model. The generator predicts posture, while the resolver refines human joints over time. And, by using normalization technologies in the confidence evaluation mechanism, the generator can pay more attention to the prominent body joints, improving the algorithm's body detection accuracy of nodes. In MPII, LSP, and FLIC datasets, the proposed algorithm has shown to have a good detection effect. Its positioning accuracy is about 95.37 percent, and it can accurately locate the joints of the entire body. Several other algorithms are outperformed by this one. The algorithm described in this article has the best simultaneous runtime in the LSP dataset.

1. Introduction

The goal of human posture estimation is to predict positions from the input images of body joints. At the moment, human posture estimation relies on a variety of methods [1–6], such as Google's G-RMI, which uses target detection to open a human posture estimation method. The OpenPose system [7–9] proposed by Carnegie Mellon University (CMU) greatly improved the construction of human posture. OpenPose is an open-source library written in the Caffe programming language that can track human facial expressions, torsos, limbs, and even fingers. It is based on convolutional neural networks and supervised learning, not only for a single person, but also for a group. The introduction of AlphaPose has significantly improved the accuracy of human pose detection. The AlphaPose system [10,11] is a highly accurate real-time multiplayer posture estimation system. The algorithm uses a top-down structure, that is, to detect the inverted human body first and then obtain the key points and skeleton. Therefore, his accuracy and Ap values are higher than OpenPose. But the disadvantage is that as the number of people on the picture increases, his calculations increase and the speed becomes slower. These algorithms still have the problem of being frustrated in the face of occlusion problems—problems such as high accuracy, obstruction of real time, and limited small size images.

This article proposes an adaptive generative adversarial network to improve the human pose detection algorithm in order to address the aforementioned issues. Based on the robustness of the generative adversarial network (GAN) in occlusion conditions, the coherence of the shape, and the fidelity of the details, the algorithm improves the generative adversarial network (GAN) model [12–16]. The generator generates the human body posture, the discriminator distinguishes the actual heat map, and the human joint is gradually improved. The existing posture resolution effect is improved through continued training. Finally, the normalization technology is used to perform confidence processing on the generator's generated data in order to keep the correct key nodes, improving the algorithm's body node detection accuracy. Through experiments, compared with the existing methods, the proposed algorithm can improve the accuracy of the position of known people and search for poses in these areas through the GAN model.

2. This Article Algorithm

Human posture estimation is a very basic problem in computer vision. From the perspective of the name, it can be understood as an estimate of the position of the posture of the "human body" (key points, such as head, left hand, right foot, etc.). The traditional human skeleton key point detection algorithm is basically based on the idea of template matching on the basis of geometric a priori, so the core lies in how to use the template to represent the entire human body structure, including the representation of key points, the representation of limb structure, and the representation of the relationship between different limb structures. A good template matching idea can simulate more attitude ranges, so that it can better match and detect the corresponding human posture.

Human posture estimation can be divided into two lines of thought:

(1) "top-down," which refers to the detection of human body areas first and then the detection of key points in the human body in the area.

(2) "bottom-up:" which refers to detecting all the key points of the human body in the picture first and then corresponding these key points to different individual characters. It should be mentioned here that the first scheme is slower because it needs to detect each area of the human body separately for forward key point detection, while OpenPose uses the second scheme.

There are disadvantages of the "bottom-up" method: (1) the priori information of the global context is not used, that is, the key points of other people's bodies in the picture. (2) Corresponding key points to different individuals, the algorithm complexity is too high.

OpenPose improvement point: in the proposed "Part Affinity Fields (PAFs)," each pixel is a 2D vector for characterizing position and direction information. Based on the detected joint nodes and joint connection areas, using the greedy inference algorithm, these joint nodes can be quickly corresponded to different individual characters.

2.1. Heat Map

2.1.1. Critical Point Detection. Calculate the ground truth of S through the 2D points $x_{j,k}$ and $x_{i,k}$ marked in the image. Among them, $x_{j_1,k}$ and $x_{j_2,k}$ represent the real pixels corresponding to the two key points j_1 and j_2 of a certain person k in Figure 1. Calculation method: when the pixel point p is close to the annotation points $x_{j,k}$ and $x_{i,k}$, it reaches the peak of the normal curve. Then the S of the j-th joint in each image is the peak of the normal distribution of k individuals in the image.

Figure 1 is the heat map of each joint point. The first picture on the left is the input image and the final predicted joint position. The second picture is the probability result predicted by the channel responsible for the neck node. Red and yellow represent the high probability that the corresponding pixel location is the neck. The other blue areas mean that it will hardly be the neck location. The following pictures, respectively, represent the p probability results of different nodes predicted by different channels of heat map.

$$S^*_{j,k} = \exp\left(-\frac{\left\|p - x_{j,k}\right\|_2^2}{\sigma^2}\right),$$
$$S^*_j(p) = \min_k S^*_{j,k}(p). \tag{1}$$

2.1.2. Joint Connections. If a pixel p is located on this torso, the value of $L^*_{c,k}(p)$ represents the unit vector from the key point j_1 to the key point j_2. For pixels not on the torso, the corresponding vector is the zero vector.

Then the value of $L^*_{c,k}(p)$ is as follows:

$$L^*_{c,k}(p) = \begin{cases} v, & \text{if p on c}, k, \\ 0, & \text{otherwise}. \end{cases} \tag{2}$$

Among them, $v = (x_{j_2,k} - x_{j_1,k})/|x_{j_2,k} - x_{j_1,k}|_2$ represents the unit direction vector corresponding to this torso.

Pixels belonging to this torso satisfy the following function:

$$0 \le v\left(p - x_{j_1,k}\right) \le l_{c,k},$$
$$\left|v_{\perp}\left(p - x_{j_1,k}\right)\right| \le \sigma_l. \tag{3}$$

The inner table σ_l shows the distance between pixels. The length of the torso is $l_{c,k} = |x_{j_2,k} - x_{j_1,k}|_2$, $v_{\perp}$ represents the vector perpendicular to v. The whole image is the average value corresponding to all people in the image. $n_c(p)$ is the number of nonzero vectors corresponding to k persons at pixel p in the image.

$$L^*_c(p) = \frac{1}{n_c(p)} \sum_k L^*_{c,k}(p). \tag{4}$$

Figure 2 is an image of the key nodes of the human body extracted by the above algorithm. The article extracts the key points of the image and then connects the key points to the image of the human body posture.

2.2. Generative Adversarial Network (GAN). The generative adversarial network (GAN) was proposed by GOOdfellOw, using two convolutional neural networks using game training to generate samples similar to the original pictures [17–19].

Figure 1: Key point probability distribution plot.

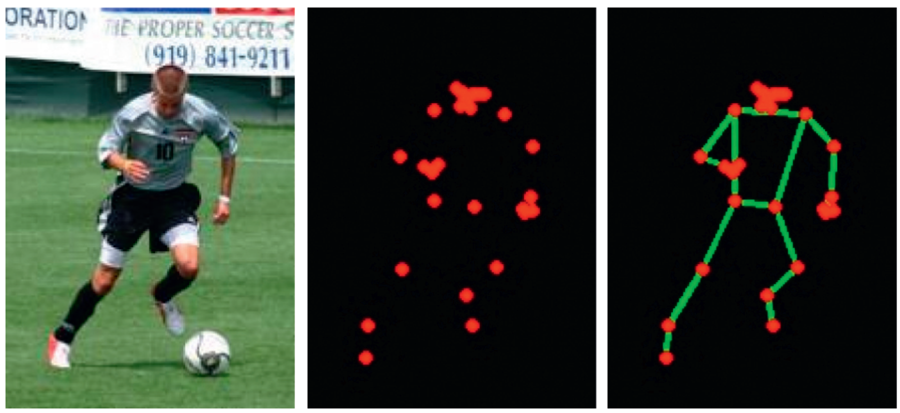

Figure 2: Human body posture design diagram.

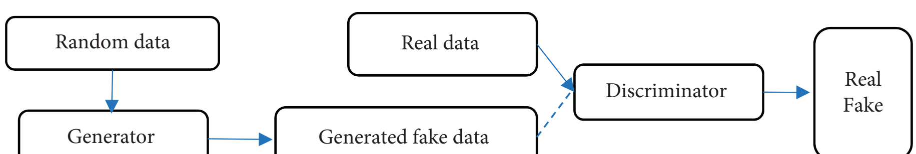

Figure 3: Generative adversarial network structure.

Figure 3 shows the structure of the generated confrontation network, which shows that GAN is primarily made up of a generating network *G* and a discriminating network D. It makes use of a conflicting relationship. The goal is for the generator to be able to generate data that is similar to real data distribution while giving the impression of being fake. GAN, which is aimed at the problem of data prediction, trains the generator to learn the data distribution and predicts the image distribution data. The success of confrontational ideas benefits the GAN network as well. Machine learning and artificial intelligence are two fields where the concept of confrontation has been introduced. Confrontation is present in the two behaviors of "game" and "competition." Game machine learning is the result of combining game theory and machine learning.

The advantages and disadvantages of GAN: compared with other generative models, GAN has the following four advantages:

(a) From the actual results, GAN seems to produce better samples than other models.

(b) Most other frameworks require the generator network to have a certain functional form; for example, the output layer is Gaussian. It is important that all other frameworks require that the generator network be distributed with nonzero quality. The generative confrontation network framework can train any type of generator network and can learn to generate points only on thin manifolds close to the data.

(c) Any generator network and any discriminator will be useful because it does not need to design a model that follows any type decomposition.

(d) There is no need for reasoning during the learning process and no need to use Markov chain for repeated sampling (inference), thus avoiding difficult approximate calculation problems of probabilities.

2.3. The Generative Adversarial Network of Pose. The model in this paper is divided into two networks, the generator and the discriminator, similar to the traditional GAN model [20, 21]. A convolutional network is the first network generator. The generator generates a set of heat maps that show the confidence score of each position of each key point after forward calculation. The second network discriminator uses the same architecture as the generator, but it encodes the input heat map along with the RGB image and decodes it into a new set of heat maps in order to distinguish between the real and fake heat maps. The generator is strengthened to generate the human body posture as a result of the game between the generator and the discriminator, and the discriminator's human joints are gradually improved. The existing pose estimation model is improved through continuous training, as shown in Figure 4.

2.3.1. Generator. The generator is responsible for predicting the posture, and its role is to generate accurate information about the key points of the human body. Of course, as part of the generational confrontation, the main function of the generator is to allow the generated key points to fool the final discriminator, so that the discriminator cannot distinguish whether the current key point heat map is actual or generated by the generator.

That is to say, the purpose of the counter loss is to make the key points generated by the generator conform to a more reasonable posture. More directly, the purpose of L_{adv} is to make the false heat map generated by the generator fool the discriminator as much as possible, making it impossible to distinguish between the GT heat map and the false heat map. The process of generating confrontation is reflected here. Finally, the loss shown in formula 3 is used to optimize the generator. λ is a hyperparameter. The generator loss function is as follows:

$$\begin{aligned} L_{\text{MSE}} &= \sum_{i=1}^{N}\sum_{j=1}^{M}\left(C_{ij}-\widehat{C}_{ij}\right)^2,\\ L_{\text{adv}} &= \sum_{i=1}^{N}\left(\widehat{C}_j - D\left(\widehat{C}_j, X\right)\right)^2,\\ L_G &= L_{\text{MSE}} + \lambda L_{\text{adv}}, \end{aligned} \tag{5}$$

where L_{MSE} is the loss of the generator, L_{adv} is the counter loss from the resolver, and λ is a hyperparameter.

2.3.2. Differentiator. The discriminator's goal is to improve human joints over time. The goal is to determine whether the input heat map is the real thing or a forgery created by the generator. The discriminator's ultimate training goal is to be able to tell the difference between the data generated by the generator and the real heat map as much as possible. As a result, a confrontation game with the generator is formed.

The encoded new heat map is obtained by inputting the false heat map generated by the generator into the discriminator. And calculate the distance between the new heat map and the fake heat map generated by the generator to calculate the L_{fake} loss. As mentioned above, the purpose of the discriminator is to distinguish the false heat map from the actual heat map as much as possible. That is to say, the classifier hopes that the output reconstructed heat map after the actual heat map input is as close as possible to the actual one. The loss function of the discriminator is as follows:

$$\begin{aligned} L_{\text{real}} &= \sum_{j=1}^{N}\left(C_j - D\left(C_j, X\right)\right)^2,\\ L_{\text{fake}} &= \sum_{j=1}^{N}\left(\widehat{C}_j - D\left(\widehat{C}_j, X\right)\right)^2,\\ L_G &= L_{\text{real}} + k_t L_{\text{fake}},\\ k_{t+1} &= k_t + \lambda_k\left(L_{\text{real}} - L_{\text{fake}}\right). \end{aligned} \tag{6}$$

The *kt* in the above formula is used to constrain the capability of the discriminator. Constraining *kt* through the formula can make the network easier to train. But GAN is unstable and difficult to train because the discriminator converges too fast. This will cause the network to easily collapse and train an invalid generator. In response to this problem, in order for the network to be able to generate enough truth to deceive the discriminator. By studying the relationship between L_{fake} and L_{real}, it can be found that, with the increase of kt, L_{fake} has more advantages, which makes the discriminator more training to recognize the generated heat map. But *kt* is not an infinite stack. To this end, this paper extracts the confidence heat map information from the discriminator and feeds it back into the generator, thereby enhancing the generator's accurate prediction of the key nodes of the human body on the ground.

2.4. Confidence Evaluation Mechanism. The generator can pay more attention to prominent body joints because the confidence evaluation mechanism uses normalization technology. As a result, the algorithm's body node's detection accuracy increases. To determine the key points' credibility, compare the generated heat map with the actual heat map. Following that, improve the algorithm's key point extraction accuracy. The following are the techniques.

The discriminator is used to process the generated heat maps and truth heat maps in this paper—confidence heat maps that were derived from the data. The pose resolver requires two tags to calculate two losses. The identification network marks the real samples as 1 and the pseudosamples as 0, in the traditional work of image conversion using GAN. We discovered that using only 0 or 1 as the label for the human body pose estimation problem makes convergent network difficult. As a result, this paper relies on the discriminator's confidence heat maps to direct the generator's data generation.

Set the initial setting of the generator to a low-confidence heat map. Then the confidence discriminator classifies the result as fake. The generator will self-optimize based on this result error to generate a higher degree of confidence until it can make the discriminator think that the result of the generator is true. Therefore, even if there is occlusion, this process will help the generator to generate a high-confidence heat map.

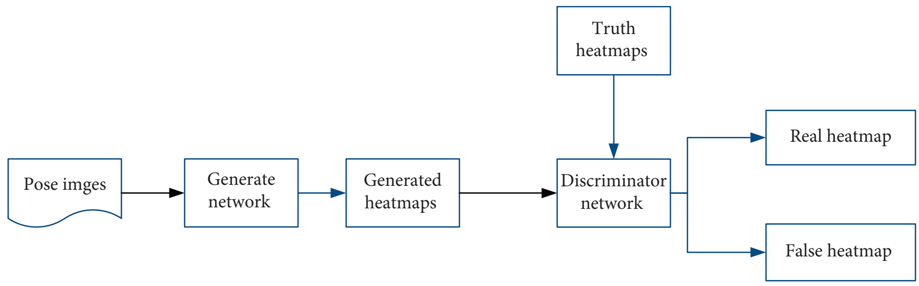

Figure 4: Human pose generation confrontation network structure model.

The vector corresponding to the feature map with the corresponding key point value is 1, and the vector corresponding to the feature map without the key point is 0, where *di* is the normalized distance between the predicted position of the i-th body part and the true position. For fake samples, if the predicted body part is far away from the real position, then the posture in this image is obviously not believable to the body structure. Therefore, if the distance is relatively close, the corresponding vector is 1; otherwise the corresponding vector is 0.

Then the corresponding value of C_{fake} is shown in the following formula. When the generated key point heat map is relatively close to the actual heat map (the distance is less than the threshold), the corresponding vector is 1. Otherwise, the corresponding vector is 0.

$$C_{\text{fake}} = \begin{cases} v, & \text{if } \left\| d_i - \hat{d}_i \right\| < \tau, \\ 0, & \text{if } \left\| d_i - \hat{d}_i \right\| \geq \tau. \end{cases} \quad (7)$$

Among them, for the feature map, first transform x into feature space f and g. And make it satisfy

$$\begin{aligned} f(x) &= W_f(x), \\ g(x) &= W_g(x). \end{aligned} \quad (8)$$

$W_f(x)$ is the weight matrix of generated heat maps. $W_g(x)$ is the weight matrix of confidence heat maps.

The distance is normalized to [0, 1] through element transformation.

$$d_i = \frac{e^{\|f(x_i) - g(x_i)\|_2} - 1}{e^{\|f(x_i) - g(x_i)\|_2} + 1}. \quad (9)$$

In the end, the best key points are obtained, and the network model of the algorithm in this paper is shown in Figure 5.

Figure 6 is the result of adopting the human body pose generation confrontation network structure that introduces confidence. The human body posture is generated by the generator, and the discriminator is gradually improving the human joints. Finally, the normalization technology is used to perform confidence processing on the generator's generated data to retain the correct key nodes. In turn, the detection accuracy of the body node of the algorithm is improved. The effect is shown below.

Through observation, it can be seen that the above method can accurately locate the characters of the image and can accurately locate all key nodes of the whole body. In order to better verify the feasibility of the algorithm, the following is a detailed experiment.

3. Simulation Experiments

3.1. Experimental Environment and Datasets. The experimental environment of this article: Ubuntu 16.04.4 platform is implemented by Python programming with open CV 3.4 and Tensorflow 1.5 frameworks, processors: Intel Core i7 7700 HQ (up-to 3.8 GHz), 16 GB Memory, nVidia Geforce GTX 1060 6 GB VGA, training with a total of 20,000 images, training time of 80 hours.

Dataset: this paper selects three widely used human posture datasets as follows.

3.1.1. LSP Human Posture Estimation Dataset (Address: https://sam.johnson.io/research/lsp.html). Leeds Sports Pose is a dataset of sports postures divided into categories such as athletics, badminton, baseball, gymnastics, parkour, soccer, volleyball, and tennis, all of which are images from physical activity and thus very challenging in terms of appearance, particularly joints. The dataset consists of 2,000 annotated images of postures primarily sourced from Flickr and labeled with the labels shown above. The length of the most prominent person has been scaled to approximately 150 pixels in these images. Each image has 14 joint positions labeled.

3.1.2. FLIC Human Detection Dataset (Address: https://bensapp.github.io/flic-dataset.html). FLIC is a dataset of images that label people in frames of movies, which contains 5,003 images collected from mainstream Hollywood movies. The training images are derived from a character detector running in 30 movies and are manually annotated for them after the pictures are taken, including 10 upper body joints. In addition, there are 5 median markers in the image to ensure that the outlier annotation is robust. Publishers voluntarily reject images that are obscured or have too low picture clarity and reserve 20% of about 1016 images for testing.

3.1.3. MPII Human Posture Estimation Dataset (Address: https://human-pose.mpi-inf.mpg.de/). MPII is a dataset for evaluating human posture estimates and related

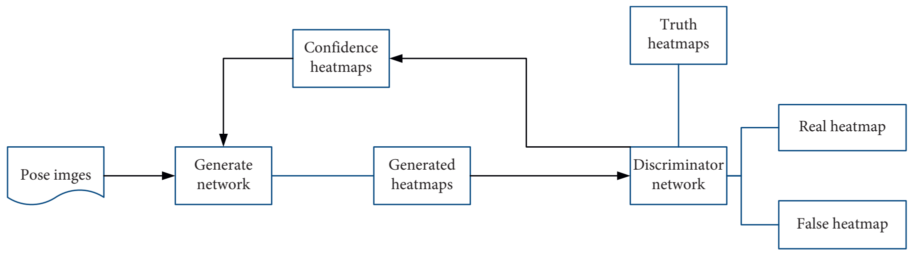

Figure 5: Introduces confidence in human posture generation of adversarial network structures.

Figure 6: Human posture setting effect.

benchmarks, with approximately 25,000 images and more than 40,000 people with annotated joints, systematically collecting images using established taxonomies of human activity.

Overall, the dataset covers 410 human behaviors and each image provides an activity tag, each image is from a YouTube video, and provides a related unnoticed framework. In addition, the test set's annotations include body part occlusion, 3D torso, and head orientation.

3.2. Evaluate Metrics. The article selects the LSP human pose estimation data set for verification and uses the percentage of correct key points (PCK) to measure the performance of the LSP data set. We choose the traditional OpenPose algorithm; [20] algorithm, and [21] algorithm to verify the accuracy of the algorithm by calculating the percentage of correct detections that fall within the normalized distance and recording the data results. Table 1 shows the data obtained by measuring the key nodes of the whole body using the abovementioned algorithms, as shown in the table.

This article selects head, shoulder, elbow, wrist, hip, knee, and ankle as 7 nodes for data comparison; through the observation of the data, it can be seen that the proposed algorithm synthesis data is better than several other algorithms. Among them, the algorithm of this paper has achieved the best results in head, shoulder, elbow, and ankle of 96.64%, 95.16%, 95.97%, and 95.16%, respectively. The average values of each algorithm were 89.83%, 92.30%, 94.71%, and 95.37%, respectively; you can see that using the algorithm of this article in the key point extraction effect is the best. We aimed to verify whether the algorithm can still maintain good results in different environments. In this paper, we use LSP human pose estimation data set to verify that the difference is motion pictures. After testing, the result of the test is shown in Figure 7.

Through observation, it can be seen that the data obtained by the algorithm of this paper can accurately locate the characters in the image. And in the key extraction renderings of the human body, the key points will not appear to be missing and elegant. The algorithm can accurately locate according to the different actions of the characters. It further verifies the key point extraction accuracy of the algorithm.

By collecting the iterative data of each algorithm, and according to the number of iterations of the algorithm, the data curve shown in Figure 8 can be obtained, which is marked according to the number of iterations and accuracy of each algorithm, as shown in Figure 8.

By observing the curve data graph in Figure 8, it can be seen that the final accuracy of the algorithm in this paper is higher than the other three algorithms, but the cost is that the number of iterations required by the algorithm is higher than that of other algorithms. It can be seen that the accuracy of the algorithm in this paper is stable at about 96.20%, and the number of iterations needs to meet more than 350 times to achieve. In contrast, the number of iterations of other algorithms can reach the highest value of the algorithm at about 200 times.

3.3. Qualitative Analysis. The article selects the LSP human pose estimation data set for qualitative analysis. And on the basis of the above, the key points are connected and displayed in the actual image. At the same time, combined with target detection, on the basis of human posture, the detection effect of target detection is strengthened. Reflect in the following. The detection image is shown in Figure 9.

By observing Figure 9, it can be seen that using the algorithm in this paper, good key point extraction and target locking can be maintained in different motion environments. This method strengthens the processing of extraction and confidence through high-performance network architecture and loss function. In turn, the high-precision human body posture positioning effect is obtained, and the pedestrian detection capability is better.

3.4. Comparison of Average Running Time. In this paper, we train on the MPII human body pose estimation data set, LSP human body pose estimation data set, and FLIC human

Table 1: Correct detection percentage.

Method	Head	Shoulder	Elbow	Wrist	Hip	Knee	Ankle	Average value
Traditional algorithms	89.01	85.40	91.72	89.06	89.90	91.45	92.30	89.83
Literature [20] algorithms	91.96	91.57	88.32	90.21	94.65	94.90	94.51	92.30
Literature [21] algorithms	93.81	98.76	93.57	94.51	95.68	93.05	93.56	94.71
This article algorithm	96.64	95.16	95.97	94.73	94.88	95.08	95.16	95.37

Figure 7: Key point extraction rendering.

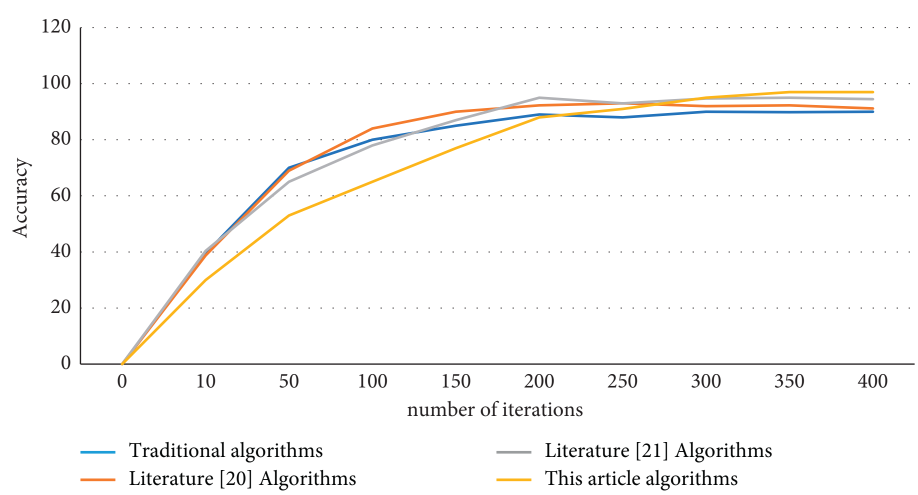

Figure 8: The number of iterations and the accuracy of each algorithm into the data curve.

body detection data set. And the various running times are compared, and the results are shown in Table 2.

Verify the algorithm's running time in various environments by observing the data differences to see if the algorithm can maintain a stable running effect. We can see

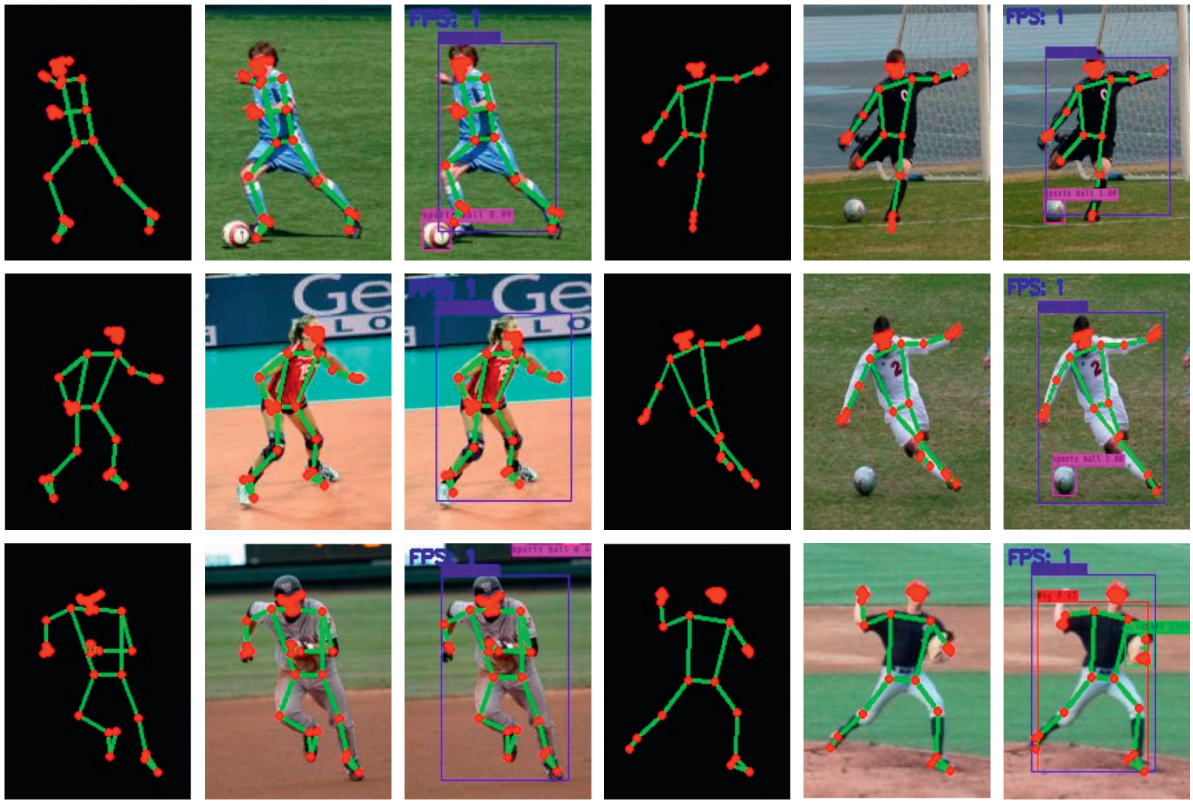

Figure 9: Human body posture design effect figure.

Table 2: Average running time under each data set.

Method	Model size (M)	Runtime(s) on MPII test set	Runtime(s) LSP test set	Runtime(s) FLIC test set
Traditional algorithms	162.1	1.242	0.234	1.07
Literature [20] algorithms	157.3	1.201	0.325	0.921
Literature [21] algorithms	196.21	1.266	0.238	0.951
This article algorithm	201.2	1.191	0.229	0.806

that the algorithm in this paper performs well in each data set by comparing the data in Table 2. The model used in this paper is the largest of them all, but in terms of running time, it can be applied to a variety of other algorithms. The effect expressed in the LSP data set is the best, with a time of only 0.229 s, effectively proving the algorithm's feasibility.

4. Conclusion

The article proposes an adaptive generative adversarial network to improve human pose detection algorithm. In the algorithm model of this article, the generator is responsible for predicting the posture, and the discriminator is for the gradual improvement of the human joints. However, in the actual training process, the predicted nodes generated by the generator sometimes deviate from reality. Therefore, this paper introduces a confidence evaluation mechanism into the system to determine the credibility of the generated key points, so that the generator can pay more attention to the prominent body joints, thereby improving the detection accuracy of the algorithm. Finally, by using three standard data sets to evaluate the algorithm, it can be seen that the algorithm is superior to other algorithms in terms of detection accuracy and running time. This effectively proves the effectiveness of our method. Compared with the existing methods, the algorithm in this paper can use the GAN model to search for the positions of known persons and search for poses in these areas and improve the prediction of subsequent poses based on the existing data, and the accuracy is greatly improved. In the next step, we will conduct in-depth research on the improvement of model training stability and how to improve the resolution of generated images.

Retracted: Study of Trunk Morphological Imbalance and Rehabilitation Outcome of Adolescent Idiopathic Scoliosis with Intelligent Medicine

Computational Intelligence and Neuroscience

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

In recent years, artificial intelligence technology has been widely used in various medical fields to effectively assist physicians in patient treatment operations. In this paper, we design and implement a deep biblical network model-based orthotic design for adolescent idiopathic scoliosis to quickly and effectively assist physicians in designing orthotics for adolescent idiopathic scoliosis. A fuzzy set is used to express the knowledge of adolescent idiopathic scoliosis orthosis design, and a fuzzy reasoning based on the confidence level is implemented. Finally, the efficiency of the design of adolescent idiopathic scoliosis orthoses was improved by 50% through two cases of adolescent idiopathic scoliosis patients, and the deviation rate between the inference value and the actual operation value of the domain experts was less than 10%.

1. Introduction

Adolescent Idiopathic Scoliosis (AIS) is a skeletal and muscular disorder of unknown etiology that occurs during preadolescence or before skeletal growth and maturation, mostly in females aged 10 to 18 years. The prevalence of scoliosis in adolescents is increasing year by year, and the prevalence of scoliosis in adolescents is reported to be more than 5% in Guangdong and other regions [1–3], and the increase in prevalence is especially obvious in junior high school (12–15 years old).

AIS can cause great physical and psychological harm to the affected adolescents and one of the most easily detected and most important concerns of the patients themselves is the physical appearance deformity. The most easily recognized and most important concern is the deformity of the physical appearance. Since the human torso is an integral part [4], AIS not only manifests as distortion and deformity of the spine but also affects the position of the scapular girdle, thorax, and pelvis, resulting in high and low shoulders, razor backs, thoracic deformities, and pelvic disorders [5, 6].

If left untreated, it can lead to secondary symptoms such as chronic pain and pulmonary dysfunction, and severe scoliosis deformity can also can cause irreversible damage to respiratory function and spinal nerves, bringing great harm to individuals and families [5]. Therefore, the prevention and treatment of the prevention and treatment of AIS has been the focus of attention of experts and scholars in the field of spinal surgery and spinal rehabilitation for patients with idiopathic scoliosis and their corresponding X-ray images, as shown in Figure 1.

Surgery is recognized as an effective treatment for AIS, but according to statistics, only 1% of AIS patients require surgery and surgery can cause limitations in spinal motion. In Europe, exercise therapy interventions for scoliosis were first developed and have resulted in many mature rehabilitation systems; in China, research on AIS rehabilitation started later and there are more case studies and interventions [7, 8]. Therefore, experimental research on the idea or system of AIS rehabilitation therapy is needed.

Since the Cobb angle became the gold standard for scoliosis, the focus of AIS treatment has been on how to reduce the scoliosis angle and slow the progression of the scoliosis curve, while the local or overall morphological imbalance of the trunk caused by scoliosis has been increasingly neglected. Because the visual impact of poor posture is more severe, it is important to assess the trunk imbalance in patients with AIS before developing a rehabilitation program and to design a customized program for the patient [9].

AIS, as shown in Figure 2, is one of the most common types of scoliosis, accounting for approximately 80% of all idiopathic scoliosis, with the prevalence of AIS reaching 1% to 3% in the 10- to 16-year-old risk group. AIS not only affects the physical appearance of adolescents but also impairs their respiratory function, motor function, psychological status, and overall quality of life [10].

It is proposed that the difference of about 5° in scoliosis measurements is usually an error in measurement rather than a difference in the degree of scoliosis itself.

AIS is a common orthopedic disorder of uncertain etiology that affects the normal growth and function of the spine. 1%–3% of the normal population has AIS, and the main principle of clinical intervention is to control the progression of scoliosis using AIS orthoses [11–13]. An expert system contains a large amount of knowledge of domain experts inside and it can simulate the expert's reasoning methods to solve problems in the domain [14–16]. The currently popular expert systems are mainly classified as rule-based reasoning-based expert systems [17–20], artificial neural network-based expert systems [21], and rough set-based expert systems [22]. In [23], a generative-based expert system shell design method was proposed and applied to the treatment of AIS; however, the system could not be fully applicable to the knowledge expression and reasoning of uncertain information in the design of AIS orthoses.

2. Related Work

The authors of [24] found that the Cobb angle measurement error was around 3.2°, and this measurement difference should be taken into account when diagnosing and treating scoliosis. In addition, errors in the Cobb angle measurement can lead to differences in subsequent staging. The typing reliability of radiographs based on a given angle was found by [24]. The authors of [25], only general intraobserver ($\kappa = 0.50$) and interobserver reliability ($\kappa = 0.60$) were found for Lenke typing in cases where the ab initio Cobb angle measurements were required. The authors of [2] proposed that T1 tilt signifies that patients may have upper thoracic segment scoliosis and validated that this method of determining the presence or absence of upper thoracic curvature was included in the King typing, but subsequent studies by [3] reported that patients with AIS with T1 tilt do not necessarily show differences in the appearance of high and low shoulders, and therefore, the T1 tilt direction and T1 tilt angle do not reflect the imbalance of the patient's shoulders. In [14], the angle between the line connecting the highest points of the left and right clavicles and the horizontal plane was defined as the clavicle angle (CA) and used as a parameter to measure the balance of the shoulder. A study by [7] showed a significant correlation between reduced cervical physiological curvature and inadequate thoracic kyphosis in patients with AIS; in addition, cervical curvature correlated with lumbar anterior convexity angle, independent of thoracolumbar lateral bending angle and pelvic parameters. Reference [6] performed an imaging study of sagittal pelvic parameters in normal Chinese adults and concluded that the mean value of PI in Chinese adults was $45.1^\circ \pm 9.6^\circ$.

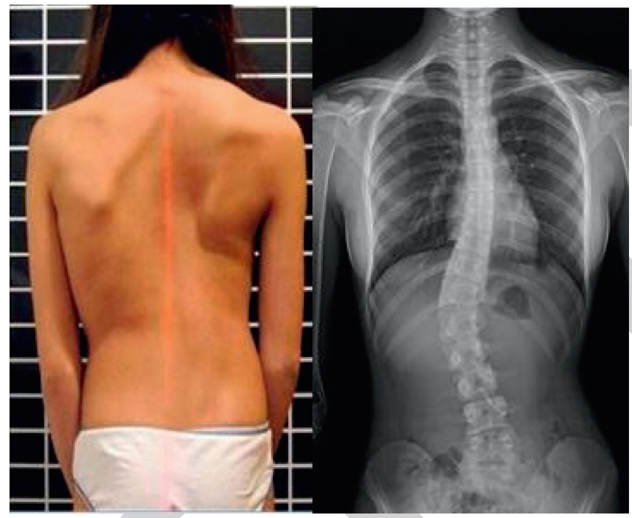

Figure 1: Patients with idiopathic scoliosis and their corresponding x-ray images.

In the field of spinal surgery, AI is widely used for diagnosis of diseases, especially for image processing, measurement, and classification. Theoretically, the successful development and application of AI-based automated measurement systems will provide an objective, accurate, and rapid solution to these problems and improve the diagnosis and treatment of AIS patients.

3. U-Net-Based Scoliosis Typing Algorithms for Idiopathic Scoliosis

The original data set is expanded, and the expanded data set is fed into the network for training and prediction to obtain the segmentation results; then, the segmentation results are fed into the automatic Cobb angle measurement algorithm designed in this paper to obtain the identified upper and lower endplate positions and Cobb angles; finally, the center points of the segmented images are extracted and fitted to obtain the curve fitting coefficient features, and the corresponding Cobb angles are measured by the automatic Cobb angle measurement algorithm. Finally, the center point of the segmented image is extracted and fitted to obtain the curve fitting coefficient features, and the corresponding

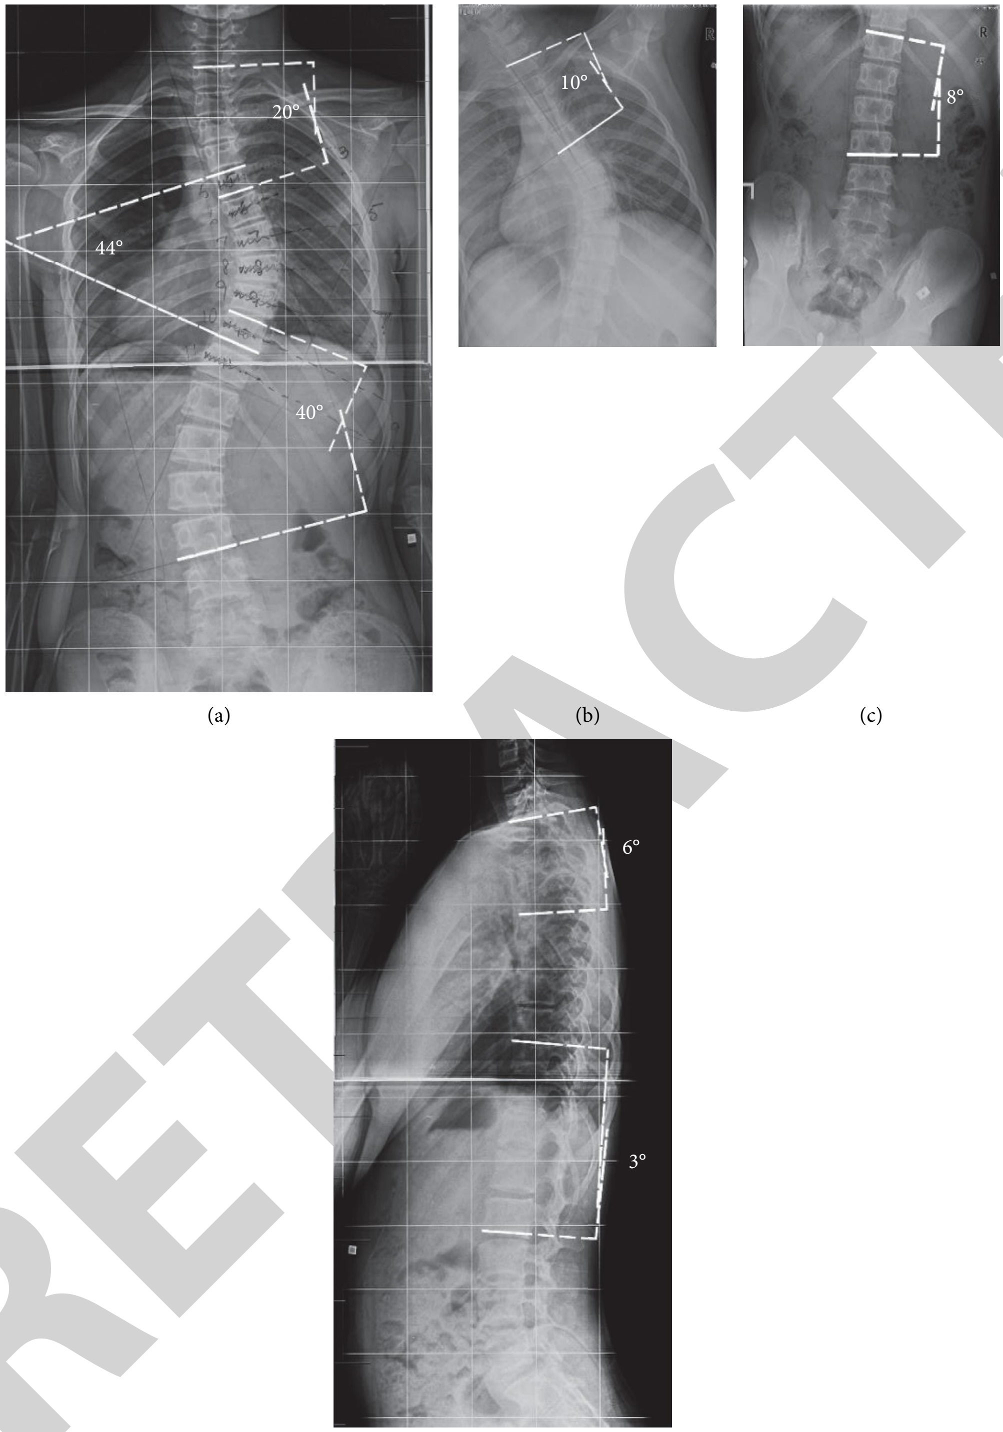

Figure 2: Cobb angle measurement method.

bending bits and Cobb angles of the side slices are measured by the automatic Cobb angle measurement algorithm and used as auxiliary feature materials. The overall framework is shown in Figure 3, and the automatic Lenke typing algorithm based on the U-net partition network can be implemented by experimenting according to the process shown in the overall framework.

4. Overall Design

The AIS expert system infers diagnostic and therapeutic solutions to assist physicians in solving complex medical problems [19]. The method in this paper can reason out the selection and design parameters of the AIS orthosis from patient information, and its structure is shown in Figure 4.

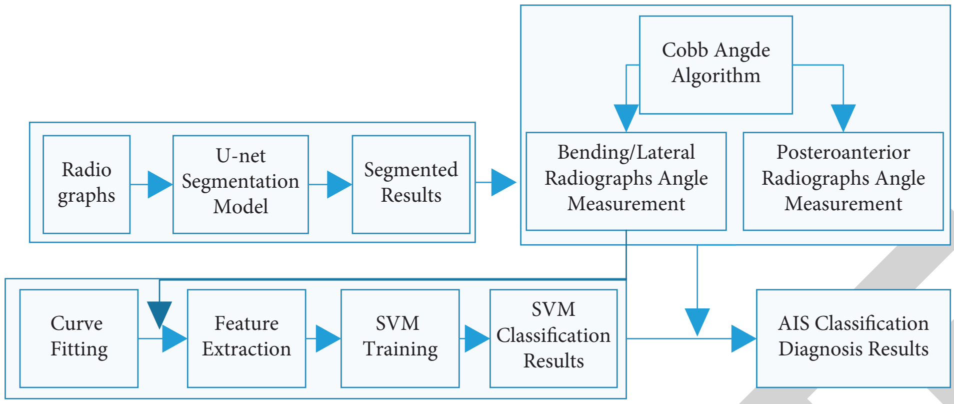

Figure 3: Flowchart of the overall framework of the U-net-based automatic typing algorithm.

The architecture functional modules in this paper include the fuzzy reasoner, knowledge base, knowledge base management system, agenda, interpreter, and human-machine interface. They are described separately as follows. They activate rules from the knowledge base for questions posed by the user according to the established reasoning strategy and process the facts until the end of reasoning. A dynamic storage space containing all facts in the fact base and intermediate results in the reasoning process is present.

Real-time operations such as adding, deleting, modifying, and querying the knowledge base, as well as consistency and integrity checking of the knowledge therein are performed.

A database for storing domain expert knowledge is found. The knowledge base serves as the basis for reasoning and is the foundation of the expert system's reasoning.

A functional module explains the reasoning process of an expert system in a way that is easy to understand by the user. It gives the user a clear understanding of the reasoning process and decision making of the expert system.

The functional module that performs real-time operations such as adding, deleting, modifying, and querying the fact database, as well as displaying the expert system decisions and explanations by the interpreter is present.

The workflow of the method in this paper is shown in Figure 5.

Its fuzzy reasoning unit is shown in Figure 6.

In the fuzzy inference stage of the method in this paper, the confidence degree CFRHS of the right-hand side (RHS) of the activation rule is calculated as [10].

$$CF_{RHS} = CF_{LHS} \times CF_R, \tag{1}$$

where CFLHS is the confidence of the left part of the rule; CR is the confidence of the rule.

In the deblurring stage, the deblurring algorithm of the method in this paper uses the weighted average method [21], which is given as follows:

$$x = \frac{\sum_{i=1}^{n} x_i \mu(x_i)}{\sum_{i=1}^{n} \mu(x_i)}, (n = 1, 2, 3, \cdots), \tag{2}$$

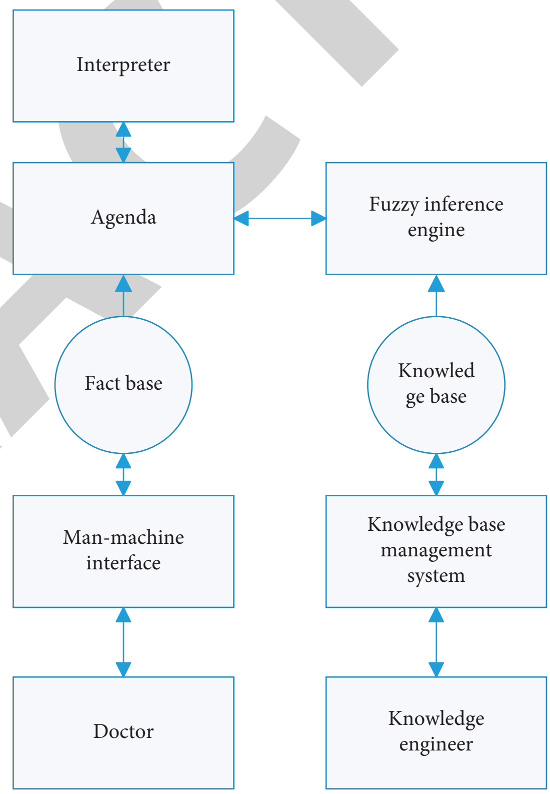

Figure 4: Structure of the scoliosis orthosis design expert system (SODES).

where x is the clear amount of design parameters; x_i is the value of fuzzy subset; $\mu(x_i)$ is the affiliation degree of fuzzy subset.

The AIS orthosis is then shaped and manufactured from the patient's phantom according to the shaping volume. After the patient has tried on the AIS orthosis, the doctor determines the amount of trim adjustment for the AIS orthosis based on the patient's feedback and adjusts the trim of the AIS orthosis according to the amount of trim adjustment. By adjusting the height of the pressure application zone of the AIS orthosis, the orthotic force exerted on the patient is thereby adjusted until the patient no longer experiences discomfort while wearing the orthosis [23]. As

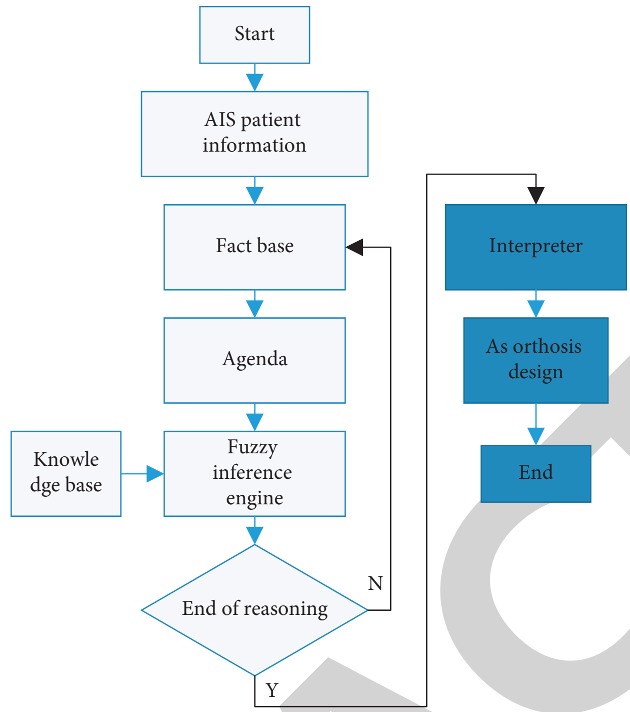

Figure 5: Workflow diagram of the expert system.

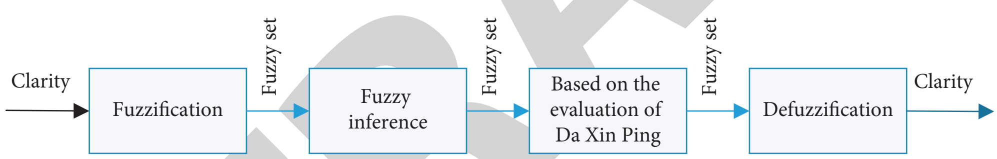

Figure 6: Fuzzy inference unit of the scoliosis orthosis design expert system.

shown in Figure 7, the determination of the amount of trim and trim adjustment is an important factor in ensuring that the AIS orthosis meets the individual needs of the patient.

The fact sheet in the knowledge base management system is used to maintain the known facts in the fact base. The knowledge engineer conceptualized and formalized 848 AIS treatment and AIS orthotic design rules through interviews and case studies with AIS conservative treatment specialists [26].

5. Application Examples

To verify the feasibility of the proposed expert system design method for AIS orthosis design based on the fuzzy reasoning, the method in this paper was applied to the AIS orthosis-assisted design of 2 cases of AIS patients.

The method in this paper was successfully applied to the AIS orthosis-assisted design of 2 AIS patients. The average design time of the AIS orthoses for Patient A and Patient B was reduced from 4 h to 2 h with the aid of this method, which improved the design efficiency of the AIS orthoses by 50% as shown in Figure 8. The deviation rates of some of the methods in this paper are shown in Table 1, and the deviation rates of the inferred values from the actual operational values of the domain experts in the AIS orthosis design of this paper are less than 10%. This shows that the method of this paper can assist physicians in designing AIS orthoses quickly and efficiently.

6. Experimental Analysis

The raw data of the spine were provided by Shenzhen University General Hospital, and the spine segmentation performed in this chapter The experiments were performed for the thoracic, lumbar, and full spine segmentation of the

Figure 8: Patients A and B wearing the scoliosis orthosis design expert system (method in this paper) assisted by the before and after comparison of adolescent idiopathic scoliosis orthoses designed with the aid of the design expert system.

Table 1: Deviation rate of the expert system component.

Project	Patient A				Patient B			
	Opening diameter of release area (CM)	Opening angle of release area (°)	Three-point force modification (CM)	Adjustment amount of three-point force repair (CM)	Opening diameter of release area (CM)	Opening angle of release area (°)	Three-point force modification (CM)	Adjustment amount of three-point force repair (CM)
Inference value	15.8	54.8	6.3	1.5	14.5	48.4	5.1	2
Recommended value	15	60	6	1.6	14.9	52	5.5	1.8
Deviation rate	5%	9.4	4.7	6.7	3.4	7.4	7.8	10

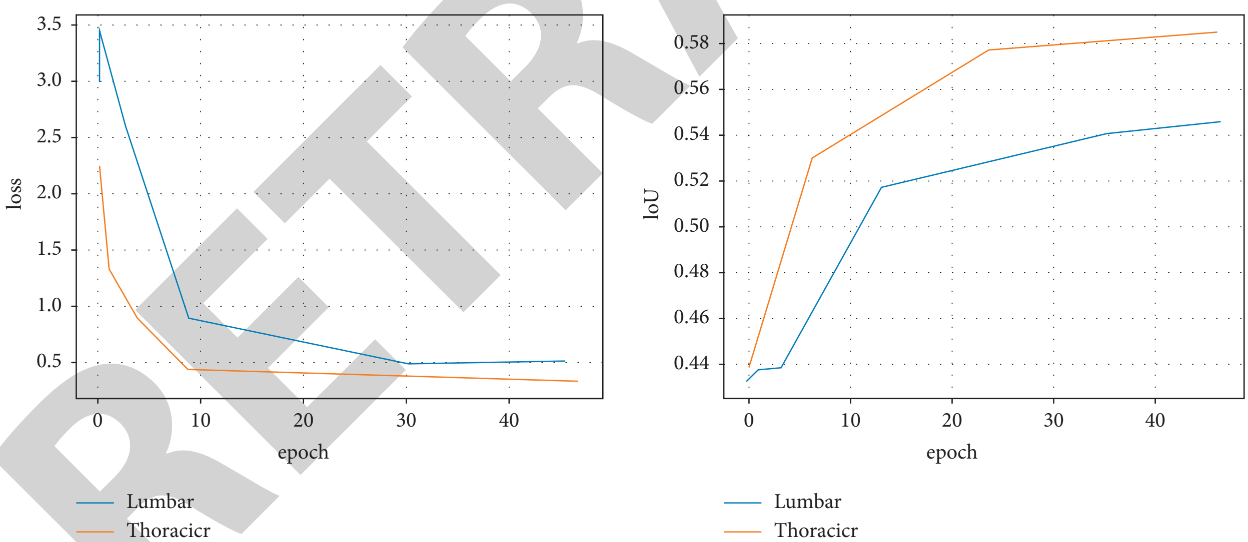

Figure 9: Data display of the thoracolumbar spine training process.

orthopantomographs of the spine. Among them, the original data volume of lumbar spine was 84. The original data volume for the lumbar spine was 84 cases, the original data volume for the thoracic spine was 166 cases, and the original data volume for the coronal position was 88 cases. Each of these cases is derived from different patient x-rays. Since the original data could not be trained for deep learning, the data were expanded by rotation, flip, and offset [27, 28]. The expanded data were 1050 for lumbar spine, 4910 for thoracic spine, and 6302 for coronal spine. The size of the data expansion was determined by the ease of segmentation. The experimental platform is based on the Window 7 system and the Kares deep learning library.

From the training process, in Figure 9, the Loss curves of the training and validation sets show a steady decreasing trend, and the IOU shows an increasing trend overall. After 50 iterations, the loss values of the training and validation sets of the lumbar spine drop to 0.033 and 0.0754, and the loss values of the training and validation sets of the thoracic spine drop to 0.0537 and 0.050. The IOU values of the

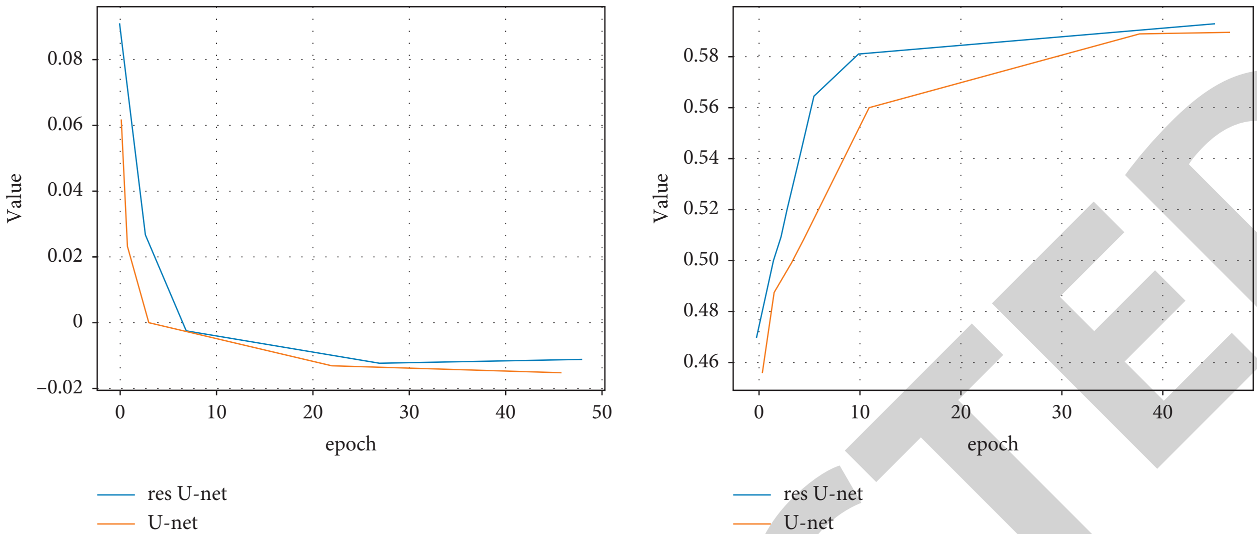

Figure 10: Training results of the U-net network and its improved network in coronal position.

training and validation sets of the thoracic spine can reach 0.6341 and 0.6342, and the IOU values of the training and validation sets of the lumbar spine can reach The training and validation sets for the lumbar spine were 0.5947 and 0.5948, respectively.

The training process of full spine segmentation is shown in Figure 10 below, from which we can see that the red discounted represents the improved U-net model and the blue-dashed line represents the original U-net model. The improved U-net model is able to segment the contours of the coronal spine well, and it is very meaningful for medical diagnosis to be able to achieve the segmentation of the coronal position. With good segmentation results, the accuracy of the subsequent series of automatic measurements will also be improved.

7. Conclusions

The accuracy rate of the system in this paper is more than 80%. The above studies are all applications of the expert system technology in the direction of scoliosis-assisted diagnosis and treatment and have achieved a certain accuracy rate, but their inference models have not yet reached the optimal accuracy rate. The main reason for this is the use of the traditional generative reasoning model, which relies on the physician's empirical knowledge in the treatment of scoliosis and contains a large amount of uncertain information. Fuzzy logic is a method that can effectively handle uncertain information based on multivalued logic and can effectively realize the expression and inference of uncertain knowledge in expert systems. The future research direction should be to further investigate the influence of individual and gender differences on this method by increasing the number of subjects.

Data Availability

The data underlying the results presented in the study are available within the manuscript.

Disclosure

The authors confirm that the content of the manuscript has not been published or submitted for publication elsewhere.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Qin Zhao and Yiming Huang made equal contributions to the manuscript. They worked together.

Rice is a major food crop around the world, and its various quality and safety problems are closely related to human health. As an important area of food safety research, the rice supply chain has attracted increasing attention. Based on blockchain technology, this study investigated problems of data privacy and circulation efficiency caused by complex rice supply networks, long circulation cycles, and various risk factors in each link. First, we deconstructed the quality and safety of each link of the rice supply chain at the information level and established a key information classification table for each link. On that basis, we built a rice supply chain information supervision model based on blockchain. Various encryption algorithms are used to secure the sensitive data of enterprises in the supply chain to meet regulators' needs for efficient supervision. Moreover, we propose a practical Byzantine fault-tolerant consensus algorithm that scores the credit of enterprise nodes, optimizes the selection strategy of master nodes, and ensures high efficiency and low cost. Then, we built a prototype system based on the open-source framework of hyperledger fabric, analyzed the model's viability, and implemented the system using cases. The results indicated that the proposed system can optimize the information supervision process of rice supply chain regulators and provide a feasible solution for the quality and safety supervision of grain and oil.

1. Introduction

In recent years, consumers have paid increasing attention to food quality and safety, which provide a basic guarantee for human health and are directly related to improving people's lives [1]. Rice is among the world's major food crops, but in recent years, various quality and safety problems have arisen, such as cadmium-laced rice, mercury-laced rice, and aging grain [2–4]. Such problems can not only affect human health but also threaten social stability. It is necessary, therefore, to establish a safe and efficient rice supply chain information supervision system. Compared with other foods, rice is characterized by long supply chains, complex supply networks, long circulation cycles, and numerous risk factors in all links [5, 6]. Moreover, each link of the rice supply chain is relatively independent, and there is little information exchange between them. It can be difficult, then, for enterprise nodes in the supply chain to trust each other, and supervision efficiency is low [7, 8]. In addition, traditional supervision systems rely on a centralized database to store data. This can give rise to problems such as enterprises tampering with detection data in different links of the supply chain, which compromises the credibility of supervision results [9, 10].

Blockchain technology can provide effective solutions for issues related to centralization, security, and tamperability [11–13]. Blockchain can automatically execute a code according to business rules set by the system and can record the whole process in the chain to reliably transfer information, logistics, and capital flow information in a supply chain [14, 15]. In recent years, researchers have investigated the supervision and management of blockchains combined with food and agricultural product supply chains. They have focused on areas such as establishing product identification through various technologies and developing supply chain management systems for data uploading, real-time monitoring, early risk warning, and information tracing using sensor technologies [16–19]. It has been found that blockchain can improve data security and traceability for food-related supply chains and provide a guarantee for food quality and safety. However, there is still much room for improvement in the areas of blockchain storage modes, consensus overhead, and rice supply chain information supervision.

In light of the above, this study deconstructed and analyzed the quality and safety information of each link of the rice supply chain at the information level and established a key information classification table for each link. Then, a rice supply chain information supervision model was constructed based on blockchain. The model adopts a hierarchical privacy encryption and storage mode, as well as a practical Byzantine fault-tolerant consensus algorithm based on credit scoring (CPBFT). Finally, a prototype system was designed, and the model and system were analyzed to provide a reference for the current theoretical research and actual construction of rice supply chain information supervision system.

2. Related Work

Researchers have investigated the application of blockchain technology in related fields from different perspectives. Baralla et al. [20], for example, developed a blockchain-based system to manage and trace the food supply chain, using smart contracts to ensure the credibility of the whole process. Based on an analysis of the wheat-processing supply chain, Zhang et al. [21] proposed a blockchain-based grain and oil supply chain system architecture using a multimode storage mechanism. Wang et al. [22] proposed a framework based on consensus and smart contracts to achieve traceability and sharing in the agricultural product supply chain and improve the integrity and security of transaction records. In their model, data are stored in an interstellar file system, and the data hash is stored in the blockchain network, which saves storage space and ensures security. Mao et al. [23–25] built a blockchain-based food supply chain trading system to provide more reliable and authentic information. Pigini and Conti [26] used Near Field Communication (NFC) technology to achieve effective traceability and safety tracking to collect product information in all links of the food supply chain. Salah et al. [27] analyzed the traceability and business processes of the soybean supply chain and proposed using smart contracts to control and ensure the safety and credibility of supply chain information.

The aforementioned studies addressed the security problems of food supply chains to a certain extent. However, with the rapid expansion of supply chain nodes, existing traditional consensus modes have too much overhead, and sharp increases in the amount of data have corresponding requirements for consensus security. Researchers have sought to solve this problem by improving the blockchain consensus algorithm. Liu et al. [28], for example, improved the Delegated Proof of Stake (DPOS) consensus algorithm to keep the consensus process from being controlled by a few nodes. Meanwhile, to achieve node consensus in large-scale distributed systems, Li et al. [29] proposed an extensible multilayer PBFT consensus mechanism that groups nodes hierarchically and limits communication within the group, such that PBFT consensus is not limited to small consensus networks. In rice supply chains, however, the key data in each link are complex, and enterprise entities cannot form a unified standard. It is necessary, then, to adopt a targeted consensus scheme, that is, to reduce the consensus cost and ensure consensus reliability at the same time. In addition, because the nodes in the blockchain are not completely anonymous, there are privacy risks, which necessitate privacy encryption for uplink data.

To meet these challenges, this study analyzed the information for each link in the rice supply chain and output a classification table of key information for each link. Combining the principles of cryptography and blockchain, we proposed a data encryption and storage mode that protects the sensitive data of supply chain enterprises and meets the needs of regulators for efficient supervision. In addition, our proposed credit score-based PBFT consensus algorithm reduces the probability that the master node is a Byzantine node and ensures high efficiency and low overhead. In summary, this research can help optimize regulators' information supervision processes in rice supply chains and provide a feasible solution for rice quality and safety supervision in the future.

3. Analysis of Supply Chain Process and Key Information

Many enterprises are involved in each link of the rice supply chain, including growers, purchasers, storage enterprises, processing enterprises, logistics enterprises, and distributors. The rice supply chain is therefore characterized by a long life cycle and complex links. From rice planting to sales, there are many potential safety hazards in the supply chain, which are summarized in the following:

(1) In the planting process, rice needs to absorb a large amount of water, which makes it more vulnerable to pollution than other crops. Farmers' fertilization practices are not always standardized. Some even irrigate farmland using untreated domestic sewage and industrial wastewater, resulting in excessive heavy metal pollution [30].

(2) Rice processing is a lengthy process, and problems such as broken rice and fumigant residue easily arise in the process of impurity removal [31]. China's rice-quality standards stipulate that no flavor or pigment is allowed in rice. Yet, to increase profits, some enterprises in China add fragrance to rice or treat it to increase its brightness. When polishing rice, it not

only adds water but also illegally adds mineral oils, thus processing ordinary rice into “poisonous rice.”

(3) With regard to packaging, the plastic woven bags mainly used for rice commodities offer a simple, low-price packaging method. However, the material has a poor moisture barrier and moisture resistance, resulting in problems such as oxidization and mildew.

(4) Storage and transportation links: improper warehouse storage makes rice prone to mildew. In addition to changing the color of rice, mildew can produce harmful molds and microorganisms [32].

(5) The sales link of rice is widely distributed and contains a large amount of information. As the terminal link of the supply chain, it directly faces consumers. If there is an information supervision problem in this link, it can seriously affect the whole supply chain.

In summary, the types of hazards in each link of the rice supply chain are complex, and safe and efficient supervision is needed. However, traditional blockchain supervision systems generally have problems such as large differences in inspection standards and inconsistent data storage formats in all links of the supply chain. It is difficult to effectively enter the multilink information of a complex supply chain. It is also difficult to build models and systems based on these data in the follow-up process, making it difficult to solve the problem of rice quality in terms of data security.

Based on the rice supply chain process and the business characteristics of enterprises in the supply chain, we divided the rice supply chain into 13 links and five types of key data: main information, basic information, environmental information, hazard information, and transaction and price information (Table 1).

The subject information is the enterprise information in different links of the supply chain, including the enterprise name, the person in charge, and contact information. The basic information is the information recorded by the enterprise staff in each link, such as rice type, sampling inspection record, rice milling method, and whether it is genetically modified. Environmental monitoring information is the information recorded by sensors in the supply chain, including temperature and humidity, carbon dioxide concentration, and real-time photos. Hazard information mainly refers to the content of mycotoxins, pesticide residues, and heavy metals in rice during sampling inspection. Mycotoxins mainly include aflatoxin B1, ochratoxin A, and deoxynivalenol. Heavy metals include lead (Pb), cadmium (Cd), Mercury (Hg), arsenic (As), and chromium (Cr). Pesticide residues include chlorpyrifos, triazophos, carbofuran, and bensulfuron methyl. Transaction records and price information include the commercial information circulating among various links, and their confidentiality is high. Table 1 summarizes the key information in each link. Taking the processing link as an example, processing enterprises accept rice stored in multiple granaries, including storage enterprises. After the rice is transported to the processing plant, the processing plant also needs to carry out various processes, such as removing the husk, rice milling, color selection, and polishing. This study regarded the abovementioned processes as independent links. Detailed information classification can further optimize the process architecture of the supply chain business system and can be used as the basis for establishing an information supervision model for the safety and quality of the rice supply chain.

4. Blockchain-Based Supervision Model for Rice Supply Chain Information

Traditional rice supervision systems store supply chain information in a central database. Its supervision timeliness is poor, data are easily tampered with, flow between enterprises is difficult, and the enterprise data query efficiency is low. A blockchain stores enterprise data with a distributed ledger instead of a central database to achieve data sharing and value transfer between upstream and downstream enterprises in a supply chain. Using blockchain technology, an improved consensus algorithm, and the principle of cryptography, this study built a rice supply chain information supervision model based on supply chain processes and the characteristics of enterprises in the chain. The model includes not only complete supervision of the supply chain but also government agency supervision, as well as the data uploading and data sharing of enterprises. Querying and consumer commodity traceability are employed to achieve integrated supervision. In this way, rice information can be supervised and managed from the supply chain, which ensures the security and authenticity of data circulated in the supply chain. Meanwhile, it reduces the information gap between consumers, regulators, and enterprises in the supply chain and avoids the generation of information islands.

This study regarded each link in the rice supply chain as a node in the blockchain, and each node corresponds to a cloud database. Each node in the supply chain invokes a smart contract deployed in the blockchain network through the supervision system and carries out network consensus through an improved PBFT consensus algorithm. Enterprises in all links can encrypt and store the data in the system through this system. After blockchain network consensus, plaintext and ciphertext data in the supervision system are recorded in a cloud database, and a small part of the plaintext data, information summary, and key are saved in the blockchain network (Figure 1).

Combining regulatory authorities and supply chain enterprises and based on the key information classification table, we standardized the data uploading or traceability of supply chain links (e.g., production, processing, warehousing, transportation, and sales), which can achieve effective information supervision of the entire rice supply chain.

The model mainly includes rice supply chain network nodes, data hierarchical encryption, storage mode, and CPBFT. The data hierarchical encryption and storage mode combined symmetric encryption and hash encryption

Table 1: Key data of each link in the rice supply chain.

Links in rice supply chain		Key data classifications				
		Main information	Basic information	Environmental information	Hazard information	Transaction and price information
Plant		Identity information of growers; planting license information; contact information; business license information (optional)	Seed source; rice varieties; origin information; planting and harvesting time; pesticide and fertilizer information and use records	Pictures of rice growth cycles; real-time ambient temperature; real-time ambient humidity; actual illumination intensity of environment; soil moisture content	Pictures of rice growth cycles; real-time ambient temperature; real-time ambient humidity; actual illumination intensity of environment; soil moisture content	Seed price; fertilizer price; total cost; selling price; collect and store enterprise information
Acquisition and storage	Acquisition	Enterprise name; business address; corporate information; person in charge of relevant links; license information; enterprise contact information	Pesticide sampling inspection records; transgenic or not	None	Mycotoxin: fumigant and insecticide residues	Grower information; purchasing price; drying, impurity removal, storage, and other costs; selling price; processing enterprise information
	Dry		Drying method; moisture content before drying; moisture content after drying	Real-time ambient temperature; real-time ambient humidity		
	Impurity removal		Impurity content; impurity removal rate			
	Storage		Inventory number; product source; warehousing time; delivery time	Ambient temperature, humidity, oxygen concentration, carbon dioxide concentration, and various toxic gas concentrations produced by long-term storage		

Table 1: Continued.

Links in rice supply chain		Key data classifications: Main information	Basic information	Environmental information	Hazard information	Transaction and price information
Machining	Removing the husk	Enterprise name; business address; corporate information; person in charge of relevant links; license information; enterprise contact information	Ridge and valley mode (brand of ridge and valley machine); roughness; shelling rate	Real-time ambient temperature; real-time ambient humidity	Mycotoxin: broken needle foreign body; chemical reagents; heavy metals	Processing cost; processing price
	Rice milling		Rice milling method (chemical method/ mechanical method); whole meter rate; broken rice rate			
	Color selection		Color separation accuracy; bringing out the ratio			
	Polishing		Polishing rate			
	Packing		Product package number; product batch number; product quality information			
Storage		Name of warehousing enterprise; address of storage enterprise; corporate information	Inventory number; product source; warehousing time; delivery time	Ambient temperature, humidity, oxygen concentration, carbon dioxide concentration, and various toxic gas concentrations produced by long-term storage	Mycotoxin	Storage cost; storage price
Transport		Name of logistics enterprise; address of logistics company; information of the person in charge of transportation	Means of transport; place of departure; departure time; destination	Ambient temperature inside the vehicle; ambient humidity in the vehicle; oxygen/carbon dioxide concentration in the vehicle	Fungi and toxins produced by temperature and humidity metamorphosis	Logistics cost; logistics price
Sale		Merchant name; shop address; information of the person in charge of the store; business license information; business contact information	Product name; product quantity; purchase time; purchase number; shipping time	Sales environment photos	None	Purchasing price; selling price

algorithms to ensure the security and privacy of the data uploaded to the blockchain network and the cloud database in the process of circulation and storage. Advanced Encryption Standard (AES) is used to ensure data confidentiality. It is characterized by that both sides of communication use the same key in the process of encryption and decryption. Hash encryption algorithms can compress arbitrary length data into information summary of fixed length to realize digital signature and data integrity. As a partial synchronous pattern consensus algorithm, PBFT has been widely used in the alliance chain. The algorithm can solve the Byzantine problem, which is relatively efficient and widely used [33]. However, when the algorithm is applied to the supervision of agricultural products with many coverage links, there are still some problems, such as high overhead, low throughput, and low performance. CPBFT introduces the credit-scoring mechanism in PBFT, which scores and grades the credit of supply chain enterprise nodes to ensure the efficiency of consensus. At the same time, the algorithm improves the reliability of supply chain supervision. In addition, based on the model, this study designs the information supervision prototype system, constructs the system infrastructure, and analyzes the complete operation process of the system.

4.1. Hierarchical Data Encryption and Storage Mode. Based on the above classification of key information in each link of the rice supply chain, as well as the integration of data privacy, encryption algorithm security, algorithm time complexity, and space complexity in each link, we performed the hierarchical encryption and secure storage of supply chain circulation data. Figure 2 shows the data flow in the encryption and storage mode.

We mainly used the AES encryption algorithm and SM3 password hash algorithm to encrypt and decrypt the supply chain information. The AES encryption algorithm uses ECB and CBC working modes. The difference between AES working modes is reflected in the association between plaintext data blocks, although the processing flow inside the AES encryptor is the same. Algorithm 1 shows the AES encryption process, and Algorithm 2 shows the decryption process. NR is the number of encrypted rounds. For different key lengths, the number of rounds is different, and W is the extended key array. The SM3 hash algorithm is a commercial hash algorithm standard published by the State Encryption Administration of China. The algorithm has excellent anticollision ability and is very suitable for privacy data encryption in a rice supply chain. For a plaintext message m with a length of less than 264 bits, the SM3 hash algorithm generates a hash value (ciphertext) after filling and iterative compression. The hash value length is 256 bits. Algorithm 3 shows the encryption process.

4.1.1. Level I Privacy Data Encryption. Hazard information is defined as level I privacy data. In this mode, the AES algorithm ECB mode is used to encrypt level I privacy data and then transmit it to the cloud database. In this mode, the encryption of each plaintext block is completely independent. The data are grouped with 128 bits, and the remaining insufficient bits are filled to reach the integer multiple of the packet:

$$x_1, x_2, x_3 \ldots . \tag{1}$$

Each group of data and the key of the same length are used as input, and new data packets are generated by independent encryption. The same is true for decryption. The encryption process is

$$y_1 = E_k(x_1), y_2 = E_k(x_2), y_3 = E_k(x_3) \ldots . \tag{2}$$

The decryption process is

$$x_1 = D_k(y_1), x_2 = D_k(y_2), x_3 = D_k(y_3) \ldots . \tag{3}$$

The AES algorithm ECB working mode can carry out a large number of parallel calculations, which is suitable for rice hazard information with large amounts of data. In this mode, the data key is randomly generated by the algorithm and uploaded to the blockchain network for storage to ensure the randomness and security of the key and mitigate the risk of key disclosure in symmetric encryption.

4.1.2. Level II Privacy Data Encryption. Transaction records and price information are defined as level II private data. For level II private data, the AES algorithm CBC mode is used for encryption, and ciphertext data are transmitted to the cloud database.

In the process of privacy data encryption, the first plaintext data packet is XOR with the randomly generated initial vector IV. Then, packet encryption is carried out, and the ciphertext output by this group and the XOR of the next plaintext packet are used as the input of the next packet encryption. In this way, until encryption is completed, the decryption process is the same.

Encryption process:

$$\begin{aligned} y_0 &= IV, \\ y_1 &= E_k(y_0 \oplus x_1), \\ y_2 &= E_k(y_1 \oplus x_2) \ldots . \end{aligned} \tag{4}$$

Decryption process:

$$\begin{aligned} y_0 &= IV, \\ x_1 &= D_k(y_1) \oplus y_0, \\ x_2 &= D_k(y_2) \oplus y_1 \ldots . \end{aligned} \tag{5}$$

The output of each ciphertext in this mode is related to its corresponding plaintext packet and all previous plaintext packets; thus, the ciphertext generated by the same plaintext may be different. Therefore, compared with the ECB mode, the CBC mode has stronger security and is suitable for commodity value guarantee with a higher security level. In addition, in this process, the data key is generated and stored in the same way as with level I privacy data.

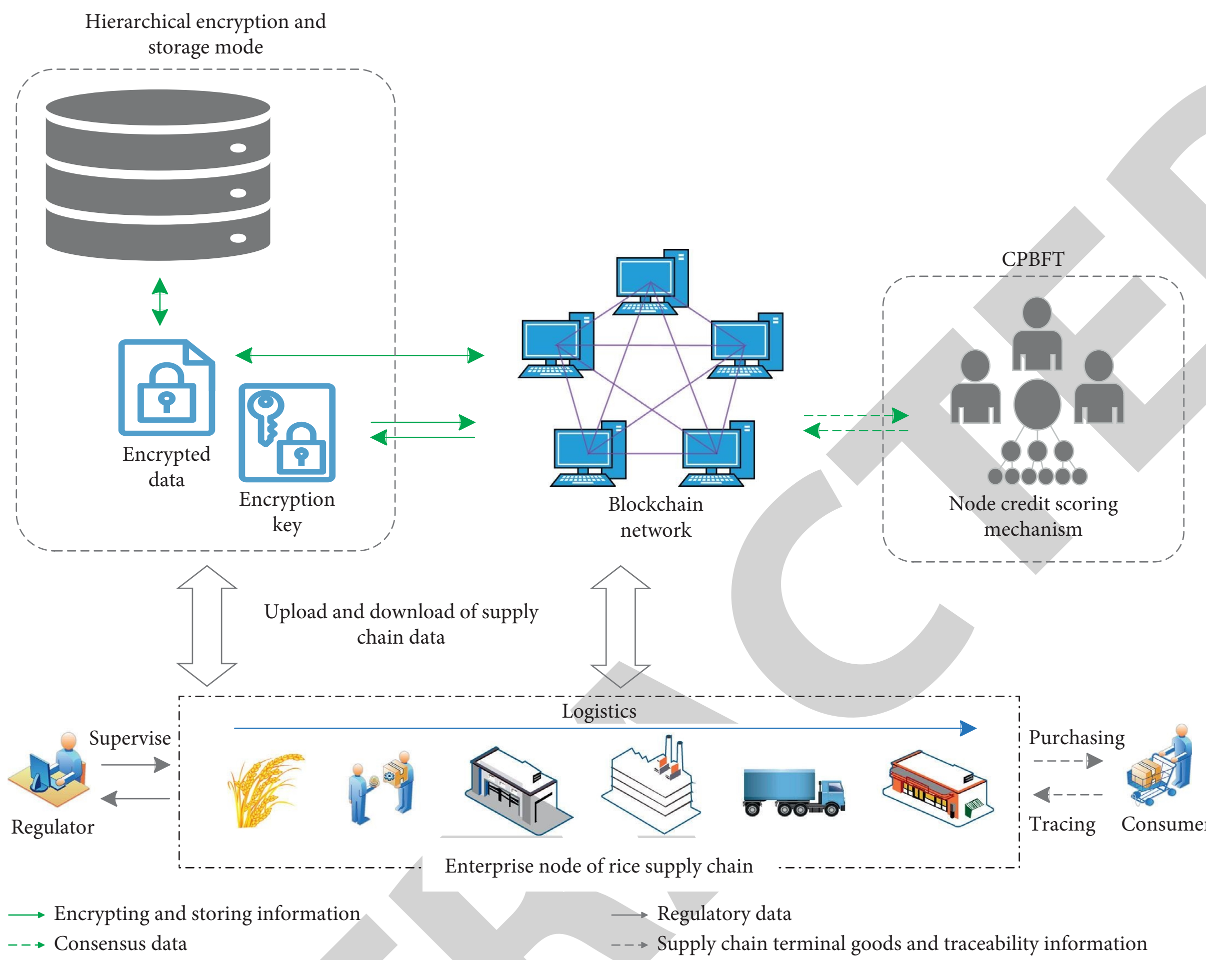

Figure 1: Rice supply chain information supervision model.

4.1.3. Level III Privacy Data Encryption. Subject information, basic information, and environmental information are defined as class III privacy data. For subject information, the amount of data is small, and the degree of importance is high. This mode adopts the method of directly transmitting data to the blockchain network. For all level III privacy data, the SM3 cryptographic hash algorithm is used for encryption. The algorithm first fills the data and then expands the filled data, iteratively compresses the expanded data, and finally generates an information summary with a length of 256 bits. Finally, the encrypted information summary is uploaded to the blockchain network, and the level III privacy data are uploaded to the cloud database in plaintext. The compression function of the SM3 cryptographic hash algorithm has a similar structure to that of SHA-256, but the structure of the compression function of the SM3 cryptographic hash algorithm and the design of the message expansion process are more complex. Each round of the compression function uses two message words, and each round of the message expansion process uses five message words, which can further ensure that high-privacy data are nontamperable.

4.2. Practical Byzantine Fault-Tolerant Consensus Algorithm Based on Credit Score. The PBFT algorithm is a partially synchronous mode consensus algorithm. To ensure that nonfault nodes execute client requests in the same order, third-order broadcast communication is needed to ensure security in the asynchronous mode, resulting in a great deal of communication overhead. At the same time, PBFT lacks the mechanism of troubleshooting nodes, and the selection of master nodes is arbitrary. The probability of selecting Byzantine nodes as master nodes is high, and the frequent replacement of master nodes greatly affects system efficiency [28, 34]. Therefore, this study improved the original PBFT algorithm and designed CPBFT (PBFT based on credit score) according to the characteristics of rice supply chains. Taking the transaction time and honesty of the nodes in the rice supply chain as the main reference factors, we scored the behavior of all nodes participating in consensus in the supply chain. The credit-scoring model divides the nodes into fault, ordinary, supervision, and candidate nodes according to the score and then optimizes the selection strategy of the main node, reduces the possibility of the main node becoming a Byzantine node, reduces the amount of view switching, and improves the efficiency of the information supervision system. Figure 3 shows the classification and conversion mode of consensus nodes.

4.2.1. Credit-Scoring Mechanism of Nodes. In this model, it is necessary to first conduct multiple rounds of PBFT consensus and then select the consensus set, eliminate nodes that fail in the consensus process or send messages inconsistent with most nodes, and conduct node credit scoring to remove most nonsystem interference factors.

After each correct consensus, the credit score of the corresponding node is added β. After n rounds of consensus, all honest nodes will correctly complete the consensus, and the node's credit score will be η. The traditional PBFT consensus algorithm has $3f+1$ nodes, and at least $2f+1$ honest nodes can complete consensus. If a malicious node wants to join the consensus set, it must be honest every time. At this time, the credit score of more than $2f+1$ nodes will be divided into η and is marked as an honest node. This will be reached within specified time η. The node with the score is marked as an ordinary node and can only participate in consensus. A node that fails to reach the score is regarded as a fault node. After multiple consensuses, according to the credit score of the node, the nodes participating in consensus can be divided into ordinary, supervision, candidate, and fault nodes. These nodes perform different functions in the consensus to maintain the stable operation of the rice supply chain information supervision system. Table 2 shows the specific node division method.

In the unimproved PBFT consensus mechanism, the master nodes are randomly selected by formula $p = v\mathrm{mod}|R|$, where p is the master node number, v is the view number, and $|R|$ is the number of nodes. The probability that the selected master node is a Byzantine node is 1/3. In this model, the node with the highest score among the candidate nodes is selected as the master node of the next view. If there is no single node with the highest score, the system randomly selects a node with the highest score among the candidate nodes as the master node. After a period of time t, the master node resets the node credit score and downgrades to an ordinary node to avoid the problem of overcentralization of the system. The main node selection mechanism of this model reduces the possibility of a Byzantine node becoming the main node, reduces the number of attempts to switch, reduces communication overhead, and improves system efficiency and security.

In the process of consensus, there are often objective fault nodes and subjective malicious nodes caused by unavoidable physical conditions, such as enterprise host failure, communication system delay, and supply chain link change. The role of the monitoring node is to eliminate the problem nodes in these situations. In the process of consensus, the monitoring node can record information that has been judged malicious by the system and then deprive it of consensus authority. In addition, the monitoring node can also record the node that does not send feedback information to the client within the specified time, or the feedback information is inconsistent with the feedback information of most nodes. Then, the system will mark the node as a failed node and temporarily deprive it of consensus authority. When the problems of malicious or failed nodes are repaired, the system will initialize them as ordinary nodes. The existence of a supervision node further reduces the possibility of fault nodes in the consensus node, improves consensus efficiency, and reduces system overhead.

4.2.2. Consensus Process. Figure 4 shows the CPBFT algorithm flow. After a consensus is started, all nodes are initialized and classified according to their credit scores. However, since the credit scores of the nodes are all 0, all nodes are ordinary nodes at the beginning, and the primary node is randomly selected according to the $p = v\mathrm{mod}|R|$ formula for consensus. After multiple consensuses, each node receives a corresponding credit score, and the node credit score system is gradually established. The model divides all nodes into four types with different functions and permissions and selects the main node according to the node credit-scoring mechanism. After the client sends the request, the master node broadcasts the proposal. If the replica node does not respond, the mechanism determines that the master node has a problem and records the delayed response information to the monitoring node. Then, the monitoring node judges whether the primary node is a failed node or a malicious node. Then, the mechanism will perform credit score reduction and node consensus authority deprivation for the corresponding nodes. The consensus process then returns to the node classification stage after view switching and finally reclassifies the nodes to select a new primary node for consensus. If the master node is an honest node, the consensus is completed at one time, and the algorithm will add points to the node that successfully records the information to the local node.

4.3. Design of the Information Supervision Prototype System. Based on the above model and the needs of all links in the rice supply chain, we designed a rice supply chain information supervision prototype system. Figure 5 shows the system architecture, which is divided into application layer, consensus layer, storage layer, and perception layer.

As the data-acquisition end of the system, the sensing layer mainly collects the various business data and hazard information of supply chain enterprises through temperature and humidity sensors and infrared scanning and photographing equipment. It then transmits the data to the data storage layer through wireless sensor networks, 4G/5G, Wi-Fi, and other networks. The storage layer includes a cloud database and hyperledger fabric blockchain platform storage, in which data in the blockchain are stored in the form of files. Enterprises first perform data cleaning, transformation, and fusion and then encrypt and store data according to its privacy level through smart contracts. The hierarchical encryption and storage mode can ensure storage efficiency, decentralize data, and make data more secure and reliable. Meanwhile, this mode also facilitates user data query. The consensus layer encapsulates the improved consensus algorithm and mechanism. The credit-scoring model divides the consensus nodes into four categories,

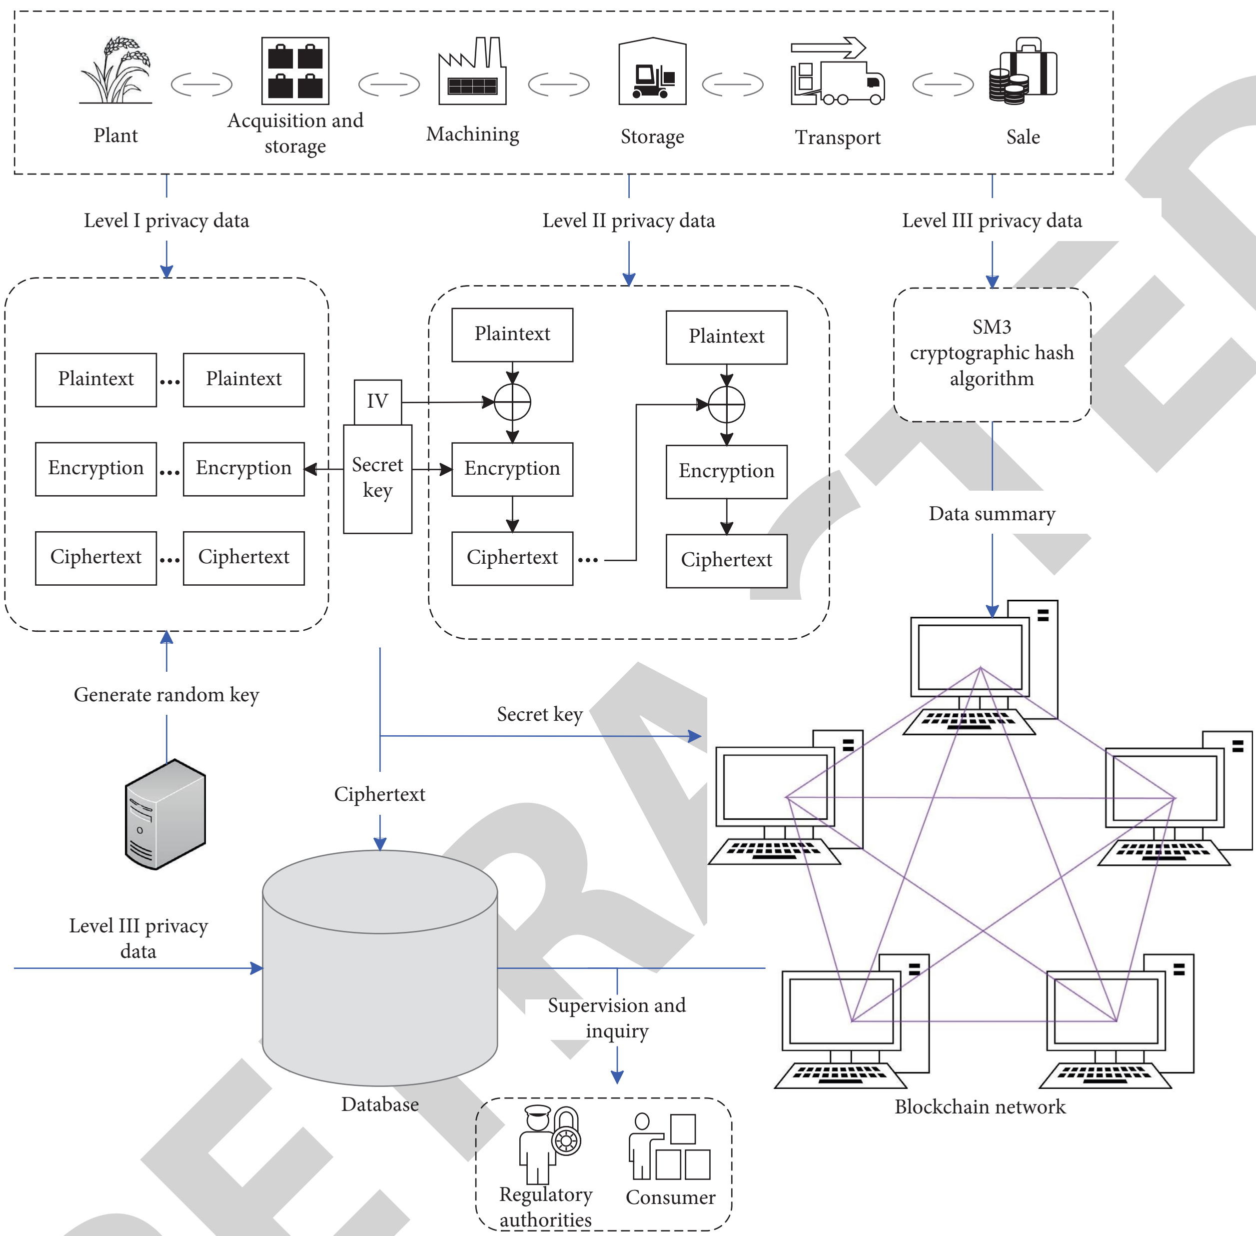

Figure 2: Hierarchical data encryption and storage mode.

which can enable highly decentralized nodes to efficiently reach consensus on the effectiveness of block data in a decentralized blockchain network. The application layer provides corresponding functions to regulatory authorities, enterprises, and consumer users in the form of web pages and mobile apps. Further, it divides authority levels according to different users, mainly including information traceability, enterprise authority management, and supply chain supervision functions. It can also observe the number of nodes and score changes in real time.

The system adopts a hyperledger fabric open-source blockchain platform to construct the supply chain blockchain network. Its essence is the uploading and querying of the blockchain ledger and cloud database by supply chain node users through the client interface. The system adopts a B/S structure, CentOS 7 as the operating system; Docker 18.09 as the container engine; and go, JavaScript, HTML, and CSS for program development. CouchDB, LevelDB, and MySQL are used as database servers. MySQL is the main data storage database, and CouchDB and LevelDB are the status databases in the blockchain network. The state database is just an index view in the transaction log in the chain and can be regenerated from the chain at any time. Before data transactions, the state database will be automatically restored when the peer node starts or is generated as needed. LevelDB stores chaincode data as key value pairs, while CouchDB, which is mainly used in this system, uses JSON to store data, which can support richer queries.

In this study, different users who log in to the system have different permissions, which can be achieved by the

```

Algorithm 3: Process of SM3 encryption.

hyperledger fabric's own management user ID and membership authentication function for all blockchain participants. Moreover, the fabric access control list can also enable different users to authorize different permissions. Figure 6 shows the system sequence diagram. The personnel of multiple production, processing, transportation, packaging, and sales enterprises and regulatory agencies in the supply chain can use the system, and the user has the authority to upload and query data. Users log in to the system and upload data. At this time, the system calls up the smart contract and encrypts it according to the data privacy level of the rice supply chain. The encryption key is randomly generated by the system. Part of the data is saved to the traditional database, and the other part of the data and the key participate in node consensus and upload to the blockchain. At the same time, the system updates the enterprise node credit score of the supply chain to ensure efficiency consensus.

5. Performance and Effect Analysis

5.1. Model Analysis. In the practical application of a traditional rice supervision model, due to the use of a central database, data are easily tampered with, and enterprise data traceability and query efficiency are low. Blockchain stores enterprise data with a distributed ledger instead of a central database, which can achieve data sharing and value transfer between upstream and downstream enterprises in the supply chain. Based on rice supply chain processes and the business logic of enterprises in the chain, we built an information supervision model using blockchain, an improved consensus algorithm, and cryptography principles to ensure the safe, efficient flow of data in the chain.

In our model, symmetric and hash encryption algorithms are used to encrypt rice supply chain data twice before data connection. The blockchain network stores a small amount of plaintext data, information summary, and keys at a high security level. Most ciphertext and plaintext data are stored in a cloud database, which can ensure the security of information storage and circulation in the whole system. In addition, this mode differentially encrypts different data safely registered in the supply chain information flow, standardizes the data storage and management process of the whole system, completes the hierarchical storage of data, and makes system resource investment proportional to data importance. In this mode, various encryption algorithms are used to ensure the confidentiality, integrity, and availability of sensitive data. This helps protect the key sensitive data of rice supply chain enterprises; the hierarchical structure can also meet the needs of regulators for efficient supervision.

In terms of the safety of the algorithm, the selection of master node is arbitrary in the consensus process of PBFT. The algorithm can select the master node in turn according to the node number. CPBFT uses PBFT as the consensus core, and its intragroup consensus and global consensus antiattack capabilities are consistent with PBFT. The following focuses on the security performance of CPBFT against witch attack and conspiracy attack.

Sybil Attack refers to Byzantine node illegally inventing multiple identities to attack the network. In this study, the credit-scoring method is used to elect high credit nodes to participate in the consensus, while the nodes with low credit will be stripped of the authority of consensus by the system so as to reduce the probability of Sybil Attack.

Collusion attack means that multiple Byzantine nodes give a trust evaluation higher or lower than the actual level, which makes the trust value of the evaluated node deviate from the actual trust value. When the total number of Byzantine nodes in CPBFT does not exceed 1/3 of the total

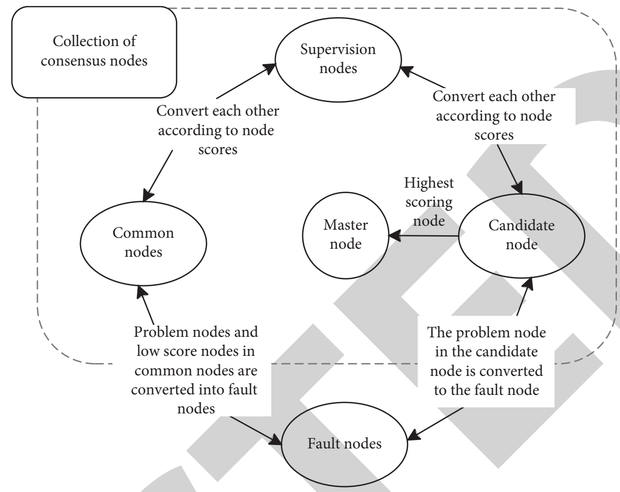

Figure 3: Category and transformation of consensus nodes.

number, even if all Byzantine nodes collude, the system can still reach a correct consensus. And once malicious behavior occurs in the consensus proposal, the node is highly likely to be determined as a Byzantine node, and the monitoring node can record the information that has been determined as a Byzantine node by the system and then deprive its authority of consensus. Therefore, the node collusion attack can only increase the opportunity for Byzantine nodes to enter the set of alternative nodes through voting collusion, and the node credit-scoring mechanism of CPBFT can adjust and divide the credit score in real time according to the situation. When there are great differences in the credit evaluation of the attacked node, the system will change the parameters in the mode of division in Table 2 in real time to reduce the impact of collusion attack on consensus security so as to ensure the high reliability of the candidate node.

In addition, we conducted a system simulation on a hyperledger fabric platform and compared the traditional PBFT algorithm with the proposed CPBFT algorithm in terms of total communication between nodes and throughput. The communication overhead of the node was directly proportional to the number of communications between nodes in the consensus process. The main purpose of the CPBFT algorithm is to reduce the number of failed nodes in the consensus node to reduce communication. In the system simulation, one-third of the nodes were set as fault nodes. As shown in Figure 7, the communication of the CPBFT algorithm increases slowly, while the communication of the PBFT algorithm before improvement increases rapidly. Therefore, it can be seen that the CPBFT algorithm can effectively reduce communication overhead and broadband pressure.

Throughput refers to the number of transactions completed in a unit of time. CPBFT can effectively reduce the number of consensus nodes and shorten communication time. The probability that the master node is a reliable node is higher, the probability of error is smaller, the amount of view switching is reduced, and the time to complete consensus is shortened. For our experiment, we sent 800 requests to the client, recorded the number of transactions that

Table 2: Division mode of nodes.

Node name	Node classification	Node function
Common node	Node that reaches credit score η within time t	Can only participate in consensus
Supervision node	$2(2f+1)/3$ nodes that first reach credit score λ among ordinary nodes	Can participate in consensus and can record the information of the problem node
Candidate node	$2(2f+1)/9$ nodes that first reach credit score μ among ordinary nodes	Can participate in consensus and select the master node from it
Fault node	Nodes that do not reach η score within time t	Cannot participate in consensus

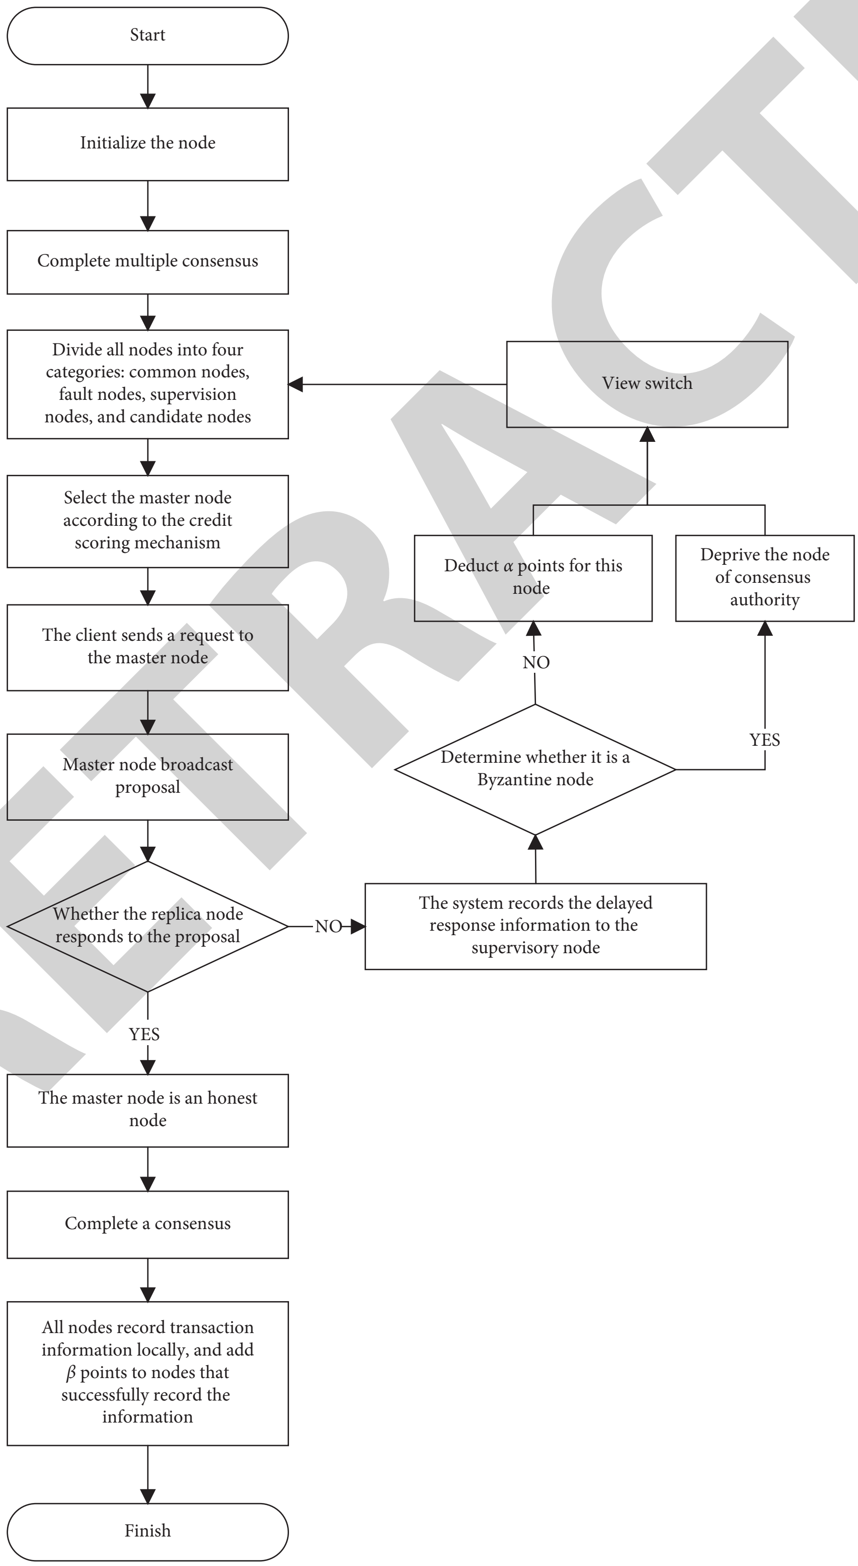

Figure 4: The process of CPBFT.

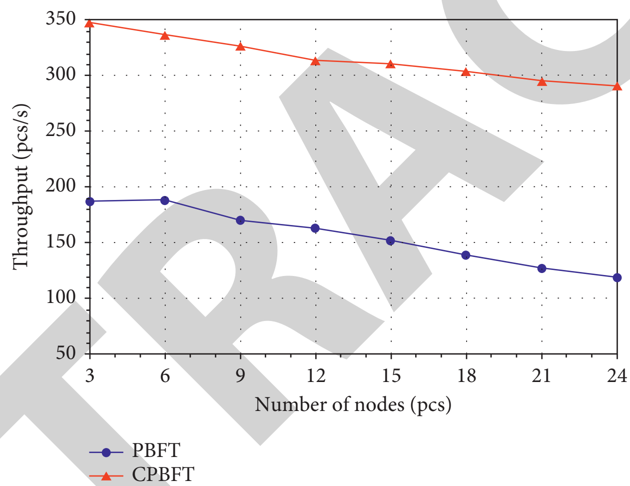

Figure 8: Comparison of throughput.

could complete consensus per second, and tested it with different numbers of nodes. Figure 8 shows the CPBFT algorithm. With the increase in the number of nodes in the network, the throughput of both algorithms shows a downward trend. Overall, however, the throughput of the CPBFT algorithm is much higher than that of the improved algorithm.

5.2. Systematic Analysis. After the field investigation of several rice enterprises, we initially chose to apply the system to a grain and oil enterprise in Changde City, Hunan Province, China, to verify the system's effectiveness. The enterprise's industry involves all links of the rice supply chain. All links have complete monitoring and inspection equipment and stable communication, and all data records are detailed and complete. However, as a result of internal information storage among enterprises and various exchanges between companies, the difficulty of supervision is further increased. In addition, all supply chain data of the enterprise are stored in the central database, and data security is difficult to ensure. Therefore, the proposed rice supply chain supervision system was selected to optimize the supervision and management ability of the enterprise.

Figure 9 shows the system interface. Figure 9(a) is the login interface of the supervision system. After logging in to the system, a supervisor user with administrator authority can supervise and manage all circulating data in the rice supply chain. After logging in to the system, the enterprise user can upload and query information for the entire rice supply chain. The supervision user can search and query all data uploaded by an enterprise in the supply chain supervision interface, including its main information, basic information, hazard information, environmental information, and transaction and price information. As shown in Figure 9(b), all query information is the main data of the supply chain enterprise, which is encrypted and uploaded to the blockchain network and cloud database by the system. The system decrypts the plaintext data again. This mode effectively ensures security and privacy in the process of data storage and transmission. If it is verified as bad data, the

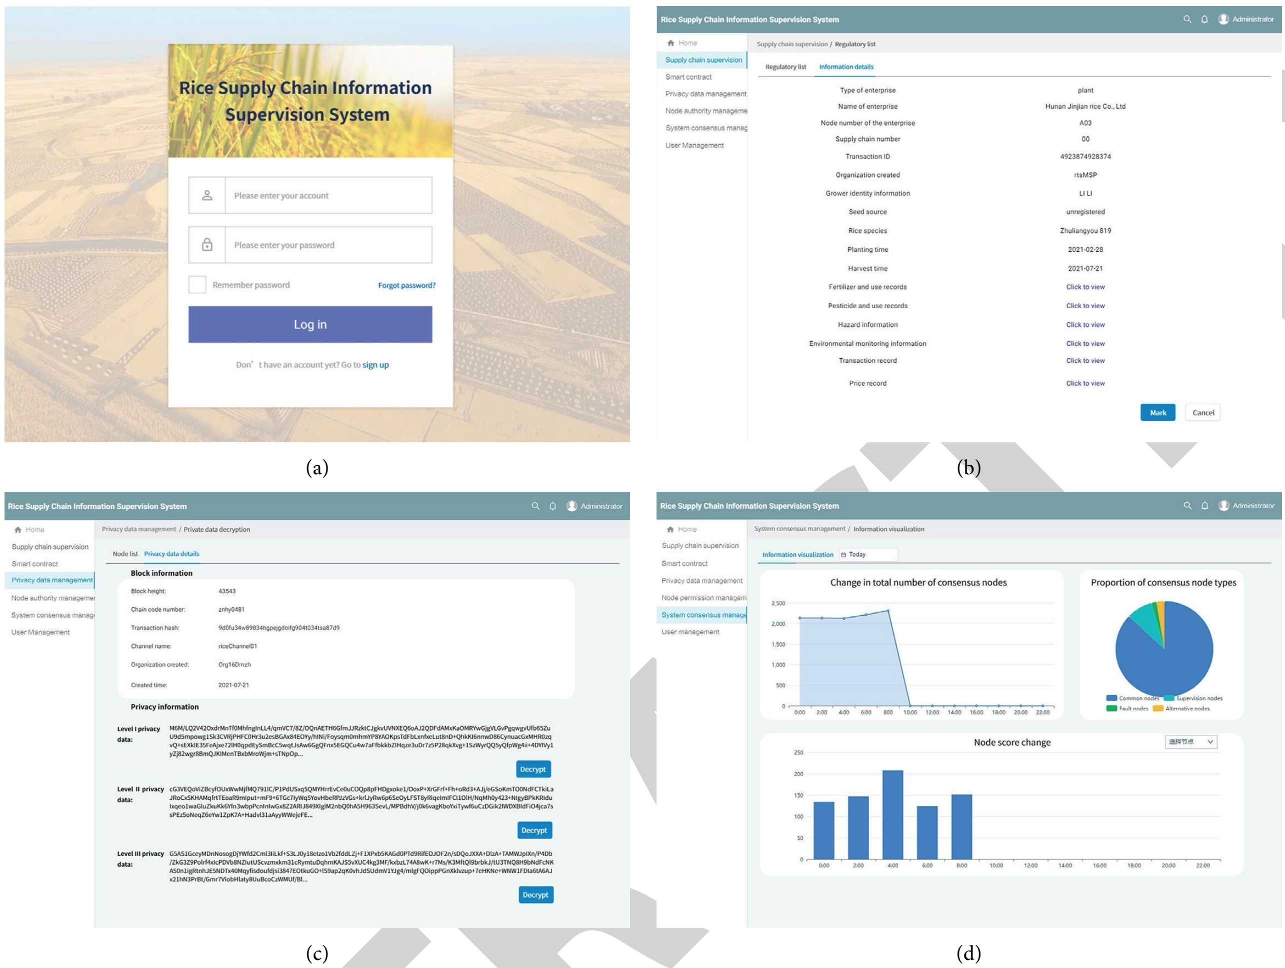

Figure 9: Front-end interface of the prototype system. (a) Supervision system login interface. (b) Supply chain supervision interface. (c) Privacy data management interface. (d) System consensus management interface.

regulator can mark the data and conduct a secondary sampling inspection of the information to finally determine whether the enterprise information is true and reliable and whether the rice quality is good. Users can query the information and stored data of each block in the privacy data management interface of the enterprise. Moreover, the user can decrypt the stored data according to the privacy level, as shown in Figure 9(c). Figure 9(d) shows system consensus management. The main interface is a visual interface. The user can see real-time changes in the total number of consensus nodes and real-time changes in the type proportion of consensus nodes. Users can also select an enterprise node to view real-time changes in the credit scores of the node. Regulators can learn the latest change trend in consensus nodes through the consensus management function and adjust the credit score value in a timely way to improve consensus efficiency.

Compared with traditional systems, the proposed rice information supervision system has a detailed division of permissions. Regulators can query all supply chain circulation data in the system, while enterprise users can upload data and view node consensus. The corresponding permissions are different according to the different supply chain links of the enterprise. In addition, the regulator can query information and analyze privacy in real time according to data privacy level to determine the authenticity of enterprise information and the security of rice-quality data. Moreover, while monitoring the supply chain nodes, the system's visual interface can more intuitively show the data transmission efficiency of the supply chain.

6. Conclusions

The traceability, decentralized, and tamper-resistant characteristics of blockchain technology are in line with the requirements of information supervision system, and blockchain technology has broad development prospects in the field of information supervision system for rice supply chains. This study deconstructs and analyzes the quality and safety information of each link of the rice supply chain at the information level and establishes a key information classification table for each link. Combining cryptography with the characteristics of rice supply chains, a hierarchical data encryption and storage mode is proposed to ensure the security and privacy of data uploaded to the blockchain and cloud database in the process of circulation and storage. In addition, a scoring mechanism is introduced into the consensus process of the blockchain network. Supply chain enterprise nodes are scored to improve consensus efficiency. The improved consensus algorithm also improves the reliability of supply chain supervision.

Verified using practical cases, this research can help optimize regulator information supervision processes in rice supply chains, and the proposed rice supply chain information supervision system can provide a feasible solution for grain and oil supervision. The proposed approaches in the paper can combine other deep-learning algorithms to study the identification and prediction problems, and can be applied to other fields such as signal processing and engineering application systems [35–41].

Intelligent control technology is not only the use of the so-called highly sophisticated technology in the daily life of the elderly but also control services according to the individual needs of the elderly. This paper combines research in psychology and ergonomics to explore how to use the living space to build indoor scenarios that influence the behavioural and psychological changes of the elderly based on satisfying functionality. The external environment influences the user's perception, and the perception determines the user's behaviour. Through the construction of scenarios, objects and people can interact with each other, thus achieving the objective of "solitude but not loneliness" for the elderly living alone and providing a modern ageing environment with high safety, convenience, quality, and comfort for the elderly.

1. Introduction

With the development of ageing population, developed countries such as Europe and the United States are entering an ageing society first. More and more attention is being paid to the issue of elderly people's retirement. With their strong economic strength and the advantages of science and technology, developed countries have been developing their medical and healthcare services. Especially with the rapid development of electronic and information technology, developed countries have taken the lead in exploring the use of information technology to help traditional elderly care [1]. After IBM put forward the concept of "smart city," countries such as the UK, the US, and Japan have also put forward the concept of "intelligent old-age care" or "intelligent care for ageing." The market-oriented operational characteristics of smart old-age care in developed countries are obvious, and the degree of commercialisation is high [2].

Commercial enterprises carefully analyse the needs of the elderly for elderly care services, constantly optimise user experience, and apply new technologies, so as to develop newer and better products for smart elderly care services, including health and medical information sharing data platforms for the elderly, smart elderly community management platforms, emergency call systems, and intelligent elderly care terminal products. A theoretical system and industrial chain for smart elderly care have been initially formed [3].

Old and frail, with children at home, but living alone in a small space or courtyard bungalow is the current situation of the elderly living alone in China. They are relatively capable of taking care of themselves, but can only maintain the status quo for the time being. As they grow old and live alone in small space for long periods of time and rarely leave their homes, they gradually become isolated from their neighbours and society and have a great need for spiritual comfort. The elderly long for companionship, but their families cannot be there for long.

Every family has an elderly person, but not every elderly person has a family member with them. It is easier to know than to do. At least one-third of urban families are of the empty nest type, that is, elderly people living alone or an elderly couple with no children. While paying more attention to these elderly people, the research aims to address the loneliness of the elderly living alone, improve the quality of their lives and living environment, and meet their physical and mental needs through scenario-based design so that they do not feel lonely even when living alone. The study aims to improve the quality of the elderly's living and living environment through scenario-based design, so that they do not feel lonely even when living alone [4].

China has also entered a phase of rapid population ageing. On the whole, the problem of insufficient supply of elderly services and products and the structural imbalance in the supply of social elderly service resources is also becoming increasingly prominent. Taking advantage of the opportunities brought about by the rapid development of the Internet and information technology, it has become an important task to build a well-off society to resolve the contradiction between the growing demand for elderly services and the unbalanced and insufficient development. Compared with developed countries, China is relatively late in the process of population ageing, and the development of the domestic smart elderly care industry is still in the initial exploration stage. Therefore, by comparing and studying the smart ageing in developed countries such as Europe, America, and East Asia and then combining the actual situation of ageing in China, summarising the experience suitable for the development of smart ageing in China will help to build and improve a smart ageing service system with Chinese characteristics [5].

The birth of intelligent device control technology is the result of the mutual reaction between the pursuit of high-quality physical and mental health of the elderly and the rapid development of information technology. Intelligent control technology is not only the use of the so-called highly sophisticated technology in the daily life of the elderly but also control services according to the individual needs of the elderly. This paper combines research in psychology and ergonomics to explore how to use the living space to build indoor scenarios that influence the behavioural and psychological changes of the elderly based on satisfying functionality. The external environment influences the user's perception, and the perception determines the user's behaviour. Through the construction of scenarios, objects and people can interact with each other, thus achieving the objective of "solitude but not loneliness" for the elderly living alone and providing a modern ageing environment with high safety, convenience, quality, and comfort for the elderly.

2. Related Work

Many efforts have relied on existing Internet resources and social forces to build public information platforms and senior care information service network platforms using technologies such as cloud computing and big data to provide community-based care and nursing, health management, rehabilitation, and other home care services. For example, the authors of [6] proposed the concept of "digital community" and "digital elderly care" and conducted research and discussion. The authors of [7] introduced the Hangzhou digital community to realize the livelihood project of "digital elderly care" in the district. Söker et al. [8] proposed a networked home care model. Ostrowski [9] proposed a strategy for the construction of digital elderly care services in the context of new urbanisation. The authors of [10] put forward the concept of smart elderly care, pointing out that smart elderly care is the use of the Internet of Things, cloud computing, and other technologies to carry out comprehensive, online and offline, integrated medical care and all-round elderly care services. Glavič et al. [11] emphasised that smart ageing provides comprehensive services for the elderly in terms of clothing, food, housing, transport, entertainment, and health, helping them to improve their quality of life while not forgetting to help them reflect their value and dignity. The authors of [12] argued that smart ageing is a new model of elderly care services, the core of which lies in taking the needs of the elderly in groups as the guide, mobilising various elderly care resources to coordinate the actions of various elderly care-related parties through the integration of advanced management and information technology, so as to systematically, intelligently, and humanely improve the capacity and level of community elderly care services at home, and strive to provide the lowest cost, highest efficiency, and most convenient services, solving the problem of ageing in place for the elderly in the community.

In response to the characteristics of the scattered population living in the United States, a fleet of medical services for the elderly (mobile medical network) has been established in major cities in the United States, providing a variety of services such as home medical services and home care services in a midbus for the home-bound elderly in need [13]. It adopts market-oriented operation and professional management, so that the elderly can share service resources and reduce the cost of elderly care services. The UK was the first country to introduce the concept of "smart ageing." The UK believes that community-based ageing is the most suitable model for ageing in the country. More old people mainly are in the community, including senior housing, day care centres, senior activity centres, and care institutions. [14]. The UK has a high level of enthusiasm for volunteer participation in community-based ageing. Germany is currently one of the most ageing countries in Europe, with 23% of the elderly over 60 years old. The elderly in Germany do not rely on their children for their old age, but mainly rely on themselves and the support of the state and society. In order to cope with the shortage of manpower, Germany is actively developing smart ageing [15]. Japan has the highest level of ageing in the world. In order to cope with the problem of ageing population, Japan attaches great importance to the development of smart ageing as an economic industry. The Housing Authority of Singapore has tested and developed the "Smart Alert System for the Elderly at Home." The system monitors the lives of the elderly and notifies caregivers in the event of an accident [16].

3. Intelligent Device Control

3.1. Intelligent Equipment Control. Since its introduction, intelligent device control technology has sparked heated discussions in all sectors of society and has been highly respected by many elderly care institutions in particular as a new type of industrial development driver [17]. Intelligent device control technology not only pushes the development and innovation of intelligent elderly care services to a higher level but also allows the elderly to pursue a more comfortable, safe, and convenient living environment as their living standards continue to improve [18].

The birth of intelligent device control technology is the result of the mutual reaction of the elderly group's pursuit of high-quality physical and mental health and rapidly developing information technology. Intelligent control technology is not only the so-called highly sophisticated technology used in the daily life of the elderly but also control services according to the individual need of the elderly group [19]. Intelligent control technology is the product of a high degree of integration of innovative technologies such as Internet of Things technology, deep neural network algorithms [20], intelligent control technology, and elderly service technology, providing a modern elderly environment with high security, convenience, quality, and comfort for the elderly [21].

3.2. Indoor Fall Detection. In this study, it was found that there are two main causes of accidental falls in the elderly population, namely, intrinsic physical factors and extrinsic environmental factors.

A review of the literature on the epidemiology of falls in China revealed that intrinsic factors include dulled senses, reduced vision, slower reflexes, muscle deterioration, reduced balance, and central nervous system disorders, while extrinsic factors include uneven surfaces in the area, poor lighting, cluttered surroundings, and regular use of medications with dizzying side effects. These factors all contribute to the increased likelihood of accidental falls in the elderly population [22]. Reduced balance in older people is a key factor in falling. Factors contributing to unintentional falls in older people are shown in Table 1.

As people walk on their left and right feet, the associated parts of the body work in tandem to maintain balance, and in doing so, they go through a tedious process of musculo-neurotransmission, in which three main mechanisms—perceptual, central, and musculo-organisational—work together. If disturbances in balance occur in the elderly population, such as peripheral neuropathy, vertigo, and visual or muscle strength problems, the risk of accidental falls increases significantly [23].

Falls in older people generally occur when the body's balance mechanisms are accidently disrupted, often within 2 seconds. This is much shorter than normal movements such as squatting, lying down, or standing up. Because the human body falls within a short period of time, the body's centre of gravity is shifted significantly in the direction of the fall, and the fall is accompanied by three specific instantaneous values of acceleration in the X, Y, and Z axes and the angle of tilt in the three axes.

Most studies of accidental falls have used the change in the 3D acceleration and tilt angle values during the fall as a criterion for fall detection. The relationship between the 3D coordinates and the human body is shown in Figure 1.

4. Fall Detection Algorithms

The experiment consisted of 8 normal state transitions and 4 indoor fall states. A total of 1080 simulated data were collected, 720 for daily activities and 360 for falls. It was found that placing the integrated sensor at the waist to obtain the acceleration signal of the human body can more accurately reflect the degree of change of the overall movement state, while the more complex transformation of the wrist or arm cannot fully reflect the information of the human posture transformation. Therefore, the optimal position for the sensor was chosen to be the waist and the sensor was fixed directly in front of the volunteer's waist. The required example data are shown in Tables 2 and 3.

When experimenting with the fall detection algorithm, it is important to first sort out the general idea of the entire algorithm process and visualise it using a flowchart. The general framework of the fall detection experiments is shown in Figure 2, with each part of the experiment module described later.

Through the algorithm flowchart, we have a clear understanding of the process of this study on the detection of accidental falls in elderly people, and each step of the algorithm and its principles will be described in detail next.

Noise reduction: based on the fact that the original signal of the sensor is mixed with a large amount of white noise, which must be removed when applied in practical scenarios, this experiment uses wavelet threshold noise reduction to preprocess the original signal [24]. The wavelet threshold noise reduction process is as follows:

(1) Wavelet transform of the original signal $f(x)$ containing noise to obtain the wavelet coefficients $w(j,k)$

(2) Thresholding the coefficient set $w(j,k)$ to obtain an estimated coefficient set $w(j,k)$ such that the difference between $w(j,k)$ and $w(j,k)'$ is as small as possible

(3) The estimated coefficient $w(j,k)'$ is reconstructed as a wavelet, and the estimated signal $f(k)$ is the noise-free signal required for the experiment

The angular velocity reflects the tilt of the human body in the room, and the angular velocity of the human body on the three axes during movement can also accurately characterise the change in posture of the elderly. The angular velocities in the three axes are also an accurate representation of the changes in the posture of the elderly. The improved formulae for calculating SMA and angular velocity are shown in equations (1) and (2), where the acceleration values in the X, Y, and Z axes are taken and axis(t) is taken as the angular velocity value in the X, Y, and Z axes, respectively.

Table 1: Factors contributing to the occurrence of unintentional falls in older people.

Factor type	Fall inducement
Physical internal factors	Sensory retardation, vision loss, slow response, and central nervous system diseases
External environmental factors	Skeletal muscle degeneration, uneven road surface, insufficient light, disordered environment, inappropriate height of bed and chair, and dizziness and weakness caused by taking some drugs

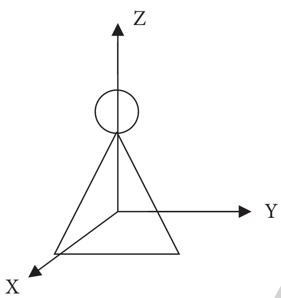

Figure 1: Schematic diagram of the correspondence between 3D coordinates and the human body.

Table 2: Simulated data on daily behavioural activities required for the fall algorithm.

Behaviour type	Human body state transformation	Number of experiments
Daily behaviour activity simulation	From standing to sitting	90
	From sitting to standing	90
	From standing to lying down	90
	From lying down to standing	90
	From sitting to lying down	90
	From lying down to sitting up	90
	Stand and turn left	90
	Stand and turn right	90

Behaviour type	Human body state transition	Number of experiments
Indoor fall anomaly simulation	Fall to the left	90
	Fall to the right	90
	Fall forward	90
	Fall back	90

$$SMA(\text{axis}) = \sum_{i=1}^{n} |\text{axis}(i)|, \quad (1)$$

$$ta(\text{axis}) = \int_{t=1}^{\text{timewindow}} w\,\text{axis}(t)\cdot \mathrm{d}t. \quad (2)$$

Kernel principal component analysis first maps the original set of feature vectors to a high-dimensional space through a nonlinear transformation and then achieves linear separability in the high-dimensional space to obtain better feature attributes than in the original space [25].

The set of feature vectors $\{B_n\}_{i=1}^{N}$ represents the normalised set of human feature data, where B_n represents the row vector of the nth human feature data. For each vector in the set of feature vectors, a suitable nonlinear transformation $\Phi(B_i)$: $R^m \longrightarrow H\,B_i \longrightarrow B_i'$ is used to map the feature vector B_i into the high-dimensional space H. In kernel principal component analysis, the nonlinear transformation $\Phi(B_i)$ corresponds to a different kernel function $k(B, B')$. The covariance matrix of the high-dimensional space H is shown as follows:

$$\sum = \frac{1}{N}\sum_{n=1}^{N}\Phi(B_n)\Phi(B_n)^T. \quad (3)$$

The formula for solving the eigenvalues of the covariance matrix $\sum$ and its corresponding eigenvectors is shown as follows:

$$\lambda u = \sum u. \quad (4)$$

The ith eigenvector u_i of the covariance matrix $\sum$ can be represented by a linear combination of $\alpha_n^{(i)}$, where $\alpha_n^{(i)}$ is the summation coefficient, as shown in the following equation:

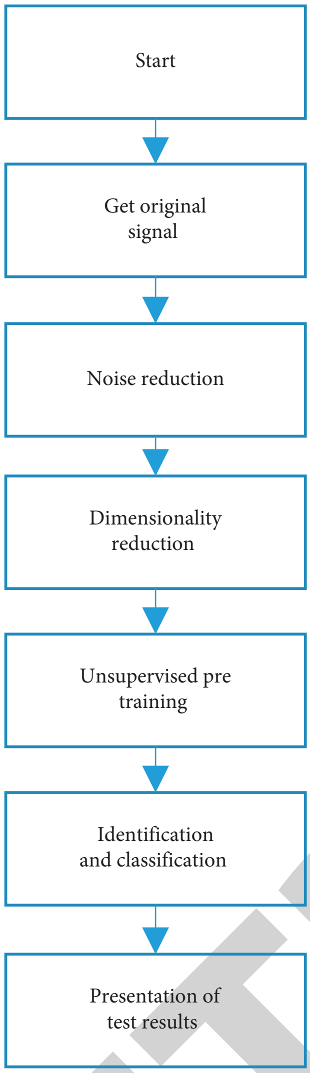

FIGURE 2: General framework of the fall detection experiment.

$$u_i = \sum_{n=1}^{N} \alpha_n^{(i)} \Phi(B_n). \tag{5}$$

Substituting equations (3) and (4) into equation (5) gives

$$\lambda_i \sum_{n=1}^{N} \alpha_n^{(i)} \Phi(B_n) = \frac{1}{N} \sum_{n=1}^{N} \Phi(B_n) \Phi(B_n)^T \sum_{m=1}^{N} \alpha_m^{(i)} \Phi(B_m). \tag{6}$$

The inner product operation in the high-dimensional feature space is replaced by a kernel function to obtain

$$k(B, B') = \Phi(B)^T \Phi(B'). \tag{7}$$

Multiply both sides of the equal sign in equation (6) by $\Phi(B')^T$ at the same time to obtain

$$\lambda_i \sum_{n=1}^{N} \alpha_n^{(i)} k(B', B_n) = \frac{1}{N} \sum_{n=1}^{N} k(B', B_n) \sum_{n=1}^{N} \alpha_m^{(i)} k(B_n, B_m). \tag{8}$$

According to (8), it is possible to calculate the elements of the kernel matrix as shown in the following equation:

$$K_{mn} = k(B_m, B_n). \tag{9}$$

To make the mean $(1/N) \sum_{i=1}^{N} \Phi(B_i) = 0$, the kernel matrix K in the centralized high-dimensional feature space is also needed.

Unsupervised pretraining: for the data feature of accidental indoor falls by elderly people, this topic uses self-encoders for layer-by-layer unsupervised pretraining to solve the gradient diffusion problem. The hidden layers of the deep neural network are pretrained layer by layer, and the parameters obtained from the pretraining are used as initialisation values for the corresponding parameters of the full algorithm.

To facilitate the computation of feature vector sets, the raw signals including all anomalies and daily behaviour are intercepted as time segments in this experiment. The length of the time slice contains enough information about the elderly action transformation for the computation of the feature vector set and does not produce too long a response delay. The calculation of the components of the feature vector set in this experiment is based on the original signal data population within the time window.

Detection and recognition classifier: based on the efficiency and real-time criteria of the fall anomaly detection algorithm, especially the requirement that the fall algorithm can accurately determine the behavioural characteristics of the elderly, this experiment decided to use a deep neural network based on the back propagation algorithm as the detection and recognition classifier for the whole fall algorithm. The deep neural network classifier designed in this experiment has 2 neurons corresponding to the classification output and a forward fully connected pattern between the layers.

5. Assessment of Fall Test Results

Evaluation metrics for determining whether a fall detection algorithm is efficient usually include sensitivity and specificity. In this study, in order to effectively compare the performance of classifiers, it was decided to use an evaluation performance metric commonly used in deep learning and statistics, namely, the error matrix [26]. The error matrix is a standard format for accurate evaluation, and these metrics reflect the performance of the classifier from different aspects. The error matrices are shown in Table 4. Sensitivity refers to the rate at which all fall abnormalities are accurately identified in older people, and specificity refers to the rate at which all normal everyday behaviours are accurately detected in older people.

The experiment was evaluated three times to assess the classification effectiveness of each part of the feature vector group. Using a comparative validation approach, each feature vector group was selected to train the neural network for recognition and classification.

5.1. Single-Variable Controlled Experiments. In this experiment, a single-variable control approach was used, i.e., the selected feature vector sets were not dimensionally reduced

Table 4: Error matrix.

	Positive sample	Negative sample
Correct	Accidental falls	Daily behaviour
Error	False accidental fall	Pseudo-daily behaviour

Table 5: Results of fall detection based on single-variable control method.

Data preprocessing	KPCA dimensionality reduction	Unsupervised training	Recognition classifier	Sensitivity (%)	Specificity (%)
Have	Nothing	Have	Deep neural network	96.32	95.48
Have	Have	Have	Deep neural network	99.21	99.87

Table 6: Results of fall detection based on bivariate control methods.

Data preprocessing	KPCA dimensionality reduction	Unsupervised training	Recognition classifier	Sensitivity (%)	Specificity (%)
Have	Nothing	Nothing	Deep neural network	94.57	93.32
Have	Have	Have	Deep neural network	99.21	99.87

Table 7: Fall detection results for different recognition classifiers.

Data preprocessing	KPCA dimensionality reduction	Unsupervised training	Recognition classifier	Sensitivity (%)	Specificity (%)
Have	Have	Have	Support vector machine	97.36	97.52
Have	Have	Have	Shallow neural network	96.93	95.41
Have	Have	Have	Deep neural network	99.21	99.87

by kernel principal component analysis and then trained for deep neural network recognition classification, all other conditions being identical. The classification recognition results based on the single-variable control are shown in Table 5. According to the data in the table, the sensitivity of the feature vector group without kernel principal component analysis dimensionality reduction reached 90.32% and the specificity reached 93.48%. However, there is still a significant difference between the training results obtained by the algorithm and the results obtained by the algorithm.

5.2. Bivariate Controlled Experiments. This experiment uses a bivariate control approach based on the above to evaluate the effect of kernel principal component analysis down scaling and unsupervised pretraining on the classification of the test set. Each human activity contained 14 coefficient matrices obtained by modelling the preprocessed example data for training the deep neural network and 14 coefficient matrices obtained by the same method for classification tests of fall abnormal and normal behaviour. The recognition classification results are shown in Table 6. The experimental results show that the sensitivity of recognition classification without kernel principal component analysis and unsupervised pretraining can reach about 94.57% and the specificity can reach about 93.32%. This is still a significant difference compared to 99.21% sensitivity and 98.97% specificity of the algorithm. It can be seen that the deep neural network with kernel principal component analysis and unsupervised pretraining is more robust and has better generalization ability.

5.3. Identifying Classifier Experiments. The aim of this experiment was to evaluate the effect of different recognition classifiers on the classification of the test set of fall anomalies. The classifiers selected were support vector machines, shallow feedforward neural networks, and deep neural networks. The tilt angle and signal amplitude were combined into a 14-bit feature vector set, and for each human activity, there were 14 coefficient matrices obtained by modelling the coefficient data after data processing, dimensionality reduction, and unsupervised pretraining for training the three classifiers mentioned above, and 14 coefficient matrices obtained by the same method were used for testing the fall detection classifier. The classification results of the different recognition classifiers are shown in Table 7. According to the experimental results, although the classification results of the first two classifiers have reached a high level of accuracy, there is still a significant gap compared to the deep neural network, which has the advantage of balancing sensitivity and specificity that other classifiers do not have.

6. Conclusions

In this paper, a fall detection algorithm based on kernel principal component analysis and deep neural networks is proposed to address a series of urgent problems such as the vulnerability of elderly people to fall indoors and the potential for multiple injuries after a fall. The algorithm takes the raw signal from the integrated sensor, acceleration, and body tilt as the feature vectors to be input, and after dimensionality reduction by kernel principal component analysis and unsupervised pretraining by self-encoder, a deep neural network based on backpropagation algorithm is

The importance of the humanities in promoting economic and social development is becoming increasingly clear. Combining humanities with higher medical education in order to meet the needs of medical talent training in the new situation has become a key component of higher medical education reform and development. Adult higher medical education is an integral part of higher medical education, but it has different training objectives and training objects than regular higher medical education. These technological advancements are certain to hasten the continued emergence of education cloud or industry cloud, create a good information-based environment for education informatization improvement, and pose technical challenges to resource allocation in intelligent computing environments. Humanistic quality higher medical education based on the Internet of Things and intelligent computing makes the efficient intelligent information system more open, interactive, and coordinated, allowing students and teachers to perceive a variety of teaching resources more comprehensively.

1. Introduction

With the development of modern science and technology, the role of humanities in promoting all-round economic and social development is becoming more and more obvious. The combination of humanities and higher medical education to meet the needs of medical talent training in the new situation has become an important content of the reform and development of higher medical education. In the era of increasingly prominent humanistic spirit, higher medical education should cultivate talents with all-round development of both humanistic quality and scientific knowledge [1]. For a long time, Chinese medical education has paid attention to the technical training of medical science and ignored the humanistic nature of medicine, resulting in the unreasonable knowledge structure of medical students and the lack of humanistic spirit. From ancient times to the present, the process of world medical education has experienced the initial integration and separation stage of humanistic and professional education and gradually moved towards a new level of integration [2, 3]. The development of medical science also poses a severe challenge to the training mode of new medical talents. The World Health Organization proposed five-star doctors as a global strategy in 1995, stating that doctors should be healthcare providers, decision makers, health educators, community leaders, and service managers in the future [4]. This necessitates not only professional knowledge but also a broad understanding of the humanities and social sciences in today's medical professionals. Adult medical college education is a vital component of higher medical education, but it differs from traditional higher medical education in terms of training objectives and objects. The key points of medical education reform in China are focusing on humanistic quality education and closing the gap between Chinese and developed countries' medical education [5].

Nowadays, with the proposal of the concept of humanistic quality higher medical education, colleges and universities across the country have carried out research on the Internet of Things and big data based on intelligent computing. These technological innovations are bound to accelerate the continuous emergence of education cloud or industry cloud and create a good information-based environment for the improvement of educational informatization. At the same time, it brings technical challenges to resource allocation in intelligent computing environment [6]. The task of the transport layer of the Internet of Things is to reliably transmit the information collected by a large number of terminals to the background central server. However, at present, the construction of the transport layer network is far from reaching the level of welcoming the explosion of the industrial scale of the Internet of Things. The massive data collected by the perception layer will flow into the transport layer network in real time, which will lead to network congestion or node failure. Therefore, how to quickly find network fault nodes is the guarantee for reliable data transmission of the Internet of Things. Intelligent computing is a powerful comprehensive computing method that combines grid computing, parallel computing, and distributed computing. Cloud computing has achieved previously unimaginable results by using server cluster [7, 8]. The campus Internet of Things construction needs to rely on powerful storage and efficient computing technology to realize higher medical education and humanistic quality education [9].

The storage and processing of massive data is the prominent feature and ability of intelligent computing [10, 11]. The intelligent computing mode of humanistic quality education system in higher medical education can ensure the security and normal operation of the data resources of the medical education platform. Students and teachers can access the medical education platform and read data at any time through the Internet [12]. Internet of Things technology, like intelligent computing technology, is network-based. The Internet of Things allows for human-computer interaction as well as human-to-human interaction. As a result, the Internet of Things is a physical Internet that can cover everything in the world [13]. The application benefits of Internet of Things technology in humanistic quality higher education and medical education are primarily manifested in that it makes the efficient intelligent information system more open, interactive, and coordinated and enables students and teachers to perceive all kinds of teaching resources more comprehensively, so as to effectively collect all kinds of required information, realize intelligent learning and teaching modes, and assist in the realization of e-learning.

2. Related Work

Marques et al. [14] assert that, in terms of humanistic quality, higher medical education's mastery of humanistic knowledge is not promising, as evidenced by a lack of literary knowledge, historical knowledge, philosophical knowledge, artistic knowledge, and language skills. Many domestic scholars have recognized the seriousness of the problem, conducted more research on how to inject humanistic spirit into medical science education, discussed some important theoretical problems of humanistic education in medical colleges, and made many positive explorations in methods and means [15] using the big data analysis method. According to literature [16], most higher medical education students have a strong desire and urgent need to strengthen humanistic education, improve self-cultivation and cultural taste, and perfect and realize life ideals and values. The majority of medical students are positive, but their humanistic quality needs to be improved, and humanistic education in medical schools is not given enough attention. There is a significant disparity between investment in humanistic education and the construction of teaching resources, teachers and disciplines, and a campus cultural atmosphere. According to literature [17], most medical courses are interspersed with some strong humanist courses, and the teachers who teach them are mostly former Marxism, Leninism, and ideological politics teachers. They equate humanistic education with ideological education and the cultivation of the humanistic spirit with ideological politicization, causing humanistic education to lose its vitality. Humanistic spirit cannot develop as well as science and technology in medicine. Zhu et al. [18] conducted practical research on the necessity of humanistic spirit in medical colleges from the perspective of curriculum through the method of big data analysis and came to the conclusion that medical courses must be combined with humanistic and social courses in order to cultivate talents meeting social needs. Thibaud et al.'s research [19] shows that only by integrating professional education with humanistic education can the fundamental purpose of medical respect and caring for life be restored. Mao et al. [20] pointed out that higher medical education does not have a deep understanding of the concepts of humanistic quality, humanistic quality education, humanistic spirit, etc. It is thought that the current humanistic education model has to be enhanced because it is primarily focused on a single curriculum and a single teaching technique, neither of which can inspire learning interest. The most significant humanities subjects are psychology, literature, and law, which should be made mandatory. According to the literature [21], students do not pay enough attention to humanistic quality higher education and medical education while using the big data analysis approach. 58.3% of the students are not satisfied with the humanistic quality education courses offered by the school, ignoring humanistic quality education. Due to the lack of teachers' investment, curriculum arrangement, and teaching equipment, students spend most of their time studying professional courses. Wei et al.'s research [22] shows that under the background of diversified socialist values, humanistic quality higher medical education is seriously affected by bad social atmosphere, such as money worship, hedonism, extreme individualism, and some corruption. The value orientation of medical students is somewhat deficient, and humanistic quality education is ignored, and understanding is vague. Khanna and Kaur [23] suggest that more cross courses should be added to medical education and practice in order to achieve the mutual penetration of medical humanities and medical natural sciences.

Based on the Internet of Things and intelligent computing, this paper studies the humanistic quality higher medical education, analyzes the connotation, history, function, influencing factors, and development characteristics of humanistic education in medical education, explores the training strategies of humanistic quality education for medical students under the new situation, and puts forward some suggestions and countermeasures to improve the humanistic education for medical students.

3. Principles and Algorithms of Internet of Things and Intelligent Computing

3.1. Concept and Algorithm of Internet of Things. The concept of Internet of Things was put forward by American scholars. It is a network technology that can identify, locate, track, monitor, and manage information resources. Under the Internet of Things environment, humanistic quality higher medical education is proposed, and a network model is constructed, as shown in Figure 1.

The components of the four-tier architecture of the Internet of Things are as follows.

3.1.1. Perceptual Layer. The perception layer is mainly responsible for identifying objects and collecting information. The work of the perception layer needs to be completed by some terminal devices. At present, the more popular devices include two-dimensional code tags and readers, RFID tags and readers, cameras, GPS, various sensors, and so on.

3.1.2. Transport Layer. The transport layer is mainly responsible for information transmission. The current mainstream technologies include communication network, wireless private network, Internet, and converged network.

3.1.3. Intelligent Processing Layer. The intelligent processing layer creates the dynamic view corresponding to the physical world in the digital/virtual space mainly through processing and services such as dynamic aggregation, decomposition, and merging of sensing information.

3.1.4. Application Layer. The application layer provides rich specific services for users by using the analyzed information. However, at present, the application of the Internet of Things shows the characteristics of "narrow but small," and it is still dominated by single and customized applications, and the sharing and use of item information is not high. The process of humanistic quality higher medical education based on the Internet of Things is shown in Figure 2.

The hierarchical clustering method is used to construct the data acquisition tree. The data sensors in each unit of the Internet of Things are regarded as a class. N classes are divided according to N units. These classes are aggregated one by one according to the distance relationship. The calculation process is shown in the following formula:

$$D_{mn} = \sum_{m-1,n-1}^{a-x,b-y} \frac{d_{ab}}{(x \times y)}. \tag{1}$$

In formula (1), let the classes of hierarchical aggregation be $M = \{m_1, m_2, m_3, \ldots\ldots, m_n\}$, $N = \{n_1, n_2, n_3, \ldots\ldots, n_n\}$, the distance between m_n and n_n is dab, and the distance between classes is D_{mn}. According to formula (1), a data collection tree can be constructed to provide the basis for data collection.

The distribution of data in the entire network has been understood after the data acquisition tree has been constructed using formula (1). The next step is to organize the electronic data. The grouping effect is influenced by two factors: intragroup distance AI and intergroup distance B_i. As a result, the intragroup distance AI and intergroup distance B_i must be calculated in order to determine the grouping data. The following is the procedure for calculating intragroup distance AI. Calculate the total number of nodes in each group first.

$$x = \frac{\sum_{Ljex} d_{ij}}{d_{ab}(i, j)}. \tag{2}$$

In formula (2), it is assumed that there are n data sensors in the network, which can be divided into two categories: A and B, where I is the degree of intragroup separation, J is the number of groups, d_{ab} is the distance between two groups of data, and X is the calculated data node. After calculating the data nodes, calculate the distance variance of two groups of data, as shown in the following formula:

$$y = \frac{\sum_{m,ney} d_{mn}}{d_{ab}(m, n)}, \tag{3}$$

where M represents the number of nodes in the cell, n represents the number of data in the cell, and Y is the variance of data distance. Root work formulas (2) and (3) calculate the distance AI in the data group:

$$AI = \sum_{b}^{a} \frac{x}{y}, \tag{4}$$

where $a = \{a_1, a_2, a_3, \ldots, a_n\}$, $b = \{b_1, b_2, b_3, \ldots, b_n\}$, x is the calculated data node, and y is the variance of data distance. The calculation process of intergroup distance BI is shown in the following formula:

$$BI = \sum_{i-1}^{m} \sum_{j-1}^{n} (x - y). \tag{5}$$

The intragroup distance AI can be calculated by formula (4), and the intergroup distance B_i can be calculated by formula (5). When the number of groups is large, the intragroup distance AI will expand and the intergroup distance B_i will decrease; when the number of groups is small, the intragroup distance AI will be reduced and the intergroup distance B_i will be expanded. The grouping process of electronic data can be completed through the above formula.

If there is at least one path to connect $\forall v_i, v_j \in V$ in a graph G composed of complex networks, then G is called a connected graph. Because there may be many paths between nodes v_i and v_j, the shortest path is called the shortest path connecting v_i and v_j. Assuming that $\sigma(vi, vj)$ is the number of shortest paths between nodes v_i and v_j and $\sigma(v_i, v_j, v_k)$ is the number of shortest paths passing through vertex v_k between nodes v_i and v_k, then the intermediary centrality $B(v_k)$ of node VK in Figure 2 is defined as follows:

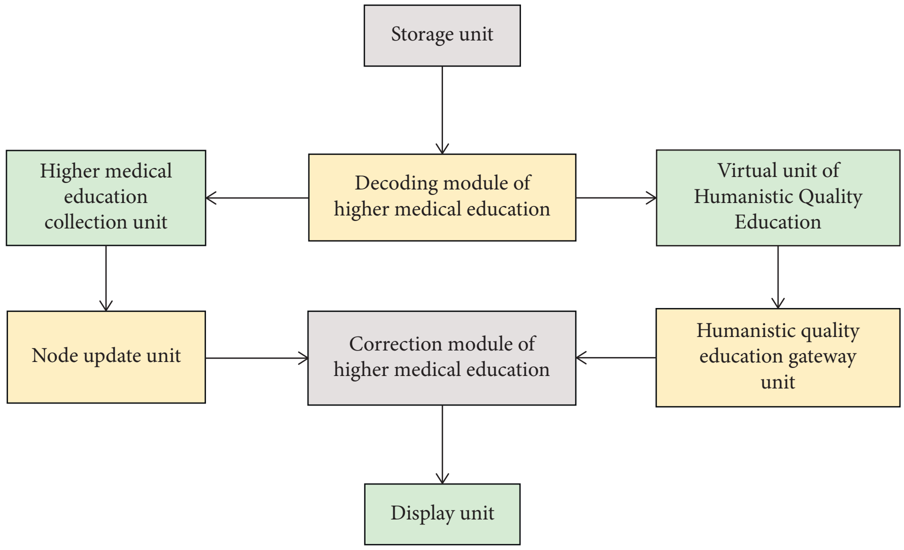

FIGURE 1: Network model of humanistic quality higher medical education.

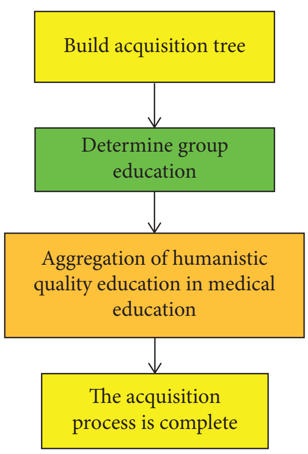

FIGURE 2: Humanistic quality education process in higher medical education.

$$B(v_k) = \sum_{v_i, v_j \in V} \frac{\sigma(v_i, v_j, v_k)}{\sigma(v_i, v_j)}. \tag{6}$$

As can be seen from the above definition, the more the shortest paths passing through a node, the greater its node intermediary centrality, and the shortest path in the network topology is often the path for rapid information transmission. Therefore, node intermediary centrality reflects the bearing degree of nodes on information transmission in the network.

In the figure, assuming that the degree of node v_i is $\deg(v_i)$, then the sum of the degrees of all nodes in the graph is $\sum_{v_i \in V} \deg(v_i)$; then, the degree centrality $D(v_i)$ of node VI is defined as

$$D(v_i) = \frac{\deg(v_i)}{\sum_{v_i \in V} \deg(v_i)}. \tag{7}$$

As can be seen from the definition above, a node is a structure that connects two or more nodes together. The ratio of a node's degree to the sum of all nodes' degrees in a graph is known as degree centrality. The number of nodes directly connected to a node is referred to as its degree centrality. If a node has a high degree of centrality in a computer network, the node could be in the middle of data transmission. After a node is removed, the average shortest path is an important indicator for determining network connectivity, as it reflects the network's reliability and connectivity. The following is the definition:

$$l \equiv (d(v, w)) \equiv \frac{1}{N(N-1)} \sum_{v \in V} \sum_{w \neq v \in V} d(v, w), \tag{8}$$

where $d(v, w)$ is the shortest path length between two dissimilar nodes V and W in the network. In the small-world network, the value of L is around 6; in WWW, the value of L is around 17. After some nodes in the network are removed, some nodes cannot be connected, and the distance between them tends to $+\infty$, which is a value that cannot be calculated conveniently. The concept of reverse average shortest path L is put forward, and its definition is as follows:

$$l \equiv \frac{1}{d(v, w)} \equiv \frac{1}{N(N-1)} \sum_{v \in V} \sum_{w \neq v \in V} \frac{1}{d(v, w)}. \tag{9}$$

When two dissimilar nodes cannot communicate with each other, $1/d(v, w) = 0$. It should be noted that L is not the reciprocal, and the larger the value of L, the better the connectivity of the network.

The size of the largest connected subgraph is the number of nodes in the largest connected subgraph in the graph, which reflects the connectivity among the nodes in the graph and is an important measure of the connectivity within the graph. Assuming that each connected subgraph set of graph

$G = (V, \varepsilon)$ is $\{g_1, g_2, g_3, g_4, \ldots, G_N\}$ and there are paths between any two different nodes in these subgraphs, the relative size of the maximum connected subgraphs is defined as follows:

$$S = \frac{\mathrm{Max}\left\{\left|V_{g1}\right|, \left|V_{g2}\right|, \left|V_{g3}\right|, \ldots, \left|V_{gn}\right|\right\}}{|V|}, \tag{10}$$

where $|V|$ refers to the number of nodes in the whole computer network graph and I% I refers to the number of nodes contained in the connected subgraph GI.

3.2. Concept and Model of Intelligent Computing. The development of intelligent computing technology is based on the development of network information technology. It is a computing mode, which can realize the integrated computing of a large number of data and information resources. Intelligent computing technology architecture mainly depends on three-tier architecture. The relationship among the three is closely related and interdependent, which is progressive step by step, from the bottom hardware to the application software for the end customers. Its concept is developed on the basis of SaaS (Software as a Service). In different levels of intelligent computing, people play the role of users or providers. The process of humanistic quality education in intelligent computing higher medical education involves decision making, comprehensive guarantee, financial management, student management, teaching management, teaching staff management, scientific research management, and application. Combing the business mainly solves the systematic problems of information construction, avoids more complex systematic problems caused by a single process, and provides relevant basis for the intelligent integration of various businesses. Combined with the situation of higher medical education and the development of informatization at home and abroad, Figure 3 shows the relationship between business income and humanistic quality higher education medical education.

Multiple computers can be linked together using intelligent computing technology to create a powerful technical system with massive storage and processing power. Intelligent computing's greatest advantage is that it can customize services to meet the needs of users. It will be able to meet the various network personalized service needs of school teachers, students, and teachers in this way. Intelligent computing does not alter these SAA patterns, but it does provide application providers with more options for delivering SAA products without having to configure the data center. Intelligent computing allows SaaS to be deployed without building or providing data centers, and the scale of SaaS can be scaled according to needs, just as the emergence of semiconductor OEM allows chip companies without production lines the opportunity to design and sell chips.

Intelligent computing is a revolutionary measure, which means that computing power can also be circulated as a commodity; of course, this commodity is transmitted through the Internet. The main goal of intelligent computing is to get all the services we need through network services, even including tasks such as supercomputing, with only a notebook or a mobile phone and other clients. A task space dimension can include many different resource types, and a task space can be divided into many different dimensions, and different dimensions indicate different tasks requested by users. Nowadays, intelligent computing technology has become a very popular and concerned technology in various industries, including academia. With the deepening of educational informatization construction, intelligent computing will play an increasingly important role in the construction of intelligent campus system.

4. Application of Humanistic Quality Higher Medical Education Based on Intelligent Computing and Internet of Things

4.1. Humanistic Quality Higher Medical Education in Intelligent Computing and Internet of Things. Let us compare the time required for intelligent computing and humanistic quality higher medical education. Firstly, the data blocks are divided into 5M, 60M, 120M, and 500M, respectively. On machines with the same configuration environment, serial k-means algorithm and intelligent computing algorithm are used to process these data blocks, respectively. The value of k in the experiment is 5. The experimental results are shown in Table 1.

The experimental results show that the memory occupied by k-means algorithm increases with the increase of the size of data file, until the memory resources are exhausted. However, parallel programs based on intelligent computing are competent, and there will be no shortage of memory. This fully proves that the intelligent computing algorithm has the ability to process large-scale data.

Intelligent computing and k-means algorithm are used to cluster the data of humanistic quality higher medical education, and finally different user groups are obtained. Four different data block sizes were used in this experiment, as shown in Table 2.

Medical education describes the performance of an intelligent computing algorithm as a result of a reduction in running time, which is an important metric for assessing intelligent computing performance. Medical education is the time spent on solving problems at a single node, which is the time spent on solving problems at the same node using P intelligent computing algorithms. In the following experiments, two, four, six, and eight nodes are chosen as different computing resource nodes, and their effects on the processing results are observed. The experimental results are shown in Tables 3–5.

The above table shows that increasing the number of cluster nodes reduces the processing time for the four different datasets A, B, C, and D, demonstrating that increasing the number of cluster nodes can increase the system's processing capacity. We clustered datasets of various sizes in the previous section, and the final results are similar. As a result, we only look at dataset D's clustering results. The dataset's clustering results are shown in Tables 6 and 7.

Through the Internet of Things and intelligent computing clustering, it can be seen that the online time, clicks, and network traffic generated by most mobile Internet users are very low. How to strengthen the loyalty of such users to mobile Internet services has become the primary task of network service providers.

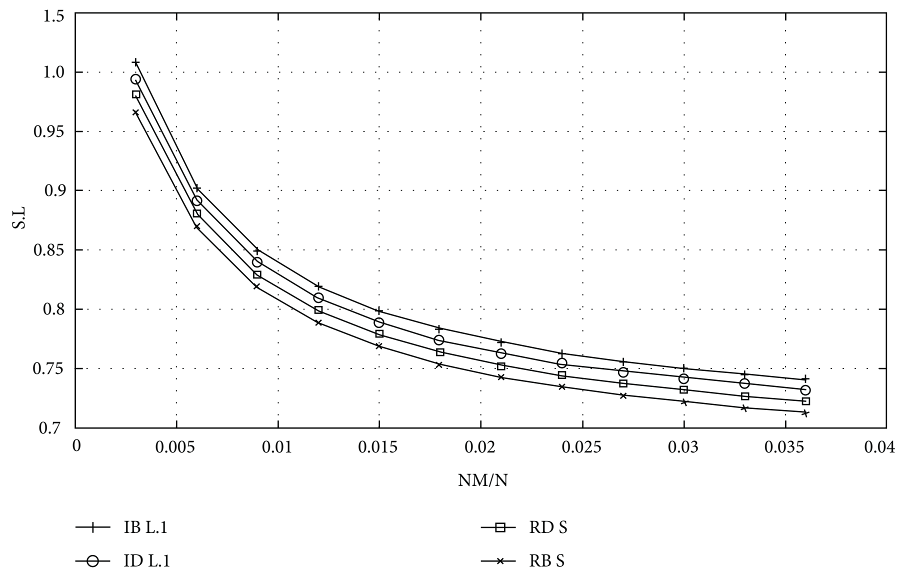

Figure 4: Results of S and L after simulating humanistic quality higher medical education.

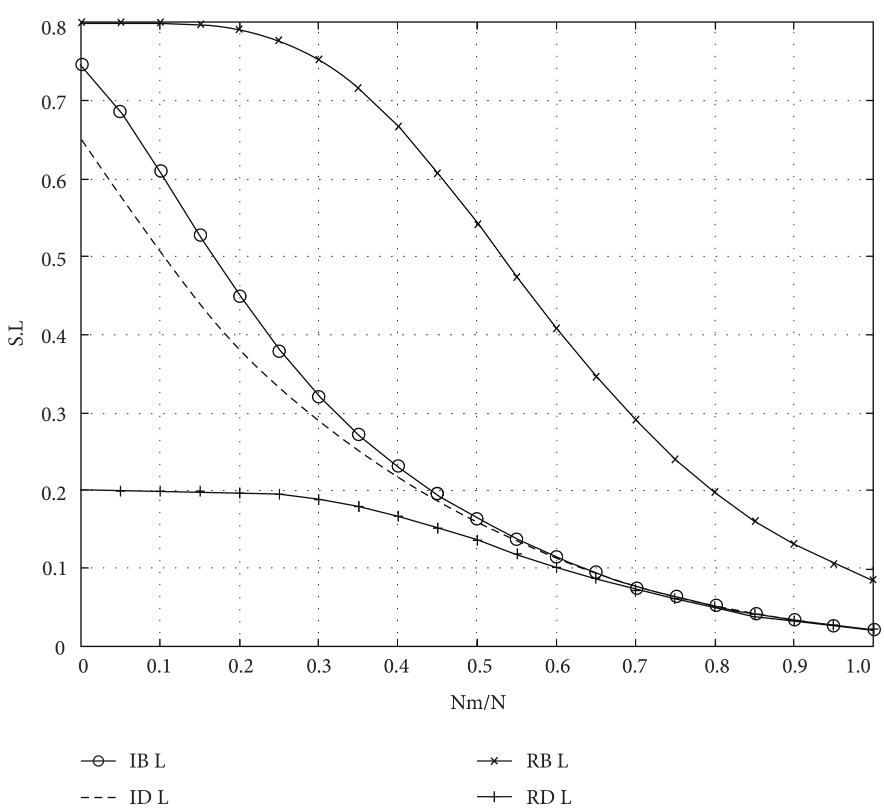

Figure 5: Results of S and L after simulating humanistic quality higher medical education.

4.2. Experimental Results and Analysis. Because the scale-free network accurately depicts the scale-free structure characteristics of higher medical education, it is selected as the higher medical education network simulation data set in this study. In Figure 4, the Y axis represents the relative values of S and L (the ratio of the values of S and L to that of the original graph is recalculated after removing the faulty nodes every time), and the data points on the curve are the results obtained by calculating the values of S and L on 210 networks after removing 51 faulty nodes in the same original BA scale-free network by four different mechanisms, as shown in Figures 4 and 5.

The following conclusions can be drawn from Figure 4. (1) For the BA scale-free network D with 1510 nodes, s

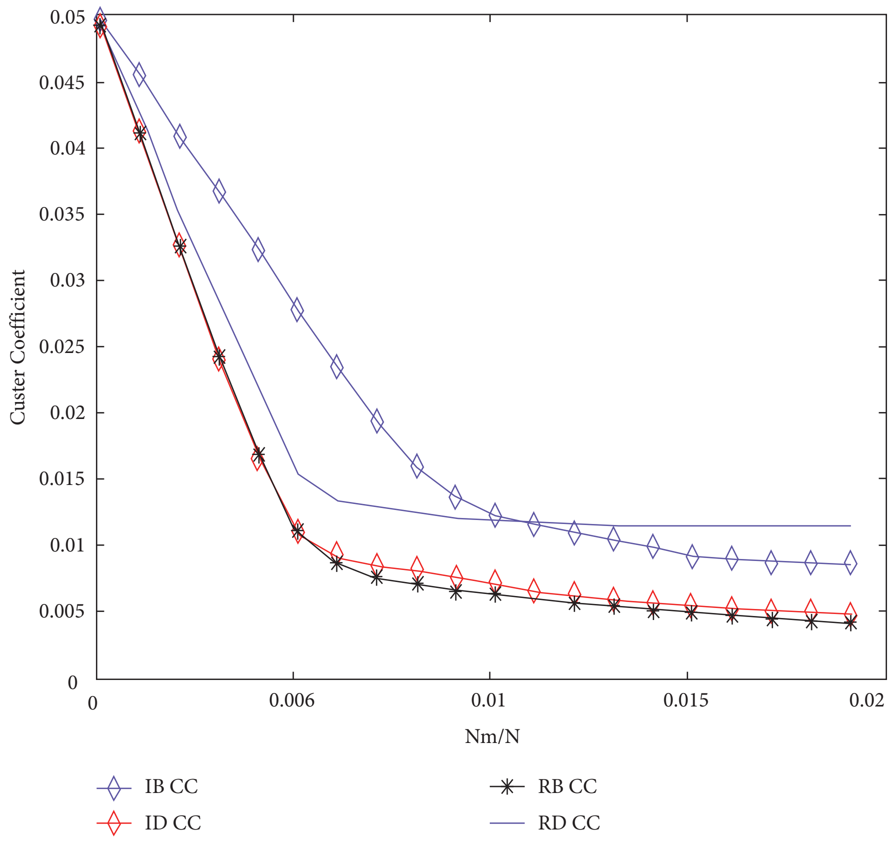

Figure 6: Cluster efficiency results after simulating humanistic quality higher medical education.

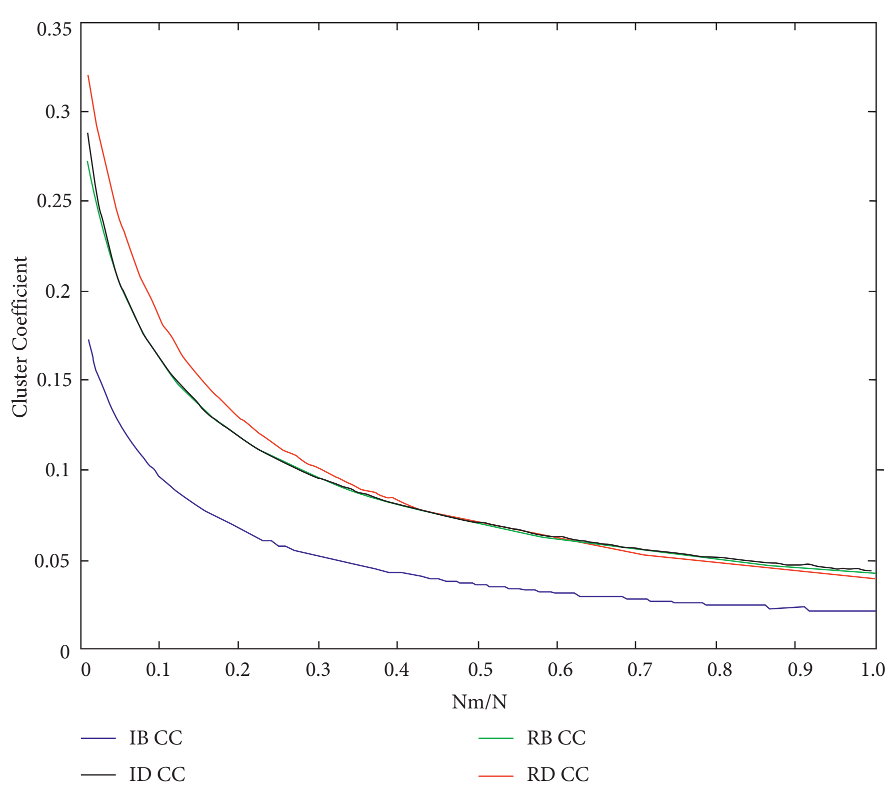

Figure 7: Cluster efficiency results after simulating humanistic quality higher medical education.

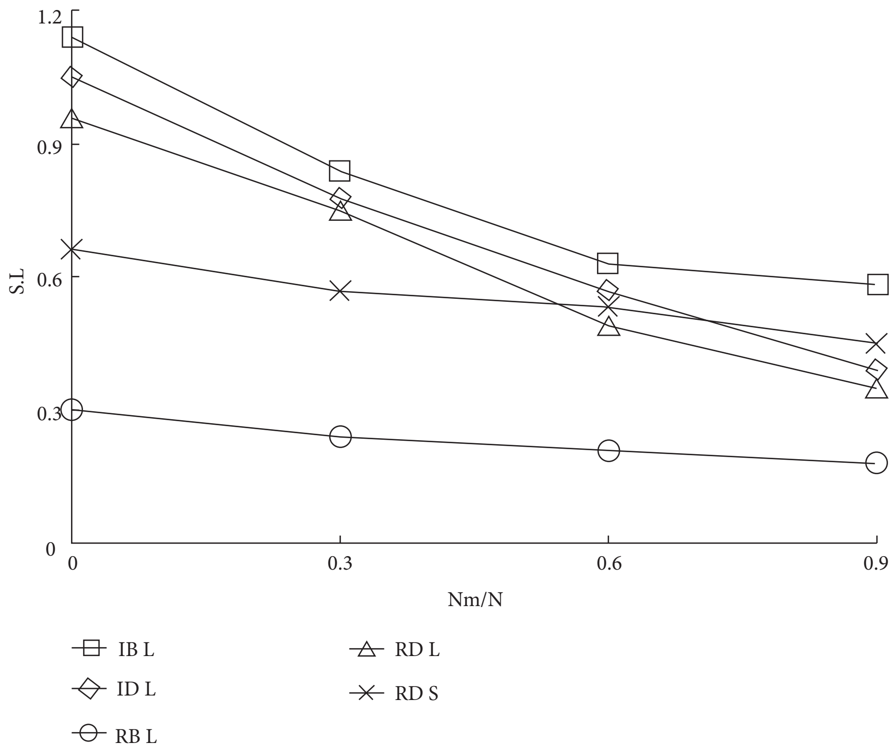

Figure 8: S and L results of humanistic quality higher medical education based on intelligent computing.

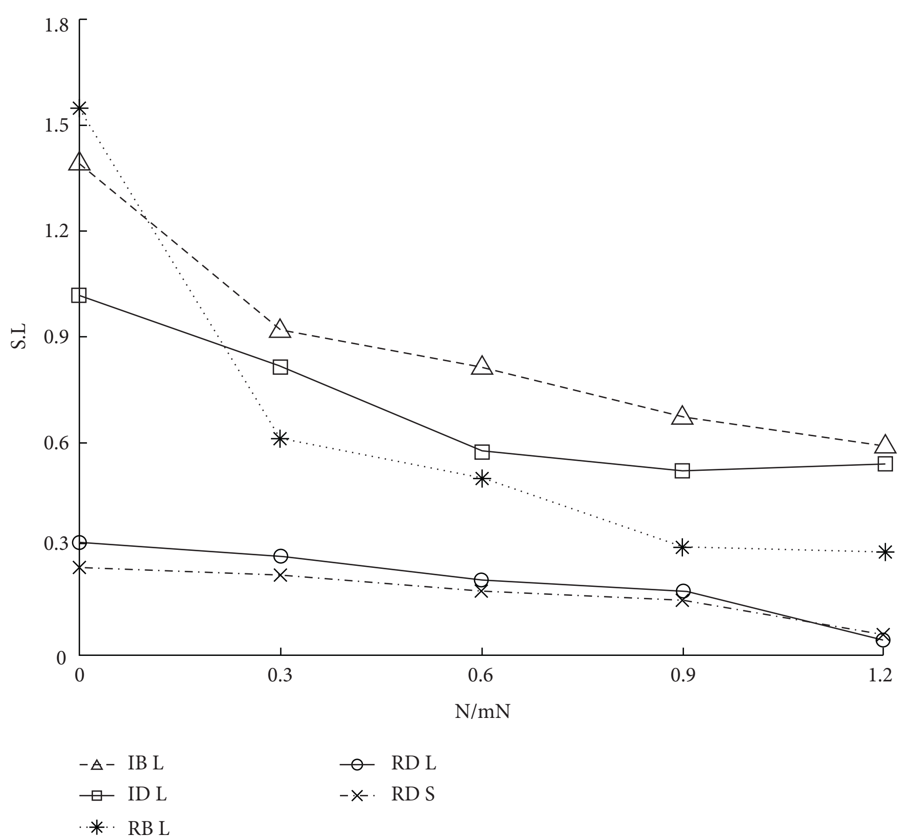

Figure 9: S and L results of humanistic quality higher medical education based on Internet of Things.

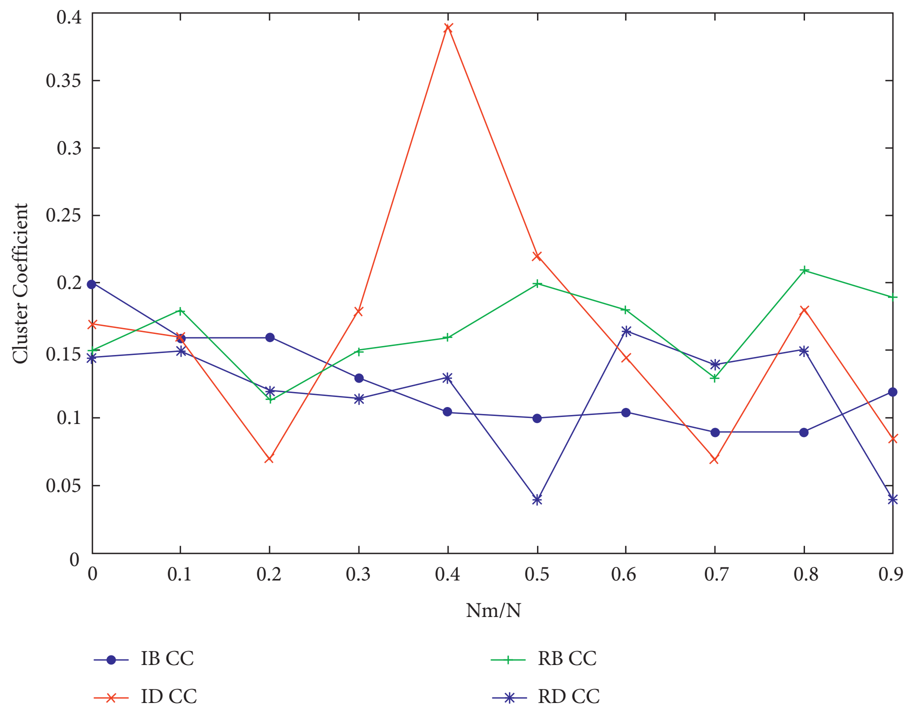

Figure 10: Cluster coefficient results of humanistic quality higher medical education based on Internet of Things.

generated by the four mechanisms is basically the same after the removal of the first 51 failed nodes. (2) When $0.76 < l < 0.93$, the curve of Rb is the lowest after the implementation of the four mechanisms, and the influence of Rb is the largest for L in the whole interval.

Figure 5 shows the graph clustering coefficient corresponding to each data point in the graph. Under normal circumstances, the higher the graph clustering coefficient, the denser the graph; otherwise, the rarer the graph. However, when the graph clustering coefficient of a curve suddenly increases from decreasing all the time, it shows that the graph suddenly produces disconnected subgraphs, which further aggravates the sparseness of the graph, as shown in Figures 6 and 7.

Figure 6 shows the following. (1) On the whole trend, IB has the greatest influence on network performance. (2) When $0.0000 < \mathrm{NRM}/n < 0.0060$, the effects of the four mechanisms are quite consistent. (3) When $0.0060 < \mathrm{NRM}/n < 0.0300$, the mechanism of IB and RB has the greatest influence, and the sudden upward trend caused by IB curve is the most obvious. The graph clustering coefficient corresponding to each data point can be obtained from Figure 7. For the whole curve, when each branch has no upward trend, IB has the greatest influence on the network performance, while for IB, it jumps the most, generates the largest number of disconnected subgraphs, and has the greatest influence.

Three real computer network topologies are introduced to discover and analyze the impact on the actual network. The experimental results of S and L on network A are shown in Figure 8. The network model is one of the few provincial secondary trunk communication network datasets available, which, to some extent, reflects the topology characteristics of the real provincial communication network.

It can be seen from Figure 8 that for L, (1) when $0.1 < l < 1.0$, Rb has the greatest impact and (2) when $0.0 < l < 0.1$, it roughly presents the relationship of Rb > Rd > ID > IB. For the whole curve of S, Rb has the greatest impact. Because the number of nodes in the whole graph is too small, the linear relationship between S and IB is not obvious.

Figures 9 and 10 show the experimental results of S, l, and graph clustering coefficients on network B. In Figure 9, it can be found that RB has the greatest impact on L, and the impact effect relationship is roughly RB > ID > Rd > IB. For the whole curve of S, Rb has the greatest influence, and the linear relationship between S and IB is obvious. In Figure 10, it can be found that IB has the strongest impact on network performance, with the largest number of hops, followed by RB. For the whole clustering coefficient curve, IB > RB > ID > Rd.

5. Conclusion

Higher education should consciously and effectively combine the cultivation of the scientific spirit of seeking truth with the cultivation of the humanistic spirit of seeking goodness, so that students understand with whom to discuss scientific truth. You know how to act when you are studying humanities. Teachers hold the key to providing high-quality humanistic education. Humanistic quality education is meaningless without high-level teaching staff. Basic medical teachers are the strongest in adult medical colleges, while humanities and social sciences teachers are the weakest. This paper examines the humanistic quality of higher medical education, examines the humanistic quality of medical education, and discusses the practicality and participation of students in humanistic education, and finally our curriculum system will incorporate humanistic spirit education into every curricular and clinical practice instruction. Strengthening teaching staff's humanistic quality construction, cultivating a group of teachers with professional skills and humanistic quality through internal training and external introduction, and intensifying cultivation can not only increase students' interest in learning but also strengthen their belief in occupation.

Graphics innovation must adapt to the changing trends of the times in order to stay ahead of the curve. This article investigates the use of graphic vision in print advertising design, using image segmentation as a starting point and examines the current state of visual innovation in print advertising graphic design and its various expressions and applications. A series of homogeneous regions are generated and outlined using an image segmentation algorithm based on adaptive local threshold. The user then paints different colors on the area sets that make up the various targets. Finally, the image segmentation is completed by merging the color mark region sets. Automatic extraction of the initial curve of an active contour model, construction of an active contour model based on saliency and level set solution, automatic selection of training samples when a classifier is used for image segmentation, and so on are all problems that this method effectively solves. Experiments show that this algorithm not only satisfies users' demands for more intuitive input and more accurate interactive image segmentation results but also enables multiregion and multitarget image segmentation with ease.

1. Introduction

Graphics and image processing [1] has become one of the most active research directions today as a result of the advancement and perfection of computer science and related mathematical theories. Among them, graphic image segmentation has long been a hot topic in this field. Image segmentation is the process of dividing an image into several disjoint regions based on a similarity measurement criterion, with pixels in the same region having similar features and pixels from different regions having low similarity [2]. Graphic image segmentation technology has found widespread use in a variety of fields, including computer animation, medical image processing [3], virtual reality, computational visualization, and so on. Graphics have become synonymous with fashion in the irresistible visual space. Changing time and space gives graphic vision a new lease on life, as well as revealing its glory. Many image processing tasks necessitate the extraction of some image areas. We can divide the pixels by means of image segmentation [4, 5] technology and separate the target areas from the background. At present, many image segmentation methods have been proposed, but there are still some problems, such as poor universality, dependence on user interaction, and inconsistency between segmentation results and human visual perception. With the deepening of the era of reading pictures and the development of artistic interoperability, the aesthetic ability and demand of the public are further improved, and the print advertising design industry is facing new challenges. Graphics in modern print advertisements are intuitive, vivid, lively, distinctive, unique, and changeable. The language displayed by graphics can be our perception of daily life or the trend of the times [6].

Print advertising is an important part of today's social and economic life, and it helps to promote the circulation of goods [7]. Every designer working in print advertisement design is concerned about how to make print advertisements better serve today's society [8]. Currently, issues such as design material simplification and homogenization are more prominent in the industry. Design practitioners are concerned about how to use image processing technology to improve the innovation of print advertising design [9]. The data item established by the local algorithm is the first part of the energy function of the traditional graph cutting algorithm, and the smoothing term of disparity difference between neighboring pixels is the second part. The local algorithm data items will cause relatively large errors due to occlusion and other reasons, and the smoothness assumption of occluded areas is often not valid, so parallax mismatch will occur in some occluded areas [10]. With people's access to images becoming more convenient and quick, more image segmentation algorithms are being used for Internet and mobile device image processing tasks like image classification, marking, retrieval, and thumbnail generation, among others, which necessitates image segmentation algorithms that are fast, accurate, and have the advantages of automatic and real-time processing [11]. Image segmentation is a key step from bottom image processing to image recognition and understanding because the result has a direct impact on subsequent visual tasks [12]. Humans can accurately separate the target area in an image, but computers find it difficult. This article investigates and analyzes the visual innovation of graphic design in print advertisements using image segmentation technology.

At present, in this era of visual transmission everywhere, our sights or thoughts are usually filled with various kinds of graphics [13]. Graphics spread information everywhere in the world, and it has become an expression language without national boundaries. On the one hand, modern print advertising is a new way to promote commercial advertising; on the other hand, it is also the expression of aesthetic symbolism in the market economy [14]. Graphic vision in modern print advertising design, as a combination of technology and art, embodies the diversity and richness of modern culture all the time. As a force that cannot be ignored in visual art, it promotes the development of modern print advertising design and promotes print advertising design to enter a new visual era. This kind of commercial works combined with artistic sense can often stimulate the infinite imagination of the audience, and at the same time, it will leave a deep impression on the audience [15]. This will also greatly promote the products involved in the advertisement. Graphic vision in graphic advertising design is not just a picture to convey information, but a kind of symbolic sentiment, which can deeply attract people, move people, and inspire people. Graphic vision will show different advertising themes according to different advertising concepts [16]. As print commercial advertising is an outstanding performance of innovation, the graphic design of print advertising not only plays the role of information transmission in external publicity but also is a prominent performance of corporate culture. Based on image segmentation, this study analyzes the innovation of graphic design vision in print advertisements and discusses how graphic design vision will face the public. The potential position of the target object is predicted using a saliency map, and the result is further refined using a morphological operation to obtain the target object's contour information. The objective function is defined to quantitatively describe the visual information in an image based on human visual characteristics. The global optimal threshold of each subgraph is obtained by optimizing the objective function. The final threshold segmentation result is then obtained by performing a local adaptive threshold operation using the image's local characteristics. The results of the experiments show that this method is active and adaptive. Furthermore, the segmented binary image has a pleasing visual effect, and its overall visual quality is closer to that of human perception.

2. Related Work

People are tired of traditional marked graphics, according to Zhang et al. [17], and the era of traditional print advertising is over. According to Wang [18], it is necessary to combine innovative ideas in advertising art with technical science, as well as to demonstrate cultural diversity, while considering the economic benefits of advertising. In order to encourage in-depth visual concept innovation in print advertising design, discussing the importance of graphic vision and studying the innovative elements of graphic vision in print advertising design, according to Walter et al. [19], will help graphic vision better serve people and encourage them to use graphic visual language more quickly. Soldow [20] discussed iconology and conducted a pedigree study on the visual images used in print advertisements. The visual images used in print advertisements are systematically classified and studied in groups as a result of this. According to Ramezani et al. [21], graphic image processing is usually based on graphic image segmentation technology, which allows the target area to be accurately separated from the graphic image background. Javan and Zeman [22] proposed a new interactive image segmentation algorithm. This algorithm overcomes the shortcomings of many current interactive algorithms, such as cumbersome operation and ineffective multiobjective segmentation and is very practical. Based on the analysis and research of existing graphics and image segmentation algorithms, combined the characteristics of human vision and related theories with the segmentation process, Miller et al. [23]proposed new graphics and image segmentation algorithms, respectively. Zeller [24] compared the visual images of graphics in print advertising design in different times. At the same time, through the analysis of the development process of print advertising, the connotation of graphic vision in modern print advertising design is interpreted.

This article summarizes the composition and characteristics of the human visual system and comprehensively analyzes the problems that exist in current graphic image segmentation based on an in-depth review of related literature. A new adaptive image segmentation method is proposed that combines the threshold selection process with human visual characteristics. The geometric attributes of the mesh model, which include arc length, angular distance, and correction term, define the distance function between mesh vertices. Visually meaningful segmentation results are obtained by clustering the grid's vertices. This research combines print advertising design with image processing technology, resulting in a unique artistic effect and increased advertising information transmission accuracy. It is also

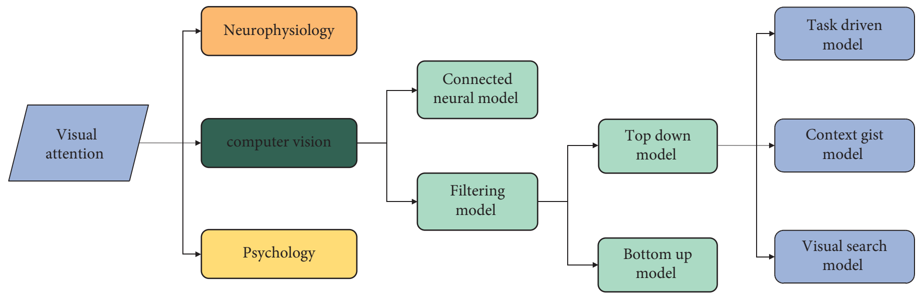

FIGURE 1: The category of attention mechanism.

more in line with the current aesthetic trend, and it is more conducive to the spread of digital network media and other forms of communication.

3. Methodology

3.1. Visual Innovation in Graphic Design of Modern Print Advertisements. Vision is one of the important ways for human beings to obtain information about the surrounding environment. The human visual system generally consists of two parts: the human eye and the central nervous system of vision. Among them, the human eye is responsible for perceiving visible light information, which projects a two-dimensional image on the human retina [25]. The visual central nervous system is responsible for the reconstruction, positioning, discrimination, analysis, and research of two-dimensional images. Visual perception is a highly complex visual perception process, which is from the direct response to the attributes of the target object to the acquisition of its advanced semantic information. At present, many methods in graphics and image processing are based on mathematics, computer, and other disciplines. Because human intuition and analysis of things will play an important role in the process of selecting methods, this selection process is usually based on human subjective visual judgment. Therefore, understanding the composition of human visual system and its visual characteristics is of practical significance for solving the problems in graphic image processing.

In modern society, due to the progress of science and technology, all kinds of images that human beings can see have far exceeded the sum of the visual images of any era after the emergence of human beings. The visual attention mechanism [26] helps the brain to process all kinds of information in the visual field in parallel, and visual salience can help the visual attention system to realize automatic real-time target selection. After calculating the saliency of each object in vision, the vision system will use different eye movement strategies to determine the attention order of several prominent objects in vision, and then transfer attention among these prominent objects [27]. The main feature of human visual concentration is that the human visual system can quickly fix the visual attention on several obvious visual targets that it is interested in and automatically screen out other visual targets when faced with a large number of complicated visual information. When dealing with complex scenes or facing a large amount of visual information, the human visual system can quickly focus on several prominent targets while ignoring other uninterested objects. This process is called visual attention mechanism. The visual mechanism is shown in Figure 1.

In modern print advertising design, the creative elements of graphic vision are important in design expression techniques. Each designer may have different ways and means of conceiving and express the connotation of print advertising works through graphic vision creativity. To study the visual innovation of graphic design, we must analyze it from the most fundamental elements. This kind of element is the tool of creation. Visual creativity refers to the expression of creative ideas [28]. In the graphic design of contemporary print advertisements, the visual innovation elements of graphic design play an important role in the way of expression. Different designers have different ways of thinking and show the specific meaning of advertising works by means of graphic design visual creativity. In the design of modern print advertisements, graphic creative elements commonly used can be divided into abstract graphic creative elements and realistic graphic creative elements.

In a broad sense, visual image refers to all images that human beings see. The premise is to have a normal visual system. Images in nature are complicated and rich. As a specialized visual discipline, the visual image of print advertisement needs more strict classification standards. Classifying all kinds of images will help us to better grasp the fundamentals of image application. Among the graphic design elements, the design of Chinese and English fonts is quite common [29]. Chinese characters are the accumulation of Chinese traditional culture, and characters are one of the best graphic elements to accurately convey information. Usually, designers design graphic visual creativity from the pictographic consciousness of characters. The creativity of Chinese characters is to re-create graphics on this basis. Using the product of modern social development, modern element symbols, and regraphics and creativity in the structure of Chinese characters, people can imagine another meaning after the change in the basis of familiarity with existing Chinese characters.

Graphic vision is an important way of expressing oneself in the graphic creation of contemporary print advertisements, and it is the focus of the audience's attention. Good advertising creation can reveal the ideas to be expressed in advertising creation using its own distinct graphic language and can succinctly and effectively show the theme with profound meaning [30]. Graphic advertisement, as a concrete manifestation of graphic design, bears most of the design features of graphic design, particularly the design innovation of graphics and pictures, which plays a significant role in the design process. Graphic design vision, in particular, is the soul of print advertising design. To fully comprehend the overall design work, start with these subtle elements, consider graphic elements as the building blocks of graphic design, and consider the visual effect of the results as the standard for testing the properties of graphic elements. The premise foundation of this type of advertising product is innovative ideas of vision and creative forms of expression of ideas. With the increasing variety of visual expression creation, graphic design's visual language should use new ways to realize ideas in the creation process. It is clear that graphic vision creation plays a vital role in the graphic creation of contemporary print advertisements. The graphic creation elements in the graphic creation of print advertisements are also investigated, and it can be concluded that graphic vision creation plays a vital role in the graphic creation of print advertisements. In the current graphic design process, the graphic elements involved are abstract and concrete. Analyzing and grasping these two elements will promote the development of the whole print advertisement. The visual information processing model is shown in Figure 2.

Visual traction is a bright spot in the graphic design process of current print advertisements. There are two aspects to draw the visual audience's information: using color and using graphics, the audience can follow the designer's ideas to appreciate the works. Most existing print advertisements are guided by dots, lines, and planes. The subjective initiative quota of people plays an important role in the design process. Different designers often design different graphics to express different artistic feelings as a result of their diverse life experiences, and even the same type of graphic design can be interpreted in different ways depending on the language used. Visual metaphorical expression in graphic works is an extremely important, unique, and inventive expression form in today's print advertising, and we can also use metaphorical expression techniques in graphic design of contemporary works in large quantities. This type of graphic expression can help to advance graphic vision in works, as well as focus the audience's attention, which can benefit businesses financially.

In the design of modern print advertisements, realistic graphics, a creative element, also occupies an important position, which is equally divided with abstract graphics. Although realistic graphics have not changed in various ways, it can make the audience feel the real sense of existence and narrow the sense of distance between audiences. Excellent image creation advertising works do not care how much the graphics change but the extraction and processing of creative thinking. No matter how the graphic design itself changes, we cannot interpret without the two scales of abstraction and concreteness. The correct use of these two tools will not only help the audience to understand the graphic design but also promote the inspiration of designers.

The idea of minimalism comes from the minimalism of contemporary school. The designers of this school all

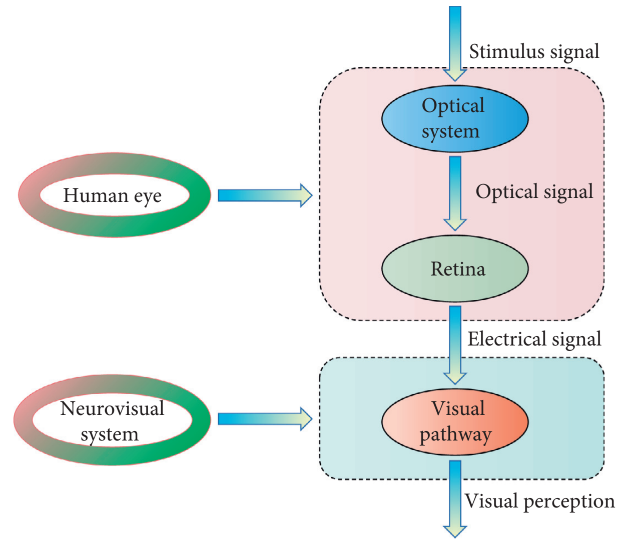

Figure 2: Schematic diagram of visual information processing model.

encourage minimalist drawing methods, and the purpose of the simplest treatment of creation is to find a simple scheme that is rich in content and pure in Chinese and modern classics. In order to create advertising works with more special visual effects, I should pay attention to the existence of minimalist style, master it, and use it properly in the visual creation of graphic works. Learn about graphic effects and how to use them. We should concentrate on displaying the bright spots of graphics during the graphic design and postdecoration processes in order to fully attract the audience's attention and increase their interest in graphic culture and persuade the audience to accept the advertisement's content while admiring and being drawn to the beauty.

3.2. Graphic Design and Implementation of Print Advertisement Based on Image Segmentation. Image segmentation has always been one of the most difficult problems in computer vision, with the ultimate goal of allowing computers to mimic human visual cognition and recognize the meanings represented by different regions in an image. Traditional image segmentation methods and image segmentation methods combined with new theories are the two main types of image segmentation methods. Early image segmentation methods relied on analyzing image features, such as grayscale, orientation, size, and shape. This category includes histogram threshold segmentation methods, region-based segmentation methods, edge-based segmentation methods, and hybrid segmentation methods. With the advancement of computer vision and research into human cognitive ability, the question of how to use human visual characteristics to produce more reasonable image segmentation results has become a hot topic in research.

The basic principle of threshold-based image segmentation method is as follows. Let the original image as f, the image size as $M \times N$, the image grayscale as L, and $f(x, y)$ represents the gray level of the pixel whose coordinates are (x, y),then $x \in [1, M]$, $y \in [1, N]$. The single-threshold segmentation method is to determine a segmentation threshold T, segment the gray levels of all pixels, and obtain the segmentation result $g(x, y)$:

$$g(x, y) = \begin{cases} 0, & 0 \leq f(x, y) \leq T, \\ L - 1, & T < f(x, y) \leq L - 1, \end{cases} \tag{1}$$

where T is a constant that applies to the whole image, the processing method given by this formula is called global thresholding. When the value of T changes constantly and is determined by (x, y) and its neighborhood characteristics, the processing method is local thresholding. The multi-threshold image segmentation method adopts multiple thresholds, set the number of thresholds as n, and denote T_1, T_2, ..., T_n as the segmentation threshold, then the image $g(x, y)$ after segmentation is

$$g(x, y) = \begin{cases} L_0 & 0 \leq f(x, y) \leq T_1, \\ L_1 & T_1 < f(x, y) \leq T_2, \\ \cdots & \cdots \\ L_{n-1} & T_{n-1} < f(x, y) \leq T_n, \\ L_n & T_n < f(x, y) \leq L - 1, \end{cases} \tag{2}$$

where $L_0, L_1, \ldots, L_n$ are the $n + 1$ gray levels of the segmented image.

There are four major flaws in the segmentation of two-dimensional images in the computer image processing process right now. (1) An insufficient number of image segmentation methods are available. (2) Image segmentation has a low level of accuracy. (3) There is no perfect quality evaluation standard for image segmentation. (4) Image segmentation results are difficult to match human visual perception requirements. The threshold segmentation method is a simple image segmentation method that uses the gray level difference between the target object and the background in the image to select one or more thresholds based on the image gray histogram and divides the image into target and background areas with different gray levels. The key to using a threshold segmentation algorithm is to pick the right one. When the gray histogram of an image has a bimodal shape, the gray value corresponding to the valley between two peaks is selected as the threshold, depending on the number of thresholds used in segmentation. Different thresholds or dynamic thresholds can be used in different positions of the image using variable and multiple thresholds. The visual mechanism is still under investigation due to the complexity of the human visual system. Many image segmentation methods currently use visual saliency as a visual mechanism, with the image's saliency map being used to simulate vision.

Interarea contrast GC indicates the gray contrast between the divided areas:

$$\mathrm{GC} = \frac{(f_1 - f_2)}{f_1 + f_2}, \tag{3}$$

where f_1 and f_2 are the average gray levels of pixels in the target area and the background area, respectively. Internal uniformity UM indicates the degree of uniform distribution of pixel characteristics in each area in the segmented image.

$$\mathrm{UM} = 1 - \frac{1}{C}\sum_{i=1}^{2} \sum_{(x,y) \in R_i} \left[I(x, y) - \frac{1}{A_i} \sum_{(x,y) \in R_i} I(x, y) \right]^2. \tag{4}$$

C is the normalization coefficient, and R_1 and R_2 represent the segmented target and background regions, respectively. A_1 and A_2 represent the areas of the target and background areas. Pixel distance error FOM is defined as follows:

$$\mathrm{FOM} = \frac{1}{N} \sum_{i=1}^{N} \frac{1}{1 + p \times d^2(i)}. \tag{5}$$

Among them, N is the number of misclassified pixels, p is the scale coefficient, and $d^2(i)$ represents the distance between the i-th misclassified pixel and its correct position. Pixel segmentation error PE is the number of misclassified pixels due to segmentation errors:

$$\mathrm{PE} = P(o) \times P(b|o) + P(b) \times P(o|b). \tag{6}$$

Among them, $P(b|o)$ and $P(b|o)$ represent the probability of misclassifying the target pixel as the background, and the probability of misclassifying the background pixel as the target, respectively. $P(o)$ and $P(b)$ are the prior probabilities of the object and background in the image, respectively.

The original image is divided into multiple homogeneous connected regions by minimizing the energy function. Using the specific law of the boundary curve of the target object, the homogeneous region with small intensity changes is represented by a piecewise smooth function, although the intensity changes are drastic. The region's boundary is represented by the union of short smooth functions, with the discontinuous point set of the function close to the target object's boundary to achieve effective image segmentation. The algorithm's specific implementation process is divided into three steps: (1) divide the pixels in the image, (2) make a new two-dimensional image, and (3) determine the image segmentation threshold for the corresponding image. It is necessary to determine the corresponding objective function based on human visual characteristics and optimize the corresponding objective function in this link. Finally, it is combined with the image's local pixels to scientifically calculate an image segmentation threshold that is consistent with human visual characteristics, and the image is segmented.

The target area is extracted from the background area of the image by calculating and selecting the image threshold. Although the image separated by the threshold segmentation algorithm has a small amount of data, it occupies less storage space, which significantly simplifies the subsequent image analysis and image processing links, and speeds up the efficiency of image processing. Compared with the original image, the amount of binary image data generated by threshold segmentation is reduced, which can highlight the target area of interest, but the process of thresholding will also cause the loss of many other important information in the original image, thereby reducing the binary value and the visual quality of the image. Therefore, reducing the loss of main information in the threshold segmentation process is the key to improving the quality of the final binary image.

Based on the quality of the reconstructed image, peak signal-to-noise ratio measurement method is given as

$$\mathrm{PSNR} = 10 \times \log_{10}\left(\frac{\mathrm{MAX}_i^2}{\mathrm{MSE}}\right),$$
$$\mathrm{MSE} = \frac{1}{N}\sum_{(x,y)} \|\mathrm{Rco}\,(nx, y) - Or\,(ix, y)\|^2, \tag{7}$$

where MAX_i is the largest pixel in the image, Rcon is the reconstructed image, Ori(x, y) is the real image of the reconstructed image, and N is the total number of pixels.

The active contour model is founded on curve evolution theory and the level set method. The zero level set of the traditional level set function represents the contour curve. By updating the level set function, the model achieves its goal of moving the contour line. The level set function can remain effective even if the contour line undergoes topological changes such as splitting or merging. The algorithm uses human visual characteristics as a starting point for image segmentation, then uses advanced methods to optimize the image's segmentation threshold from a humanized perspective, and finally makes the segmented target 2D image better meet human visual perception needs. The algorithm automatically merges the target region sets according to these marks to complete the separation of the target from the background. Users can clearly and roughly mark the regions that make up the target.

4. Result Analysis and Discussion

Image segmentation gathers pixels in an image into different connected regions according to certain similarity criteria, and its purpose is to simplify the expression form of the image and extract more abstract and compact useful information from complex image information, which is beneficial to subsequent processing and analysis. The key of threshold segmentation method is how to select the appropriate threshold, which will directly affect the final segmentation result. We use the optimization method to solve the optimal threshold of the image, so as to give visual meaning to the threshold and then combine the local properties of the image to produce threshold segmentation results that are more in line with human visual perception.

When people observe a scene, the processing unit is not pixels, but an area or outline composed of many pixels, according to the working principle of the human visual system. Pixels are merely a representation of the transition from continuous to discrete in the image digitization process, and they do not exist in the human visual system or brain. People can only have visual perception significance when pixels are combined. Experiments are used to verify the effectiveness of the adaptive threshold segmentation method proposed in this chapter, and we have verified a large number of images and did subjective visual comparison of the experimental results, as well as quantitative comparison using various image quality evaluation indicators. The process of calculating the global optimal threshold for each subgraph is the most time-consuming part of the algorithm. Before we can calculate the optimal threshold for each subgraph, we must optimize the objective function twice. The time comparison of the algorithm proposed in this article with fuzzy clustering and particle swarm optimization algorithms is shown in Figure 3.

Experiments show that compared with the calculation time of particle swarm optimization algorithm and fuzzy clustering algorithm, the calculation efficiency of the algorithm adopted in this article is obviously improved. The mean shift algorithm is used to divide the color image into several regions. The purpose of this step is to divide the image into related areas according to the color characteristics of the image. Similar to the steps of parallax optimization, the depth map has strict statistical correlation in a segmentation plane, and the plane consistency of the segmentation area of the depth map is used for optimization.

Calculate the image's boundary map, then find the path through the image on the boundary map with the least weight, and segment the image at the location with the lowest boundary cost. The image is continuously divided into two parts by searching for the optimal path in both vertical and horizontal directions, resulting in the superpixel of regular grid. The algorithm uses the minimum cut method and the dynamic programming method to find the best path. The former can generate nonregression paths, whereas the latter can generate arbitrary topological paths. When looking for the best path, make sure that no two vertical and horizontal paths cross and that each vertical and horizontal path crosses only once. We use two indicators, accuracy and recall, to verify the effectiveness of this algorithm and compare it to fuzzy clustering and particle swarm optimization algorithms, yielding the following results. The accuracy of the three algorithms is compared in Figure 4. The recall rates of the three algorithms are compared in Figure 5.

According to the proportion and number of segmentation points corresponding to the confidence matching points, it is divided into reliable areas and unreliable areas. For the reliable region, the template parameters are calculated by the weighted least square algorithm according to the confidence matching points. For the unreliable region, the calculated template parameters are unreliable. Using the adjacent good or bad region as the initial template, the final parameters of the unreliable region are obtained through global template parameter optimization. In each iteration, we first rank all the particles according to their contribution to the global optimal solution. In addition, considering the diversity of the population and the fitness value of the optimal solution cannot exceed the average, we will eliminate the particles that are lower than the average fitness value of the whole population.

The depth plane of each image segmentation area passes through the infrared camera, and the infrared light and the sensor receiving the infrared light are in different positions, so the blocked area has no infrared reflection, so the depth value is useless. In addition, the surface of highly bright

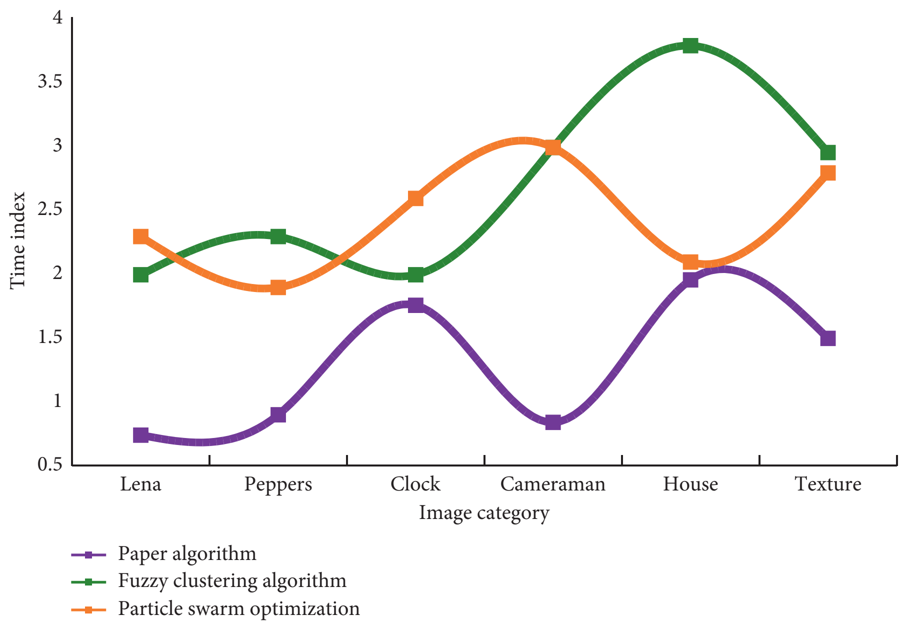

FIGURE 3: Comparison of calculation time of three algorithms.

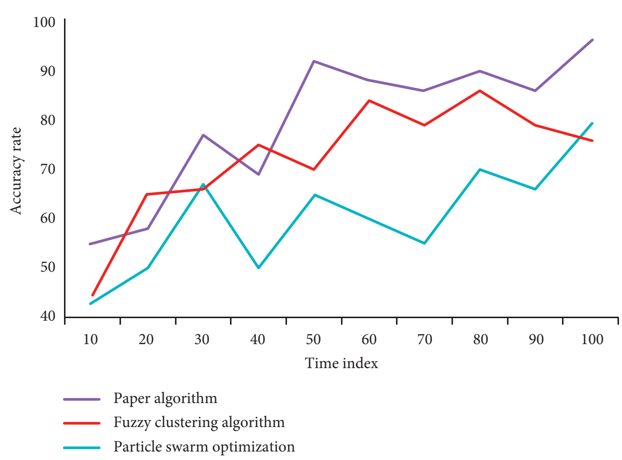

FIGURE 4: Comparison of accuracy of three algorithms.

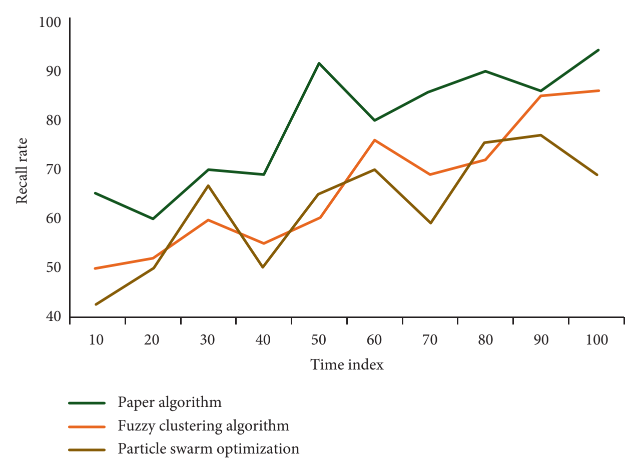

FIGURE 5: Comparison of recall rates of three algorithms.

object does not diffuse the infrared light, which leads to the receiving sensor not receiving the reflected infrared structured light. In order to better test the performance of the algorithm proposed in this article, we compare the proposed method with fuzzy clustering method and Otsu method. Figure 6 shows the comparison of experimental results of test images.

Different from most image threshold segmentation methods, the method proposed in this article combines the human visual characteristics with the threshold calculation process to automatically extract the target area in the image. The experimental results show that the binary image obtained by this method achieves good visual effect, and its overall visual quality is more in line with the visual perception.

Halftone image is essentially a special kind of binary image. Halftone image pays more attention to layering, whereas general binary image pays more attention to boundary information and contrast. In addition, compared with texture information and multiple gray levels of pixels, general binary images have richer structural information. The extraction method is adaptive and active, without user intervention or any prior information of the image to be segmented. Different input images get different initial contours, and the initial contour contains the target object of the image, which corresponds to the region of visual interest and also accords with the visual cognitive characteristics of human beings. Moreover, the saliency detection algorithm based on frequency domain analysis is simple and easy, with fewer adjustable parameters, and it will not add extra operation time when used in the preprocessing stage before image segmentation. The gray value of each pixel represents its significance, that is, the ability of the pixel to attract the attention of the observer. The larger the significance value, the more likely it is that the pixel is the region of interest, that is, the brighter the

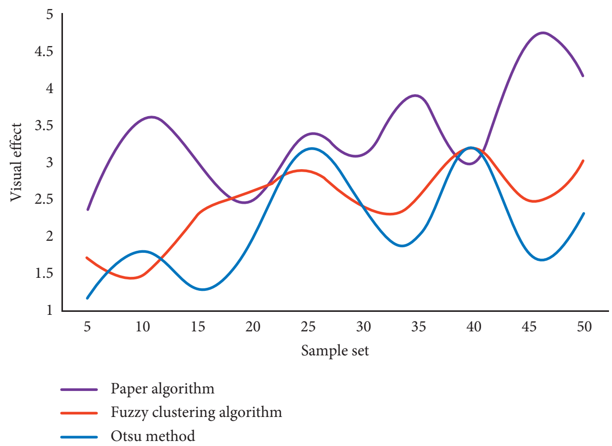

Figure 6: Comparison of image threshold segmentation results.

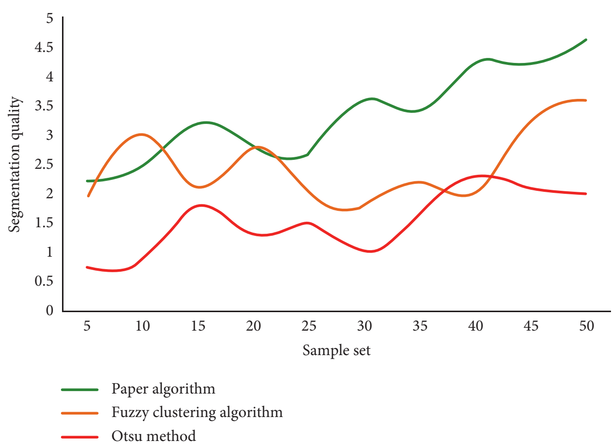

Figure 7: Comparison of segmentation quality of different threshold segmentation methods.

region in the saliency map, the potential position of the target object.

The image pixels are grouped and clustered, and the image plane is divided into a series of "meaningful" areas, based on the similarity criterion of some features or feature sets of images, greatly reducing the amount of data to be processed in later advanced processing stages such as image analysis and recognition, while retaining the information about image structural features. Using the original gray image as a reference image, we compare the visual quality of binary images generated by this method to that of other threshold segmentation methods. Figure 7 shows the segmentation quality evaluation results of different threshold segmentation methods.

It can be seen from the graph that the method proposed in this article achieves better scores compared with the other two image segmentation methods. Its segmentation quality is higher than that of fuzzy clustering method and Otsu method. This shows that this method has certain advantages compared with other methods, and the binary image generated by this image threshold segmentation method is more in line with human visual perception.

In this section, the active contour model and image segmentation application are updated to include the saliency detection mechanism of human visual cognitive characteristics, and the shape features of the target object in the image can be accurately described using knowledge of the image's bottom features. For various image contents and target objects, different initial contours are constructed adaptively. In the process of image segmentation, two subimages are first constructed in order to reduce the loss of main information from the original image during threshold segmentation, and the calculation of the optimal threshold is transformed into solving an optimization problem. After solving the objective function, the final binary image is created by analyzing the local properties of pixels. Various images were examined and compared with other threshold segmentation methods. Experiments and subjective and objective analysis show that the binary image generated by the proposed image threshold segmentation method is more in line with human visual perception.

5. Conclusions

Graphics in modern print advertising design can cross all obstacles, such as language, words, time, space, countries, nationalities, beliefs, and the like, and spread widely all over the world, blending and infiltrating with each other. Graphic vision really realizes the silent spread of advertisements. Modern print advertising plays an increasingly important role in modern political, economic, and social society, and the effect of its advertising communication is closely related to our industry. Only by deeply studying the related elements of print advertising and looking at the development of the whole discipline from the intersection of multiple disciplines, we can have a good grasp of its inherent laws. The visual creation of graphic advertisement is the perfect combination of science and art. Excellent visual creation of graphic advertisement can spread the information of advertisement and can also make the audience get a beautiful visual experience.

This article examines the innovation of graphic design vision in print advertising using image segmentation. From bottom-level image processing to image recognition and understanding, image segmentation is a critical step. Image threshold segmentation is a popular image segmentation method because of its clear physical meaning, high efficiency, and practicality. In the segmentation process, the threshold segmentation method only considers the image's grayscale characteristics and spatial information, ignoring the impact of vision on the segmentation results. In this article, the image's threshold selection process is combined with human vision characteristics, and the original image's information is presented in two subimages. The objective function is optimized by the optimization method to calculate the global optimal threshold of each subimage, and the visual information of each subimage is quantitatively described by human vision characteristics. Finally, the image is subjected to a local adaptive threshold operation based on the image's characteristics, resulting in segmentation results that are more in line with human vision perception. It can handle a wide range of graphics and image segmentation needs.

Depression is a severe mental illness with an unknown pathogenesis. Clinical diagnosis is based primarily on symptoms and does not include objective biological markers. Finding objective markers for diagnosis and treatment from imaging, on the contrary, is becoming increasingly important. The SOM (self-organizing feature mapping) model was used to identify the depression tendency of users in order to investigate the emotional experience and psychological intervention of patients with depression. On this foundation, the concept of depression index is developed further, and the relationship between depression index and the severity of depression in patients is thoroughly investigated. The system can accurately and quickly identify the depression state by applying it directly to the original EEG signals, without any preprocessing or feature extraction. When combined with traditional classifiers, the analysis and comparison results show that SOM can not only effectively select features but also improve the accuracy of depression classification. This research proposes a new research direction for deep learning in the context of large-scale big data analysis.

1. Introduction

Depression is a common emotional disorder with a high occurrence rate, a high recurrence rate, a high suicide rate, a high rate of disability, and a high social burden [1]. Currently, the rate of depression recognition is low, and the proportion of patients who can be identified and treated in a timely, sufficient, and adequate manner is even lower [2]. Depression is a complex negative emotional [3, 4] experience characterised by subjective distress. The most recent findings from the China Mental Health Survey are as follows. The six mental disorders (mood disorders, anxiety disorders, alcohol/drug addiction disorders, schizophrenia and related mental disorders, eating disorders, and impulse control disorders) accounted for 9.3% of the total, with mood disorders accounting for the majority of the cases. The prevalence of depression in the disorder was 3.4 percent over a lifetime and 2.1 percent over a 12-month period, respectively. Domestic and international experts and scholars have made significant progress in the study of depression in recent years [5]. These advancements include the exploration of aetiology and pathogenesis, as well as the development of new diagnostic criteria and the emergence of new and better treatments, particularly the emergence of a large number of new antidepressants, which have given patients with depression good news and enabled clinical doctors to provide more effective treatments.

SOM (self-organizing feature map) neural network [6–8] is an unsupervised learning method that imitates the characteristics of self-organizing signal processing in animal and human cerebral cortex. It can automatically extract the intrinsic important statistical features of samples according to the rules of samples. This makes it widely used in intelligent control, pattern recognition, computer vision, nonlinear optimization, signal processing, etc., and now, it has become one of the important fields of artificial intelligence research [9, 10]. According to the emotional recognition results based on EEG signals, medical staff can accurately judge the current mental state of patients and the real activity of the brain and guess the degree of their illness, so as to realize accurate nursing. Personalized nursing pays more attention to the patient's own characteristics, and a reasonable nursing plan is tailored according to the patient's condition, age, education level, etc., and comprehensive in-depth nursing is implemented to improve the recovery speed of patients. When the neural network makes a correct classification by identifying the key features that can depict brain diseases, the system is considered reasonable. On the contrary, although the final result is correctly identified, the neural network does not analyze the key features, but the peripheral factors even make decisions due to the correct identification of noise or interference. Obviously, the neural network cannot meet the medical requirements due to too high false positives.

At this time, research indicates that the mechanism of depression is primarily related to abnormal activity in emotional regulation brain regions, and a large number of studies have focused on specific brain regions and neural circuits, such as the prefrontal cortex, anterior cingulate cortex, and subcortical amygdala, hippocampus, habenular nucleus, and hypothalamus [11, 12]. Long-term use of antidepressants causes damage to the liver, kidneys, extra-vertebral system, and other organs, and the recurrence rate is very high after stopping antidepressants, so the psychological state of patients has not improved significantly, and patients frequently cannot receive appropriate treatment, and their prognosis is poor. The purpose of this study is to understand the emotional experience and psychological intervention of patients with depression, explore the effect of psychological intervention on their negative emotional experience, provide suggestions for clinical nursing, and provide reference for the majority of clinical medical staff to implement intervention measures for patients with depression.

2. Related Work

China's society is experiencing a high incidence of psychological problems, and depression has become a major social problem that plagues China. Social factors are directly related to the rising prevalence of depression. In [13], studies show that depression is a high-cost disease. Early detection and treatment, especially, early diagnosis and effective treatment by physicians in general hospitals, can reduce the course of depression and suicide and can significantly reduce functional impairment and medical resource consumption, thus reducing the total burden of depression. In [14], the study also found that the negative and rejection attitude of the public towards mental illness has changed little or even worsened over the years. Literature [15] holds that it is necessary to encourage the patient's spirit of tenacious struggle against the disease, mobilize the patient's subjective initiative to fight against the disease, and work with doctors to obtain the patient's cooperation and improve the curative effect. According to [16], identifying the harbinger of disease recurrence can encourage patients to see a doctor sooner rather than later, thereby controlling symptoms, significantly improving discharged mental patients' compliance, and effectively lowering the recurrence rate. Literature [17] examines 241 living relatives of 163 first-episode schizophrenia patients and finds that the proportion of patients with high emotional experience (50.3%) is similar to that reported by foreign countries, which shows that 54 percent of patients live in families with high emotional experience. In [18], the relatives of 56 anxiety disorder inpatients were followed for 9 months, and it was discovered that the recurrence rate of patients in the high emotional experience family group was significantly higher than that of the low emotional experience family group. In [19], the results of a study of 86 psychotic patients and their relatives revealed that patients with a lot of emotional experience had higher depression and anxiety scores, but no significant difference in psychotic symptoms. This study suggests that emotional experience may be more reliable than schizophrenia in predicting depression outcomes. According to [20], patients in the experimental group had a 9.1% one-year recurrence rate, while those in the control group had a 33.3 percent recurrence rate. The two groups differed significantly. Family intervention can help patients with schizophrenia have fewer relapses and improve their social functioning.

Early brain imaging studies based on voxel morphological measurement found that patients with unipolar depression had reduced gray matter volume, which was related to their psychopathology and cognitive dysfunction [21]. Literature [22] collected 40 subjects' emotional self-rating scale data and used Lasso regression to establish a two-category model of depression prediction. In [23], uUsing BPNN (BP neural network), the recommendation algorithm of industrial organization psychology under big data is constructed. Literature [24] has built an intermediary model, which shows that depression factors in families are influenced by family identity factors and insomnia factors. Thus, sleep quality, study, family identity, and other dimensions all have an important influence on depression, indicating that the diversity of dimensions also has a positive effect on the identification of depression. In [25], from the point of view of online healthy community users' comment analysis, this study analyzes how different factors affect users' comments in online healthy communities by building a user voting adoption model. In [26], through research, it is proved that users with mental illness in online healthy communities can get certain medical care decision information by communicating with others. Literature [27] classifies patients into different types for the purpose of using online healthy communities, analyzes the patients' network information behaviors, and finds that there are significant differences in personal health information management behaviors of patients with depression in online healthy communities. Literature [28] holds that family members with high emotional experience are more inclined to attribute the patients' symptoms to personal, internal, and controllable factors and that patients can try their best to change their problem behaviors, thus showing more negative attitudes, criticisms, and controllable behaviors.

To summarise, the emotional experience of depression patients is a multidisciplinary problem, involving medicine, sociology, and psychology. The widespread negative emotional experience of depression patients has had a significant impact on their rehabilitation and quality of life and is a roadblock in the development of health care. Psychotherapy research on emotional experience can gradually be expanded to other related fields of mental diseases, and further and deeper research can be conducted to investigate other factors that affect emotional experience and patient rehabilitation from a variety of perspectives, as well as to demonstrate the characteristics of these influencing factors in the disease progression process.

3. Research Method

3.1. Analysis of Emotional Experience of Patients with Depression. Social learning theory was put forward by American psychologist Bandura. Behavior acquisition is learned by observing and imitating others. Behavior, environment, and personal internal factors interact and influence each other, and environment plays a decisive role. And through the motivation of the group, achieve collective change and driving force. Other family members will adjust themselves to better adapt to life by observing and imitating benign behaviors in daily life.

A good family environment is conducive to the healthy development of every family member's body and mind, and it is the primary environment for one's survival. Family members have an impact on and interact with one another. The behavior, cognition, and emotional changes of one family member will influence the behavior, cognition, and emotional changes of others. The suffering that depression causes patients and their families is difficult to put into words. The emotional experiences of patients and family members have a significant impact on their rehabilitation and physical and mental health. The family emotional experience of depression can be improved, the mental health of family members can be improved, family harmony can be promoted, and depression patients' symptoms can be alleviated through targeted group counseling for family members, which can meet the actual needs of family intervention for depression patients more economically and effectively. It is a novel approach and method for depression patients' family intervention.

To explore the characteristics of brain activation in patients with depression under the task of positive and negative emotion induction and to test the hypothesis of emotional background insensitivity, during the experiment, each picture is presented as an experiment. The experimental process is as follows. First, the gaze point is presented for 2 seconds, reminding the subjects to pay attention to the center of the screen. Then, positive and negative emotional pictures are presented at the top of the screen, and the subjects are asked to pay attention to the emotional pictures and experience emotional arousal for 8 seconds. This study adopts the experimental design of randomized controlled study, and its specific technical route is shown in Figure 1.

After the experiment, the degree of instruction execution was checked, and all the subjects could understand the instruction and implement the instruction requirements during the experiment, including the distribution characteristics of family emotional experience of depression patients, the proportion of high emotional experience and low emotional experience, the mental health status of depression patients and their families, coping styles, and social support,. These studies are the basis of group counseling. Carry out group counseling research on family emotional experience intervention of depression patients, and design targeted group counseling implementation scheme based on the investigation of family emotional experience status of depression patients.

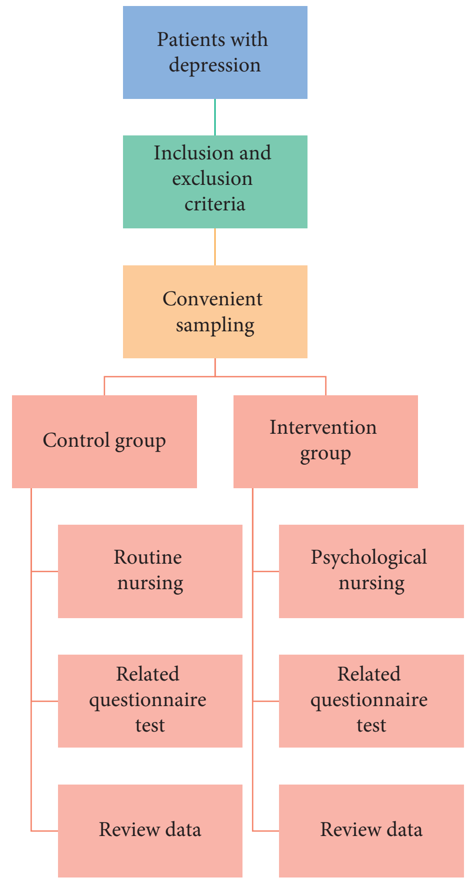

Figure 1: Schematic diagram of research route.

According to the scanning parameters and stimulus presentation mode, the statistical model is selected, the experimental variables and related time and space information are brought into the model, deconvolution is carried out according to the hemodynamic function, and the high-frequency and low-frequency images are filtered out by filtering so that the experimental design is fitted and the parameters are estimated.

Events directly affect a person's mental state, and they are also events that need certain psychological adaptation in individual life, including positive events and negative events. The former refers to events that trigger positive emotions of individuals, while the latter refers to events that trigger negative emotions of individuals. It is found that the frequency and severity of life events within two years are related to the onset of mental disorders. Negative life events and independent events may be important factors for the occurrence or recurrence of depression, while positive life events are obviously related to the occurrence or recurrence of mania. On the one hand, it shows that life events may be one of the causes of depression. On the other hand, it may be that patients' habitual defense style and its characteristics make them experience some negative life events more easily and actively than ordinary people, such as lovelorn or friends turning against each other.

3.2. Psychological Intervention of Depression Patients Based on SOM. As a subconscious response to conflict, a defense mechanism is a set of habitual adaptive behaviors that people use to avoid and relieve mental stress such as anxiety when confronted with a variety of frustrating situations. Patients with depression have different psychological defense styles, according to studies. Neurosis patients, including neurotic depression patients, use immature defense mechanisms more than mature defense mechanisms, according to a comprehensive study [21]. Qualitative research is sensitive to patients' subjective feelings and worldviews, which can elaborate their real experiences of diseases and health. Qualitative research encapsulates the overall concept of nursing and allows nurses to understand and feel the inner world of patients on a deeper level.

SOFM has two characteristics similar to human brain information mapping.

First, the topological mapping structure is not realized by the movement and reorganization of neurons, but a topological structure formed by each neuron in different excited states. Secondly, the formation of this topological mapping structure has the characteristics of self-organization [10]. The topological structure of the network is introduced into SOFM, and the concept of changing neighborhood is further introduced into the structure to simulate the side inhibition phenomenon in the biological neural network, so as to realize the self-organizing characteristics of the network. The SOFM mapping model is shown in Figure 2.

The network consists of an input layer and an output layer. The input layer receives signal input, and the output layer is a two-dimensional grid, which maps the output of network signals by self-organization. Each node in the two-dimensional plane grid is connected with the source node of the input layer. Each neuron in the output layer makes competitive selection in learning. The winning neuron not only strengthens itself but also drives the neighboring neurons around it to strengthen accordingly. Functionally, it can connect the change rules of individual neurons with the group change rules of one layer of neurons. After learning the network, the spatial distribution of the connection weight vectors among neurons in the output layer can correctly reflect the approximate distribution of the input pattern space.

PC (principal construct) projection is the intermediate variable of PC analysis algorithm. It is the projection matrix from the original large sample data to small samples. This method not only reduces the computation of the later algorithm but also retains the original features. Consider the projection of the sample on the PC:

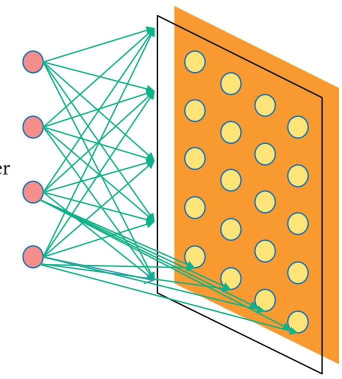

Figure 2: SOFM mapping model.

$$\eta_d = \frac{\lambda_1 + \lambda_2 + \cdots + \lambda_d}{\sum_{i=1}^{n} \lambda_i},$$
$$y_{mi} = x_m p_i = \sum_{k=1}^{n} x_{mk} p_{ki}. \tag{1}$$

It can be seen from the above formula that the projection of each data point in the original dataset on the PC is a linear combination of all the original features, and the effect of each feature on the new features can be expressed by the elements multiplied by it in the projection matrix. Therefore, the projection matrix can also be expressed as

$$C = [v_1, v_2, \cdots, v_n]^T, v_i = \{p_{i1}, p_{i2}, \cdots, p_{i\,d}\}. \tag{2}$$

For each original feature, there is a line component corresponding to it, and the correlation between original features is closely related to the similarity of line components. Therefore, the original data $X_{m\times n}$ are converted into a projection matrix $C_{n\times d}$ by PC projection, the sample size of the original data is reduced from m to d, and the original feature number is maintained.

The learned "distributed feature representation" vector is mapped to the sample tag space by the full connection layer, and the tag $\overline{y}$ of Weibo content text, that is, positive, neutral, and negative probability distribution, is discriminated. The calculation formula is as follows:

$$p(y \mid s) = soft\max(w \cdot v^* + b^*),$$
$$\overline{y} = \arg\max p(y \mid s). \tag{3}$$

Among them, $y \in R$ is the true emotional tag of Weibo content, which is expressed by unique heat coding. $\overline{y} \in R$ is the emotional tag vector of Weibo content obtained through training. For each predicted emotional category probability, the tag with the highest probability is selected as the output.

When judging the depression tendency of online users from the perspective of text analysis, the depression index of users is calculated by the proportion of depression Weibo to the total Weibo number of users, so as to measure the depression tendency of users in a certain period of time. A depression index based on online healthy community is proposed, and the calculation formula is as follows:

$$DI = \frac{N_{cd}}{2N_{ct}} + \frac{N_{md}}{2N_{mt}}, \tag{4}$$

where N_{cd} refers to the number of Weibo posts with depression tendency published by users in other accounts within a certain period of time, N_{ct} refers to the number of Weibo posts published by users in other accounts within a certain period of time, N_{md} refers to the number of Weibo posts with depression tendency distributed and forwarded by users in personal accounts within a certain period of time, N_{mt} refers to the number of Weibo posts distributed and forwarded by users in personal accounts within a certain period of time, and DI is the depression index.

The time complexity of the whole sub-SOFM is calculated as follows:

$$O(S(N, L)) = O\left(\sum_{l=1}^{d} n_{l-1} \cdot s_l^2 \cdot n_l \cdot m_l^2\right), \tag{5}$$

where l is the index of convolution layer and d is the depth, n_l is the number (also called width) of filters in the lth layer, n_{l-1} represents the number of input channels in the lth layer, and s_l^2 and m_l^2 represent the spatial size of the filter and the size of the output feature map, respectively.

LSTM (long short-term memory) network is a special RNN (recurrent neural network), which can learn long-term dependent information. Through a special design, long-term information can be remembered. The core idea of LSTM is similar to a conveyor belt. The characteristic information is placed on the conveyor belt, and there is only a small amount of linear interaction so that the information can circulate on it and remain unchanged. LSTM has a well-designed structure called “gate” to remove or add information.

Besides text information, there are other types of feature information that can be used in the analysis of depression tendency prediction to help improve the recognition rate. Because these features are time-sequential and change with the interview, this section uses LSTM to study the audio features of each time stamp. Finally, combining the prediction results of the three features, the following prediction collaborative classification prediction models are given, as shown in Figure 3.

The predicted results of the test set based on these three characteristics are brought into the function expression, and the results between 0 and 1 are obtained. If the calculated result is greater than or equal to 0.5, it will be counted as 1, and if it is less than 0.5, it will be counted as 0.

4. Results’ Analysis and Discussion

After experiencing the emotional group counseling, members fill in the feedback form of group counseling activities and evaluate the whole group counseling. All members feel that group counseling has a lot of gains, as shown in Figure 4.

It can be seen that the psychological intervention activities of the group members (including the arrangement of psychological intervention game activities and group atmosphere) as well as the group members themselves (including self-expression, satisfaction, and harvest, among other things) have been greatly affirmed. Excel calculates the arousal rating of depression patients and normal CG emotions (1–4 grades, representing “almost no feeling,” “weak,” “strong,” and “very strong”), as well as the average value for each group. There was no significant difference in arousal degree evaluation of neutral, positive, and negative emotional materials and CG in patients with depression, according to the findings (Figure 5). The arousal degree evaluation of positive and negative emotional materials is consistent, and it is higher than the arousal degree evaluation of neutral emotional materials.

The images collected at different time points are corrected at the same time point. Due to the differences of anatomical structures of different individuals, the functional images of individuals are registered with templates, and the brains of individuals are registered into the standard MNI space for functional localization of activation areas. Gaussian smoothing adopts the full width at half maximum of 8 mm to improve the signal-to-noise ratio and make the smoothed image obey the nature of random Gaussian field. For positive emotional stimulation, the differences of brain activation areas induced by two groups of subjects are shown in Figure 6.

Independent double sample T test was used to compare the brain activation areas and their intensity of emotional stimulation materials with a different potency in depression group and normal CG emotional evaluation task. For negative emotional stimulation, the differences of brain activation areas induced by two groups of subjects are shown in Figure 7.

The differences in brain activation of negative emotional stimulus materials between the two groups are as follows: the activation of right posterior cingulate gyrus, anterior cingulate gyrus, and right anterior wedge lobe in depression group are less than that in normal CG. The descriptive statistics of behavioral results show that the arousal degree of positive, medium, and negative emotional materials in the patient group is lower than CG, in which the arousal degree of positive and negative emotions is consistent and higher than that of neutral emotions, and the arousal degree of positive emotions is slightly lower than that of negative emotions.

Only the activated and weakened brain regions were discovered in the patient group when positive emotion induction was used, and only the activated and enhanced brain regions were discovered when negative emotion induction was used. Negative feelings activate the brain more than neutral or positive feelings. Patients with depression may have a negative bias in their emotional responses, but this hypothesis must be tested against normal CG. The anterior cingulate gyrus was activated in normal people under both positive and negative emotional conditions, which is consistent with the previously reported nonselective activation of anterior cingulate gyrus potency [18]. Dorsal cognitive control system includes the anterior cingulate gyrus. The anterior cingulate gyrus and the prefrontal cortex are jointly responsible for cognitive control, with the prefrontal cortex performing the majority of the control process and the anterior cingulate gyrus determining whether the

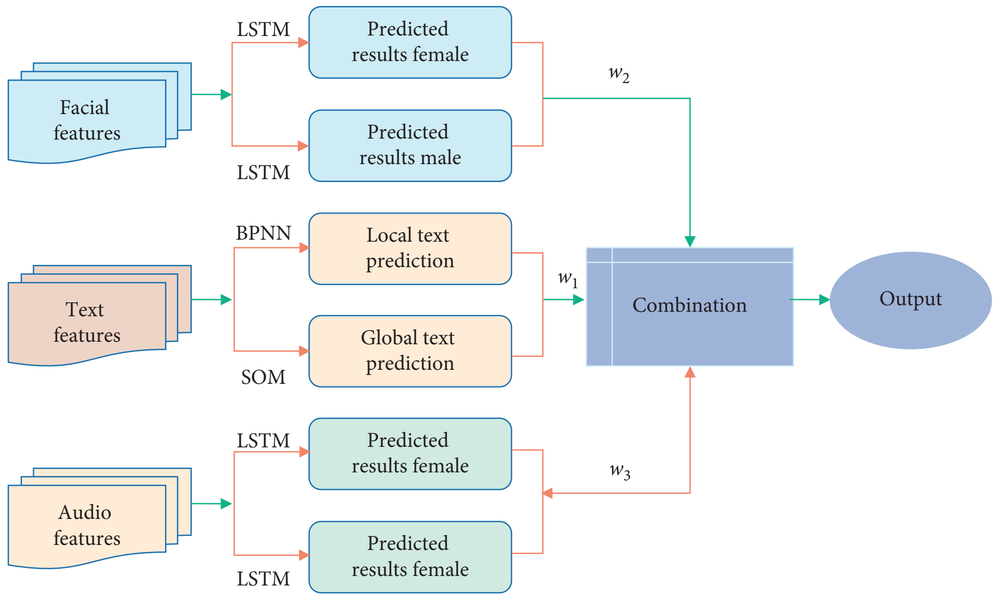

FIGURE 3: Comprehensive model.

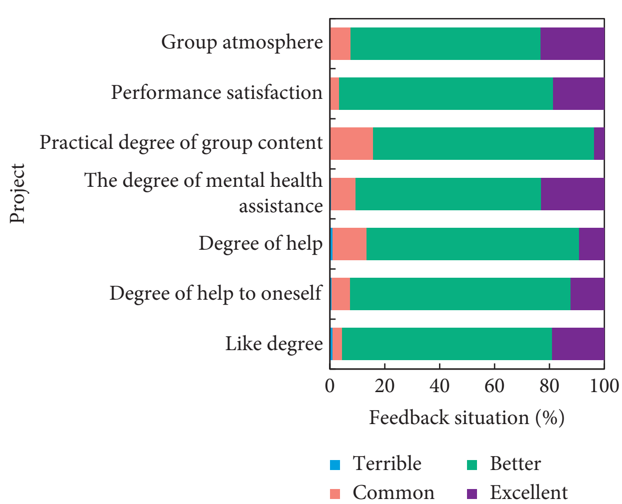

FIGURE 4: Psychological intervention effect feedback.

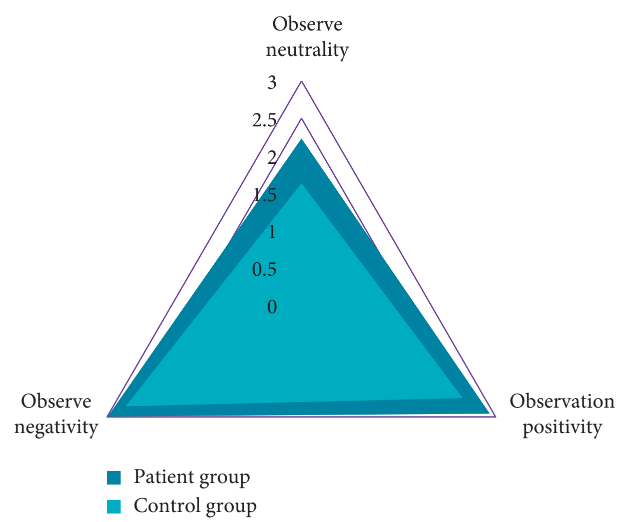

FIGURE 5: Awakening degree evaluation.

control process needs to be changed based on the degree of reaction conflicts and errors.

It was found that the activation of anterior and posterior cingulate gyrus and right anterior cuneiform lobe was weakened under the condition of negative emotion induction in patients with depression. When comparing the positive and negative emotional evoked conditions of depression patients horizontally, it is found that these areas are not activated compared with neutral conditions. Therefore, it is speculated that the activation and weakening of these areas is not caused by emotional valence, but there is abnormality in the level of nerve spontaneous activity or basic activity. This part of the study did not make a deeper discussion about it.

As can be seen from Figure 8, the immature defense style and intermediate defense style of depression group are significantly higher than those of CG, but there is no significant difference between mature defense style and masking factor.

Great changes in the environment are the source of stress for many people. When the stimulus event breaks the balance and load capacity of the organism or exceeds the individual's ability, it will be reflected in stress. These stimulus events include all kinds of situations from outside or inside, collectively referred to as stressors. Researchers have found many ways to study the relationship between life events and health. It is found that the frequency and severity of life events within two years are related to the onset of mental disorders. Negative life events and independent events may be important factors for the occurrence or recurrence of depression, while positive life events are obviously related to the occurrence or recurrence of mania. The results show that the frequency of negative life events and the total intensity of life

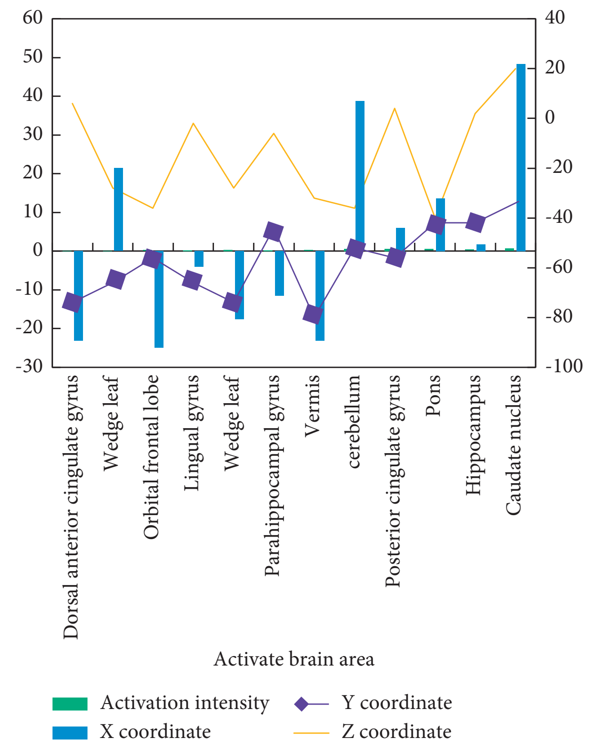

Figure 6: Localization and intensity of brain activation difference in positive emotion evaluation task.

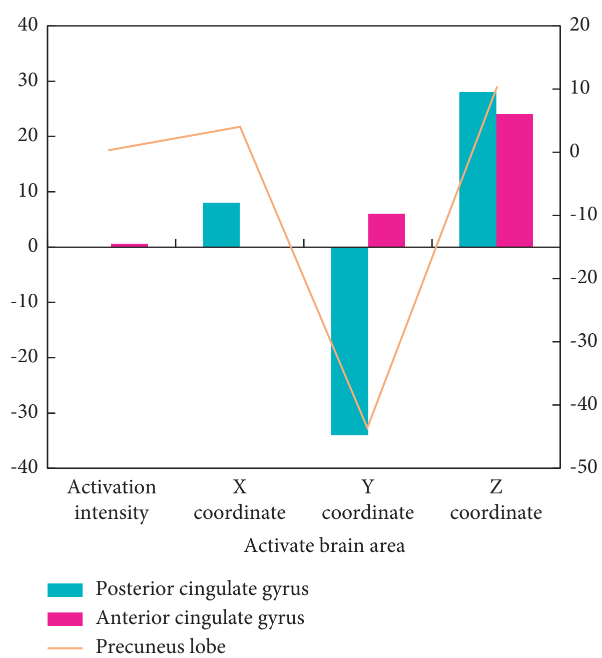

Figure 7: Differences of brain activation differences in negative emotion evaluation tasks.

events in depression group are higher than those in CG, and there are significant differences. This shows that, with the increase of the frequency of negative life events and the total intensity of life events, the possibility of individuals suffering from depression will increase.

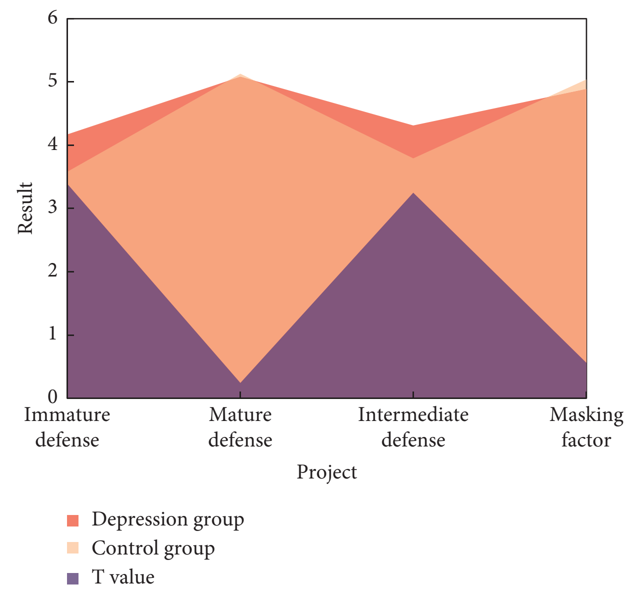

Figure 8: Comparison of the results of two groups of defense style questionnaires.

Some people in the CG have a higher frequency of negative life events and a higher total intensity of life events, whereas some people in the depression group have a lower frequency of negative life events and a lower total intensity of life events, suggesting that the occurrence of negative life events can help us predict or explain the occurrence of depression in general. Any event may have different meanings for different people. The same life events and different cognitive styles will have different effects on individuals. As some scholars have pointed out, life events can affect mental health in two ways: one is direct influence and the other is indirect influence through intermediary variables.

In this study, there is no significant difference between the mature defense mechanisms of depression group and CG, which also show that the defense mechanisms are mixed and not used independently. Even in depression patients, mature defense mechanisms will be used, but the frequency that depression patients may use immature and intermediate defense mechanisms is much higher than that of them. Instead, take these three defense mechanisms as a whole. Psychological problems such as depression are not caused by the obstacles in the use of certain defense mechanisms, but related to the imbalance in the use of immature defense mechanisms, intermediate defense mechanisms, and mature defense mechanisms.

The F1-score of four variants of SOM and the control model in different depression grades are shown in Figure 9.

The classification performance of SOM in this study has obvious advantages over CG. Compared with other models, SOM (especially mul + add) can better and more accurately identify people with severe depression, which is very valuable in the screening of depression. Therefore, by comparing with the control model, it can be seen that the deep neural network model designed in this study shows a good classification ability, and the introduction of factor

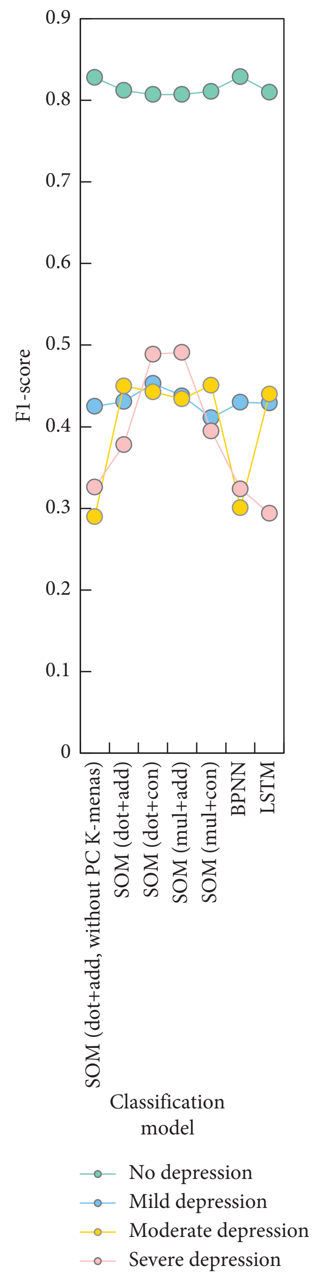

Figure 9: Classification of each depression level F1-score.

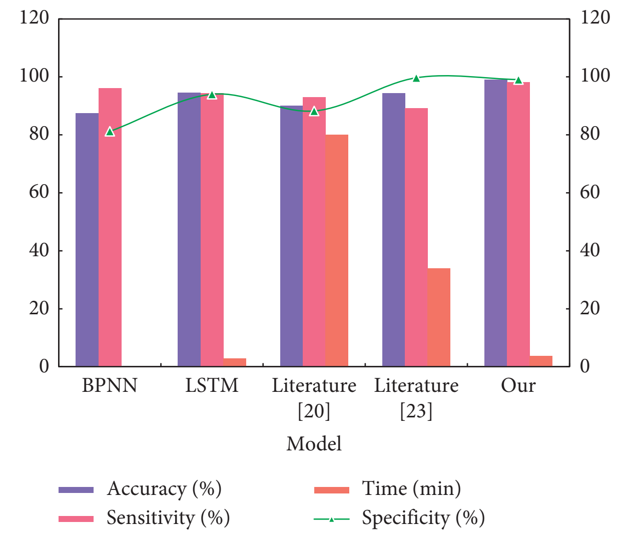

Figure 10: Comparison of classification performance of correlation methods.

decomposition machine also plays a significant role in optimizing the network structure.

On the same dataset (MPHCs emotional experience G data), different classifiers are used to classify depression, and the classification performance indicators are shown in Figure 10.

Figure 10 shows that the classifier proposed in this study is the best in all classification indexes, and the higher sensitivity and specificity also indicate that the classifier can effectively screen out not only depressed patients but also normal people.

According to psychologists, the narrator's process of putting past fragments and scattered experiences into complete stories is a way for the narrator to actively give meaning to changes in his or her life and bring order to disorder, which is therapeutic for the narrator. Hospital administrators should allocate medical human resources appropriately so that medical staff have enough time to sit down and communicate with patients, provide appropriate opportunities for patients to talk about their inner pain, patiently listen to their inner voice when they need it, provide emotional comfort when they are in pain, and truly enter their hearts and earn trust. They walk alongside them to help them overcome depression and pain, stay away from death's edge, and rediscover the meaning and value of life.

5. Conclusion

This study proposes a research method of emotional experience and psychological intervention in patients with depression based on SOM. In the face of depression-scale big data, the SOM algorithm of PC projection automatically selects the optimal feature subset on the basis of retaining the original feature space, thereby eliminating redundant information in depression-scale big data. The identification of the user's depression emotional state is divided into the judgment of the depression emotional tendency of a single text and the judgment of the user's depression state to measure the user's depression and depression. Interpretation results of the complexity of the SOM show that the classifier effectively captures the intrinsic characteristics of depression. The abnormal emotion regulation in patients with depression is mainly manifested in two aspects: one is that it is difficult to use cognitive resources needed to enhance positive emotions through cognitive reappraisal, and the cognitive control ability declines; secondly, cognitive reappraisal weakens negative emotions. It is difficult to call the required cognitive resources, and cognitive control ability declines, but it also fails to effectively reduce the activation of brain regions related to emotional evaluation.

Indoor three-dimensional layout has a strong application background, such as virtual office three-dimensional layout planning, museum three-dimensional layout planning, and cave scene three-dimensional layout planning, which have been widely used in telecommuting, education, tourism, and other industries. In view of this, this paper proposes an indoor landscape reconstruction method based on VR (virtual reality) and draws indoor landscape information and images by using VR technology to generate an indoor landscape reconstruction panorama. A model is established to correct the distance error and reflectivity error of depth image, improve the accuracy of the depth image, and finally improve the accuracy of three-dimensional indoor scene TDR (three-dimensional reconstruction). In the process of optimizing layout, the Monte Carlo sampling method is used based on the Markov chain, and constraints are used as density functions to guide layout sampling and generate a number of reasonable scene layout suggestions in the iterative process of the sampler. Experiments show that this method can provide scientific and reasonable guidance to users' scene layout and help them complete the furniture layout quickly.

1. Introduction

With the vigorous development of VR (virtual reality) technology and the continuous emergence of new devices, TDR (three-dimensional reconstruction) has become a hot research topic in the field of computer vision [1]. The main task is to build a three-dimensional model of the real physical world based on the data collected by various sensors, using mathematical tools such as multiview geometry, probability statistics, and optimization theory, and building a bridge between the real world and the virtual world [2, 3]. The design inspiration of three-dimensional indoor scenes often comes not from simple imagination but from the backwardness of existing scene designs, and there happen to be a large number of realistic scene images on the Internet. In practice, when collecting large amounts of scene image data, such as crowded shopping malls, it is inevitable that dynamic objects will appear, which greatly limits the application of the TDR algorithm in real life [4]. Three-dimensional layout planning of indoor scenes is one of the key research contents in the field of computer vision and an important part of autonomous navigation and unknown environment model reconstruction of mobile robots.

At present, three-dimensional point cloud data acquisition methods are based on a three-dimensional laser scanner and RGB-D camera. The former point cloud based on laser scanning is of high quality, less influenced by the surrounding environment, and is usually used in outdoor large-scale scenes. Because the equipment is complex to operate, inconvenient to carry, and expensive, which usually reaches millions of levels, it is not convenient to collect indoor point clouds [5, 6]. The 3D point cloud reconstruction method based on vision camera mainly uses a multiview stereo geometry algorithm [7]. The motion recovery structure algorithm is an important off-line TDR method that uses several images of a scene to recover the pose of each exposure point and create a three-dimensional point cloud at the same time. It is characterized by time-consuming calculations, but the reconstruction results are extremely accurate [8]. It is necessary to develop an information-based interior color design method based on computer VR technology in order to help users better understand the effect of interior color design and to make it easier for designers to create interior color designs that are more in line with customers' wishes and needs. As a result, the current research hotspot is holographic image based on laser technology, and the research foundation is model building of 3D layout planning of 3D indoor scenes. Data collection, automation degree, model building range, and other issues plague traditional model building of 3D layout planning of indoor scenes [9].

At present, the application in 3D indoor scene design is mainly done by VR technology, which has a good reconstruction effect for noisy animated scene images, and also helps to enhance the realism and immersion of scene design, so as to realize the optimal design of 3D indoor scene model. With the development of deep learning research, some researchers have also proposed an end-to-end method based on deep learning, which is used to directly infer indoor 3D layout from image data. This kind of innovative method is very attractive, but the results often lack accuracy and rigor. Compared with traditional methods, there are still some big defects in practical application. In order to facilitate the reasonable reconstruction of 3D indoor scenes, this paper proposes a brand-new 3D scene modeling method based on VR technology, which mainly solves the two core problems of restoring 3D scenes from a single picture and optimizing the layout of scenes. Based on the solutions of these two problems, the corresponding prototype system of picture scene restoration and layout is designed and implemented. The research in this paper not only makes it convenient for users to get pictures from the Internet and restore picture scenes quickly with little interaction but also puts forward diversified layout suggestions on this basis, which enriches the established 3D scenes.

2. Related Work

TDR of the three-dimensional indoor scene based on RGB-d sensor spans many fields such as computer vision and robotics. The author of [10] analyzes the calibration of the Kinect v1 sensor and analyzes its depth image information in terms of accuracy and resolution. This paper studies how to use Kinect v1 to build a dense 3D map of the indoor environment for robot navigation, semantic mapping, and remote presentation. The author of [11] studied the physical measurement principle and capability of TOF technology used in the depth image of Kinect v2 sensor and its error source analysis and put forward a new calibration method of Kinect v2 sensor. The experiment verified that the calibration effect of the two open-source calibration methods was improved, and the reconstruction of a single image was effectively simplified by introducing appropriate interaction. These methods mostly started from the image's own information and realized the geometric reconstruction of a single image by interactively specifying the vanishing point information and any variables, but there were some limitations. The data-driven suggestion method is introduced into 3D modeling in [12], allowing artists to easily use existing 3D models for innovation. To achieve the idea of redesigning a 3D model, their method combines graphics, retrieval, and connection technology among graphics. The improved random sampling consistency algorithm in [13] can effectively eliminate outliers in feature point matching, allowing the SLAM (simultaneous localization and mapping) algorithm to maintain its high robustness in a dynamic environment. The author of [14] proposes Dyna SLAM, which uses a Mask R-CNN network to identify and segment dynamic objects based on prior information, and then repairs the background after removing the dynamic objects. It not only removes dynamic objects but also repairs the background area that has been blocked by dynamic objects and accurately reconstructs the map of pure static scenes. The author of [15] predicted the boundary characteristics of the cavity area using a convolution neural network model combined with a color image and a depth image and realized the filling of the cavity area through function optimization. This method works well and preserves details, but it is heavily influenced by the training data set and takes a long time to learn.

Three-dimensional point cloud is the most basic representation method of three-dimensional scenes, and furthermore, algorithms are needed to mine the scene structure information and semantic information contained in it. The characteristics of buildings in the indoor virtual environment are different from those in the outdoor environment. When building in the indoor environment, the density of the 3D indoor scene needs to be considered. This paper presents a method of constructing solid geometry based on 2D, which can build a more complex indoor layout in layers. The author of [16] focuses on automatic methods to reconstruct the basic semantic information of interior layout, including walls, doors, and windows. The author of [17] proposed a plan reconstruction method based on the Manhattan world hypothesis, so as to reconstruct the visual layout of the room. The author of [18] also proposed an indoor structure reconstruction method based on the Manhattan world hypothesis. The image method is also used in [19] to synthesize the model's facade, and the use of texture allows users to see the real street scene. A data-driven method for generating the room layout of the building plane was proposed in [20]. 120 architectural schemes were used in their study to train a Bayesian network to determine the relationship between rooms. The author of [21] encapsulates architectural design knowledge into an expert system, allowing it to assess the evaluated architectural plane in accordance with government regulations and interior design guidance, and then provides reasonable revision opinions. A similar method for furniture layout is used in [22]. Every furniture object will be connected to its parent, and the constraint relationship between parent and child objects will be specified ahead of time. However, as the number of furniture models in the model library grows, the relationship between parent and child models must be specified on a regular basis, which is a time-consuming task.

3. Research Method

3.1. 3D Indoor Scene Reconstruction Based on VR Technology. Color camera of RGB-D sensor collects color images, while infrared camera collects depth images. They all calibrate based on the pinhole model and establish the transformation relationship from 3D world coordinates to 2D image coordinates. Before using any camera, it is necessary to calibrate it, and so is the RGB-D sensor. It is necessary to get the internal and external parameters and distortion coefficient of the RGB-D sensor.

RGB-D image hardly changes in scenes such as changing illumination and complex background, but the image is affected by environmental noise and equipment noise when shooting, so it is impossible to encode the depth of every point in space. To improve the rationality of segmentation, the following types of points are removed:

Boundary point: in a neighborhood of image pixels, the local normal consistency is used to judge boundary points, which mainly include object edges, high curvature edges, and occluded scene edges.

Missing points of data [2]: when acquiring scene data, there are some areas that are not perceived, which leads to data missing.

According to the above definition, the boundary area is excluded in a neighborhood of each pixel, and the calculation formula is

$$A(c) = F \sin(a, b), \tag{1}$$

where $\sin(a, b)$ represents a pixel; F is the image boundary area.

The input image is over-segmented using an image segmentation algorithm [23, 24]. Although the scene cannot be correctly segmented, the segmentation result can be used as the over-segmentation result. Usually, the corresponding retrieval is completed by calculating the matching degree between the image features of the 2D object and the projected image features of the 3D model in the library. Therefore, the retrieval process will mainly involve the following main issues: how to unify the 2D object and the 3D model into the same representation form and analyze the features; what matching mechanism is used for efficient retrieval?

The viewpoint coordinates are converted to spherical coordinates, and binary $\langle \phi, \theta \rangle$ is used to represent the deflection angle of viewpoint relative to the model, ϕ is used to represent the horizontal deflection angle, and θ is used to represent the rigid deflection angle

$$\begin{aligned} \phi &= \arctan \frac{\sqrt{X_E^2 + Y_E^2}}{Z_E^2}, \\ \theta &= \frac{\pi}{2} - \arctan \frac{Y_E}{X_E}. \end{aligned} \tag{2}$$

To keep all two-dimensional models consistent with the structure of the object to be built, all scene observation viewpoints should be projected under this viewpoint. The basic process of sparse point cloud reconstruction based on incremental TDR is depicted in Figure 1, which is divided into two parts: image feature matching, camera pose recovery, and spatial structure recovery.

To begin, geometric constraints are used to filter out mismatches in the initial feature point matching pairs. Basic and essential matrices are two of the most common geometric constraints. Second, two images must be chosen in order to reconstruct the initial model. The use of two good images for initialization is crucial in the TDR algorithm. The global optimal solution will not be found if the initialization falls into the local minimum. By performing a beam adjustment on the model reconstructed from the two initial images, the initial model can be made more accurate. Because of noise, calculation errors, and certain errors in image feature matching, errors in camera pose estimation and 3D coordinate restoration occur in incremental TDR every time a new image is added. The cumulative error increases as the number of images increases, resulting in poor TDR results.

Assuming that the number of images participating in TDR is n, and C_i is the internal participation and external parameter of the i th image, m three-dimensional space points are reconstructed, the coordinate of the j th three-dimensional space point is X_j, and the objective function optimized by the beam adjustment method is

$$g(C, X) = \sum_{i=1}^{n} \sum_{j=1}^{m} w_{ij} \left\| q_{ij} - P\left(C_i, X_j\right) \right\|^2, \tag{3}$$

where w_{ij} is the indicator variable, which represents whether point j exists in image i, if point j is in image i, w_{ij} is 1; otherwise, it is 0. $P(C_i, X_j)$ is the coordinate of point j on image i after projection transformation, and q_{ij} is the actual image coordinate of point j on image i.

In practice, Levenberg–Marquardt algorithm is usually used to iteratively optimize the minimum reprojection error [10], which is the most widely used nonlinear least square algorithm, and its iterative formula is as follows:

$$\Delta = -\left(J_f^T J_f + \lambda I\right)^{-1} J_f^T f, \tag{4}$$

where λ is the weight parameter; when $y\,\lambda$ is large, the above formula is the gradient descent method with a small step size, and when λ is small, it is the Gauss-Newton method.

The process of solving the optimal value is that after one iteration, when the objective function drops successfully, the value of λ will be reduced; otherwise, the value of λ is increased and iterated again. After several iterations, the optimized parameter variables can be output when the error value is less than a certain threshold.

3.2. Research on 3D Indoor Scene Layout. In reality, it is common for people to need to decorate a new room when they move in. Sofas, coffee tables, televisions, tables, chairs, and benches are frequently arranged in disarray at this time, and people frequently want to know how to arrange these items to create a comfortable, beautiful, simple, and generous new home. There are some established rules to guide experienced designers on how to lay out furniture, such as in a living room, how to lay out furniture to make it easier for people sitting in different positions to talk, how to consider the room layout reasonable, visual balance, and compactness.

The input of this chapter is the furniture model randomly placed by users. Based on the functional rules such as pairing and conversation and visual rules such as balance

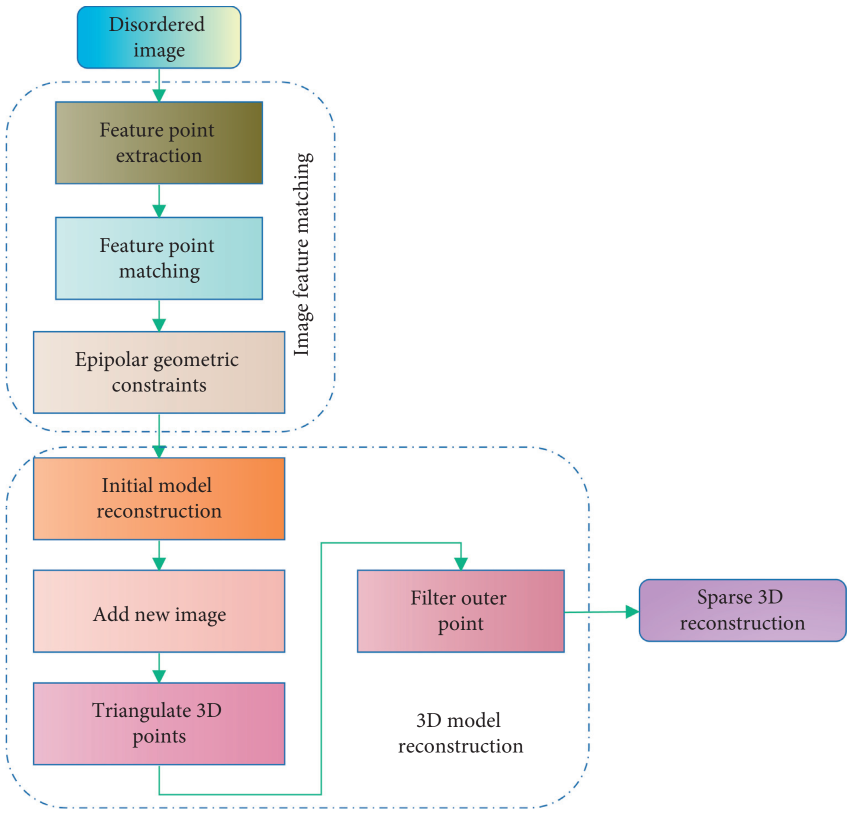

Figure 1: Basic flow chart of sparse TDR.

and neatness, a series of reasonable furniture layout suggestions are obtained through Markov chain Monte Carlo sampling. The flow of the whole algorithm is shown in Figure 2. Next, the algorithm flow of each stage is briefly introduced.

The layout proposal is generated by sampling through the density function, which associates the defined rules and represents the layout state of the furniture collection in the current space. The sampling method adopts the Markov chain Monte Carlo method to optimize and display different furniture layout suggestions through iteration and state transition.

The functional rules of furniture layout are based on human physiological constraints and the influence of spatial layout on human behavior. The statistics of human physical characteristics, such as body size and shape, are called anthropometry. Conversation comfort is often affected by the relative placement of seats, and strong factors such as sight, body orientation, and speaking distance all greatly affect conversation comfort. People's normal walking is similar. It requires that the layout can make a person walk around the room unimpeded without being affected.

For many furniture, it is necessary to reserve a certain space around them so that people can walk to the furniture or make the furniture work normally. The furniture onto a two-dimensional plane is projected, and the constraint space to Minkowski sum of furniture projection is added, thus defining a set of formulas J_F that describe the areas of individual furniture and surrounding space. We use $C_{cv}(I)$ to minimize the overlapping area of the surrounding space of different furniture.

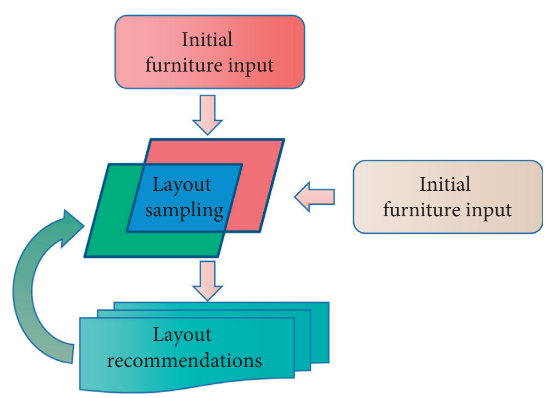

Figure 2: Method is not intended.

$$C_{cv}(I) = \sum_{f,g \in J_F \cup \{\overline{R}\}} A(f \cap g). \quad (5)$$

Among them, $A(\cdot)$ represents the area operator, $\overline{R}$ represents the polygon area of the room, and J_F is estimated from the area of the whole room.

The following are the methods for optimizing and designing indoor color using VR technology: the entire interior scene of a home is modeled, as well as individual models of each room, and then presented in a three-dimensional model. First and foremost, two-dimensional graphics must be collected and input, which is done using cameras. Following the creation of the two-dimensional model, the computer converts it into the corresponding three-dimensional model. The 3D model is then given a second color design and a corresponding light rendering. The final step in creating a 3D indoor scene is to improve the details of all types of furniture. Other objects can be used as an aid to help the 3D indoor scene achieve a more realistic simulation effect, assuming the number of models has been fixed.

u is defined as the distance from floodlight to plane, k is the radius of attenuation distance of long-distance light, and g is the corresponding display lamp distance. If there is a line segment n perpendicular to the light source on the x axis, and the corresponding number of light sources is m, then the corresponding illumination brightness is obtained according to the following formula:

$$W\left(x_j\right) = \sum_{j=1}^{m} W_j\left(x_j, \rho_j\right). \tag{6}$$

The simulation effect corresponding to indirect light is obtained, and the lighting feeling with perfect color brightness in indoor home design is realized.

In order to facilitate more convenient and intuitive color matching, different furnishings and furniture of indoor homes can be colored by establishing different material units to ensure more flexible color matching and higher efficiency. The materials are relatively independent, and they can be superimposed on each other to ensure the richness of colors. The material unit can be widely applied to tables, chairs, sofas, pendants, doors, and windows in indoor home design.

Then, geometric modeling of indoor object models is carried out by using laser holographic images. After mapping and color simulation of the built models, the 3D indoor scenes and models are further optimized to form a 3D layout planning model of example scenes that can be displayed by laser holographic images [8].

Because the RGB-D image sequence is not an accurate result in the layout prediction of new layout instances, there are certain layout conflicts, such as the phenomenon that the functional areas across the wall and the functional areas overlap [10]. Therefore, in the layout planning of 3D indoor scenes, the occlusion edges in RGB-D images are calculated, mainly including no wall penetration, no overlap, and no door blocking. The constraint conditions are set as follows:

$$E = \sum_{i=1} \frac{d\left(a_1, a_2, \cdots, a_n\right)}{A}, \tag{7}$$

where $a_1, a_2, \cdots, a_n$ represents wall-crossing constraint, door-blocking constraint, and overlapping constraint, respectively; $\sum_{i=1} d$ represents the description parameter of layout information.

When planning a path for a more complex indoor environment, it is necessary to browse and switch the indoor environment, determine the path to be planned, select the navigation type that can be used for path planning, and select the key position in the indoor environment and the key position of the data in the holographic image. Then, the set related service parameters are imported into the navigation service item, and the expression state of the result is finally determined so that the holographic image can perfectly express the 3D indoor scene [16].

4. Results Analysis and Discussion

Indoor point cloud reconstruction based on VR technology is an important basic work in this paper. A key improvement point on this issue is the combination of real-time reconstruction and off-line reconstruction. In off-line reconstruction, feature matching and incremental reconstruction processes are enhanced for the prior information of position, and attitude is obtained through real-time reconstruction.

In this paper, four algorithms, 4PCS (4-points congruent sets), PFH (point feature histogram), FPFH (fast point feature histograms), and NDT (normal distribution transform), are used to test two pieces of indoor point cloud data, respectively. At the same time, in order to enhance the comparability, the parameters set by these four algorithms are all the optimal parameters. After running in vs2017 + pcl environment, the result is shown in Figure 3.

From the error analysis in Figure 3, it can be seen that the 4PCS algorithm divides the original two disordered point clouds into upper and lower layers, and the initial attitude of the target point cloud has been well corrected, but the stability of the algorithm is not strong. Through a large number of parameter adjustments, this paper finds that the above-mentioned effects are random, and the generated results will be different every time the program is run. Comparing PFH and FPFH algorithms, although the basic principles of these two algorithms are similar, they can correct the attitude of the target point cloud.

Compared with 4PCS algorithm and NDT algorithm, it is obviously much higher, so it is not suitable for the real-time registration and splicing of point clouds in 3D indoor scenes, which makes it unsuitable for the real-time construction of 3D indoor scenes. Through the above analysis, it can be concluded that although the grid parameters of the NDT algorithm are the key to its registration accuracy, its high registration accuracy and high running efficiency will become the preferred coarse registration algorithm in the construction of 3D indoor scenes.

Through ICP (iterative closest point) fine matching operation, the positions of the point clouds to be matched have been greatly adjusted, and they are more coincident with the corresponding points. As mentioned earlier, a good initial position is the key to determine ICP fine matching. Figure 4 shows the algorithm's time-consuming and error analysis.

It can be seen from Figure 4 that the FPFH algorithm and PFH algorithm are not suitable for the real-time construction of 3D indoor scenes in terms of registration accuracy or running efficiency. Although the registration accuracy of the 4PCS + ICP algorithm is high, when the overlapping area of two point clouds is small, this algorithm runs unsteadily and takes a relatively long time. Experiments show that the NDT + ICP algorithm is obviously superior to other algorithms in registration accuracy and running efficiency, and it is effective for point clouds of 3D indoor scenes.

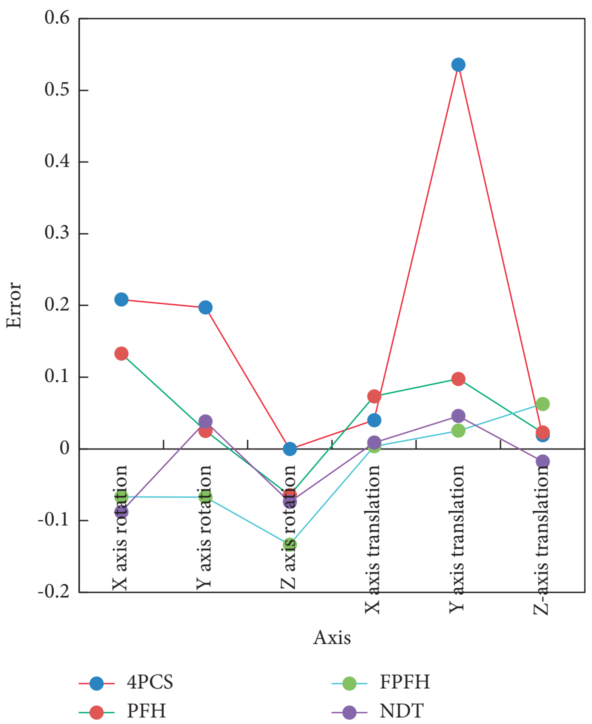

Figure 3: Error analysis.

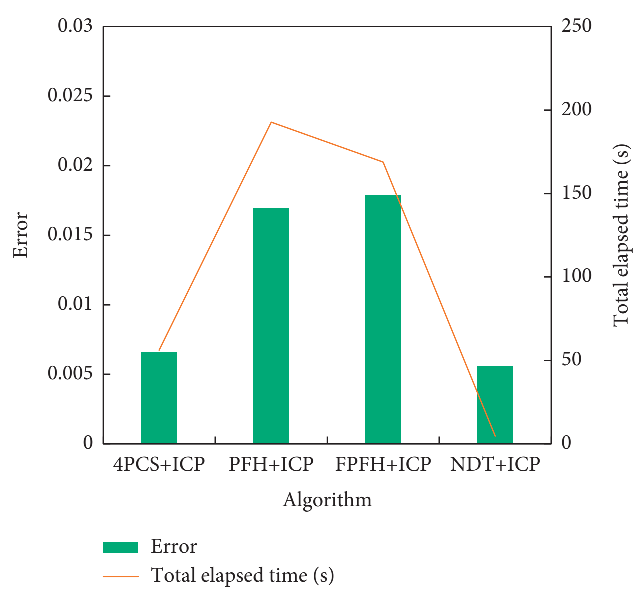

Figure 4: Algorithm time-consuming and error analysis.

The original point cloud scale represents the number of 3D points in the reconstructed dense point cloud, the preprocessed point cloud scale represents the number of 3D points in the point cloud after downsampling, statistical denoising, and smooth resampling, the number of candidate wall faces represents the number of candidate wall faces after plane fitting, plane merging, and plane classification, and the number of reconstructed wall faces represents the number of wall faces in the final room layout after optimal solution.

In order to establish the model of the relationship between reflectivity and depth values captured by different types of sensors, this paper designs and utilizes strip plane templates with six different gray levels. The gray value of the plane is divided into six levels, and the reflectivity of each level is shown in Figure 5.

The proposed neural network-based model is trained by optimizing the polynomial logistic regression objective using the RMSprop algorithm. There are five hidden layers in both Kinect v1 and Kinect v2. This procedure entails adjusting various parameters on a regular basis in order to achieve the desired results. The test set contains 260 data points, based on the above distribution ratio because the total data set used in this paper is 1300. The experimental results are shown in Figures 6 and 7.

Using this more than intelligent postcorrection neural network, for Kinect vl, depth accuracy is increased by 1.1 mm and depth accuracy by 4.3 mm. Meanwhile, for Kinect v2, the depth accuracy is increased by 115.6 mm, and the depth accuracy is increased by 0.3 mm. However, the author of [12] used the most advanced correction method to obtain the depth accuracy of its report. In addition, the results of the previous method are compared with those of this method, and it is found that the accuracy and precision of this method are better than those of the previous methods.

The room is encircled by white walls, storage cabinets, and glass walls, among other things. Many weak textures and repetitive and nondiffuse reflection environments present significant challenges for the motion recovery structure algorithm. Although the visual inertia odometer results are used for spatial local matching, cumulative drift errors are introduced into the incremental motion recovery structure algorithm, causing wall reconstruction artifacts.

The experiment will compare the data collection effects of the two methods in 3D indoor. The two methods not only collect the overall conditions of 3D doors and windows, buildings, and rooms but also collect the details of indoor modules, floors, and network structures, which can more comprehensively reflect the advantages and disadvantages of the two methods in data collection. Figure 8 shows the comparison of the two experimental methods in data collection.

According to the comparison results in Figure 8, it can be seen that the proposed method has a better effect in indoor data collection. It mainly applies a variety of key algorithms to optimize and analyze indoor-related data and also carries out unique data collection ideas according to the characteristics of data, which effectively improves the efficiency of data collection.

The relative motion between the static object in the scene and the camera is caused by the camera's motion, whereas the motion of the dynamic object in the scene is affected by both the camera's relative motion and its own motion at the same time, so the motion of each dynamic object differs from the motion of the static object in the scene. The number of moving objects in the image influences the number of static and dynamic feature points, and the number of dynamic and static feature points influences the estimation of camera internal and external parameters. The effect of the number of moving objects in the scene on the TDR algorithm is discussed using various numbers of moving objects. The

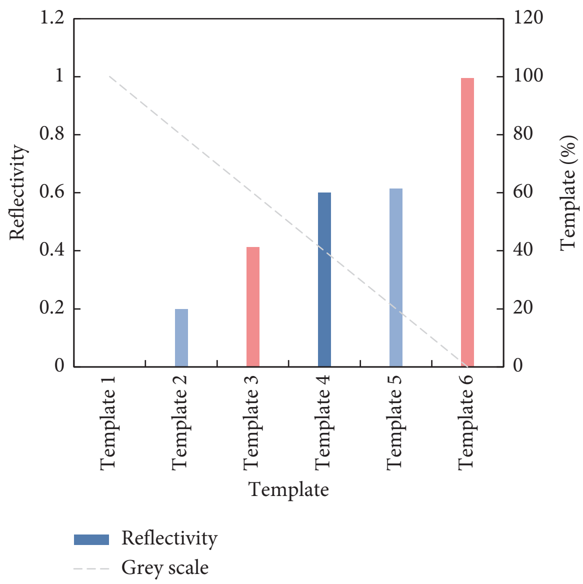

Figure 5: Reflectivity of different gray levels.

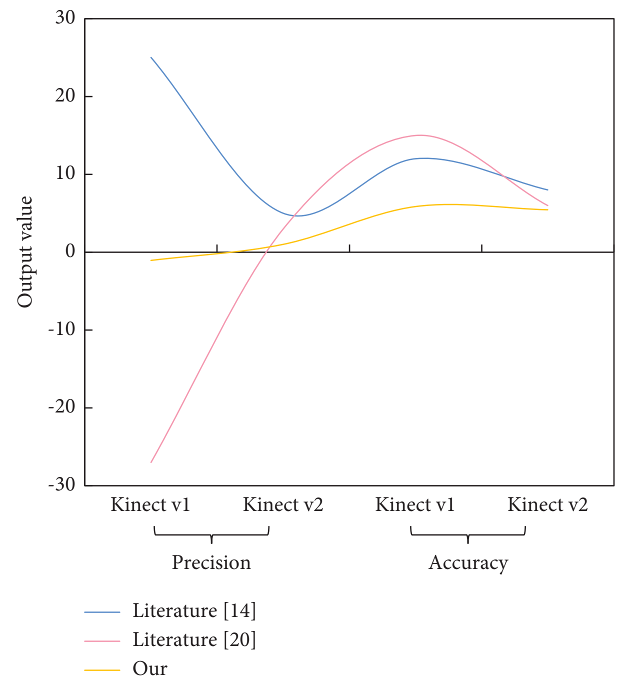

Figure 7: Comparative result.

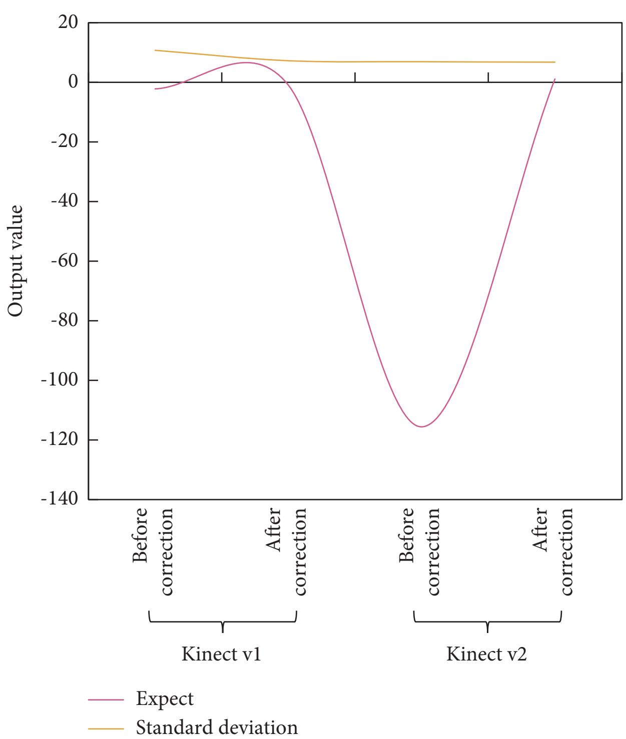

Figure 6: Expected value and standard deviation.

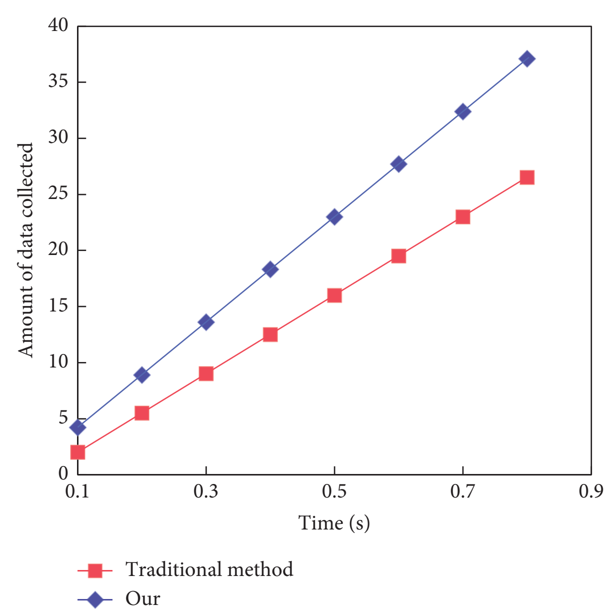

Figure 8: Comparison of effectiveness in data collection.

bedroom group's experimental data were subjected to the same TDR experiment, with 380 images in total. Three experiments were carried out, including 90 single moving targets, 90 multiple moving targets, and no moving targets. Detailed reconstruction data results are shown in Figure 9.

The experimental scenes are the living room and bedroom. Each scene is set with three modes, namely, no dynamic objects, single dynamic objects, and multidynamic objects. TDR is carried out before and after removing dynamic objects. From the experimental results, it can be seen that the reconstruction effect after removing dynamic objects is better than that without removing dynamic objects, and the reconstruction effect of single dynamic objects is better than that of multidynamic objects. In the 3D target test of the reconstructed point cloud model, more accurate recognition results can be obtained.

In the aspect of the indoor effect, not only the indoor path is optimized but also the effects such as details coloring and details perfection are carried out on the already built model. However, the traditional method lacks the adjustment of

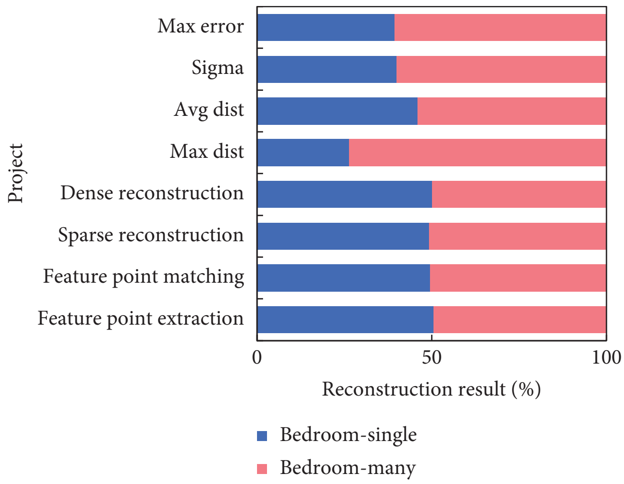

Figure 9: Reconstruction result of bedroom scene after removing dynamic objects.

details, which makes the layout planning of 3D indoor scenes too monotonous to immerse users in images.

5. Conclusion

A digital model of indoor landscape reconstruction can be created using VR technology. Dense TDR is realized in a 3D indoor scene using an RGB-D sensor, and real-time operation is achieved for an extended period of time using only the CPU. Experiments show that when the initial position and pose of the two point clouds are good, the ICP algorithm is ideal, and there is no problem with finding the local optimal solution. Experiments show that, based on the characteristics of indoor point clouds, the NDT + ICP registration scheme can achieve ideal registration and mosaic results in terms of time and accuracy, which can be used to construct 3D scenes in real time. A layout recommendation method based on the Markov chain Monte Carlo sampling method can complete diversified furniture layout recommendations quickly and efficiently with little interaction. However, based on the current research, the model deformation method will be introduced into the modeling process, which will be changed according to the model's own style, in order to obtain a layout result that is more realistic with the actual scene.

Data Availability

The data used to support the findings of this study are included within the article.

Based on the concept of responsible holistic nursing care, a whole-process dual-tutor nursing practice model is established and its application effects are explored. This paper firstly reviews the research progress of nursing workload prediction methods at home and abroad, in order to provide a reference for clinical nursing workers in China to choose a scientific, reasonable, and easy-to-use nursing workload prediction method. It is proposed to construct a nursing education management model based on small data to provide ideas and references for nursing education management to effectively predict the evolutionary trend of students' behaviour and improve the level of accurate services. The experimental group adopted a dual-tutor responsibility system for the whole-process nursing practice model, including a complete three-level supervision system: a dual-tutor teaching system, a PDCA responsibility system for continuous improvement, and a multichannel teacher-student interaction platform; the control group adopted the traditional nursing practice model.

1. Introduction

In recent years, with the acceleration of the internationalization of medical education and the localization of international standards, nursing education has taken on the multiple missions of optimizing the cultivation of talents, leading to the development of disciplines and deepening the connotation of the profession, and the development of education needs to adapt to the development of social economy, the progress of science and technology, and the coordination of health undertakings [1]. The former Ministry of Health and the Ministry of Education jointly put forward the strategic point of building an integrated teaching mode of industry-university-research and clearly defined the development goal of deepening teaching reform and cultivating higher technical application talents [2]. The former Ministry of Health and the Ministry of Education jointly put forward the strategic point of building an integrated teaching model of industry-academia-research, specifying the development goal of deepening teaching reform and cultivating higher technical application-oriented talents. The changes in the clinical environment have put clinical nursing education in a new period of conceptual transformation and practical reform, and it is one of the core issues of nursing higher education to realize an effective interface and buffer between theory and practice and to explore a clinical practice model that fits the cultivation objectives of higher nursing education at this stage [3].

The information system-based nursing workload forecasting method refers to the use of information system retrieval and statistical functions to present medical order entries and nursing project data that reasonably and effectively reflect nursing workload so as to analyse and forecast nursing workload [4]. Currently commonly used in the USA is the GRASP nursing management information system (Grace Reynolds Application and Study of Peto, GRASP), which predicts workload and manpower in advance by forming a database of nursing workload for different categories of patients, depending on the type of patient admitted each day [5].

The GRASP system divides nursing items into 11 categories with 50 nursing operations and assigns a fixed number of points to each operation based on the average time spent on each item, plus a certain percentage of delay or fatigue time points to predict work hours and prospectively arrange manpower [6]. In Singapore, scholars developed a nursing intensity system based on nursing diagnosis, which identifies the type of nursing diagnosis based on the type of intervention performed on the patient, quantifies the relationship between the nursing time required and the type of nursing diagnosis through a regression equation, and obtains the number of patients with different nursing diagnoses to predict the nursing work hours required per shift [7]. In addition, Japan has developed a Nursing Care Assignment Management (NCAM) system to visualise daily workloads and use the quantified workload data to efficiently assign staff and tasks [8]. In China, scholars have used the Hospital Information System (HIS) to obtain and predict workload data. In [9], the HIS system was combined with the work hour measurement method, and the nursing work hours of each operation were correlated with the frequency of HIS medical orders to establish an HIS-based nursing work our database. The relationship between the number of nursing hours and the number of nurses was calculated by linear regression analysis; for example, Nephrology: number of nurses $= 1.577 + 0.030x$ working hours, predicted nursing manpower required for tomorrow $= 1.577 + 0.030x$ total nursing hours of yesterday $\div$ actual number of admissions yesterday $\div$ expected number of admissions tomorrow. By programming the formula into the information system, the manager only needs to enter the number of hospital admissions for tomorrow to predict the number of people who will work on tomorrow.

Nursing projects are mostly derived from doctors' orders and nursing workflows and are selectively retrieved from information systems in a simple and operational way [10]. Overseas information systems mainly quantify the categorisation of patient need and use statistical analysis to identify the relationship between patient categories and workload, thereby predicting the number of nursing hours required for each category of patients and allocating manpower. Domestic information systems are based on the prediction of workload purely statistical nursing items to get nursing workload, but due to the imperfect data dictionary of information systems, in practice there are many non-chargeable items and indirect nursing work that are not included in the dictionary of medical advice, such as health education, linen change, material collection, and so on, which cannot be directly retrieved for statistics. In addition, the different information system environments of individual hospitals, the fact that standard nursing hours have not yet been unified, and the lack of uniform standards for screening nursing items make the results of some scholars' research not universally applicable and externally applicable [11, 12].

The contributions of this article are as follows:

This article proposes to build a nursing education management model based on small data, which provides ideas and references for nursing education management to effectively predict the evolution of student behavior and improve the level of precise service.

Based on the in-depth analysis of the concept and characteristics of small data, we design a dynamic portrait label system from two aspects of student surface behavior and deep driving factors and propose a research method to realize dynamic portrait and form an overall framework model.

The experimental group adopts the whole-course dual-mentor responsibility system holistic nursing practice model and comprehensively evaluates the two groups of nursing students, investigating the professional identity of the nursing students, the evaluation of the internship model, and the satisfaction of patient care services.

2. Related Work

2.1. A Predictor-Based Approach to Nursing Workload Prediction. Predictor-based methods for forecasting nursing workload are based on statistical methods such as regression analysis, which explores the factors inherent in nursing workload data, use the main influencing factors as predictors, and identify parameters to be determined in order to construct a mathematical model, followed by regression modelling of the identified predictors using polynomial Logistic, LASSO, and other methods [13]. Common predictors used overseas include Hours Per Patients Day (HPPD) [14], Case Mix Index (CMI) [12, 14], and International Classification of Function (ICF) [15].

In addition, studies have also shown that the Unit Activity Index (UAI), the number of discharges, transfers, or discharging (Admitting, Transferring, or Discharging Patients (ADT)) [16] have a positive impact on the inclusion of workload prediction. Reference [17] used multiple stepwise linear regression analysis to identify the factors influencing work hours and used them as classification factors to build a query table of direct nursing hours and indirect nursing hours required by different categories of patients. The table was used to identify the factors influencing the working hours and use them to establish a table of direct nursing hours and indirect nursing hours required by different categories of patients for dynamic manpower deployment. In [18], the results of a survey in a general adult ward in a tertiary care hospital showed that there was a linear relationship between the Barthel Index and Simple Clinical Score (SCS) of patients and the 24-hour direct nursing hours of patients, and a mathematical model using least squares and multiple linear regression was developed to identify the nursing hours of patients in different levels of care, thus enabling prediction of nursing workload.

2.2. Grey Dynamic Model. Grey systems theory consists of the use of dynamic predictive models to process incomplete small sample "information-poor" data to establish a quantitative relationship between the present and the future on a timeline, through which things can be predicted [19]. Nursing workload is the result of a combination of internal and external environmental factors, such as patients, environment, and nurses, which are covered by grey information. In contrast, workload measures are specific and defined, covered by white information, and meet the requirements for predictive modelling of data grey systems [20]. Reference [21] used a grey system prediction model to quantitatively predict trends in nurse performance, using 12 nurses in the unit as the study population and selecting four months of performance for each nurse as the basic data for modelling and predicting nurse performance over the next five months. Nursing performance is a quantitative assessment of nurses' workload, and the prediction of performance can indirectly help managers predict workload, scientifically set work standards, and reasonably assign work tasks.

2.3. Time Series Models. Time series models are forecasting methods that apply mathematical models to describe the changes in variables over time and their development patterns, that is, predicting their future values from the past and present values of the time series. The Autoregressive Integrated Moving Average Model (ARIMA) is one of the most widely used and well-known time series forecasting methods, which is able to integrate seasonal, trend, and random disturbance factors and has good forecasting function, and is gradually used in the field of health care [2]. Reference [22] used the ARIMA model to predict daily patient occupancy in a short-term acute care ward for optimal management of human resources, and the results showed that the model predicted with high accuracy for up to one week, which is a good guide for managers. Reference [23] used an ARIMA model prediction combined with linear correlation and regression analysis to obtain a predictive model for the number of obstetric outpatient card builds and deliveries. Reference [24] used time series analysis to construct a time series prediction model for daily nursing workload in the neurology department.

2.4. Discrete Event System Simulation. Discrete event simulation (DES) is a method of experimenting with computer simulation of discrete events for evaluating, predicting, and optimizing the efficiency of existing systems. The DES model was used by [25] to predict caregiver demand in a nursing home. Data on the daily care needs (ADLs) of older people were collected and entered into the DES model to predict the relationship between care workload and staffing to meet the daily care needs of older people so as to determine the optimal staffing for different care needs. Reference [26] collected 1 month of inpatient care data from a general hospital in Canada into the system and logically simulated the impact of different nurse-patient ratios on quality of care as well as nursing workload to help managers predict and optimally manage nursing workload. Discrete event simulation is a nurse-centred approach to workload prediction.

3. Questions to Ask

3.1. Small Data. The concept of small data was first discovered by Professor D. Eestrin of Cornell University, who believed that students' health could be dynamically monitored through the tracking of a full range of data on their daily behaviour [27]. There is no clear definition of small data, but it is accepted that small data is a collection of all data on a person or team-centred, multilevel behavioural pattern, and situational awareness. Over time, these data collections have become richer and richer, providing a powerful support for dynamic mining of student needs and preferences and behaviour patterns. Current research on small data focuses on personalised recommendations and accurate services, interest discovery and prediction, and theoretical discussions on the fusion of small data, but there is a lack of conceptual concepts for building academic app portraits based on small data.

3.2. Nursing Education Management Student Portrait. Traditional student portraits only capture data at a certain point in time; that is, they abstract a static model of a student's reality and history based on their behavioural characteristics, habits, and other data tags. A dynamic portrait of a student in nursing education management is one that introduces a time segment based on a conceptual picture of the student and uses a scientific approach to dynamically and continuously outline trends in the behavioural trajectories of students as they interact with the platform.

4. Overall Design

The dynamic portrait model based on small data proposed in this paper places more emphasis on the relevance and three-dimensionality of the labelling system. Therefore, the process of the small data-based student profiling model for nursing education management should be divided into four segments, as shown in Figure 1:

Step 1. Design a three-dimensional dimensional label that includes deeper drivers of student behaviour from a small data perspective, combined with the characteristics of nursing education management.

Step 2. Collect and preprocess student data-based on the dimension labels.

Step 3. Classify the data according to the temporal information in the student microdata and use clustering algorithm to cluster the data in specific time segments to classify students into different groups and build a time-phased portrait, which will be stored in the database.

Step 4. Based on the time-phased portrait, identify the cluster centres of each time period (the cluster centres can be regarded as the typical representatives of the group of students).

The above design process not only refers to the basic aspects of traditional student profiling, but also incorporates the special features and requirements of the small data based dynamic profiling proposed in this paper, which ensures practical value and innovation.

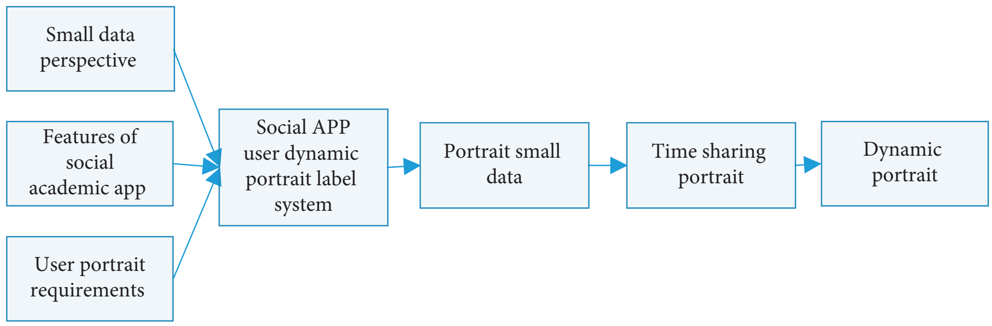

Figure 1: The process of constructing a student portrait for nursing education management based on small data.

5. Nursing Education Management Systems and Small Data Acquisition

5.1. Label Dimension. The psychological activity of students is an intrinsic factor that underpins behaviour, and any behaviour is driven by certain intentions before it occurs. Social psychologist Levin developed the field dynamics theory to analyse the driving forces and behavioural change processes that underpin individual behaviour. Field dynamics theory consists of field theory and dynamics theory, in which field theory defines "field" as the overall form of interdependence between the individual and the environment, also known as individual life space (LS). The individual's psychological and behavioural processes always take place and move within this space, which can be expressed in a functional equation as

$$B = f\left(P^{*}E\right) = f\left(LS\right), \tag{1}$$

where B represents the externalised behavioural expression. P represents the intrinsic needs of the individual, E represents the psychological environment, that is, the situation that stimulates the intrinsic needs of the individual, and f is a function of the interaction between the individual and the environment. Thus, field theory considers individual behaviour as a result of the interaction between the subject and the situation.

5.2. Small Data Collection. Based on the field dynamics theory and the characteristics of nursing education management, this paper argues that the factors driving student behaviour in nursing education management include students' value orientations, cognitive abilities, situational characteristics, and social relationships. Combining the two basic factors of student natural attributes and behavioural preferences, a six-dimensional portrait system is constructed, as shown in Figure 2. The internal relationship of each dimension is as follows: students' natural attributes and behavioural preferences are the basic framework of the portrait, while values, cognitive abilities, situational characteristics, and social relationships drive the production of behaviour, among which values and cognitive abilities are driven by students themselves, that is, internal drive P, and situational and social situations are the stimulus of external situations (i.e., trigger). E. Behavioural preferences are the external effect of the combination of natural attributes, values, cognitive abilities, situational characteristics and social relationships. E. Behavioural preferences are the externalisation of a combination of natural attributes, values, cognitive abilities, situational characteristics, and social relationships.

Basic student information and care data are stored in the administration backend; behavioural preferences can be obtained from behavioural data stored in student logs and student-generated content; value orientations can be obtained by mining student-generated content or through research methods such as questionnaires and interviews (e.g., targeted electronic questionnaires distributed by the platform to understand students' visions and current needs); cognitive abilities can be obtained from authentication data submitted by students and analysis of interaction data. Cognitive skills can be obtained from student submissions and interaction data analysis; situational awareness can be obtained from sensors, location systems, and smart wearable devices; social relationships can be obtained from log mining and social network analysis.

5.3. Small Data Processing. In the past, most of the data used in student profiles were basic attribute data and behavioural data, which could be coded and transformed numerically or simply processed for direct experimental analysis. This paper builds on this foundation by incorporating comment or posting text (i.e., content features). The professional and domain-specific nature of nursing education management and the fact that students' nursing topics are often related to their own specific domains makes it possible to mine and analyse students' areas of interest from the textual content. Therefore, this paper proposes a text data modelling approach based on the LDA topic model (see Figure 3):

Step 1. The text content was collected, stitched, and stored as text documents by student IDs, cleaned and imported into the domain word list for Chinese word separation and deactivation filtering, and the original text was cut into a sequence of feature words; then, the TF-IDF was used to calculate feature word weights from both word frequency and importance perspectives, and important feature words were retained.

Step 2. Use the easy-to-use Gibbs sampling in the LDA (Latent Dirichlet Allocation) topic model to mine the

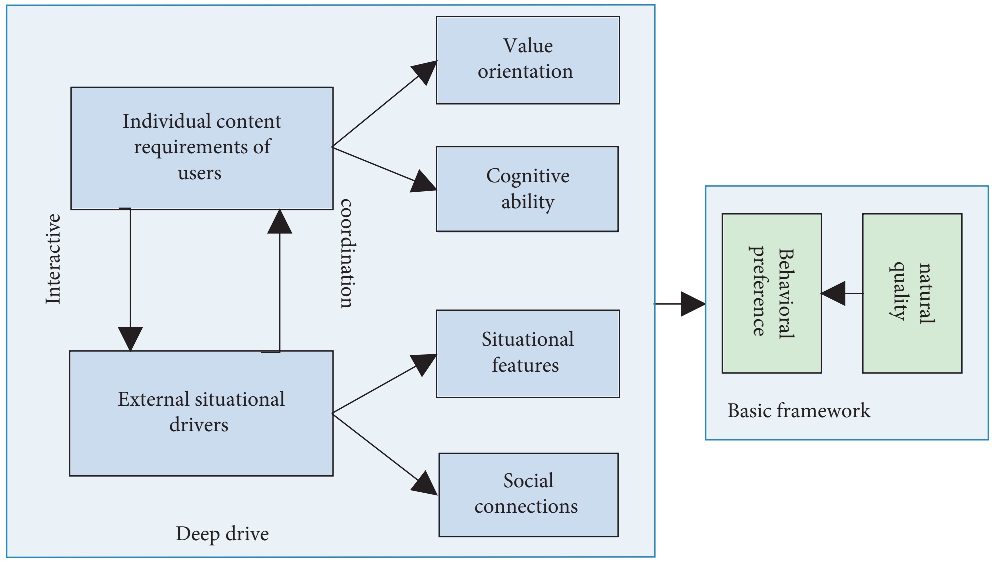

Figure 2: System of nursing education management student portrait dimensions.

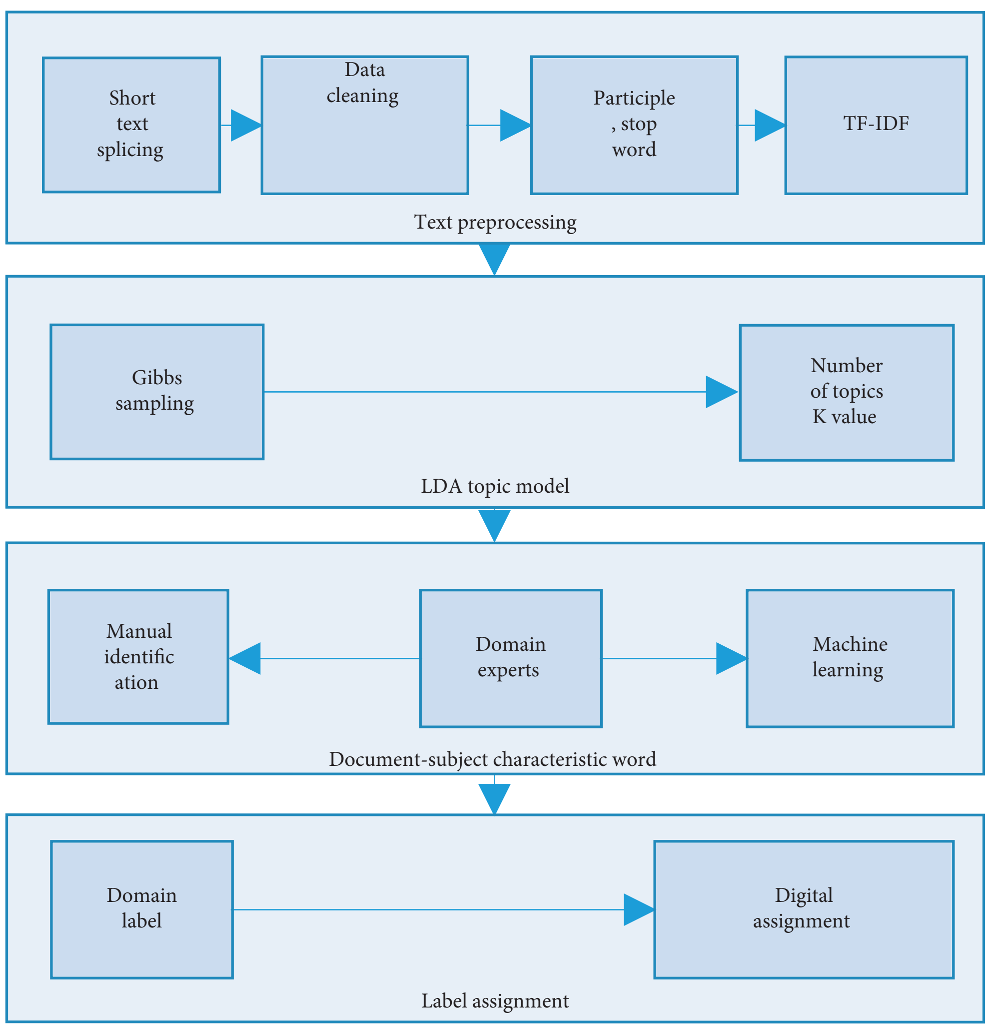

Figure 3: Steps for modelling unstructured text based on LDA topic models.

implied topics of the text; that is, project the complex text into the potential topic space according to the statistical idea, and obtain the "document-topic" distribution θ topic distribution θ and "topic-featured word" distribution:

$$\text{perplexity}(D) = \exp\left[-\frac{\sum_{d=1}^{M}\log(P(W)_d)}{\sum_{d=1}^{U} N_d}\right],$$
$$p(w) = p(z|d) * p(w|z). \quad (2)$$

Step 3. After obtaining the "document-topic-feature word" matrix, if the sample is small, each topic word cluster can be identified manually, taking into account the distribution of words and semantic relationships under the topic. As most of the nursing education management apps are industry vertical platforms, such as the Dingxiangyuan App for the medical field and the House of Economics and Management App for the management field, we can consult with experts in the relevant fields to set a domain label for each document that summarises its characteristics when identifying thematic feature words.

Step 4. After obtaining the domain labels for each document, the labels are digitally assigned, for example, the labels "internal medicine," "surgery," and "Chinese medicine" are assigned {1, 2, 3}, respectively. The result is the identification of student interest areas from student-generated content and their conversion into numerical values.

The above method can quantify the textual data and also reveal the textual characteristics at the thematic level, which is both practical and scientific, and achieves the research goal of combining textual data and other data to portray the portrait, avoiding distortion of the portrait to the greatest extent possible.

6. Case Studies

6.1. Study Subjects. A convenience sampling method was used to include 200 nursing students who underwent a clinical internship in a tertiary care hospital from August 2014 to April 2015. The experimental group consisted of 200 nursing students who underwent clinical internship from August 2014 to April 2015, and the control group consisted of 200 nursing students who underwent an internship in the same hospital, all with bachelor's degree. During the study period, 3 nurses were dropped out of the experimental group and 6 from the control group. The reason for the dropout was that the nursing students were transferred to other hospitals at the end of their internship and were unable to complete the comprehensive assessment and related questionnaires. Therefore, a total of 192 nursing students in the experimental group and 185 in the control group were included in this study [28].

6.2. Evaluation Methods. At the end of the internship, nursing students are assessed in a unified manner, including theoretical and operational assessments, with a score of 100 points each. Each student is evaluated by the first- and second-level managers according to the "Internship Performance Assessment Form," which covers five major categories: professionalism, professional skills, communication skills, study and research skills, and teamwork, each with 20 points, totalling 100 points [29].

A survey of nursing students at the end of their placement was conducted using the "Nurse Professional Identity Scale" developed by the Department of Nursing Management, Faculty of Medicine, University of Tokyo, Japan. The scale consists of 21 items with 7 dimensions: a sense of control, a sense of consistency, a sense of meaningfulness, sense of self-efficacy, sense of self-determination, sense of organisational influence, and sense of patient influence. The items are rated on a 7-point Likert scale, according to "not at all," "less," "less," "not sure," "not sure," "not at all," and "not sure." The dimensional score is the average of the scores of the included items. The higher the score, the higher the degree of professional identity of nursing students. Cronbach's alpha coefficient for the Chinese version of the scale was 0.84 and the content validity was 0.92. In this study, Cronbach's alpha coefficient was 0.817.

A self-made patient care service satisfaction questionnaire was distributed to patients at the end of the practice, including five dimensions of nursing student service quality, professional skills, patient education, humanistic care, and overall evaluation, with a total of 16 items. "Dissatisfied," "average," "satisfied," and "very satisfied" were assigned a score of 1 to 5, respectively. The higher the score, the higher the patient's satisfaction with the nursing student. Six experts in nursing education, nursing management, and clinical nursing were invited to evaluate the relevance of each item to the content expressed in the questionnaire on a 4-point scale (i.e., 1 = not relevant, 2 = weakly relevant, 3 = strongly relevant, and 4 = very relevant). The Cronbach's alpha coefficient for this questionnaire was 0.923.

A self-made questionnaire was used to survey nursing students at the end of the placement, which included five items: rationality, replicability, the quality of teaching, quality of management, and overall evaluation of the placement model.

6.3. Results. Comparison of overall assessment scores of nursing students is presented in Table 1.

Clinical practice is an integral part of higher nursing education, and the quality of clinical teaching is crucial to the overall standard of higher education. It is an innovation and development of the traditional mobility practice paradigm, adhering to the student-centred talent training concept, based on the development of nursing students, based on clinical nursing practice, facing the frontier of discipline development, adapting to the educational market demand, aiming to cultivate excellent nursing students, and devoting to the comprehensive training of nursing students' knowledge, ability, and quality so as to become talents with greater development potential. As shown in Table 1, the experimental group was the first to be trained in nursing. As shown in

Table 1: Comparison of the comprehensive assessment scores of nursing students in the two groups ($\overline{x} \pm s$).

Project	Experimental group ($n = 182$)	Control group ($n = 165$)	t/t' value	P value
Theoretical assessment	79.70 ± 8.12	77.19 ± 6.78	3.108	0.002
Operation assessment	85.48 ± 7.33	82.56 ± 8.25	3.491	<0.001
Practice performance	72.02 ± 10.12	66.58 ± 12.27	4.472	<0.001
Professional quality	14.72 ± 1.92	13.55 ± 1.94	5.621	<0.001
Professional skills	15.04 ± 2.22	14.29 ± 2.98	2.631	<0.001
Communication skills	13.25 ± 2.21	11.48 ± 2.45	5.843	0.009
Learning and scientific research ability	14.81 ± 2.38	13.57 ± 5.24	4.512	<0.001
Teamwork	14.21 ± 2.1	13.26 ± 2.49	3.815	<0.001

Table 2: Comparison of professional identity between the two groups of nursing students ($\overline{x} \pm s$).

Project	Experimental group ($n = 182$)	Control group ($n = 165$)	t value	P value
Sense of grasp	5.86 ± 0.99	5.33 ± 1.04	4.862	<0.001
Sense of consistency	5.52 ± 1.41	4.36 ± 1.68	6.988	<0.001
Sense of meaning	5.88 ± 1.25	5.40 ± 1.36	3.426	<0.001
Self-efficacy	5.91 ± 0.85	5.64 ± 0.93	2.826	0.005
Self-determination	4.35 ± 1.84	3.76 ± 1.92	2.922	0.004
Sense of organisational influence	3.66 ± 1.53	3.38 ± 1.65	1.640	0.102
Patient's sense of influence	5.15 ± 1.20	4.39 ± 1.33	5.465	<0.001

Table 1, the assessment scores and overall practice performance of nursing students in the experimental group were higher than those of the control group ($P < 0.05$), and the comparison was statistically significant in terms of professional quality, professional skills, communication ability, study and research ability, and team writing ($P < 0.05$) [30].

Comparison of professional identity of nursing students is shown in Table 2.

Professional identity is a socialised self-identification of the individual's values, attitudes, behaviour, knowledge, and skills in their professional role, and is the process of integration and development of self-value and professional value that overcomes the sense of professional externalities and alienation. Clinical practice is a critical period for nursing students to strengthen their professional awareness, experience their professional values, and transform their social roles and has an important impact on the formation and development of their professional identity. As shown in Table 2, through the clinical practice of the whole nursing internship model of double censorship, in which the mentor is responsible for the whole process and the nursing students are independently assigned to beds at the end of the internship, the nursing students in the experimental group have a higher sense of grasp and consistency of the professional role of nurses than those in the control group ($P < 0.05$), their clinical skills have been improved, their degree of nursing decision-making and influence on patients has been deepened, and their sense of self-worth has been elevated, and they are higher than those in the control group in the above related dimensions ($P < 0.05$). All comparisons were higher than those of the control group ($P < 0.05$). It is possible that this is due to the limited time spent on rotation in different departments and limited participation in the nursing organisation. The nursing students in both groups scored lower on this dimension, with there was no statistical difference between the two groups ($P > 0.05$). In conclusion, the holistic nursing practice model with dual membership can continuously enhance the professional experience of nursing students and promote the positive transition of nursing students to their social roles [30].

Comparison of patient satisfaction with care services is shown in Table 3.

Table 3 shows that the overall satisfaction of patients with nursing students in the experimental group was higher than that of the control group ($P < 0.05$), and there was a statistical difference in the comparison of satisfaction in terms of service quality, professional skills, patient education, and humanistic care ($P < 0.05$). Patient satisfaction is the evaluation yardstick of quality nursing service and is the starting point and footing point of nursing practice. The nursing students are the new force in the nursing team and should inherit and carry forward the "patient-centred" service concept. Under the dual-tutor system, the tutors focus on the cultivation of nursing students' service consciousness and professional ability, supervising them to implement basic nursing care and health education for patients and guiding them to communicate effectively with patients; the nursing department organises regular humanities lectures and health education competitions to motivate nursing students to provide quality nursing services [31].

Comparison of nursing students' evaluation of placement models is shown in Table 4.

The results of the nursing students' evaluation of the practice model (Table 4) show that the overall nursing practice model with dual tutors is more reasonable than the traditional practice model and is highly scalable. In the construction of this model, a complete three-level supervision system, a dual-tutor teaching system, a PDCA accountability system for continuous improvement, and a multichannel teacher-student interaction platform have been formed after continuous experience summing up and perfecting practice, which is worth promoting at one time.

Table 3: Patient care service satisfaction ($\overline{x} \pm s$).

Project	Experimental group ($n = 182$)	Control group ($n = 165$)	t value	P value
Service quality	3.91 ± 0.84	3.62 ± 0.93	3.056	0.002
Professional skills	4.00 ± 0.88	3.46 ± 0.95	5.496	<0.001
Patient education	4.05 ± 0.92	3.53 ± 0.86	5.425	<0.001
Humanistic concern	3.60 ± 0.89	3.26 ± 0.87	3.592	<0.001
Overall evaluation	3.86 ± 0.94	3.52 ± 0.97	3.314	0.001

Table 4: Evaluation of placement patterns by nursing students in both groups ($\overline{x} \pm s$).

Project	Experimental group ($n = 182$)	Control group ($n = 165$)	t/t' value	P value
Rationality	4.26 ± 0.76	3.70 ± 0.94	6.075	<0.001
Generalizability	4.40 ± 0.73	3.34 ± 0.82	12.760	<0.001
Teaching quality	4.20 ± 0.78	3.62 ± 1.02	5.900	<0.001
Management quality	4.25 ± 0.79	3.55 ± 0.95	7.382	<0.001
Comprehensive evaluation	1.30 ± 0.81	3.53 ± 0.89	8.424	<0.001

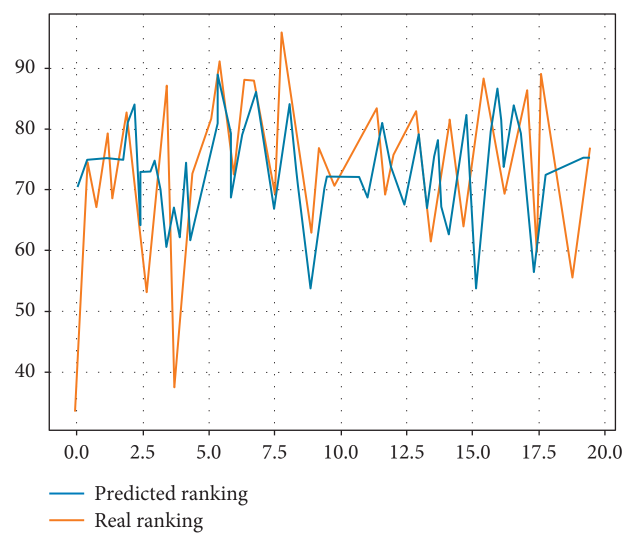

Figure 4: Predicted performance for different management.

7. Experimental Analysis

In the process of data collection and analysis, the metadata that is exchanged as information is standardised in order to fully exploit, share, and utilise information resources. The standardisation of nursing language has been researched earlier overseas, and information systems predict nursing workload based on the Nursing Outcome Classification (NOC), the North American Nursing Diagnostic Association Nursing Diagnosis (NANDA), and other standardised language captures, providing a good basis for full data mining and analysis. As nursing work records in China are still dominated by semistructured, nonstandardised data, the lack of a common standardised nursing language and terminology system has resulted in a large amount of nursing workload data that cannot be directly analysed and processed, and a low rate of sharing and utilisation of data resources across institutions and systems as shown in Figure 4, with different management of prediction models.

In the context of the era of medical informatization, it is urgent for China to establish a unified coordination mechanism, promoted by the state and professional academic organizations, to develop a standardised system of nursing data suitable for China, such as the different prediction modules shown in Figure 5.

As shown in Figure 6 for the short-term nursing effect, the difficulty in achieving the prediction of nursing workload is not in the use of data mining tools, but in choosing which data mining tools are more applicable to the reality of nursing workload in China, which currently presents diverse, complex, and fragmented data. When predicting, the traditional regression approach inevitably leads to errors and even biases, and due to the expanding volume of data, there is an urgent need for working methods that are more in line with the volume of nursing data. Currently, methods such as support vector machines and random forests are increasingly becoming mainstream mining tools, and more suitable research methods should be actively incorporated in the prediction methods of nursing workload.

8. Conclusions

This paper proposes the construction of a nursing education management model based on small data to provide ideas and references for nursing education management to effectively predict the evolutionary trends of student behaviour and improve the level of precise services. The experimental group adopted a full dual-mentor responsibility system holistic nursing practice model, specifically including a complete three-level supervision system, dual-mentor teaching system, PDCA responsibility system holistic nursing practice pathway for continuous improvement, and a multichannel teacher-student interaction platform.

Data Availability

The data underlying the results presented in the study are included within the manuscript.

Retracted: A New Generation of ResNet Model Based on Artificial Intelligence and Few Data Driven and Its Construction in Image Recognition Model

Computational Intelligence and Neuroscience

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

The paper proposes an A-ResNet model to improve ResNet. The residual attention module with shortcut connection is introduced to enhance the focus on the target object; the dropout layer is introduced to prevent the overfitting phenomenon and improve the recognition accuracy; the network architecture is adjusted to accelerate the training convergence speed and improve the recognition accuracy. The experimental results show that the A-ResNet model achieves a top-1 accuracy improvement of about 2% compared with the traditional ResNet network. Image recognition is one of the core technologies of computer vision, but its application in the field of tea is relatively small, and tea recognition still relies on sensory review methods. A total of 1,713 images of eight common green teas were collected, and the modeling effects of different network depths and different optimization algorithms were explored from the perspectives of predictive ability, convergence speed, model size, and recognition equilibrium of recognition models.

1. Introduction

Green tea is good for people's physical and mental health and is a popular beverage among consumers. At the same time, green tea is also the most diverse and the most produced tea in China, and appearance is an important basis for its classification and differentiation of grades, as well as an important part of team sensory evaluation. However, the traditional tea sensory review method uses review terminology that has not been perfected [1]. The uncertainty of the objective environment, the low prevalence of standard quantities, the interference of subjective factors by tea evaluators, the poor repeatability, and other limitations do not match the increasing consumer demand for accurate information and safe and high quality tea products in the current new era [2]. Therefore, the development of open, standardized, and intelligent [3] green tea classifications and identification methods is an inevitable trend. New classification and assessment methods for green tea have been emerging, such as physicochemical review methods [4, 5], fingerprinting assessment methods [6, 7], intelligent sensory review methods [8, 9], and infrared spectral imaging technology detection methods [10, 11], but these methods have their limitations to a certain extent, such as relevant instruments and cumbersome and complicated operations, and most of them are based on the overall tea leaves. It is necessary to propose an objective, simple, fast, and low-cost method for green tea classification, since most of them are based on the whole tea leaves for review, which requires specific and time-consuming requirements.

Convolutional neural networks, as an important member of image classification algorithms, have the advantages of high recognition accuracy, fast detection speed, and great development potential [12], have achieved considerable success in image classification [13], object detection [14], pose estimation [15], image segmentation [16], and face recognition [17, 18], have great scaling advantages [19], and have been widely used in agriculture [20], healthcare [21], education [22], energy [23], industrial inspection [24], and other fields [25]. Currently, convolutional neural networks have been used for tea tree pest and disease identification [26], tea grade sieving [7], and the sorting of tea tree fresh leaves [8], but for the recognition and classification of different species of green tea based on ResNet, a typical convolutional neural network is proposed by researchers in recent years to perform computer vision tasks, which minimizes the gradient disappearance problem caused by increasing the depth of the network due to the introduction of the residual module and reduces the redundancy of information in the data while maintaining a high accuracy rate, which is simple and practical.

Based on ResNet convolutional neural network, this study constructs a deep learning model capable of distinguishing 8 kinds of green tea by selecting the appropriate optimization algorithm and model depth, aiming to develop an efficient, accurate, and objective identification model and apply it to mobile, realizing the recognition of green tea pictures in different backgrounds and environments, which can be shared and used by multiple people and devices, saving resources and realizing deep learning in tea recognition. The identification of green tea is a new way of thinking.

2. Materials and Methods

2.1. Data Acquisition and Test Platform Construction. The dataset of this study consists of 8 kinds of green teas, such as Lishui fragrant tea, Xinyang Maojian, Lu'an Guapian, Taiping Monkey Kui, Anji White Tea, Biluochun, Bamboo Leaf Green, and Longjing. The number of images of each kind is shown in Table 1, with a total of 1,713 images. Part of the dataset of this study is shown in Figure 1. The eight kinds of green tea with different appearance and quality characteristics present different states in different scenes with different backgrounds, which better reproduce the actual scenes of tea in life. These images are manually searched from different Internet platforms, such as the shopping platform Jingdong (https://www.jd.com), Tao Bao (https://www.taobao.com), the social platform Weibo (https://weibo.com), and Baidu Post (https://tieba.baidu.com), with different brightness, background, and angle. The higher the resolution of the image is, the more features it contains, and the better it is for model learning. Therefore, the image datasets selected in this study are basically above 100 KB in size, and extended formats are basically JPG and PNG.

The experimental platform for this study was built as shown in Table 2, and the modeling scripts used are available on github (https://github.com/seldas/DL_Beetles).

2.2. Image Preprocessing. The original images obtained in this study vary in size, and conducting some preprocessing of the images can enhance the recognition of the target objects by the model and also avoid overfitting of the network. In this study, the tea images in the training set were first randomly cut into RGB images in the image format of $224 \times 224 \times 3$ and then flipped. The images in the test set are first scaled and then cropped to $224 \times 224 \times 3$ RGB images with the center as the reference. In this study, the preprocessing of the images in the test is a data enhancement operation, which can effectively improve the fitting ability and generalization ability of the model [9].

2.3. Data Processing and Evaluation Indicators. The images were randomly selected and sampled according to the training set : validation set = 3 : 1. The training data were used for parameter learning, and the validation data were used for model performance evaluation. The same preprocessing was strictly followed, and to ensure the accuracy of the validation results, each set of experiments was repeated at least three times, cross-validation was adopted to avoid the arbitrariness in dividing the training and test sets, and the data were analyzed by one-way ANOVA ($p < 0.05$) using SPSS 21.0 software for significant differences, and finally the data were divided into batches of the same size The data were divided into equal-sized batches to facilitate subsequent model training.

In order to evaluate the performance of ResNet model for green tea species classification, accuracy, error rate, precision rate, recall rate, F-value, and the confusion matrix were adopted as the evaluation indexes in this experiment. Taking the eight types of green tea in this study as an example, the accuracy rate is the average of the overall performance of the model in recognizing the eight types of green tea, and the error rate corresponds to the accuracy rate, which can be suitable for the comparison of recognition balance because of its small base. Accuracy, recall, and *F*-value are performance evaluations for each of these categories. Taking Anji white tea as an example, the accuracy rate is the proportion of all samples predicted to be Anji white tea which are predicted correctly; the recall rate is judged on the basis of samples whose true label is Anji white tea, and it is the proportion of those predicted correctly to all samples whose true label is Anji white tea; and the F-value is a composite index, which is the summed average of the accuracy rate and recall rate. The confusion matrix can summarize and compare the classification prediction results and the actual target, and from the presentation in the form of $N \times N$ matrix, the sum of each row is the number of real samples of the category, and the sum of each column is the number of samples predicted as the category, which can directly evaluate the effectiveness of the classification method.

3. Related Theories

3.1. Traditional ResNet Network Structure. Since Alexnet [11], the CNN structure has been deepening, and VGG and GoogLeNet [12] have 19 and 22 convolutional layers, respectively. With the increase of network depth, the existence of gradient disappearance problem makes the network training more difficult and the convergence result is not good, and then the ResNet network [13] is introduced, as shown in Figure 2.

Table 1: Number of pictures of different kinds of green tea.

Name	Number	Size range of each image	The size of dataset	The source of images/piece		
				Shopping platform	Social platform	Portal site
Lishui Xiangcha	210	102–1201	61	117	66	27

Hardware environment	Intel(R)Core(TM)i7-7700hq CPU@2.80 GHZ 2.80 GHZ
Basic configuration	Anaconda Python3. Version 7

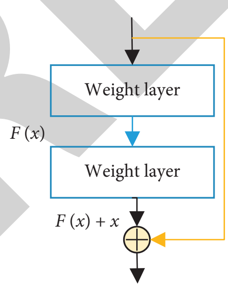

Figure 2: Shortcut connection method.

The output of the residual module in ResNet is obtained by summing the backbone network with the jump connection, and the shortcut connection adopts a constant mapping. ResNet network can better weaken the gradient disappearance phenomenon, retain more original information in the input image, reduce the loss, and also improve the convergence speed in deeper networks compared with the traditional VGG network, essentially reducing the training. The redundancy of data information in the training process is essentially reduced, but the shortcut direct connection makes it less focused on the local target information in multiple categories, which reduces the classification accuracy.

3.2. Dropout Layer. The dropout layer is a layer that is used to temporarily discard neurons with a certain probability during the training process of the network. When the data samples are small, it can prevent the model from overfitting and effectively improve the classification accuracy. Reference [14] introduced the dropout layer into the convolutional neural network, which not only solved the overfitting phenomenon but also obtained good classification accuracy.

3.3. Residual Attention (Attention) Network. Attention networks can highlight local target information and allow the network to focus more on finding useful information related to the output in the input image, thus improving the classification accuracy of image targets [8, 15, 16]. Reference [8] proposed a residual attention network in 2017, which enables the classification accuracy to be improved by focusing more on the target information through residual attention networks. A residual attention network is a convolutional neural network containing an attention mechanism, which is constructed by superimposing an attention mechanism in an end-to-end training approach combined with a forward feedback network architecture.

The residual attention network is composed of several attention modules superimposed on each other, and the attention module is divided into two branches: the main branch and the mask branch. The structure of the attention module is shown in Figure 3.

The mask branch contains both upsampling and downsampling layers, which can be both quickly feed-forward scan to collect global information of the image and top-down feedback to combine the global information with the original image features. Each trunk branch has its corresponding mask branch, which is used to learn the attention information of its corresponding layer features, prevent the trunk branch from updating the wrong weight parameters, and can gradually refine the attention features of complex images by superimposing the network structure. The formula for calculating the residual attention block can be shown in the following equation:

$$H_{i,c} = \left(1 + M_{i,c}(x)\right) * F_{i,c}(x), \tag{1}$$

where $F_{i,c}(x)$ denotes the result of convolutional neural network output and $M_{i,c}(x)$ denotes the result of mask branch weight output, which takes values in the range of [0, 1], and the closer it is to 0, the closer the output is to $F(x)$, which can then represent the network as a residual learning network. $M_{i,c}(x)$ as a feature selector can enhance useful information and suppress undesirable noisy information from the trunk branch, but the increase of attention mechanism makes more parameters in the network, which may cause overfitting and make the training converge slowly.

4. Intersection Based on ResNet Network (A-ResNet)

In order to improve the training convergence speed and classification accuracy, the traditional ResNet network model is improved and the A-ResNet network model is proposed and applied to the traffic sign recognition system.

The A-ResNet network is composed of convolutional layer, pooling layer, residual unit, residual attention unit, and softmax layer. Its structural composition is shown in Table 3.

The input image of A-ResNet network has fixed size 224×224, and the 112×112 feature map is generated after the first convolutional layer and then input to 4 residual units and 3 attention units after the pooling layer is reduced in dimension. Compared with the original ResNet network, we add attention units, adjust the structure of each unit, and add dropout layer, which can speed up the convergence of the loss value of the network training and improve the classification accuracy of the network in recognizing traffic signs.

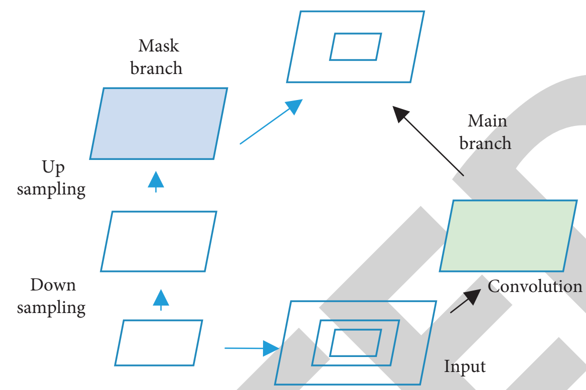

Figure 3: Structure of attention module.

Table 3: A-ResNet network model structure.

Arrangement	Output size	A-ResNet
Input layer	224×224	
Convolution layer 1	112×112	7×7, 64
Maximum pooling	56×56	3×3
Residual element	56×56	$\begin{pmatrix} 3 \times 3, & 64 \\ 3 \times 3 & 64 \end{pmatrix} \times 1$
Attention unit	56×56	Attention ×1
Residual element	28×28	$\begin{pmatrix} 3 \times 3, & 64 \\ 3 \times 3 & 64 \end{pmatrix} \times 1$
Attention unit	28×28	Attention × 1
Residual element	14×14	$\begin{pmatrix} 3 \times 3, & 64 \\ 3 \times 3 & 64 \end{pmatrix} \times 1$
Attention unit	14×14	Attention × 1
Residual element	7×7	$\begin{pmatrix} 3 \times 3, & 64 \\ 3 \times 3 & 64 \end{pmatrix} \times 2$
Average pooling	1×1	7×7
Softmax	43×1	

4.1. Improvement of Residual Module in A-ResNet. The structure of the residual unit in the conventional ResNet network is shown in Figure 4(a). The training speed of the ResNet network composed of this structure is slow, and the recognition accuracy is not high, so the structure of the residual unit after adjusting the network to improve the classification accuracy and training convergence speed is shown in Figure 4(b).

The scale normalization layer (BN layer) and the activation layer (ReLU layer) are adjusted to the convolutional layer before the BN layer to normalize the data for stabilizing the network convergence, and then the processed data are input to the Re-LU activation function for activation, which can not only increase the nonlinear relationship between the layers, but also enhance the network sparsity and prevent the overfitting phenomenon, and the activated data are input to the convolutional layer. The data after activation is input to the convolutional layer, and the dropout layer is added

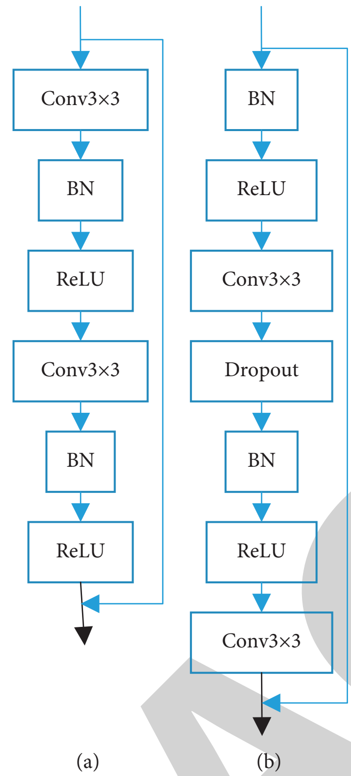

Figure 4: Residual module before and after improvement. (a) Original residual module. (b) Adjusted residual module.

between the convolutional layers to avoid overfitting of the network parameters.

4.2. Improvement of Residual Attention Module in A-ResNet. To address the problem of slow convergence of the residual attention network in the network training phase, an improved residual attention network is proposed in this paper to speed up the convergence of the network training while stabilizing the recognition accuracy. The attention network used is shown in Figure 5.

The basic structures of the residual block, upsampling, downsampling, and jumping branch modules are all consistent with the improved residual unit of this paper. However, the shortcut connection mechanism is not used directly. If the shortcut mechanism is used directly as the structure of the mask branch, it will cause the problem that the gradient of the deep network is not inverted, so the structure of the mask branch is combined with the upsampling and downsampling process, which can obtain the global feature information in the image and convert the extracted global information into a dimensionally consistent feature map. Finally, dimensionally consistent feature maps obtained from the trunk branch and the mask branch are combined by the dot product to form the final output feature map. In the downsampling stage [27], the extracted feature maps are downsampled to a minimum size of 7×7 using the maximum pooling layer, and then in the upsampling stage, the feature map dimensions are expanded layer by layer using bilinear interpolation, and the feature maps obtained from downsampling are summed with them to obtain the final feature maps. The purpose of doing so is to combine global and local features to further enhance the characterization capability.

5. Results and Analysis

5.1. Comparison of Optimization Algorithms. In this study, four algorithms such as SGD, RMSprop, Adam, and Adadelta are compared based on the selection of ResNet-18 as the network model. Due to overfitting, the parameters that converge on the training set are not optimally implemented on the test set [28]. Therefore, in this study, the accuracy and training time of the validation set are chosen as the criteria for comparison, and the experimental data are shown in Figure 6, and it can be seen that SGD performs optimally in both aspects, with the highest average accuracy of 90.99% and the shortest training time of 71.37 min. Therefore, SGD is chosen as the optimal algorithm in this experiment.

5.2. Comparison of Model Depth. ResNet uses constant mapping to avoid the "degradation" problem of deep networks and thus can reach very deep network layers. Usually, the increase in the number of layers of the network leads to an increase in the performance of ResNet, but there are also problems such as larger computation, slower convergence, and increased training time [29].

5.2.1. Model Convergence Speed. Convergence in this study means that the accuracy of the network model is infinitely close to the optimal accuracy of the model as the epochs

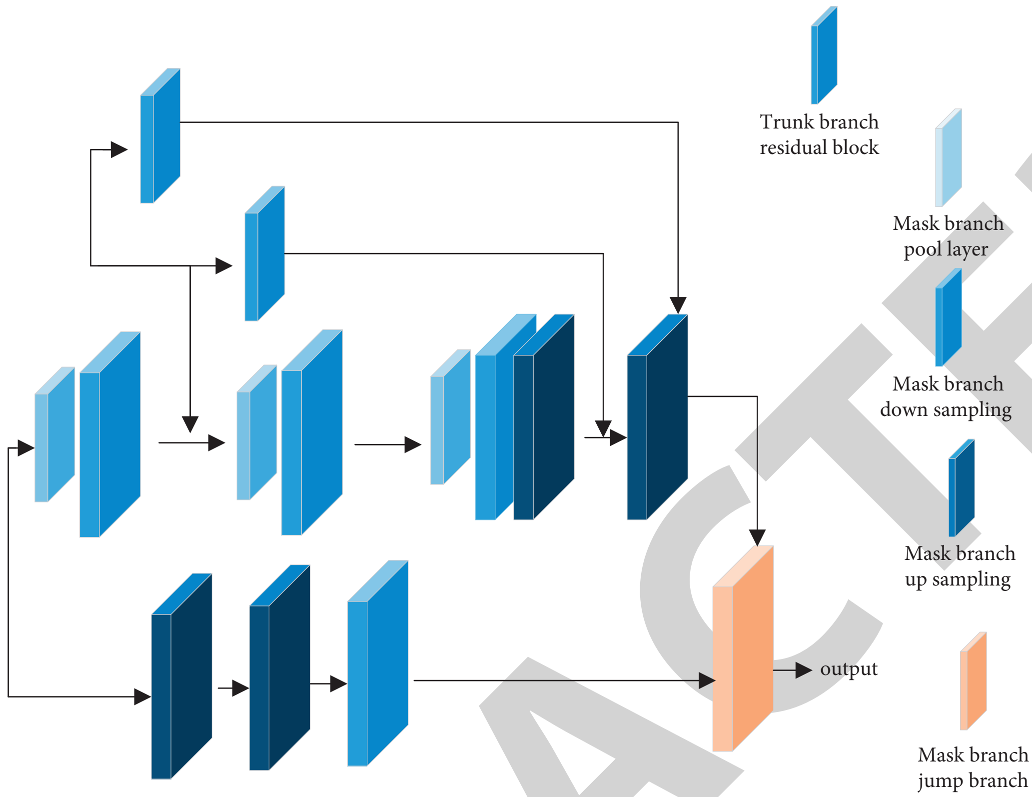

Figure 5: Structure of attention module.

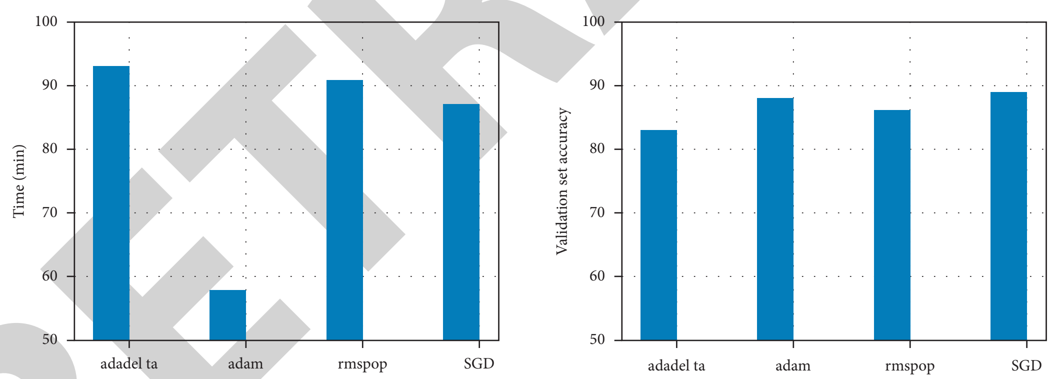

Figure 6: Comparison of different optimization algorithms.

tend to infinity (the maximum value of epochs in this study is 19). ResNet networks of different depths have different rates of approaching their optimal accuracy as epochs become larger. Faster convergence means fast and robust fusion, avoiding overfitting or getting stuck in a local optimum. Progressively deeper colors are used to represent the number of ResNet layers at different depths, and the speed of reaching the optimal accuracy is represented by a line of corresponding color from top to bottom [30]. As shown in Figure 7, all four ResNet models with different depths show no convergence jitter and eventually converge, among which ResNet-18 has the fastest convergence speed and is able to show a stable convergence when the epochs reach 7.

5.2.2. Model Size. At present, as the research on network models continues, the model structure shows a deeper and deeper trend, the complexity of computation deepens, and the size of the model and the amount of memory it occupies increase. Although the hardware facilities of computers are being constantly updated and upgraded, they are still unable to accommodate large-scale complex network models at this stage, which can limit their use on smart devices such as cell phones and computers. Therefore, on the basis of ensuring high accuracy, this study is to find the network models of suitable depth that are lightweight and easy to use on end devices. The sizes of ResNet models with different depths are shown in Table 4. ResNet-18 has a model size of 43.7 MB and requires the least space, which is about 52% of ResNet-34

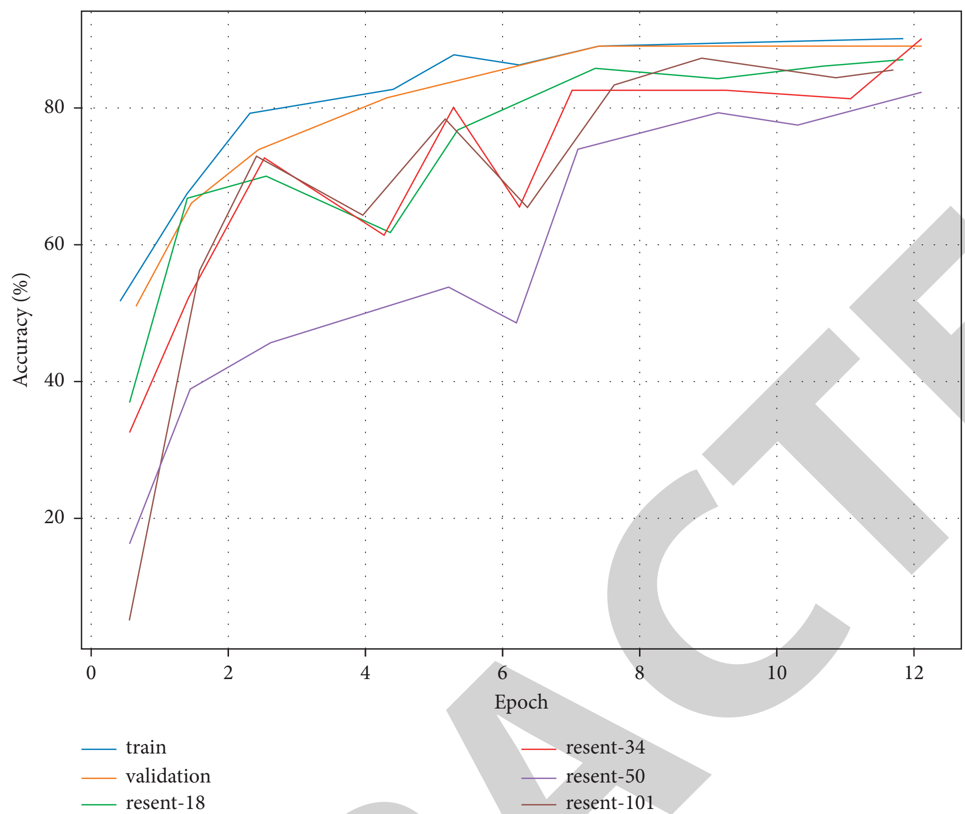

Figure 7: Convergence speed of ResNet models with different depths.

Table 4: Efficiency and size of ResNet models with different depths.

Model	Identification time per graph	Accuracy %	Size/MB
ResNet-18	0.097 ± 0.0011	90.99 ± 0.37	42.1
ResNet-34	0.112 ± 0.0013	90.94 ± 0.95	82.2
ResNet-50	0.134 ± 0.0009	91.47 ± 0.57	90.2
ResNet-101	0.147 ± 0.001	90.05 ± 0.37	154.5

and 26% of ResNet-101, implying that it takes up less memory, has faster computing time, and is more suitable for mobile.

5.2.3. Equilibrium of Model Identification. The improvement of the balance of the model recognition accuracy is more beneficial to the application of the model in practice and can avoid the problem of poor recognition of specific species. As can be seen from Figure 8, using the average deviation of the recognition error rate of the eight tea samples as the measurement index, the smaller the average deviation value, the stronger the recognition balance of the model.

From Figure 8, it can be seen that the ranking of the balance of the training set is ResNet-18>ResNet-101>ResNet-50>ResNet-34, and the ranking of the balance of the validation set is ResNet-34>ResNet-18>ResNet-50>ResNet-101, ResNet-18. The balance of the recognition in both the training and validation sets is better, and the equilibrium of both the training and validation sets is also better.

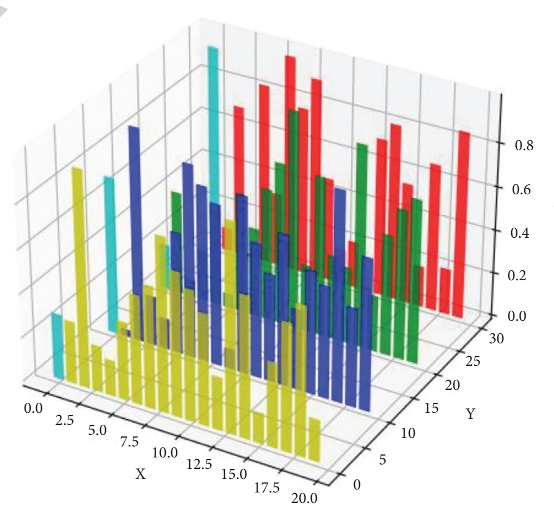

Figure 8: Mean deviation of recognition error rate of 8 green tea species.

In this study, the model performance is measured from four perspectives: convergence speed, size, efficiency, and recognition balance, and finally ResNet-18 is chosen as the basis of the model to build a green tea recognition model, which requires the shortest training time for the fastest convergence speed, effectively maintains the accuracy of

Table 5: Precision, recall, and F-value of the eight green teas.

Classification performance metrics	Precision	Recall	F-value
Lishui Xiangcha	0.85 ± 0.15	0.93 ± 0.008	0.89 ± 0.01
Xinyang Maojian	0.94 ± 0.02	0.95 ± 0.01	0.94 ± 0.01
Lu'an Guapian	0.88 ± 0.01	0.82 ± 0.02	0.85 ± 0.03
Taiping Houkui	0.94 ± 0.03	0.087 ± 0.03	0.91 ± 0.02
Anji Baicha	0.90 ± 0.01	0.88 ± 0.02	0.89 ± 0.04
Biluochun	0.95 ± 0.05	0.97 ± 0.01	0.95 ± 0.02
Zhuyeqing	0.87 ± 0.14	0.95 ± 0.12	0.90 ± 0.12
Longjing	0.98 ± 0.01	0.87 ± 0.02	0.95 ± 0.01

image recognition on the basis of the smallest memory occupation and the fastest recognition speed, and performs better in recognition balance. The problem of poor recognition of specific categories can be avoided. As the dataset of this study is more realistic, it proves that the model has a strong practical application capability and breaks through the limitation of many previous studies that cannot fully reproduce the actual diversity. Based on this, the model can be improved in terms of accuracy by using uniform background and field photography to obtain more valid information. In the classification recognition of species by convolutional neural network, the average recognition accuracy of maize [9], chrysanthemum [4], and pepper [1] with different total datasets (3,600, 6,300, and 65,000) and average number of samples per class (1,200, 1,260, and 13,000) reached 95.49%, 95.9%, and 99.35%, respectively (all with clean scenery, with little noise). Therefore, the model can also be optimized and improved by expanding the dataset and selecting more representative team pictures. Green tea species in China are far more than the eight species in this study and can be extended to other tea types in the next study to achieve intelligent recognition of more tea types [31–33].

5.3. Green Tea Predicted Classification Results. As shown in Table 5, the low precision, recall, and F-value of Lishui fragrant tea, Lu'an Guapian, bamboo leaf green, and Biluochun indicate that they are more easily confused with other teas, and it can be seen from Figure 9 that Anji white tea and bamboo leaf green, Biluochun, and Lishui fragrant tea are easily confused with each other: in the three validation sets with combined statistics, 10 Anji white teas were misconceived as bamboo leaf green, 12 bamboo leaf green teas were misconceived as Anji white tea, 12 Lishui fragrant teas were misconceived as Biluochun, and 18 Biluochun teas were misconceived as Lishui fragrant tea. This may be due to the similarity in the characteristics of the tea, with Anji white tea and bamboo leaf green both having a certain straight shape, and Biluochun and Lishui aroma tea having a similar curly shape.

The above results may also be due to the existence of some interference in the background which makes some of the tea characteristics not well discriminated, and a higher quality and larger quantity of dataset are needed to support the model for further learning. Data is the driving force of deep learning, and quantity, quality, preprocessing rationality, and labeling accuracy are all important factors. You can expand the dataset by random

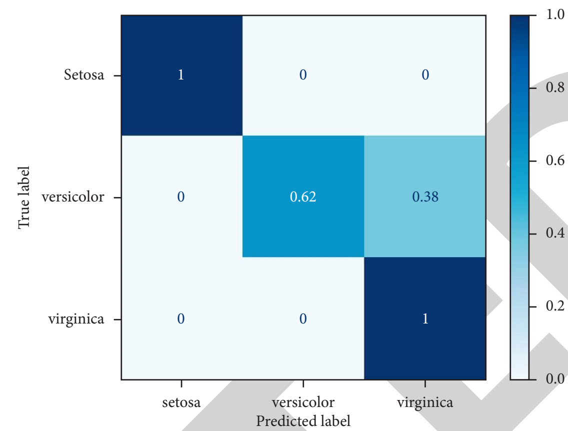

Figure 9: Heat map of confusion matrix for ResNet-18.

cropping, random inversion, random brightness transformation, a clean set to take different angles of field shooting to obtain a higher quality dataset. You can also preprocess cropped into smaller and more focused images, and multiple people check the labels to improve labeling accuracy.

6. Conclusions

In this study, a new model based on ResNet convolutional neural network to recognize different kinds of green tea was constructed by comparing four different optimization algorithms and investigating the effect of the depth of ResNet model from different aspects. The four optimization algorithms, SGD, RMsprop, Adam, and Adadelta, were compared, and it was found that the stochastic gradient descent (SGD) algorithm required the shortest time and had the highest recognition accuracy.

ResNet-18, ResNet-34, ResNet-50, and ResNet-101 were used to investigate the effect of depth of the ResNet model. ResNet-18 lost only 0.15% accuracy (ResNet-50 had the highest average recognition accuracy of 91.14% and ResNet-18 90.99%). In this study, the heat map of confusion matrix and the respective accuracy, recall, and *F*-value of eight tea types were clarified, and it was found that Lishui fragrant tea, Lu'an Guapian, Zhuyeqing, and Biluochun were more easily confused with other tea types, while Anji white tea and Zhuyeqing, Biluochun, and Lishui fragrant tea were easily confused with each other.

The model constructed in this study is a preliminary application of deep learning in the field of tea variety recognition, and through the selection of optimization algorithm and the exploration of model depth, a better recognition effect is achieved overall. It not only provides a simple and efficient new method for the recognition of green tea species, but also lays a corresponding foundation for further application of deep learning in the field of tea.

Deep learning-based image compression methods have made significant achievements recently, of which the two key components are the entropy model for latent representations and the encoder-decoder network. Both the inaccurate estimation of the entropy estimation model and the existence of information redundancy in latent representations lead to a reduction in the compression efficiency. To address these issues, the study suggests an image compression method based on a hybrid domain attention mechanism and postprocessing improvement. This study embeds hybrid domain attention modules as nonlinear transformers in both the main encoder-decoder network and the hyperprior network, aiming at constructing more compact latent features and hyperpriors and then model the latent features as parametric Gaussian-scale mixture models to obtain more precise entropy estimation. In addition, we propose a solution to the errors introduced by quantization in image compression by adding an inverse quantization module. On the decoding side, we also provide a postprocessing enhancement module to further increase image compression performance. The experimental results show that the peak signal-to-noise rate (PSNR) and multiscale structural similarity (MS-SSIM) of the proposed method are higher than those of traditional compression methods and advanced neural network-based methods.

1. Introduction

In the age of information technology, pictures have become important information carriers, and massive amounts of image data can lead to enormous transmission and storage pressures. For example, an original RGB image with a resolution of 512×768 has a theoretical storage size of about 1.125 MB, and after compression, the storage size of the image is only one-sixtieth of the original image or even smaller. Therefore, image compression is crucial in computer vision, and the trend of information technology has put forward higher demands on image compression efficiency. Traditional image compression methods [1–3] have achieved better performance through finely designed manual features and complex processing. For example, JPEG [1] employs the discrete cosine transform (DCT) [4] to eliminate redundancy among pixels. Traditional compression algorithms, on the other hand, lack learning capabilities. Thanks to the advancement of deep learning, this also gives new ideas for image compression methods.

In contrast to the traditional methods, where a linear transform module is replaced by a nonlinear neural network, the performance of image compression methods is determined by how the network structure is constructed to produce more compact latent features. In addition, accurate entropy estimation is one of the pivotal factors to improve the performance of image compression. A good entropy model can better suit the true distribution of an image. A further important task is to design the quantization module, which has a significant impact on compression performance.

A classical deep learning-based image compression structure converts images into compressible latent representations by stacking convolutional neural networks [5]. These latent representations are then entropy coded through statistical redundancy, and lossless compression is performed through entropy coding to create bitstreams. At the same time, the joint optimization decoder decodes the latent representations into images. Classical learning-based image compression algorithms [6, 7] use a variational autoencoder structure, and significant progress has been made in various technical components of this architecture, including the use of generalized divisive normalization (GDN) modules in nonlinear transformers, which has been validated for probabilistic modeling and image compression tasks. A nonlocal model was used in the literature [8], and a CNN-based wavelet transform was used in the literature [9] to reduce redundancy among pixels. The entropy estimation model with hyperprior was first proposed in the literature [7] to capture the hidden information of latent representations, aiding the generation of entropy model parameters and improving the mismatch between entropy model and hidden marginal distributions. In the literature [10, 11], the autoregressive module was introduced, and the autoregressive and hyperprior modules complement each other to improve the entropy estimation. The literature [12] proposed a parallelizable checkerboard grid context model and changed the decoding order so as to speed up decoding without breaking performance. The literature [13] used importance maps to guide image compression based on generative adversarial network loss functions for enhancing the subjective image quality. The literature [14] used a manually set distortion weight map to control the bit-rate allocation and assigned a larger distortion weight to the region of interest in the image, thus enhancing the quality of the region of interest. The problem that DNN-based networks cannot be directly used for near-lossless coding is addressed in the literature [15]. It is possible to see that the design and improvement of the deep neural network-based image compression methods focus on improving the main encoder-decoder, the quantization module, and the entropy estimation module structures.

In addition, improving the image compression quality is the eternal theme of image coding and decoding. We need to understand that enhancing the image quality at the decoding end is equivalent to improving the compression efficiency. Moreover, since the actual lossy compression standards are not theoretically optimal, there are information redundancies that can continue to be explored and utilized. Furthermore, we find that there are still some limitations in the existing methods. For example, the information transmitted using a hyperprior is not standardized and fully utilized. This part of the information, which is encoded into the bitstream to construct the entropy model, is not used for image reconstruction. We want to eliminate compression artifacts and blur, despite the fact that existing compression algorithms offer decent compression efficiency. The purpose of this study is to investigate how to build an effective learning-based image compression approach. To summarize, the following are the study's innovations:

(i) This study describes a hybrid domain attention mechanism that was embedded into the transform encoder-decoder and hyperprior module to output latent representations and hyperpriors with channel global context-adaptive activation. Our hybrid domain attention mechanism was embedded into different network layers, which is not only applied to quantized latent representations. The created attention mask dynamically analyzes the relevance of the features to be compressed through the deep learning-based architecture and allocates more bits to more essential features, which will help increase the entropy coding efficiency.

(ii) In addition, because quantization poses a zero-gradient problem, the training of a deep learning-based network cannot be carried out. We use the hybrid quantization approach to fix this problem, that is, the forward propagation adopts the rounding function and the backward propagation adopts the form of straight propagation. Apart from the nondifferentiable problem, quantification also leads to a loss of information. This study proposed an inverse quantization module to alleviate the errors induced by quantization.

(iii) Finally, as our image compression method is lossy, the reconstructed images will inevitably contain compression artifacts. In order to further increase image compression quality, obtain results with rich texture information, and generate vivid details, we perform a filtering process on the compressed image.

2. Related Work

2.1. Traditional Image Methods. Traditional image compression standards use artificially designed encoders, such as the discrete cosine transform used by JPEG [1], separating high-frequency information from low-frequency information and allocating bits according to signal importance to reduce information redundancy. To improve compression performance, entropy coding is also used. The coding of a source according to its probabilities is known as entropy coding. The process of entropy coding is lossless, i.e., there is no loss of image information. Entropy coding includes Huffman coding, tour coding, and arithmetic coding.

2.2. Deep Learning-Based Methods. Deep learning-based image compression is not independent of traditional image compression and is more built on top of it. There are two main approaches, a convolutional neural network-based compression approach using automatic encoders and a compression method with postprocessing filtering combined with traditional encoders. Traditional image compression uses transform coding that introduces block effects and compression artifacts, and while many methods can deal with these issues well, deep learning has a superior ability to solve these types of problems. For the design of transform encoder-decoder, some works [16, 17] used recurrent neural networks (RNNs) to achieve recursive compression of residual information, while other parts of works [6, 7, 10, 11] used stacked convolutional blocks to achieve this. Considering the limited perceptual field of convolutional blocks, Cheng et al. [18] used residual blocks to increase the perceptual field. Rippel and Bourdev [19] proposed the use of feature pyramid pooling (FPN) to obtain more powerful feature representations. In addition, since convolutional operations share features, this would lead to information redundancy. Li et al. [20] proposed using an importance map to adjust the bit allocation of images. The importance map is derived by training a branch of a 3-layer convolutional network. However, according to the method in [20], the explicit learning content needs weight, which increases the computational overhead, and it is difficult to adaptively allocate bits for deep features. Attention mechanisms have demonstrated considerable strength in adaptive learning of feature importance in recent years. In tasks such as natural language processing [21] and semantic segmentation [22], significant results have been made. Furthermore, introducing nonlocal block (NLB) into neural networks can greatly increase image denoising and image super-resolution reconstruction performance [23, 24]. This study, therefore, presents a hybrid domain attention mechanism that is embedded into both main and hyper coders, which allows features to have adaptive responses, reinforcing important features, weakening unimportant ones, and further improving the compression performance. Akbar et al. [25] employed multiplicative convolution. The use of multiplicative convolution is also based on the idea of allocating more bits to important regions and reducing spatial redundancy.

Because deep learning-based methods require network the training, quantization operations are not differentiable. The literature [6] proposed the use of adding uniform noise as an alternative to true quantization. The literature [11] sets the gradient of the quantization operation to a fixed value to ensure that deep learning training takes place. To make the quantization smoother, a soft-to-hard quantization is utilized instead of direct scalar quantization in the literature [26].

In the entropy coding section, different entropy models are proposed for the quantized latent representations. In the earlier literature [6], an entropy model constructed by a linear segmentation function was used for bit-rate estimation, the model has fixed parameters of its probabilistic model at the end of training, and the quantized latent representations are entropically encoded and entropically decoded based on these probabilities. To improve the entropy model, a hyperprior structure was proposed in the literature [7], in which the authors used a Gaussian-scale mixture (GSM) (Gaussian with different means and scales) modeling approach to estimate the probability of latent features. While the parameters needed for GSM modeling are derived by the hyperprior module, the latent features are then encoded into the bitstream and sent to the decoder. This achieves image adaptive coding and also obtains better performance than BPG (4 : 4 : 4) [3]. In the literature [10], an autoregressive context module is proposed to perform parameter prediction of the entropy model in conjunction with the hyperprior structure proposed in the literature [7].

To enhance the image reconstruction quality even more, many research studies [26, 27] used generative adversarial network (GAN) as a distortion measurement in the training phase to guide the decoder to generate more realistic texture structures, resulting in reconstructed images with good subjective quality, but the texture structures generated in this way are not real textures and do not have fidelity. For this reason, TuCode technology in [28] proposed an enhancement module that acts on full-resolution images to reduce compression artifacts in images by building a simple neural network to filter the reconstructed images. The literature [29] investigated the effect of decoding network complexity on image compression performance and concluded that postprocessing networks do not significantly improve compression performance when the network at the decoding end has a strong enough reconstruction capability. When using neural networks for traditional encoding schemes, the auxiliary information generated during the encoding process has a significant effect on image denoising, and ByteDance uses predictive information and coding unit (CU) block segmentation information to assist the neural network in replacing the deblocking (DB) and sample adaptive offset (SAO) modules for loop processing. Qualcomm uses a network of BS-assisted information to replace the DB filter for block filtering.

3. The Proposed Image Compression Method

3.1. Image Compression Architecture. Figure 1 shows the network structure. We deploy a deep learning-based automated encoder network. This method mainly includes the main encoder-decoder, hyper encoder-decoder, autoregressive context module, and postprocessing enhancement module. In particular, given the training images $\mathbf{x}$, a transformer encoder generates corresponding latent features $\mathbf{y}$. The quantization quantizes the latent features to $\widehat{y}$, and subsequently, entropy codes the quantized $\widehat{y}$ into a bitstream for transmission. The autoregressive context module combined with the hyperprior module is used for entropy coding. The entropy coding in this way will first estimate the distribution of latent representations $\mathbf{y}$ through the hyperprior network, and the output of the hyperprior encoder will be then quantized and encoded into bitstream. The reason why it will be encoded into the bitstream is that this part of the bitstream is required during decoding, and the accurate entropy model will improve the compression efficiency. The use of autoregressive prior information to estimate the distribution of latent representations $\mathbf{y}$ is to capture an accurate entropy model.

The attention module is used to adjust bit allocation based on the importance of the information. Considering that the goal of the image compression algorithms is to obtain the highest possible quality reconstructed image for a given bit-rate target, the method in this study adds a postprocessing enhancement module, and the image decoded by the main decoder and the mean information generated for modeling the Gaussian distribution are jointly fed into the postprocessing network to assist in generating the final reconstructed image.

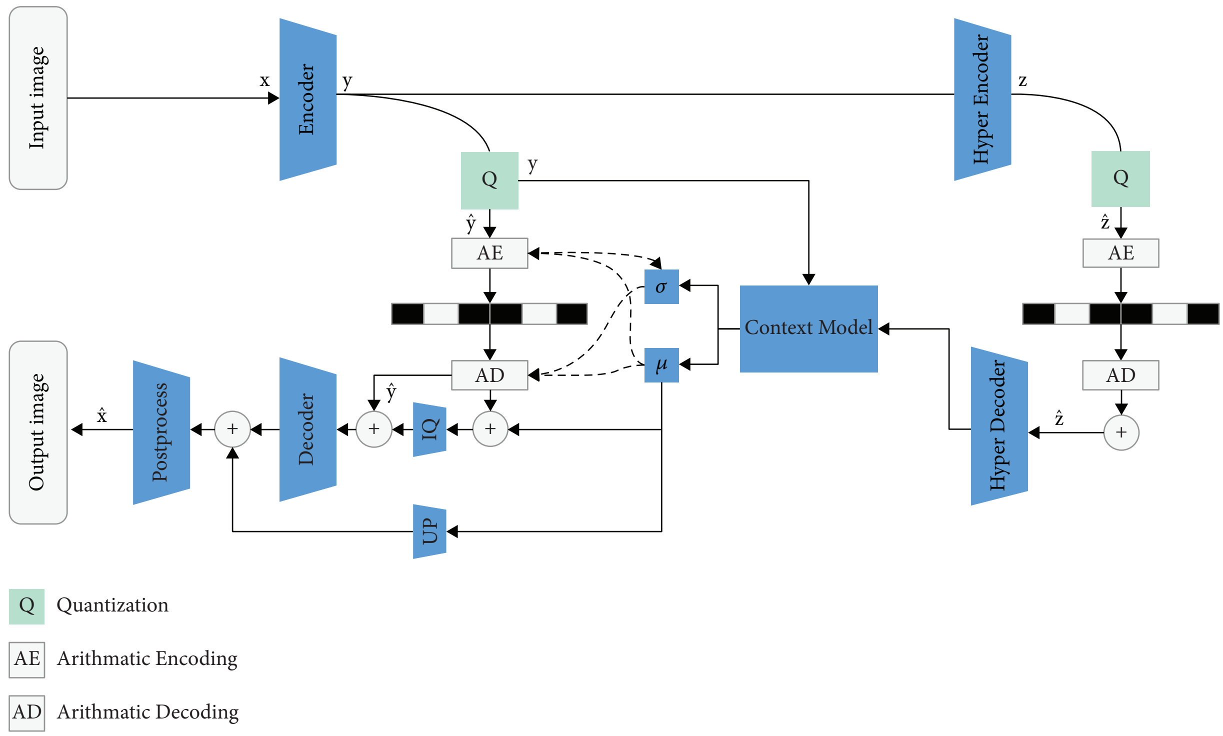

FIGURE 1: Network frame architecture of the proposed method.

We can deduce from our understanding of information theory that when the required coding features are concentrated, the smaller the value of information entropy, the fewer bits are required, and the resulting reconstructed image has more distortion. On the other hand, when the information entropy of the features is higher, the more bits are required, and the image distortion is lower; therefore, we need to use the hyperparameter λ to establish a trade-off between the two. The entire training of the compression method is optimized by means of the following loss function [30]:

$$\text{Loss} = \lambda D(\mathbf{x}, \hat{x}) + R_{\hat{z}} + R_{\hat{y}}, \quad (1)$$

where R refers to the bit rate, and D indicates the distortion between the images before and after compression. There are two commonly used distortion metrics, namely, multiscale structural similarity (MS-SSIM) and mean square error (MSE) [31]. The distortion and bit rate are weighed by. λ.

In training, we use an entropy estimation approach consistent with the model in the literature [10], and we model the latent features as follows:

$$p_{\hat{y}|\hat{z}}(\hat{y}|\hat{z}) = \prod_i \mathrm{N}\left(\boldsymbol{\mu}^i, \boldsymbol{\sigma}^{2(i)}\right) * u\left(-\frac{1}{2}, \frac{1}{2}\right)(\hat{y}_i). \quad (2)$$

Each latent representation $\hat{y}_i$ is modeled as a Gaussian distribution with μ^i and σ^i, which are forecasted by the distribution of the hidden variable $\hat{z}$. $\hat{z}$ is called the hyperprior, $u(\cdot)$ denotes a uniform distribution, and $*$ denotes the convolution operation. Because prior information about $\hat{z}$ does not exist, we model the hyperprior $\hat{z}$ as follows:

$$p_{\hat{z}|\psi}(\hat{z}|\psi) = \prod_i \left(p_{z^i|\psi^{(i)}}\left(\psi^{(i)}\right) * u\left(-\frac{1}{2}, \frac{1}{2}\right)\right)(\hat{z}_i), \quad (3)$$

where $p_{z^{(i)}|\psi^{(i)}}$ represents each univariate's distribution, and $\psi^{(i)}$ represents the parameters of this distribution. Finally, the bit rate in our method consists of the bit rate of the latent representations $\hat{y}$ and the bit rate of the hidden variable $\hat{z}$. These bit rates are denoted as follows:

$$\begin{aligned} R_{\hat{y}} &= \sum_i -\log_2\left(p_{\hat{y}_i|\hat{z}_i}(\hat{y}_i|\hat{z}_i)\right), \\ R_{\hat{z}} &= \sum_i -\log_2\left(p_{\hat{z}_i|\psi^{(i)}}\left(\hat{z}_i|\psi^{(i)}\right)\right). \end{aligned} \quad (4)$$

Table 1 shows the network architecture and related parameters for separate components in our compression method. One of them is the hybrid domain attention mechanism (HDAM), which will be described in Section 3.2. In addition, the inverse quantization module will be described in Section 3.3 and the postprocessing module will be described in Section 3.4.

3.2. Hybrid Domain Attention Mechanism. In previous studies, transform encoders were often implemented using stacks of convolutional neural networks. In learning-based image compression, learning a transform encoder with less redundant information and more critical reconstruction information through convolutional neural networks is one of the keys to better compression performance. While the convolutional layers are limited by the range of perceptual fields and have only local bias induction capabilities, increasing the depth of the network allows for deeper dependencies, but at the same time brings with it a significant increase in computational

effort. Many recent studies have used attention mechanism modules to improve image recovery and compression performance [8, 32], where attention modules were introduced into transformers to model the global dependencies between features, resulting in a less redundant latent representation of the image on the transformer encoder side. The attention mechanism starts from the human visual mechanism by adaptively learning the weights of different features and acquiring the areas that need to be focused on. Previous works have used only spatial information to generate attention maps, which do not allow for good mining of correlations between channels of latent features. As shown in Figure 2, we experimented with the effect of the first 32 channels of the latent representations on the distortion performance of the reconstructed images and came to the conclusion that each channel has a different importance in the final reconstruction effect. Unlike previous works and inspired by [33], we proposed a hybrid domain attention mechanism that works in both the channel and spatial domains. The hybrid attention module is embedded in the transformer encoders and adaptively learns relevant compression features to obtain a transformer encoder with reduced information redundancy and with reconstructed key information. In our hybrid domain attention mechanism module, the input features are first passed through the channel attention module to obtain the channel domain attention map, which is then multiplied element by element with the input features to obtain the features required by the spatial attention mechanism. The output of the channel domain is utilized as the input feature map for the spatial attention mechanism, and then, the spatial domain attention map and the input features are multiplied element by element to obtain the final output. Figure 3(a) depicts the architecture of the channel attention mechanism, and the channel mask can be described as follows:

$$A_c(\mathbf{X}) = \sigma(\mathrm{MLP}(\mathrm{AvgPool}(\mathbf{X}))), \tag{5}$$

where $\mathbf{X}$ is the input feature map, $A_c(\cdot)$ denotes the channel domain attention map, MLP stands for a 2-layer neural network, and σ represents the sigmoid activation function. The spatial information of the aggregated feature map $\mathbf{X}$ is first derived by averaging pooling over spatial dimensions of the feature map, the spatial information is then sent to the MLP to compress its spatial dimensions, and then it undergoes a sigmoid activation operation to create the feature map of channel attention.

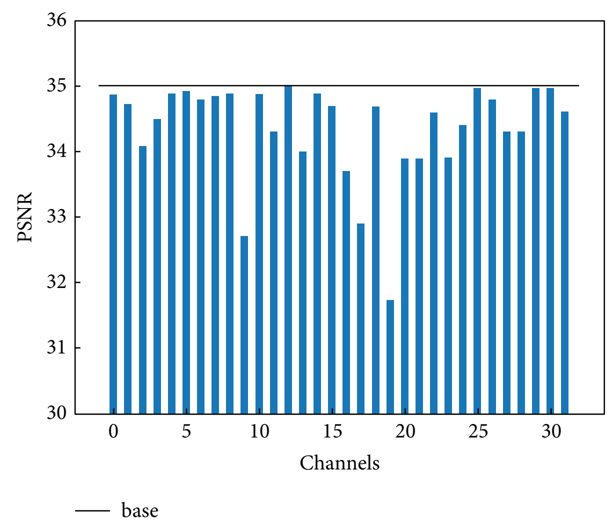

Figure 2: Channel influence on reconstruction distortion (PSNR degradation of the first 32 channels).

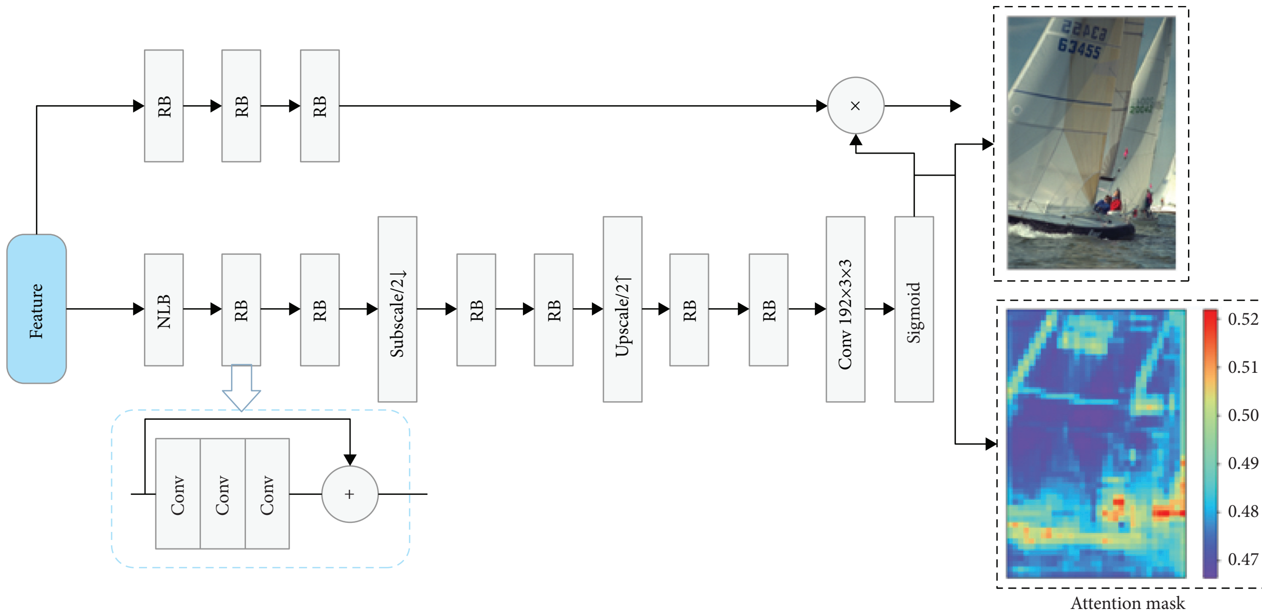
The spatial attention module is divided into a backbone branch, which uses traditional residual blocks to generate features, and a mask branch, in which the nonlocal block (NLB) [34] is embedded. Figure 3(b) depicts the spatial attention mechanism (b), and the spatial mask can be described as follows:

$$A_S(\mathbf{X}) = \sigma(F_{\mathrm{NLB}}(\mathbf{X})), \tag{6}$$

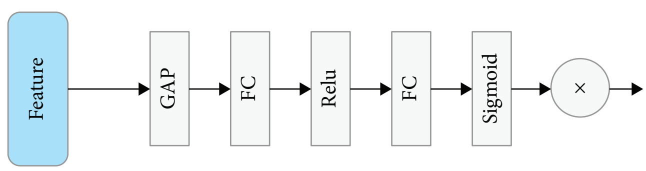
where $A_S(\cdot)$ represents the attention mask, and $F_{\mathrm{NLB}}(\cdot)$ denotes the result of utilizing *NLB* and the subsequent residual blocks and convolution.

As shown in Table 1, we integrate hybrid domain mechanisms into the framework of the proposed method. The attention module aids the network's global adaptive response by reinforcing essential features while weakening unimportant ones, thus implicitly learning feature importance mapping and delivering more bits for textured regions, resulting in better visualization with the naked eye at similar bit rates.

3.3. Hybrid Quantization. For lossy image compression, all features need to be quantized into integer form for entropy coding. Deep learning-based training, on the other hand, is



(a)



(b)

Figure 3: (a) The structure of spatial attention in hybrid domain attention module. "RB" is for resblock. "NLB" is for nonlocal module proposed in [34]. (b) The structure of channel attention in hybrid domain attention module. "FC" is for 2-layer fully connected layer. "GAP" is for global average pooling.

hampered by the inherently nondifferentiable nature of quantization. In the training phase, quantization methods for deep learning-based image compression methods [6, 7] typically take the form of approximate quantization by adding uniform noise for end-to-end optimization:

$$Q(\mathbf{y}) = \mathbf{y} + \Delta\left(-\frac{1}{2}, \frac{1}{2}\right). \tag{7}$$

The other part of the work uses straight-through estimation (STE) of the gradient and manually sets the backward propagation expression for the rounding function:

$$\begin{aligned} \frac{d}{d_{\mathbf{y}}}\{\mathbf{y}\} &:= \frac{d}{d_{\mathbf{y}}}[\{\mathbf{y}\}] \\ &= \frac{d}{d_{\mathbf{y}}}\mathbf{y} = 1. \end{aligned} \tag{8}$$

In our method, we integrate two quantization methods. For the encoder output $\mathbf{y}$, we use STE quantization to round up and feed the quantized one into the decoder, while for the entropy model network, we use approximate quantization with added noise for entropy modeling. In addition to this, to reduce the loss of information due to quantization, we incorporate an inverse quantization subnetwork. We treat the loss of floating-point numbers due to rounding operations as being added to the noise in the range of (−0.5, 0.5), which is why most compression methods today use an approximate quantization operation in the form of added noise. The inverse quantization network is similar to existing image denoising efforts, making the inverse quantized feature data as close as possible to the prequantization data.

Figure 4 depicts the specific network structure. The addition of uniform noise treats the loss of floating-point numbers due to quantization as a random form of noise, but the loss due to rounding is actually traceable, which also helps the inverse quantization network to perform a more accurate "denoising job."

3.4. Postprocessing Module. Since image compression approaches based on deep learning are lossy, the model in the form of hyperprior needs to ensure that the dimensionality of the latent representation is low; otherwise, the latent representation itself may contain redundancy, which will result in inevitable compression artifacts and poor compression performance. In this case, the hyperprior module may have some loss of information that affects the accuracy of the parameters required to model the entropy rate, especially for high bit rates and high resolutions. Taking into account the degradation information in image compression and the necessity to improve the compressed image's quality and provide better visual effects, we proposed introducing the postprocessing module into the main decoding end. In

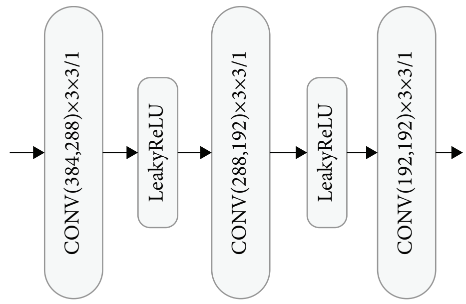


FIGURE 4: The architecture of our dequantization network.

addition, we proposed reuse of the mean information μ derived from the hyperprior module joint autoregression module. As shown in equation (2), through the training of the neural network, μ will capture the hidden information in $\hat{y}$, so μ contains rich structural information. To exploit the full potential of the auxiliary information, we feed the mean information into the postprocessing module to further assist the postprocessing network in removing compression artifacts.

As inspired by image noise reduction and super-resolution network design strategies [35], our postprocessing network uses a residual network structure for quality enhancement of the reconstructed image. As illustrated in Figure 5, we started by adding two convolutional layers to get shallow features, and at the same time, the number of channel dimensions was changed from 6 to 32 and then cascaded through three identical modules for detailed enhancement. Because we are dealing with full-resolution images, we use only three enhancement blocks in order to keep the computational cost from rising as the network depth grows. The enhancement blocks are added with two multiscale residual blocks to extract multiscale features. In addition, three different convolutional kernel sizes are used in these blocks, including 5×5, 3×3, 1×1, and PReLU activation functions, and finally, the convolution is used to change the channel dimension in the image before implementing global residual learning to obtain the enhanced image.

In fact, a general postprocessing module is not necessary because it will fail if the decoder network is powerful enough [29]. However, our postprocessing can increase the quality of the decoded images even further due to the reuse of information from μ. In the ablation experiments in Section 4.3, we proved the effectiveness of the postprocessing module we offered.

4. Experiments

4.1. Operation Details

(1) Experimental environment. We used PyTorch to implement our method, and we ran all of our tests on an NVIDIA-2080TI GPU with 11 GB of video RAM.

(2) Experimental data. To ensure that the recommended technique is effective, we conducted a series of tests. Since image compression tasks are unsupervised tasks that do not require additional label files, most of the image compression methods crawl high-resolution image data on the web as the dataset for the training model. We used 20,745 high-quality images provided by Flick.com. After preprocessing, these images were randomly cropped to size 256×256, and a total of around 800,000 images were obtained as the training set after preprocessing. To assess the efficiency of image compression methods, we tested the performance of various image compression methods using the Kodak Photo CD image dataset [36] as testing data.

(3) Comparison of methods. Our comparative experiments include classical traditional image compression methods (JPEG2000 [2], BPG [3]) and more recent deep learning-based image compression methods (Ballé et al. [6, 7], Minnen et al. [10], Lee et al. [11]). JPEG2000 [2] compression was tested using the official test model OpenJPEG 2000 configured in YUV 420 [37] and was implemented, and BPG [3] compression was tested using the BPG software [9] in the format YUV 440.

(4) Our method. To plot the rate-distortion performance curve, we trained different models according to different distortion measures. In the models with PSNR as the metric, we employed MSE as the distortion function D in the loss function, while in the distortion metric with MS-SSIM, we used (1-MS-SSIM) as a function of D. Six models are trained for each distortion scale based on different bit rates, for a total of twelve models, where the size of the bit rate is controlled by hyperparameter λ, we use different values (256, 650, 2048, 4096, 6144, and 8192) to train our models, and each λ corresponds to a rate-distortion point. The performance of the image compression method is represented by the line obtained by connecting each of the rate-distortion performance points. Initially, we assigned λ to 8192 for training and the model's batch size to 16, we used the Adam optimizer [38] for parameter optimization, the starting learning rate is 1×10^{-4}, and because the learning rate is updated using the callback function 'ReduceLROnPlateau' in the PyTorch framework, it will reduce the learning rate after the loss is no longer reduced. For the other rate-distortion points, we used the initially trained model as the pretrained model for the next training and fine-tuned the initially trained model to obtain the other rate-distortion points while keeping the training settings the same. In the model with MS-SSIM as the distortion metric, we used the original model with PSNR as the distortion metric as a pretraining model and changed the distortion metric in the loss function in this model. In addition, we set λ to 384 and the other rate-distortion points in the model with MS-SSIM as distortion metric on top of this pretraining model. The values of λ are, respectively, 16, 32, 64, 128, 256, and 384.

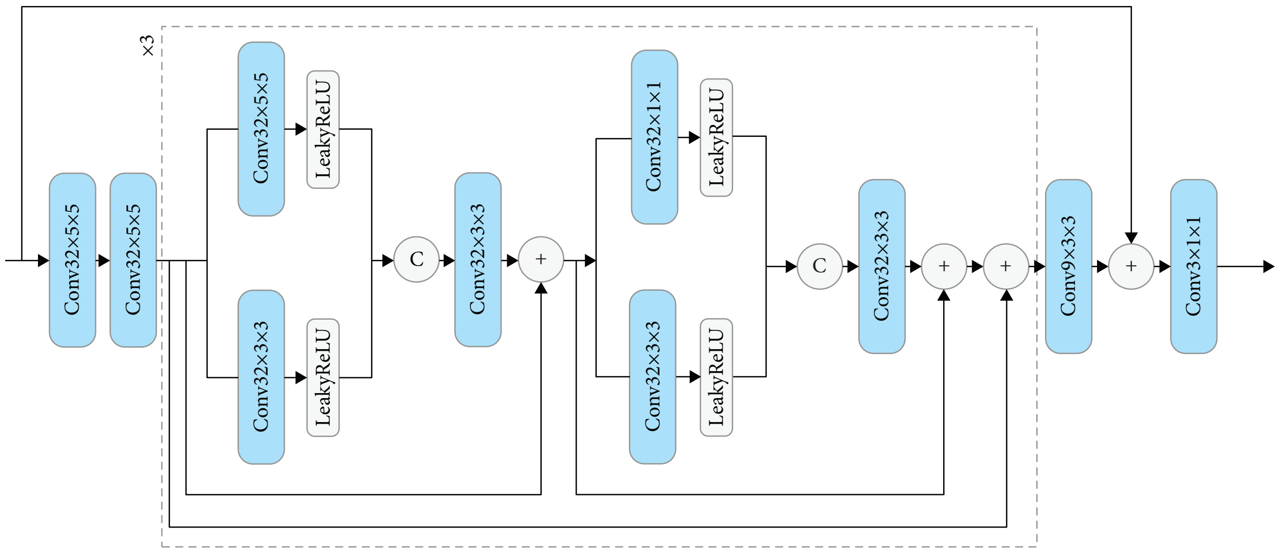

Figure 5: The architecture of our postprocessing module. “C” is for concatenation.

(5) Evaluation metric. Bit per pixel (BPP) reflects an image’s compression ratio. For images with the same aspect ratio, the smaller the BPP, the higher the compression ratio. For the image quality evaluation indicators, PSNR and MS-SSIM indicators are used to evaluate, respectively. PSNR is based on element-by-element comparison of differences, does not take into account human visual perception, and lets alone human esthetics, so PSNR can reflect pixel-level distortion, while MS-SSIM measures image similarity in terms of luminance, contrast, and structure, respectively.

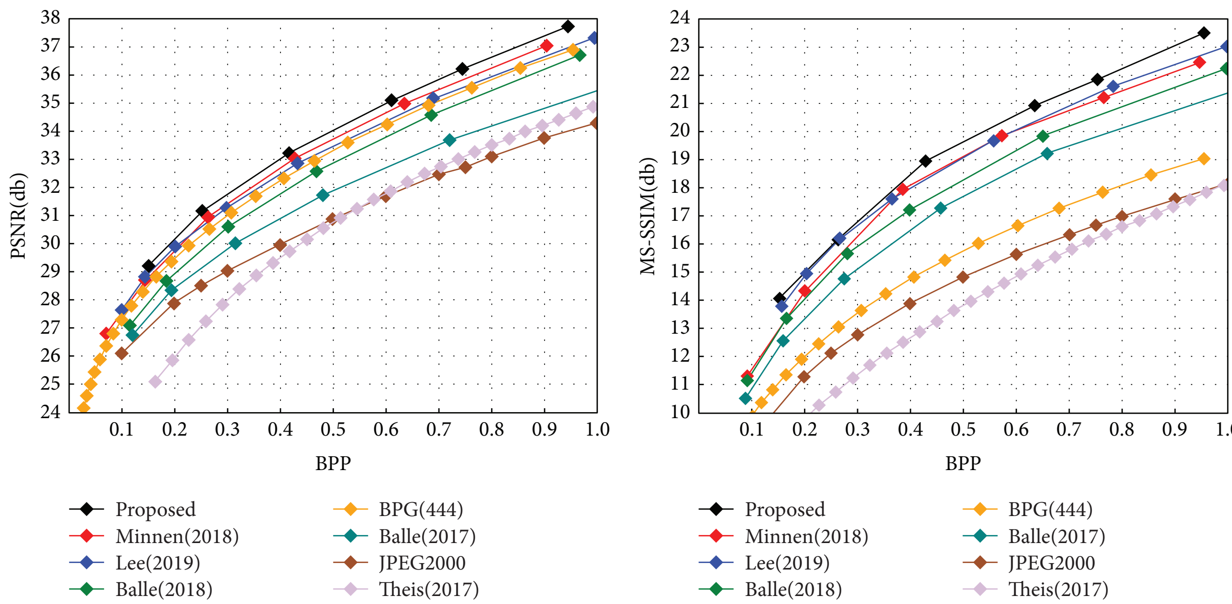
4.2. Compression Performance. The unit of PSNR and MS-SSIM is db, and a higher value means less distortion and better visual impact. As shown in Figure 6 our rate-distortion curves plotted using PSNR (see Figure 6(a)) and MS-SSIM (see Figure 6(b)) as distortion metrics shows that our method has significant performance advantages over JPEG 2000 [2], BPG [3], Ballé2018 [7], and at the same BPP for both of the evaluation indicators mentioned. Our technique exhibits equivalent performance gains to Minnen [10] at low bit rates, and intuitionistic performance increases above Minnen [10] at large bit rates. Furthermore, our method improved performance at all bit rates, demonstrating the efficacy and stability of the suggested method in this study.

We have also conducted ablation studies to validate the effectiveness of each module. As seen in Figure 7, we retrained the model that embeds the hybrid domain attention mechanism into the baseline (four sets of models were trained), and it can see that it produced a rise of around 0.2 db over the baseline model. We also retrained the model by changing the quantization in the baseline to our hybrid quantization (four sets of models were trained), and it can be seen to produce a rise of about 0.2 db over the baseline, with more gain at higher bit rates. We retrained the model with our postprocessing module added to the baseline (four sets of models were trained), and it can be seen to produce a rise of nearly 0.2 db over the baseline as well.

There are four aspects that affect the efficiency of image compression. One is how to extract more compact features. One is the reduction in quantization losses. One is the reconstruction ability of the decoder. One is the accuracy of the entropy estimation. In our method, we improved the baseline model in these four dimensions, and from our ablation experiments, we can conclude that the hybrid domain attention mechanism has the greatest impact on performance.

4.3. Visual Comparison. To make the effectiveness of our framework clearer, we provide some visualization results. Figure 8 shows the visualization of some images compressed using different compression methods in the Kodak Photo CD dataset [36]. Since neural network-based image compression methods cannot strictly limit the BPP of an image, we can only compare different compression methods at similar BPP of the compressed images. As can be seen from the figures, our method has a higher evaluation index at similar BPP.

In terms of qualitative observation, the image compression methods JPEG 2000 [2] and BPG [3] have obvious block effects and blurring phenomena, and the deep learning-based image compression methods of Lee et al. [11] and Minnen et al. [10] have some loss of edge texture information in the reconstructed images, although they do not have as obvious blurring compression artifacts as the traditional compression methods, while the reconstruction quality of the compression methods in this study is higher. This is because our method embeds a spatial channel mechanism that is accordingly globally adaptive, reinforces



(a) (b)

important features (e.g., edge texture details), and allocates more bits to important features, and our framework also uses a hybrid quantization mechanism with the addition of an inverse quantization module and a postprocessing module, all of which can guide the network to use fewer bits to obtain higher reconstruction quality. Overall, the approach in this study is also superior in quality of visual comparison.

5. Conclusions

We proposed an efficient trainable image compression method and achieve good performance. In particular, we add a hybrid domain attention module that not only improves the transforming capability of the encoder-decoder network but also generates more compact attention masks with hyperprior distribution, which facilitates more accurate probability estimates and thus improves entropy coding efficiency. In addition, our method combines the reuse of intermediate layer information to synthesize the final reconstructed image through a postprocessing enhancement module. We add a quantization adaptive adjustment module to repair quantization losses. This method reduces the total error by optimizing the network parameters through backward propagation. The results of experiments suggest that our method offers a substantial improvement over both traditional compression methods JPEG 2000 [2] and BPG

[3], and the learning-based method of Ballé et al. 2017 [6], compared to the advanced learning-based image compression methods of Minnen et al. [10]. This method also has a higher performance index and better visual effect. In the realm of learning-based image compression, extracting compact latent features is especially significant. Attention mechanisms can be still unable to completely eliminate data redundancy in latent features, and better capable attention mechanisms are still being explored. The addition of a postprocessing module on the decoder side and the inverse quantization module in hybrid quantization and the nonlocal block (NLB) [34] in the hybrid domain mechanism all add to the computational complexity, but the performance advantages are significant. We expect that more efficient and lightweight attention mechanisms for extracting latent features can be explored.

Objective. To observe the controlled effect of dexmedetomidine for neurosurgery and the effect on postoperative cognitive function. The main task of this paper is to use data from a small sample. The proposed feature extraction algorithm based on the bilinear convolutional neurological network (BCNN) is based on a small sample of data. BCNN involves the simultaneous extraction of highly discriminative cross-sectional features from the input image using two parallel subnetworks. By optimizing the algorithm to minimize losses, the two subnetworks can be supervised by each other, improving the performance of the network and obtaining accurate recognition results without spending a lot of time adjusting parameters. The mean arterial pressure (MAP) and heart rate (HR) levels of cerebral oxygen metabolism were compared between the two groups before (T0), after (T1), immediately after (T2), and after intubation (T3). In the observation group, MAP and HR values at T3, arterial-internal jugular vein bulb oxygen difference $[D(a-jv)O_2]$ at T1, T2, and T3, cerebral oxygen uptake (CEO_2) levels, and postawakening agitation scores were lower than those of the control group during the same period ($P < 0.05$).

1. Introduction

Craniocerebral injury in surgery is more traumatic and patients suffer from nervousness and fear, which require appropriate anaesthetic hypnosis to reduce the occurrence of stress reactions and improve surgical safety. Postoperative extraction, aspiration, and postoperative pain stimulation can lead to excitation of the sympathetic-adrenergic system, increased blood pressure levels, increased heart rate, and even cardiovascular and cerebrovascular accidents [1]. Dexmedetomidine is highly selective for α_2 receptors, with an affinity more than 1,600 times that of α_1 receptors, inhibits norepinephrine release [2], reduces postsynaptic membrane excitability, has a low preoperative aerodynamic impact, has no respiratory depressant effect, effectively inhibits sympathetic excitation, lowers catechol levels, and reduces the stress response. When combined with opinions, it can prolong the duration of opiate analgesia and enhance the sedative effect with significant effect [3].

Craniocerebral injury is a difficult procedure as the vertebral body and the surrounding tissues are rich in blood vessels and the operation site is deep, making it difficult to stop bleeding [4]. Patients undergoing craniocerebral injury are mostly middle-aged and elderly, mostly combined with underlying diseases, so maintaining the hemodynamic stability of patients is of positive significance to improve the safety of surgery [5]. Dexmedetomidine is a new highly selective α_2-adrenergic agonist that can reduce the stress response during surgery and maintain aerodynamic stability [6]. This study will look at the effect of dexmedetomidine in controlled hypotension during craniocerebral injury and its effect on patients' postoperative cognitive function.

Under normal conditions, cerebral oxygen metabolic rate changes in synchrony with cerebral blood flow. When the cerebral oxygen metabolic rate increases, the cerebral vasculature also strengthens and automatically dilates, resulting in elevated cerebral blood flow, which can cause secondary brain damage to occur when the cerebral oxygen supply and demand are in an imbalance [7, 8]. In this study, we compared and analysed the differences in postoperative cognitive function between the two groups, and the results showed that cognitive function in the observation group was higher than that in the control group within a short period of time after surgery, which is consistent with the findings of Gunduz et al. [9], indicating that dexmedetomidine is beneficial to the recovery of cognitive function after anaesthesia. This may be due to the cerebral protective effect of dexmedetomidine, which reduces the cerebral oxygen metabolism rate, increases the superoxide dismutase content, and antagonises the brain damage caused by the anaesthetic.

In conclusion, dexmedetomidine is safe and effective for controlled hypotension in craniocerebral injury, effectively inhibiting cardiovascular responses during tracheal intubation, reducing the patient's preoperative cerebral metabolism level, and improving postoperative cognitive function.

2. Knowledge Background

2.1. Restlessness and Impact. Song et al. [10] define agitation as the hyperexcitability of the patient during the awakening period after the application of ether, cyclopropane, or ketamine anaesthesia, which is mainly manifested by unconscious movements of the limbs, uncontrollable crying, irrational speech, excitable agitation, and disorientation.

The causes of agitation are multiple and include surgical-related factors (postoperative incision pain and prolonged passive position), anaesthetic factors (partial anaesthetic drugs and residual effects of inotropic drugs), and various adverse stimuli (catheter and tracheal tube stimulation) [11]. However, it is still not possible to explain the exact mechanism by which all postoperative agitation occurs. Some scholars believe that it may be related to the different degrees of suppression of the central nervous system by anaesthetic drugs; such patients may have recovered consciousness during the awakening period of general anaesthesia, but due to the residual effects of some anaesthetic drugs, the patient's cerebral cortex is still suppressed, while their subcutaneous central functions have been restored. This inconsistent neurological state results in a lack of functional integrity of the brain, which ultimately leads to a state of central nervous system hyperexcitability [12]. This lack of functional integrity can take many forms, for example, after awakening from anaesthesia, the patient is generally quiet and drowsy, with a small number of patients having mild disorientation and a gradual normalisation of the functional brain response from blurred or sluggish, but a few of these susceptible patients can be agitated (reflexively antagonised) by any adverse stimulus (pain, distress, or discomfort) during the period of blurred or sluggish functional brain response [13].

2.2. Dexmedetomidine. a_2 adrenoceptor (a_2-AR) agonists are favoured by anaesthetists because of their unique mechanism of action in anaesthesia and the fact that they do not inhibit breathing. Dexmedetomidine (Dex) is a relatively recently discovered and used a_2 adrenoceptor agonist, which was first used in the USA in 1999 for short duration (<24 h) sedation of ICU patients; it has since been used in a wide range of clinical applications due to its unique pharmacological properties [14]. DEX inhibits the release of norepinephrine from neurons by making brainstem pontine, calms the brain, and resists anxiety. Its unique feature is to keep the brain awake in the case of hypoxia. This advantage makes Dex unique in the type of surgery that requires intraoperative patient cooperation [15].

In the perioperative period, many patients have an excessive stress response due to fear of anaesthesia and surgery, resulting in excitation of the sympathetic nervous system and increased release of catecholamines, which is reflected in circulatory fluctuations such as increased heart rate and blood pressure [16]. Dex significantly inhibits sympathetic hyperexcitability and the release of noradrenaline from neuronal endings, improving perioperative blood flow stability and thereby reducing the risk of perioperative myocardial ischemia [17].

3. Bilinear Convolutional Neural Network (BCNN)

The main task of this paper is to identify the craniocerebral injury of dextromethorphan. Our proposed BCNN structure is shown in Figure 1 [19]. Its innovation lies in (1) using two parallel subnetworks to simultaneously extract highly discriminative cross-sectional features from the input image; (2) fusing the extracted features to obtain fine features that help in recognition; and (3) minimizing losses through an optimization algorithm; the two subnetworks can supervise each other to improve the performance of the network and obtain accurate recognition results without spending a lot of time to adjust the parameters. The following will introduce the method of this paper in detail at network initialization, data acquisition and preprocessing, BCNN network design, etc.

3.1. Network Initialization. Network initialization has a significant impact on training, and poor initialization tends to trap the neural network in a gradient-depletion trap. Aryan et al. [7] pointed out that low-level CNNs learn features similar to the edge portion of the mask obtained by Gabor kernel filtering, and as depth grows, the CNN gradually learns distinctive features of the object; Therefore, many researchers have tried to fine-tune the parameters of the classification layer of the model to cope with different task scenarios using a migration learning-based training strategy. For the case of this study, which has a small sample of labelled dextromethorphan surgery data and is prone to overfitting in training, a migration learning strategy was adopted to initialize the subnetwork of the BCNN model using the ImageNet pretraining model, while the remaining parameters were initialized using Kaiming [21] initialization. The Kaiming initialization makes the output in training

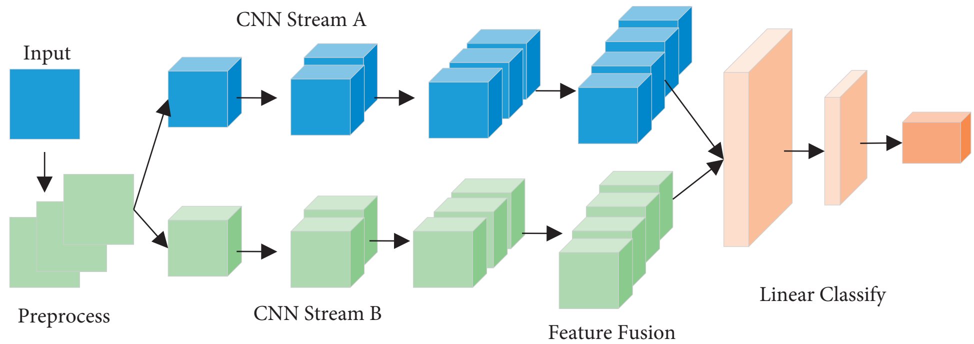

Figure 1: BCNN structure.

closer to the Gaussian distribution, which is conducive to the convergence of the network. The learning rate is set to 0.1 for the migration learning parameter layer and 1 for the Kaiming initialization parameter layer and decreases as the number of model iterations increases to provide a fine-tuning effect. This strategy allows the network model to maximize the learning of the distribution of the target data.

3.2. BCNNs. In the BCNN dextromethorphan surgery recognition algorithm constructed in this paper, the feature extraction part consists of two parallel CNN subnetworks, using ResNet and SqueezeNet as the backbone of the subnetworks, referred to as BCNN-R and BCNN-S in the following. $\beta = (F(A)F(B), P, C)$ represents the whole model, where F denotes the feature extraction layer of the network, F(A) and F(B) denote the features extracted from the two subnetworks, respectively, P denotes the outer product pooling function, and C is the classification function. The function of the feature extraction layer F is to map a point l on the input image L to a $J \times M$ dimensional feature, which is pooled by the P function given by equation (1), and the classification function C outputs the identified types using the softmax function in equation (2), where O_i is the output for class i.

$$(l, \mathrm{L}, \mathbf{F}(A), \mathbf{F}(B)) = \mathbf{F}(A)(l, L)^{\mathrm{T}}\mathbf{F}(B)(l, \mathrm{L}), \tag{1}$$

$$C_i = \frac{\exp(O_i)}{\sum_i^c \exp(O_i)}. \tag{2}$$

BCNN-S chose SqueezeNet [22] as the backbone network, mainly using the Fire module, which consists of two parts: compression and extension. The compression module fuses features of multiple dimensions into fewer dimensions, firstly convoy the input image using 3×3 convolution kernels to obtain a feature map with a higher number of channels and then convoying the feature map of the previous layer using fewer 1×1 convolution kernels to integrate features across channels to achieve the goal of reducing the number of feature dimensions. The extension module adopts a design similar to that of the Inception network [23], extending from the width of the network, using 1×1 and 3×3 convolution kernels to convolve the obtained feature maps in cascade, increasing the linear representation of the model, and improving the generalisation capability. The structure of the Fire module is shown in Figure 2.

In target recognition tasks, the only commonly used classification model is the single-branch network, consisting of a convolutional layer, a pooling layer, and a fully connected layer. The fusion of F(A) and F(B) yields a bilinear feature $X = \mathbf{F}(A)^{\mathrm{T}}\mathbf{F}(B)$ of size $M \times M$, transforming X into a bilinear vector of $M_2 \times 1$ for classification using linear layers. Intuitively, the bilinear form allows the features $F(A)$ and $F(B)$ to be constrained to each other and the outer product can be calculated for all forms of their combination, similar to the expansion of the perfect square formula. The feature fusion formula is shown in the following equation:

$$\mathbf{F}(A)^{\mathrm{T}}\mathbf{F}(B) = \begin{pmatrix} \mathbf{a}_1^{\mathrm{T}} \\ \vdots \\ \mathbf{a}_m^{\mathrm{T}} \end{pmatrix} \begin{pmatrix} \mathbf{b}_1 & \cdots & \mathbf{b}_m \end{pmatrix}. \tag{3}$$

As the convolutional neural network is end-to-end, i.e., the input is the original data and the output is the prediction, the training can be optimized using the backpropagation algorithm. Let $\mathrm{d}\ell/\mathrm{d}x$ be the gradient of the loss function with respect to the input x. Then, the gradient is chained to $F(A)$ and $F(B)$, respectively, and the gradient is shown in the following equation:

$$\begin{aligned} \frac{\mathrm{d}\ell}{\mathrm{d}A} &= \mathbf{F}(B)\left(\frac{\mathrm{d}\ell}{\mathrm{d}x}\right)^{\mathrm{T}}, \frac{\mathrm{d}\ell}{\mathrm{d}B} \\ &= \mathbf{F}(A)\frac{\mathrm{d}\ell}{\mathrm{d}x}. \end{aligned} \tag{4}$$

From equation (4), we can see that A and B influence each other's gradients, i.e., they play a supervisory role, so the model can fully learn the subtle differences between the different categories to avoid overfitting, and even without deliberately adjusting the model hypermastigote, we can get better recognition results [24, 25].

4. Case Studies

4.1. Materials. The study was approved by the hospital ethics committee. Patients undergoing craniocerebral injury in our hospital from August 2016 to October 2018 were selected.

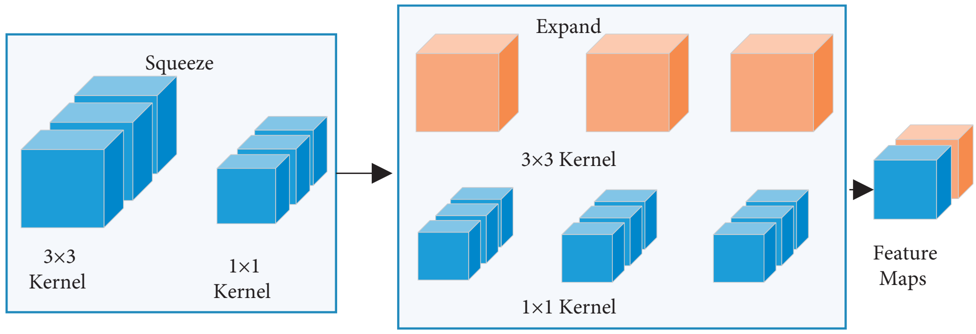

Figure 2: Structure of the Fire module.

Inclusion criteria were as follows: (1) patients with lumbar disc herniation or lumbar spine fracture who underwent elective surgical treatment in our hospital; (2) age 18–80 years; (3) American Society of Anesthesiologists (ASA) classification: grade I-II; (4) complete clinical data. Exclusion criteria were as follows: (1) combined with cranial trauma or severe central nervous system injury; (2) combined with hypertension, coronary artery disease, cardiac insufficiency, or severe cardiac arrhythmia; (3) combined with cardiac, hepatic, or renal dysfunction; (4) combined with coagulation or immune dysfunction; (5) presence of opium addiction, alcoholism, or drug abuse; (5) long-term use of immunosuppressive drugs; (6) combined with acid-base or electrolyte disorders; and (7) other internal endocrine disorders such as acid-base balance or electrolyte disorders. The 50 cases in the observation group were missing 2 cases due to follow-up, and a total of 48 cases were included, including 30 males and 28 females (age 35–77 years, mean (58.9 ± 5.9) years; body mass 47–81 kg, mean (61.9 ± 3.2) kg); 3 cases were illiterate, 8 cases were primary school students, and 37 cases were junior high school students or above; ASA classification: 29 cases of grade I and 19 cases of grade II. In the control group, there were 50 cases and 4 cases were missing from the follow-up, and a total of 46 cases were included, including 30 males and 16 females (age ranged from 37 to 78 years, mean (58.9 ± 5.8) years; body mass ranged from 48 to 80 kg, mean (61.8 ± 3.2) kg); 5 cases were illiterate, 9 cases were in primary school, and 32 cases were in junior high school or above; ASA classification: 25 cases in class I and 21 cases in class II. There was no statistically significant difference between the above general information of the two groups $(P > 0.05)$ [26].

5. Results

The differences in HR and MAP values at T0, T1, and T2 between the two groups were not statistically significant $(P > 0.05)$. The HR and MAP values at T3 in the observation group were lower than those in the control group $(P < 0.05)$ (see Table 1).

The differences in CE O_2 and $D(a - jv)O_2$ levels between the two groups at T0 were not statistically significant $(P > 0.05)$, while CE O_2 and $D(a - jv)O_2$ levels at T1 and T2 were higher than those at T0 in the same group $(P < 0.05)O_2$, $D(a - jv)O_2$ (see Table 2).

T4, T5, and T6 were higher in the observation group than those in the control group $(P < 0.05)$ (see Table 3).

The observation group had longer extubation and awakening times than the control group; the controlled hypotension time was shorter than that of the control group, and the postawakening agitation score was lower than that of the control group $(P < 0.05)$ (see Table 4).

The difference in the occurrence of adverse reactions between the two groups was not statistically significant $(P > 0.05)$ (see Table 5).

6. Postoperative Agitation Effect

There was no statistically significant difference in the time to recovery of breathing, time to awakening, and time to extubation between the two groups $(P > 0.05)$ (see Table 6).

The HR and MAP of group C were significantly higher than those of group D at all time points within 60 min after intubation, which was statistically different $(P < 0.05)$. The differences in HR and MAP at 120 min after intubation were not statistically significant between the two groups $(P > 0.05)$ (see Figures 3 and 4).

The Riker sedation and agitation scores at 60 min after extubation were statistically significantly higher in group C than in group D $(P < 0.05)$. There was no statistically significant difference in the Riker sedation agitation scores at 120 min after extubation $(P > 0.05)$ (see Figure 5).

The degree of agitation from the end of surgery to 120 min after extubation was higher in group C than in group D. The incidence of agitation was significantly higher in group D. There was a statistical difference $(P < 0.05)$ (see Table 7).

The Ramsay sedation scores of patients in group C were statistically significantly lower than those of group D at all points within 60 min after extubation $(P < 0.05)$. There was no statistically significant difference in Ramsay sedation scores between the two groups at 120 min after extubation $(P > 0.05)$ (see Figure 6).

The results should be related to the sedative effect of dexmedetomidine, and dexmedetomidine can also reduce patients' pain and relieve the negative emotion of nervousness and anxiety and fear to a certain extent while sedating them, thus reducing the occurrence of agitation [2].

Group	Number of cases	Each agitation grade count					Incidence of agitation (%)
		3 points	4 points	5 points	6 points	7 points	
Group C	20	0	4	6	7	3	80
Group D	20	2	13	4	1	0	25

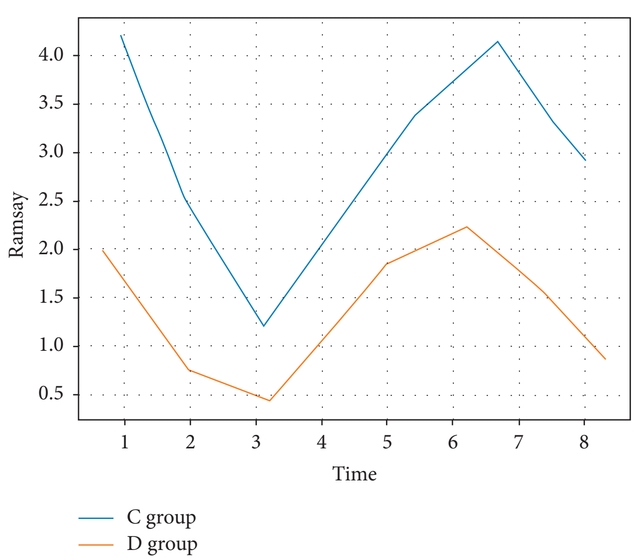

Figure 6: Ramsay score.

This study also showed the Ramsay sedation scores at the moment of awakening and the moment of exultation.

In addition, oversedation is a possible risk after dexmedetomidine application. Ramsay sedation score is commonly used by clinicians and anaesthetists to analyse the level of sedation of patients. In this study, the Ramsay sedation score of both groups was below 4, although the score of group D was higher than that of group C, suggesting that dexmedetomidine infusion had a good sedative effect and that no oversedation occurred in this study.

In conclusion, dexmedetomidine hydrochloride is an adjunct to general anaesthesia with certain advantages. The treatment protocol of a preinduction loading dose of 1 μg/kg (10 min) and a maintenance dose of 0.5 μg/kg-h continuous infusion is effective and safe to use, resulting in smoother hemodynamics during recovery from general anaesthesia after craniotomy in patients with, less postoperative agitation, and less interpretative anaesthetic. It is safe to use and results in more stable hemodynamics, less postoperative agitation, less introspective anaesthesia, and a lower incidence of postoperative chills and delirium.

7. Conclusions

The proposed feature extraction algorithm based on a bilinear convolutional neural network consists of simultaneous extraction of highly discriminative cross-sectional features from the input image using two parallel subnetworks. Dexmedetomidine can be safely used for controlled hypotension in craniocerebral injury to reduce preoperative cerebral metabolism and improve postoperative cognitive function.

Data Availability

The data underlying the results presented in the study are available within the article.

Conflicts of Interest

The authors declare that there are no conflicts of interest.

The flipped classroom is a revolutionary teaching method that reverses the traditional roles of teachers and students, as well as the traditional classroom and after-school schedules. The flipped classroom is currently the most popular English teaching reform, so the design and development must meet the practical needs of college physical education teaching. Subverting the classroom is a highly effective service for college physical education that promotes college physical education quality improvement. The research topic of this study is the application of the flipped classroom teaching model based on few-shot learning in public physical education in ordinary colleges and universities. It analyzes the conceptual advantages of the flipped classroom teaching model based on few-shot learning, combining its benefits with the current common college environment. There are issues in physical education, and a teaching model suitable for public physical education in ordinary colleges and universities is gradually being developed in order to improve students' enthusiasm for independent learning and classroom teaching quality. The flipped classroom teaching model has given rise to new ideas for the construction of a physical education model: first, students' physical learning is no longer limited to the physical education classroom, thanks to the use of network technology to change the learning environment. Teaching resources have been expanded to include many online sports resources, so students' physical learning is no longer limited to the physical education classroom. Students can learn anytime and anywhere, which allows them to continue their education throughout their lives; second, flipped classrooms increase teacher-student interaction and play an important role in re-establishing a harmonious teacher-student teaching relationship: third, online courses help students develop their skills. Autonomous learning's ability to shape students' personalized learning is better suited to the development of students' core literacy.

1. Introduction

The purpose, principles, and production process of the few-shot learning design for the general physical education major of college physical education are discussed in this article, which first outlines the general few-shot learning design and development. A typical case is taught in few-shot learning, a general physical education course [1]. The fifth section aims to develop the few-shot learning method, which is currently being used in general physical education teaching at colleges and universities, in conjunction with the flipped classroom teaching mode, in order to carry out actual teaching, strictly control the experiment process, and verify the few-shot learning teaching method. It is more beneficial to assist students in learning about sports technology [2].

Teachers and students use various methods in the teaching process to achieve common teaching goals and complete common teaching tasks, which is referred to as a teaching method. The teaching method chosen has a significant impact on the teaching effect, and different teaching methods have different teaching effects. The current physical education teaching method uses a class teaching system, which makes it difficult to respect student differences and even more difficult to provide personalized instruction [3].

The flipped classroom, on the other hand, is a new type of personalized teaching mode based on few-shot learning in the context of information technology. Students can learn anytime and anywhere using the teaching videos created by teachers, and they can track their progress based on their own understanding ability. Students can interact with one another if they have any doubts or incomprehension while self-studying [4]. Above all, teachers can gain a better understanding of each student's learning situation by receiving feedback from students prior to class. At the same time, teachers can group the students of different learning levels in class or group the students according to their mastery of a specific knowledge point and conduct hierarchical teaching according to the actual situation of each group in a targeted manner, taking into account each of them [5].

This article combines my own experience with few-shot learning, identifies flaws and areas that need to be addressed, and then presents my own insights and prospects for future research into few-shot learning. The traditional teaching method emphasizes the importance of continued training in order to improve technology quality. Excessive learning repetition will inevitably bore students and cause them to lose interest in learning. Few-shot learning, which became popular in the 1990s, helped to solve some of these issues [6]. Few-shot learning is being used in college physical education classes to reflect a more free and flexible teaching method, and the content of few-shot learning is being streamlined [7]. Physical education is a skill-based collective project, so it avoids students' resistance to a large amount of teaching content during the learning process, which reduces the classroom's teaching effect, reduces students' learning efficiency, and prevents students from mastering technical movements. A sense of learned helplessness is produced by weakness [8]. The use of the flipped classroom teaching model has improved the status and performance of physical education, facilitated the continued acquisition of physical skills at the university level, and improved the overall development of quality education. The flipped classroom teaching model promotes the advancement of sports reform, the achievement of student-centered physical education goals, the fulfillment of personal needs, and the development of students' interest in sports learning and practice. This study establishes a new practical physical education teaching model, changes the teaching model and organizational form simultaneously, and increases students' enthusiasm for learning and practice.

2. Related Work

In recent years, the research on the flipped classroom teaching model is relatively early, and various theoretical methods are relatively mature. Two high school teachers (Jonathan Berman and Aaron sans) from the United States were unable to use screen recording software to record courseware or lecture audio and upload these materials to the Internet, which made the absent students unable to enjoy the relevant course content. The essence of the flipped classroom is to "reverse" or "flip" the traditional teaching form, that is, to transform the traditional "teaching first and then learning" into "first learning and then teaching." It is subverting the traditional classroom form and forming new teachers and students. Relationship, this is not only a flip of the teaching form but more importantly, the change of teaching philosophy [9]. At the same time, flipping is just a means. Its real purpose is to leave more time in the classroom for teachers and students to fully communicate and interact, stimulate each other's intellectual potential, and free the teacher from the heavy work of repeated teaching. The time guides students to construct the correct knowledge framework and improve the efficiency of students' learning [10].

Literature [11] found through a large number of tests that human memory capacity is infinite in a sense, but people have limited access to learning and acquiring knowledge. There are too many things to learn, which is more than that from a psychological point of view. People's cognitive ability, in layman's terms, is that they are too greedy to chew. Few-shot learning focuses on its "micro" characteristics, the content is refined, the important and difficult points are prominent, and it is easy to quickly internalize the learned knowledge for personal use.

Few-shot learning, also known as few-shot learning process, is the abbreviation of microvideo network courses, according to literature [12]. It focuses on specific subject knowledge points using microteaching videos as the primary carrier, such as key points, difficult points, and doubts. Designed and developed a new type of contextualized and support for a variety of learning methods of online course resources, such as test sites or teaching links, such as learning activities, themes, experiments, and tasks. "Few-shot learning" is defined by literature [13] as "an online teaching video document aimed at explaining a certain point of knowledge, using short and succinct online videos as the form of expression, with the purpose of learning or teaching applications." Reference [14] considers "few-shot learning" to be beneficial. It is a type of situational and interesting development carefully designed and developed for a specific subject knowledge or teaching link in order to support a variety of learning methods such as flipped learning, blended learning, mobile learning, and fragmented learning, using short and succinct microteaching videos as the main carrier. The package of scientific and visual learning resources "few-shot learning" or "few-shot learning process" means that the time is less than 10 minutes and there is a clear teaching goal and content, according to literature [15]. A brief, small course aimed at explaining a problem. Microlearning is defined as a new type of learning based on microcontent and media that exist in the new media ecosystem, according to the literature [16]. Microlearning, according to the theory, can learn in a reasonable amount of fragmented time, with flexible learning time, no fixed learning location, and a variety of learning forms, including mobile phones, IPAD micromedia application terminals, and systematic learning microcontent to complete knowledge and skill learning tasks.

Literature [17] believes that few-shot learning is a kind of teaching aid resource, which is the basis for implementing flipped classrooms and the carrier of knowledge transfer. It needs a concise but complete teaching design, and an analysis of the learning situation and teaching purpose must be carried out first. Subject development and the actual needs of students choose the appropriate few-shot learning type, and then make a script recording, plus a series of exercises, tests, and other links, to produce short and concise teaching resources, which is a complete teaching system, and vice versa. The flipped classroom is the way to achieve the purpose of few-shot learning and teaching. Only by combining few-shot learning as a teaching resource, the flipped classroom can be effectively realized. Due to the accelerating pace of today's society, people's purpose of acquiring knowledge is stronger, most of them are to meet current needs. The learning time for a few-shot learning is basically between 5 and 15 minutes, and various fragmented ones can be used. Time to study, make full use of time reasonably, and the time requirement is not too high. The 60-second organic chemistry course proposed in the literature [18] was originally designed to allow more ordinary people to understand some basic chemistry knowledge in different situations and hope to apply it to other disciplines. This research has laid a good foundation for the future proposal of "few-shot learning."

Therefore, it is an urgent need to apply the theoretical results of previous studies to practical teaching in an efficient and reasonable manner, and it is also the greatest significance of this thesis. This article takes the application of few-shot learning in the teaching of general physical education courses of college physical education as the research object. Through the analysis of the disciplinary characteristics and teaching goals of the general physical education courses of physical education in colleges and universities, it uses the form of questionnaires to develop the general physical education The investigation of the current teaching situation of the course, and the measurement of the students' various sports indicators related to this research. Based on this, the design and development of few-shot learning and teaching resources are carried out. A comprehensive analysis of the influence of physical exercise attitude is carried out.

3. Few-Shot Learning and Flipped Classroom Related Theories

In the context of deep learning, each class requires at least thousands of training samples to saturate the performance of the CNN on the known classes [19, 20]. In addition, the generalization ability of neural networks is weak. When a novel class comes, it is difficult for the model to learn to recognize novel concepts through a small number of labeled samples. However, all of this is not a problem for humans. We humans have the ability to quickly learn from a small number of (single) samples. Even for a five- or six-year-old child, he has never seen a "panda." After his father showed him a picture of a panda, the child will recognize the dark circles when he arrives at the zoo. The fat animal is called "panda."

The following sentence "In Australia, humans have never seen a platypus. Humans will recognize a platypus if you show us a picture of one!" is considered as an illustration Ducks, civet cats, fish, and other animals we've seen in our lives represent prior knowledge of knowledge, while the platypus represents the unknown. This prior knowledge of knowledge is referred to as meta-knowledge, and our brain can quickly access it. A quick comparison of the platypus that has never been seen before and this meta-knowledge (there may be some other mental activities, such as visually extracting the features of objects) [21] leads to the conclusion that this one has the beak of a duck and can swim like a fish. The platypus is a new flat-bodied animal. The example in the preceding paragraph grossly undervalued the human brain. I'm just trying to demonstrate how novel concepts and established knowledge are inextricably linked. Of course, if we are completely unfamiliar with something, we need time to learn. Figure 1 depicts the general flow of the few-shot learning design.

There is a data set D, which we divide into two parts: Dbase and Dnovel, which do not overlap. Dbase is the basic training set that we used to train our model, while Dnovel is the test data. As an example, the 5-way 5-shot is considered. Each time Dnovel is tested, 5 classes (meaning 5-way) are collected. If each of these five classes has 100 samples, we will choose 100 samples at random. Among the 100 samples collected, 5 samples are used as the support set, and the remaining samples are used as the query set [22].

The traditional classroom model is to put the knowledge explanation part in the classroom, mainly to explain the teacher in the classroom, which is a complete teaching model; the flipped classroom model is to use Internet technology to liberate the knowledge of knowledge to the Internet. Students complete the teaching ahead of time through self-learning before class, which greatly reduces the teacher's teaching time in the classroom, allowing students more time to think independently, complete their homework, and communicate with each other in the classroom. The flipped classroom model greatly increases the students' "preparatory time," and teachers must do their best to achieve the high efficiency of "class time" [23]. The flipped classroom model is shown in Figure 2.

The role of the classroom has changed. In this mode, the teacher has changed from the former classroom teacher to the student's classroom coach. The change in the roles of teachers and students has greatly increased the students' interest in learning, making them more active, profound, interesting in their learning, and more proficient in sports training techniques and improving the quality of learning. In the traditional teaching model, the teacher is the center of the entire class. In the classroom, teachers mainly explain knowledge, while students passively accept knowledge [24]. Due to the lack of interaction and communication, students have lost interest in physical education. However, under the flipped classroom teaching model, the roles of teachers and students have undergone great changes, and students have gradually become the center of the entire class. This is the exchange and discussion of students in the classroom, and the teacher guides and answers questions. In the whole teaching process, teachers only need to control the learning process of students, and when appropriate, divide students into several study groups for communication, discussion,

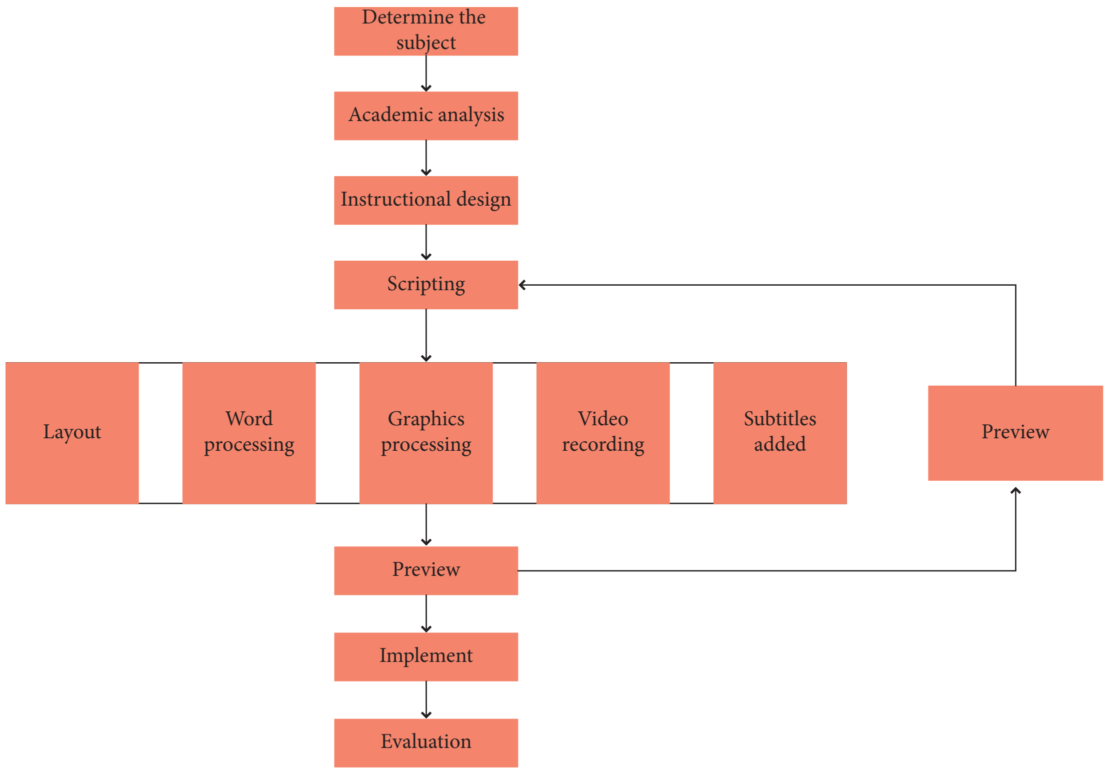

Figure 1: Few-shot learning design process.

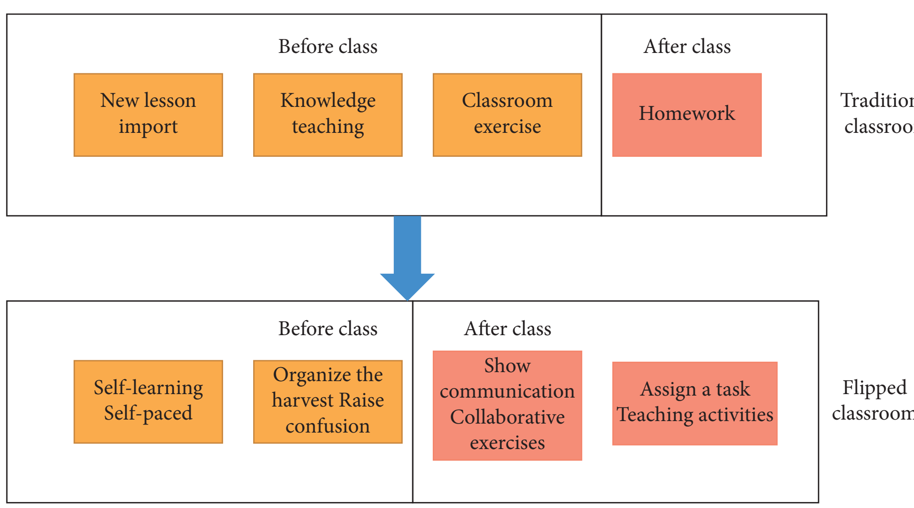

Figure 2: Flipped classroom mode.

and learning. Students not only learn knowledge but also improve their ability to operate sports techniques.

Few-shot learning is a type of educational resource. It serves as the foundation and knowledge transfer vehicle for flipped classroom implementation. It necessitates a concise but comprehensive teaching strategy. It must first assess the academic situation and teaching purpose in light of the subject's development and the students' current situation. To create short and concise teaching resources, you must first choose the appropriate few-shot type, then record a script, as well as a series of exercises, tests, and other activities, to create a complete teaching system. As a result, the flipped classroom is a one-shot deal. To effectively realize the flipped classroom, the method for achieving the teaching purpose must be combined with few-shot learning, a teaching resource. According to cognitive load theory, the human cognitive structure is made up of short-term and long-term memory. Working memory is another name for short-term memory. It has a very limited capacity. It can only store 5–9 pieces of basic data in most cases. The cognitive load will be exceeded if there is too much learning content. As a result, few-shot learning was born. It is based on small, refined learning content that follows the cognitive load theory and is gradually applied to various teaching methods.

4. Design and Practical Application of PE Teaching Model Based on Few-Shot Learning Flipped Classroom Model

The activities of teachers in the preclass stage are mainly the collection of teaching resources and the production of microvideos. Microvideos are mostly the key and difficult points in the teaching content. Therefore, teachers should formulate teaching goals and select teaching content according to the actual situation of students when making. At the same time, it is necessary to consider the individual differences of students, make multiple versions of videos, and explain the teaching content to different levels in a targeted manner. Detailed learning tasks are arranged, a variety of practice methods is provided, and students' problems in the learning process are collected. In the preclass stage, students mainly study independently on the teaching videos provided by the teacher and complete the tasks assigned by the teacher. First, a solution to the problems arising in the study is addressed or discussed and communicated between teachers and students, and between students and students through online platforms. The preclass stage mainly stimulates students' interest in learning and cultivates students' awareness and ability of independent learning, independent thinking, problem-solving ability, and innovative ability. The physical education teaching model design of the flipped classroom model based on few-shot learning is shown in Figure 3.

In the course of the class, the teacher mainly explains and demonstrates the problems that students have before class, organizes students to discuss and practice in groups, and corrects students' wrong actions in time during the tour guide. Students relearn what they have learned in the classroom to achieve knowledge internalization. In the middle of the class, the group discussion exercises mainly cultivate the students' unity and cooperation ability and language organization ability. The skill display link not only cultivates the students' sense of competition but also exercises the students' psychological quality. After class, teachers mainly reflect on the effect of classroom teaching and further improve and optimize the teaching plan. The main purpose is to improve teaching quality and improve student learning efficiency. Students' relearning after class is mainly to consolidate knowledge and further improve their technical level. The after-school period mainly cultivates students' good study habits and develops the consciousness of lifelong sports.

Teaching evaluation is the process of evaluating the process of teaching activities and results using certain standards and methods based on the teaching goals, that is, evaluating the process of teaching activities and results. Its purpose is to make course, teaching, and student training program decisions, with the most important aspect being to evaluate students' academic performance. Traditional teaching evaluation is primarily summative, that is, the assessment of students' learning outcomes at the end of each learning stage. This method focuses on assessing students' mastery of the curriculum, and while the generalization level is high, it may lead students to believe that they do not work hard in normal circumstances. During the exam, the "scallop effect" appears, which is not conducive to boosting students' learning motivation and forming a positive learning outlook.

When teaching evaluation is based on the few-shot teaching method, it uses a teaching evaluation method that is consistent with quality education, focusing on the developmental evaluation of students, and the overall development of student quality is used as the evaluation index. The fundamental principle is that each individual is responsible for his or her own actions. A student's development is based on the student's previous experiences, with a focus on the student's current situation and a greater emphasis on the student's future. The identification of learning levels and the description of student development characteristics are for the future development of students, with a focus on student evaluation in the learning process. Encouragement evaluation is carried out in the classroom, and students' classroom performance is factored into the evaluation of their academic performance. Among them, the timely, quality, and quantity completion of the after-school homework arranged by the teacher is also included in the student's score, that is, after each class, after the smashing skills are strengthened after the class, it is for everyone to communicate and evaluate and give extra points to active students. This evaluation method can not only provide timely feedback through teacher and student comments and help students improve their motor skills, but it can also promote students' subjective initiative and increase their motivation to learn.

5. Experimental Process and Design

5.1. Academic Analysis. Few-shot learning and instructional design is different from traditional instructional design. At the beginning of the design, it must take into account its short and powerful characteristics and highlight its original intention of explaining the important and difficult points. Compared with traditional teaching methods, few-shot learning with the help of videos, animations, and exquisite diagrams can attract the attention of students, increase their interest in learning, ignite their passion, stimulate their vitality in learning this sport, let them enjoy learning basic knowledge and skills and action methods in a happy atmosphere and learning by playing and playing while learning, constantly stimulate their potential, mobilize students' enthusiasm and subjective initiative in learning, and let them experience the joy of success through the learning of technical movements.

Before the teaching experiment, the subjects were surveyed with relevant questionnaires, and the survey results are shown in Figure 4.

It can be seen that the new teaching method is supported and welcomed by the students. At the same time, in the questionnaire survey, the learners' learning attitudes are analyzed, and when they have poor skills or technical actions that are not well understood in the learning process, which solutions students prefer, the results of the survey are shown in Figure 5:

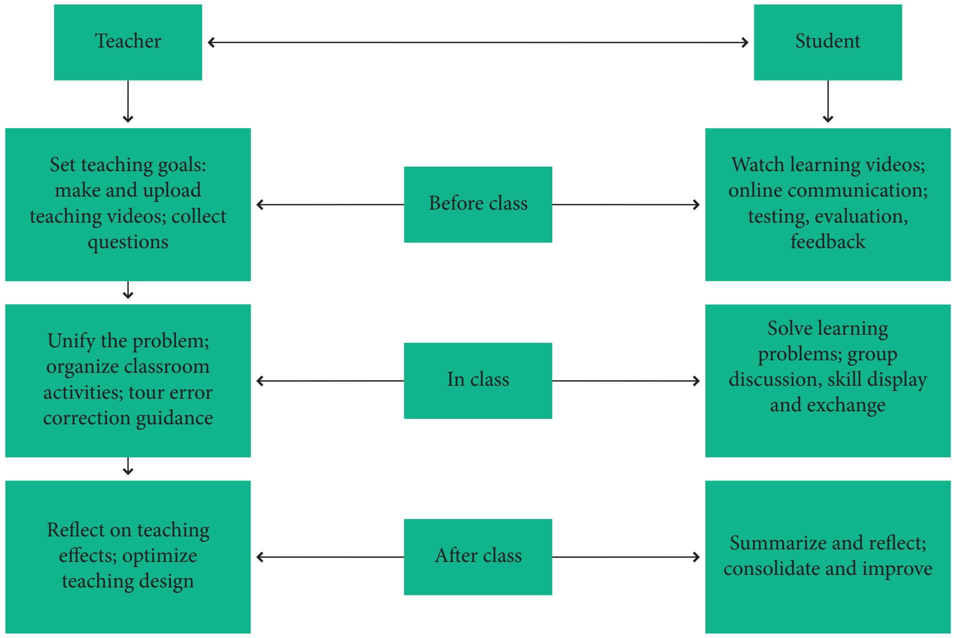

Figure 3: The design process of physical education model.

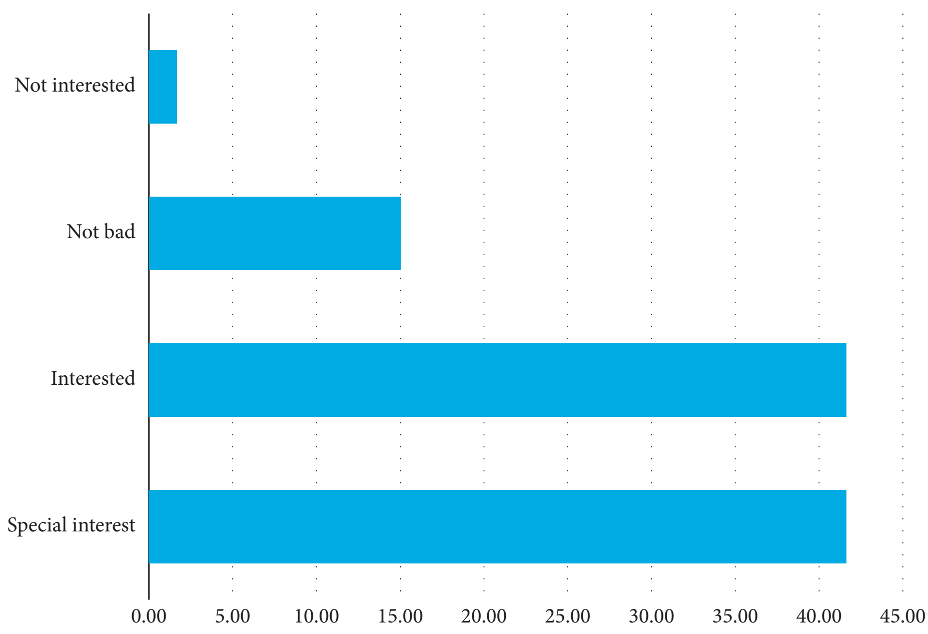

Figure 4: Attitudes toward physical education.

In the process of students learning in the past teaching methods, 83.33% of the students tend to ask the teacher and 11.67% of the students choose to watch the teaching video. Although these data are relatively small, it can be seen Although the number of samples we collected is relatively small, it can be seen from the results that the flipped classroom teaching model meets the requirements of current students' learning.

6. Instructional Design

This article randomly selects students from eight classes of the same grade. The body shape and physical fitness are used as the breakthrough test data to explain the problem, the four classes with no significant differences are chosen as the experimental class, and the other four classes are chosen as the control class. The experiment class adopts the new teaching mode of flipped

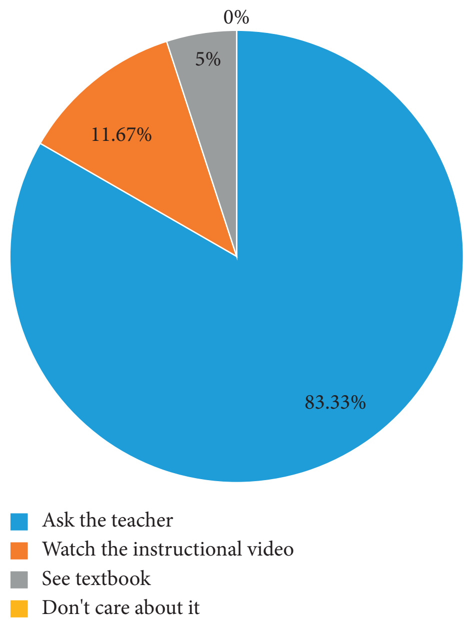

Figure 5: Students' problem-solving methods.

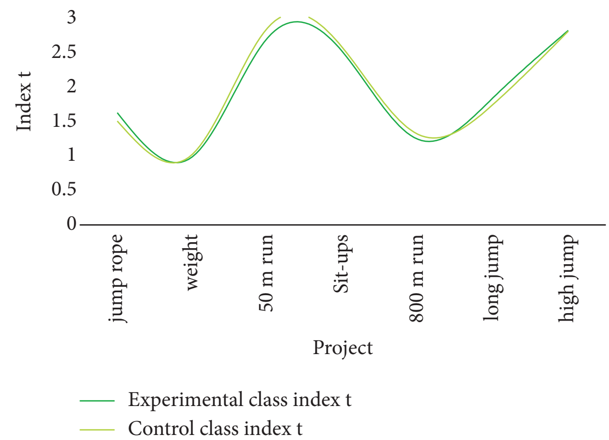

Figure 6: The physical condition of the students before the experiment.

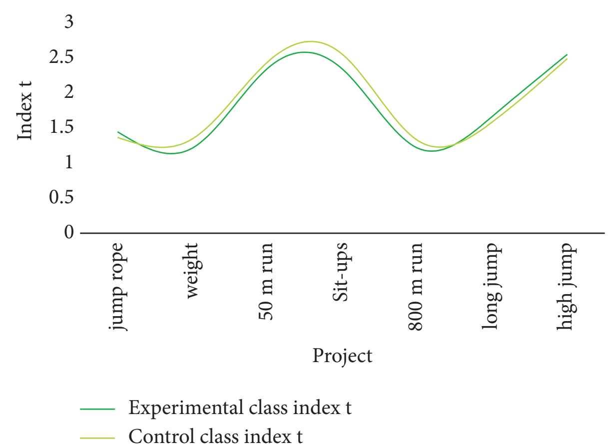

Figure 7: The physical fitness of students after training.

classroom, and the control class adopts the traditional teaching mode. Finally, the collected data were compared and the relevant data during the experiment was recorded.

Through the analysis of the pretest data of the experimental class and the control class, as shown in Figure 6.

The test data include height, weight, 50 m, and sit-ups (female) items. The data index t-test before the test showed that the P value was higher than 0.05, indicating that the experimental group and the control group had no significant differences in body shape and physical quality.

The data of students' physical fitness after training can be obtained from Figure 7.

The precheck items of human body shape and athletic ability were retested after the flipped classroom teaching model experiment. The P values are both large after t-testing, the height and weight test data are statistically obtained. The results revealed that there was no significant difference between the experimental and control groups' test results.

7. Significance Analysis of Attitudes toward Physical Training after Experimental Class and Control Class

After one semester of physical education, both classes have basically completed the smash and serve skills. At the same time, the physical exercise attitude of the two classes was investigated. The t-test was used to reflect the physical exercise attitude before and after the two semesters. Change, the difference in physical exercise attitude between the two classes, is shown in Tables 1 and 2. The corresponding results can be found in Figures 8–11.

Through analysis, it can be seen that the control class's attitude toward physical activity has slightly changed, whereas the experimental class's attitude toward physical activity has greatly improved, owing to the fact that the new teaching method is relatively new and the teaching method is relatively new. It is one of a kind and better suited to their learning styles. In conclusion, few-shot learning combined with a flipped classroom teaching mode has a greater impact on improving students' physical exercise attitudes than traditional teaching methods, resulting in increased physical activity behavior. This demonstrates that few-shot learning combined with the flipped classroom teaching mode can effectively improve students' basic level and their spiking skills. For middle-level students, both teaching methods have improved and the degree of improvement has increased. Few-shot learning combined with flipped classroom teaching mode is almost as good as traditional teaching methods in terms of improving students' high-level learning.

It was found that the physical fitness of the two classes had improved before and after the experiment. This was an inevitable result of one semester of sports training, and the improvement of the physical fitness of the two classes was roughly the same. This shows that this teaching method and traditional teaching methods are improving students There is no obvious advantage in physical fitness. The reason is that

Table 1: The analysis of the students' attitudes toward physical exercise before and after the experiment in the experimental class.

	Before the experiment		After the experiment	
	Mean	Standard deviation	Mean	Standard deviation
Action	27.58	4.37	28.78	5.42
Manner	41.89	6.05	45.95	7.39
Cognition	26.42	4.30	28.13	4.76
Habit	32.31	6.25	34.29	7.61
Emotion	31.72	4.81	23.81	5.40

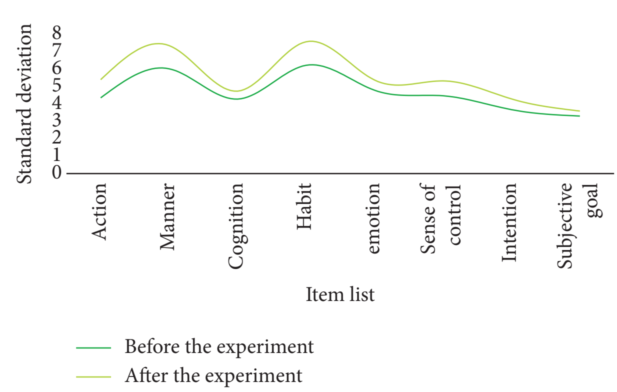

Figure 9: The standard deviation of students' physical exercise attitude before and after the experiment in the experimental class.

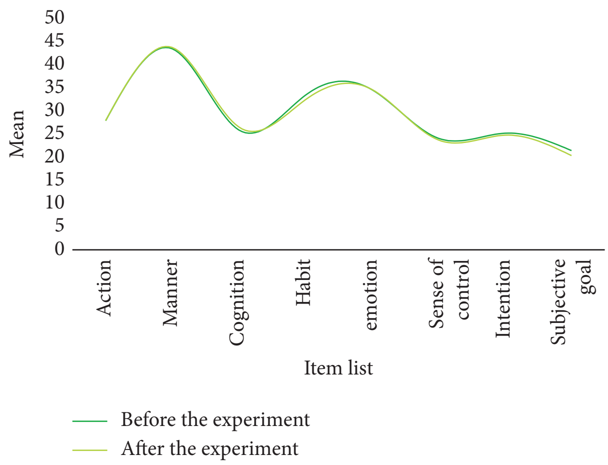

Figure 10: Mean values of students' physical exercise attitudes before and after the experiment in the control class.

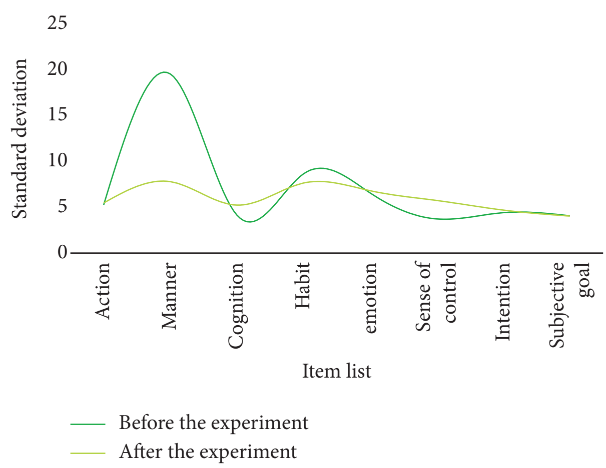

Figure 11: Standard deviation of students' physical exercise attitude before and after the experiment in the control class.

physical education has a lot of content and heavy tasks. In the teaching process, the teacher focuses more on skills and skills teaching and does not carry out special physical fitness exercises.

8. Conclusions

Both the school leaders and the teachers themselves must attach importance to the learning of few-shot learning and production technology and vigorously promote the use of few-shot learning and educational resources, but we should also pay attention to the effectiveness of the above methods in practical application. At the same time, the school should regularly invite few-shot learning and production experts to train all teachers, so that teachers can master the technology as soon as possible and complete the teaching tasks with quality and quantity.

When teaching evaluation is based on the few-shot learning and teaching method, it uses a teaching evaluation method that is consistent with quality education, focusing on the developmental evaluation of students and using the overall development of student quality as the evaluation index. The fundamental principle pertains to a student's development. Teachers who are quick to accept can help other teachers form a learning environment of mutual help and mutual assistance based on their own experience and expertise resource and encourage teachers to develop their own style of few-shot learning education based on their own experience and expertise resource. Furthermore, in order to more effectively share teaching resources, schools should create a few-shot learning and education resource information sharing platform as soon as possible to maximize information sharing. The traditional teaching method limits the assessment of students' learning to a review of their theoretical knowledge and skills. The evaluation method is relatively simple, which is detrimental to students' overall development. As a result, the content of future learning evaluations will be more diverse. The performance of students' affection and sense of cooperation should be given more attention. Similarly, evaluation methods should be varied, and a combination of methods can be used to make an objective and fair assessment of students' learning situations. It is based on the student's previous experiences, with a focus on the student's current situation and a greater emphasis on the student's future. The identification of learning levels and the description of student development characteristics are for the future development of students, with a focus on student evaluation in the learning process. Encouragement evaluation is carried out in the classroom, and students' classroom performance is factored into the evaluation of their academic performance. Students who are active will receive extra points for completing after-school homework on time, in a good quality and in a quantity that the teacher has assigned. This evaluation method can not only provide timely feedback through teacher and student comments and help students improve their motor skills, but it can also promote students' subjective initiative and increase their motivation to learn.

The teaching time for this experiment is relatively short for a variety of reasons, and there are some important and difficult points that students do not fully grasp. Simultaneously, the number of samples in the teaching experiment should be increased to make it more convincing. The use of this teaching method is encouraged.

Eye tracking is currently a research hotspot in the territory of service robotics. There is an urgent need for machine vision technique in the territory of video surveillance, and biological visual object following is one of the important basic research problems. By tracking the object of interest and recording the tracking trajectory, we can extract a structure from a video. It can also analyze the abnormal behavior of groups or individuals in the video or assist the public security organs in inquiring and searching for evidence of criminal suspects, etc. Moving object following has always been one of the frontier topics in the territory of machine vision, and it has very important appliances in mobile robot positioning and navigation, multirobot formation, lunar exploration, and intelligent monitoring. Moving object following has always been one of the frontier topics in the territory of machine vision, and it has very important appliances in mobile robot positioning and navigation, multirobot formation, lunar exploration, and intelligent monitoring. Moving object following in visual surveillance is easily affected by factors such as occlusion, rapid object movement, and appearance changes, and it is difficult to solve these problems effectively with single-layer features. This paper adopts a visual object following algorithm based on visual information features and few-shot learning, which effectively improves the accuracy and robustness of tracking.

1. Introduction

With the rapid expand of computer picture capabilities and technologies, and the improvement of the cost-effectiveness of a large number of digital picture equipment, vision systems have been widely adopted by mobile robots [1]. Computer vision is the most common method for humans to obtain environmental data via computers. Understanding the visual attention mechanism allows humans to process salient information in complex scenes quickly and efficiently, while masking and ignoring nonsalient regions autonomously. Machine learning is a century-old technology that is destined to thrive in the age of data. Machine learning's [2] advantage is that it can automatically analyze and process unknown data by mining and learning from existing data, reducing the need for human resources to the greatest extent possible. Scholars in the United States and abroad have conducted extensive and in-depth research on object recognition, object following, navigation, monitoring, and other technologies based on robot vision [3]. Machine vision's primary goal is to enable computers to mimic human thinking activities, obtain information from visual sensors to gain an understanding of the environment, and finally realize the computer's autonomous adaptation to the environment [4]. Researchers in the United States and abroad are using computers to create a visual attention model that simulates the human attention mechanism and incorporates it into the processes of object detection [5], object recognition, and moving object following, in order to bring the object processing process closer to the human cognitive mechanism and improve the algorithm's performance. This area of research has become one of the most active in the field of pattern recognition. Video image data contains the most information of all the data circulated or saved on the Internet, but extracting it is extremely difficult. According to the number of cameras mounted on the robot, monocular vision and stereo vision can be distinguished. Computer vision is a multidisciplinary field that includes computer science, physics, physiology, psychology, artificial intelligence [6, 7], semaphore processing, and applied mathematics.

The traditional mean-shift algorithm is based on the matching search process of the object color feature histogram, but the color features are not sensitive to noise and occlusion. So many surveillance cameras will generate massive amounts of surveillance video data every day, and these surveillance videos contain useful information that can be used to cardinaltain social stability, travel safety, and traffic guidance. Although the traffic police department has the right to use these surveillance cameras, there are many problems in analyzing these surveillance videos solely by the human eye. The cardinal difficulty in the research of moving object following algorithm in complex scene is the robustness and accuracy of the tracking algorithm. Monocular vision is inferior to stereo vision in terms of depth extraction, but it is comparable to stereo vision in terms of feature extraction and matching, and it avoids the problem of stereo vision binocular objecting, improves real-time performance, and has a simple structure. Machine vision technology has now penetrated many areas of the national economy, including aerospace, remote sensing and telemetry, medical aided diagnosis, map drawing, industrial security, multimedia communications, intelligent robots, and other areas. Simply relying on the human eye to analyze surveillance video will consume a significant amount of human resources, and the human eye has a blind spot and causes visual fatigue, making it impossible to maintain a long-term focus on the surveillance video [8]. This shows that there is an urgent need for machine vision technique in the territory of video surveillance [9]. With the expansion of machine vision, vision-based object following technique has become a hot spot in engineering and academia. Moving object tracking refers to the detection, identification and sports tracker objects in the video, and obtaining some motion parameters of the moving objects, such as speed, position, acceleration, and motion trajectory, so as to achieve higher-level processing and analysis [10]. The behavior of the object is understood and prepared to complete a specific task.

Object recognition is the foundation of tracking in an eye tracking system, and accurate object recognition is required for effective tracking [11]. This paper uses a visual object following algorithm based on visual information features to achieve accurate object following in complex backgrounds while overcoming partial occlusion and background fusion interference.

2. Related Work

The Harris affine detector was proposed in [12], which combines the Harris corner detector and the Laplace equation to ensure that the detected features are scale-invariant. Reference [13] proposes an edge-based area detector that constructs parallelograms around Harris corners using curved and straight edges. The most stable extremum region detector, which is a watershed-like approach, is proposed in [14]. To achieve effective multiview matching, [15] proposed using complex filters to generate kernel functions. Reference [16] proposes phase-based local features to improve lighting change robustness. Literature [17] proposed PCA-SIFT, which uses principal component analysis to simplify the SIFT descriptor, standardize the gradient region, and achieve fast matching and invariance under image distortion. Reference [18] proposes a rotation-invariant feature transformation, which divides each standard circle into a series of concentric circles, and each concentric circle is associated with a gradient orientation histogram. Reference [19] proposed that the gradient position and orientation histogram is an extension of the SIFT descriptor. Similar to PCA-SIFT, GLOH also reduces the dimensionality of descriptors through principal component analysis. Literature [20] proposed four color descriptors, namely, RGB histogram, hue histogram, vertex angle histogram, and spherical angle histogram. Reference [21] proposed a global positioning way for mobile robots based on monocular vision. Reference [22] proposes a hierarchical real-time localization and map creation way for mobile robots based on an active closed-loop strategy.

In this paper, a visual object following algorithm based on visual information features is adopted, which has good real-time performance, accuracy, and practicability. It combines sequential detection mechanism, binocular disparity information, and binocular vision calibration model to complete object recognition and localization and can achieve good tracking accuracy.

3. Research on Visual Object Tracking

3.1. Robot Vision. The identification and tracking module, the robot control module, and the robot platform make up the vision system [23]. Since their first appearance in the 1960s, robots have gone through three historical stages around the world. With the rapid growth of the robot industry at home and abroad, as well as significant progress in the field of artificial intelligence, the role of robots in human life has become increasingly important in recent years. Eye tracking is a hot topic in the field of machine vision as well as an important research direction in the field of intelligent mobile robots. With the advancement of science and technology in recent years, an increasing number of products have begun to use machine vision-related technologies, and an increasing number of scholars have devoted themselves to picture-related territories for research and expansion [24]. Algorithms started to evolve into useful devices. The advantages of visual semaphores include a wide range of semaphore detection and a large amount of data acquisition. Eye tracking has become one of the cardinal expansion orientations in the field of robotics, thanks to the rapid expansion of picture technique and computer processing capability in recent years. Robots currently perform the majority of their work by following preprogrammed instructions to perform repetitive and specific tasks [25]. The robot must be reprogrammed to adapt to the new operating environment if the operating environment changes.

Machine vision is booming, and it is providing a lot of technical support for robot technique improvement. Visual servosystems have recently emerged as a key research topic in the field of robot control. One of the key technologies of mobile robot vision is real-time sports tracker objects [26]. The basic principle block diagram of maneuvering object following is shown in Figure 1.

In order to achieve fast and effective tracking of the object, this paper proposes an improved eye tracking algorithm for mobile robots, which is based on the mean-shift algorithm, uses color features as the basis for eye tracking, and introduces Kalman filtering to predict the iterative window. The identification and tracking module adopts the improved Camshift algorithm and the way of Kalman filter [1] to identify and track the selected tracking object; the robot control module cardinally completes functions such as sending robot control instructions. With the continuous expansion of domestic and foreign scientific and technological level, computer technique, sensor technique, artificial intelligence, and robotics have developed rapidly, so that the application of robots is no longer limited to the industrial territory. Military territories such as territory, underwater, and space, as well as indoor environments such as hospitals and exhibition halls, have also been included in the application within the range [27]. At the same time, in recent years, the state has proposed the establishment of a smart city and a safe city where all things are perceived, connected, and intelligent, so that the domestic security industry can gain opportunities for rapid expansion, so that machine vision research continues to be hot, and robots can be obtained through the vision system and a large amount of information and then through the information processing and finally making a decision.

Eye tracking technique is an important research orientation in the territory of intelligent mobile robots, and it is also a hot issue in the territory of machine vision. Vision-based mobile robot tracking techniques have advanced rapidly in the last two decades. The robot's recognition and sports tracker objects require segmenting the image sequence obtained by the vision sensor into moving objects in the time do cardinal, as well as modeling, recognizing, and tracking these objects in the time do cardinal. The research on the robot with the object detection function can give the robot the ability to perceive the environment and perform servocontrol in response to changes in the environment. The visual servosystem completes the acquisition of visual image information through the camera during the robot control process, and the robot's function to obtain information from the outside world is realized. A mobile robot's intelligence is based on its ability to coordinate with external objects such as the environment and people. The vision system is crucial in this regard. A laptop and a control board comprise the robot platform. The eye tracking software is run on the laptop. The control board is in charge of driving the motor and gathering sensor data. The vision system can provide a wealth of information to the intelligent mobile robot, such as position and motion parameters, so that it can correctly perceive itself. Make the best decisions about your own behavior and the work environment in which you live.

3.2. Vision Based Object Tracking

3.2.1. Object Recognition Based on Local Features. Object recognition has been widely used in medical diagnosis, military technique, security detection, and other domains as an important research orientation in the field of picture and pattern recognition. Image understanding, automatic image segmentation, moving object following, and scene understanding are all built on this foundation. Traditional object detection and tracking algorithms typically only use the image's underlying visual features to construct object descriptors in order to obtain a description of the object's appearance for object detection and tracking and obtain the object's location information in order to realize the object's detection and tracking. Machine vision research's main goal is to use computers to simulate and realize visual functions similar to those performed by the human eye, such as object, scene, and motion detection, as well as three-dimensional reconstruction. The most important way for humans to obtain external information is through their vision system, and object recognition is a key topic in the field of machine vision and pattern recognition, which has a wide range of potential applications. Long-distance object recognition is difficult due to the image's complex background and the object's small number of pixels. Object detection is a hotspot of machine vision research, with applications in image retrieval, intelligent transportation, intelligent video surveillance, advanced human-computer interaction, and other areas. However, existing object detection methods have significant drawbacks, and a high-precision, high-efficiency, and high-robustness object detection algorithm in the field of machine vision is still urgently needed.

Common moving object detection ways can be divided into three categories: interframe difference way, optical flow way, and background subtraction way. Feature extraction is a key technique in object recognition, which plays a decisive role in the final result of recognition. Aiming at the problem of viewing angle, scale, and brightness condition changes in automatic object recognition, and the disadvantage of low recognition rate of local features is when the viewing angle and brightness change are large. The images generated in real scenes often have many complex situations such as changes in illumination intensity, object scale scaling, different imaging perspectives, object occlusion, and redundant background interference [28]. A problem in the actual process, in addition to the pose, scale, rotation, and translation changes of the object itself, is that there are also challenges such as illumination changes, complex backgrounds, and object occlusion. Recognition of objects/objects is one of the important orientations and can be divided into 3 categories according to the generality of the recognition objects: recognition of specific objects (the same thing), recognition of a series of objects (such as aircraft, ships, people, and face), and object recognition in general (and the ability to spot any object). In national defense construction, object recognition is a key technique in training, reconnaissance, and defense systems. For example, defense systems mostly use object recognition technique to track, identify, and guide missiles on mobile military objects. Robot is a multidisciplinary application technique that integrates machinery, computer, automatic control, etc.

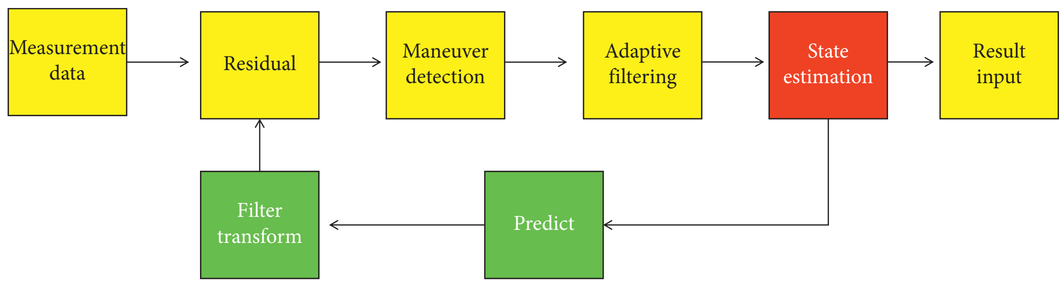

Figure 1: Basic principle block diagram of maneuvering object following.

At present, the research in this territory is active and the application is increasingly widespread. Object detection has become a challenging problem due to the uncertainty of the appearance shape of different objects, the complexity of the application scene, the mutual occlusion between objects and between objects and the background, etc. Neurophysiological studies have revealed in recent years that, in the primitive visual cortex of mammals, a sparse coding strategy is used. The human visual system can break down objects into a variety of small, meaningful pieces and use this information to identify the object robust to occlusion and pose changes, in addition other excellent properties. The object detection method based on local features has quickly become a research hotspot at home and abroad. The purpose of the local feature synthesis link is to combine a large number of local features into a single feature, resulting in more reliable features for the classifier design. The detection algorithm based on joint features is a new trend in current expansion because a single feature mode cannot accurately detect the object.

3.2.2. Object Description and Data Fusion in Visual Tracking. In recent years, with the rapid expansion of computer technique, computers no longer have simple data processing functions, but have become more and more intelligent. Target tracking is a research topic with extensive practical application significance in military and civilian territories. To realize the effective and accurate identification and tracking of the object under the difficult problem of tracking, the key is how to describe the tracking object adaptively and accurately model the tracking object. Since the expansion of object following technique in the middle of the last century, it has been widely used in various territories such as industrial robots, video surveillance, and missile interception. Intelligent video surveillance is a new type of video surveillance technique gradually developed by introducing relevant research results in machine vision into traditional video surveillance. Since the birth of the first robot in 1959, robot technique has made great progress and expansion and has become a comprehensive cutting-edge science that integrates machinery, electronics, computers, control, sensors, semaphore processing, and other disciplines. The role of robot object tracking in indoor environment is becoming more and more important.

Artificial intelligence technique subverts the traditional way of thinking of human beings, so that human beings have a new understanding of artificial intelligence. The key to effectively complete the corresponding tasks of the UAV lies in the various information provided by the external sensors mounted on it. The sensors usually used are mostly sonar, inertial navigation systems, barometers, magnetometers, etc., relying on Global Positioning System. The so-called machine vision is a simulation of biological vision using computers and related equipment. The origin of object following can be traced back to 1937, that is, on the eve of World War II, when a tracking radar named SCR-28 appeared for the first time, and its appearance marked that object following officially entered people's territory of vision. Intelligent video surveillance automatically comprehends image content without human intervention. When the individual or group behavior is abnormal, the alarm can be timely, so that the video surveillance can get rid of the dependence on the all-weather manual supervision. Intelligent robots can acquire, process, and recognize a variety of information and autonomously complete more complex tasks.

Continuous and stable sports tracker objects can not only obtain the position information of the current moving object, but also help to conduct a more in-depth analysis of the moving state of the object, so as to achieve precise positioning and intelligent control of moving objects. Guidance, vehicle navigation, human-computer interaction, and other territories have broad application prospects and great economic value. Detecting objects in videos solely using still image object detection methods is insufficient because they cannot handle useful information such as temporal and contextual information. Sensors commonly used are slightly insufficient for obtaining more accurate information about the surrounding environment or objects. When faced with this problem, applying machine vision techniques and visual sensors to UAVs, which have developed rapidly in recent decades, is an effective way to compensate for the shortcomings of traditional common sensors. Computer vision is the use of cameras or computers to simulate the capture of external objects instead of human eyes, and machine vision can process visual information according to the characteristics of computer systems through processing to enable people to understand intuitively. The technique of target tracking has grown in importance as a field of study. It has been widely concerned and applied, and it plays a pivotal and important role in industry, military affairs, and everyday life.

4. Visual Object Tracking Algorithm Based on Visual Information Features

4.1. Object Recognition Based on SIFT Features. Images have become a necessary means for humans to obtain information from the outside world as society has progressed and information technology has rapidly expanded, and the use of computers to process images to obtain information of interest to humans has become a hot research topic. Many vision appliances use image matching as a key technique. In this paper, the video stream monitored by the camera is used to control the specific object. Finally, key frame image matching is required, and the effect of matching has a direct impact on the effect of subsequent analysis and processing. Detecting and tracking moving objects has always been a challenge in video surveillance systems. Many scholars have conducted extensive research on this issue in recent years, but it remains a difficult subject. At the moment, the most common method of background modeling is to update the background statistics, with single Gaussian models, mixed Gaussian models, and their improved algorithms being the most commonly used methods. By modeling the surveillance area scene's mixed Gaussian background in the video stream, each pixel of the background image is modeled by a mixed Gaussian model made up of K Gaussian distributions:

$$\begin{aligned} P(X_i) &= \sum_{i=1}^{K} \omega_{i,t} \bullet \mu\left(X_t, \eta_{i,t}, \Sigma i, t\right), \\ X_t &= \left(x_t^r, x_t^g, x_t^b\right), \\ \eta_{i,t} &= \left(\mu_{i,t}^r, \mu_{i,t}^g, \mu_{i,t}^b\right). \end{aligned} \tag{1}$$

Before extreme point detection, the original image is preprocessed to remove noise. Then, an upscaled linear interpolation is performed on the image. Next, construct Gaussian pyramid and DOG pyramid to filter the image.

The scale space $L(x, y, \sigma)$ is established as follows:

$$L(x, y, \sigma) = G(x, y, \sigma)) * I(x, y). \tag{2}$$

Here $I(x, y)$ is the original image, σ is the standard mean square error, * is the convolution operation, and $G(x, y, \sigma)$ is the scale-variable Gaussian.

$$G(x, y, \sigma) = \frac{1}{2\pi\sigma^2} e^{-\left(x^2+y^2\right)/\left(2\sigma^2\right)}. \tag{3}$$

The DOG filter is defined as follows:

$$D(x, y, \sigma) = L(x, y, k\sigma) - L(x, y, \sigma). \tag{4}$$

Here k is a constant.

At the moment, most commercial object recognition systems use a template-matching approach. This method, however, places strict limitations on the object's position and brightness, and the matching effect is not ideal when the object's rotation, scaling, brightness, or 3D pose change. Many feature points are extracted by the traditional SIFT algorithm during the feature extraction stage, lengthening the recognition process and increasing the false matching rate. The camera is mostly stationary in most practical scenes, creating a "static background." However, as technology advances and the need to cut costs grows, the camera must move more and more to achieve continuous sports tracker objects and thus expand the monitoring range. The work-based object recognition technique is a type of pattern recognition that has both theoretical and practical applications. Despite the fact that significant progress has been made in this research, there are still numerous obstacles to overcome. Moving object detection and tracking has become commonplace in areas such as traffic management, image analysis and processing, video conferencing, and bank surveillance. The object position, including the object's pose change, can be accurately identified using the method described in this paper, and the recognition effect is good as shown in Figures 2, 3, and 4.

Because of its excellent matching performance, the matching algorithm based on multiscale space has attracted the attention of many researchers in recent years, and it has achieved great results by applying it to various appliances. A SIFT extreme value detection algorithm based on significant edge constraints is used to detect the bottom of the pyramid in the research on the identification of specific building areas in remote sense images, based on the characteristics of large territory of view remote sense images with large imaging range and complex scenes, combined with the geometric characteristics of the building area to be identified. To obtain binary images, adaptive threshold segmentation of images is used. To meet the requirements of object recognition, the SIFT feature matching algorithm needs to be improved according to the specific scene. Because image feature matching and object recognition have a lot in common, it is a good idea to use feature matching to achieve object recognition. The entire background changes as the camera moves, making it more difficult to detect moving objects against a static background. The flowchart of the background subtraction way is shown in Figure 5.

The identification of a specific object belongs to static image matching. The feature point extraction of the image and the calculation of the minimum distance are used as the cardinal ways to find the difference between the pixels of the same scene projected to the specific object image in the two images of the specific object and the given scene. Correspondence: in the past, object recognition technique based on image features has achieved good results in specific territories, and the emergence of feature extraction algorithms has brought a new idea and way to object recognition research. The detection of moving objects can obtain the relevant information of the object objects in the sequence images. By extracting the moving objects and their related information in the sequence images and segmenting and analyzing the objects, it lays the groundwork for the later part of the object following. In video surveillance system, moving object detection is the basis and premise of moving object tracking, which plays a very important role in many territories and is of great significance to video surveillance and so on.

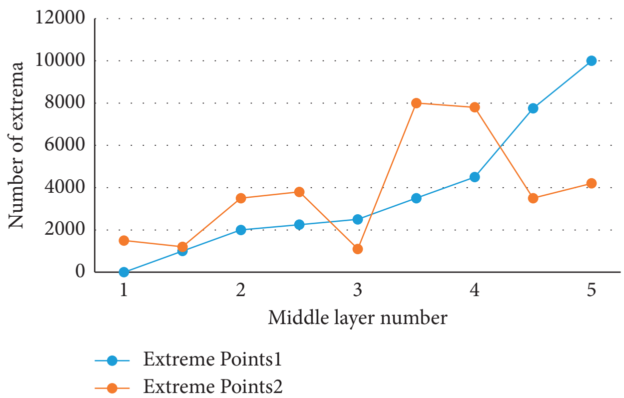

Figure 2: The relationship between the number of intermediate layers and the number of extreme points.

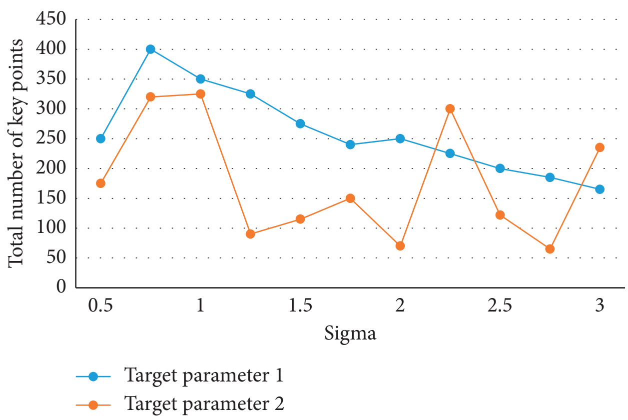

Figure 3: Relationship between the number of feature points and object parameters.

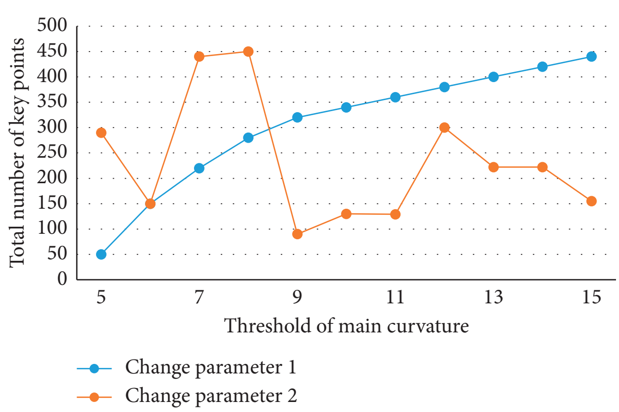

Figure 4: The relationship between the number of feature points and the changing parameters.

4.2. Tracking Algorithm Analysis. After decades of unremitting efforts of scholars, moving object detection and tracking technique has made great progress. However, due to the complexity of the application environment of the eye tracking system, such as illumination, occlusion, and other factors and the diversity of the object itself, it brings great difficulties to the object detection and tracking technique. In terms of accuracy, the appearance of the background and the object in the video image may change at any time, and it is difficult for the existing picture algorithms to accurately identify the object in the image sequence. Computer vision is a highly comprehensive subject with many interlaced disciplines. Its content involves many disciplines such as picture, artificial intelligence, pattern recognition, and neural network. The image is sent to the computer for related processing. Among the many research orientations of machine vision, eye tracking has always been one of the most important research hotspots at home and abroad and belongs to the middle-level processing part of machine vision. Its purpose is to process, detect, locate, and track objects of interest in the video sequence captured by the camera. Robotics is a combination of theoretical and scientific research achievements in various territories such as computer technique, automatic control, communication, machinery, and artificial intelligence. As robots play an increasingly important role in the current human economic expansion and technological progress, the application territories of robots continue to expand, the tasks faced by robots are becoming more and more complex, and the working environment is becoming more and more complex.

The research of machine vision has two meanings. One is to meet the requirements of artificial intelligence appliances, i.e., to use computers to realize the requirements of artificial vision systems. These findings can be installed on a variety of robots, giving them the ability to "see." Second, the machine vision model's research findings can help us better understand and study the human visual system's mechanism, as well as the human brain's mechanism, which is also important to know about. Picture algorithms generally model the appearance and background of the object in the image based on pixel points, which has the characteristics of a large amount of calculation, especially when faced with a large number of images to be processed, and the real-time performance of the object following algorithm can be solved significantly. Due to some flaws in human beings, they are unable to meet the current needs in terms of time and work intensity in such a big data era that today's society is experiencing. As the times demand, the intelligent video surveillance system emerges, successfully defeating traditional surveillance systems as well as human beings. The intelligent video surveillance system converts the traditional passive monitoring strategy of "forensics after the event" into an intelligent and active monitoring mode that incorporates "real-time monitoring and prior prevention." For incremental subspace learning in this paper, two eigenvectors are used. Figures 6 and 7 show how this works.

The trend of each monitored object and the interaction between the monitored objects can be obtained by tracking in the intelligent monitoring system, allowing for more in-depth analysis of the monitored object's behavior and the detection of specific events. In the realm of intelligent transportation, vehicle and pedestrian tracking can improve the degree of automation in traffic accident detection, as well as enabling judgment of vehicle driving states, which can then be used to understand road traffic conditions and

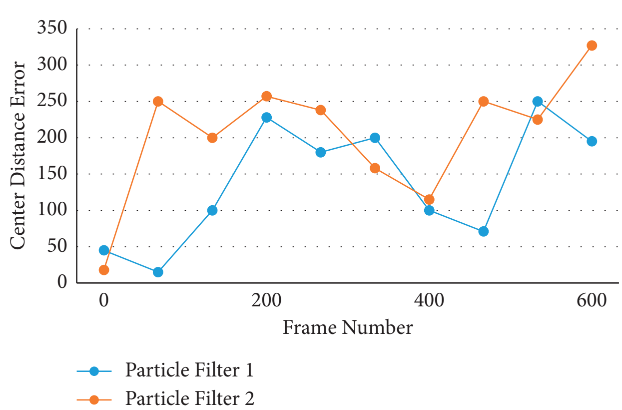

Figure 7: Center distance error 02.

provide intelligent traffic guidance. It is becoming increasingly difficult to meet the task requirements due to the limitations of a single robot's movement and perception abilities. The collaborative theory of heterogeneous robots was born out of this situation. People give multiple heterogeneous robots the ability to collaborate with one another, expand the robot's scope of action, and improve the robot's ability to complete complex tasks. Many researchers have conducted fruitful research on the eye tracking problem and proposed many tracking algorithms in order to achieve the goal of intelligent motion perception. They have proposed a number of solutions to the eye tracking issues. Through the collaboration and cooperation of multiple heterogeneous robots, the system can integrate all individual resources, and the entire system has parallelism in terms of space, time, information, and task execution. Improve the efficiency of processing tasks, thereby improving the completion rate of tasks and enhancing the robustness of the system.

5. Conclusions

Computer science, machine vision, picture, pattern recognition, artificial intelligence, automatic control, and other theories have come together to form mobile robot navigation and positioning. Through correlation filtering operations, the affine transformation information experienced by the object during motion can be extracted. A visual object following algorithm based on visual information features is proposed in this paper. The algorithm uses pixel-level object background segmentation to obtain a rough object distribution template and then uses that information to perform threshold-adaptive voting decision classification in the superpixel area to eliminate noise interference and obtain a more accurate object distribution. Video object tracking combines machine vision, image processing, pattern recognition, and artificial intelligence. It is a relatively new research approach. In recent years, it has attracted more and more researchers' interest. However, despite the extensive use of video tracking, there are still a number of issues that need to be investigated further.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Data mining technology and methods are used to effectively optimize manufacturing process parameters due to the complexity and uniqueness of the process parameters. The data-mining-based optimization method for traditional Chinese medicine (TCM) process parameters is presented, along with a list of process parameters that have shown to be effective in actual production. The influencing factors of process parameters are analyzed and modeled using an attribute weight analysis and classification analysis algorithm. The optimization scheme of process parameters that meet the requirements is selected, and an example is given for verification, by selecting data records that fall within a certain error range and incorporating the rules of association knowledge discovery. The support vector classification algorithm has a higher accuracy, despite the algorithm's results being understandable. The support vector regression algorithm developed a reliable process optimization model.

1. Introduction

Traditional Chinese medicine (TCM) is the treasure of the Chinese nation. TCM-manufacturing industry is a sunrise industry with international competitiveness and independent intellectual property rights in China's pharmaceutical industry [1]. The active ingredient extract of TCM has various uses and can be used in drugs, health products, and cosmetics. Therefore, the extraction of effective components of TCM has a wide range of practical scope and application prospects [2]. However, at present, the technical level of China's TCM-manufacturing industry has become increasingly backward compared with foreign countries. It is urgent to use modern science and tech to transform the traditional manufacturing mode of TCM products, promote the modern production of TCM, and then pave the way for TCM to rush out of the country and go to the world [3]. TCM production has moved from digitization to intelligence as a result of the rise of intelligent manufacturing technology around the world. It is necessary to continuously optimize the production process in the process of intelligent TCM production in order to gradually improve the product quality index [4]. One of the important contents of the modernization of TCM manufacturing is extracting stable active components from medicinal materials and ensuring the uniformity and stability of the drug dose-response relationship. As a result, TCM extraction is a critical step in the TCM-manufacturing process [5, 6]. It is the process of a solvent entering a medicinal material and transferring the active ingredients from the solid to the liquid phase. The choice of process parameters, such as extraction temperature, extraction time, and solvent volume, has a significant impact on the leaching of effective components in medicinal materials during the extraction process. Currently, orthogonal design is used to optimize the extraction process parameters [7].

With the promotion of advanced production technology, the manufacturing of TCM has gradually tended to be standardized. However, at present, the intelligent production of TCM has just started. It is a typical interdisciplinary subject, which needs the cooperation of control theory, pharmaceutical theory, and computer theory [8]. In the production of TCM, the selection of process parameters has an important impact on production efficiency and economic benefits. The selection of process parameters generally depends on workers' experience. These parameter values are only applicable to specific TCM products. When the production conditions change, the product quality is difficult to guarantee [9]. In the production of TCM, the production process needs to be continuously optimized to ensure the stability of the production process and the reliability of product quality. At present, the optimization of production process is still in the primary stage. The common method is to design comparative experiments in the laboratory environment to obtain the optimal production process scheme and then move the last to the production environment. In order to complete the comparative experiment, it often requires huge human and material resources [10]. TCM contains a variety of effective components, and different effective components have different effects. The extract can be used in medicine, health care products, and cosmetics. Therefore, the extraction of effective components of TCM has a wide range of practical value and application prospects. In this paper, data mining technology is applied to the optimization of process parameters of TCM, and the optimization model of process parameters of TCM is established.

Large-scale production data can be obtained as a result of the development of intelligent TCM manufacturing, and these actual production data have more practical significance than laboratory experimental data [11]. It contains the harsh conditions that occur during mass production. Using production data to create a production process model and optimize it through data mining rather than design and comparative experiment is not only a future trend but also a pressing problem to solve [12]. In the production of modern TCM, computers collect a large amount of data. Manually understanding, identifying, and optimizing these data and their relationships is typically difficult. There is no reference experience or manual for a new TCM product in the face of a new process, only accumulated data, especially for a new TCM product. At this time, it is necessary to quickly establish optimized process parameters according to traditional technologies and methods. The difficulty is great. As the manufacturing system of Chinese patent medicine is too complex and the front and rear sections interact with each other, at present, the TCM production still adopts the endpoint detection standard of production quality index for quality control, which means that the inspection of the effective components of finished drugs is the only standard to judge whether the drugs are qualified [13]. In the actual machining process of flexible manufacturing system, there are often many factors affecting the results. It is difficult to give an accurate mathematical model by using the traditional reasoning method. Through in-depth study of industrial process optimization, this paper puts forward an intelligent optimization scheme of TCM production process. Decision tree algorithm and support vector classification algorithm are used to construct the classifier of extraction times. Support vector regression algorithm is used to establish regression prediction models for extraction time and solvent amount, respectively. The experimental results show that the error of the optimal process parameters obtained by this algorithm is small, the results are accurate and reliable, and it has practical value, which can provide some reference for the industrialization of the extraction of effective components of TCM.

2. Related Work

Zhang et al. [14] used association rules to investigate the drug use law of ancient and modern asthma prescriptions, compare ancient and modern asthma drugs, and identify the core drugs for asthma treatment. Liu et al. [15] collected data from qualitative and quantitative angles to explore the syndrome differentiation of kidney yang deficiency syndrome based on the scale of kidney yang deficiency syndrome. A qualitative score was used to calculate the occurrence frequency of syndrome differentiation factors, and a quantitative score was used to perform hierarchical cluster analysis. Chen et al. [16] discussed the stroke cases of ancient famous doctors using data mining technology to analyze association rules, obtain the TCM commonly used by ancient famous doctors in the treatment of stroke, and identify common medicinal materials for stroke treatment. Data samples must be manually measured off-line in the research field of ultrasonic extraction of effective components of TCM, according to Hoogeveen et al.'s study [17]. This method of data collection has a long cycle and is extremely difficult. As a result, the amount of sample data available is limited, which is a small sample problem. Chaovalitwongse et al. [18] believe that although there are many medical record databases, the simple database has only query function and loses the core analysis function of the database. Bandaru et al. [19] emphasize the application of data mining technology in TCM medical case sorting and give the process of data mining technology in medical case information mining and the data mining method applied to medical case sorting. Lee et al. [20] propose to use data warehouse and data mining technology to save the clinical diagnosis and treatment data of old experts, analyze and mine the collected data using association rule analysis, factor analysis, discriminant analysis, and decision tree and form a knowledge base. Statistical analysis software is a data mining tool, which uses descriptive statistics analysis, frequency analysis, correlation analysis, discriminant analysis, decision tree, and neural network to analyze and mine the data related to syndrome differentiation in the database [21]. This paper explores the dialectical thinking mode of famous TCM in the diagnosis and treatment of vertigo and makes a preliminary summary of the law. Asadi et al. [22] proposed a set of relatively perfect time-series modeling theory and analysis method. In the process of optimizing the process parameters of coal plant sorting, Hyunjin and Eunok [23] designed a process-prediction real-time feedback system, which can detect the process parameters on the line in real time, predict the sorting index in real time, provide feedback and guide the production, and finally achieve the optimal sorting effect. Guo and Zhou [24] proposed data mining on medical records of threatened abortion, summarized the treatment characteristics and academic ideas of famous doctors in treating specific diseases, and played a guiding role in clinical diagnosis and treatment of diseases. When optimizing the high-pressure water jet cutting process, Angeli et al. [25] and Yd et al. established a polynomial regression model using the process parameters and cutting depth of the cutting process and optimized the parameters in the cutting process through the regression model. However, the ultrasonic extraction mechanism is complex, and the optimal process parameters are difficult to determine. Therefore, the information technology method can be combined with the ultrasonic extraction process. Introducing data mining technology into the study of modernization of TCM is another new attempt of applying computer technology to the study of modernization of TCM. This paper proposes an intelligent optimization solution of production process based on data mining, uses production data to establish an accurate quality index prediction model, screens key process parameters, and then optimizes key process parameters based on the above two steps. Thus, the intelligent optimization of process parameters using historical data is realized. The optimized process parameters are used for actual production, and the process parameters are monitored in real time. The results show that the model can optimize the process parameters and achieve good results in practical application.

3. Methodology

3.1. Data Mining. Data mining is a very dynamic research direction in the field of artificial intelligence [27, 28] and database, including classification, clustering, regression, association rule discovery, and other mining tasks. Data mining is a process of automatically searching for hidden and special relational information from a large amount of data. For massive and disorderly data, comprehensive analysis based on individual thinking will be limited by cognitive level, thinking mode, subjective factors, research methods, and research scope. It is an important part of the research on modernization of Chinese medicine to use data mining technology to acquire knowledge, remove the false and preserve the true, remove the rough and extract the fine from numerous Chinese medicine resources, so as to promote the development of Chinese medicine.

For complex and multidimensional systems, data mining technology is appropriate. We can find the rules using corresponding algorithms and break through the limitation of "information is jumbled and knowledge is scarce" in TCM with the help of a large amount of data. The primary function of data mining is discovery or prediction, and it encompasses a wide range of disciplines and methods. After "discovery," find out the hidden information patterns in a large amount of data, or find out the things or special cases in the designated area that deviate from the normal situation [29]. Prediction is the process of predicting the future based on patterns discovered. It is currently a very active research area in the fields of artificial intelligence and databases, with mining tasks such as classification, clustering, regression, and association rule discovery being included.

For the continuous storage and multilevel mining of TCM data, a high-quality and long-term updating of the data mining platform is essential. In the age of Big Data, creating a multimethod collaborative Chinese medicine mining model can help with TCM inheritance and development. Finding valuable hidden knowledge in large databases is the main problem that data mining must solve. We can create a systematic model and provide it to relevant departments for reference by analyzing and summarizing this valuable information. The medical field frequently employs drug frequency analysis, association rules, factor analysis, cluster analysis, and neural network analysis. Each of these algorithms has its own set of characteristics, and different algorithms can be used for different topics.

3.2. Application of Data Mining Technology in Optimizing Extraction Process of TCM. TCM prescription is the main means of TCM treatment. Through legislation based on differentiation of symptoms and signs, prescription is unified by law, and medicine is sent by prescription. In the prescription, there is an intricate correspondence among prescription, medicine, and syndrome [30]. As data mining technology can reflect the mutual mapping relationship between multidimensional data, it provides a very powerful research tool for the research of modern prescriptions. Under the premise of the trend of Big Data in the whole medical industry, at present, there is no system as a research system of TCM to be popularized and used in various famous doctor research systems. Only by accumulating data can we develop more knowledge to guide clinical or prescription research, which is more conducive to systematic experience inheritance of famous doctors. China's medical industry is currently in the primary stage of Big Data, which brings opportunities to the development of TCM. Through the platform of Big Data, there are more researches focusing on the origin of academic theory of TCM. A common problem is that the interpretation of data mining is not detailed enough. Using data mining to dig out potential and meaningful rules from the database can only be transformed into knowledge through high-quality data interpretation and analysis. The system established in this paper consists of four main modules: data preparation, data sorting, data analysis, and data analysis result visualization module. The main functional modules of the system are shown in Figure 1.

At present, in the field of TCM, data mining is most widely used in the research of TCM, and some progress has been made. In the process of extraction, the changes of temperature, density, pressure, liquid inlet, and other parameters have an impact on the quality of semifinished products. Using the data mining algorithm for scientific data analysis, the process parameters closest to the production results and the data interval of the process parameters that can produce qualified semifinished products can be obtained. Data mining can find the relationship between syndrome types and symptoms through a large number of

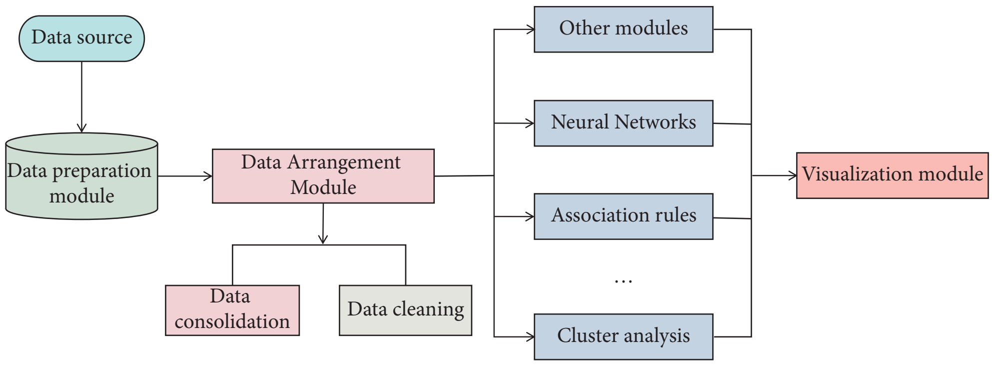

Figure 1: The functional structure diagram of the data mining system for Chinese medicine production.

clinical data, so as to assist clinical diagnosis. It has certain reference value for clinical treatment of diseases to obtain the commonly used drugs, pairs of drugs, and core prescriptions for the treatment of diseases through data mining, but it has the disadvantage of not ensuring the authenticity, accuracy, and universality of the data.

Medical records are complicated records of Chinese medicine diagnosis and treatment activities. We can master more and more objective syndrome rules if the factors are standardized first, and then data mining technology is used to analyze the contribution of qualitative variables to diseases and syndromes. The study should focus on the quality of screening documents, obtain first-hand case data from the original authors, further investigate the etiology and pathogenesis, improve clinical practice and observe the curative effect, or conduct animal experiments to further verify the effect and mechanism. The characteristics of data in TCM are discrete, continuous, mixed, and so on. The preprocessing of these data is extremely difficult, and the mining process necessitates frequent human-computer interaction, necessitating the use of professional technicians at every stage. We can only dig out truly valuable knowledge by choosing reasonable digging methods for different problems under the guidance of TCM theory and closely combined with clinical practice.

3.3. Optimization of Process Parameters of TCM Based on Data Mining. In the research of TCM, there are a lot of qualitative descriptions and a lot of vague concepts about the description of drugs, diagnosis and treatment process and disease symptoms. Especially for the description of drugs, the phenomenon that one drug has the same name as different drugs is also very common. The prescription of TCM takes the disease as the main body, adopts legislation based on syndrome differentiation, unifies prescription by law and sends medicine by prescription, and is determined by clinical practice. As data mining technology can reflect the mutual mapping relationship between multidimensional data, it provides a very powerful research tool for the research of modern prescriptions. In this paper, through the seamless integration of database and data mining algorithm, a process parameter optimization model based on data mining is constructed, which mainly uses data mining method to analyze and predict the extraction data of TCM. The data mining model of process parameter optimization is shown in Figure 2.

This system includes the function of adding multiple data files for analysis. Users do not need to combine multiple files into one by hand or third-party software to prepare data. The data related to the production of TCM are stored in different files according to the date. When importing these files, they are merged into a complete data set according to the records, and the data are cleaned to ensure that more accurate information can be mined.

The basic idea of support vector machines (SVMs) is dimension upgrading and linearization. Through the kernel function, the sample space is mapped to a high-dimensional or even infinite-dimensional feature space, the optimal linear hyperplane is found in the feature space, and the solution of the optimal hyperplane of the SVM is reduced to solving a convex optimization problem, so that the global optimal solution. SVM includes support vector classification (SVC) and support vector regression (SVR).

Let the sample set be AAA. For the linearly separable case, the sample set is separated by the hyperplane $wx + b = 0$. The problem of constructing the optimal hyperplane is transformed into

$$\begin{aligned} \min \varphi(w) &= \frac{1}{2}\|w\|^2 \\ &= \frac{1}{2}\left(w^T w\right), \\ s.t. \quad & y_i\left(x_i \cdot w + b\right) \geq 1, \quad i = 1, \ldots, n. \end{aligned} \tag{1}$$

Then, the original problem can be transformed into the dual problem of convex quadratic programming as follows:

$$\begin{aligned} &\max \sum_{i=1}^{n} a_i - \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n} a_i a_j y_i y_j \left(x_i^T x_j\right), \\ &s.t. \sum_{i=1}^{n} a_i y_i = 0, \quad a_i \geq 0,\ i = 1, \ldots, n. \end{aligned} \tag{2}$$

According to the Kuhn–Tucker condition, this optimal solution must also satisfy:

$$a_i\left[y_i\left(w^T x_i + b\right) - 1\right] = 0. \tag{3}$$

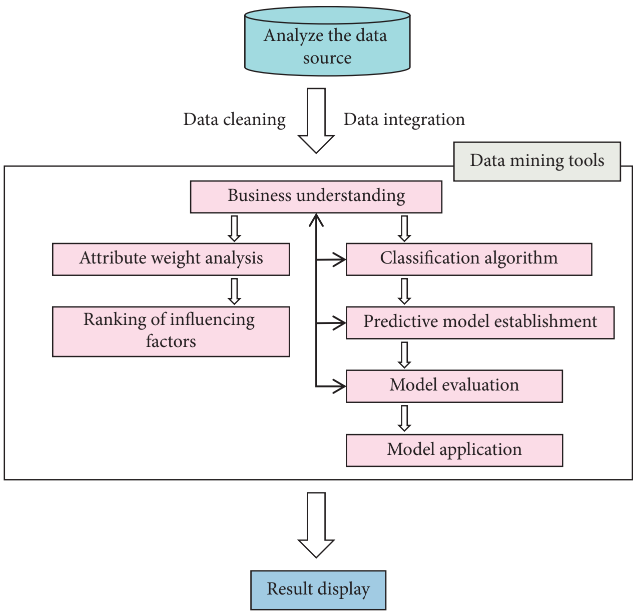

Figure 2: Data mining model for optimization of process parameters.

In the case of linear inseparability, non-negative relaxation variables can be introduced. The specific solution method is similar to the case of linear separability. Data mining analysis function includes three functional modules: cluster analysis, association rules, and neural network. By analyzing the characteristics of data that enterprises need to cluster, we know that all data attributes are continuous attributes, and the demand of enterprises is to try to divide the data with similar values into a group, so the best grouping method is to group the data with similar values according to the Manhattan distance between the data.

The multiobjective problem is transformed into a single-objective problem by linear fusion method, and then the single-objective problem is solved. Assuming that the number of process parameters to be optimized is N_v, the number of optimized objective functions is N_0, and the objective function is f, the problem can be described as follows:

$$\max F(x) = \max\left(f_1, f_2 \ldots, f_{N_o}\right). \tag{4}$$

Among them, the following constraints l and h, respectively, represent the threshold range in the parameter.

$$X = \left\{x_1, x_2 \ldots, x_{N_v} | l \leq x \leq h\right\}. \tag{5}$$

Usually, the optimal global objective function is constructed by multiobjective fusion, and the multiobjective problem is transformed into a single-objective problem. The general fusion methods include: (1) linear fusion. Linear fusion is the sum operation of each objective function according to a certain proportion, as shown in the following formula.

$$F(x) = \beta_0 + \beta_1 f_1 + \beta_2 f_2 + \ldots + \beta_n f_n. \tag{6}$$

(2) Logical integration: Logic fusion means that the output of the previous objective function is used as the input of another objective function as shown in the following formula.

$$F(x) = f_n(f_{n-1}(\ldots f_2(f_1))). \tag{7}$$

Regardless of which model fusion method is used, the goal is to reduce a multiobjective function to a single-objective function, which can then be solved using constraints. In the preparation process, there are many process parameter points to investigate, and each process parameter has a different unit of measurement. Even though some parameters have the same unit of measurement, their measured values vary widely, sometimes dramatically. If the collected data are directly analyzed and modeled based on their actual values, the role of some parameters with larger dimensions will be exaggerated, and the actual change relationship between the parameters will be obscured, resulting in the so-called false variation. As a result, the original data must be processed before being analyzed in order to eliminate the influence of dimensional effects of various variables on the model.

Many studies are unable to use randomized controlled trials due to the influence of traditional medical treatment modes and evaluation methods, and their clinical efficacy evaluation is limited to some extent, and the efficacy evaluation system is not perfect, making their research results difficult to be internationally recognized. The majority of data mining analyses are based on disease differentiation and syndrome differentiation laws, such as drug frequency analysis, association rule analysis, and cluster analysis and are combined with current disease understanding. Association rules can be used to analyze the patterns or rules of prescription compatibility. We can analyze the results of correlation data mining among different attributes such as drugs and symptoms, drugs and pathogenesis, and symptoms and pathogenesis using the frequent set method.

4. Results Analysis and Discussion

The neural network module uses the derived association rule module to integrate data, and its attributes include extracting the mean value of liquid inflow, extracting the variance of liquid inflow, extracting the mean value of temperature, extracting the variance of temperature and blending the liquid-solid content. When using attribute weight analysis algorithm and classification analysis algorithm to analyze the data, it is necessary to discretize the surface roughness in the sample data. The main technological parameters affecting the water content of TCM include the water content of extract, the temperature of feed liquid, the dripping humidity, the dripping time, the melting time, and so on. Their changes are shown in Figure 3.

From Figure 1, it can be seen that there are many uncertain factors in the process of dropping the preparation because the parameters affecting the water content change irregularly. Through the prediction of water content, the value range of each process parameter can be further determined, or the value range of some process parameters can be reduced, so that the production quality can be controlled.

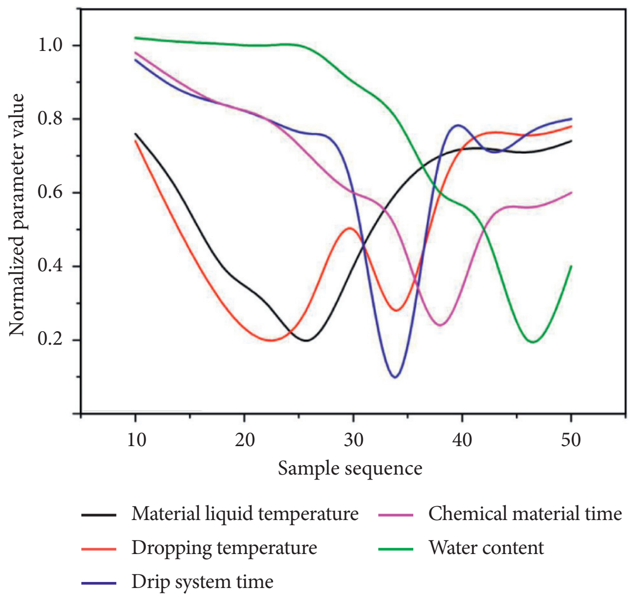

Figure 3: Changes in the main variables.

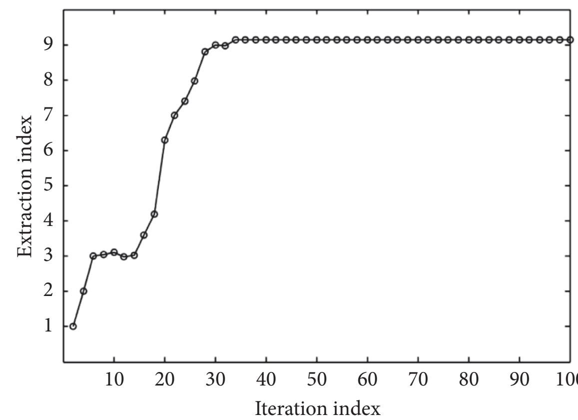

Figure 4: Forecast model optimization.

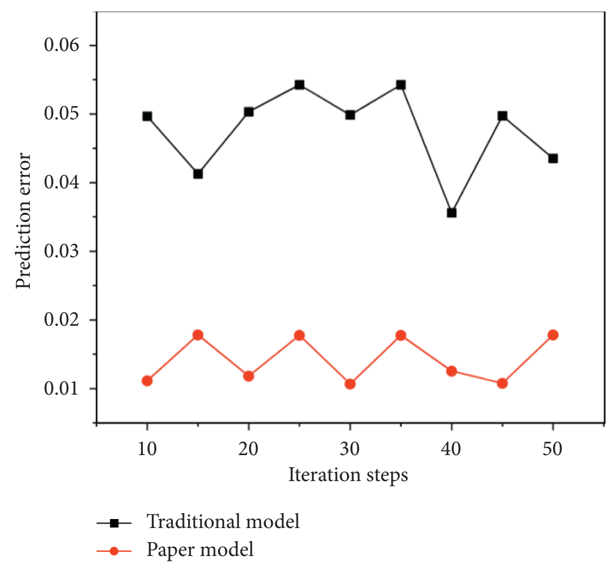

Figure 5: Forecast error analysis.

The optimization process of process parameters based on the prediction model in this paper is shown in Figure 4. To obtain the optimum conditions for ultrasonic extraction of Shaoyao Gancao Decoction.

The process parameters are modified, and the process parameters are tested in parallel for three times, with the average value taken, according to the aforementioned method, which takes into account the limitations of actual operation. The application of data mining in the field of TCM is dependent on the development of a data platform, and the continuous storage and multilevel mining of TCM data requires a high-quality and long-term updating of the data mining platform. To better serve the inheritance and development of Chinese medicine in the era of Big Data, a good data mining platform must have powerful data collection, management, and analysis functions, as well as the ability to establish a multimethod collaborative Chinese medicine mining model. The association rule module's data discretization system automatically discretizes data using a program that only requires the user to specify the number of divided intervals. When discretizing, it is necessary to keep track of the symbols for different attributes and intervals, as well as the attribute names and marks, which adds to the system's complexity but makes it easier to use.

Fingerprint of TCM is characterized by quantification, specificity, reproducibility and reproducibility, stability, integrity, and fuzziness of detail processing. Through data mining of TCM fingerprint, we can extract the hidden and potentially useful and ultimately understandable information. Taking the collected samples as the test set, the prediction model is simulated and analyzed, and the comparison results of prediction errors of different methods are shown in Figure 5.

Generally, neural network is a specific analysis of specific problems. There is no fixed model for all problems. The design of this system has a wide range of applications. It does not mean that a neural network structure is suitable for many practical problems, but users can set the network structure by themselves. Configure the input layer, output layer, and intermediate nodes according to different actual problems, so as to achieve the purpose of predicting results. In order to determine the relationship between process parameters and solid content, we select each attribute in the data except solid content as the input node, including: extracting the mean value of the liquid volume, extracting the variance of the liquid volume, extracting the average temperature, and extracting the four attributes of the temperature variance. The system predicts the solid content based on the information of these several production processes. The optimized input and output parameter values are converted into maximum and minimum inverse transformations, and the process parameter values of the preparation process can be obtained. Based on basic principles and training sample sets, a prediction model was established for the ultrasonic extraction of licorice and peony process parameters. The training result is shown in Figure 6, the test result is shown in Figure 7, and the test error is shown in Figure 8.

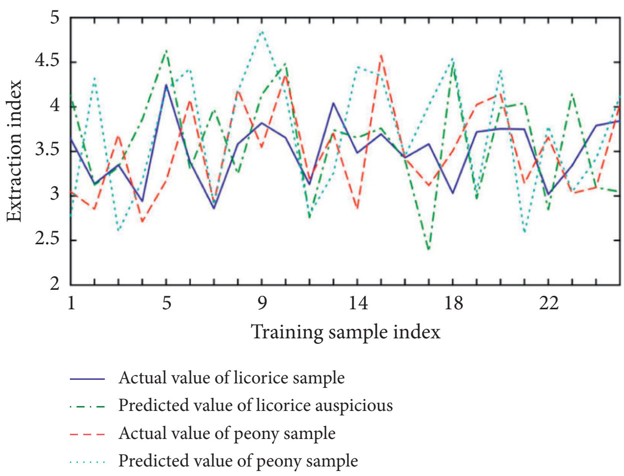

Figure 6: Predictive model training results.

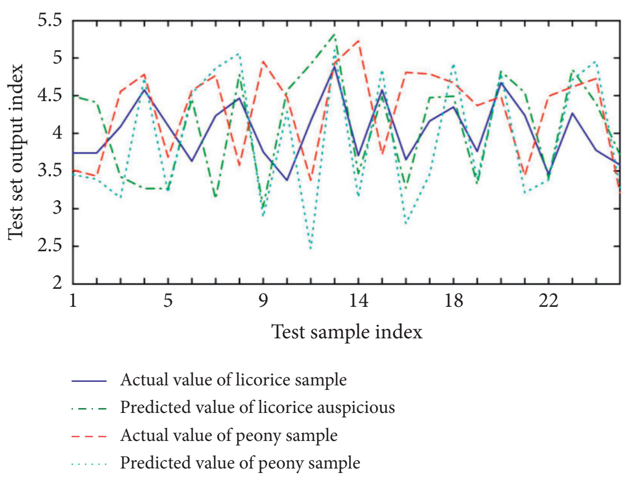

Figure 7: Predictive model test results.

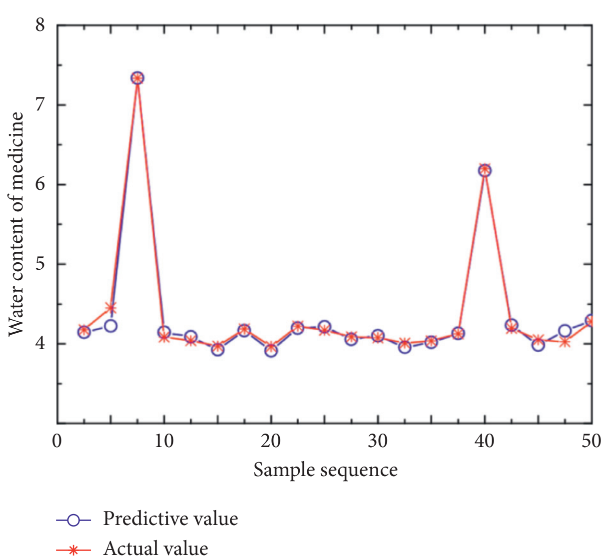

Figure 8: Comparison of predicted and true values.

Figure 6 shows that the prediction model's training effect is good. Figures 7 and 8 show that the difference between the predicted and actual values of the test sample obtained by the prediction model is generally small, indicating that this model's prediction accuracy is high. Process design knowledge is at the heart of all data in process parameter optimization. This model allows you to mine and analyze any type of continuous data. The importance of influencing factors is determined by establishing the association model of data mining and using attribute weight analysis, and the classification model of data mining is used to predict the cutting parameter scheme, and the scheme is optimized based on the predicted results. The system can analyze quality analysis data and TCM extraction data while also analyzing the data mining function of various data in various fields. It has the advantages of flexible deployment, free configuration, and expandability, and it better solves the problems of TCM extraction production data quality inspection standard optimization and process parameter optimization.

With the development of the times, the number of TCM information resources is increasing rapidly, but the characteristics of TCM information resources are complex and disorderly, which has formed a serious contradiction with the demand for information of professional and technical personnel. To solve this contradiction, an important way is to process all kinds of information and establish a relatively perfect information resource database. The algorithm of data mining part consists of attribute weight analysis algorithm and classification algorithm, and the classification model is built by data mining tools to predict the results. Show the results to users through visualization technology. In this paper, a data mining system platform is built to realize data mining of process parameter data and quality inspection data. Using data mining technology, the relationship between the extraction parameters and the description of the characteristics of TCM was discovered from the extraction data of TCM. The discovered knowledge can guide technologists to scientifically select the influencing factors of orthogonal test and the variation range of each factor level when determining the extraction process of a new drug, so as to ensure that the orthogonal test can obtain reliable optimized results.

5. Conclusion

In the research of modernization of TCM, the advanced information processing technology, represented by data mining, is used to study the knowledge acquirement of its implied essence. Systematizing and standardizing the documents left over from past dynasties can further extract and excavate the hidden essence. The research on knowledge acquisition with data mining technology has driven the improvement of the academic level of TCM. In this paper, an intelligent optimization scheme of TCM production process is proposed. From the historical data of TCM extraction process, the relevant knowledge of determining extraction parameters is mined, which is used to guide technologists to choose the influencing factors and the level of each factor in orthogonal test. Theoretical analysis and simulation research show that this method has fast learning speed, good tracking performance, strong generalization ability, low dependence on samples, and good popularization ability. In today's information explosion era, the combination of data mining technology and TCM is an inevitable trend. Data mining technology will further accelerate the pace of knowledge renewal of TCM, lay a solid foundation for the construction of modern TCM theory, and is the only way for the vigorous development of TCM.

Academic Editor: Xin Ning

Online education is a popular way for college students at present, and it is also a good compensation way to meet the special situation that traditional offline teaching cannot complete the teaching task. Traditional classroom teaching methods have been difficult to meet the learning requirements of contemporary college students, while online classroom has made up for the shortcomings of traditional classroom teaching to some extent because of its short class hours, prominent focus, and online mobile learning. First, this paper proposes an online SSL (small sample learner) model for college students to integrate healthy emotional factors. The characteristics of learners are divided into three categories: basic characteristics of learners, characteristics of behavioral factors, and characteristics of emotional factors, and the problem of solving mapping functions is transformed into the problem of solving kernel functions. Second, a novel curriculum recommendation model integrating healthy emotional factors is proposed, which fully considers the influence of user comments on similarity and transforms the similarity of users in the overall score of the project into the similarity of users in the emotional tendency of the special attributes of the project. Through the experimental evaluation, the accuracy and stability of the recommendation are greatly improved.

1. Introduction

With the continuous deep integration of big data, the Internet of Things, cloud computing, and other information technologies and education fields, the intelligent transformation of education has been promoted, and the advanced educational form in the era of educational informationization 2.0 represented by intelligent education has been achieved [1, 2]. At present, there are still some technical problems in intelligent education in the aspects of learning guidance, recommendation, answering questions, and evaluation, such as how to eliminate the semantic gap between learners and resources in resource recommendation; how to realize the large-scale online learners' answering guidance [3]; how to carry out refined teaching evaluation on learners, teachers, learning environment, and other objects.

Learning and communication through the online learning community provide people with a generalized learning method without the limitation of the number of participants and time and place [4]. Learning activities in such an environment can make everyone enjoy high-quality teaching resources and fair learning opportunities. Learning behavior data of learners in online learning communities can complete modeling and analysis of learners' behaviors, which can promote teachers and community managers to be more professional and meticulous in teaching management. A large amount of data has promoted the prosperity and development of artificial intelligence in recent years, especially the direction of DL (deep learning) [5, 6]. Due to its extremely nonlinear characteristics, DL can learn hidden patterns from a large amount of data. On the other hand, the rapid development of artificial intelligence in recent years largely depends on the development of data. Using learning data for modeling and analysis can help them to improve the quality of community content and various functions and inspire new ideas: from the perspective of teaching mode reform [7], by studying learners' learning behaviors, and can predict their learning trends, which can help them further in the rapid development of educational informationization.

Building a user portrait system can accurately depict each learner's personalized characteristics and then create a targeted study plan based on the subtle differences between different learners, which includes recommending currently suitable subjects based on learners' background knowledge structure, arranging course schedules based on learners' learning ability, recommending relevant counterpart courses based on learners' interests and hobbies, and predicting a learner's future success. Based on a review of the literature on learner models, this paper focuses on the recognition of learners' facial expressions and methods for obtaining emotional data and builds an online SSL (small sample learner) learner model that incorporates healthy emotional factors in an online classroom setting. Following that, a quantitative analysis method of curriculum recommendation model [8] suitable for integrating healthy emotional factors is discovered through an in-depth study of quantitative analysis technology of learners' characteristics.

2. Related Work

In the analysis and mining of educational big data, related universities have done a series of research and applications. For example, literature [9] developed an online learning assistant based on learner behavior analysis and intelligent dialogue. Taking the learning subject as the object, the key technologies such as the construction of an intelligent teaching environment, educational measurement, and evaluation are studied. Literature [10] constructs a learner behavior model by extracting the characteristics of learners' course completion rate and dropout rate and then predicts learners' learning behavior and judges whether learners can finally complete the course learning. Literature [11] studies the learning track and behavior data of college students learning Russian on an online education platform, extracts the data set of behavior characteristics for clustering analysis, and classifies learners according to the clustering results, so as to complete the special recommendation for learners. The literature [12] proposes a decision tree-based user performance prediction model. The end result reveals that the majority of students are in a passive learning mode. It also demonstrates how to use data mining technology to improve online teaching and learning, as well as making recommendations for students. Literature [13] proposes a comprehensive cognitive model for reconstruction analysis that integrates learners' comprehensive factors. A multimedia cognitive model has been proposed in the literature [14]. Literature [15] investigates the relationship between Facebook photos and users' personalities, primarily through Facebook's basic visual feature coding, which associates the activities associated with users' photos with the five-factor personality model. According to the literature [16], learners' utterances contain a great deal of information about their personalities, feelings, opinions, and habits in addition to semantic content.

FSL is an important goal of researchers in the process of exploring intelligent systems. Most researches on FSL are focused on neural networks [16, 17]. Literature [18] proposes to use a hierarchical nonparametric Bayesian model to realize FSL. In this model, categories are represented as tree-like hierarchical structures, such as sheep and horses for animals, cars and trucks for motor vehicles, and both animals and motor vehicles belong to a superclass. Each category is represented by two parameters, mean and variance, and knowledge transfer between different categories is realized by transfer parameters. Literature [19, 20] put forward the application of twin networks to small sample problems, which opened the prelude of neural networks to deal with small sample problems. Literature [21, 22] also proposed probability matrix decomposition and Bayesian probability matrix decomposition. Literature [23] puts forward a recommendation algorithm, which can push hot topics personalized for users to solve the problem of information overload faced by users. The content-based recommendation is simple and intuitive, but limited by the description degree of project content, and the recommendation effect is not good. Literature [24] combines and uses a variety of machine learning methods to complete the classification of a large number of movie commentary corpuses. Literature [25] introduces new feature words of semantic role tagging and discusses the application effect of multifeature word combination mode through experiments. This method has some shortcomings. The manual tagging process will take a lot of time and manpower, and it is not suitable for large-scale corpus analysis and research.

3. Research Method

3.1. Online SSL Modeling. The set of fluctuating emotions generated by learners in the learning environment that accompanies the entire learning process is referred to as learning emotion. Detailing learners' emotional characteristics, particularly the classification of basic emotional types and specific emotional characteristics, is crucial to developing an online SSL model that incorporates healthy emotional factors. In an online classroom setting, the basic learning emotions are divided into six categories: happiness, surprise, boredom, sadness, fear, and anger. Emotions can be expressed in a variety of ways, the most intuitive and quickly recognized being a change in facial expression.

The learner model, which incorporates healthy emotional factors, is the foundation and key to online classroom learners' learning analysis. This chapter focuses on the study of learners' emotional characteristics, referring to the norms of learners' models and various learners' personalized models, and divides learners' characteristic models into learners' basic characteristics, behavioral factor characteristics, and emotional factor characteristics, based on conceptual combing and theoretical analysis. A learner model incorporating healthy emotional factors is formed based on the above research. Most learners' models are currently built by analyzing and mixing learners' models from a single dimension, and most studies focus on the characteristics of learners with behavioral factors, with little attention paid to the study of learners' emotional factors. However, as intelligent teaching evolves, more educators must consider the impact of learners' emotional states on learning outcomes, and the analysis of learners' emotional states is becoming a common concern in learning analysis.

In this chapter, on the basis of summarizing the learner model specification and referring to the learner's personalized model, an online SSL model integrating healthy emotional factors is proposed, as shown in Figure 1.

Social network features include dot centrality, feature vector, and reciprocity. Emotion features include emotion data collection, expression recognition, and basic learning emotion, and the model mainly shows the basic learning emotion features. The learner model integrating healthy emotional factors is the basis and key to analyze the diverse characteristics of learners in an online classroom environment.

To analyze learners' dynamic cognitive level, first, the learning behavior of learners is indexed and then judged whether these behavior indicators obey normal distribution. It can be analyzed with corresponding correlation analysis methods, and the significant correlation detection results are obtained and judged whether to predict the model or abandon the indicators. First, a learning behavior index set is established, and the learning behavior index set is set as U, then

$$U = \{u_1, u_2, \ldots u_n\}. \tag{1}$$

Among them, u_n represents the learning behavior index, and n represents the number of learning behaviors. The goal of creating a learning behavior index set is to convert learners' specific learning behaviors into data and visual set elements, as well as to accurately present the cognitive level hidden behind learning behaviors so that learners' cognitive level can be accurately analyzed.

The data processed in SSL is often high-dimensional, and the distribution of data has no obvious structural information. Similarity w_{ij} between samples depends on the mapping function to map samples into a new space and then calculate w_{ij} in the new space. The specific calculation is as follows:

$$w_{ij} = \begin{cases} e^{\dfrac{\left\| f(x_i) - f(x_j) \right\|^2}{2\sigma^2}}, & i \neq j, \\ 0, & i = j. \end{cases} \tag{2}$$

where $f\colon R^D \longrightarrow R^M$ represents a mapping function. f map all samples to an M-dimensional space.

Let the optimal solution of the objective function be the kernel matrix K^*. The next task is to infer the category of query samples from K^*. The category to which query $\hat{x}$ belongs is obtained by the following type of weighted voting:

$$\hat{y} = \arg\max_i \sum_{x_j \in s_i} k_j^*, \tag{3}$$

where s_i represents the set of all support set samples of category i. In fact, the formula classifies the query samples into the category with the largest sum of kernel similarity, which is consistent with the classification idea in the matching network.

The frequency of course visits, the length of learning time, the degree of test completion, the number of data downloads, and other factors reflect the degree to which learners pay attention to education and reflect their behavior after accepting an online education platform. As a result, extracting and analyzing the characteristics of learners' learning behaviors are necessary in order to analyze learners' attitudes. To construct a learner's personalized model, relevant data from the database and behavior log data of an online education platform are extracted and mined. Personalized modeling, to put it simply, is the process of creating a detailed and personalized portrait of a learner.

The specific steps of the learner attitude analysis model are shown in Figure 2. In this paper, both the original data set and the feature set related to learners' behaviors are continuous data by default.

To analyze learners' attitude model, data collection is first needed. The click data, watching video data, discussion area data, and test data of learners are extracted from the online education platform, and the data related to learners' learning behaviors are extracted from them.

3.2. Curriculum Recommendation Integrating Health Emotional Factors. Generally, universities offer many elective courses, and students' elective courses are limited to some extent, so it is easy for students' scoring data to be extremely sparse. Due to the extreme sparseness of student rating data, the traditional similarity measurement method cannot effectively calculate the nearest neighbor of the target user, and the quality of CFR (collaborative filtering recommendation) system is also difficult to guarantee. The key to construct the student rating data matrix is to solve the sparseness of the data set.

Teaching quality evaluation, as an integral part of the teaching management system, aids teachers and schools in significantly improving teaching quality. Teaching quality evaluation is the process of systematically collecting data and assigning a value to teaching activities and outcomes in the classroom based on the requirements of teaching objectives and principles. The main source of teaching feedback information is the evaluation of teachers' classroom teaching quality, and it is also an important way to test teaching effect and evaluate teaching quality.

Research shows that in many recommendation methods, the most critical "emotional intelligence" factor in communication between recommendation system and people is often ignored. Especially for specific courses, such as music and movies, emotional factors often play a decisive role in recommendation, which requires the recommendation system to be able to actively meet the emotional needs of students.

The main idea is to pay attention to and mine the user comment data, mine the user's evaluation attitude towards each feature of the project, instead of calculating the user

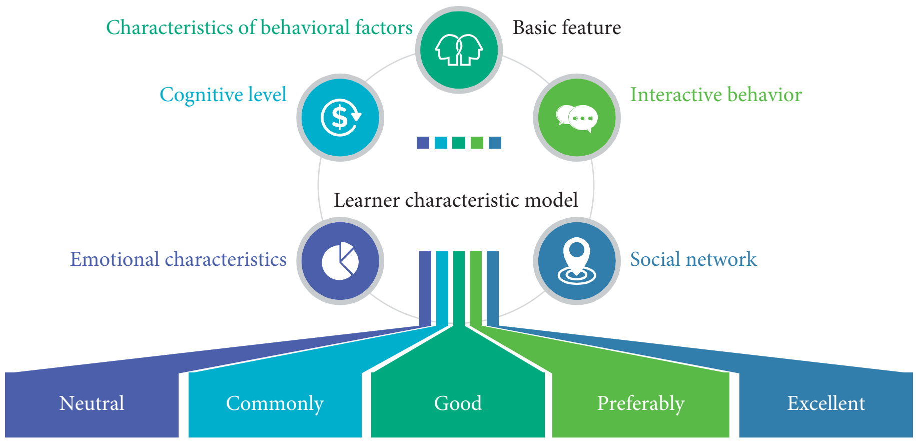

Figure 1: Online SSL model integrating health emotional factors.

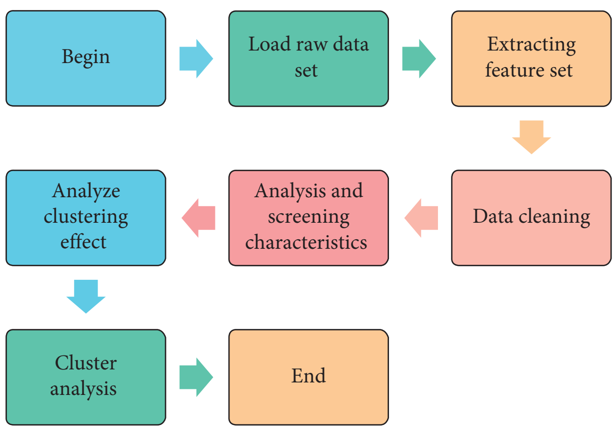

Figure 2: Generation flow chart of the multivariate cluster analysis model.

similarity based on the score information, measure the user's emotional similarity to the feature level of the project, and calculate the similarity and clustering by using the user's score of the feature of the project, so as to find the most similar N users for recommendation. The recommended framework is shown in Figure 3.

Content-based recommendation algorithm uses feature attributes to define course objects and makes recommendations based on students' evaluation of course objects. Therefore, the algorithm can be used to recommend courses in a sparse situation. First, the similarity between courses in the database and favorite courses is calculated, and formula (4)is used.

$$f(P, A) = \sum_{i=1}^{n} w_i \times \left(1 - \left|p_i - \alpha_i\right|\right), \tag{4}$$

where P represents a course in the database; A is a course that has been evaluated as a favorite by some students; n represents the number, of course, attributes corresponding to the category to which the course belongs; w_i represents the weight values of the above attributes; m_i represents the value of the i-th attribute of the course P; α_i represents the i-th attribute value of favorite course A.

By analyzing and calculating all the historical review data of a project, with the help of popular wisdom, it is possible to predict the scores of different attributes of the project.

$$\overline{R}_k = \frac{\sum_{i=1}^{N} s_{ik}}{N}, \tag{5}$$

where N represents N comments under a specific course, and $\overline{R}_k$ represents the average emotional score of the specific course on the k-th feature.

Using natural language processing technology to analyze the comment texts in the check-in history records, and further explore the emotional tendency of the texts, can accurately understand users' preferences and further improve the recommendation quality of POI (point-of-interest) [12].

Text is composed of words, and the polarity of emotional words in comments represents the tendency of text, so the tendency of comments can be obtained by calculating the polarity of emotional words. There are many ways to calculate emotion, and PMI (point mutual information) method is the simpler and more effective one.

Emotional polarity calculation usually assumes that when a word has a strong correlation with positive words, it has positive emotional polarity and vice versa. The polarity of emotion words is determined by calculating PMI between target emotion words and terms in emotion vocabulary. The PMI value between words w_i, w_j is defined as shown in formula (6).

$$PMI\left(w_i, w_j\right) = \log_2 \frac{p\left(w_i, w_j\right)}{p\left(w_i\right) * p\left(w_j\right)}, \tag{6}$$

where $p(w_i), p(w_j)$ is the probability of w_i, w_j in corpus, and $p(w_i, w_j)$ is the probability of w_i, w_j co-occurrence.

Friends often have similar behaviors and many common interests. Users usually refer to their opinions before visiting unknown POIs. Friends can influence users' choices of POIs more than ordinary users [14]. The distance between friends can be described by the number of the same friends among friends, and the similarity of interests among friends can be measured by the number of friends visiting the same POI.

Therefore, the strength of the social relationship between users and their friends can be calculated by equation.

$$sr_{ij} = \frac{\left|F_i \cap F_j\right|}{\left|F_i \cup F_j\right|} * \frac{\left|L_i \cap L_j\right|}{\left|L_i \cup L_j\right|}, \tag{7}$$

where F_i, F_j, respectively, represents the friend set of user u_i, u_j, and L_i, L_j, respectively, represents the sign-in POI set of user u_i, u_j.

Project recommendation generation is as follows:

$$R = \sum_{k=1}^{8} \overline{R}_k \times \lambda_k, \tag{8}$$

where λ_k is the attention of the target user to the k-th feature, and R is the predicted score of the candidate project, which can be regarded as the recommendation degree.

4. Results Analysis and Discussion

4.1. Emotional Feature Analysis. In this paper, emotional analysis refers to the process of gathering user feedback on a product, analyzing the content of the feedback, determining the polarity of the user's emotional tendency at the feature level of the project, that is, the favorable or unfavorable attitude and opinion toward the course or project, and then extracting more useful information.

According to the facial expression data of learners acquired by depth camera technology, the emotional state of learners is identified. The recognition result of the obtained layered RF (random forest) in the mixed expression database is shown in Figure 4.

Figure 4 shows that the hierarchical RF algorithm has a high recognition rate for learners' emotional state and can accurately judge learners' emotional state in the online classroom learning process.

It can be deduced from this that learners' emotional states changed during the stage of introducing the curriculum and teaching new lessons, and that learners always pay attention to the gradual progression of teaching content, and that learners' cognitive levels turn old and new, and that they actively construct meaningful knowledge. Features related to learners' learning behavior are extracted from all learners' features to form a feature set, which is used to analyze learners' learning attitude. Figure 5 shows the comparison of clustering results using SVS (single variable selection), RFE (recursive feature elimination), PCA (principal component analysis), and FSRF (feature selection based on the random forest).

It can be seen that when the clustering is 4 and the feature selection method is PCA, the contour coefficient reaches the maximum, and the classification effect is the best. Finally, the learner's feature data set is divided into four categories; that is, the learner's attitude model is divided into four categories.

In order to evaluate the performance of the algorithm, a small sample experiment was carried out on two data sets, namely, Omniglot [16] and miniImageNet [18]. On Omniglot data set, this paper tests the performance of the algorithm under 5-way 1-shot and 20-way 1-shot tasks. The experimental results are shown in Figure 6.

It can be seen from the figure that the performance of the SSL method based on graph regularity is slightly worse than that of prototype network with interval, because when there is only one sample in each class, the relationship between classes cannot be propagated, and it is a good strategy to simply take this sample as the representative of this class.

4.2. Course Recommendation Analysis. Here, the criteria for evaluating recommendation quality are set as MER (mean error rate) and SV (standard variance). MER is to determine the recommendation quality by predicting the deviation between the category and the actual category. The higher the MER value, the worse the recommendation quality. The calculation of SV follows the statistical method, which can directly measure the recommended quality. Here, the content-based recommendation algorithm and CFR algorithm are compared, and the three algorithms are repeatedly executed 80 times, respectively, and the recommendation quality is shown inFigures 7 and 8:

The hybrid algorithm has higher recommendation accuracy and better stability than the other two recommendation algorithms, as shown in the above figure, and clearly improves recommendation accuracy. This paper designs and compares four simplified models of curriculum recommendation model incorporating healthy emotional factors, namely, GP, CPP, SI, and ET, in order to analyze the importance of GP (geographical position), CPP (classification popularity preference), SI (social intensity), and ET (emotional tendency) factors in POI recommendation in the curriculum recommendation model incorporating healthy emotional factors.

As the evaluation indexes, AR (accuracy rate) and RR (recall rate) are chosen. The experimental results are shown in Figures 9 and 10.

Foreign countries have already integrated microcourses into daily teaching for students to preview and study independently, but domestic research on the application of microcourses is still relatively lagging behind, and the research on the process and effect analysis and evaluation of microcourses applied to teaching is not deep enough, and the research on the application of microcourses resources and learning experience tracking is almost blank. Because of the different teaching systems at home and abroad, the application of this model in China is still in the exploratory stage. Lessons from the successful experience of foreign applied microclass flipped classrooms are drawn, and the curriculum standards of various disciplines in our country are combined.

In this paper, the course features are clustered into 8 categories by analyzing the course evaluation set, and then, the attention of users to various attribute features is statistically obtained from the user's own comment set to form user preferences.

Traditional information literacy courses, like other courses, mostly use classroom teaching as the mainstay, supplemented by computer operation, and teachers as the

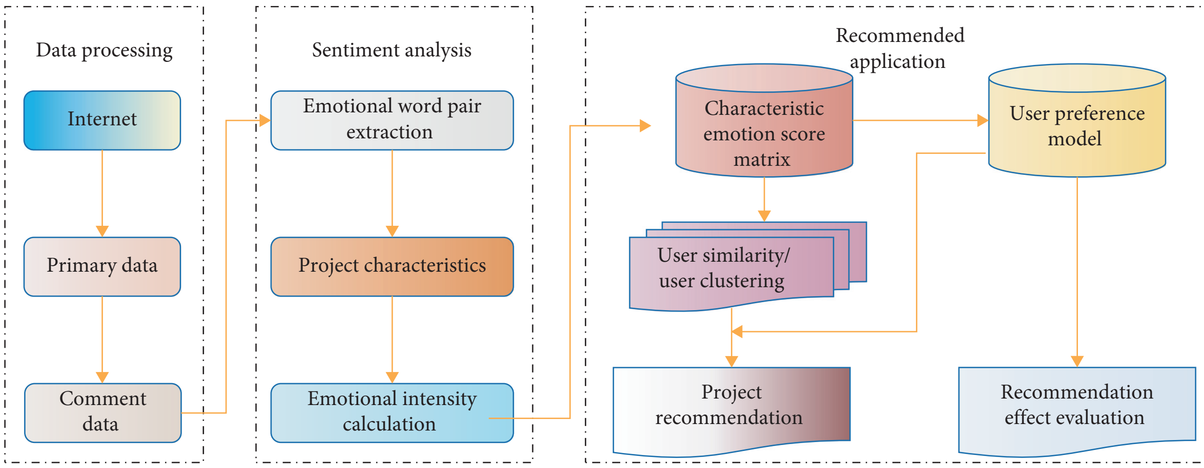

Figure 3: Personalized recommendation framework based on sentiment analysis.

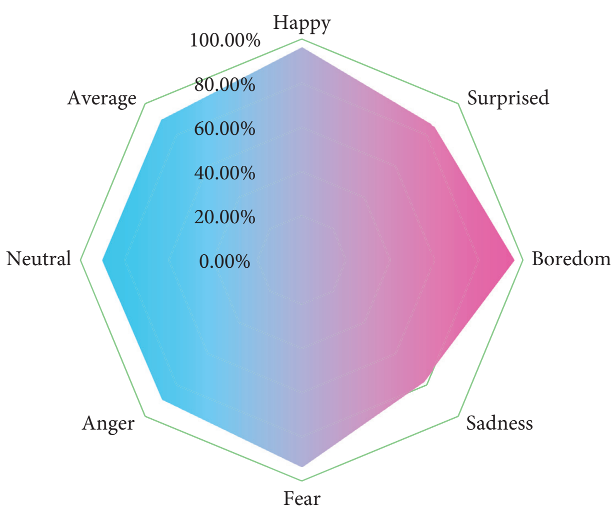

Figure 4: Recognition results of layered RF in mixed expression database.

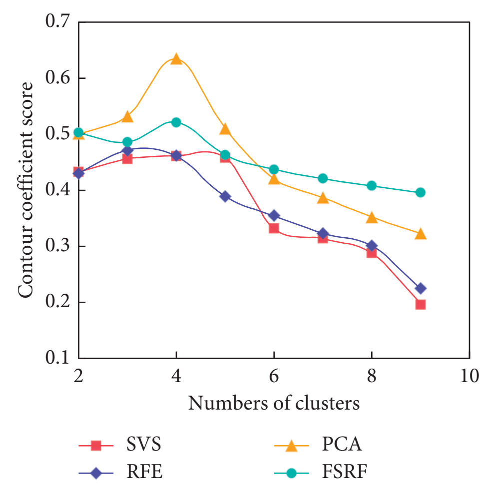

Figure 5: Influence of different feature selection methods on clustering effect.

mainstay and students as the supplement in the classroom, so it is difficult for students to reflect their personalized learning, and the teaching atmosphere can be imagined. Microcourses, on the other hand, have outstanding advantages, such as short time, abundant resources, and long online time, which meet the needs of students to flexibly choose learning time, learning place, and learning content to the maximum extent, and autonomous learning is relatively easy. At the same time, students can also reproduce the classroom teaching situation of a certain knowledge point at any time, which can well solve the problem of memorizing in class and forgetting after class, which is an important supplement and resource expansion of traditional classroom learning [7].

The key link in consolidating and digesting the curriculum's key and difficult problems is classroom teaching. Teachers break down teaching tasks and create various links to assist students in solving problems based on the syllabus. Teachers must periodically assess their students' knowledge and provide appropriate guidance and correction, as well as timely feedback. Teachers should be at the forefront of curriculum development, extracting a series of knowledge points from each class's teaching tasks based on the needs of class hours, and carefully designing and developing these knowledge points into special microcourses and series microcourses.

4.3. Teaching Suggestion. For starters, online education prevents students from interacting with teachers in real time, reduces teacher-student communication, fails to stimulate students' thinking, and causes them to lose their ability to think. Second, plagiarism in students' homework is a serious issue. Students are more likely to copy other people's learning achievements as the Internet has evolved, and they are unable to do so independently. Finally, the impact of paying attention in class has waned. After signing in before class, many students fall asleep and only watch the video, leaving the teacher to "perform" alone. To summarize, the quality of online education cannot be guaranteed at this time, and a good educational effect cannot be obtained in a

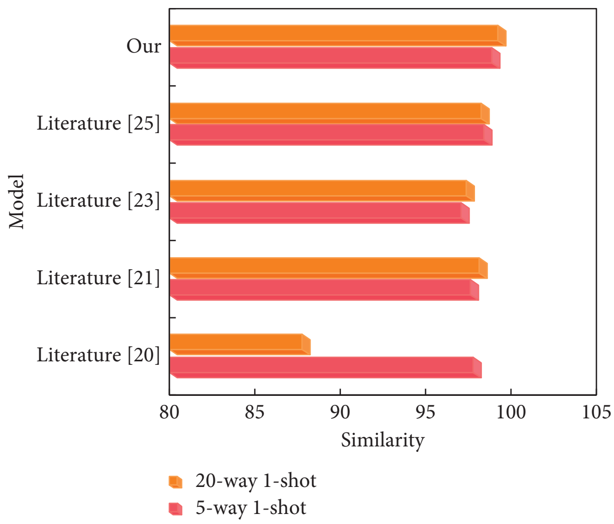

Figure 6: Small sample experimental results.

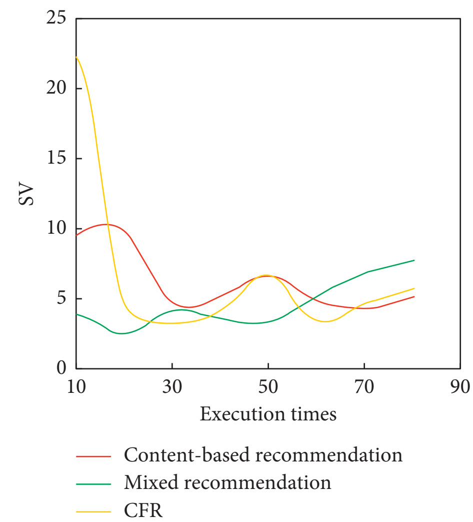

Figure 8: SV algorithm comparison.

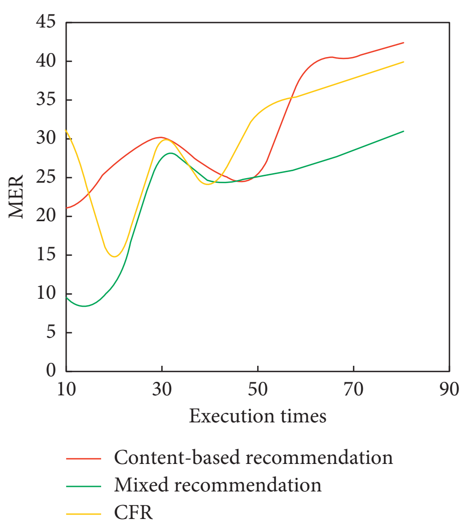

Figure 7: MER algorithm comparison.

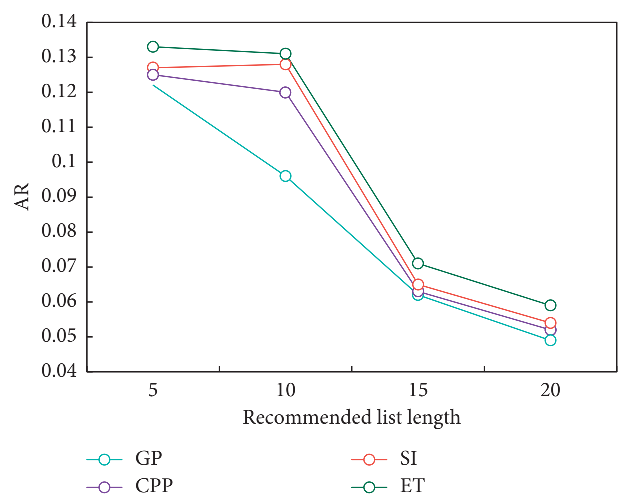

Figure 9: Comparison of different factors affecting recommended AR.

holistic manner. This development raises concerns about the future of online education.

To digitize teaching, the online classroom makes use of big data and cloud computing technologies. It comprehensively assesses students' learning quality and efficiency, starting with daily classroom study, daily assessment, semester assessment, and other aspects, making teachers' evaluation of students more objective, accurate, and fair, making teachers accurately assess students' growth, making teachers' teaching more targeted, and improving classroom teaching quality and efficiency. Students can interact with teachers more effectively in an online classroom environment. Interactive activities such as sign-in, selection of students, competition for answers, and the combination of online and offline interaction greatly improve the interaction efficiency between teachers and students, which is conducive to students' autonomous learning and teachers' accurate grasp of students' learning situations.

Teachers in the new era should change their roles in time, from the leader of the traditional classroom to the leader of the online classroom, guide, organize, and coordinate students' learning activities, and cultivate students' autonomous learning and cooperative learning ability. The ability to master and apply modern information technology is a new test for teachers, which not only requires teachers to skillfully use all kinds of learning tools and software but also requires teachers to establish data awareness, master relevant data processing technologies, and digitize and visualize the teaching process, so as to more efficiently and accurately analyze the learning situation. To improve the information-based teaching quality, an information technology mutual assistance group is established, intragroup exchange and discussion activities are organized, and teachers are helped with weak information technology to improve their information technology teaching ability.

In the aspect of educational content, a student-centered educational philosophy is established, pay attention to the combination of theory and practice, the material needs of

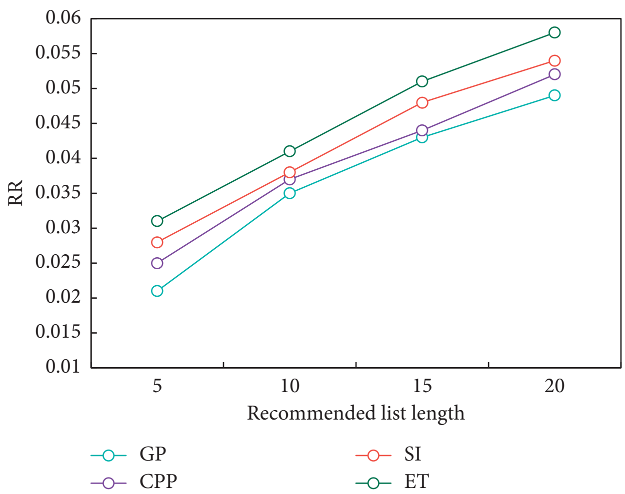

FIGURE 10: Comparison of recommended RR influenced by different factors.

students are met, and their spiritual needs are emphasized; that is, a balance among objective knowledge, value, and morality is sought.

In terms of teachers, teachers should change their teaching role orientation in time according to the changes of the times, change the traditional knowledge transmitter to become an interactive learner, and change the teaching controller to become an activity leader. Only when teachers take the lead in the initial change, students can make progress.

5. Conclusion

Personalized learning research is based on the construction of the learner model. This study integrates the above research emphases. In view of the current situation of insufficient research on the characteristics of learners' emotional factors in the study and analysis of learner model, combined with online classroom teaching environment, online SSL model research integrating healthy emotional factors is carried out. Based on the proposed learner model, this paper studies the learner feature analysis technology, focusing on the learner's emotional feature analysis technology. In the experimental part, experiments of multiple tasks are carried out on data sets, which proves that SSL based on graph regularity is effective. According to the social relationship, the social intensity among users is calculated, and the emotional tendency of users according to the comment text is analyzed and effectively combined them with collaborative filtering recommendation technology, so as to get the social-emotional score. Through experiments, even under extreme test conditions, the algorithm still shows good recommendation accuracy and timeliness, which greatly improves the recommendation quality.

In the future work, we will further explore the influence of time factors and content information such as photos and videos generated by users in POI on users' sign-in behavior, so as to further improve the recommendation quality.

Speech recognition and semantic understanding of spoken language are critical components in determining the dialogue system's performance in SDS. In the study of SDS, the improvement of SLU performance is critical. By influencing the factors before and after the input text sequence information, RNN predicts the next text information. The RNN language model's probability score is introduced, and the recognition's intermediate result is rescored. A method of combining cache RNN models to optimize the decoding process and improve the accuracy of word sequence probability calculation of language model on test data is proposed to address the problem of mismatch between test data and training data in recognition. The results of the experiments show that the method proposed in this paper can effectively improve the recognition system's performance on the test set. It has the potential to achieve a higher SLU score. It is useful for future research on spoken dialogue and SLU issues.

1. Introduction

Spoken Dialogue System (SDS) is composed of automatic speech recognition, spoken language understanding (SLU), dialogue management, language generation, speech synthesis, and so on. SLU performance is very important for SDS. The SLU system is a key component of SDS, which aims to help the computer "understand" the text recognized by the speech recognition module [1]. An important task in SLU is to automatically extract and classify semantic intentions or to fill in a set of parameters or slots embedded in the semantic framework so as to achieve the goal in man-machine dialogue [2]. Although related researchers have conducted research for many years, the task of slot filling and intention determination in SLU is still a challenging problem. The traditional methods to solve SLU are mainly conditional random fields, hidden Markov models, and other traditional methods based on statistics [3]. Natural language understanding is an important factor that determines the usability and naturalness of human-computer SDS. Its robustness directly affects the success rate of dialogue and the user-friendliness of the system [4]. However, due to the randomness of user sentences in spoken dialogue and the imperfection of speech recognition module, the traditional whole sentence analysis method cannot achieve a correct understanding of user sentences, but it is necessary to introduce a robust understanding mechanism to extract the key information in sentences. With the rise of deep learning, the application of Neural Networks (NN) training in the field of Nature Language Processing (NLP) has achieved great success. People began to explore different functions of NN.

With the rapid development of artificial intelligence, there are countless tasks in our society that need to process serialized data [5].The main goal of the early language calculation method is to automatically analyze the language structure and develop basic technologies like machine translation, speech recognition, and speech synthesis [6]. Researchers can use these technologies to create SDS and speech-to-speech translation engines in practical applications, mine social media content for health or financial data, and identify customers' feelings about products and services [7]. The goal of SLU is to automatically identify the fields, categories, and intentions of users' spoken language in order to express natural language and then extract related concepts in order to achieve the goal of system understanding of users' language. Through speech recognition, the computer converts it into corresponding text information, which is then processed by SLU. In recent years, the NN method has demonstrated remarkable performance in a variety of Natural Language Processing (NLP) tasks, particularly the method based on Recurrent Neural Networks (RNN), such as language model, language semantic understanding, and machine translation [8]. This paper employs RNN and its variants to improve the performance of SLU. On this foundation, an RNN-based SDS language understanding method is proposed.

An important task in SLU is to automatically extract and classify semantic intentions or to fill in a set of parameters or slots embedded in the semantic framework so as to achieve the goal in human-computer dialogue [9]. RNN has great advantages in extracting sequence information of natural language characters and using it to build mathematical models to solve corresponding problems [10, 11]. RNN has been verified to have a remarkable effect in solving the serialization problem. In this paper, an algorithm based on recurrent neural network is proposed, which stacks multiple nodes at one time node to deepen the complexity of nonlinear transformation. This method can store longer-term information with fewer parameters by adding storage history state information. According to more information obtained, feature information is extracted to increase the effectiveness of obtained information, improve the accuracy of SLU, and shorten the experimental time. The feature fusion network structure is applied to the data set for SLU experiment. Experimental results verify the effectiveness and reliability of the algorithm.

2. Related Work

A new framework for understanding probability was proposed in the literature [12]. A two-level search and comprehension algorithm is also used by the framework. The concept map is created at the second level using a rule-based tree expansion robust syntactic analysis algorithm in order to effectively obtain the overall structure information of the sentence. It solves the problem of a sentence's meaning being ambiguous and it being difficult to accurately extract the sentence's semantic information. To improve the robustness of language comprehension in SDS. Literature [13] proposed a two-level search understanding algorithm. Concept bundling is used to generate the concept map in the first level, and some interference components on the word map provided by the recognition module are removed. The improved robust syntactic analysis based on tree expansion is used to search for the best understanding result at the second level. The literature [14, 15] primarily investigates and implements the related technology of the SLU system's slot filling task. A joint model based on a two-way long- and short-term memory network and label splitting was proposed in the literature [16]. Furthermore, due to the ATIS data set's low-resource characteristics, an attempt was made to introduce external semantic information using foreign pretraining word vectors. An improved RNN language model based on context word vector features was proposed in the literature [17]. Enhance the RNN model's structure by adding a feature layer to the input layer. In response to the issue of language models' poor adaptability to different corpora, literature [18] proposed an adaptive method based on the CNN language model. Literature [19] proposes an RNN that uses external memory to improve memory ability. Literature [20] proposed a feature fusion-based RNN on the basis of RNN and introduced the application of the structural principle and method in SLU. Literature [21] proposed a feature fusion RNN structure based on the analysis of the basic RNN and its LSTM network and GRU network structure. Literature [22] uses adaptive data to adjust the parameters of the general background model and extracts topic features in the adaptive data to join the adaptive training of the RNN language model, enhances the model's ability to describe the adaptive corpus, and improves the language model's ability to adaptability under the corpus. Experimental results show that this method can improve the system's language recognition effect. Literature [23] mainly introduces the principle and performance index of SLU and the structural principle of basic RNN, mainly introduces two basic RNNs in detail, and analyzes its main methods. Literature [24] successfully trained a language model on a text corpus using feedforward NN. By mapping discrete words into continuous real number vectors, it successfully overcomes the impact of data sparseness on statistical modeling and at the same time solves the dimensionality disaster of model parameters' problem. Literature [25] compares the NN language model with other language models and finds that the NN model is compared with other models. For example, when the cache model or the part-of-speech-based model is combined, the resultant hybrid model has a better effect. The article summarizes the key and related research progress of the SLU task and compares the structure and principle of RNN with different structures. Propose an SDS language understanding algorithm based on RNN. The input is sent to the hidden layer for training to obtain a feature representation; then the feature information is sent to another hidden layer for training along with the source input and historical output information; finally, it is sent to the output layer to get the result. Select the data set and performance evaluation method widely used in this field and compare it with several other advanced models on the data set. The results show that the proposed RNN is effective for SLU tasks and has good accuracy and robustness.

3. Methodology

3.1. SDS. Oral English is the most direct and simple communication medium for people to communicate with each other in their daily lives. People can get information through language communication, which is one of the most important communication ways [26]. Based on this, whether people can communicate with computers directly is one of the research directions in the field of artificial intelligence, and spoken language is the natural language between people. In oral conversation, the speaker's psychological state inferred from various information can also be used to supplement the system's knowledge about the content of user statements [27].

The purpose of SLU module is to extract semantic information from the user's sentences, that is, to identify the intention of the input sentence and extract the corresponding semantic slot concept. The main function of SLU is to analyze sentences' input by users, extract semantic information, and obtain semantic representation. For the whole SDS, the key parts are SLU and dialogue management part [28]. Research shows that deep learning can extract high-level features from shallow features because of its special hierarchical structure. The problems of lack of information and excessive dimension in semantic representation of unified text have been well developed in the fields of image, pronunciation, and so on. At the same time, it has achieved some research results in the field of NLP and shows more potential application value.

SLU is an important component of the dialogue system, and its purpose is to allow the computer to "understand" the input language as if it were spoken by a human. As a result, SLU's performance is closely linked to that of the dialogue system. SLU research can help people apply SDS more accurately, which is more convenient for people's lives and work [29]. SLU's goal is to automatically identify the fields, categories, and intentions of users' oral natural language expressions and then extract related concepts in order to achieve a systematic understanding of the language they use. Domain detection, intention identification, and slot value filling are the three main components of SLU. Slot filling is a labeling task, while domain detection and intention identification are classification problems. The term "slot filling" refers to the practice of marking every word in a sentence [30]. Different semantic representations are used for different SLU tasks. We can use the semantic framework and semantic slot that conform to the semantic structure of the SLU task to model the input intuitively and clearly in the simple understanding task. This framework and semantic slot approach, on the other hand, are no longer suitable for more complex SLU tasks, such as tasks with long phrases.

The first step in a man-machine dialogue system is SLU. Its primary function is to analyze the user's conversation and collect other relevant data about conversation behavior and tasks. According to the information, the dialogue management part updates the current state of the dialogue and generates a dialogue strategy. The dialogue generation part outputs the natural language generated by the dialogue management strategy to the user. Three parts constitute a complete task-driven man-machine dialogue system, and each part has an important influence on the performance of the whole man-machine dialogue system, as shown in Figure 1 below.

Deep Neural Network (DNN) is a successful SLU model applied in NLP field. The biggest feature of DNN is that it can train massive data and then extract the feature information of these data by learning a lot of data. A remarkable feature of NLP applied deep learning is that the input comes from a large number of lexical symbols, which leads to the initial work of Neural Networks (NN) language modeling; that is, these lexical symbols are distributed through learning in the input or output layer, and these embedding and tasks are jointly trained and learned. Following this principle, various network architectures and training methods have been successfully applied.

The main difference between RNN language model and feedforward NN language model lies in the different representations of the historical information of words. In feedforward NN model, the representation method of historical information is similar to that of n-gram model, and the first $n-1$ words are still used. RNN model, on the other hand, obtains historical information through the constant circulation of hidden layer and learning from it. In RNN, the hidden layer can represent historical information, not just the first $n-1$ words. This model can theoretically represent longer context information.

RNN is an NN structure composed of an input layer, a circulation layer, and an output layer. Among them, the input layer reads each input word and the probability that the output layer generates the corresponding semantic tag. The most prominent feature of RNN is that the current predicted value can be obtained through the common information of the previously input words and the current input words. From the information processing ability of the network, the nodes in the network include input nodes, which are nodes that connect the outside world with the internal network structure of the network; implicit layer nodes and output nodes are nodes with processing capability. The RNN structure of feature fusion is shown in Figure 2.

SDS is like a communication tool for communication between human beings and machines. Through this communication tool, computers can communicate with human beings without obstacles, and computers can give correct answers to various demands of human beings. SDS will meet different users, and different users will have different speech habits. Moreover, dialogue systems usually have to face a lot of first-time users, and first-time users are generally not familiar with the "capabilities" of dialogue systems.

RNN can theoretically predict current word tags based on arbitrarily long historical data. However, because the weight parameters are updated using the random gradient descent method, there will be issues with gradient disappearance and explosion, resulting in the error information being unable to be transmitted far away in the back propagation. At the same time, it restricts RNN's storage and memory capabilities. The accuracy rate is the ratio of relevant labels to all labels trained by NN, which measures the experiment's accuracy rate; the recall rate is the ratio of trained related labels to all related labels, which measures the experiment's recall rate. To put it another way, the accuracy rate is the number of trained labels that are correct, while the recall rate is the ratio of trained correct labels to all correct labels.

3.2. SLU Algorithm Based on RNN. A careful analysis of the sentences of the participants in the oral conversation shows that the variability of sentence structure is mainly caused by two reasons: (1) flexibility of word order and (2) frequent use of nonkey components such as colloquial words, auxiliary words, and parenthesis. The key components in the field

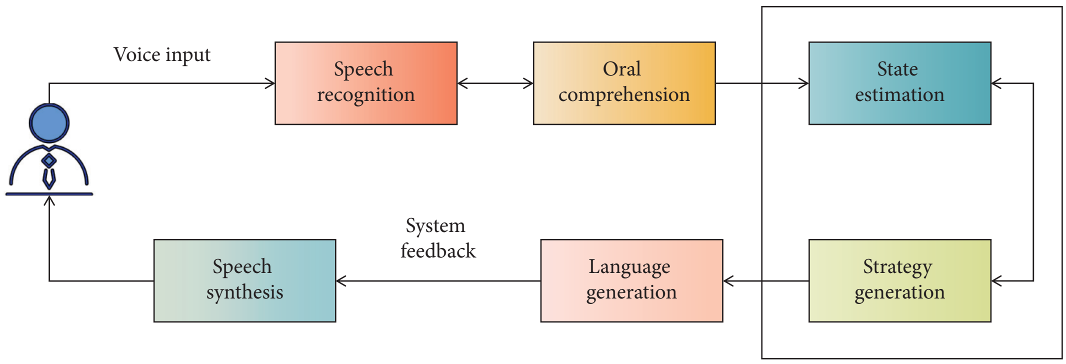

FIGURE 1: Man-machine dialogue system.

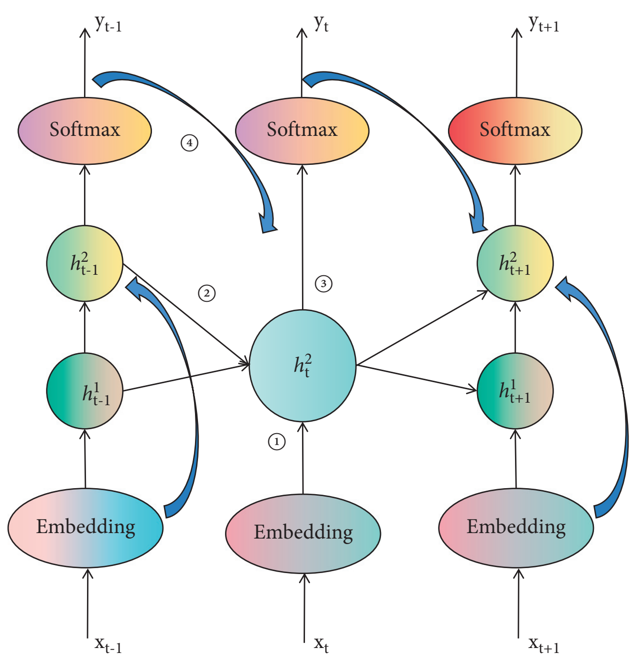

FIGURE 2: RNN structure of feature fusion.

often have relatively stable structures. Language understanding system is to process and output the input sentence and predict the tag of each word in the sentence. Generally, the input and output of these tasks are one-to-one correspondence, the input is a sequence of words, and the output is the corresponding tag sequence.

The function of nonlinear NN is more powerful than that of linear NN. The main reason is that nonlinear network can distinguish the nonlinear boundary between different data. With nonlinear NN structure, unlike linear NN, neurons with nonlinear activation function have strong learning ability, which can learn new representations through the nonlinearity of several hidden layers. This is because the input and output of the nonlinear activation function are mapped from one limited range to another.

The number of neurons and activation function in each layer of the NN, as well as between each layer, are mostly determined by the different task types. What kind of function can we use if it is a classification task? There will be different activation functions if it is a regression task. In general, only the best sentences generated by the recognition module are processed, but it is difficult to make use of the word graph's wealth of information. It is decided to use two-level processing. As the understanding result, the word graph is first transformed into a concept graph, and then an optimal path is searched on the concept graph using the concept binary grammar. The purpose of long-term dependence of information can be achieved by putting forward three gate units, the input gate, the forgotten gate, the output gate, and the corresponding cell state, and the gradient problem of RNN can be effectively solved by increasing the state of control unit.

The network structure of the model includes input layer, hidden layer, and output layer. The network does not calculate in the input layer and preprocesses the training corpus according to a certain representation; then, the calculation formula of the output of the input layer is

$$x(t) = w(t) + s(t-1). \tag{1}$$

The hidden layer of the RNN processes the information sent by input neurons, and the output layer is used to represent the network's output results. The neurons between layers in the network communicate via synapses, and the layers are linked by a weight matrix. The formula for the hidden layer and the output layer is as follows:

$$\begin{aligned} s_j(t) &= f\left(\sum_i w_i(t)u_{ji} + \sum_l s_l(t-1)w_{jl}\right), \\ y_k(t) &= g\left(\sum_i s_j(t)v_{kj}\right). \end{aligned} \tag{2}$$

In which $f(z)$ is sigmoid activation function $f(z) = 1/1 + e^{-z}$. $g(z)$ is sigmoid activation function $g(z_m) = e^{z_m}/\sum_k e^{z_m}$. i, j, and k represent the number of neurons in each layer. The output of the network is expressed in matrix form, and the above formula can be rewritten as

$$\begin{aligned} s(t) &= f(Uw(t) + Ws(t-1)), \\ y(t) &= g(Vs(t)). \end{aligned} \tag{3}$$

The output vector $y(t)$ represents the probability distribution $P(w(t+1)$ of the word to be predicted $w(t+1)$

given the current word $w(t)$ and historical information $s(t-1))|w(t)$, $s(t-1)$. The time complexity of each step during model training and testing is proportional to

$$O = H \times H \times H \times V = H \times (H + V), \tag{4}$$

where H is the size of the hidden layer and V is the size of the vocabulary.

At the first level, based on the word map given by the recognition module, the concept is bound according to the concept rules, and all possible concept candidates in the sentence are obtained, and the concept map is generated. In the second level, according to the sentence-level rule set, a robust syntax analysis algorithm based on tree expansion that can skip noncritical components is used to search for the optimal whole sentence comprehension result on the generated concept map. In RNN structure, the state of information is mainly nonlinear activation of input information. Except for nonlinear property, the state of information can only be updated through external input. Therefore, the storage state is added in the loop layer to store and update the historical information. While adding external information input sources, different nonlinear processing information flows are added so that long-term context storage information can be obtained. Long-term historical information can be stored and new information can be added through the added information flow. The current input information and the stored historical information are processed nonlinearly together, and more feature information that can express the input concept can be obtained through the processing and activation of nonlinear functions.

When the understanding module receives a new word graph, it first creates an empty concept graph; then, it uses the bottom-up chart syntax analysis method to analyze all of the arcs in the word graph according to the defined concept rule set and merges several word arcs that can be combined into a single concept into a concept arc. By weighting the input data, the perceptron activates the output vector, which contains information about the input data. The score is calculated and added to the concept map's corresponding nodes. The interaction between the unit that stores long-term historical information and the loop node can provide the most effective feature information.

The ability of a model trained on a given data set to run on previously unseen data that is similar to the training data is referred to as generalization. The following factors affect NN's generalization ability in order to make it more applicable: (1) NN's structural complexity, capacity, and scale. (2) Sample quality, NN's information content is the sum of all samples trained in the network. The stronger the generalization ability of NN, the more information content in the training samples. (3) The starting weight. (4) Hours of study time, the time it takes for a NN to learn is another factor that influences the network model's ability to generalize.

The learning part consists of the following adjustment parameters of RNN with n output layers.

$$\Theta = \left\{E, h^{(1)}(0), U^{(1)}, U^{'(1)}, \ldots, h^{(H)}(0), U^{(H)}, U'(H), V\right\}. \tag{5}$$

To be precise, the shape of the matrix is (4) and (5).

$$U^{(1)} \in M_{d_h \times d_e(2d+1)}(R) U^{'(1)}, \ldots, U^{(H)}, U^{'(H)} \in M_{d_h \times d_h}(R), \tag{6}$$

$$V \in M_{N \times d_h}(R). \tag{7}$$

For training, use random gradient descent. After calculating the gradient for each sentence in training set D, update the parameters to minimize the negative log likelihood. A sentence is considered as a word tuple and a slot tuple.

$$L(\Theta) = -\sum_{(S,W)\in D} \sum_{t=1}^{T} \log P_{\Theta}\left(s_t | l_0^{t+d}\right). \tag{8}$$

The length of each sentence may vary from one training sample to another, and the window size of context words is a superparameter.

Because the concept extraction and sentence comprehension are handled hierarchically, only 300 rules are used at the sentence level, which basically covers all kinds of user input situations in this field. After obtaining the concept map of the current user sentence, we do not simply search for an optimal path on the concept map according to the concept binary grammar as the final understanding result, but search the sentence space composed of the concept map by introducing sentence-level rules and adopting the improved robust syntax analysis method based on tree expansion. The information about context is mainly obtained by processing the input information and the saved context state together to obtain the feature information of context. These historical feature information are activated by nonlinear functions, and finally more detailed and specific feature information is obtained. Finally, the training results of the hidden layer are sent to the output layer for judgment and calculation.

The effect of network training can be influenced by data preprocessing in some cases. As a result, some data preprocessing decisions must be made. However, network training after preprocessing can sometimes achieve the same effect as training and learning the data directly, and data without preprocessing can sometimes achieve better results, making preprocessing redundant. In an RNN structure, the unit structure with the function of saving historical information primarily sends the current moment's input data and the previous moment's historical storage data to the storage unit for activation processing. The activation function is a nonlinear function in this case, and activation of the activation function yields feature information that has a strong correlation with the input historical data and current data.

4. Results Analysis and Discussion

In SDS, the meaning of the user's current statement has a strong correlation with the conversation history, so this information can be used to infer the meaning of the current statement. In order to bind concepts, which are the key components in the word map, we first need to define a group of concepts in current application fields and their corresponding composition rules. In order to prove the practicability of the RNN model proposed in this paper, this paper uses the data set widely used in experiments such as SLU, that is, the experiment of oral semantic understanding on the data set of Air Travel Information System (ATIS).

Check the analysis results of concept map. If there is a whole sentence analysis result, select the path with the highest score for semantic extraction; otherwise, search for an optimal path on the concept map and perform semantic extraction according to the context of dialogue management. The tuning parameters in the experiment include the number of units in the hidden layer. In this experiment, the number of units in the hidden layer is set to 200, the dimension of the word vector in the word embedding layer is set to 200, and the back calculation steps of the back propagation algorithm applied in this paper are set to 10. The weight matrix and offset of NN are updated by back propagation, respectively. In this section, the traditional Condition Random Fields (CRF) is compared with Convolution Neural Networks (CNN) and this model. In order to observe the process of network training and learning more intuitively, the performance index of the network is described by describing the change process of F1 value, and the line chart is drawn as shown in Figure 3.

Considering the guiding role of historical information in SDS and the structural characteristics of user sentences in the field of train information query, it is decided to use two aspects of information to bias the search space: user intention inference based on dialogue history and sentence feature phrases. At the same time, the relationship between entropy of training sets and iteration times of different models is compared to compare their convergence speed. The results are shown in Figure 4.

The training set entropy is expressed in logarithmic form. Compared with other models, the proposed model has lower training entropy and the best convergence speed. Experimental results show that this model has good accuracy and robustness and is suitable for SLU tasks. Defining the dialogue state based on the recent dialogue history greatly reduces the dimension of the state space, but it only uses limited local historical information, which reduces the accuracy of prediction. In order to give an efficient and accurate prediction of subrule set by using historical information as much as possible, a new prediction idea is proposed, which is not based on each specific historical state of conversation but based on the preconstructed user plan model to infer the user's intention.

CRF is the most commonly used method to deal with sequence tagging, and it has achieved good results in sequence processing. In this paper, CRF model, RNN, and CNN are used to perform feature fusion experiments on ATIS dataset. By changing the neurons in the network structure to process the data, the experimental results are shown in Figure 5.

The results of the above experiments show that the deep RNN feature fusion model outperforms CRF and CNN in SLU. When the optimal path analysis results are unavailable, this algorithm analyzes all concept maps, which saves time

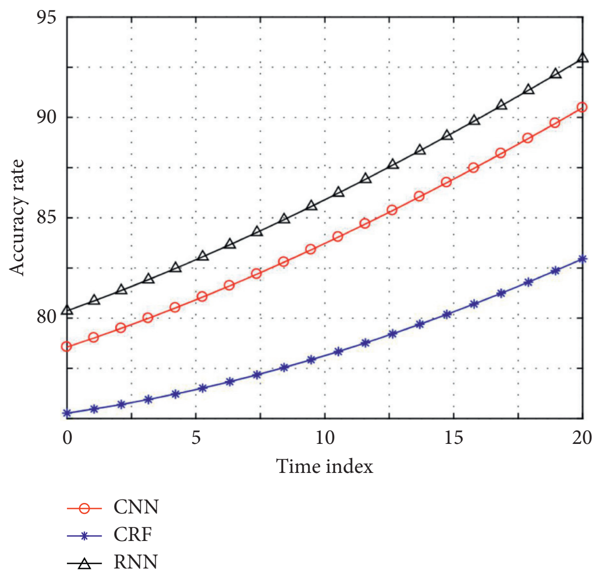

Figure 6: Accuracy comparison of different models.

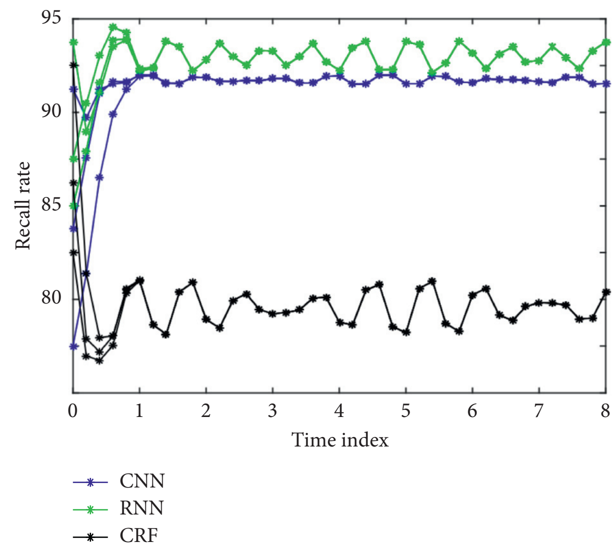

Figure 7: Comparison of recall rates of different models.

by not having to search all sentence spaces contained in concept maps. The pruning-while-expanding strategy can greatly reduce the scope of the search space during the analysis process. The precision, recall, and $F1$ performance indexes used in this experiment to assess oral semantic understanding are precision, recall, and $F1$. The proportion of correctly marked words to all correctly marked words is referred to as the accuracy rate, while the proportion of correctly marked words to all correctly marked words is referred to as the recall rate. In the labeling of evaluation data, the recall rate is the proportion of correct labels. The following is how $F1$ is written:

$$F_1 = \frac{2 \times \text{precision} \times \text{recall}}{\text{precision} + \text{recall}}. \tag{9}$$

In the process of dialogue, every time the user inputs a new sentence, the system reinfers and updates the user's intention according to the understanding result of the sentence and the historical information of the user's intention and then predicts the possible input of the next sentence by the user according to the inferred user's intention to determine the corresponding subrule set. Because the user's intention inference information and sentence feature phrase information based on dialogue history come from two independent information sources, the two kinds of information can be directly combined to restrict the search space. The three models are compared. Figure 6 shows the comparison of the accuracy of different models. Figure 7 shows the comparison of recall rates of different models. Figure 8 shows the $F1$ comparison of different models.

The SLU experiment on ATIS data set can be seen from the above results. The experimental results obtained by RNN model in this paper are always better than those obtained by CRF and CNN methods. The superiority of this method is verified. In this chapter, we propose the DNN structure of feature fusion through the NN structure described earlier and combine the features of DNN to concentrate multiple

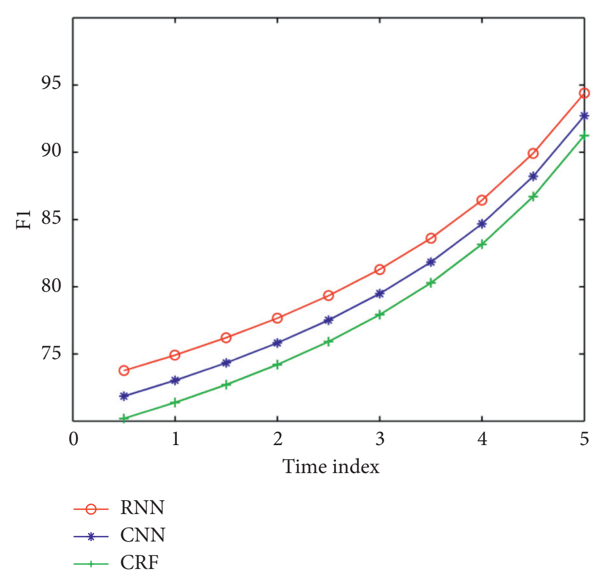

Figure 8: $F1$ comparison of different models.

features in a time node for calculation. This paper introduces the experiments of RNN, CNN, and CRF network structures on the database. The results show that the proposed RNN with external memory is effective for SLU tasks, has good accuracy and robustness, and has certain advantages in training error and convergence speed.

5. Conclusions

The basis of SLU is to represent words as symbols that can be read by machines, that is, the representation of words. In the task of SLU, it is mainly to label each word in the input text sentence with a corresponding label, and the most effective model algorithm to solve SLU is RNN. On this basis, this paper proposes an RNN that can store long-term historical information. The NN structure can solve the problem of gradient disappearance with fewer parameters. Based on the unified statistical framework of search, the information of user's intention inference and sentence feature phrases are introduced to constrain the search space, which further improves the robustness and real-time rate of understanding. At the same time, it achieves better results than CNN and GRU. In order to further improve the robustness and real-time rate of understanding, the information of user intention inference based on dialogue history and sentence feature phrases are introduced in the second level to restrict the scope of search space. The path is evaluated and pruned based on the statistical framework, which can ensure the real-time performance of the algorithm and obtain high understanding accuracy. The model in this paper is compared with other models on ATIS data set. Experimental results show that the SLU method based on RNN proposed in this paper is effective for SLU tasks and improves the robustness and accuracy of the original model. And the $F1$ value is significantly improved. The next task of this paper is to apply RNN to other NLP tasks in order to increase the universality of RNN network structure.

In recent years, entity relation extraction has been a critical technique to help people analyze complex structured text data. However, there is no advanced research in food health and safety to help people analyze the complex concepts between food and human health and their relationships. This paper proposes an entity relation extraction method FHER for the few-shot learning in the food health and safety domain. For few-shot learning in the food health and safety domain, we propose three methods that effectively improve the performance of entity relationship extraction. The three methods are applied to the self-built data sets FH and MHD. The experimental results show that the method can effectively extract domain-related entities and their relations in a small sample size environment.

1. Introduction

Food is inextricably linked to human health, particularly the nutritional components that can significantly improve health. For instance, increased spermidine intake protects against cancer, metabolic disease, heart disease, and neurodegeneration [1]. A higher intake of whole grains and dietary fiber is associated with a decreased risk of death from liver cancer and disease [2]. In addition, contaminants in food or an excessive amount of artificial additives have a detrimental effect on human health and even cause various diseases. For instance, interference with the intestinal microbiota's metabolites caused by food contaminants (polycyclic aromatic hydrocarbons, polychlorobiphenyls, brominated flame retardants, dioxins, pesticides, and heterocyclic amines) may promote the establishment of an inflammatory state in the intestine [3]. Food emulsifiers and thickeners influence the intestinal microbiota, mucosal barriers, and inflammatory pathways, and there are numerous possible pathogenic mechanisms [4].

With the proliferation of available human health data, humans use predictive or classification models to extract useful information, which helps people enjoy better health protection. Typical of this available human health data is the electronic health record (HER), the largest source of medical text data. One of the critical points in analyzing these unstructured textual data is to extract vital medical concepts, so many named entity recognition methods and entity relation extraction methods have emerged. Wan et al. proposed an ElMo-ET-CRF model approach for extracting medical named entities from Chinese electronic medical records (CEMR) using dynamic context-dependent ElMo character embedding to merge more lexical, syntactic, and semantic information that alleviate the long context-dependency problem [5]. Luo et al. proposed a novel tagging scheme considering overlapping relations to solve the overlapping problem in biomedical texts and then built the Att-BiLSTM-CRF model to extract the entities and their relations according to the rules [6]. Fei et al. proposed a new cross-graph neural model for joint extraction of overlapping entity relations in biomedical texts. They treat the entity relation extraction task as a relational triad prediction and construct entity graphs by enumerating possible candidate entity spans [7].

It is possible to help explicitly store the relationships between complex medical concepts for use in subsequent tasks by extracting them. Similarly, for the food health and safety domain, food regulators sample food products on the market and examine the ingredients and form structured data. However, in addition to structured data, more unstructured textual data goes beyond the act of food sampling and inspection to include announcements of food safety events, news reports, and knowledge about food and human health. Cenikj et al. proposed a method to detect the relationship between food and disease entities from text. They explored the feasibility of migration learning using a pretrained model based on BERT and achieved good results with few-shot learning [8]. Popovski et al. proposed a rule engine for extracting food concepts called FoodIE, a rule-based named entity recognition method with rule content describing food entities' computational linguistic and semantic information [9].

However, the food health and safety field does not have many available resources like the biomedical field, so few-shot learning becomes an effective method to improve information extraction. Qu et al. proposed a Bayesian meta-learning method for relation extraction in few-shot learning environment, applying graphical neural networks to global relation graphs to improve accuracy [10]. Sainz et al. reformulated relation extraction as an entailment task with good results for zero- or small-sample relation extraction tasks [11].

The essential technique for extracting valid information in the food health and safety domain is entity relation extraction. This task requires the model to identify entities and relations in a sentence correctly and combine them correctly. The complexity of the task and the small sample size together contribute to the difficulty of the entity relation extraction task with few-shot learning. For supervised deep learning models, small sample size can lead to an underfitting of the model. In other words, there is not enough information to train a valid model. In addition, the model tends to converge at a local optimum, leading to poorer practical results of the model.

To solve the underfitting problem, we propose two methods to enrich the semantic features of the input text. The first is to disassemble Chinese characters into radicals (https://en.wikipedia.org/wiki/Radical_(Chinese_characters)) and construct semantic input at the radical level. As pictographs, radicals are part of the structure of Chinese characters. The radicals have specific meanings; in other words, they represent part of the semantic information of the constituent characters. Therefore, constructing semantic input at the level of radicals can enrich the semantic information of the input text very well [12, 13]. The second approach to enrich semantic information is to fuse input text characters and word vectors. As units with independent meanings, characters are often given new meanings after forming words, and word information can significantly complement the interpretation of words within words [14]. For instance, the Chinese character "瘦 (lean)," "肉 (meat)," and "精 (essence)" form the word "瘦肉精," which stands for a drug that is banned from being added to animal feed. In their study, Chen and Hu also verified that Chinese words contain rich semantic information [15]. Tran et al. combined the advantages of character- and word-level translation and proposed a new method for translating Chinese into Vietnamese [16].

To solve the problem of the model falling into local optimality, we propose a text noise removal model to help the model converge quickly to the global optimum. As shown in Figure 1, for a given input text: "Enrofloxacin belongs to the third generation of quinolones, is a class of synthetic broad-spectrum antibacterial drugs, according to the "National Food Safety Standards Maximum Residue Limits for Veterinary Drugs in Food," the maximum residue limit of enrofloxacin in the skin and meat of fish is 100 μg/kg." There are four groups of entity relations combinations in the sentence.

We need to extract the two entity relation groups below the sentence in Figure 1 (index values 3 and 4 in Table 1). The two entity relation groups above the sentence (index values 1 and 2 in Table 1) are weakly related to food health and safety. In this paper, we believe that we need to accurately propose the entity relation groups that are food-health-related. The entity relation groups that are weakly related to food health and safety will become noise to affect the extraction effect.

To effectively extract entities and relations for texts in the food health and safety domain in a small-sample learning environment, this paper proposes a method for entity relation extraction in the food health and safety domain, FHER (food health entity relation extraction).

Our contribution can be summarized as follows:

(1) To reduce the influence of noise in the text, we propose a text denoising method for domain entity relation extraction to convert the text denoising task into a sequence prediction task, which effectively reduces the correct range of entity relation extraction.

(2) To address the lack of semantic information due to the small sample size under the few-shot learning, we propose constructing the input at the part-head level to enrich the semantic information.

(3) We propose the fused character and word method to improve the ambiguity problem caused by errors in Chinese word separation boundaries.

2. Related Works

There are two approaches in current research [17]. Traditionally, a pipeline approach is used to extract entity mentions using a named entity recognizer and then predict the relationship between each pair of extracted entity mentions [18, 19]. This approach inevitably brings the problem of error propagation. To alleviate the error propagation problem, Yu and Lam proposed a joint extraction approach that performs two subtasks simultaneously [20].

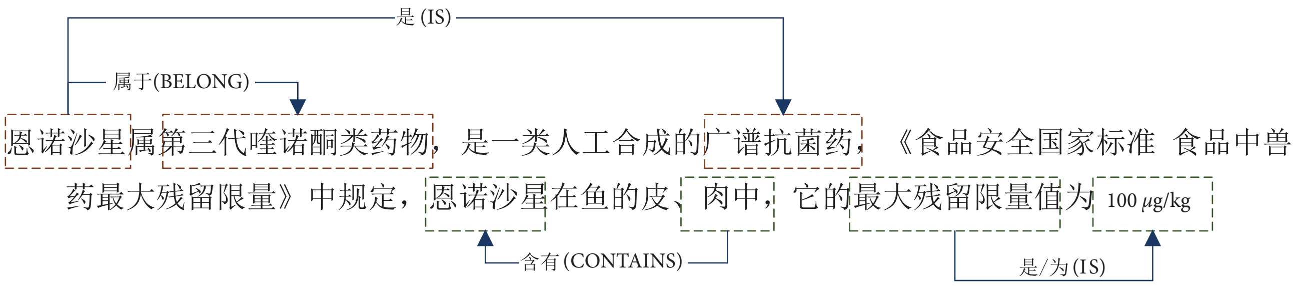

Figure 1: Examples of sentences in the field of food health and safety and the entity relations that exist within it.

Table 1: The combination of entity relations present in the text.

Index	Subject	Relation	Object	Definition
1	Enrofloxacin	Belong	The third generation of quinolones	Noise
2	Enrofloxacin	Is	Synthetic broad-spectrum antibacterial drugs	Noise
3	Skin and meat	Contain	Enrofloxacin	Useful
4	The maximum residue limit	Is	100 μg/kg	Useful

The joint extraction approach is gradually becoming mainstream in entity relation extraction tasks. Geng et al. proposed an end-to-end joint entity and relation extraction method based on a combined attention mechanism of convolutional and recurrent neural networks [21]. Wan et al. proposed a region-based hypergraph network (RHGN) for joint entity and relation extraction, introducing the concept of regional hyper nodes to enhance contextual connections [22]. Wei et al. proposed a cascading pointer labelling approach, which solves the problem of overlapping entity relations [23]. Qiao et al. proposed a joint entity relation extraction model BERT-BiLSTM-LSTM for agriculture and verified that the BERT model has better migration in agriculture [24].

Due to the scarcity of textual data in the food health and safety domain, few-shot learning can effectively improve the effectiveness of entity relation extraction. Most of the current research on small-sample learning has focused on relationship extraction tasks. For relation extraction in a few-shot learning environment, Qu et al. propose a Bayesian meta-learning method that applies graphical neural networks to global relation graphs to improve accuracy [10]. Sainz et al. reformulate relation extraction as an entailment task with good results for zero- or small-sample relation extraction tasks [11].

For the entity relation extraction task in food health and safety, we propose a joint entity relation extraction method FHER with noise removal and feature enhancement, which mainly addresses how to perform effective entity relation extraction in a few-shot learning environment with high noise and low data volume. Our model adopts a cascading pointer annotation approach [23] to mitigate the entity overlap problem in the entity relation extraction task.

3. Methodology

3.1. Overview. The FHER method divides the whole entity relation extraction task into five parts: the first is a text noise removal model, the second is the construction of a radical level input, the third is the fusion of character and word features, the fourth is the prediction of possible subjects in a sentence, and the last is the prediction of relations and corresponding objects.

Figure 2 shows the overall structure of the model. The input sentence In passes through the BERT Encoder layer to obtain vector H_c. The prediction sequence P_s is obtained after passing through the text noise removal model. The position vector E can be obtained through the binary function. Then, the input In_r of sentence In at the radical level is constructed, and the vector H_r is obtained after passing through the BERT encoder layer. The vectors H_c and H_r and the position vector E are fed into the fusion function to obtain the vector H_{cw} after fusing the characters and words. Using the position vector S and the fusion vector H_{cw}, we can obtain the possible object positions corresponding to each relation and thus the combination of entity relations present in the sentence.

We define the entity relation extraction task in the food health and safety domain: unstructured input text, output extracted human health-related concepts and their relationships, and further form food- and health-related knowledge triad. Formally, for a given sentence x, all possible triples $T\{s, r, o\}$ are extracted, with s representing the subject in sentence x, o representing the object in sentence x, and r representing the relationship between the subject and the object. For sentence x, the probability of all possible triples T that it contains is as follows:

$$\prod_{(s,r,o)\in T} p((s,r,o)|x) = \prod_{s\in T} p(s|x) \prod_{(r,o)\in T|s} p((r,o)|s,x), \tag{1}$$

where, according to the chain rule, $s \in T$ denotes the subject appearing in the triplet T, $T|s$ denotes the triplet T containing the subject, $(r, o) \in T|s$ denotes the combination of objects and relations appearing in the triplet containing the subject, and R is the set of relations. For a given training set D, the probability that all sentences may contain the triplet T is as follows:

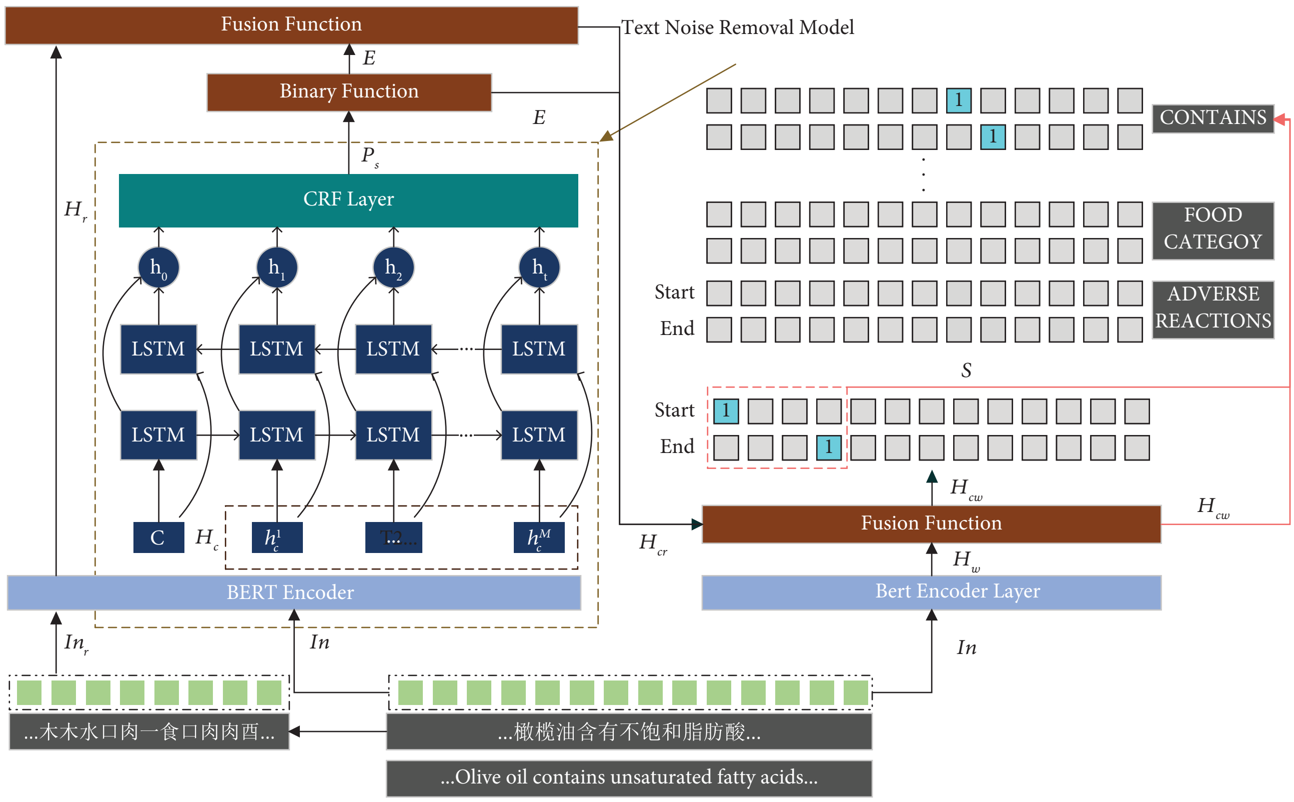

FIGURE 2: FHER model structure diagram.

$$T = \prod_{i=1}^{D} \left[\prod_{(s,r,o)\in T_i} p\left((s,r,o)|x_i\right) \right]. \tag{2}$$

The goal of the entity relation extraction task in the food health and safety domain is to find all possible triples (s, r, o) in the data set D.

3.2. BERT Encoder. The implementation of the language model basis of the model is the encoder layer (BERT encoder). The BERT model consists of a multilayer bidirectional transformer consisting of an encoder that learns the valid information in the context very well [25]. We use a pretrained BERT model using a Chinese corpus from the food domain to encode the context of the input sentence In. Formally, for a sentence of length M can be represented as $\mathrm{In} = [w_1, w_2, w_3, \ldots, w_M]$. We input these tokens into the same BERT encoder layer as the trained one to obtain a vector representation H_c of the input sentences as follows:

$$H_c = \left[h_c^1, h_c^2, h_c^3, \ldots, h_c^M\right] = \mathrm{BERTEncoder}(\mathrm{In}). \tag{3}$$

3.3. Text Noise Removal Model. We summarized the possible relationships between concepts related to food health and safety into 12 kinds by reading many food health and safety information. Table 2 lists the details of the relations since the text contains combinations of entity relations with low relevance to the domain; these irrelevant combinations of entity relations act as noise. It will interfere with identifying entity relation combinations in the food health and safety domain. To reduce the influence of noise in the text, we propose a text denoising method for domain entity relation extraction to convert the text denoising task into a sequence prediction task, which effectively reduces the correct range of entity relation extraction. Figure 3 shows the structure of the text noise removal model structure.

TABLE 2: Definition of relationships for the FH data set.

ID	Relation name (CH)	Relation name (EN)	Abbreviations
1	含有	Contains	CO
2	别名	Another name	AN
3	属于	Belong	BE
4	查处	Investigation	IN
5	功效	Efficacy	EF
6	不符合	Noncompliance	NC
7	是为	Is	IS
8	检出	Detection	DE
9	污染物	Contaminants	CT
10	食品类别	Food category	FC
11	不良反应	Adverse reactions	AR
12	无关	Other	O

We transformed the text noise removal task into a sequence prediction model. To capture the sentence context information, we used the BiLSTM layer for further feature extraction. Then, considering the dependencies between the labels, we use the undirected probabilistic statistical graphical model CRF layer to handle the exact sequence

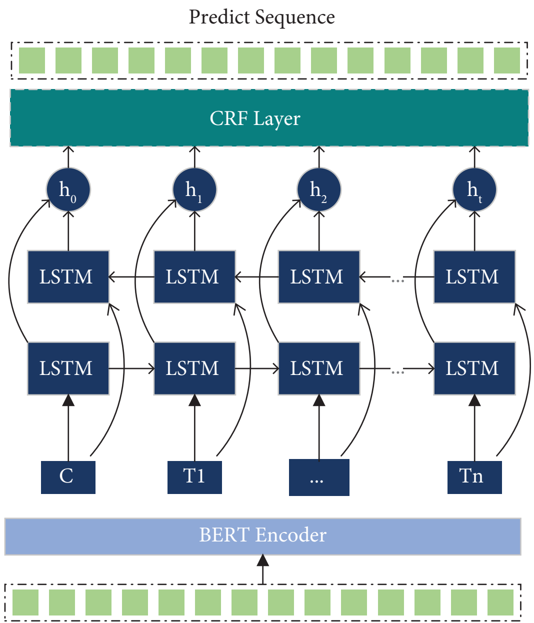

Figure 3: Text noise removal model structure.

labelling problem. Each character is assigned a BIO tag (B represents the beginning of an entity, I represents In an entity, and O represents Out of an entity). At the same time, we modified this tagging method to predict the possible types of entities (see Figure 4).

With the BERT encoder, we obtain the vector representation H_c of the sentence, which is then fed to the BiLSTM layer to obtain the intermediate vector representation H_{Bi} as follows:

$$H_{Bi} = \left[h_{Bi}^{1}, h_{Bi}^{2}, h_{Bi}^{3}, \ldots, h_{Bi}^{M}\right]. \tag{4}$$

For the input sequence In and the corresponding predicted label sequence Y, the model is trained to obtain the prediction sequence result P_s as follows:

$$P_s = \left[\hat{y}_1, \hat{y}_2, \hat{y}_3 \ldots, \hat{y}_M\right] = \mathrm{CRF}\left(H_{Bi}\right). \tag{5}$$

3.4. Construction of the Radical Feature. As the smallest semantic unit, radicals themselves have particular semantic meanings. Chinese characters are usually composed of smaller primary radicals, which are the most basic units that constitute the meaning of Chinese characters. In essence, this radical semantic information helps make characters with similar radical sequences (writing order) close to each other in the vector space, so it can be used to enrich the semantic information of the word vector and enhance the model effect. As shown in Figure 5, the sentence "Olive oil contains unsaturated fatty acids" can be represented at the radical level as "木木水口月一食口月月酉." The radical for the word fat is "月." When "月" is used as a radical, it can be interpreted as relating to the moon or meat. The radical of the character "酸" is "酉," and its meaning is related to alcohol and fermentation. The meaning of the decomposed radicals can enhance the semantic information of the word itself.

Formally, for the input sentence In, the corresponding radical input In_r is generated based on the radical decomposition, and for each character w_{ri} in In, the radical is added to In_r if there is a radical, or directly to In_r if it is a unique word. Finally, we get the input In_r at the radical level as follows:

$$\mathrm{In}_r = \left[w_{r1}, w_{r2}, w_{r3}, \ldots, w_{rM}\right]. \tag{6}$$

Similarly, the vector representation H_r corresponding to the input In_r can be obtained through the BERT encoder layer as follows:

$$H_r = \left[h_r^1, h_r^2, h_r^3, \ldots, h_r^M\right] = \mathrm{BERTEncoder}\left(In_r\right). \tag{7}$$

The sequence prediction result P_s obtained from the text noise removal model is converted into a position vector E by a binary function $I(\cdot)$. $I(\cdot)$ will mark the food health-related tag positions as 1 and the irrelevant tag positions as 0.

$$E = \left[e_1, e_2, \ldots, e_M\right] = I\left(P_s\right). \tag{8}$$

The input vectors H_c and H_r and the position vector E are input to the fusion function $G(\cdot)$. The function $G(\cdot)$ multiplies the position vectors E with the input vectors and concatenates them. At last, the vector H_{cr} is calculated as follows:

$$H_{er} = \mathrm{concatenates}\left(G\left(H_c, H_r, E\right)\right). \tag{9}$$

3.5. Character and Word Fusion. As in Section 3.1, we use the BERT encoder layer to get the vector representation of the input sentence H_w. The difference is that the BERT pretraining model used in the previous section is to segment the text into Chinese characters before training, while the BERT pretraining model used here is first to segment the text into Chinese words before training. The length of the input sentence after Chinese word separation is N.

$$H_w = \left[h_w^1, h_w^2, h_w^3, \ldots, h_w^N\right] = \mathrm{BERTEncoder}\left(\mathrm{In}\right). \tag{10}$$

Because of the difference between Chinese and English word construction methods, different characters will be combined into words in Chinese word construction. Then the generated words will generate new meanings. So, in the food health and safety domain, especially in few-shot learning, we need to use as much prior knowledge as possible to help us improve the recognition, so we fuse the character-based vector representation H_c and the word-based vector representation H_w.

We multiply the position vector E obtained from the text noise removal model with H_w to obtain the vector H_{we}. Then we concatenate H_{cr} to H_w according to the corresponding position to obtain the fused vector H_{cw} (see equation (11)), where the $K(\cdot)$ function expands the vector H_{cr} to the same length as H_w. For example, the vector for the word "食物" is A, and the vectors for the characters "食" and "物" are B and

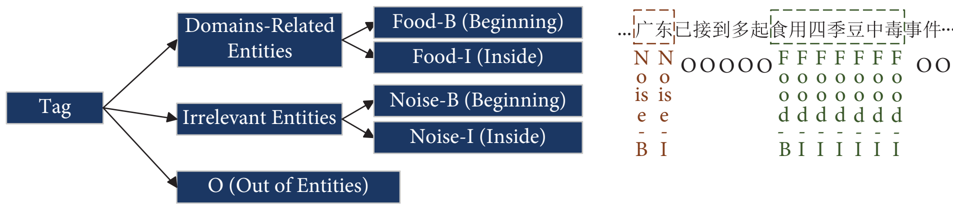

Figure 4: Modified BIO tagging method. The input text characters can be tagged as the beginning and middle positions of the entity and outside the entity. The "Food" prefix indicates that the entity is related to food health and safety, and the "Noise" prefix indicates that the entity is a noise that is not related to food health and safety.

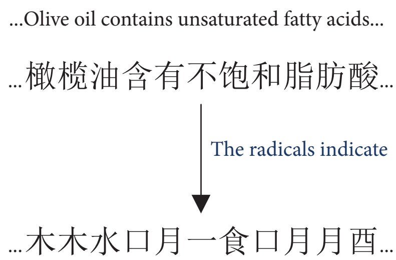

Figure 5: Representing sentences with radicals.

C, respectively. Then, concatenate vectors A and B, and concatenate vectors A and C.

$$H_{cw} = \text{concatenate}\left(G\left(H_{cr}\right)EH_{w}\right). \tag{11}$$

After combining characters and words, we can predict the location in the sentence where the subject may be. Because the entity relation extraction task itself suffers from the problem of overlapping entity relations, according to the view proposed by Wei et al. [23]: for a given subject s, any relation related to s (relations in T) corresponds to the corresponding object o in the sentence, while all other relations necessarily have no corresponding object in the sentence, that is, the set of corresponding objects is the empty set. So we first predict the possible positions of the subject in the sentence.

For a given input, we predict the location of potential subjects. Two binary classifiers form a subject marker, which marks potential subjects' starting and end positions. The subject marker is expressed as follows:

$$P_i^{\text{sub}_{\text{head}}} = \sigma\left(K_{\text{head}} H_{cw}^{i} + b_{\text{head}}\right), \tag{12}$$

$$P_i^{\text{sub}_{\text{tail}}} = \sigma\left(K_{\text{tail}} H_{cw}^{i} + b_{\text{tail}}\right), \tag{13}$$

where $P_i^{\text{sub}_{\text{head}}}$ denotes the probability that each position in the input vector may be the start position of the subject and $P_i^{\text{sub}_{\text{tail}}}$ in denotes the probability that each position in the input vector may be the end position of the subject. If this probability is greater than the threshold τ set in advance, it is for the position is a candidate for the start or end of the subject, marked as 1, and the rest is marked as 0. K_{head} and K_{tail} are learnable parameters, and b_{head} and b_{tail} are deviation parameters.

3.6. Relation Extraction. We obtain all possible sets of entity relations in the input sentence by object identification of each subject to all relations. After the subject tagger, we obtain the candidate subject position information, incorporated into the fusion vector as follows:

$$\widehat{H} = H_{cw}^{i} + \text{sub}. \tag{14}$$

Similarly, the object tagger predicts the potential object location, consisting of two binary classifiers. The object tagger is expressed as follows:

$$P_i^{\text{obj}_{\text{head}}} = \sigma\left(K_{\text{head}}^{r} \widehat{H} + b_{\text{head}}^{r}\right), \tag{15}$$

$$P_i^{\text{obj}_{\text{tail}}} = \sigma\left(K_{\text{tail}}^{r} \widehat{H} + b_{\text{tail}}^{r}\right). \tag{16}$$

The process of predicting the location of the object is similar to that of predicting the location of the subject. $P_i^{\text{obj}_{\text{head}}}$ in equation (15) denotes the probability that each position in the input vector may be the start position of the object, and $P_i^{\text{obj}_{\text{tail}}}$ in equation (16) denotes the probability that each position in the input vector may be the end position of the object. K_{head}^{r} and K_{tail}^{r} are learnable parameters, and b_{head}^{r} and b_{tail}^{r} are deviation parameters. All relations in the set R have an object tagger to mark the start and end positions of candidate objects.

4. Result Analysis and Discussion

4.1. Data Set and Evaluation Metrics. This paper uses an independently constructed food health-related data set FH (Food Health Dataset). Twelve types of food-health-related relationships are defined, and then "OTHER" relationship types are defined to represent less relevant relationships to food health in the sample data. Table 2 lists the 12 relationship types, the Chinese and English names of the included relationships, and their abbreviations. In addition, the paper constructs a small sample data set MHD (Medical Health Dataset) of medical-health-related data to measure the method's generalization performance. The data set MHD consists of 5 relationship types with 200 sentences. The training set contains 180 sentences, and the test set contains 20 sentences.

The total number of valid annotated sentences in the FH data set is 1,420. This paper divides the FH data set into a training set and a test set. Figure 6 shows the details of the data set.

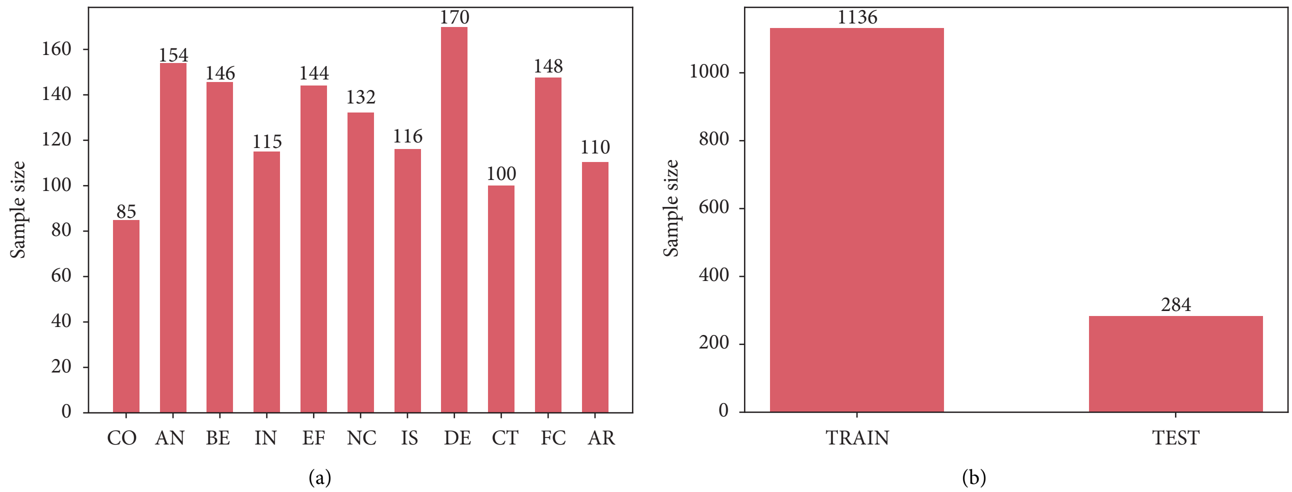

FIGURE 6: Details of the FH data set show: (a) the number of 11 food health and safety-related relationships and (b) the amount of data in the training and test sets.

To improve the performance of the model, we introduced more data samples from the public domain into the data set FH to form the incremental data set FH++, which is expanded from 1,420 sentences to 11,327 sentences to get better results in the text noise removal model. For the entity relation extraction task, we remove the "Other" relationships from the FH data set to form the FFH (filtered food health data) data set (http://39.96.33.199:9009/FFH_dataset.zip) used for entity relation extraction experiments.

For the evaluation metrics used in the experiments, we used three commonly used evaluation metrics, precision (P), recall (R), and $F1$ value, to measure the experimental results from different aspects. Their calculation criteria are as follows: in the formula, TP_i indicates that the model correctly predicts the number of relationships present in given sentence In_i, FP_i indicates that the model incorrectly predicts the number of relations that do not exist in given sentence In_i, and FN_i denotes the number of relations that the model failed to predict for given sentence In_i contained in the sentence.

$$
\begin{aligned}
P &= \frac{TP_i}{TP_i + FP_i} \\
R &= \frac{TP_i}{TP_i + FN_i} \\
F1 &= \frac{2 * P * R}{P + R}.
\end{aligned} \tag{17}
$$

For the text-to-noise model, we use the metric P to measure whether the model is predicting the location sequence correctly, the metric R to measure the model's ability to predict the location of entities in a complete way, and the metric $F1$ to measure model performance in aggregate. We focus more on metric P than on metrics R and $F1$, as it is more important to find the noise accurately.

For the entity relation extraction task, we use indicator P to measure how well the model extracts the correct combination of entity relationships in a sentence, indicator R to measure the model's ability to extract coverage in the face of sentences containing multiple relationships, and indicator $F1$ to measure the model's performance in aggregate.

4.2. Implementation Details. The pretrained BERT model we implemented in the deep learning framework PyTorch uses the Chinese pretrained BERT model (BERT-wmm) published by Cui et al. [26] with its default hyperparameter settings. The models in this research are implemented on a PC with the configuration of Intel(R) Xeon(R) CPU 3.50 GHz, 64 Gb RAM, and GTX3090 graphics. Table 3 records the other parameters used in the experiment.

The parameters used for the text noise removal model, construction of features at the part-head level, the fusion of character and word features, and entity relation extraction experiments are listed in Table 4.

4.3. Result of Text Noise Removal. The following are the experimental results of text noise removal, and the model is trained iteratively on the data set FH++. Figure 7 records the loss values and the final precision/recall curves during the training process, and it can be observed that the loss values gradually decrease, and the model gradually converges as the number of iterative training increases. The precision/recall curves indicate that the model has a good performance. Table 5 records the precision, recall, and $F1$ values for the text noise removal experiments on FH and the incremental data set FH++. The model can obtain better convergence and accuracy when training with the incremental data set. The positive and negative values in the experimental results shown in this paper are confidence intervals calculated by combining multiple results at a confidence level of 95%.

Table 6 records the experimental results obtained on the FH++ data set where we tried different structures to remove the noise, containing precision, recall, and $F1$ values. In Table 6, both the CNN and CNN-BiLSTM models use the softmax function as the activation function to transform the denoising task into a classification task. The results show that

Number of relations	P (%)	R (%)	$F1$ (%)
$N = 1$	88.64 ± 0.27	63.13 ± 0.31	73.74 ± 0.53
$N = 2$	70.12 ± 0.13	61.24 ± 0.11	65.37 ± 0.31
$N = 3$	55.45 ± 0.42	53.81 ± 0.33	54.61 ± 0.31
$N = 4$	43.10 ± 0.12	50.01 ± 0.09	46.29 ± 1.21
$N = 5$	33.10 ± 0.12	42.01 ± 0.09	37.02 ± 2.21

Table 8: Text removal noise ablation experiment results.

Model	$N = 1$ (%)	$N = 2$ (%)	$N = 3$ (%)	$N = 4$ (%)	$N = 5$ (%)
FHER (noise)	85.31 ± 0.87	63.13 ± 0.31	42.74 ± 0.53	21.10 ± 0.32	12.21 ± 0.21
FHER	**88.64** ± 0.27	**70.12** ± 0.13	**55.45** ± 0.42	**43.10** ± 0.12	**33.10** ± 0.12

the sequence task using the BiLSTM + CRF model has a better denoising effect.

4.4. Result of Entity Relation Extraction. For the entity relation extraction task, Table 7 records the effect of the model on the data set FFH, which contains the values of precision, recall, and $F1$ for a given sentence containing one to five relationships. The experimental results show that the extraction effectiveness of the model decreases as the number of relations in the input sentences increases, which is related to the imbalance of the data itself, with most of the samples in the data set having less than three relations. However, the overall recognition effect is still good.

The FHER method achieves 91.32% accuracy, 82.21% recall, and 86.52% $F1$ value on the FFH data set and achieves good extraction results in few-shot learning.

We did ablation experiments on the proposed denoising model to verify the effectiveness of few-shot learning for denoising. In Table 8, N represents the number of relations in the sentence, and the value in the table is the precision values for the entity relation extraction task. The experimental results show a significant decrease in recognition precision after the denoising model for a sentence containing multiple relations because the model identifies group or entity relations that we do not want. Therefore, denoising the input samples in few-shot learning is an effective method.

Similarly, we conducted ablation experiments to add prefix features to enhance and fuse character and word features. Table 9 records the experimental results. According to the experimental results, richer semantic information can effectively improve the effect of entity relation extraction during few-shot learning. The NIC model represents no features at the constructive radical level in the model, and the NCW model indicates that there are no fused characters and words in the model, and the whole model uses a vector of characters as units.

Table 9: Comparison of different degrees of semantic information on data set FFH.

Model	P (%)	R (%)	$F1$ (%)
NIC	88.91 ± 0.25	81.34 ± 0.86	84.95 ± 0.53
NCW	91.12 ± 0.13	80.24 ± 0.21	85.33 ± 0.31
FHER	**92.32** ± 0.14	**82.21** ± 0.23	**86.97** ± 0.77

Table 10: Method generalisation performance experiments on data set MDH.

Model	P (%)	R (%)	$F1$ (%)
NIC	75.23 ± 0.75	64.14 ± 0.77	69.24 ± 0.81
NCW	73.03 ± 0.86	66.13 ± 0.92	69.40 ± 0.91
FHER	**79.32** ± 0.53	**74.21** ± 0.99	**76.67** ± 0.63

At last, we test the generalization performance of the method on the data set MDH. The experimental results show that constructing the input at the radical level and fusing characters and words can achieve good results even with smaller data set volumes. Table 10 records the results of the method FHER on the data set MDH.

4.5. Discussion. We discuss the degree of semantic information in the text after its transformation into a radical. There are as many as 3,500 commonly used Chinese characters (http://www.gov.cn/gzdt/att/att/site1/20130819/tygfhzb.pdf). These 3,500 characters can be combined in vast amounts of meaningful words, making the vector space generated after representation learning of Chinese through language models more complex. In contrast, the radicals, which are the main constituents of Chinese characters, can

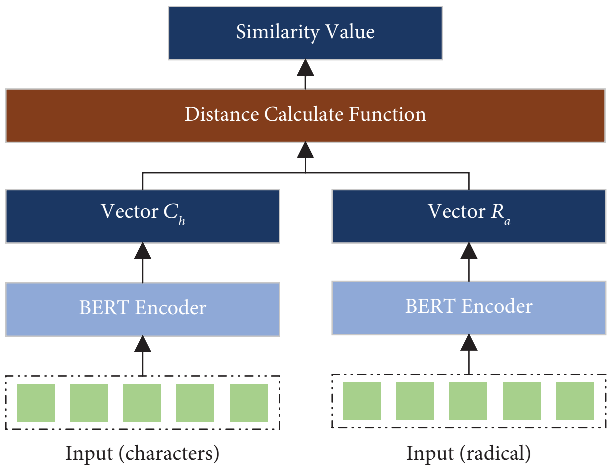

Figure 8: Text similarity calculation structure. The input at the character level and the input at the radical level are transformed by the pretrained model into vectors C_h and R_a. The text similarity is obtained by calculating the distance between the vectors C_h and R_a.

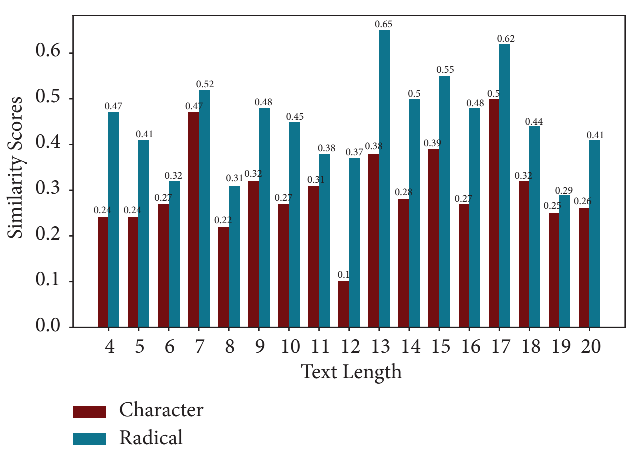

Figure 9: Results of text similarity calculations at the character level and the radical level. The horizontal coordinates represent the sum of the text lengths of the subject and object, while the vertical coordinates represent the similarity results. The blue bars represent radicals, and the red bars represent characters. The text similarity calculated at the radical level is higher than that at the character level.

be grouped into 201 radicals for 20,902 Chinese characters (http://www.moe.gov.cn/downloadvideo/yuxinsi/15hanzibushou.zip). Therefore, radicals reduce the complexity of the Chinese vector space.

For the entity groups "olive oil" and "unsaturated fatty acid" and their radical representations, we used the Chinese pretrained language model BERT-wmm to calculate their similarity based on the distance (see Figure 8). We collected subject-object combinations from the data set FFH. The sum of subject and object text lengths ranged from 4 to 20, so text similarity at the character level and the radical level was calculated between each pair of subjects and objects in them. Figure 9 shows the results of the text-similarity calculation. The experiment proves that the decomposition of Chinese characters into radical representations reduces the complexity of the text to a certain extent.

5. Conclusions

This paper proposes a method for entity relation extraction in food health and safety. Three methods are proposed for entity relation extraction under small sample learning to improve the entity relation extraction effect. Firstly, we propose removing text noise according to domain specialization. The experimental results show that removing entity relations in the text unrelated to the domain can significantly improve the effect of entity relation extraction. Then, we construct text features at the radical level by disassembling individual Chinese characters from the characters' structure. The experimental results show that the input at the radical level has low complexity and contains rich semantic features. Finally, we fuse the input text's character vectors and word vectors from the Chinese character constructions. The experimental results show that fusing characters and words can effectively enrich the semantic information in the input vectors. The above method has a good extraction effect in few-shot learning. In the method FHER, the effect of the entity relationship extraction task is subject to a threshold, which leads to an unstable performance of the model. In the future, we will further explore the influence of noise in the text on the degree of deep learning models, the semantic relationships, and differences between the three different levels of Chinese radicals, characters, and words. Moreover, we attempt to transfer the proposed method to other application fields such as agricultural image recognition, greenhouse environmental time-series prediction, and food safety risk assessment [27–31].

With the rapid development of artificial intelligence, various medical devices and wearable devices have emerged, enabling people to collect various health data of themselves in hospitals or other places. This has led to a substantial increase in the scale of medical data, and it is impossible to import these data into memory at one time. As a result, the hardware requirements of the computer become higher and the time consumption increases. This paper introduces an online clustering framework, divides the large data set into several small data blocks, processes each data block by weighting clustering, and obtains the cluster center and corresponding weight of each data block. Finally, the final cluster center is obtained by processing these cluster centers and corresponding weights, so as to accelerate clustering processing and reduce memory consumption. Extensive experiments are performed on UCI standard database, real cancer data set, and brain CT image data set. The experimental results show that the proposed method is superior to previous methods in less time consumption and good clustering performance.

1. Introduction

In recent years, smart medical care has emerged with the vigorous development of artificial intelligence (AI) technology. At present, the application of AI technology in the medical field involves many aspects such as disease prediction, intervention and consultation, disease diagnosis and treatment, drug research and development, and health service management [1]. The fusion of AI and healthcare services can help clinicians reduce reading time, aid in early detection, and improve diagnostic accuracy. The technology of clustering plays a very wide role in the fields of medical data analysis.

As a typical unsupervised learning method, clustering mines the internal relationship between data samples and then puts the samples with the same or similar attributes in the same cluster, which avoids the dependence on the label data and saves a lot of manpower and material resources [2]. Fuzzy clustering is a typical representative of clustering methods, and the most classic fuzzy clustering is the fuzzy C-means algorithm (FCM). Fuzzy clustering improves the traditional hard clustering partition. There are a large number of derivative algorithms based on the FCM, including the probabilistic C-means algorithm (PCM), which uses probabilistic methods to express fuzzy membership to improve the limitation of fuzzy membership [3]. Recently, many researchers have improved the traditional FCM method from multiple perspectives and applied them in various scenes [4]. Hua et al. [5] developed a multiview fuzzy clustering based on the framework of FCM. Gu et al. [6] proposed a probabilistic FCM method to be used for antecedent parameter learning in Takagi-Sugeno-Kang fuzzy system. Zhou et al. [7] proposed a new membership scaling FCM method by selecting the unchanged clustering centers through triangular inequality, which solves the problems of slow convergence and a large amount of calculation when a FCM algorithm is dealing with large data sets. Mishro et al. [8] proposed a new type 2 adaptive weighted space FCM clustering algorithm to solve the problem of noise misclassification and inaccurate clustering center obtained by

FCM in the process of MR brain image segmentation. Wang et al. [9] proposed an FCM algorithm for irregular image segmentation, which has higher robustness and less computational effort compared to traditional segmentation algorithms. Based on hyperplane partitioning, Shen et al. [10] developed a feasible and efficient FCM algorithm to deal with large data sets. Jha et al. [11] designed and implemented a kernelized fuzzy clustering algorithm using its in-memory cluster computing technology. Liu et al. [12] proposed a FCM algorithm based on multiple surface approximate interval membership for processing artifacts in brain MRI images. Wang et al. [13] proposed a FCM algorithm based on wavelet frame, which can effectively remove image noise and preserve image details. This algorithm can provide a new way to segment images in an irregular domain. Li et al. [14] proposed a domain-qualified adaptive FCM method for processing MRI brain images with noise and uneven intensity. Zhang and Huang [15] studied the generalization error of a FCM algorithm from the perspective of theory and limited the generalization error from the perspective of convergence, which can provide guidance for the application of the sampling-based FCM method. Wu et al. [16] proposed an online clustering algorithm by combining FCM algorithm with an online framework set to solve the problem that batch learning cannot deal with large-scale data sets. Zhang et al. [17] combined FCM with a nonlinear genetic algorithm and proposed an apple defect detection method to improve fruit defect detection. Shen et al. [18] proposed a hyperplane partition method based on FCM to deal with big data clustering. Recently, the Bayesian fuzzy clustering (BFC) [19] algorithm is proposed to combine the fuzzy method into a probability model. BFC reinterprets the fuzzy method from the perspective of probability, expands the value range of the fuzzy index, and solves the problem that the fuzzy method is prone to local optimization. The many characteristics of the BFC algorithm make it very widely used in medical data processing. But due to the high complexity of the BFC method, its efficiency is not high, and it has received great limitations in practical applications.

Inspired by the above ideas, this paper proposes the online weighted Bayesian fuzzy clustering method (OWBFC) and uses an online clustering framework, which not only retains all the advantages of the Bayesian fuzzy clustering algorithm but also improves the efficiency of the Bayesian fuzzy clustering method through the online clustering framework. We verify the OWBFC method on a series of real-world data sets. Compared with the existed Bayesian fuzzy clustering algorithms, the contributions of our study are concluded as follows:

(1) OWBFC combines the probability method with the fuzzy method and realizes the fuzzy clustering through the probability method, which has the common advantages of the probability method and the fuzzy method.

(2) In the process of solving the parameters, the Markov chain Monte Carlo method (MCMC) is used for sampling instead of a closed solution, so the global optimal solution of the parameters can be obtained in OWBFC.

(3) The online clustering framework is used in OWBFC to deal with the problem that large data sets cannot be imported into memory, and the weighting mechanism is used to improve the clustering efficiency.

2. Related Work

The BFC algorithm combines the probabilistic method with the fuzzy method. From the perspective of prior knowledge and Bayesian theory, it expands the range of the fuzzy index of the traditional fuzzy method. The BFC algorithm uses the MCMC strategy [20] and particle filter method [21, 22] to solve the optimization problem. The maximum posterior probability (MAP) is used to process fuzzy clustering, and the normal distribution is further used to predict the number of clusters. Therefore, the BFC method is superior to the previous fuzzy or probabilistic methods in many aspects. However, the algorithm complexity of BFC is relatively high. This shortcoming makes the BFC method not suitable for large-scale data, and its application range is greatly limited, which does not meet the current actual needs. The BFC algorithm aims to solve fuzzy clustering from the perspective of probability. The probability model of BFC consists of three parts, namely fuzzy data likelihood (FDL), fuzzy membership prior (FCP), and cluster center prior, as follows. The fuzzy data likelihood is as follows:

$$p(\mathbf{X} \mid \mathbf{U}, \mathbf{C}) = \prod_{k=1}^{K} \mathrm{FDL}(\mathbf{x}_k \mid \mathbf{u}_k, \mathbf{C}) = \prod_{k=1}^{K} \frac{1}{Z(\mathbf{u}_k, m, \mathbf{C})} \prod_{n=1}^{N} \mathcal{N}(\mathbf{x}_k \mid \boldsymbol{\mu} = \mathbf{c}_n, \boldsymbol{\Lambda} = u_{kn}^{m}\mathbf{I}), \quad (1)$$

where $\boldsymbol{X}$, $\boldsymbol{U}$, and $\boldsymbol{C}$ are matrices of training data, fuzzy member, and cluster centers, respectively. K and N represent the numbers of samples and the numbers of clusters, respectively. u_{kn} is the membership of data point $\mathbf{x}_k$ in cluster n. The parameters m, $\mathbf{c}_n$, and $\boldsymbol{I}$ represent the fuzzy index, the cluster center, and the identity matrix, respectively. And, $Z(\mathbf{u}_k, m, \mathbf{C})$ is the normalization constant, and m is the fuzzy index. Since $Z(\mathbf{u}_k, m, \mathbf{C})$ will be eliminated by the following equation (2), it does not need to be calculated.

The prior of fuzzy membership is expressed as

$$p(\mathbf{U}|\mathbf{C}) = \prod_{k=1}^{K} \mathrm{FCP}(\mathbf{u}_n|\mathbf{C}) = \prod_{k=1}^{K} Z(\mathbf{u}_k, m, \mathbf{C}) \left(\prod_{n=1}^{N} u_{kn}^{-m\ D/2} \right) \mathrm{Dirichlet}(\mathbf{u}_k|\boldsymbol{\alpha}). \tag{2}$$

$p(\mathbf{U}|\mathbf{C})$ consists of three parts as follows: $F_1 = Z(\mathbf{u}_k, m, \mathbf{C})$, $F_2 = \prod_{n=1}^{N} u_{kn}^{-m\ D/2}$, and $F_3 = \mathrm{Dirichlet}(\mathbf{u}_k|\alpha)$. F_1 is to eliminate the normalizing constant in equation (1). F_3 is the Dirichlet distribution as follows:

$$\mathrm{Dirichlet}(\mathbf{x}|\boldsymbol{\alpha}) = \frac{\Gamma\left(\sum_{n=1}^{N}\alpha_n\right)}{\prod_{n=1}^{N}\Gamma(\alpha_n)} \prod_{n=1}^{N} x_n^{\alpha_n - 1}, \tag{3}$$

where $x_n \geq 0, n = 1, \ldots, N$ and $\sum_{n=1}^{N} x_n = 1$. The parameter α is the Dirichlet prior parameter, which controls the membership degree of the sample. Through Dirichlet distribution, the BFC algorithm breaks the constraint that the fuzzy index in the FCM algorithm must be greater than 1, so that the fuzzy index in the BFC algorithm can take any value.

Cluster center prior is defined as

$$p(\mathbf{C}) = \prod_{n=1}^{N} \mathcal{N}(\mathbf{c}_n|\boldsymbol{\mu}_c, \boldsymbol{\Sigma}_c). \tag{4}$$

It is noted that $p(\mathbf{C})$ is to match the high degree of membership produced by equation (4). μ_c and Σ_c are the mean and variance of all samples, as follows:

$$\begin{aligned} \boldsymbol{\mu}_c &= \frac{1}{K}\sum_{k=1}^{K}\mathbf{x}_k \\ \boldsymbol{\Sigma}_c &= \frac{\gamma}{K}\sum_{k=1}^{K}(\mathbf{x}_k - \boldsymbol{\mu}_c)(\mathbf{x}_k - \boldsymbol{\mu}_c)^T, \end{aligned} \tag{5}$$

where γ is a parameter that affects the strength of the prior, which is set by the user, and we use $\gamma = 3$ in our study. The joint likelihood of $\mathbf{X}$, $\mathbf{U}$, and $\mathbf{C}$ is obtained by multiplying equations (1), (2), and (4).

$$\begin{aligned} p(\mathbf{X}, \mathbf{U}, \mathbf{C}) &= p(\mathbf{X}|\mathbf{U}, \mathbf{C})p(\mathbf{U}|\mathbf{C})p(\mathbf{C}) \\ &\propto exp\left\{-\frac{1}{2}\sum_{k=1}^{K}\sum_{n=1}^{N}u_{kn}^{m}||\mathbf{x}_k - \mathbf{c}_n||^2\right\} \times \left[\prod_{k=1}^{K}\prod_{n=1}^{N}u_{kn}^{\alpha_n - 1} \times \exp\left\{-\frac{1}{2}\sum_{n=1}^{N}(\mathbf{c}_n - \boldsymbol{\mu}_c)^T\sum_{c}^{-1}(\mathbf{c}_n - \boldsymbol{\mu}_c)\right\}\right]. \end{aligned} \tag{6}$$

According to map theory, the joint likelihood form of equation (7) is its negative logarithm, and a factor of 2 can be multiplied to simplify. The joint likelihood form is as follows:

$$J(\mathbf{X}, \mathbf{U}, \mathbf{C}) = \sum_{k=1}^{K}\sum_{n=1}^{N}u_{kn}^{m}||\mathbf{x}_k - \mathbf{c}_n||^2 - 2\sum_{k=1}^{K}\sum_{n=1}^{N}(\alpha_n - 1)\log u_{kn} + \sum_{n=1}^{N}(\mathbf{c}_n - \boldsymbol{\mu}_c)^T\sum_{c}^{-1}(\mathbf{c}_n - \boldsymbol{\mu}_c). \tag{7}$$

Finally, BFC uses MAP inference and uses sampling to filter membership and cluster centers to obtain their optimal values.

From the above introduction, we can see that the BFC algorithm breaks through the constraints of the traditional fuzzy clustering fuzzy index and can obtain the global optimal solution, but its time complexity is too high to handle large data sets.

3. Online Weighted Bayesian Fuzzy Clustering

3.1. Weighted Bayesian Fuzzy Clustering. For large data sets, it is a difficult problem that the data cannot be imported into the computer at one time. In this paper, the online clustering framework is adopted. By dividing the large data set into several easy-to-handle small data blocks, the clustering center of each data block is defined as the representative point. In the process of processing the data blocks, the representative points of each data block and the corresponding weights of the representative points are combined into two new different sets, and then, the two new sets are processed to get the clustering center of the whole data and accelerate clustering. Since the OWBFC method uses a block and weighting mechanism to introduce weights for the clustering centers of each data block, the weighted Bayesian fuzzy clustering (WBFC) algorithm is introduced, and then, WBFC is extended to its online version.

To further judge the contribution of each sample point to the cluster in the process of clustering, this paper introduces the WBFC algorithm, which adaptively weights different sample points to select the representative sample points. The objective function of WBFC is defined as

$$p(\mathbf{X},\mathbf{U},\mathbf{C}) = p(\mathbf{X}|\mathbf{U},\mathbf{C})p(\mathbf{U}|\mathbf{C})p(\mathbf{C}) \propto exp\left\{-\frac{1}{2}\sum_{k=1}^{K}\sum_{n=1}^{N} w_n u_{kn}^m ||\mathbf{x}_k - \mathbf{c}_n||^2\right\} \times \left[\prod_{k=1}^{K}\prod_{n=1}^{N} u_{kn}^{\alpha_n - 1} \times \exp\left\{-\frac{1}{2}\sum_{n=1}^{N}(\mathbf{c}_n - \boldsymbol{\mu}_c)^T \sum_{c}^{-1}(\mathbf{c}_n - \boldsymbol{\mu}_c)\right\}\right], \tag{8}$$

where $w_k > 0$ represents the contribution of the nth sample to the final cluster division. How to set w_k will be described in detail in the next section. Following [19], the MCMC parameter optimization strategy is used in the WBFC algorithm. First, we initialize the parameter $\mathbf{u}_k$ and $\mathbf{c}_n$ by Dirichlet distribution and normal distribution. We sample the $\boldsymbol{U}$ matrix according to $\mathbf{U} \sim p(\mathbf{U}|\mathbf{X},\mathbf{C}) \propto p(\mathbf{X},\mathbf{U},\mathbf{C})$ using the Gibbs sampling. We judge whether the new membership sample is accepted. If it is accepted, then $\mathbf{u}_k$ is set as $\mathbf{u}_k = \mathbf{u}_k^{\Psi}$, $\mathbf{u}_k^{\Psi}$ as a new membership sample. The acceptation rate $A_{\mathbf{u}}$ is computed as

$$A_{\mathbf{u}} = \min\left\{1, \frac{p\left(\mathbf{x}_k, \mathbf{u}_k^{\Psi}|\mathbf{C}\right)}{p(\mathbf{x}_k, \mathbf{u}_k|\mathbf{C})}\right\}. \tag{9}$$

If $p(\mathbf{x}_k, \mathbf{u}_k^{\Psi}|\mathbf{C}^*) > p(\mathbf{x}_k, \mathbf{u}_k^*|\mathbf{C}^*)$, we set the current $\mathbf{u}_k^*$ as $\mathbf{u}_k^* = \mathbf{u}_k^{\Psi}$. The $p(\mathbf{x}_k, \mathbf{u}_k|\mathbf{C})$ is computed as

$$p(\mathbf{x}_k, \mathbf{u}_k|\mathbf{C}) = p(\mathbf{x}_k|\mathbf{u}_k,\mathbf{C})p(\mathbf{u}_k|\mathbf{C}) \propto \prod_{n=1}^{N} \exp\left(-\frac{1}{2}w_k u_{kn}^m \|\mathbf{x}_k - \mathbf{c}_n\|^2\right) u_{kn}^{\alpha_n - 1}. \tag{10}$$

Then, we sample $\boldsymbol{C}$ according to $\mathbf{C} \sim p(\mathbf{C}|\mathbf{X},\mathbf{U}) \propto p(\mathbf{X},\mathbf{U},\mathbf{C})$. We judge whether the new cluster center sample is accepted. If it is accepted, then $\mathbf{c}_n$ is set as $\mathbf{c}_n = \mathbf{c}_n^{\Psi}$. The acceptation rate $A_{\mathbf{c}}$ is computed as

$$A_{\mathbf{c}} = \min\left\{1, \frac{p\left(\mathbf{x}_k, \mathbf{c}_k^{\Psi}|\mathbf{C}\right)}{p(\mathbf{x}_k, \mathbf{c}_k|\mathbf{C})}\right\}. \tag{11}$$

If $p(\mathbf{X}, \mathbf{c}_n^{\Psi}|\mathbf{U}^*) > p(\mathbf{X}, \mathbf{c}_n^*|\mathbf{U}^*)$, we set the current $\mathbf{c}_n^*$ as $\mathbf{c}_n^* = \mathbf{c}_n^{\Psi}$, $\mathbf{c}_n^{\Psi}$ as a new cluster center. The $p(\mathbf{X}, \mathbf{c}_n|\mathbf{U})$ is computed as

$$p(\mathbf{X}, \mathbf{c}_n|\mathbf{U}) = p(\mathbf{X}|\mathbf{U}, \mathbf{c}_n)p(\mathbf{c}_n) \propto exp\left\{-\frac{1}{2}\sum_{k=1}^{K}\sum_{n=1}^{N} w_k u_{kn}^m ||\mathbf{x}_k - \mathbf{c}_n||^2\right\} \times \exp\left\{-\frac{1}{2}\sum_{n=1}^{N}(\mathbf{c}_n - \boldsymbol{\mu}_c)^T \sum_{c}^{-1}(\mathbf{c}_n - \boldsymbol{\mu}_c)\right\}. \tag{12}$$

Finally, we check the maximum likelihood of all samples using equation (9). The whole training process circulates several times until the model converges. The training procedure of WBFC is shown in Algorithm 1.

3.2. Online Weighted Bayesian Fuzzy Clustering. The WBFC algorithm aims to introduce object weights based on the BFC algorithm, so more representative sample points can be selected while clustering. Based on the characteristics of the WBFC algorithm, we further proposed the online version of WBFC algorithm called OWBFC algorithm. Inspired of the online algorithm advantage, the OWBFC algorithm can handle large data sets based on the WBFC algorithm. OWBFC divides the large-scale data into several easy-to-process data blocks. Then, OWBFC uses the WBFC algorithm to process each data block, merges the cluster center of each data block into a new set, calculates the weight of each cluster center, and merges the obtained weight. Finally, the new cluster center set and the corresponding weight set are processed to obtain the final cluster center. The weight factor w_n in OWBFC is computed as follows:

$$w_q = \sum_{k=1}^{K_l} u_{kq}, q = 1, \ldots, \mathrm{Q}, \tag{13}$$

where w_q represents the weight of representative points of each data block. Here, we give the training procedure of the OWBFC algorithm as shown in Algorithm 2. The parameter K_l represents the number of sample points in the lth block, u_{kq} is the membership of $\mathbf{x}_k$ in cluster q, and Q represents the number of clusters. First, we divide the training data $\boldsymbol{X}$ into d

blocks as $\mathbf{X} = \{\mathbf{X}_1, \ldots, \mathbf{X}_d\}$, and each block $\mathbf{X}_l$ has K_l sample points, $l = 1, 2, ..., d$. $\mathbf{U}_l$ and $\mathbf{C}_l$ are the fuzzy membership and clustering center matrices, respectively. We run the WBFC algorithm in the first block $\mathbf{X}_1$ and obtain the fuzzy membership and clustering center matrices in $\mathbf{X}_1$. Then, we run the WBFC algorithm in the rest blocks with the clustering center matrix $\boldsymbol{C}_{l-1}$.

4. Experiments

4.1. Data Sets and Experiment Settings. In the experiment, we use several medical data sets, including two cancer data sets, Armstrong-2002-v2 and Bhattacharjee-2001 [23], three medical data sets, and brain images in the UCI database [24]. Armstrong-2002-v2 is a data set to distinguish the expression of leukemia genes. It is divided into three categories, with a total of 72 samples. Bhattacharjee-2001 is a lung cancer classification data set, including five categories, a total of 203 samples. Because of the small sample size of these two data sets, they are not segmented here. The heart disease data set, diabetic retinopathy Debrecen (DRD) data set, and hepatitis C virus (HCV) for Egyptian patient data set are three UCI medical data sets. The heart disease data set contains 303 samples, and only 14 of them are used in this article. The DRD data set contains 1151 samples, and the HCV data set contains 1385 samples. To facilitate the division, this study takes 1000 samples for the diabetic retinopathy Debrecen data set. The HCV data set took 1,200 samples. A total of three brain CT images were selected as CT1, CT2, and CT3, with pixels of 275×273, 273×277, and 264×271. To facilitate segmentation, the pixels of the three pictures are reduced to 272×272, 272×272, and 264×264, respectively. The comparison algorithms include OFCM [25] and SPFCM [25], which can process large-scale data clustering. Among them, the two cancer data sets and one UCI medical data set are used to compare the clustering effects of OWBFC, OFCM, and SPFCM algorithms without segmentation. The remaining two UCI medical data sets are used to compare the clustering effects and time of OWBFC, OFCM, and SPFCM algorithms in different proportions of segmentation. The brain images are used to show the running time comparison of OWBFC and BFC. The OWBFC, OFCM, and SPFCM algorithms have two parameters: fuzzy index m and prior parameter α. In this study, we set $m = 1.7$ and $\boldsymbol{\alpha} = 1$. To visually display the clustering performance, we use four clustering performance indicators of accuracy, entropy, F-measure, and purity to show the clustering results. $R = \text{full}_t/\text{block}_t$ represents the ratio of the running time of the whole processing data set and the block processing data set of the algorithm, full_t represents the running time on the whole data set, and block_t represents the sum of the running time on each block. Although this part loads the data set into the memory at one time, this paper believes that R is similar to the data that cannot be loaded, because the total amount of data is the same, whether it is processed separately or at one time. Our experimental platform is AMD R5-5600X, six cores, 16G memory, Windows10 operating system, Matlab2016a.

4.2. Experimental Results on the Armstrong-2002-v2, Bhattacharjee-2001, and Heart Disease Data Set. To make SPFCM and OFCM algorithms run better, according to the suggestions of Havens et al. [25], we set the fuzzy index $m = 1.7$. For the Armstrong-2002-v2 data set, Bhattacharjee-2001 data set, and heart disease data set, the number of clusters is set to 3, 5, and 5, respectively. Because the sample size of these three data sets is small, they are not processed in blocks. Table 1 shows the experimental results of the OFCM, SPFCM, and OWBFC algorithms. We can see that the OFCM algorithm and the SPFCM algorithm have similar clustering performances on these three different data sets, and it is difficult to compare the advantages and disadvantages of the two algorithms. But comparing the OFCM algorithm, SPCM algorithm, and OWBFC algorithm, it is easy to see that the OWBFC algorithm has the best clustering results except for some special cases.

4.3. Clustering Performance on DRD and HCV Data Set. Like the parameter setting in Section 4.2, the DRD and HCV data sets are divided into 5%, 10%, and 50% of the whole data set, and the last column of the HCV data set is selected as the basis for the number of clusters, the fuzzy index $m = 1.7$, and the number of clusters is set to 4. The OFCM, SPFCM, and OWBFC algorithms run independently 10 times on the basis of random initialization to calculate the maximum, minimum, and average values of accuracy, entropy, F-measure, and purity. The clustering results of the two data sets are shown in Tables 2–5. From Table 2, it can be seen that the accuracy of the OFCM is slightly lower than that of the SPFCM algorithm when the number of data blocks is large, and the accuracy of the OFCM algorithm is higher than that of the SPFCM algorithm when the number of blocks is small. Overall, the accuracy of OFCM algorithm is similar to that of SPFCM algorithm, and the accuracy of OWBFC algorithm is the best. Tables 2–5 show the accuracy, entropy, F-measure, and purity of these two different data sets. For example, 74.78/74.90/74.66 represents the mean, max, and min accuracy values, respectively. Compared with the OFCM algorithm and SPFCM algorithm, the OWBFC algorithm has the best results whether it is entropy or F-measure or purity. Because the OWBFC algorithm uses the MCMC sampling method to solve the parameters, it can obtain the global optimization of the parameters. Therefore, the OWBFC algorithm can obtain better clustering performance. Only from Tables 3–5, the gap between the three algorithms is not obvious. Combining with Table 8, it can be clearly seen that the OWBFC algorithm has good clustering performance and also greatly reduces the time consumption of the algorithm. Table 8 shows the running time at different division ratios. Because the data set name is too long, the abbreviation is used in the experiment.

4.4. Brain Images. Three brain images are shown in Figure 1. We use them to verify the clustering performance of OWBFC for large-scale image segmentation. We compare the OWBFC and BFC algorithms in this subsection. According to the recommendations [19, 25], the parameters α set to 1, and the

Input:Training data $\boldsymbol{X}$, fuzzy index m, number of clusters N, number of sampling iteration N_{iter}, weight $\mathbf{w}$
Output:Fuzzy membership $\mathbf{U}^*$ and cluster prototypes $\mathbf{C}^*$
Step 1. Initialize parameters μ_c and Σ_c
Step 2. Initial $\mathbf{u}_k \sim \text{Dirichlet}(\alpha = \mathbf{1}_N), k = 1, \ldots, K$
Step 3. Initial $\mathbf{y}_c \sim \mathcal{N}(\mu_y, \Sigma_y), c = 1, \ldots, C$
Step 4. $\mathbf{u}_k^* = \mathbf{u}_k, \mathbf{c}_n^* = \mathbf{c}_n$,//assign map sample to current sample
Step 5. For $iter = 1, \ldots, N_{iter}$
//Sample $\boldsymbol{U}$ according to $\mathbf{U} \sim p(\mathbf{U}|\mathbf{X}, \mathbf{C}) \propto p(\mathbf{X}, \mathbf{U}, \mathbf{C})$
Step 7. for $k = 1, \ldots, K$
Step 8. Sample new membership $\mathbf{u}_k^\Psi$ by equation (3)
Step 9. Judge whether the new membership sample is accepted by equation (10). If it is accepted, then $\mathbf{u}_k = \mathbf{u}_k^\Psi$
Step 10. if $p(\mathbf{x}_k, \mathbf{u}_k^\Psi|\mathbf{C}^*) > p(\mathbf{x}_k, \mathbf{u}_k^*|\mathbf{C}^*)$ //Use Eq. (11)
Step 11. $\mathbf{u}_k^* = \mathbf{u}_k^\Psi$
Step 12. end
Step 13. end
//Sample $\boldsymbol{C}$ according to $\mathbf{C} \sim p(\mathbf{C}|\mathbf{X}, \mathbf{U}) \propto p(\mathbf{X}, \mathbf{U}, \mathbf{C})$
Step 14. for $n = 1, \ldots, N$
Step 15. Sample new cluster center $\mathbf{c}_n^\Psi$ from $\mathcal{N}(\mathbf{c}_n, \Sigma_c/\delta)$
Step 16. Judge whether the new cluster center sample is accepted by equation (12). If it is accepted, then $\mathbf{c}_n = \mathbf{c}_n^\Psi$
Step 17. if $p(\mathbf{X}, \mathbf{c}_n^\Psi|\mathbf{U}^*) > p(\mathbf{X}, \mathbf{c}_n^*|\mathbf{U}^*)$ //Use equation (13)
Step 18. $\mathbf{c}_n^* = \mathbf{c}_n^\Psi$
Step 19. end
Step 20. end
Step 21. //Check the maximum likelihood of all samples
Step 22. if $p(\mathbf{X}, \mathbf{U}, \mathbf{C}) > p(\mathbf{X}, \mathbf{U}^*, \mathbf{C}^*)$ //Use equation (9)
Step 23. $\mathbf{U}^* = \mathbf{U}$
$\mathbf{C}^* = \mathbf{C}$
Step 24. end
Step 25. end

Algorithm 1: Weighted Bayesian fuzzy clustering (WBFC) algorithm.

Input: Training data $\mathbf{X}$, fuzzy index m, number of clusters Q, number of sampling iteration N_{iter}, weight w_n, number of data blocks d
Output: Cluster prototypes $\mathbf{C}^*$
Step 1. Divide $\boldsymbol{X}$ into d blocks $\mathbf{X} = \{\mathbf{X}_1, \ldots, \mathbf{X}_d\}$//Each block has K_l sample points, $1 \le l \le d$
Step 2. Initialize $\mathbf{w} = \mathbf{1}_{K_l}$
Step 3. Use algorithm to obtain the $\mathbf{U}_1, \mathbf{C}_1 = \text{WBFC}(\mathbf{X}_1, Q_1, m)$ with $\mathbf{w}$
Step 4. for $l = 2$ to d
Step 5. Use algorithm to obtain the $\mathbf{U}_l$, $\mathbf{C}_l = \text{WBFC}(\boldsymbol{X}_l, Q_l, m)$ with $\boldsymbol{C}_{l-1}$
Step 6. end
Step 7. $\mathbf{C}^* = \mathbf{C}_1 \cup \mathbf{C}_2 \ldots \cup \mathbf{C}_d$
Step 8. $\mathbf{w}_q = \sum_{k=1}^{K_l} u_{kq}, q = 1, \ldots, Q$
Step 9. $\mathbf{C}^* = \text{WBFC}(\mathbf{C}^*, N, m, \{\mathbf{w}_1 \cup \ldots \cup \mathbf{w}_d\})$
Step 10. end

Algorithm 2: Online Weighted Bayesian Fuzzy Clustering (OWBFC) algorithm.

Table 1: Clustering performance on Armstrong-2002-v2, Bhattacharjee-2001, and Heart Disease data sets.

Data sets	Algorithms	Accuracy	Entropy	*F*-measure	Purity
	OFCM	0.7235	0.4728	0.7948	0.7331
Armstrong-2002-v2	SPFCM	0.7237	0.4697	**0.8011**	0.7372
	OWBFC	**0.7548**	**0.4632**	0.7964	**0.7489**
	OFCM	0.8213	0.2879	0.8637	0.8235

parameters m set to 1.7. We split brain images at a ratio of 25% and set all classes to 3. Figures 2 and 3 show the clustering results of three brain images by BFC and OWBFC algorithms, respectively. Table 6 shows the experimental results on three brain images. Table 7 shows the running time results of BFC and OWBFC on three brain images. We can see from Table 6 that the clustering performance of OWBFC is better than that of BFC. Meanwhile, from Table 7, we can clearly see that OWBFC has a shorter time consumption compared with BFC. In summary, compared with BFC, the OWBFC algorithm not only maintains a good clustering effect but also consumes less time.

5. Conclusion

With the advancement of science and technology, the collection of various medical data has become more frequent and easier, which makes the scale of medical data larger and larger, and it is impossible to import the data into the memory at one time, so the hardware requirements for processing these data become higher and the time consumption increases. This paper proposes an OWBFC method, which reduces the memory consumption of the computer and the time consumption of the algorithm by introducing an online clustering framework to process the data set in blocks. From the experimental results, the block processing can effectively reduce the time consumption of the algorithm. However, the online clustering framework adopted in this paper needs to merge and save the cluster centers of each data block in the process of processing data, which raises the space consumption of the algorithm. Therefore, how to avoid excessive space consumption while ensuring low time consumption is a problem worth thinking about.

Data Availability

Soil temperature (T_s), a key variable in geosciences study, has generated growing interest among researchers. There are many factors affecting the spatiotemporal variation of T_s, which poses immense challenges for the T_s estimation. To enrich processing information on loss function and achieve better performance in estimation, the paper designed a new long short-term memory model using quadruplet loss function as an intelligence tool for data processing (QL-LSTM). The model in this paper combined the traditional squared-error loss function with distance metric learning between the sample features. It can zoom analyze the samples accurately to optimize the estimation accuracy. We applied the meteorological data from Laegern and Fluehli stations at 5, 10, and 15 cm depth on the 1st, 5th, and 15th day separately to verify the performance of the proposed soil temperature estimation model. Meanwhile, this paper inputs the variables into the proposed model including radiation, air temperature, vapor pressure deficit, wind speed, air pressure, and past T_s data. The performance of the model was tested by several error evaluation indices, including root mean square error (RMSE), mean absolute error (MAE), Nash-Sutcliffe model efficiency coefficient (NS), Willmott Index of Agreement (WI), and Legates and McCabe index (LMI). As the test results at different soil depths show, our model generally outperformed the four existing advanced estimation models, namely, backpropagation neural networks, extreme learning machines, support vector regression, and LSTM. Furthermore, as experiments show, the proposed model achieved the best performance at the 15 cm depth of soil on the 1st day at Laegern station, which achieved higher WI (0.998), NS (0.995), and LMI (0.938) values, and got lower RMSE (0.312) and MAE (0.239) values. Consequently, the QL-LSTM model is recommended to estimate daily T_s profiles estimation on the 1st, 5th, and 15th days.

1. Introduction

Soil temperature (T_s) is a main physical variable of the land surface, which has a direct influence on the atmosphere [1]. Relevant fields including geoscience and forestry application aspects have drawn attention from researchers [2, 3]. In principle, all the interactions in terrestrial ecosystems are companied by T_s variations since they involve energy exchanges. T_s is an essential factor for growing crops that can facilitate the development of the root system by impacting microbial activity, soil decomposition, and fluidity of soil water [4]. In addition, the death of animals and plants produces plenty of carbon substrates and a high volume of greenhouse gases in the soil. Consequently, it results in an increase in T_s, thus expediting carbon dioxide emission to the atmosphere [5]. Therefore, accurate T_s monitoring is crucial for agricultural management and atmosphere environment forecast. However, T_s data in most areas is still measured by using traditional sensors, and the T_s data cannot be collected at different depths [6].

Therefore, it can be used to solve some problems in different fields for the study of T_s estimation. The essential environmental factors have a great influence on the accuracy of T_s estimation. At present, T_s is mainly predicted by methods based on physical models and data-driven methods. The physical method is based on the heat conduction model to estimate T_s [7]. Meanwhile, the method is greatly affected by related physical parameters and the scale problem [8].

The data-driven methods can explore the internal relationship between T_s and the surrounding environmental factors for T_s estimation. At present, several predictive models based on machine learning methods are used for estimating T_s [9–14]. For example, ANN is composed of a complex network structure that imitates the structure and function of the brain's neural network, and it has powerful data processing capabilities. Bilgili applied the multilayer perceptron (MLP) model to adequately describe T_s distribution at a monthly temporal scale from meteorological data [15]. Kisi et al. used three machine learning models to estimate monthly T_s at the soil depth of 5 cm and 10 cm, respectively, and verified the predictive performance of radial basis neural networks performed better than that of generalized regression neural networks and multilayer perceptron models [9]. But generalized regression neural networks had the better performance for deeper depth (50 cm and 100 cm). Kisi et al. applied ANN-based models to predict long-term T_s at a monthly temporal scale, and they found that genetic programming generated the best performance with the meteorological data [16]. Zeynoddin et al. applied a multilayer perceptron (MLP) model to describe daily T_s distribution at three soil depths (5, 10, and 20 cm) from past measurements of T_s [17]. Samadianfard et al. processed the meteorological data such as Ta, W, RH, Rs, Sunshine hours (Sh), and air pressure (Ap) and integrated ANN-based models separately to predict T_s at a monthly temporal scale [18]. Mehdizadeh et al. noted that machine learning models combined with time series models performed better performance than the predictive models based on the single machine learning method or single time series method for predicting T_s at a daily temporal scale [19]. Moazenzadeh et al. proposed SVR with krill herd algorithm (SVR-KHA) method in modeling T_s estimation at different depths (5, 10, 20, 30, 50, and 100 cm), which achieved the best performance, compared to SVR and SVR with firefly algorithm (SVR-FA) [11]. Delbari et al. proposed an SVR-based model to compute daily T_s at three depths (5, 30, and 100 cm) in Iran [12]. The ELM network featured by a single hidden layer could improve the learning speed and accuracy of the algorithm and can model the accurate T_s. Nahvi et al. used the improved ELM model on daily T_s estimation based on the self-adaptive evolutionary method and verified the improved predictive model can estimate the adequate T_s [20]. Sanikhani et al. tested the data from the Mersin station, and the results that show the performance of ELM has the best predictive performance than other predictive models. [14]. Feng et al. tested the loess plateau data with ELM and random forests (RF) and ANN-based models showed that ELM had the better performance for estimation T_s of half-hourly at different soil depths [13].

As a time loop neural network containing complex neural network modules, LSTM is used in this paper to solve long-term dependence problems, which can effectively alleviate gradient vanishing through the extraction of required features by the gate control unit. LSTM network [21] can learn long-term and short-term behaviors, and it has seen application in vast areas. By integrating LSTM and SVR, Guo et al. significantly improved the prediction accuracy of abnormal passenger flow fluctuations [22]. In hydrology, Zhang et al. designed a novel LSTM model with the dropout scheme to estimate the depth of the water table [23]. In the atmosphere field, Qing et al. estimated the solar irradiance based on the LSTM network [24]; the results showed the method could avoid the overfitting of the model. Li et al. designed a new GANs-LSTM model and noted that it could serve as an alternative method to estimate T_s [25].

This article focuses on the following issues. First, we select the environmental factors which will affect T_s estimation. T_s memory can help the predictive model "remember" a warm or cold condition when the anomaly is forgotten by the atmosphere forcing. In addition, recent literature reviews have revealed that the input for prediction models is either the past measurements of T_s or other meteorological information (Ta, W, RH, Rs, Sh, and Ap). Assume that the prediction models are constructed using input combinations of past T_s and other meteorological information; how does the prediction model performance? The second question is about the construction of loss function in LSTM. The predictive model for T_s estimation is a regression predictive modeling problem that involves predicting a real-valued quantity. The loss function is crucial for optimizing the predictive model which could express the degree of difference between predicted and observed T_s; meanwhile, it can optimize the predictive model by updating the weights. Recently, most previous studies in loss function of regression predictive model mainly focused on the distance metric learning between predicted values and real values [26–29]. However, the distance metric learning between the sample features (environmental factors) is usually ignored which has already been successfully applied to image processing [30–32]. To enrich information processing in loss function and further improve the estimation performance, how can we construct a novel loss function by combinations of distance metric learning? The last question is about timescale evaluating for T_s estimation. In previous studies, any evaluation at short-term T_s estimation (half-hourly, hourly, daily timescales) does not consider the timeliness of long-term T_s estimation. However, any evaluation at long-term T_s estimation (monthly timescale) does not include the information of T_s in a small timescale. An ideal decision-support tool for T_s estimation should provide a multifarious decision-making basis. How can we design a prediction scheme at the same timescale evaluation that provides not only the short-term decision-making basis but also the long-term decision-making basis?

This paper proposed a novel quadruplet loss function based on the LSTM network that combines traditional squared-error loss function with distance metric learning between the sample features, called QL-LSTM. The traditional squared-error loss function is usually applied to the predictive task with great accuracy. The current limitation of this loss function, however, involves the special variation on Ts based on different predictors. As shown in Figure 1, we have made labels according to T_s

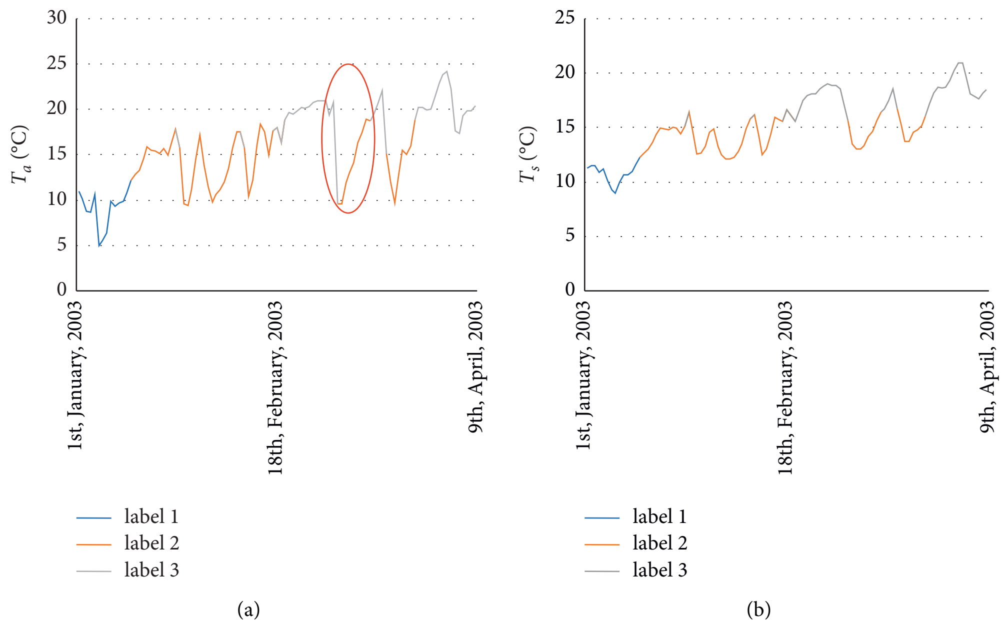

FIGURE 1: Variations of the daily air temperature (a) and soil temperature (b) at Laegern station (located in Switzerland) during 1st, January 2003–9th April 2003 (100 days).

values. The T_s data which are in the same range are made the same label (the T_s data which are in the range of 8–12°C are labeled as "1", the T_s data which are in the range of 12–16°C are labeled as "2", and the T_s data which are in the range of 16–22°C are labeled as "3"). Meanwhile, Ta data are labeled as the same as T_s data. In Figure 1(a), we noticed that the T_s data with the same label are almost within a stable range. However, in the red ellipse, Figure 1(b), we observed that similar Ta values may have different labels (T_s data with similar Ta values may vary considerably). The data with this feature will prevent predictive models from accurately exploring the internal relationship between T_s and the surrounding environmental factors discovering. To address this problem, the idea of triplet loss [33] is considered in this paper. Triplet loss optimization allows the anchor and positive points to accumulate and therefore prevent the negative points and realize the similarity calculation of samples. This approach can enrich processing information of loss function and overcome the disadvantage of the traditional squared-error loss function and further improve the estimation performance.

The main three contributions of this research paper are summarized as follows:

(1) As we know, the proposed method that combined traditional squared-error loss function with distance metric learning between the sample features is a new approach to be used for T_s estimation.

(2) Daily-scale prediction scheme was designed to provide the multifarious decision-making basis and was used to estimate the T_s on the next 1st, 5th, and 15th day. To achieve this end, we input the meteorological and past T_s data to the estimation model.

(3) Results showed that our QL-LSTM method outperformed the existing advanced methods in most cases.

2. Data and Methods

2.1. The Framework of Soil Temperature Estimation. The corresponding meteorological data T_s as the input of our QL-LSTM model are obtained from FLUXNET at first. In the meantime, several other advanced models based on data-driven technology (SVR, BPNN, ELM, and LSTM) were considered in T_s estimation. Traditional squared-error loss function and distance metric learning between the sample features were integrated into our model for accurate exploration of the internal relationship between T_s and the surrounding environmental factors. Finally, the comparison of model performance is reflected by five evaluating indicators (RMSE, MAE, NS, WI, and LMI). Figure 2 denoted the flow chart of soil temperature estimation.

2.2. Long Short-Term Memory (LSTM) Network. LSTM can process and learn long-term dependence problems. Due to the characteristics of the LSTM network, we use it to explore the internal relationship between T_s and the surrounding predictors. LSTM controls the transmission state through the gating state, remembers what needs to be remembered, and forgets unimportant information. Figure 3 shows the internal structure of an LSTM cell, and the calculation formula of the LSTM is as follows:

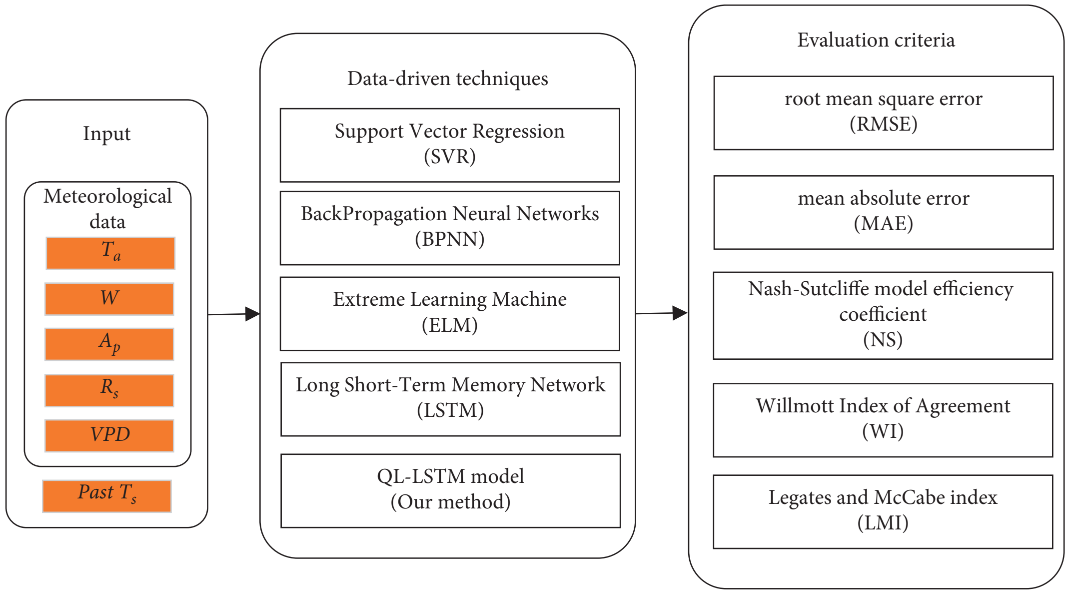

Figure 2: The flow chart of soil temperature estimation.

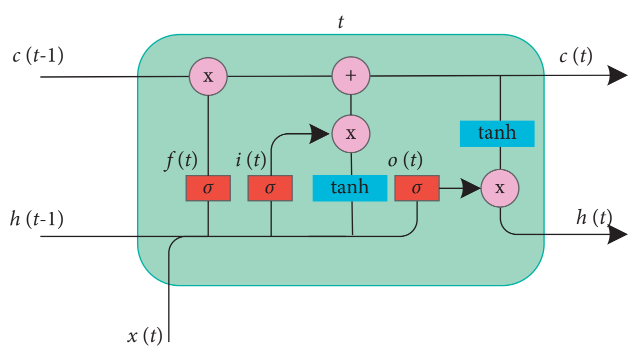

Figure 3: The internal structure of an LSTM cell.

$$
\begin{aligned}
i(t) &= \sigma\left(W_{ih}h(t-1) + W_{ix}x(t) + W_{ix}c(t-1) + b_i\right),\\
f(t) &= \sigma\left(W_{fh}h(t-1) + W_{fx}x(t) + W_{fx}c(t-1) + b_f\right),\\
c(t) &= f(t)\otimes c(t-1) + i(t)\otimes \tanh\left(W_{ch}h(t-1) + W_{cx}x(t) + b_c\right),\\
o(t) &= \sigma\left(W_{oh}h(t-1) + W_{ox}x(t) + W_{oc}c(t) + b_o\right),\\
h(t) &= o(t)\otimes \tanh(c(t)),\\
\hat{y}(t) &= W_{yh}h(t) + b_o,
\end{aligned}
\tag{1}
$$

where $x(t)$ is the input data, and $\hat{y}(t)$ is the output data; $i(t)$, $f(t)$, and $o(t)$ denote the input gate, forget gate, and output gate; $c(t)$ represents the unit status at the current moment; $h(t)$ is the current output value; $\sigma(\cdot)$ and $\tanh(\cdot)$ are the activation functions; W and b denote the weight matrix and bias term.

2.3. Triplet Loss. Triplet loss is a significant "learning criterion" for optimizing the predictive models, which is applied for adjusting the weight parameters of predictive models, including anchor (Anchor) example, positive (Positive) example, and negative (Negative) example. The similarity calculation of the samples is realized through triplet loss learning, which makes the anchor-to-positive distance smaller than the anchor-to-negative distance. And Figure 4 denoted the visual representation of triplet loss.

Equation (2) expresses the objective function of triplet loss as follows:

$$
\sum_{i}^{N}\left[\left\|f\left(x_i^a\right) - f\left(x_i^p\right)\right\|_2^2 - \left\|f\left(x_i^a\right) - f\left(x_i^n\right)\right\|_2^2 + \alpha\right]_+, \tag{2}
$$

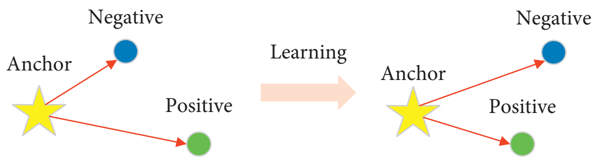

Figure 4: A visual representation of triplet loss.

where $f(x_i^a)$, $f(x_i^p)$, and $f(x_i^n)$ are the corresponding feature expression obtained by training a parameter in the triplet; α represents the minimum interval between the anchor-to-positive distance and the anchor-to-negative distance; the value of $[\cdot]_+$ defines the degree of loss.

2.4. QL-LSTM Model. Previous analysis shows that LSTM with traditional squared-error loss function could not accurately discover the special relationship between T_s and surrounding predictors. To address this problem, inspired by the study of triplet loss, we combined a predictive model with distance metric learning between the sample features. As far as we know, the method based on distance metric learning between the sample features has not been used to estimate T_s ever. It must be noted that the distance metric learning between the sample features is first proposed in the field of image processing. However, there is no description of the similarity of samples for T_s estimation. In this paper, the clustering method is used to label samples; thus, distance metric learning between the sample features could be further applied in T_s estimation.

The framework of our QL-LSTM is shown in Figure 5. Firstly, for its ability to cluster data efficiently and scalability, the T_s data were quantized by the clustering method (called Birch) [34]. In the quantization step, any T_s data quantized to the same label will be defined as similar samples (positive). In contrast, any T_s data quantized to different labels will be defined as the dissimilar samples (negative). It is worthwhile to observe that the number of labels should be neither too large nor too small [35]. Hence, the Calinski Harabasz Score (*CH*) and Y_Silhouette_score (*S*) are used to evaluate the quality of the cluster [36]. The larger value of CH or *S*, the better quality of the clustering results. Second, the labeled data are input into the predictive model (LSTM network). Finally, the weights of the predictive model are updated to reduce the loss based on our quadruplet loss function.

We set $X = \{(x_i, l_i)\}_{i=1}^{N}$ as the input data, where l_i represents T_s labeled as "i" and x_i represents the labeled environmental factors. Assume C is the total number of labels, where $l_i \in [1, 2, 3 \ldots, C]$. Then, we project an instance x_i onto the estimate T_s by $f_{\text{LSTM}}(.;\theta)$: $R^d \longrightarrow S^1$, where f_{LSTM} is an LSTM network parameterized by θ. Let $\{X_i^c\}_{i=1}^{N_c}$ be the environmental factors in the i -th labeled samples. N_c represents the total number of samples. We evaluate the similarity between samples through cluster analysis and expect the output of the model closer to the true value.

2.4.1. Hard Sample Mining. Hard sample mining generally refers to hard negative mining. Adding negative sample sets to participate in model training can improve the effectiveness of learning and training and mine hard negatives as much as possible [37, 38]. For each fixed picture, the farthest sample picture and the nearest negative sample picture in a training batch are applied to train the network to enhance the generalization ability of the network, so that the network can learn better representations.

Inspired by TriHard loss, we first define x_i^c as the test sample: $P_{c,i}\,(P_{c,i} = \{x_j^c | j \neq i\}, |P_{c,i}| = N_c - 1)$ is a collection, which includes the samples with the same label; $N_{c,i}\,(N_{c,i} = \{x_j^k | k \neq c\}, |N_{c,i}| = \sum_{k \neq c} N_k)$ represents the other samples' collection. $(x_i^c, y_i^c, P_{c,i}^*, N_{c,i}^*)$ is the quadruplet data set we defined. $P_{c,i}^*$ is the positive set; $N_{c,i}^*$ represents the negative set, $|P_{c,i}^*|$ and $|N_{c,i}^*|$ represent positive and negative sample pairs, and these tuples form the training sample pairs. The query sample is represented as x_i^c; when S_{ij}^+ satisfies the formula (3), $\{x_i, x_j\}$ is the pair that we need.

$$S_{ij}^+ > \min_{x_k \in P_{c,i}} S_{ik} + \mu, \tag{3}$$

where $S_{ij}^+ \langle f_{\text{LSTM}}(x_i;\theta), f_{\text{LSTM}}(x_j;\theta)\rangle$ represents the similarity between two samples, where $\langle \cdot, \cdot \rangle$ represents the calculation of an $n \times n$ similarity matrix. S_{ij} is the element in S at (x_i, x_j), and μ as a hyperparameter impacts the quadruplet that can control the number of hard positive samples. The condition for selecting a hard and negative pair is the same as above:

$$S_{ij}^- < \max_{x_k \in N_{c,i}} S_{ik} - \mu. \tag{4}$$

2.4.2. Optimization Objective. For each test sample x_i^c, we use the margin m to make it as close to the positive set $P_{c,i}$ as possible, and as far away from the negative set $N_{c,i}$ as possible. All the nontrivial positive points in $P_{c,i}$ are pulled together by minimizing:

$$L_P(x_i^c; f_{\text{LSTM}}) = \frac{1}{2} \sum_{x_i^c \in P_{c,i}^*} \left(\left[\left\| f_{\text{LSTM}}(x_i^c) - f_{\text{LSTM}}(x_j^c) \right\| - (r - m) \right]_+ \right)^2, \tag{5}$$

where $f_{LSTM}(x_i^c)$ and $f_{LSTM}(x_j^c)$ denote the estimated T_s of samples x_i^c and x_j^c, respectively, and $\| f_{LSTM}(x_i^c) - f_{LSTM}(x_j^c) \|$ is the Euclidean distance between $f_{LSTM}(x_i^c)$ and $f_{LSTM}(x_j^c)$. Similarly, all nontrivial negative points in $N_{c,i}$ need to push out of the boundary τ, by minimizing:

$$L_N(x_i^c; f_{\text{LSTM}}) = \frac{1}{2} \sum_{x_j^k \in N_{c,i}^*} \left(\left[\tau - \left\| f_{\text{LSTM}}(x_i^c) - f_{\text{LSTM}}(x_j^k) \right\| \right]_+ \right)^2. \tag{6}$$

Meanwhile, we applied the squared-error loss function to the LSTM model for T_s estimation, as follows:

$$L_{MSE}(x_i^c; f_{\text{LSTM}}) = \frac{1}{2} \sum_{x_i^c \in N_c} \left(f_{\text{LSTM}}(x_i^c) - y_i^c \right)^2. \tag{7}$$

In the QL-LSTM, three minimization objectives were put into the model, and they are optimized at the same time:

$$\begin{aligned} L_{\text{QL-LSTM}}(x_i^c; f_{\text{LSTM}}) = {} & L_P(x_i^c; f_{\text{LSTM}}) + L_N(x_i^c; f_{\text{LSTM}}) \\ & + L_{\text{MSE}}(x_i^c; f_{\text{LSTM}}), \end{aligned} \tag{8}$$

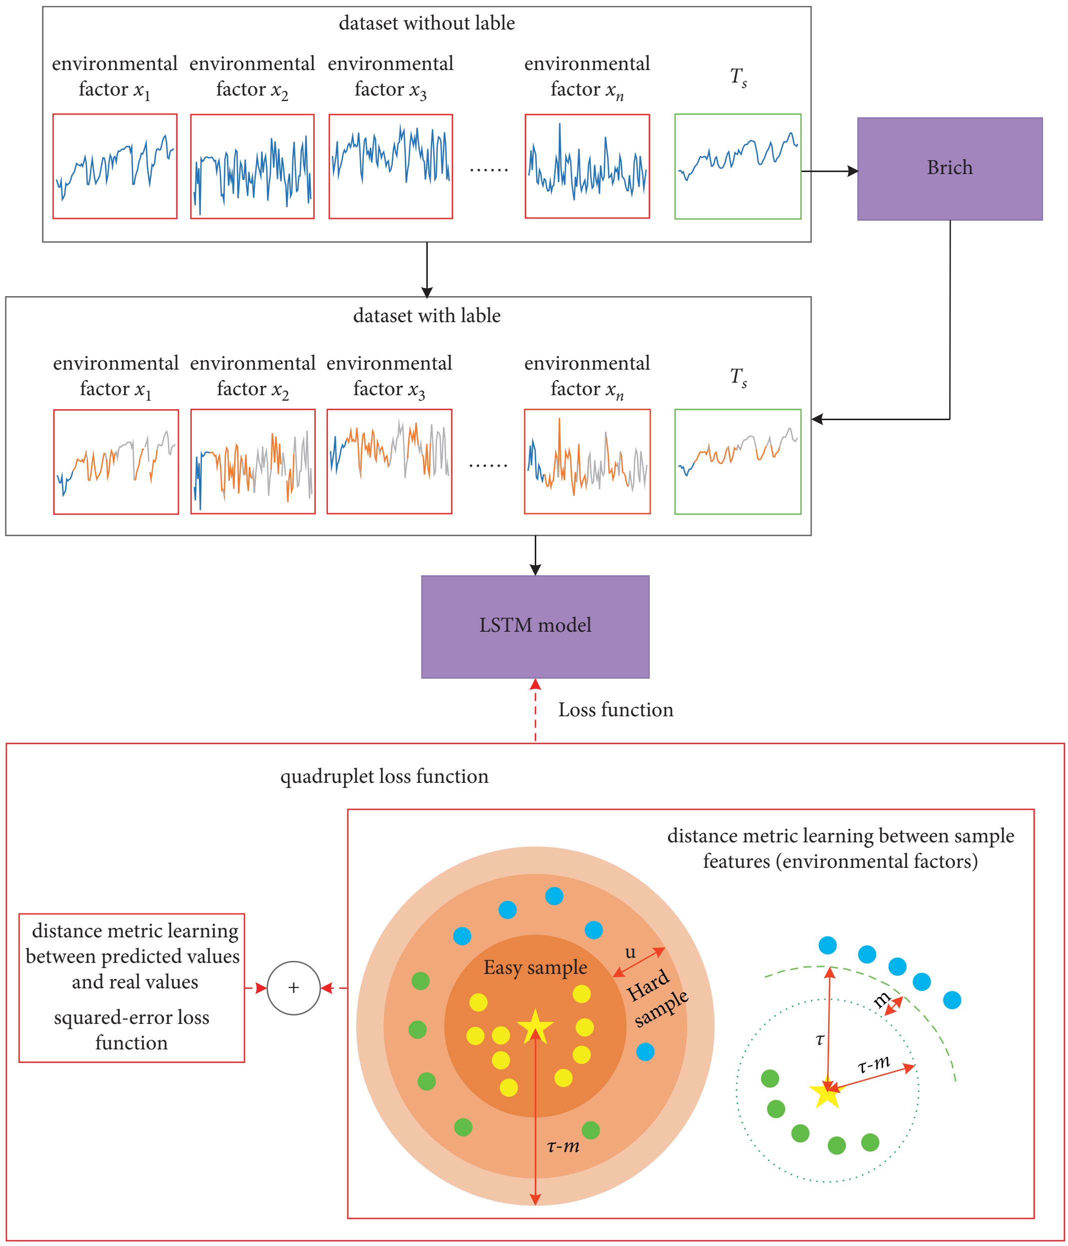

Figure 5: The framework of QL-LSTM.

We incorporate stochastic gradient descent and minibatch into the QL-LSTM to optimize the estimation model.

x_i^c is a sample of the minibatch, which is obtained by sampling the labels of the training samples randomly, and serves as an anchor. We represent the QL-LSTM of each minibatch as

$$L_{QL-LSTM}(X; f) = \frac{1}{N} \sum_{\forall_c \forall_i} L_{QL-LSTM}(x_i^c; f), \qquad (9)$$

where N denotes the batch size. Figure 6 represented the learning procedure of our QL-LSTM model.

2.5. Model Training and Testing. The input of our model is the corresponding meteorological data (T_a, W, A_p, R_s, VPD, and T_s) from Laegern and Fluehli stations in Switzerland. And we downloaded the data at https://fluxnet.fluxdata.org/ on FLUXNET with a total of 3,287 patterns from 2006 to 2014. Training datasets had 2465 patterns, and the rest as testing datasets.

Comparing our QL-LSTM model with the other advanced methods (SVR, BPNN, ELM, and LSTM), meanwhile, we calculate several evaluation criteria to analyze the model performance, including model fitting degree and the accuracy of the estimation model, as follows:

$$\mathrm{RMSE} = \sqrt{\frac{\sum_{n=1}^{N} \left(y_i - \hat{y}_i\right)^2}{N}},$$

$$\mathrm{WI} = 1 - \frac{\sum_{n=1}^{N} \left(y_i - \hat{y}_i\right)^2}{\sum_{n=1}^{N} \left(\left|\hat{y}_i - \overline{y}\right| + \left|y_i - \overline{y}\right|\right)^2},$$

$$\mathrm{NS} = 1 - \frac{\sum_{n=1}^{N} \left(y_i - \hat{y}_i\right)^2}{\sum_{n=1}^{N} \left(y_i - \overline{y}\right)^2}, \tag{10}$$

$$\mathrm{MAE} = \frac{\sum_{n=1}^{N}\left|y_i - \hat{y}_i\right|}{N},$$

$$\mathrm{LMI} = 1 - \frac{\sum_{n=1}^{N}\left|y_i - \hat{y}_i\right|}{\sum_{n=1}^{N}\left|y_i - \overline{y}\right|},$$

where N is the number of the whole data, y_i denotes the observed value, $\hat{y}_i$ is the predicted value, and $\overline{y}$ is the average of the true values.

2.6. Experiments. The data within half an hour is obtained from two meteorological stations in an ecological nature reserve, located in Switzerland, namely, Legern and Fluley. The corresponding meteorological data (T_a, W, A_p, R_s, VPD, and T_s) and past T_s data were input into the models. Meanwhile, the input variables are normalized to eliminate the dimensional influence between indicators. And the formula is as follows:

$$x_{\mathrm{norm}} = \frac{x - x_{\min}}{x_{\max} - x_{\min}}, \tag{11}$$

where the minimum value of the sample data is represented by $x_{\min}$, and the maximum value is represented by $x_{\max}$. Moreover, we have conducted research on the influence of the surrounding environmental factors on the model prediction. And we found the value of R_s in the data of the two stations is low, which is close to the normal distribution.

We conducted a statistical analysis of the data from the two stations. Table 1 listed the details of variables (minimum value ($x_{\min}$), maximum value ($x_{\max}$), average value (x_{mean}), standard deviation (z_{sd}), skewness (z_s), and variation coefficient (z_v)). We used the daily data to verify the performance of the model with every half an hour data. The results showed in Table 1 that A_p had the highest negative skewness and presents a normal distribution at 5 cm depth, which presented similar characteristics in both stations. Meanwhile, z_v showed the biggest difference between the two stations. T_s at the 5 cm, 10 cm, and 15 cm depths range −1.888–26.876°C, −0.181–22.193°C, and 0.16–20.826°C, respectively. In summary, results showed that the values of z_{sd}, z_s, and z_v change very slightly.

3. Results and Discussion

For testing the superiority of our QL-LSTM model performance for T_s estimation using scikit-learn, we compared our test results with those of other advanced models (SVR, BPNN, ELM, and LSTM).

We choose default parameters for the SVR model. For the BPNN model, the square error is used as the loss function, and the optimization is Adam. The number of samples selected for the model is 400, the iteration is set to 500, the learning rate is set to 5.0e-4, and the size of the nodes is set to 128. The elm function was used to model the ELM model, the sigmoid served to activate the function in the hidden layer, and we set the same size of the nodes to BPNN. Furthermore, we set the hyperparameters of the LSTM to be the same as that of QL-LSTM. As can be seen from Table 2 and 3, the different values of the hyperparameter can generate the different predictive results. When the number of samples selected for the model is set to 400, the iteration to 500, the $\mathrm{num}_{\mathrm{QL-LSTM}}$ to 128, and set the learning rate to 1.0e-3, the QL-LSTM model has the best performance.

3.1. Evaluation for the Hyperparameters in Quadruplet Loss Function. The quadruplet loss function has five main hyperparameters, which are the total number of labels C, hyperparameter μ in equations (3) and (4), and τ and m in equations (5) and (6). When we evaluate the above hyperparameters in the quadruplet loss function, we set the parameters $\mathrm{num}_{QL-\mathrm{LSTM}}$ to 128, the learning rate to 1.0e-3, the iteration time to 500, and the batch size to 400. We first select the best C based on the Calinski Harabasz Score and Y_Silhouette_score. Figure 7 denotes the Calinski Harabasz Score and Y_Silhouette_score with different numbers of labels. It is observed that both scores achieve the best result when C is 25. Then, we gradually tune the hyperparameters, τ and m. Figure 8 represented the results of the estimation model with different μ, τ, and m in Laegern meteorological station. We can see that when we set μ to be 5.0e-3, τ to be 1.0e-3, and m to be 5.0e-5, and our QL-LSTM model could achieve the best estimation performance (RMSE = 0.789, MAE = 0.605, NS = 0.977, WI = 0.994, and LMI = 0.865). It is probably because the smaller hyperparameters we set, the less hard samples would be computed. Meanwhile, when we set the larger hyperparameters, the more redundant samples would be computed.

3.2. The Impact of Different Inputs on the Performance of the Predictive Model. In this part, we analyzed the environmental factors that may affect our QL-LSTM model for T_s estimation. Considering that the interaction between different environmental factors would have an impact on the T_s estimation, we combine the meteorological variables accordingly and input them into the submodels we set as follows:

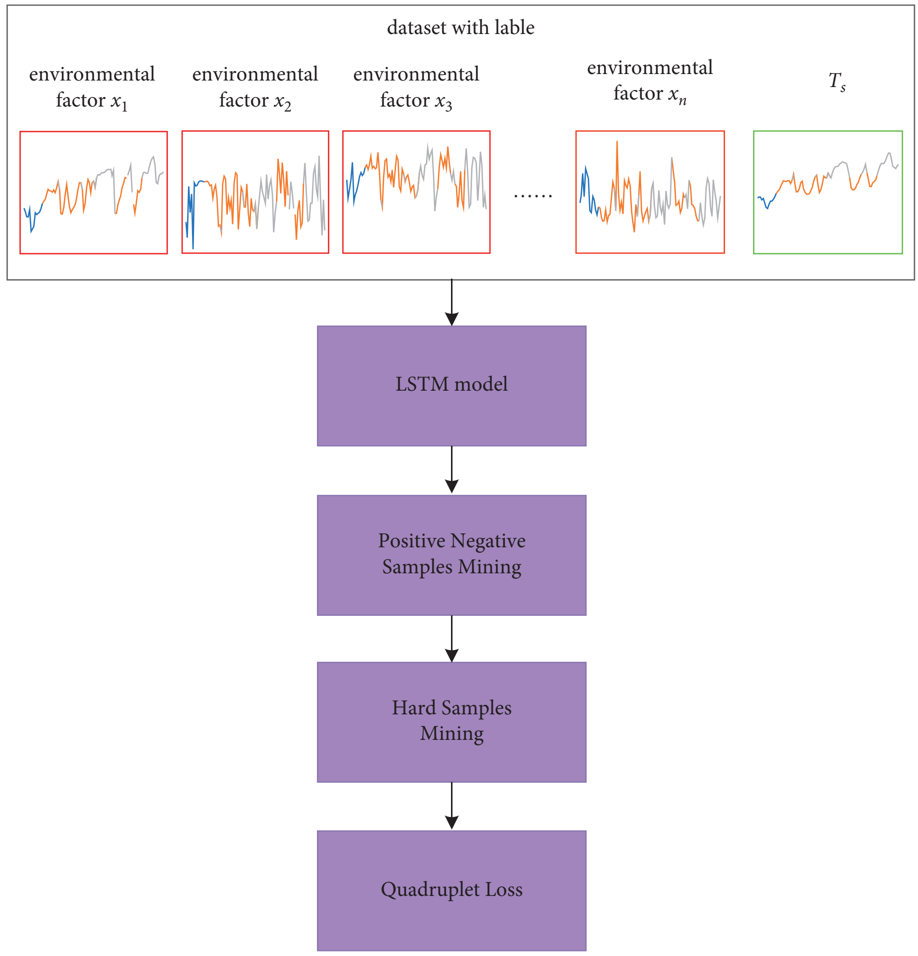

Figure 6: The learning procedure of QL-LSTM.

Table 1: Statistical results of the applied data for Laegern and Fluehli stations.

Station	Variable	$x_{\min}$	$x_{\max}$	x_{mean}	$z_{s\,d}$	z_s	z_v

(iii) Input I_8: T_s (d − 1) + T_s (d − 2) + T_s (d − 3)

(iv) Input I_9: T_s (d − 1) + T_s (d − 2) +T_s (d − 3) + T_s (d − 4)

(v) Input I_{10}: T_s (d − 1) + T_s (d − 2) +T_s (d − 3) + T_s (d − 4) + T_s (d − 5)

(vi) Output: T_s (d)

We input what we specified above into QL-LSTM to predict the T_s (d) at the 5 cm depth of the Laegern station. For our model, we first selected the hyperparameters μ as 5.0e-3, τ as 1.0e-3, m as 5.0e-5, C as 25, num$_{\text{QL-LSTM}}$ as 128, learning rate as 1.0e-3, iteration time as 500, and batch size as 400, and the results are presented in Table 4. Obviously, the methods of QL-LSTM(I_3) and QL-LSTM(I_8) are better than the others, respectively. Meanwhile, we could conclude that W (d − 1), A_p (d − 1), T_s (d − 4), and T_s (d − 5) all have an influence on the performance of the predictive model. In addition, by comparing the estimation results between meteorological variables input and past T_s input, we found that our model with past T_s could achieve greater accuracy in modeling than the one with meteorological variables. The reason may be that the predictive model with past T_s input has stronger memory for T_s variables. The estimation of the future T_s should make the best use of its continuity; in this way, we can make a reliable T_s estimation, which not only continues its historical tendency but also conforms to its actual performance. Hence, we construct the predictive model (QL-LSTM(I_{11})) by combining the environmental factors (T_a (d − 1), R_s(d − 1), VPD(d − 1)) with past T_s (T_s (d − 1), T_s (d − 2), T_s (d − 3)), which is also considered in estimating the T_s (d) at the 5 cm depth of the Laegern station. Experiment results prove that it could achieve the best estimation performance (RMSE = 0.789, LMI = 0.865, WI = 0.994, NS = 0.977, and MAE = 0.605). Hence, the final input for the predictive models is the environmental factors (T_a(d − 1), R_s(d − 1), VPD(d − 1)) and the past T_s (T_s (d − 1), T_s (d − 2), T_s (d − 3)).

The three methods (QL-LSTM(I_3), QL-LSTM(I_8), and QL-LSTM(I_{11})) are used to test the data of the Laegern station. Figure 9 shows the linear relationship between the predicted value and the observed value. The QL-LSTM(I_{11}) model gets the best predictive performance with $y = 0.9899x + 0.3022$ and the higher R^2 (0.9792) compared with the others. In the frequency diagram (Figure 10) of the models (QL-LSTM(I_3), QL-LSTM(I_8), and QL-LSTM(I_{11})), the QL-LSTM(I_{11}) also has a higher frequency (91%) compared to the others. Therefore, we can draw a conclusion that the predictive model (a combination of the environmental factors and the past T_s) normally outperformed the other two (by either past measurements of T_s or other meteorological information) in the T_s estimation.

3.3. Comparison with Different Models. In this part, our QL-LSTM model was compared with several advanced models, including SVR, BPNN, ELM, and LSTM. The data of T_a, R_s, and VPD on day "d − 1", and T_s data on different days were acted as input data to different predictive models, and the output was the predicted value of T_s on days "d", "d + 5", and "d + 15". Time steps were in days.

The testing results of five different models at 5, 10, and 15 cm depth on the 1st, 5th, and 15th days of the Laegern station were shown in Table 5. And we can see that our QL-LSTM model performs better than the existing advanced models at the 5 cm depth on the 1st day. Specifically, the value of RMSE is 0.789, which is reduced relative to 13% (LSTM), 22% (ELM), 28% (BPNN), and 22% (SVR), respectively. The MAE values amount to 0.605 (QL-LSTM), and the others are 0.813 (SVR), 0.872 (BPNN), 0.824 (ELM), and 0.821 (LSTM). Meanwhile, the QL-LSTM model achieved a higher value of NS, WI, and LMI. Hence, it is obvious that our model had the best performance in this case. For the results of 5 cm depth on the 15th day, the LSTM achieved a higher WI (0.892) than estimation from other models on the 15th day, but it is similar to the WI (0.891) of our model. For 10 and 15 cm depth results on the 1st, 5$^{\text{th}}$, and 15th days, the performance of our QL-LSTM model remains stable, although our QL-LSTM model has the lower values of WI (0.952 and 0.933) than the values of WI (0.954 and 0.934) on the LSTM model in individual cases. It can be found that the predictive performance will get better as the soil depth decreases (from 5 cm to 15 cm), but it will decrease as time goes on (from 1st to 15th days). The systematic errors caused this phenomenon for long-term estimation [39].

The same strategy was applied in the Fluehli station to further verify the performance of the models, with the results shown in Table 6. And our QL-LSTM model performs better compared with others. However, for 5 cm depth on the 15th day and 15 cm depth on the 5th day, the BPNN model performs better with the results of RMSE = 2.081, LMI = 0.584, WI = 0.937, NS = 0.769, and MAE = 2.099, and RMSE = 1.832, LMI = 0.726, WI = 0.973, NS = 0.897, and MAE = 1.352 and LMI = 0.726. Our method does not

perform well in some cases probably because the weights of the LSTM model are randomly selected to generate the nonoptimal solution. Meanwhile, our novel loss function (quadruplet loss) is applied based on the LSTM model; it only improved estimation performance to a certain extent against the LSTM model. All in all, the results of our testing on the data of different regions show that the performance of our QL-LSTM model is usually better for T_s prediction with different depths and days.

4. Conclusions

Soil temperature (T_s) is a main physical variable of the land surface, which has an impact on many aspects, such as the growth and yield of crops. Therefore, how to predict T_s accurately is very important. This paper proposed the QL-LSTM model and compared it with the state-of-the-art predictive models to use the meteorological data and past T_s of the Laegern and Fluehli stations (Switzerland) for daily T_s estimation at 5, 10, and 15 cm depth on the 1st, 5th, and 15th days. The experiment results showed that the QL-LSTM model performed better than the existing advanced models for T_s estimation in multifarious cases.

In addition, to enrich processing information in loss function and further improve estimation performance, we attempt to design the novel quadruplet loss function that combines the traditional squared-error loss function with distance metric learning between the sample features. Similar samples can be zoomed and the dissimilar samples can be pushed.

The distance metric learning between the sample features is combined with the squared-error loss function, which could improve the estimation performance to a certain extent. However, the many hyperparameters in our method may cause sensitivity issues in estimation, which may lead to poor generalization ability of other estimations. In the future, the parametric adaptive method will be explored for a new loss function in the follow-up study.

Retracted: Sports Video Athlete Detection Based on Associative Memory Neural Network

Computational Intelligence and Neuroscience

Received 26 September 2023; Accepted 26 September 2023; Published 27 September 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Aiming at the detection of athletes in sports videos, an automatic detection method based on AMNN is proposed. The background image from the image sequence is obtained, the moving area is extracted, and the color information of pixels to extract the green stadium from the background image is used. In order to improve the accuracy of athletes' detection, the texture similarity measurement method is used to eliminate the shadow in the movement area, the morphological method is used to eliminate the cracks in the area, and the noise outside the stadium is removed according to the stadium information. Combined with the images of nonathletes, a training set is constructed to train the NN classifier. For the input image frames, image pyramids of different scales are constructed by subsampling and the positions of several candidate athletes are detected by NN. The center of gravity of candidate athletes is calculated, a representative candidate athlete is obtained, and then, the final athlete position through a local search process is determined. Experiments show that the system can accurately detect the motion shape of moving targets, can process images in real time, and has good real-time performance.

1. Introduction

Detecting and tracking athletes in sports videos can provide important information for high-level sports video processing, such as motion analysis, event detection, and 3D reconstruction [1, 2]. Attaching various sensors to athletes and then acquiring data through sensors are the traditional method of detecting and tracking athletes. These methods, on the other hand, place additional constraints on athletes and have a negative impact on their normal performance [3]. As a contactless method, the video-based athlete detection and tracking method developed in recent years have been widely studied and applied [4].

It is of great significance to detect and track athletes in sports videos, which is conducive to various higher-level processing of videos, such as adding automatic explanation function to videos, quick retrieval of important events in videos, and tactical analysis of videos [5, 6]. Moving target detection and tracking mainly involve the knowledge of image processing, pattern recognition, computer vision, artificial intelligence, and other disciplines, in many fields. For example, human-computer interaction, video surveillance, traffic management, and content-based video retrieval have wide application prospects and potential economic value [7]. Therefore, researchers have been inspired to do a lot of research on it, and many different methods have been put forward. Another important direction in sports video analysis is the detection of exciting events. Segmentation and tracking of sports videos can assist the detection of exciting events, as well as semantic and strategic analysis. We can judge the detection of some specific events through target detection and tracking analysis. In this paper, the neural network (NN) technology [8, 9] with associative memory (AM) function is studied. And, a sports video athlete detection model has been put forward based on associative memory neural network (AMNN).

Digital video technology has been developed and popularized in tandem with scientific and technological advancements. It is now possible to obtain various types of videos through various channels, thanks to increased network transmission bandwidth and lower costs of various hardware devices [10]. Computers can now execute various complex algorithms, thanks to increasing storage capacity and computing power [11]. These technological and equipment advancements lay the groundwork for future image processing and video analysis systems research and development. The focus of these people's attention to sports video also focuses on sports targets, balls, or players. Detecting athletes' areas in sports videos is the premise of tracking athletes [12]. The application based on AMNN can extract athletes' trajectory and other information from the game video, which can help coaches analyze players' behaviors and study opponents' strategies and weaknesses. Based on the analysis of the current main moving target detection and tracking algorithms, this paper focuses on the methods of detecting and tracking athletes in sports videos and improves the traditional moving target detection and tracking algorithms. Aiming at the characteristic that AMNN is easy to fall into local minimum, particle swarm optimization is introduced to optimize the network weights, and a network with high convergence performance is obtained. A prototype system is developed to verify the effectiveness of the algorithm.

2. Related Work

The athlete detection algorithm based on middle-level feature blocks and the athlete segmentation algorithm based on superpixel classification are realized in the literature [13, 14] based on a detailed analysis and summary of the characteristics of sports videos and related rules. The literature [15] proposed a method for detecting the stadium area by obtaining the stadium's adaptive color. A method to automatically extract the venue color in sports videos was proposed in the literature [16, 17]. It uses a Gaussian mixture model to calculate the parameters with an algorithm, which is different from previous studies, and the experiment is similar to the previous one. The Kalman filter models each pixel and tracks its change in the literature [18, 19]. This method can handle scene lighting changes, but it becomes invalid when new objects are added to the scene or the original objects are removed. For the detection of multiscale athletes in sports videos, literature [20] proposes an automatic detection method based on CNN. The literature [21] describes the function realization and concept of AM in detail, as well as the drawbacks of having to use a binary input signal in practice. By combining the advantages of strong nonlinear processing of BP networks with the advantages of fitting the network structure reasonably, the network structure can be widely used in practice. The dynamic method based on prediction is used to model the dynamic scene in literature [22, 23]. This method can deal better with light changes and subtle movements in the scene, such as water waves and branches swinging, but it requires a large number of images without moving objects to train the model. A key pose extraction system for weightlifting video was designed by literature [24]. A display module and a key frame extraction module are included in the system. The key frame extraction module includes feature extraction and key frame extraction of weightlifting video frames, while the display module includes video playback and key frame display. Literature [25] uses the Gaussian mixture model to model every pixel in the scene and updates the model in real time by the online approximation method, which can reliably deal with the situation of illumination change and disturbance of chaotic motion in the scene. At present, the commonly used tracking methods include model-based tracking, region-based tracking, and feature-based tracking. Literature [26] studied discrete Hopfield NN and discussed the structure and the theory of convergence stability in detail. The continuous adaptive mean shift algorithm proposed in literature [27] uses the color features of objects to track irregularly moving nonrigid objects in video frame sequence quickly and robustly. Literature [28] uses the combination of adaptive Gaussian mixture model and CamShift algorithm to detect and track players in badminton video. In this paper, a method of moving object detection in sports video based on the AMNN model is proposed. The experiment shows that the system can accurately detect the motion shape of moving targets, process images in real time, and has good real-time performance.

3. Methodology

3.1. AMNN. Artificial neural network (ANN) is an information processing system that simulates the structure and function of a simplified biological NN and abstractly utilizes some basic characteristic theories. This network receives external information through vision [29], smell, and taste, processes it in the brain, and then outputs signals through the executive organs, thereby forming a system with the characteristics of a closed-loop control system.

Humans can study ANN in the same way they can study the various functions of the human brain. Distributed storage and fault tolerance, large-scale parallel processing capabilities, self-learning, self-organization and adaptability, and the ability to handle complex systems are all features of ANN [30]. AM is a key component of NN theory, as well as a key function of NN in intelligent control, pattern recognition, and artificial intelligence. It primarily makes use of NN's high fault tolerance, which allows it to reconstruct incomplete, defaced, and distorted input samples into a complete prototype suitable for identification, classification, and other purposes.

The Hopfield network, also referred to as the AM network, is a type of computer network. Hopfield network is a typical single-layer feedback NN, with rich dynamic behavior, simple structure, and higher computing power when compared to other networks. A discrete-time system is a discrete Hopfield neural network (DHNN). A weighted undirected graph can be used to show it. Every node has a threshold, and each side of the graph has a weight. The graph's order corresponds to the network's order. As a standard network for classification tasks, NN will typically add a fully connected layer and a classifier to the final layer. During the training process, a dropout operation is added to the fully connected layer to prevent overfitting, and the output value of the node is randomly set to 0 to prevent overfitting. Although this slows down training, it effectively prevents overtraining. The basic structure of the Hopfield network is shown in Figure 1.

The network weakens the false state by adding an additional attractor to improve the fault tolerance of the network. Because one of the fundamental problems of Hopfield is that in addition to the existence of attractors with memory samples, there are also "redundant" stable states, that is, the existence of pseudo-states. The existence of pseudo-states affects Hopfield's fault tolerance. If the pseudo-states can be reduced or even eliminated, the attraction domain of the state can improve the fault tolerance of Hopfield and increase the memory capacity. Because the neurons in the Hopfield network are connected to each other, this fully interconnected way makes the output of each neuron in the network feedback to the input of other neurons at the same level, so the network has no other external input. Under these circumstances, it can also enter a stable state.

The learning process of DHNN, like that of other NNs, is the formation of a network connection weight matrix. Hopfield is a constantly changing system. Once the network's connection weight matrix is learned and formed, as long as a specific pattern sample is input, the network will continue to evolve until the system reaches the state space's steady state. This steady state is the network's output state, or the input vector's associative memory output. After the network has been trained, it can be run with an initial input X to determine the network's initial output state. This state is fed back to the input terminal and used as the input signal for the network processing stage's next iteration. Because the network takes a certain amount of time to transmit and process information, the two input signals may differ before and after the new input gives birth to the next output. The network's operation process, or the repeated feedback process, is an example of such a cycle. If the network is stable, the change in the output state of the network will decrease as the network runs with multiple feedbacks until it no longer changes and reaches a steady state.

3.2. Detection and Tracking of Moving Objects in Sports Videos. The so-called moving target tracking is to detect each independently moving target or region of interest to users in each frame of images and locate these targets or regions in subsequent frames. In practical application, tracking the moving target is very important. By tracking the moving target, we can get its motion parameters, such as position, velocity, and acceleration, which not only helps to calculate the motion trajectory of the moving target but also provides a reliable data source for the motion analysis and scene analysis of the target in the scene. Sports videos have different characteristics of different lens types, which can provide prior knowledge for video content analysis. The video is divided into shot sequences by shot boundary detection, and the types of shots are detected; that is, the shots are divided into short shots, medium shots, and long shots. This series of processing before athlete detection and segmentation is called video preprocessing. The athlete detection process is shown in Figure 2.

There are three commonly used algorithms in motion detection research: interframe difference, background subtraction, and optical flow. The difference between the current frame and the previous frame image is calculated using the interframe difference method, which is suitable for a dynamically changing environment. However, it only extracts the part of the logo that moves in relation to the background; it is not a fully moving object. The optical flow method is used to detect the application logo's changing optical flow characteristics over time. Its advantage is that it can detect moving objects independently without prior knowledge of the scene, and it can be used while the camera is moving. The disadvantage is that the calculation is time-consuming and difficult. Real-time detection is difficult to achieve without the necessary hardware support. Background subtraction is the most common technique for separating moving objects from a scene, particularly when the scene is relatively stable. The background subtraction method's main idea is to compare the current image to the background image by using a reference image that represents the background. If there are differences in pixel features, pixel area features, or other features in the same position, these are motion areas, which may correspond to actual moving targets.

Before detecting and identifying the image, it is necessary to preprocess the image, try to eliminate the noise, improve the image quality, protect the trade information, reduce the calculation amount of subsequent processing, and improve the accuracy of processing. There are strong rules in shooting and editing techniques in sports videos, and the characteristics of different shots and the differences between different shots are obvious. In the telephoto lens, the competition field occupies the largest proportion, and the athletes are also concentrated on the competition field, so the competition field area is detected first, and after the athletes are detected, more accurate athletes can be obtained by using the uniform color of the sports field and removing the color of the sports field. In the middle shot, the field color still occupies a certain proportion in the image, and if the telephoto scene has been processed, the stored ground color is used to remove the nonathlete area of the image of the middle shot that belongs to the competition field part.

In order to achieve an accurate positioning effect, a local search process is performed on the area around the center of each candidate athlete in the image scale space. In the image scale space, a small search space focused on the position of the candidate athlete is defined, which corresponds to a small pyramid focused on the center of the candidate athlete. The pyramid covers a scale from 0.8 to 1.5 times the size of the candidate athlete. For each scale, the candidate athlete is marked with a 16×16 pixel grid around the center of the candidate athlete. Mutual information can measure the similarity between two things. If two things are more similar, the mutual information between them will be smaller; otherwise, it will be larger. For shots, the frame images inside a shot are very similar, but the frame images between different shots are quite different. Therefore, mutual information is considered to measure the similarity between two frames.

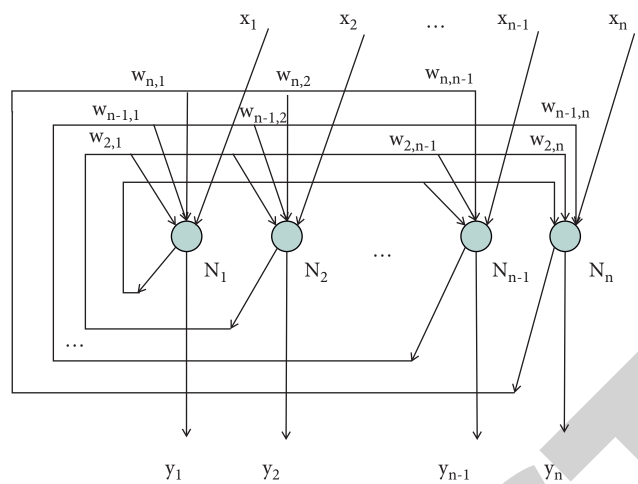

Figure 1: Basic structure of the Hopfield network.

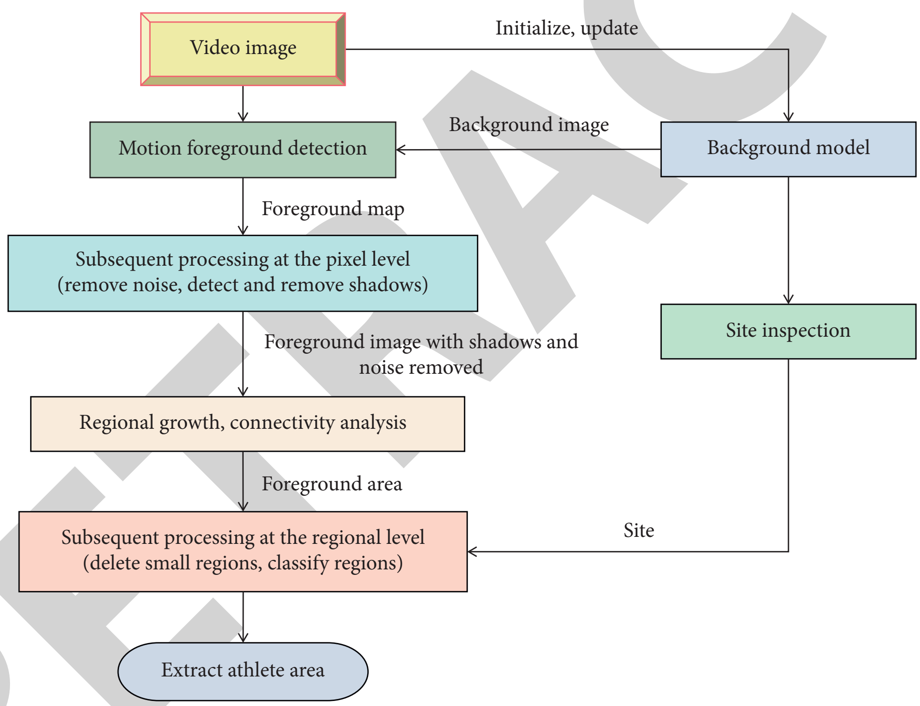

Figure 2: Athlete detection process.

3.3. Construction of the Detection Model Based on AMNN. The model-based tracking method models the shape characteristics of the target object and then tracks the model in the image sequence. The extraction of moving targets, that is, on the basis of existing images, extracts the required foreground targets through image segmentation.

Because an object is sometimes not a whole after image segmentation, it will be divided into several parts, or an object will be divided into several close independent areas. This paper makes a copy of the segmented image, expands it, and then assigns a number to it. If the areas after the expansion are connected to form a whole, they are identified as a whole, and the whole is marked as a region to be detected on the original image. The tracking accuracy of a model-based tracking method is dependent on the accuracy of the target object's geometric model. The main state transformations for a rigid moving target during movement are translation, rotation, and so on. When tracking a moving target, this method can produce better results.

Suppose a group composed of M particles flies at a certain speed in the n-dimensional search space, and the state attributes of particle i in the t-th iteration are set as follows:

Location:

$$\begin{aligned} X_i^t &= \left(x_{i1}^t, x_{i2}^t, \ldots, x_{in}^t\right), \\ x_{in}^t &\in \left[L_n, U_n\right]. \end{aligned} \tag{1}$$

L_n and U_n are the lower limit and upper limit of the search space, respectively.

Speed:

$$\begin{aligned} V_i^t &= \left(v_{i1}^t, v_{i2}^t, \ldots, v_{in}^t\right), \\ v_{in}^t &\in \left[v_{\min,n}, v_{\max,n}\right], \end{aligned} \tag{2}$$

where $v_{\min,n}$ and $v_{\max,n}$ are the minimum and maximum speeds, respectively.

Individual optimal position:

$$P_i^t = \left(p_{i1}^t, p_{i2}^t, \ldots, p_{in}^t\right). \tag{3}$$

Global optimal position:

$$P_g^t = \left(p_{g1}^t, p_{g2}^t, \ldots, p_{gn}^t\right). \tag{4}$$

Here, $1 \le i \le M$. With the above definition, the iterative formula of the algorithm can be described as follows:

$$\begin{aligned} v_{in}^{t+1} &= w v_{in}^t + c_1 r_1 \left(p_{in}^t - x_{in}^t\right) + c_2 r_2 \left(p_{gn}^t - x_{in}^t\right), \\ x_{in}^{t+1} &= x_{in}^t + v_{in}^{t+1}. \end{aligned} \tag{5}$$

Here, r_1, r_2 is a random number between (0, 1). c_1, c_2 is the acceleration factor. w is called the inertia weight, which determines how much the particle inherits to the current velocity. Appropriate value helps to balance search ability and development ability, and usually, a linear decrease method from 0.9 to 0.4 is used. The linear decreasing formula is

$$w = w_{\text{start}} - \frac{w_{\text{start}} - w_{\text{end}}}{t_{\max}} \times t, \tag{6}$$

where$t_{\max}$ is the maximum number of iterations; t is the current iteration number; w_{start} is the initial inertia weight; and w_{end} is the termination inertia weight.

Because the selection of threshold can't make all video frames have a better segmentation effect, when this paper intercepts the region of interest, more background information will be mistakenly regarded as foreground information. Mapping the detected pixel points of candidate athletes into the input image, the candidate athletes are grouped according to their distance in the image and scale space. Each group of candidate athletes is fused into a representative candidate athlete, whose center and size are the average of the center and size of each candidate athlete in this group. After the grouping algorithm is applied, a representative set of candidate athletes is obtained, which is used as the basis for accurately locating athletes and eliminating false positives in the next stage of the algorithm.

Occlusion between athletes and other objects is common in sports videos. In some videos, for example, athletes are blocked by the net, and there are various types of motion disturbances, as well as shadows. Because of the complexity of sports video, the detected motion foreground map frequently contains a lot of noise or has gaps in the motion area. To extract the athlete area more precisely in subsequent processing, the foreground image must be processed at the pixel level, removing noise, filling gaps, and eliminating shadows. Pixels are divided into boundary points and nonboundary points, with boundary points being classified as brighter or darker depending on the brightness of their surroundings. The gray level corresponding to the highest peak in the two histograms is used as the threshold, and the gray level corresponding to the highest peak in the two histograms is used as the histogram. This method is recursively applied to image system points whose gray levels are higher or lower than this threshold until a predetermined threshold number is obtained. In the iterative process, the centroid (x_c, y_c) of window w is as follows:

$$\begin{aligned} x_c &= \frac{\sum_{x\in w}\sum_{y\in w} xP(x, y)}{\sum_{x\in w}\sum_{y\in w} P(x, y)}, \\ y_c &= \frac{\sum_{x\in w}\sum_{y\in w} yP(x, y)}{\sum_{x\in w}\sum_{y\in w} P(x, y)}. \end{aligned} \tag{7}$$

Resize the window to

$$s = 2 \times \sqrt{\frac{\sum_{x\in w}\sum_{y\in w} P(x, y)}{256}}. \tag{8}$$

If only a fixed global threshold is used to segment the entire image when there are some situations in the image, such as shadows, uneven illumination, different contrasts in different places, sudden noise, and changes in background gray level, the segmentation effect will be affected because the situations in different parts of the image cannot be taken into account. To segment each part of the image separately, one option is to use a set of thresholds related to pixel positions. Athlete detection results based on middle-level feature blocks can provide polygonal areas of athletes in addition to rectangular box representation. To obtain more accurate segmentation results, the relationship between polygon domain representation and athlete contour is combined, using superpixels as the basic unit, marking the classification of superpixels according to the overlapping ratio of superpixels and polygon regions, and using the marking information and rectangular frames as interactive information.

4. Results Analysis and Discussion

In sports videos, athletes' movements are irregular, and their postures will change in various ways. The colors of athletes and scenes may be similar, and there is often mutual occlusion between athletes. In this paper, the obtained video is converted into a frame-by-frame video stream image as the system input. The system detects the input image, and if it is the first frame image, the image as the background is preprocessed and initialized the background model. Then, it is judged whether the input image is the second frame image, and if it is the second frame image, the image is preprocessed. The experimental results are shown in Figure 3.

Expansion is the process of merging the reasonable area in contact with the edge of an object into the object and expanding the boundary outward. If the number of expansions is too small, the lines forming the capture area are too thin to cover all possible ranges of soldiers, resulting in missing capture. If the expansion times are too large and the lines forming the capture area are too thick, the range of the capture area will be too large, which will increase the number of pixels searching for nonzero gray values and slow down the running speed of the algorithm. In further experiments, the detection speed of moving targets by different methods is compared, and the results shown in Figure 4 are obtained.

Noise and light sources often affect the sample points around the players, reducing their reliability. The farther away from the center of the athlete's area, the lower the pixel's reliability, and the greater the chance that the pixel is covered by other objects or belongs to the background. As a result, when calculating the histogram of the athlete area, it is reasonable to give different weights to pixels at different positions in the athlete area. The greater the weight corresponding to the pixel, the closer it is to the region's center, and vice versa. When the same video sequence is fast-forwarded at 4x speed under different quantization parameters, Figure 5 compares the number of transmission bits required by this method and the traditional method.

Even in the case of occlusion, the head of the human body still has obvious characteristics, so it is possible to divide multiple human bodies that are stuck or occluded into a single human body according to the characteristics of the head of the human body. Figure 6 is a comparison result of moving object segmentation results by different threshold processing methods.

There is a lot of foreground noise in the picture, which will have a great influence on the detection results. Because the moving target is blocky and has a moving rule, the foreground noise appears sporadically, and the position is random. In the following moving target tracking algorithm, the foreground noise can be removed according to these features to get the accurate moving target.

We can compare the textures of the corresponding areas in the foreground area and the background image and judge whether the foreground area is a shadow or a real moving target according to the similarity of the textures. The verification of the detection range is extracted from the position coordinates of the correct moving target in the detection result, as shown in Figure 7.

It can be seen that this method is superior to the other two methods in detecting athletes in sports video. The other two methods and this method are also used to detect athletes. The comparison results of interference handling capabilities of these three methods are shown in Figure 8.

As can be seen from the data in Figure 8, this method has the best interference handling ability. This method provides a better tracking effect while also achieving the desired result. To fully realize the detection of moving targets, a frame of the system's input image will first undergo image

scale transformation, filtering, and denoising through image preprocessing and then undergo the steps of image binarization, morphological processing, target edge detection, and so on. Finally, the blocks in the tracking area are merged based on adjacency and similarity, and a unified gray value is assigned, revealing the moving target's detected shape. Experiments show that the system can detect the motion shape of moving targets with high accuracy, process images in real time, and perform well in real time.

5. Conclusions

Motion detection and tracking are difficult fields of study. In this field, researchers have done a lot of work and have made some breakthroughs in theory and application. The key step in analyzing and processing sports videos is detecting and tracking athletes. This paper focuses on the methods of detecting and tracking athletes in sports videos, based on an analysis of the current commonly used methods of detecting and tracking moving targets. This paper proposes an AMNN-based method for moving object detection in sports video that takes full advantage of various technologies and processing means and outperforms previous inspection models. To address the issue of the model's learning rate being too slow in the early stages, the model's updating method has been improved, and the learning rate has been accelerated. The detection method used in this paper is more capable of dealing with slow changes in illumination in a dynamic background. Furthermore, different lens types in sports videos have distinct characteristics, and athletes who use the same lens type compete under the same set of rules. This paper summarizes these traits and rules and employs a middle-level feature block classifier to distinguish between different lens types and train different athletes to detect athletes in the video. Simulation experiments back up the method presented in this paper. The results show that the method presented in this paper has a wide detection range and strong interference processing ability. This scheme has a high rate of detection.

Data Availability

The data used to support the findings of this study are included within the article.

Choreography is an art form in and of itself. Because music and dance have always appeared at the same time throughout human history, music has had a significant influence on dance arrangement. It is important to arrange appropriate dance movements based on the music pieces chosen by users when creating choreography. This paper proposes a mixed density network-based music choreography algorithm in response to the current state of music choreography. The algorithm should be able to convert motion and music signals into a high-level semantic meaning that is compatible with human cognition, compare the degree of matching, and arrange the dance based on the music and motion segments that match. Furthermore, the consistency and authenticity of the movements in the dance created in this paper have been improved. Users' subjective feedback indicates that the choreography results in this paper are more closely aligned with the music. In the field of music choreography, it has some practical utility.

1. Introduction

Dance with music, as a form of artistic expression, enriches people's cultural lives and stimulates the public's creative enthusiasm [1]. It is the heart and soul of both music and dance. The most common variation is that the dance form changes as the music changes. The information of the music theme is conveyed through various forms of dance. Dance action matching technique in music choreography [2] is a type of dance work that is determined by the music style. People's matching effect of music and dance in modern music choreography requires strong synchronization between music changes and dance movements, as well as a deep understanding and strong grasp of music [3, 4]. In computer choreography, two major issues must be addressed. First, without using motion capture or manual production, how can you get real and unique dance moves? Second, how to improve the synchronization of music and dance by using appropriate music and motion features and matching algorithms.

As we all know, the element of music that appeals to individuals the most is "rhythm." We can see from the evolution of music in various countries that, even if the language is absurd, people in various countries will express their personal feelings through the rhythm of music [5]. As a result, it can be said that "music rhythm" has become a universal element. We pay more attention to rhythm than ever before, especially with the development of modern music [6]. Movement and rhythm are two essential core requirements in the process of music development, starting from the very beginning. In the fields of choreography and score, the matching of movements and music pieces is widely used [7]. It is necessary to arrange appropriate dance movements according to the music pieces chosen by users in choreography; it is also necessary to create appropriate background music for the dance actions chosen by users in score creation [8]. Action and music, on the other hand, are time series signals from two different perceptual channels. It is necessary to establish a reasonable action-music feature matching model [9] in order to properly evaluate the degree of matching between them. In light of this, this paper proposes a mixed density network-based music choreography model.

Dance is a form of performing art in which the main means of expression is rhythmic movements accompanied by music [10]. It necessitates a good sense of movement control and balance, accurate timing and rhythm, a rich imagination, and high aesthetic quality because it involves complex sensory and cognitive processes. In music and dance, the phenomenon of alternating strength and length is known as "rhythm" [11]. Humans can perceive human walking gait, strength, and action rhythm, as well as musical characteristics such as tone, pitch, timbre, and musical rhythm of note duration. The most easily perceived feature by the audience is rhythm, which is a common feature of dance and music, according to research. Animators manually establish the matching model of action and music in the traditional animation creation process. Animators must frequently create and listen to different music for the soundtrack and then manually select the music segment that best matches the given dance action segment. This is a time-consuming and tedious task. Based on the foregoing, this paper proposes a hybrid density network-based automatic music choreography algorithm. The algorithm uses a deep learning (DL) algorithm [12, 13] to train the model, which can automatically and intelligently generate dance actions that meet the expectations in combination with screening conditions, based on a large amount of existing music and dance data. Also, according to the established matching relationship, effectively store, retrieve, and edit the dance data. This algorithm can generate unique and imaginative dance movements, which is extremely useful.

2. Related Work

Based on genetic theory, literature [14] proposed an optimization method for matching dance technical movements to music. This method's correspondence can effectively show synchronization of music and dance movements, but it has some drawbacks, such as a time-consuming and tedious calculation process. Based on music emotion and sports style, literature [15] created a matching model of motion and music features. The choreography process is primarily driven by the rhythm of music and movements, as well as the correlation of density characteristics, according to literature [16]. By preconstructing an action graph to search for candidate actions, literature [17] improved the search efficiency of the choreography system. Literature [18] used an artificial neural network to create a motion-music matching model and to automate the creation of gesture animation based on music. A method of synthesizing dance movements was proposed and introduced in literature [19]. Manually marking the movement as a specific pattern synchronized with the beat is required during the training stage. First, beat detection is used to segment the audio, and then, the Mel frequency cepstral coefficient-recognized audio pattern is used to select the action pattern to be generated during the generation stage. Literature [20] used a dynamic programming algorithm to create a matching model between dance action and music feature points and then edited the music to match it, resulting in a semiautomatic score. Literature [21] suggests using machine learning to optimize the matching of dance technical movements and music in music choreography. First, by combining machine learning theory and historical sample data sets, the mapping relationship between dance movements and music is established, and the evaluation function of the dance movements-music matching relationship is obtained. As matched dance action feature sequences, we use constraint-based dynamic planning process matching and input music. Although this method has a high matching efficiency, the quality of the music and dance movements that it matches is poor. On the basis of greed theory, literature [22] proposed an optimization method for matching dance technical movements with music. This method produces a good match between dance movements and music rules, but it is time-consuming. Literature [23] introduces a sample-based matching model and uses it to test the feasibility and practicality of computer-generated choreography using the soundtrack score system of movies. Literature [24] sets scheduling rules based on aesthetic concepts, uses basic action segments to generate dance sequences unrelated to music, and then edits them properly when matching with music. The final result obtained is affirmed by dance professionals. Literature [25] puts forward the rhythm analysis method, which defines the rhythm of movements according to the vertical direction of feet and the change speed of hand displacement, takes the extreme point of joint angular velocity as the rhythm segmentation point, and then refits the movement characteristic curve. Literature [26, 27] added intensity features to the rhythm features and then used the rhythm and intensity features of music and movements as the matching basis to synthesize dance movements. The algorithm holds that the rhythm of music and the rhythm of action have a strong correlation, and the rhythm of action presented by "Stop Action" should be synchronized with the rhythm point of music. At the same time, the intensity of action has a strong correlation with the intensity of music and should also be synchronized. This paper proposes an automatic music choreography algorithm based on mixed density network. In addition, the entire process of computer music choreography is thoroughly examined, and a framework for computer music choreography is proposed. User control is introduced into the dance choreography module to improve the framework's practicability, and the user influences the choreography results by setting the thresholds of local bone speed and spatial characteristics. This framework can generate dance movements that are synchronized with the music. The results of the experiments show that this framework is very stable and generalizable.

3. Methodology

3.1. Automatic Music Choreography Technology. Automatic music choreography has a long history of study. The goal of the study is to use computer technology to reduce the amount of manual intervention in the music choreography process. People have gained a lot of valuable experience in the matching model of motion and music features [28] up until now. In terms of choreography, a matching model of motion and musical features is developed based on musical emotion and sporting style. To make the choreography process go more smoothly, research how to use the rhythm and density characteristics of music and movements. It is also possible to create action diagrams in advance for searching and selecting, which will improve the choreographer system's searching efficiency.

To create computer-assisted music choreography, dance action data must first be collected. Motion data are currently classified into two categories: motion capture data and key frame-based motion data. These two types of data, on the other hand, require a lot of manual processing, which is costly to obtain and difficult to edit. The DL algorithm has been applied to the field of motion generation as artificial intelligence technology [29] has progressed.

In music or dance, "rhythm" refers to the phenomenon of regular intensity and length appearing alternately. There are numerous types of perceptible human movements and musical characteristics. Rhythm is one of the most easily perceived features of an audience, according to research, and it is a common feature of dance movements and music. The action and rhythm sequences are both interdependent and independent in terms of the overall development of music. No matter how inventive the action sequences are, they are always bound by the rules of rhythm and melody. This is the rule that governs the progression of rhythmic sequences and movements. The introduction and widespread use of computers have resulted in a more precise system for dividing rhythm and the formulation of a set of standards. However, as computer technology advances and people's expectations for sound discrimination rise, the requirements for music rhythm measurement become more stringent [30]. The motion segments matching the target music are selected from the constructed motion database using the traditional artificially designed music and motion features and feature matching algorithm, synthesizing the dance. The motion database is usually composed of motion capture data. Figure 1 shows the framework of music choreography system.

In order to match the rhythm of computer action and music, it is necessary to turn the action and music signal into a sequence of feature points in rhythm semantics, that is, to express the rhythm information of music and action data abstractly in the form of functions. The collected music data are segmented, the action segments in the dance action database are connected and organized, the underlying features of historical music and dance actions are obtained, some feature pairs are extracted by correlation analysis, and the correlation coefficient between music and dance action features is calculated in order to establish the principle model of dance technical action system. It is more reasonable for all kinds of specifications required in the database to match the movements and music rhythms with computers. The function of information is required for its expression, and the final forms of expression are sequence and rhythm.

As computer animation and robotics advance, more and more applications require a large amount of real human motion data. In general, action diagrams and music diagrams are used to store and organize movement and music data, and automatic choreography and score are performed. That is, rhythm is used to segment motion and music data, and each segment is then turned into a node in the motion or music map. Data set construction, model training and action generation, dance choreography and synthesis, and dance visualization with 3D character animation are the four parts of the framework for music choreography system based on mixed density network proposed in this paper. Model training, action generation, and dance choreography based on music and action features are the main steps. Figure 2 shows the overall framework of the music choreography system based on mixed density network.

In comparison with traditional computer animation of a 3D model based on key frames, motion capture technology can more easily reconstruct complex motion and realistic physical interaction, and the obtained motion data are more realistic, as well as the workload of acquiring motion. Motion capture, on the other hand, necessitates specialized hardware and software to capture and process the data. The cost of required software, equipment, and personnel may be prohibitively expensive for small-scale production. Furthermore, editing the captured data twice is difficult. If there is a problem with the data, all you have to do is reshoot the scene. The path with the highest degree of matching will be chosen by the output result of automatic choreography or score. However, because the calculation process is time-consuming, it is necessary to create an action-music map based on rhythm to speed up the search for potential actions or music data.

When the action sequence is converted into the sequence value of action rhythm feature points and the music sequence is converted into the sequence value of music rhythm feature points, the matching degree between them needs to be calculated. The methods include using the classical Euclidean distance to solve the above problems, but the movement and music feature point sequences tend to have similar trends and they cannot be aligned on the time axis. In order to train the action generation model, it is necessary to construct the action data set and express the action data as vector as the input feature of the model.

3.2. Action Generation Algorithm Based on Mixed Density Network. The hybrid model is primarily used in computer vision for inverse or ambiguous problems. Instead of relying on manual production and motion capture data from users, it is necessary to solve the problem of motion generation in order to realize an effective computer choreography algorithm and ensure that the choreographed dance is real enough and novel. The mixed density network-based action generation algorithm is implemented in this chapter. The hybrid model has the capability of simulating the general distribution function in its entirety.

Extract the angular velocity curve of each joint point of the action data, and mark the extreme point of the curve as

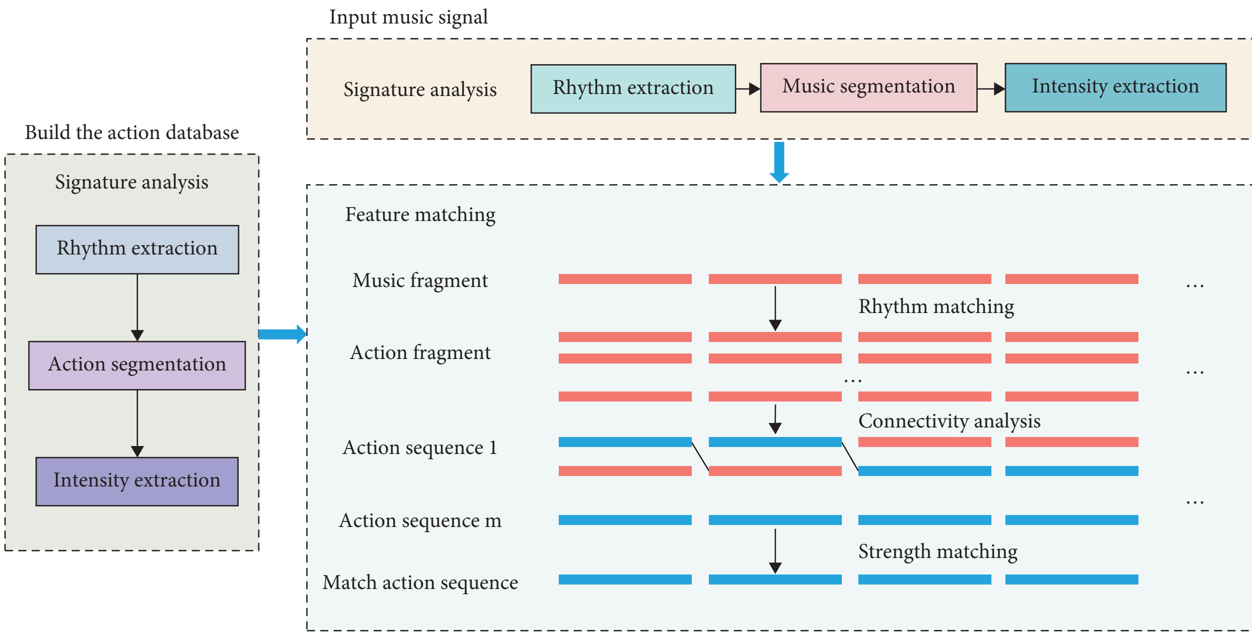

FIGURE 1: Music choreography system framework.

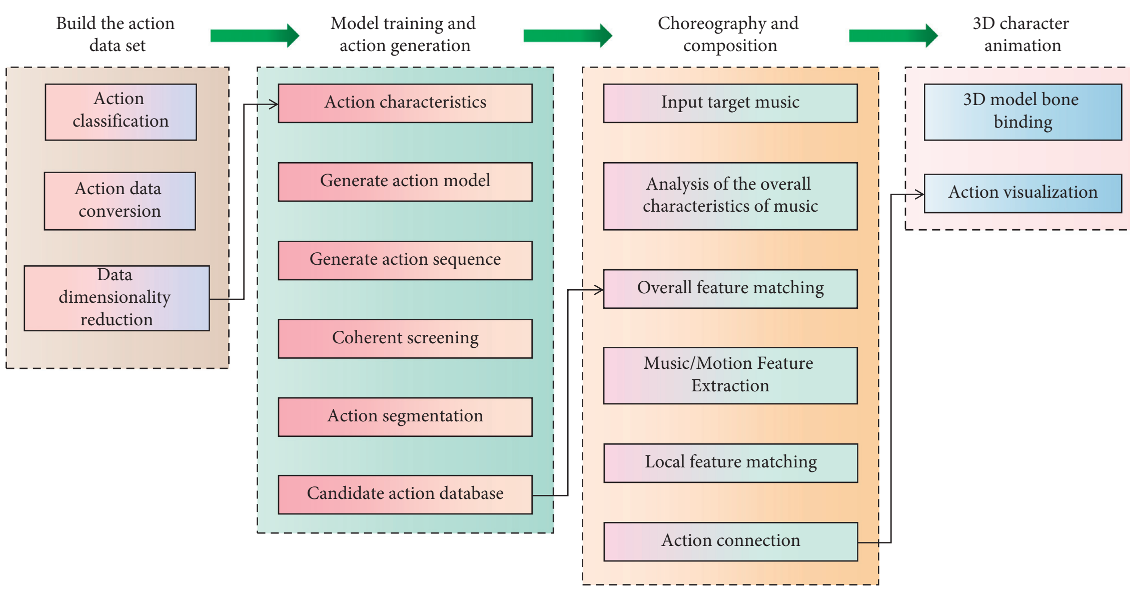

FIGURE 2: The overall framework of this system.

the rhythm reference point to form the time series $(t_0, t_1, \ldots, t_k, \ldots, t_n)$ of the reference point. Then, use the cosine curve to fit all the reference points, and the construction of the cosine function uses:

$$y_t = \begin{cases} \cos\left[2\pi\left[\dfrac{t - t_{k-1}}{t_k - t_{k-1}}\right]\right], t_{k-1} < t < t_k, \\ k = 2, \ldots, n, \\ 1, t = t_n. \end{cases} \tag{1}$$

Among them, y_t is the function value of the curve fitting at time t, and the extreme point of the angular velocity curve of the joint point is regarded as the rhythm candidate point of the joint point.

Convert the input music data file into discrete sampling points, and take 2N sampling points as a time window. There are N sampling points between different time windows, and the Fourier coefficient $X_0, \ldots, X_{N-1}$ is obtained after combining short-time Fourier analysis. $D_H(n)$ represents the mutation point function value of the nth time window, which is expressed by the following formula.

$$D_H(n) = \sum_{k=0}^{N} k\left|X_k[n]\right|, \tag{2}$$

where $X_k[n]$ represents the k-th coefficient of the nth time window.

It is necessary to transform movements and music signals into feature point sequences in rhythm semantics, that is, to abstract the rhythm information of music and movement data into one-dimensional feature point functions, in order to calculate the degree of rhythm matching between movements and music. When the action and music sequences are transformed into the sequence values of the action and music rhythm feature points, the matching degree between them must be calculated. The matching degree can be calculated in a variety of ways. In general, the classical Euclidean distance is adequate for solving the problems listed above. However, while the general trends of the action and music feature points are similar, their similar forms are not aligned on the time axis. This problem can be effectively solved by combining time planning and distance measurement, and the cumulative distance function it provides can be used as a criterion to calculate the degree of matching between actions and music pieces.

Assuming that the mutation point function value of the nth time window is $D_s(n)$, the extreme value detection is performed on the mutation point function of each time window, the obtained extreme point sequence is aligned according to the beat, and the final mutation point function is expressed by (3) value $D_{(n)}$.

$$D(n) = D_H(n) \times D_s(n). \tag{3}$$

Assuming the position of the music beat in the performance stage of the T_n generation, the position of the next music beat can be estimated through the music beat cycle:

$$T^{'}_{n+1} = T_n + \tau_{\max}. \tag{4}$$

Among them, $T^{'}_{n+1}$ represents the predicted value, and T_{n+1} represents the real beat position.

When a user inputs a music sequence, the system automatically outputs a dance action that matches the music sequence, which is called automatic choreography. Starting from the instructions of choreography, there are a large number of dance styles and types in the computer database. Different styles and types are the main body that is proficient in the early cutting and optimized to form music resources, and meet the basic requirements mentioned by users to a certain extent.

Based on the rate of change of velocity, the consistency of the motion sequence is screened. Firstly, the sum of absolute values of the first-order velocity difference of each joint in adjacent frames V(f) is calculated:

$$\begin{aligned} V(f) &= \sum_{k=1}^{c} |v(f+1,k) - v(f,k)|, \\ v(f,k) &= \left\| x_{f+1}^{(k)} - x_f^{(k)} \right\|. \end{aligned} \tag{5}$$

Among them, f is the sequence number of the frame in the action segment N_i, and x represents the action vector. $x_f^{(k)}$ represents the k-th dimensional motion data of the f-th frame, and c is the vector dimension of each frame of motion. v(f,k) represents the speed of the k-th dimension data in the f-th frame.

In computer music choreography, it is necessary to extract features that can reflect the common characteristics of music and actions in order to select dance actions that match the given target music. The complete action-music map is useful for automatic score and choreography, and its workflow can be broken down into two stages: pre-calculation and real-time operation. However, the candidate movements and music must still be processed in order to improve the rhythm matching between them and the music, as well as to meet the quality requirements of customers.

According to prior knowledge, the actual music beat position is usually the same as the extreme point of the mutation point function. The threshold ε is set in the vicinity of the estimated music beat position $T^{'}_{n+1}$, and all the extreme points within the interval $[T^{'}_{n+1} - \varepsilon, T^{'}_{n+1} + \varepsilon]$ are regarded as aligned candidate points. Define the extreme point function according to the obtained extreme point sequence, and use the following formula to express.

$$\text{Peak}(t) = \begin{cases} 1, & t \text{ is the extreme point}, \\ 0, & t \text{ is the nonextreme point}. \end{cases} \tag{6}$$

Suppose (M_j, A_i) represents an example of combined action-music segment training in music choreography. For each action feature p in M_j and music feature q in A_i, use the following formula to calculate the correlation coefficient between the two.

$$C_{(p,q)} = \frac{E(X-\mu_X)(Y-\mu_Y)}{\delta_X \delta_Y}. \tag{7}$$

Among them, $\mu_X, \mu_Y, \delta_X \delta_Y$ stands for mathematical expectation and standard deviation, respectively. X represents the characteristic sequence of dance movements $F_{j,l}^m(p), \ldots, F_{j,6}^m(p)$. Y represents the musical characteristic sequence $F_{i,l}^a(q), \ldots, F_{i,6}^a(q)$. $F_{j,k}^m(p)$ represents the k-th window of the j-th dance action segment M_j. $F_{i,k}^a(q)$ represents the qth window of the i-th music segment A_i.

After the motion generation model has been trained, the output of the model can be used to determine the spatial distribution probability of each bone joint point in the next frame, and the results obtained using various parameter control methods when estimating the position coordinates of each joint point are also different. The action and music data are usually stored and organized in the form of an action diagram and a music diagram, respectively, when performing automatic choreography and score. That is, rhythm is used to segment the action and music data, and each segment is then used as a node in the action and music graphs. The automatic choreography and score problem is thus transformed into a traversal problem on the action chart and music chart. That is, the rhythm matching model of actions and music calculates the degree of matching of all possible combinations of actions and music pieces, and then, the path with the highest degree of matching with the input actions or music data is chosen as the automatic choreography or score's output result.

4. Result Analysis and Discussion

Music features can be roughly divided into bottom features and top features. The bottom features include amplitude envelope, short-term energy, spectrum features, short-term power spectral density, etc. High-level features include the emotion and style of music. Because it is difficult to quantify and evaluate the high-level features of music, the current popular classification algorithm of music emotional style is to use machine learning algorithm to obtain the mapping relationship between the low-level features of music and emotional style. That is, the high-level features of music can be described by the low-level features.

Integration of movement and music has always been a difficult problem that needs to be improved and addressed more thoroughly. We should start by establishing the position of the action and music rhythm points and then segment the action and music data and the distance between nodes to establish their connectivity. It is divided into two categories: timbre distance and chord distance. The cubic spline interpolation function is used to fit the curve in this paper. To begin, the maximum value of continuous frame change data in video is obtained, and the upper envelope of the data sequence is fitted by a cubic spline function, followed by the minimum value of the lower envelope of the data sequence being fitted by a cubic spline function. Finally, as the final current data series fitting result, the mean value between the upper and lower envelopes is calculated as shown in Figure 3.

After obtaining the fitting results, we can observe the obvious segmentation points between various dance movements in a dance video. Two adjacent minima can determine a simple action sequence, and the minima position indicates the segmentation position of the action sequence frame.

When creating an action map or a music map, the action and music data must be segmented separately based on the positions of the action and music rhythm points. The connectivity between nodes is then analyzed and established based on the distance between nodes, making graph traversal easier. Each action sequence in the action database is divided into "action sections" based on the position of the action rhythm point. Each action bar has four action rhythm points, which are regarded as nodes in the action diagram and simulate the score structure of 4/4 beats. The action features are divided into two categories: bottom features and high-level features. The movement speed, acceleration, movement direction change, and action shape of each joint are the low-level features, while the emotion and style of action are the high-level features. With the help of a user score, analyze the synthesis effect of three different dance styles. To begin, analyze the music style in relation to the target music's overall characteristics, and then create choreography actions to match. Several target music pieces were analyzed in this experiment, and three target music pieces appropriate for street dance, classical dance, and modern dance were chosen and choreographed. The test participants scored the degree of matching between music and dance by judging the three segments' dance styles. The evaluation results are shown in Figure 4.

The choreography only considers the action connection between the segments, rather than the connection as a whole. To deal with the problem holistically, we can improve the agreement between some paragraphs by informing the connections between them, allowing the actions in the paragraphs to achieve complete overall coherence and matching. In music, on the other hand, in order to show the perfect melody completely between segments, the connection between segments can be obtained using the music cohesion rules of a computer database in this regard, resulting in the perfect integration of the entire melody.

Using this method and the method based on genetic theory and the method based on machine learning, the optimization experiment of dance action matching in music choreography is carried out, and the matching degree of dance action matching in music choreography is compared with the three methods. The comparison results are described in Figure 5.

It can be seen from the analysis that when using this method for music choreography, the matching degree of dance movements is better than that based on genetic theory and machine learning. The superiority of this algorithm is further verified. Using this method, the method based on genetic theory and the method based on machine learning, respectively, the optimization experiment of dance movement matching in music choreography is carried out. The three methods are compared for the synchronization of dance action matching in music choreography, and the comparison results are described in Figure 6.

The analysis shows that the synchronization of dance action matching is better than that of dance action matching based on genetic theory and machine learning. The simulation results show that the proposed method can fully reflect the synchronization of music and movement changes, and the music-dance matching quality matched by the improved dance movement matching method is higher.

Although qualitative experiments can verify the algorithm's effectiveness through visual effects, relying solely on this index makes it impossible to assess the experimental results quantitatively in all aspects. It is difficult to objectively and quantitatively evaluate the choreography effect in the field of computer-assisted music choreography. There is no universal objective and quantitative evaluation index available at the moment. As a result, subjective evaluation criteria are frequently used to assess the results of experiments. 200 students were asked to research the user experience using the user manual scoring method in this paper. In the training data set, show the participants two pieces of music and dance. One piece of music is paired with a dance, while the other is paired with mismatched dances to the same music. After the manual scoring, this paper counts the final scores of the experimental segments, and the results are shown in Figure 7.

In the process of matching and optimizing dance movements in music choreography, the synchronized dance movements and music data are divided by integrating the theory of music beat extraction, and a plurality of short movements-music fragment combinations are obtained. Detect the abrupt change point of the music segment, align

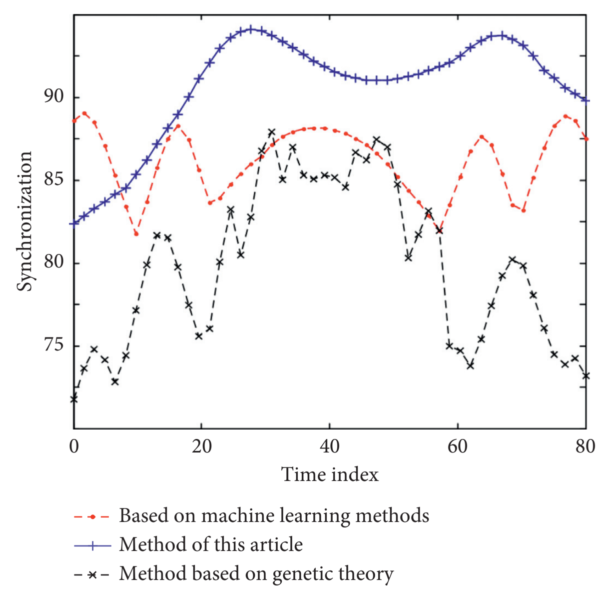

Figure 6: Method comparison chart of synchronization of different dance movement matching.

the beat predicted position obtained in each step, calculate the correlation coefficient between dance movements and music segments, and obtain the dance movement matching optimization objective function. The effectiveness of the hierarchical feature matching algorithm proposed in this paper is verified by comparing the users' scores of dances generated with or without music overall feature matching algorithm. The scoring situation is shown in Figure 8.

The results show that dance segments synthesized with the hierarchical feature matching algorithm proposed in this paper are better matched to music than dance segments synthesized with only the local feature matching algorithm. It demonstrates the effectiveness of the hierarchical feature matching algorithm proposed in this paper. The music-action data set is built in this chapter, as well as the data classification and feature representation of training data. Build an action generation model, complete the model's training and action generation, and control the parameters during the action generation process. The generated action is suitable for the subsequent dance arrangement in order to ensure the quality of the generated action. Both the local bone motion speed feature extraction algorithm and the dance spatial feature extraction algorithm proposed in this

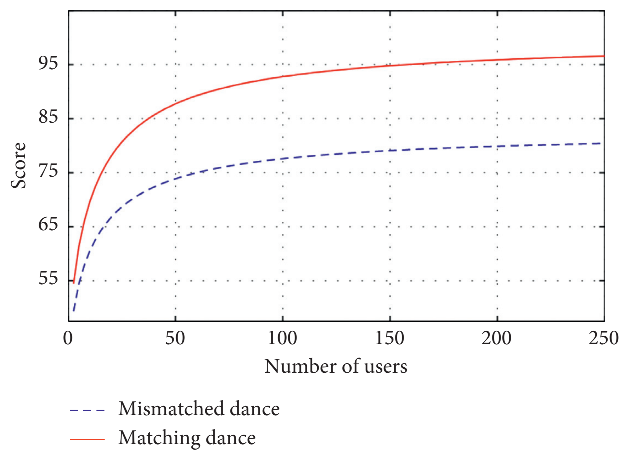

Figure 7: User experience rating.

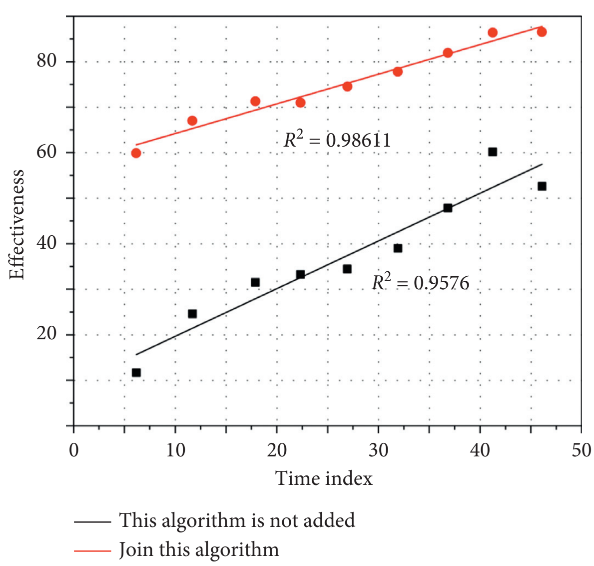

Figure 8: Effectiveness evaluation of matching algorithm.

paper can effectively reflect the corresponding dance features, according to the experimental results. Overall musical characteristics can accurately reflect musical style types and synthesize choreography actions of corresponding styles. The hierarchical feature matching algorithm outperforms the local rhythm and intensity feature matching algorithm, and the entire feature matching can be combined to create a dance that is better suited to the target music.

5. Conclusions

Dance with music enriches our cultural life as a form of artistic expression. The integration of technology and art is making a computer realize music-based automatic choreography. When artists use scientific and technological methods to create, this type of technology can act as a catalyst for inspiration and has a lot of potential. The data set created in this paper obtains enough dance data through motion capture devices, and downloading motion data corresponding to different music from the Internet is more cost-effective and convenient. The matching degree of all potential combinations of actions and music pieces in the database is precalculated with the rhythm feature matching model in the preprocessing stage, and an action-music map is created. In the real-time matching stage, the method of graph traversal is used to find the candidate actions or music that have the best rhythm match with the input, and then the rhythm feature points of these candidate actions or music data are further optimized and adjusted to form the automatic choreography result. Furthermore, the automatic music choreography algorithm proposed in this paper, which is based on a mixed density network, considers the coherence between adjacent motion segments as well as the naturalness of the entire dance motion. The experimental results show that this algorithm can generate a sufficient number of realistic and diverse dance movements, with the mean method producing the most stable movements. The human skeleton structure that generates movements becomes more and more real as training time goes on, and the relative relationship of joints becomes more and more stable. The coherence-based motion screening algorithm can also produce the desired results.

With the advent of the era of big data, the rise of Web2.0 completely subverts the traditional Internet model and becomes the trend of today's information age. Simultaneously, massive amounts of data and information have infiltrated various Internet companies, resulting in an increase in the problem of information overload. In the online world, learning how to quickly and accurately select the parts we are interested in from a variety of data has become a hot topic. Intelligent music recommendation has become a current research hotspot in music services as a viable solution to the problem of information overload in the digital music field. On the basis of precedents, this paper examines the characteristics of music in a comprehensive and detailed manner. A knowledge graph-based intelligent recommendation algorithm for contemporary popular music is proposed. User-defined tags are described as the free genes of music in this paper, making it easier to analyze user behavior and tap into user interests. It has been confirmed that this algorithm's recommendation quality is relatively high, and it offers a new development path for improving the speed of searching for health information services.

1. Introduction

Recommendation system is a smart software technology that can provide personalized recommendation services for users based on their interests, preferences, and characteristics [1]. The amount of music available is growing at an exponential rate, making it difficult for users to search for and find related music. As a result, researchers from all over the world are increasingly focusing on music retrieval research [2]. Intelligent music recommendation has become a research hotspot in current music services [3] as an effective way to solve the problem of information overload in the field of digital music. As the number of users has grown significantly, more and larger amounts of data have been generated. The recommendation system was created to address the issue of how to best use these data in order to provide more accurate services. To retrieve eligible music benefits, traditional music retrieval uses metadata. This retrieval method necessitates users remembering relevant information from the target track prior to retrieval, which is incompatible with users' fast-paced lives [4]. In modern life, what users need is to be able to play music that suits their interests continuously. However, how to provide different users with a list of songs that suit their interests or recommend interesting songs for them has become a problem that the current music recommendation system needs to solve. Intelligent music recommendation system is faced with the problems of accuracy, diversity, and novelty of recommendation, while its data set is sparse and information is missing.

In recent years, although the recommendation algorithms [5] in the fields of movies, news, and books have emerged one after another, there are not many recommendation systems in the field of music, mainly because the data in this field are often not made public, and unlike the ratings we usually use, there is basically no public data set that mentions the user's ratings [6]. Intelligent music recommendation system is an effective way to solve "information overload." The recommendation system mines users' potential interest preferences according to their historical behaviors, calculates the similarity between users and resources, and recommends music resources that users may be interested in [7]. At present, in the research of intelligent music resource recommendation methods, researchers focus on user feature modeling and resource attribute modeling and recommend by calculating the similarity between users and resources. In most cases, people background music and listen to music while studying, working, or exercising [8]. The emergence of music recommendation system enables users to quickly and continuously obtain music that suits their interests. The emergence and development of Web2.0 and social media allow users to act freely [9]. Users can define labels for music through their own understanding and feelings, and different labels can interpret users' understanding of music from different angles. Knowledge map is often used in intelligent search engines, recommendation systems, and other fields to improve its accuracy because of its strong organizational ability and relationship processing ability [10]. At present, the recommendation system based on a knowledge map is mainly divided into feature-based recommendation and path-based recommendation. Knowledge features are extracted through knowledge feature learning, and the ability of feature extraction, that is, the quality of knowledge representation, not only determines whether it can bring useful information for recommendation but also determines the quality of knowledge map construction. Therefore, this paper constructs a small-scale knowledge map in the field of machine learning and, on this basis, proposes a music resource recommendation algorithm based on a knowledge map, which integrates music connectivity and user interests.

In a broad sense, the recommendation system can be understood as recommending items that users may be interested in. The recommended items can be movies, music, books, short videos, and so on, depending on the specific field of application [11]. Today, with the continuous expansion of the Internet, the amount and types of information are increasing, and users put forward higher requirements for information retrieval and recommendation of related items [12]. Because different users have different interest preferences, the focus of attention, personal personality orientation, and so on, in order to meet the different recommendation needs of different users, an intelligent recommendation system featuring that everyone can get different recommendations from others came into being [13]. Traditional music recommendation algorithms based on "User-Item" usually only pay attention to the two-dimensional scoring relationship, ignoring the situation information of users when listening to music [14]. This paper proposes an improved algorithm based on a knowledge map, which is based on the traditional music recommendation algorithm and incorporates the users' situation information when listening to music. Simultaneously, this paper examines the existing music recommendation system in depth, combining it with some of the benefits provided by the recommendation algorithm. By analyzing the recommendation results, we can see that the system's overall performance is good and that it can effectively recommend results that users might be interested in to a degree, essentially achieving the system's intended goal.

2. Related Work

Literature [15] proposes to recommend music that meets users' needs and preferences by analyzing users' listening habits and the characteristics of the music itself. Literature [16] proposes that, in order to meet the personalized needs of different users for music, major well-known music recommendation systems are increasingly favored by consumers. Convolution matrix decomposition based on file additional information is proposed in literature [17]. Literature [18] introduces the information in the knowledge base such as structure information, text data, and image data into the recommendation system to improve the quality of the recommendation system. A session-based recurrent neural network recommendation model is proposed in literature [19]. A multirate depth learning model based on time recommendation is proposed in literature [20, 21]. Literature [22] introduces the concept of similarity based on meta path, in which meta path is a path composed of a series of relationships defined between different object types. A new similarity measure called PathSim is defined under the meta path framework, which can find objects in peer-to-peer networks. References [23,24] propose the method of using depth hierarchy model in film recommendation task. References [25, 26] propose a novel knowledge representation learning method named embodied type by using the naming of entity level type. Literature [27] introduces the potential features based on meta paths to represent the connectivity between users and projects on different types of paths and uses the relationship heterogeneity in the information network to provide high-quality intelligent recommendation results. Based on previous studies, this paper proposes an intelligent recommendation algorithm for contemporary pop music based on a knowledge map. The algorithm comprehensively analyzes user behavior by analyzing user interests and user preferences for different musical gene characteristics.

3. Methodology

3.1. Related Theories and Technologies. Music is an abstract art form that reflects people's real life and expresses their inner thoughts [28]. It is also a way to express their feelings and repose their feelings. With the rapid decline of the status of traditional records and the rapid promotion and spread of digital music, online audition and mobile music have become new ways for people to obtain music [29]. However, the keywords used by users do not correspond well with the item description tags, and converting audio information into digital information will lead to problems such as increased computation and prolonged response time. This content-based method also ignores the similar interests of different users, so it cannot adapt to the community-based network well.

Feature-based recommendation algorithms directly represent knowledge using a knowledge map, which fails to introduce multihop relationships and makes it difficult to use knowledge semantic network information. The path-based recommendation algorithm makes use of the knowledge map's multihop knowledge and effectively uses the knowledge map's semantic network information, but it usually relies on prior knowledge. As a result, studying the application of the knowledge map in the recommendation system is of great research value in addressing the problem of how to effectively use the semantic association information of knowledge in recommendation algorithms.

A web crawler is a program that requests websites and extracts information from them [30]. In the study of music recommendation systems, there are numerous data sets. However, it was discovered in this paper through the collection of various data sets that none of the existing data sets can contain weather information when users listen to music. This paper abandons existing public data sets in favor of using a web crawler to capture specific data sets in order to meet the research needs of intelligent music recommendation. The process of obtaining web page data by crawler is shown in Figure 1.

The construction of the knowledge map mainly includes three processes. They are information extraction, knowledge fusion, and knowledge processing. Through the above process, we can build a relatively complete and reliable knowledge map. According to the actual situation of users, this paper adopts a recommendation algorithm based on the knowledge map to form a recommendation list. Figure 2 shows the flowchart of intelligent recommendation of popular music based on the knowledge map.

Recommendation systems are intelligent software technologies that can provide personalized recommendations for users based on their interests, preferences, and characteristics. There are many definitions of recommendation systems available today, and different fields have different rules for defining them. The recommendation system is primarily used to estimate a user's preference for items that they have never seen before. It can be roughly divided into scoring prediction, ranking prediction, and classification prediction based on the output of the recommendation system. The scoring prediction is primarily aimed at the scoring matrix, with the goal of supplementing the matrix's vacancy scores. The ranking prediction is primarily intended to recommend items to a specific user who may be interested in them. Classification prediction is the process of categorizing items and recommending them to users who are interested in that category. Although the content-based recommendation is simple to calculate and understand and has been widely used in some fields, such as text recommendation, it is not without flaws that limit its development, as evidenced by the wide range of content feature extraction and recommendation results.

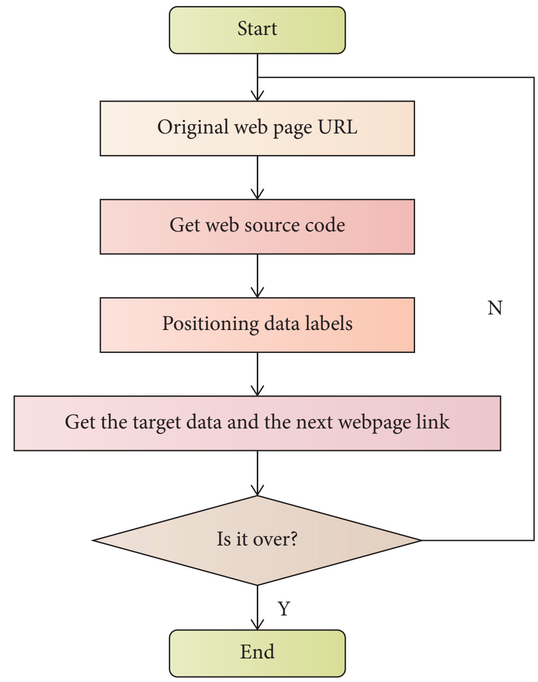

Figure 1: Process of obtaining web page data by crawler.

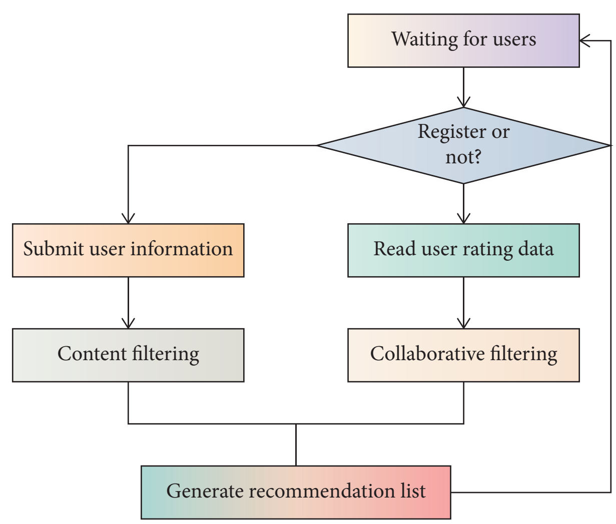

Figure 2: Technical framework of knowledge map.

3.2. Intelligent Music Recommendation System Based on Knowledge Map. The algorithm approaches the target user's score of an item according to the score of the target user's nearest neighbor. Define the target user a and the item i that has not been rated excessively, and then predict the score of a to i:

$$p_{a,i} = \overline{r}_a + \frac{\sum_{u=1}^{K}\left(r_{u,i} - \overline{r}_u\right)\omega_{a,u}}{\sum_{u=1}^{N}\omega_{a,u}}. \tag{1}$$

Among them, $r_{u,i}$ represents the score of user u on item i, r_u and $\overline{r}_a$ represent the average scores of user a and user u, respectively, and $\omega_{a,u}$ represents the similarity between user u and user a.

However, the collaborative filtering algorithm based on items thinks that users' scores of different items are similar. When users' scores of a certain item need to be estimated, users' scores of several similar items of the item can be used to estimate, as shown in the following formula:

$$p_{a,i} = \bar{r}_i + \frac{\sum_{k=1}^{M} \left(r_{a,k} - \bar{r}_k \right) \omega_{i,k}}{\sum_{k=1}^{M} \omega_{i,k}}. \quad (2)$$

Among them, $\bar{r}_i$ represents the average score of item i, and $\omega_{i,k}$ represents the similarity between item i and item k. In actual commercial applications, user-based collaborative filtering algorithms are more efficient than item-based. The number of songs in the corpus used in this paper is far greater than the number of users. In this paper, a user-based collaborative filtering algorithm is used as a comparative experiment to improve efficiency.

Knowledge map can filter data from the Internet and has multisource heterogeneous association information among entities. The filtered association information can fine-tune the feature information in users' projects, calculate the correlation between users and users, users and projects, and projects more precisely, and improve the recommendation system's interpretability, diversity, and accuracy.

If the current user's neighbors listen to a certain piece of music many times, it will greatly affect the recommendation effect. Therefore, in order to avoid this deviation, according to the characteristics of this corpus, the prediction score formula in collaborative filtering is treated as follows:

$$P_{a,i} = \frac{\sum_{u=1}^{K} \left(r_{u,i} - \bar{r}_a/\sigma_a - \bar{r}_u - \bar{r}_a/\sigma_a \right) * \omega_{a,u}}{\sum_{u=1}^{n} \omega_{a,u}}. \quad (3)$$

The threshold T_r of the number of times of listening to the same songs between two users is selected, and the number K of similar users of the current user is selected. After many experiments, it has been proved that these two parameters are $T_r = 20$ and $K = 15$, and the experimental effect is the best.

Knowledge features are extracted through knowledge feature learning, and the ability of feature extraction, that is, the quality of knowledge representation, not only determines whether it can bring useful information for recommendation but also determines the quality of knowledge map construction. When learning vectors, the knowledge model needs to construct negative triples to train the loss function. The usual method is to construct negative samples by randomly replacing the head entity or tail entity in the correct triples. The random method is effective at the beginning of training. However, with the continuous training, the scores of these randomly generated negative triples may exceed the sum of the correct triples scores and interval values, resulting in zero losses. As a result, the convergence speed gradually decreases, and the best result cannot be obtained.

For each relation r in the knowledge graph, two values are first counted. One is the average number of tail entities corresponding to each head entity, denoted as N_{tph}. The other is the average number of head entities corresponding to each tail entity, denoted as N_{hpt}. Then, defining the probability p, the calculation formula is as follows:

$$p = \frac{N_{tph}}{N_{tph} + N_{hpt}}. \quad (4)$$

Then, the replacement head entity and replacement tail entity obey the Bernoulli distribution with parameter P. Set

$$X = \begin{cases} 1, & \text{Replace head entity}, \\ 0, & \text{Replace tail entity}. \end{cases} \quad (5)$$

Then the distribution law of X is

$$P\{X = x\} = p^x (1 - p)^{1-x}, \quad x = 0 \cdot 1. \quad (6)$$

The purpose of a content-based recommendation algorithm is to make recommendations for users based on the similarity of their interests and project contents and to make recommendations independently for each user without taking into account the interests and hobbies of other users. For text information recommendation, this method is simple and effective. The goal of learning is to encode entities and relationships into a continuous low-dimensional vector space, according to the knowledge map. Many existing methods focus solely on learning representations of structured information from triples, ignoring the rich hierarchical type information of entity species available from most knowledge maps.

Assuming that the set that user u and user v have scored together is denoted by I_c and I_u, I_v are the set of items rated by user u and user v, respectively, the similarity sim (u, v) between user u and user v is

$$\mathrm{sim}(u, v) = \frac{\sum_{i \in I_c} \left(R_{u,i} - \bar{R}_u \right) \left(R_{v,i} - \bar{R}_v \right)}{\sqrt{\sum_{j \in I_u} \left(R_{u,j} - \bar{R}_u \right)^2} \sqrt{\sum_{j \in I_v} \left(R_{v,j} - \bar{R}_v \right)^2}}. \quad (7)$$

Among them, $R_{u,i}$ represents the rating of user u on item i, and $\bar{R}_u$ and $\bar{R}_v$, respectively, represent the average rating of user u and user v on the item. I_c represents the set of items scored by users u and v, I_u represents the set of items scored by user u, and I_v represents the set of items scored by user v.

Assuming that the set that user u and user v have evaluated at the same time is represented by I_c, the similarity sim(u, v) between user u and user v can be expressed by Pearson similarity as

$$\mathrm{sim}(u, v) = \frac{\sum_{k=1}^{K} \left(R_{u,k} - \bar{R}_u \right) \left(R_{v,k} - \bar{R}_j \right)}{\sqrt{\sum_{k=1}^{K} \left(R_{u,k} - \bar{R}_u \right)^2} \sqrt{\sum_{k=1}^{K} \left(R_{v,k} - \bar{R}_j \right)^2}}, \quad (8)$$

where $R_{u,k}$ and $R_{v,k}$, respectively, represent the ratings of user u and user v on item k, $\bar{R}_u$ and $\bar{R}_v$, respectively, represent the average ratings of user u and user v on a common rated item, and K is the number of repeated reviews of user u and user v.

Knowledge map is stored in triples composed of entities of entity relations, and entity relations will appear in multiple triples, presenting polysemy and complex relationship types.

In this section, several items with the highest analysis and forecast scores are presented to target users as recommended clearing units. User-based recommendation algorithm is more accurate when the data set is complete and the similarity algorithm is reliable, and it can avoid the differences in project content and make accurate recommendations and can implicitly and transparently explore the relationship between projects and user preferences.

4. Results Analysis and Discussion

The number of times users listen to a certain song to express the user's favorite degree of that song and the user's rating of the project according to his favorite degree is the data set used in this paper. When calculating the similarity between two documents in the context of data query, documents are frequently regarded as word frequency vectors, with the cosine value of the included angle between the two word frequency vectors used to express their similarity. The algorithm sort calculates the user-item relationship. A user query node in the algorithm is represented by a vector, with each dimension representing an item node in the association graph. Its value in this paper represents the number of times the user query node has listened to the music node or whether it has used the tag, indicating the degree to which users are interested in songs or tags.

The validity of the sequential user relationship model is the foundation of algorithm recommendation. To demonstrate the validity of the sequential user relationship model, the first step of the experiment is to compare the traditional nearest neighbor recommendation algorithm with the sequential nearest neighbor recommendation algorithm. The experimental results of the root mean square error comparison between them under different nearest neighbor numbers are shown in Figure 3.

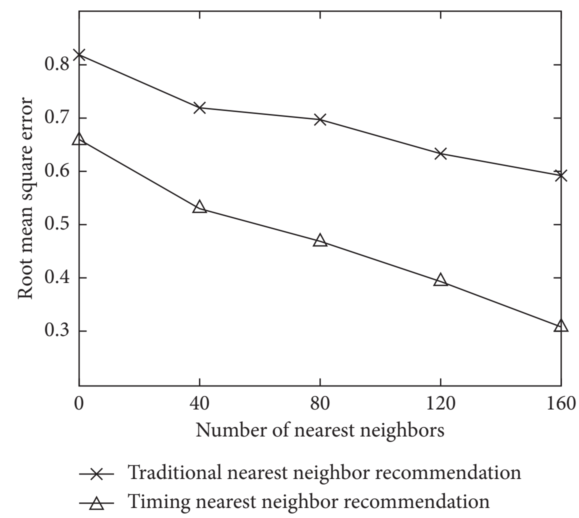

Figure 3: Comparison chart of root mean square error under different nearest neighbors.

From the graph, it can be seen that the effect of time-series nearest neighbor recommendation is always better than that of traditional nearest neighbor recommendation, whether the value of root mean square error is rising or falling, which proves the effectiveness of the time-series user relationship model. User preference extraction is the precondition of context awareness recommendation, and the purpose of contextual user preference extraction is to introduce contextual information into the user preference model. At present, there are two main types of situational user preference extraction technologies: quantitative analysis and qualitative analysis. The node type and relationship type in the knowledge map contain the design idea of the ontology library, and the entity information and semantic information between entities in the map show the extracted movie knowledge. The constructed knowledge map nodes and relationship types are reasonably designed, and the knowledge is accurate and comprehensive, which can be used for pop music retrieval.

In order to verify the effectiveness of the recommendation algorithm, the differences among traditional nearest neighbor recommendation, time-series nearest neighbor recommendation, and knowledge map recommendation are compared according to the different intervals in which users listen to music records. The root mean square error results of the three methods in different training set intervals are shown in Figure 4. The results fully prove the effectiveness of the recommendation.

The matrix decomposition model, also known as the hidden semantic model, assumes that several hidden factors influence a user's rating of a specific item. The matrix decomposition model decomposes the large problem scale "user-item" scoring matrix into the product of two small matrices, the user potential feature vector matrix and the item potential feature vector matrix, respectively, and the product of the two matrices maps the user and the item to a common hidden factor space. We ran 20 tests for each combination configuration and then averaged the test results to find the best parameter configuration based on the average ranking of the correct triples. Figure 5 shows the average ranking results under different embedded dimensions.

From the figure, we can see that, in all the dimensions of the experimental test, the improved negative sampling algorithm has a significant improvement in the average ranking compared to the original negative sampling algorithm. Figure 6 shows the top ten hit rate results in different dimensions.

The top ten hit rate results of negative sampling using the improved negative sampling algorithm are better than the original results in all dimensions, according to experimental results. The situational user preferences are converted into numerical scores in quantitative form using the quantitative analysis method, and mathematical calculations are performed using the corresponding preference extraction technology. In order to quantify situational user preferences, multidimensional vector scoring models and hierarchical models are commonly used. Heuristic and model-based technologies are two types of quantitative analysis methods. Similarity calculation, nearest neighbor algorithm, clustering, and other heuristic methods for extracting user preferences in scenarios are common. Users' playing records will

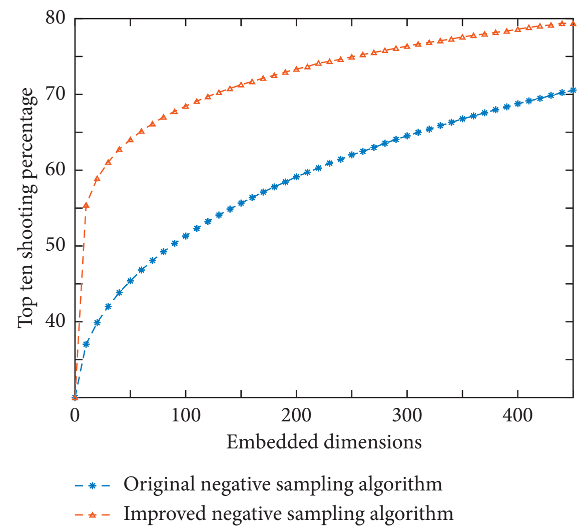

FIGURE 6: The top ten hit rates under different embedding dimensions.

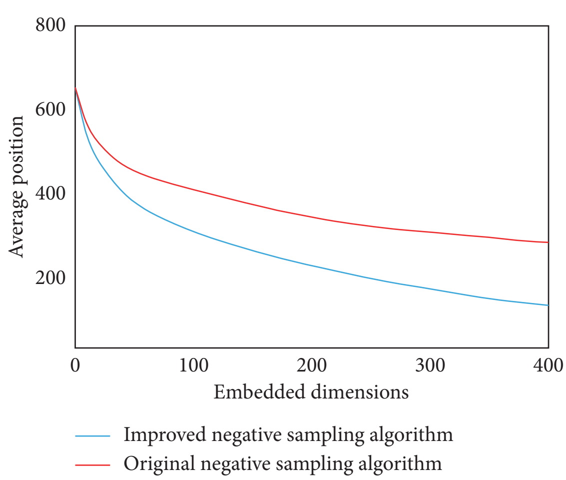

FIGURE 5: Average position under different embedding dimensions.

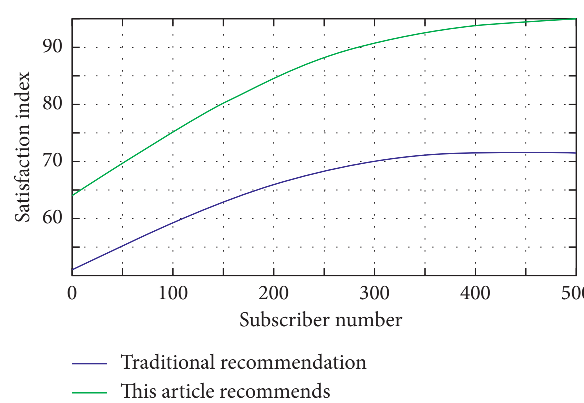

FIGURE 7: Comparison of user satisfaction evaluation.

be written into the database when they play music. All of the played music analyzed in this paper is recorded music for the sake of research. After existing users log in, the system will generate a list of recommendations based on the user's situation and then finish the prediction recommendation work. The user satisfaction of the music recommendation prototype system is assessed in this section, as well as the system's usability. The comparison of user satisfaction evaluation is shown in Figure 7.

By evaluating the recommendation results, we find that the overall performance of the system is good, and it can effectively recommend the results that users may be interested in to a certain extent, basically reaching the expected goal of the system design. Comparative experiments are carried out for different algorithms, in which each group of experiments is designed to compare the recommended algorithm with a simple model after adding tag information. The comparison results are shown in Figure 8.

It can be seen that, in the same data set, the recommendation effect of the recommendation algorithm proposed in this chapter is obviously better than the collaborative filtering algorithm based on users. The purpose of the algorithm is to get the music items that are most closely related to the user. The content-based recommendation method has the advantages of avoiding cold start and data sparseness because it does not need other users' related data. However, the premise of this method is to extract the project content into meaningful features, and the features require good structure, which is very restrictive in many recommendation systems. An important part of the recommendation algorithm experiment is to select and set reasonable experimental standards. If we want to detect the performance of the algorithm well, we must have a reliable evaluation standard. With the reliable evaluation standard, we can also detect the areas to be revised in the recommendation algorithm.

The recommendation system based on the knowledge map constructed in this paper realizes the function of recommending popular music for users and shows the actual

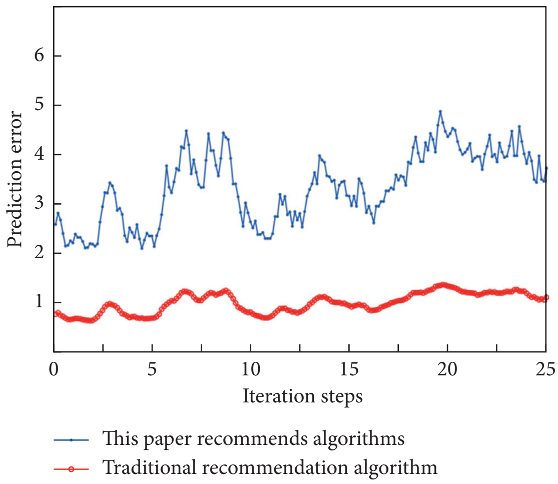

Figure 8: Comparison of two recommendation algorithms.

effect of the system. Experiments show that the algorithm can make full use of historical preferences and knowledge map relationship structure to deeply mine users' interests and hobbies. It has certain practicability.

5. Conclusions

With the advancement of the Internet and mobile networks, music has become an increasingly important form of entertainment in people's lives. Users, on the other hand, have higher standards for intelligent music recommendation. As a new application in the field of recommendation systems, intelligent music recommendation has a lot of research potential. Users' interest and loyalty to the system can be improved by using a knowledge map to analyze users' interests and accurately recommend personalized items that meet their interests, which is an inevitable trend in the development of commercial music systems and a hot field that scholars are scrambling to study. This paper builds a knowledge map-based recommendation system that is oriented to the application of music recommendation, realizes the function of recommending popular music to users, and shows the system's actual effect. A content recommendation algorithm with a unified embedding of behavior and knowledge features is proposed to solve the problem of knowledge map application in recommendation systems. To fully explore users' interests and hobbies, the algorithm makes extensive use of historical preferences and the knowledge map relationship structure. This paper uses the click prediction experiment to demonstrate the model's ability to dynamically learn related information and mine preferences deeply.

Traditional machine learning algorithms are susceptible to objective factors such as video quality and weather environment in the vehicle detection of Unmanned Aerial Vehicle (UAV) videos, resulting in poor detection results. A vehicle image detection method using deep learning in UAV video is proposed. The algorithm in this paper treats surveillance video as many frames of images for vehicle detection in the image. First, perform HSV (Hue-Saturation-Value) spatial brightness translation operation on the original sample to increase the adaptability to different light conditions and sample diversity. Then, the Single Shot MultiBox Detector (SSD) model framework is used as the basis for vehicle detection. In order to obtain a better feature extraction effect, focus loss is added to the basic SSD for optimization. Finally, the trained network model is used to analyze the UAV video, and the detection performance is analyzed experimentally. The results show that the vehicle detection rate of this algorithm has reached 96.49%. It can ensure that the vehicle is accurately detected from the drone video.

1. Introduction

As the pace of urbanization in our country continues to accelerate, the number of roads and family cars in our cities is increasing, and road traffic pressure is increasing day by day. The research of intelligent transportation system is very important to ensure the smoothness and safety of roads [1, 2]. Intelligent transportation system uses information technology, such as image recognition, computer vision, etc. to realize more intelligent and automated road transportation system. It improves the throughput capacity of the road area and greatly facilitates the dispatch of the traffic management department. However, real-time acquisition of road traffic information is the basis for the realization of an intelligent transportation system. How to obtain high-quality road vehicle information has become an urgent problem to be solved.

At present, the collection methods of vehicle information mainly include loop coil detection, infrared detection and intelligent video surveillance detection [3–5]. Among them, the loop coil detection work is stable, the detection accuracy is high, and the traffic information can be counted. It is easy to install and set up, and is mostly used in areas such as traffic toll crossings and parking lots. Infrared detection mainly uses light-emitting diodes to detect vehicle speed, with high detection sensitivity. But it is easily affected by the environment, such as temperature, humidity, etc., resulting in low detection accuracy and low robustness. With the development of technologies such as image recognition and computer vision, intelligent video surveillance and detection has taken up an increasingly important position in traffic information collection. Intelligent video surveillance detection uses a camera set up at a traffic intersection to perform target analysis on the camera monitoring area to obtain unstructured information of the target in the video. The traffic monitoring video contains a wealth of information and is an important data source for intelligent traffic monitoring systems [6]. However, the data resources acquired by fixed cameras are limited. With the development of drone technology, it has begun to be widely used in traffic monitoring, with rich data types and efficient data acquisition. But how to detect the vehicle from the massive data is the difficulty of the research [7, 8].

At present, there have been many researches on vehicle identification in surveillance video. Reference [9] proposed an automatic detection method for smoke vehicles in traffic surveillance videos based on vehicle rear detection and multi-feature fusion. Using the Vibe background subtraction algorithm to detect foreground objects and remove non-vehicle objects according to the rules. An improved integral projection method is used to detect the rear of the vehicle to obtain the key area behind the rear of the vehicle. Effectively improve the accuracy of road safety early warning. Reference [10] proposed a smoke vehicle detection method by learning spatio-temporal representation from image sequences. The motion detection algorithm is used to obtain the tail of the vehicle that needs to be identified. And using time multi-layer perception or long short-term memory network to effectively train the smoke vehicle recognition model, which effectively improves the recognition accuracy. Reference [11] proposed a preprocessing framework with virtual single-layer sequences in traffic video surveillance. By fusing the effective element estimation module and the dynamic multi-stage parallel video image processing module, the robustness and effectiveness of vehicle detection in the video are improved.

With the rapid development of computer technology, machine learning algorithms have also been widely used in the field of image recognition. Reference [12] compares several commonly used video vehicle recognition methods including deep learning models and computer vision methods. The average accuracy, the semantics of recognizing vehicles, and the robustness of recognition when applied to data sets containing images with different lighting conditions are used to compare detection accuracy. The results show that the proposed deep learning method has better recognition performance. Reference [13] proposed a driver warning and collision avoidance system based on vehicle trajectory characteristics and long- and short-term memory neural network. By judging the video behavior of vehicles, road safety is effectively improved. However, the initial detection performance of the vehicle in the video still needs to be optimized. Reference [14] proposed a new type of hybrid artificial neural network and a mobile vehicle detection system based on the opposing gravity search optimization algorithm. Used to detect moving vehicles in traffic scenes to achieve effective traffic video surveillance. Optimizing the selection weights through the opposing gravity search optimization algorithm, effectively improving the recognition accuracy and speed of the artificial neural network. Reference [15] proposed a region-based Convolutional Neural Network (CNN) in vehicle detection algorithm. The rapid aggregation of road traffic data is effectively realized to improve traffic automation management. However, the above method is limited to the transmission image of the fixed camera for traffic video, and the flexibility is poor. Compared with ordinary video surveillance scenes, the video collected by drones has the advantages of wide surveillance range, less target occlusion, and more macroscopic traffic information provided. However, most existing machine learning methods are difficult to process real-time and massive drone video data. For this reason, a vehicle image detection method using deep learning in UAV video is proposed. The innovations of the proposed method are summarized as follows:

(1) Because a variety of different models, different appearances, and vehicle videos shot from different angles are collected from multiple video scenes. Light has a great influence on video recognition. The proposed method performs a spatial brightness translation operation on the original sample. To increase the adaptability of the classifier to different light conditions and sample diversity.

(2) In order to obtain a better feature extraction effect, the proposed method adds focus loss to the basic SSD for optimization to improve the detection accuracy.

2. UAV Video Characteristics Analysis

The video data used was hovered 50 meters directly above the road by the DJI phantom3 professional drone, and the camera lens was shot at -90°. The video resolution is 3840×2160. Video characteristics affect the choice of vehicle detection methods. Compared with ground-based fixed video, UAV video is mainly different in the following six aspects:

(1) Traffic information is more comprehensive, which is more valuable for application and research. From the UAV video, not only traffic information such as traffic flow and speed can be obtained, but also the traffic density of the road section and the accurate vehicle trajectory can be directly obtained [16]. It has important value in the study of traffic flow theory, driving behavior, car following (lane changing) and other traffic theories.

(2) There are more vehicles in the detection range, the smaller the vehicle size, and the greater the difficulty of detection. The UAV video image can contain hundreds of vehicles, so the vehicle size is small and the feature information is less.

(3) The video coverage is wider and the interference information is more. Under the premise of being able to detect vehicles, the UAV video range can reach up to several hundred meters. In addition to the concerned vehicle information in the image, there is also a large amount of invalid information. For example, buildings, street lights, signs and markings, motorcycles, etc.

(4) Different vehicle imaging has different vehicle detection methods. Usually, a fixed ground camera shoots the front or back of the vehicle. The drone shoots the top of the vehicle and uses the line characteristics to detect the vehicle in the fixed video. UAV video uses other methods.

(5) Video jitter is more obvious. Although the camera is installed on the drone's airborne gimbal, the drone is affected by the wind during the hovering flight, and the captured video image still exhibits irregular jitter. This increases the difficulty of accurately detecting vehicles [17].

(6) Due to the limitations of the drone's flight capability and endurance, it is usually only possible to obtain traffic videos in better weather conditions. The effective shooting time does not exceed 20 minutes.

The experimental data is a traffic video taken by a drone in a certain place in Zhengzhou in 2020. The video frame rate is 30 frames per second, and the video resolution is 1920 × 1080. Video 01 was shot at a straight intersection. Video 02 was shot at a T-junction. Video 03 was shot on an elevated section. The first frame of the experimental data is shown in Figure 1. And the detailed information of the experimental data is shown in Table 1.

3. Algorithm Design

3.1. Design Ideas of Vehicle Classifier. To achieve vehicle detection from the perspective of deep learning, use CNN method in deep learning to design a vehicle detector. The vehicle detector is realized by detecting whether the object in each detection frame is a vehicle. Therefore, it is necessary to design a vehicle classifier with improved CNN to realize the two-class classification of cars and non-cars. The process of training and testing the classifier model is shown in Figure 2.

First carry out a preprocessing operation on the training samples. Then put the training samples and corresponding labels into CNN for training, and get an improved CNN model. Then the test samples are also preprocessed, and the prediction results of the model are obtained by improving the CNN model. The prediction result is compared with the test sample label, and the final test result is obtained.

3.2. Dataset Preprocessing

3.2.1. Sample Collection. The size of 50 × 50 is selected as the input image size of the trained classifier, which is also the size of the vehicle detection frame in the actual video. For images whose sample size does not meet the requirements, the original samples that meet the requirements are obtained through cropping and scaling operations.

Because there is no vehicle sample set that includes different models and different angles. In multiple videos and many pictures, 2503 positive samples and 2,698 negative samples are collected to form a relatively complete vehicle classification data set. The pictures in the positive sample set include vehicles of different brands and types, and the angles at which they are taken are also different. The light conditions and background of each sample are also different, which fully guarantees the diversity of positive samples. If the classifier can identify these types of vehicles with different backgrounds, it is enough to show that the proposed classifier has strong adaptability [18, 19]. The negative sample set includes various background scenes without vehicles that may appear around the road. For example, there may be road signs, tree shades, pedestrians, trees, etc., which are also sufficiently diverse [20, 21].

3.2.2. Data Preprocessing. In order to enhance the adaptability of the classifier to different lighting environments and in the shade, the original data set is preprocessed in the HSV space. In the HSV color space, the V value represents the brightness, which is the brightness of the color, and it is also expressed as a percentage. Its value ranges from 0%, which means completely black, to 100%, which means completely bright. Therefore, the brightness can roughly indicate the brightness of the entire scene, and the brightness of the scene can be changed by the brightness shift operation. Shift the average V value of each original picture to 20%, 30%, 40%, 50%, 60% (because it is too dark at 20%, and the scene is too bright at 70%). While keeping the H value and S value unchanged, the new V value corresponding to each point is:

$$V_{\text{new}}(a,b) = \frac{V_{\text{old}}(a,b) \times \overline{V}_{\text{new}}}{\overline{V}_{\text{old}}}, \tag{1}$$

where $V_{\text{new}}(a,b)$, $V_{\text{old}}(a,b)$, $\overline{V}_{\text{new}}$, $\overline{V}_{\text{old}}$ represent the new lightness value, the old lightness value, the new lightness mean value and the old lightness mean value, respectively.

Through the above processing, a sample set covering multiple different brightness values is obtained. The number of positive and negative samples in the sample set has increased to 15,426 and 17,071 respectively. Before processing, first convert the image from RGB (Red-Green-Blue) to HSV space. After processing, all pictures need to be converted back to RGB space.

After that, all the samples processed above are grayed out. Using $R(a,b)$, $G(a,b)$ and $B(a,b)$ to denote the components of the R, G, and B channels of the pixel at position (a,b), respectively. Then the gray value of the corresponding point:

$$G(a,b) = 0.2989 \times R(a,b) + 0.5870 \times G(a,b) + 0.1140 \times B(a,b). \tag{2}$$

After grayscale, the grayscale value range of the grayscale image is [0, 255]. Finally, perform a simple normalization operation on the grayscale image data to obtain the input layer sample data:

$$I(a,b) = \frac{G(a,b)}{255}. \tag{3}$$

In summary, the preprocessing process of the original image is shown in Figure 3.

3.3. SSD Target Detection. The SSD network uses the classic network VGG as the basic network. Adding auxiliary structure after the basic network produces a detection with the following main characteristics.

The SSD network uses multi-scale feature map detection. The network adds the convolutional feature layer to the end of the extreme base. The size of these layers gradually decreases, and multiple scale detections are predicted values [22, 23]. The detected convolution model is different for each feature layer. Each feature layer (or optional existing feature layer of the base network) can use a set of convolution filters to generate a fixed set of predictions. For the feature layer of size $m \times n$ with d channels, use the $3 \times 3 \times d$ convolution kernel convolution operation to generate the score of category or the coordinate offset relative to the default box. At

Table 1: Details of experimental data.

No.	Length of time	Total frames
01	3 minutes and 35 seconds	5189
02	6 minutes and 12 seconds	12037
03	5 minutes and 49 seconds	10915

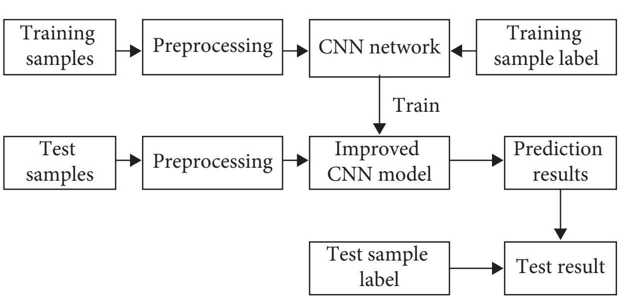

Figure 2: Process of training and testing CNN classifier.

each $m \times n$ size position where the convolution kernel operation is applied, an output value is generated. The output value of the bounding box offset is measured relative to the default box, and the default box position is relative to the feature map. The core of the SSD algorithm is to use both high-level feature maps and low-level feature maps for detection. The feature maps of different layers are used to imitate the detection of objects at different scales. The default candidate box refers to a series of fixed-size bounding boxes on each small grid of the feature map, as shown in Figure 4.

Assume that there are k default candidate boxes for each cell in each feature map. Each default candidate box needs to predict p category scores and 4 coordinate information. If the size of a feature map is $m \times n$, then each feature map has $m \times n \times k \times (p + 4)$ outputs. The meaning of these outputs is that a 3×3 convolution kernel is used, and the number of convolution kernels when convolving the feature map of this layer contains two parts. The first part of the quantity $m \times n \times k \times p$ is the output of confidence, which represents the confidence of each default candidate box, that is, the probability of the category. The second part $4 \times m \times n \times k$ is the output of the coordinate position, which represents the coordinate of each default candidate box after returning.

In training, another concept is a priori candidate box. Refers to the default alternative box selected in practice. During training, a complete picture is input to the network to obtain several feature maps [24]. For positive sample training, it is necessary to first match the prior candidate box with the correctly labeled candidate box. A successful match indicates that the a priori candidate box is the target to be

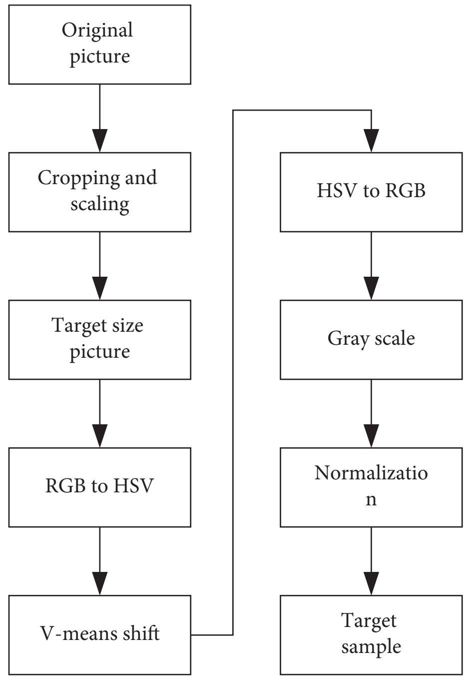

Figure 3: Preprocessing process of sample set.

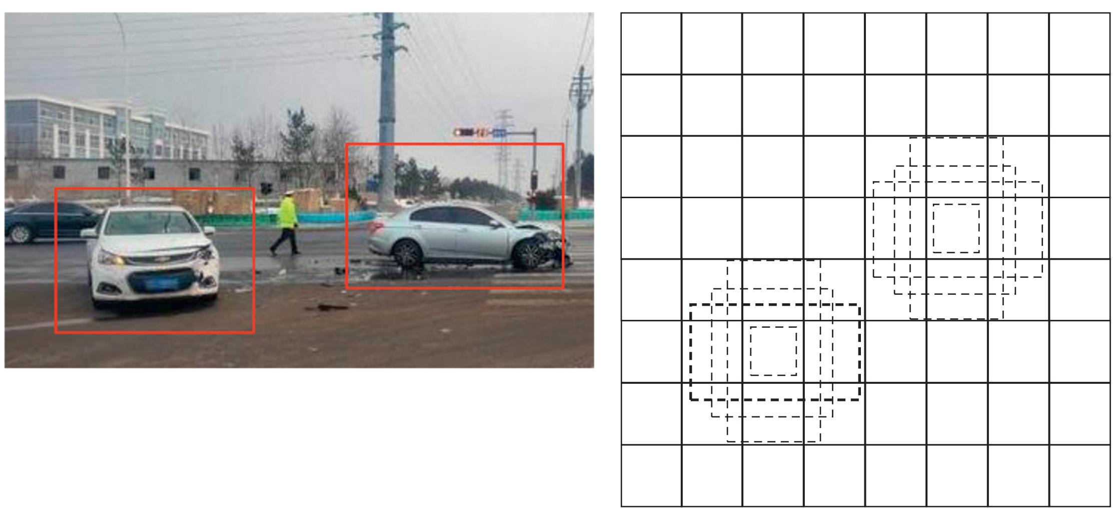
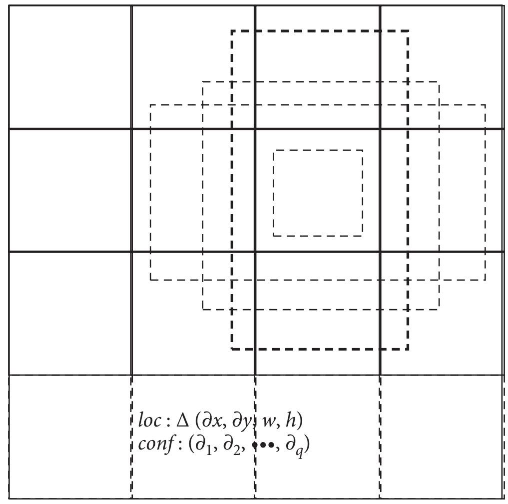


(a) (b)

Figure 4: Continued.



(c)

Figure 4: The generation of default candidate box (a) Image with GT boxes (b) 8 × 8 characteristic map (c) 4 × 4 characteristic map.

detected, but there is still a certain gap from the complete target. The purpose of training is to ensure the classification confidence of the default candidate box while returning the prior candidate box to the correctly labeled bounding box as much as possible. For example, suppose there are 2 correctly labeled bounding boxes in a training sample. There are totally 8732 default candidate frames obtained in all feature maps. Then there may be 10 and 20 a priori candidate boxes that can be matched with the two correctly labeled bounding boxes respectively. The training loss includes positioning loss and regression loss.

Experiments have shown that the greater the number of default candidate box shapes, the better the final effect. The default candidate box used here is the same as the candidate box in Faster R–CNN. The difference is that the candidate box in Faster R–CNN is only used in the last convolutional layer, but in SSD, the default candidate box is applied to multiple different feature maps. The size and aspect ratio of the default candidate box are determined by certain calculations. Assuming that g feature maps are used for prediction, the size of the default candidate box for each feature map is calculated as follows:

$$s_k = s_{\min} + \frac{s_{\max} - s_{\min}}{g-1}(k-1), \quad k \in [1, g], \tag{4}$$

where, $s_{\min} = 0.2$ indicates that the size of the bottom layer is 0.2. $s_{\max} = 0.9$ indicates that the size of the highest layer is 0.9.

For the aspect ratio, it is represented by β_r. There are five aspect ratios, namely $\beta_r = \{1, 2, 3, 1/2, 1/3\}$. Therefore, the width of each default candidate box is calculated as $w_k^\beta = s_k\sqrt{\beta_r}$. The calculation formula for height is $h_k^\beta = s_k\sqrt{\beta_r}$. In addition, when the aspect ratio is 1, specify the size as $s_k = \sqrt{s_k s_{k+1}}$ additionally. That is, there are a total of 6 different default candidate boxes.

The center position of each default candidate box on the feature map is set to $(a + 0.5/|f_k|, b + 0.5/|f_k|)$. Where $|f_k|$ represents the size of the k th feature map. The default frame coordinates captured by $a, b \in (0, |f_k|)$ make it always within [0, 1]. In fact, the distribution of default boxes can be designed to best fit a particular database.

By combining the predictions of all default boxes of different sizes and aspect ratios of many feature maps at all positions, a diversified set of predictions can be obtained, covering various input object sizes and shapes [25].

After the default candidate box is matched with the correctly labeled target box, it can be known that most of the default candidate boxes are negative samples, especially when the number of possible default selected boxes is large. This leads to a serious imbalance of positive and negative samples during training. The SSD algorithm is sorted according to the highest confidence of each default candidate box. And choosing those candidate boxes with high confidence so that the ratio between positive and negative samples is at most 3 : 1, instead of using all negative samples. After such processing, the optimization speed of the training process is faster and more stable.

In order to make the model more robust to the size and shape of various input objects, each training image is randomly sampled by one of three methods. (1) Using the entire original image as input. (2) Sampling a small fragment to make the object's smallest Intersection over Union (IoU) overlap of 0.1, 0.3, 0.5, 0.7, or 0.9. (3) Randomly sample a segment. The size of each sample segment is between 0.1 and 1 times the size of the original image, and the aspect ratio is between 0.5 and 2. If the correctly labeled target frame is in the sample segment, the overlapped part is retained. After the above sampling steps, the size of each sampling slice is adjusted to a fixed size and flipped horizontally with a probability of 0.5.

The commonly used objective loss function for multi-classification tasks is cross-entropy loss. Assuming that there are n samples in the task and the classification target has C class, the cross entropy CE is defined as follows:

$$\mathrm{CE} = \frac{1}{n}\sum_{i=1}^{n}\sum_{j=1}^{C} - y_j^{(i)} lb\Big(\widehat{f}\big(x^{(i)}\big)_j\Big), \tag{5}$$

where, $\widehat{f}(x)$ represents the predicted class probability. y is the one-hot vector of the actual category. The cross entropy function itself treats all types of objects equally. When encountering category imbalance phenomenon, it is easy to cause prediction deviation, and it is impossible to strengthen training on difficult-to-separate samples. In view of the category imbalance phenomenon, a weighting factor α can be introduced for different categories to weaken the influence of a large number of categories on the loss value:

$$\mathrm{CE} = \frac{1}{n}\sum_{i=1}^{n}\sum_{j=1}^{C} - \alpha_j y_j^{(i)} lb\Big(\widehat{f}\big(x^{(i)}\big)_j\Big). \tag{6}$$

Aiming at the problem of difficult samples, the higher the predicted probability of a sample, the stronger the model's ability to recognize the sample. This sample becomes an easy-to-separate sample, and vice versa, it is a difficult-to-separate sample. Based on the predicted probability, a weighting factor β can be introduced to weaken the influence of easily divided samples on the loss value. β is defined as follows:

$$\beta_j^{(i)} = \big(1 - y_j^{(i)}\big)^{\gamma}, \tag{7}$$

where γ is an adjustable hyper parameter. The focus loss FL is defined as:

$$\mathrm{FL} = \frac{1}{n}\sum_{i=1}^{n}\sum_{j=1}^{C} - \alpha_j \beta_j^{(i)} y_j^{(i)} lb\Big(\widehat{f}\big(x^{(i)}\big)_j\Big). \tag{8}$$

This paper applies the above-defined multi-category focus loss to the SSD model. The values of α and γ are both 0.75.

The SSD algorithm uses VGG16 as the basic network. First, perform pre-training on the data set, and convert Full Connection Layer (FC) 6 and FC7 into convolutional layers. The parameters are sampled from the FC6 and FC7 layers, and all dropout layers and FC8 layers are deleted. And using Stochastic gradient descent (SGD) to fine-tune the model. For each data set, the learning rate decay strategy is slightly different.

3.4. Network Training. Before training, perform image enhancement by performing operations such as horizontal flipping, contrast enhancement, saturation enhancement, and color transformation on all images. All models are implemented using the Tensorflow framework and trained for 400 cycles on the Nvidia1080 graphics card. For the Faster R–CNN model, the images are uniformly scaled to 1280×720 input network. The initial learning rate is 0.001. It drops to 1/10 of the previous value every 100 cycles. The gradient update method uses small batch stochastic gradient descent with momentum. The momentum factor is 0.99. For SSD models, the images are uniformly scaled to 500×500 input network. The initial learning rate is 0.001. Every 10 cycles it drops to 0.96 times the previous value. The gradient update uses RMSProp optimizer. The momentum factor is 0.99.

4. Experiment and Analysis

The hardware operating environment of the experiment is an Intel Core i5-6500 CPU, a notebook computer with a frequency of 3.20 GHz and a memory of 32 GB. The software environment mainly includes Windows 10 system, Visual Studio 2017 development environment and Open CV 3.2.0. Open CV is an open source computer vision library that provides various graphics processing functions. Open CV implements many general algorithms in graphics processing and computer vision. Among them, modules such as 2D features in Open CV, high-level interaction, video image reading and writing, image processing, and target tracking are mainly used. The proposed method is developed independently, and the development language is C++.

4.1. Evaluation Index. The goal of vehicle detection is to detect as many vehicles as possible. At the same time, as little as possible misdetection of vehicles occurs. In a real-world vehicle video stream, True Positive Rate (TPR), False Positive Rate (FPR), Average True Positive per Frame (ATP/Frame), Average False Positive per Frame (AFP/Frame), Average False Positive per Vehicle (AFP/Vehicle) and other indicators are evaluated. Among them, the last three index parameters are related to the actual video stream. Therefore, it is only used to evaluate the detection effect of the vehicle detection method in the real scene video stream. The first two parameters are not necessarily related to the video stream, and can also be applied to the training set and test set to evaluate the vehicle classification method.

TPR is the proportion of the number of vehicles Q_{TP} correctly detected as TP by the detector or classifier in a video stream segment or sample set to the actual total number of vehicles Q_{Total}:

$$\mathrm{TPR} = \frac{Q_{\mathrm{TP}}}{Q_{\mathrm{Total}}}. \tag{9}$$

FPR is the proportion of the number of targets Q_{FP} incorrectly determined as vehicles (FP) by the detector or classifier in all target Q_{P} determined as vehicles in a video stream segment or sample set:

$$\mathrm{FPR} = \frac{Q_{\mathrm{FP}}}{Q_{\mathrm{P}}}. \tag{10}$$

ATP/Frame is the average number of vehicles correctly detected per frame in a video stream segment:

$$\frac{\mathrm{ATP}}{\mathrm{Frame}} = \frac{Q_{\mathrm{TP}}}{z_{\mathrm{Frames}}}. \tag{11}$$

AFP/Frame is the number of vehicles that have been misdetected as non-vehicle targets in each frame in a video stream segment:

Table 2: Classification accuracy of different classifiers.

Classifier type	Number of correct tags/total tags	Accuracy rate (%)
LDM	2175/3068	70.89
SVM	2734/3068	89.11
Proposed method	2912/3068	94.92

$$\frac{\mathrm{AFP}}{\mathrm{Frame}} = \frac{Q_{\mathrm{FP}}}{z_{\mathrm{Frames}}}. \tag{12}$$

AFP/Vehicle is the ratio of the number of misdetected targets to the total number of vehicles $\Omega_{\mathrm{Vehicles}}$ in a traffic video stream segment:

$$\frac{\mathrm{AFP}}{\mathrm{Vehicle}} = \frac{Q_{\mathrm{FP}}}{\Omega_{\mathrm{Vehicles}}}. \tag{13}$$

By evaluating the above indicators of the video stream or sample set, the detection performance of a classifier or detector can be evaluated. Based on the above indicators, the higher the TRP, ATP/Frame, and the lower the FPR, AFP/Frame, AFP/Vehicle, the better the performance of vehicle detection method.

4.2. Compare the Classification Effects of Different Classifiers. First, compare the classification results of the proposed method with linear discriminant analysis (LDA), support vector machine (SVM) and other shallow classifiers on the test sample set.

It can be seen from Table 2 that among the shallow classifiers, the SVM classifier performs well in many sample sets. The same applies to the test sample set consisting of 3068 test samples. The classification accuracy rate using LDA is only 70.89%. Using the SVM classifier can increase the accuracy by about 19% to 89.11%. The proposed method has undergone 10-fold cross-validation, and finally obtained a relatively stable classification accuracy of 94.92%, which is 5 percentage points higher than the SVM method. This shows that the proposed method has a better classification effect than shallow classifiers in processing two-dimensional data sets. It is more suitable for vehicle detection.

Specifically, the entire test sample set is classified by the proposed method. The results are shown in Table 3.

According to the number of TP, TN, FP, and FN in Table 3, the sensitivity of the proposed method can be obtained: $S_n = \mathrm{TP}/\mathrm{TP} + \mathrm{FN} = 1399/1399 + 62 \times 100\% = 95.76\%$; The specificity is: $S_P = \mathrm{TN}/\mathrm{TN} + \mathrm{FP} = 1581/1581 + 26 \times 100\% = 98.38\%$; Therefore, the first type of error rate (false positive rate) of the classification model: $1 - S_p = 1.62\%$ indicates that 1.62% of the real non-vehicle samples were incorrectly judged as vehicle samples. The second type of error rate (false negative rate): $1 - S_n = 4.24\%$ indicates that among all the vehicle samples, 4.24% of the vehicles were not detected and were misjudged as vehicles.

The detailed classification results of the proposed method and LDA and SVM methods on the test set are shown in Table 4.

It can be seen from Table 4 that in the entire sample set, the TPR of the proposed method is 16.77% and 7.94% higher than that of the LDA and SVM classifiers, respectively. The FPR is 18.03% and 5.27% lower than LDA and SVM, respectively. It shows that under the comprehensive evaluation of these two performance indicators, the proposed method has better detection effect and fewer false detections.

The preprocessing of the original sample will have a greater impact on the later vehicle detection. Therefore, before and after preprocessing, the classification accuracy results of the three methods are shown in Table 5. The second column of data in the table is the classification accuracy of the three methods for the original samples without HSV spatial brightness translation. The third column of data corresponds to the training result after the original sample is subjected to a large brightness shift in the HSV color space.

It can be seen from Table 5 that the classification accuracy of LDA in the two cases is not much different, the difference is only 0.36%. However, the accuracy of SVM and the proposed method under the preprocessing of HSV data is about 5% higher than that of unprocessed data. It can be seen from this that sample training is required for vehicle detection. A richer sample set can significantly improve the classification performance of the classifier.

4.3. Performance Comparison of Different Models. In order to demonstrate the detection performance of the proposed model, compare it with reference [9, 11], and [15], and the results are shown in Table 6.

It can be seen from Table 6 that compared with other comparison models, the detection effect of the proposed model is better, and its TPR reaches 96.49%. Reference [9] realizes the automatic detection of smoke vehicles based on multi-feature fusion and improved integral projection method. It can accurately detect vehicles to a certain extent. However, the detection method is relatively traditional, and it is difficult to apply to UAV video data. Therefore, the detected TPR is only 81.92%. Reference [10] uses motion detection algorithms to acquire vehicle information, and uses temporal multi-layer perception or long- and short-term memory networks to train vehicle recognition models. Compared with reference [9], it can effectively improve the recognition accuracy, with a TPR of 88.61%. However, the UAV moves fast and has a lot of video data, so the recognition effect is limited to a certain extent. Reference [15] uses the regional CNN network to achieve vehicle detection, which can quickly aggregate road traffic data, thereby improving automated traffic management. However, it lacks data preprocessing, so the recognition accuracy rate of the proposed method is reduced by 3% to 6%. All the proposed models can achieve better vehicle detection. It uses HSV for data preprocessing, and both deep learning models can complete accurate learning of massive data.

Table 3: The classification effect of the proposed method in the test sample set.

Number	Judged as positive sample	Judged as negative sample	Total
Actual positive sample	1399 (TP)	62 (FN)	1461
Actual negative sample	26 (FP)	1581 (TN)	1607
Total	1425	1643	3068

Table 4: Detailed classification results of different methods in the test sample set.

Method	LDA	SVM	Proposed method
Number of positive samples	1461	1461	1461
Number of positive samples detected	1154	1283	1399
Number of negative samples	1607	1607	1607
Number of negative samples detected	1288	1493	1581
TPR (%)	78.99	87.82	95.76
FPR (%)	19.85	7.09	1.82

Table 5: Classification accuracy of different methods before and after pretreatment of original samples.

Method	Accuracy rate (%) (Raw data)	Accuracy rate (%) (HSV)
LDA	70.88	71.24
SVM	82.01	88.26
Proposed method	90.79	95.03

Table 6: Vehicle detection results of different models.

Model	TPR (%)
Ref. [9]	81.92
Ref. [11]	88.61
Ref. [15]	90.27
Proposed method	96.49

5. Conclusion

The accuracy and stability of UAV video vehicle detection is crucial to extracting traffic information. For this reason, a vehicle detection method using deep learning in UAV video is proposed. Based on the HSV spatial brightness translation operation of the original samples, two deep learning models, the improved Faster R–CNN and SSD, are used to detect vehicles in UAV videos. Based on the DJI UAV's shooting video data set for experimental analysis. The results show that the use of HSV for data transformation can enrich the sample set, thereby improving the detection accuracy. The accuracy before and after pretreatment is increased by about 5%. The SSD model of the proposed method processes the data after HSV transformation, and the powerful data learning ability of the model can improve the detection effect. Its vehicle detection rate reached 96.49%. And the SSD model can act on multiple feature maps, and its detection effect is better.

Deep learning technology has shown great potential in target detection, and it is more advantageous for rapid target detection in complex scenes. However, deep learning requires large samples for support, and speed is not an advantage. These two determine the limitations of deep learning in real-time target tracking applications. Therefore, in the future, we will focus on the application of deep learning under small sample training in video target detection, and focus on solving real-time problems.

To overcome the limitations of conventional breast screening methods based on digital mammography, a quasi-3D imaging technique, digital breast tomosynthesis (DBT) has been developed in the field of breast cancer screening in recent years. In this work, a computer-aided architecture for mass regions segmentation in DBT images using a dilated deep convolutional neural network (DCNN) is developed. First, to improve the low contrast of breast tumour candidate regions and depress the background tissue noise in the DBT image effectively, the constraint matrix is established after top-hat transformation and multiplied with the DBT image. Second, input image patches are generated, and the data augmentation technique is performed to create the training data set for training a dilated DCNN architecture. Then the mass regions in DBT images are preliminarily segmented; each pixel is divided into two different kinds of labels. Finally, the postprocessing procedure removes all false-positives regions with less than 50 voxels. The final segmentation results are obtained by smoothing the boundaries of the mass regions with a median filter. The testing accuracy (ACC), sensitivity (SEN), and the area under the receiver operating curve (AUC) are adopted as the evaluation metrics, and the ACC, SEN, as well as AUC are 86.3%, 85.6%, and 0.852 for segmenting the mass regions in DBT images on the entire data set, respectively. The experimental results indicate that our proposed approach achieves promising results compared with other classical CAD-based frameworks.

1. Introduction

Breast cancer is one of the leading causes of diseases in women worldwide, and it is also the most common cause of cancer deaths in women. Since the late 70s of the last century, the incidence of breast cancer worldwide has been increasing. According to the report "The Status and Trends of Cancer in China 2017" released by the National Cancer Center, the incidence of breast cancer ranks first among female malignant tumours [1]. Early diagnosis and treatment can effectively reduce the mortality of breast cancer patients and improve their quality of life [2]. In developed countries, organized and opportunistic screening programs have significantly reduced breast cancer mortality. Although two-dimensional mammography uses a new detector, it is well known that it still has its limitations because the normal structures and pathological structures may overlap each other when obtaining the transmission X-ray image [3].

Digital breast tomosynthesis (DBT) is a quasi three-dimensional imaging technology. An X-ray tube rotates in a limited arc, and a digital detector obtains a series of low-dose projection images to reconstruct the tomographic images [4]. DBT can evaluate the dense breast tissues in detail by describing the breast tissues in three dimensions to overcome the limitation that standard mammography only displays a two-dimensional image. In addition, the reconstructed DBT slice images can partially reduce the often called "anatomical" or "structure" noise caused by tissue superimposition in conventional mammography [5]. It is crucial to segment the breast mass regions in DBT slice images to provide accurate radiologists' qualification. Although DBT has higher sensitivity and specificity in breast mass regions detection, it has dramatically increased the amount of data in the image, resulting in manually annotating breast mass regions in DBT images. It is not only tedious but also time consuming for radiologists [6]. Hence, it is significant to develop a computer-aided segmentation framework for DBT mass regions to aid radiology clinicians to reduce the workload of manual annotation for the radiologists.

Automatic segmentation of breast mass regions is challenging because the breast mass regions have low contrast differences among their neighboring tissues [7]. Although it is difficult to achieve accurately segment breast mass regions, many studies focus on designing various automatic or semi-automatic learning-based approaches for breast mass regions segmentation in recent years [8–10]. Whereas automatic segmentation of breast masses from two-dimensional (2D) mammography has been widely investigated, little has been reported on segmenting breast mass regions automatically for DBT slice images. For each mass region, eight shape parameters and ten enhancement texture features were extracted and then an artificial neural network was used to build the diagnostic model; the average area under the receiver operating curve (AUC) reported by the system was 0.76 [11]. Breast tissues detection results were obtained using the multivariate statistical analysis of mass spectrometer data with a sensitivity of 90.9% and specificity of 98.8% [12]. If two-dimensional projected slice images and three-dimensional reconstructed volume can be combined for analysis, a computer-aided diagnosis (CAD) system of DBT can produce a lower false-positive rate [13]. In addition to research on breast segmentation by maximizing the radial gradient index in three dimensions of Reiser et al. [14], some publications only used a single representative two-dimensional slice [15, 16] to quantitatively evaluate the accuracy of mass regions segmentation in DBT images. Chan et al. [17] presented an approach on automatic detecting for breast mass regions. van Schie et al. [18] proposed an automated segmentation approach of breast mass regions, which used the mammography image data set to train the models. Kim et al. [19] concentrated on the influence of the saliency of the reconstructed slices on DBT mass regions' detection performance and then presented an automated detection system of breast mass regions based on the saliency of DBT reconstructed slices. Palma et al. [20] built a CAD framework based on the antagonistic reasoning and fuzzy theory, which can detect breast mass regions in reconstructed DBT images.

In recent years, deep learning has been successfully utilized in various medical image recognition tasks, such as tumour boundary detection, region segmentation, and pattern classification, because it does not adopt various handcrafted features in supervised manners [21–23]. The ResNet-50 model pretrained with transfer learning and class activation map technique were employed in breast cancer classification and localization, resulting in an AUC of 0.96 [24]. Sampaio et al. [25] proposed a computational methodology, where the quality of mammography image was improved initially by preprocessing, and the external region of breast was removed to reduce noise and highlight the internal structure of breast; next, the region was segmented and shape descriptors (such as eccentricity, circular disproportion and density) were extracted by using cellular neural networks, followed by an SVM classifier; they reported a sensitivity of 80% and AUC of 0.87. Wichakam and Vateekul [26] used support vector machines (SVMs) with ConvNets to detect mass on mammograms, where the reported accuracy was 98.44%, which was superior to the baseline (ConvNets) by 8%.

In this study, we combine DBT, a breast cancer screening method, with the latest machine learning and deep learning technologies. We focus on the accurate segmentation of the mass regions in DBT images using a deep convolutional neural network (DCNN) architecture, which is a fully convolutional network with dilated filters (dilated DCNN) instead of pooling filters. Besides, instead of training the model with the whole image, we implement a patch-based training approach. To produce an end-to-end segmentation output, we apply a fully convolutional network approach. Our system is used to every slice in a volume separately.

The structure of the paper is as follows: In Section 2, the data sets used and dilated DCNN architecture are introduced in detail, and then the training and testing methods of the dilated DCNN model for the mass regions segmentation in DBT images are introduced; Section 3 provides the details and results of the experiments performed in this study; Section 4 introduces the discussion, and the paper ends with Section 5, in which the conclusions and future work are presented.

2. Methodology

In this section, we will describe the data set used, the sampling procedure for generating input image patches, the architecture of the dilated DCNN, and the strategy for training the dilated DCNN, followed by the approach applied to segment the mass regions in DBT images and the evaluation metrics used.

A fully automatic framework for mass regions segmentation in DBT images is developed, an overview of the proposed architecture is shown in Figure 1. We apply a fully convolutional network approach to produce an end-to-end segmentation output. Our system is used to every slice in a volume separately.

2.1. DBT Image Data sets. The benchmarking clinical DBT image data used in this study are obtained from the Zhejiang Chinese Medical University Affiliated Guangxing Hospital (DBT_gx) and Zhejiang Provincial Hospital of Traditional Chinese Medicine (DBT_tcm) with Institutional Review Board (IRB) approval. Each DBT volume is produced by low-dose exposure, and the total shot dose should be within the range of a regular mammogram dose. Each patient's DBT data is acquired in medio-lateral oblique and cranio-

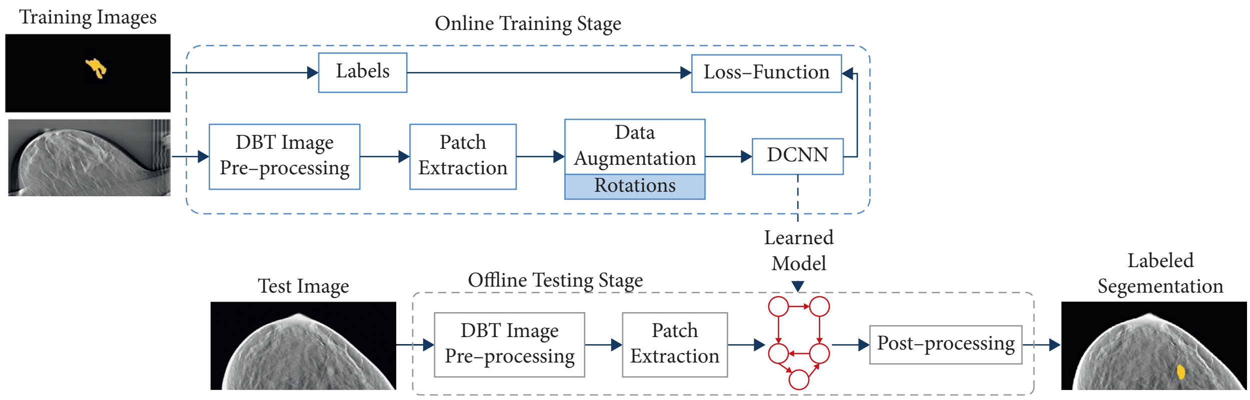

Figure 1: Overview of the proposed dilated DCNN approach.

caudal views (Siemens Mammomat Inspiration DBT system), using a total tomographic angular range of 60° with a 5° rotation increment and 12 projection views. Both sets of DBTs are reconstructed to 1 mm spacing slice with a resolution of 1200 × 901 pixels using the simultaneous algebraic reconstruction technique. We convert the images into TIFF stack/slices and used data in TIFF format to keep more details.

A total of 66 cases of breast cancer patients is included with a mean age of 53.65 years and an age range of 28–70 years. The entire DBT data set includes 146 views from 73 breasts with 97 masses, with size ranged from 4.7 to 37.8 mm (mean = 16.3 mm, median = 17.6 mm). Among them, 42 are benign lesions (absolutely healthy) and 55 were malignant lesions as determined by biopsy with subsequent histopathologic analysis. For each view (medio-lateral oblique or cranio-caudal), the number of slices ranged from 50 to 80 (mean = 69, median = 61). Two experienced radiologists manually annotate 97 masses and compared their annotations to reduce possible subjective errors. If there are any inconsistencies, the correct annotation of the mass regions in the image is determined by doctor consultation.

2.2. Slice Image Preprocessing. For a typical DBT screening system, radiation exposure is a vital factor to avoid the risk of radiation-induced cancer. Hence, the low radiation dose is usually used to generate the DBT images. However, the total radiation dose of DBT is slightly higher than that of standard mammography. Generally, DBT image generally contains Poisson distribution noise. Considering the top-hat transformation can not only preserve more local details and highlight the hidden information but also suppress noise amplification. DBT images are preprocessed before the input patch extraction step, including using the top-hat transformation to enhance the contrast between the candidate breast mass location regions and background tissues. Furthermore, to improve the low contrast of breast tumour candidate regions and depress the background tissue noise in the DBT image effectively, a constraint matrix generated by an isotropic radial basis function centered on the candidate breast mass location region with a variance δ^2 (δ is 5 mm) is established and multiplied with the DBT image. Figure 2 shows the DBT image preprocessing results before and after preprocessing procedure, where Figures 2(a), 2(b) are the DBT image before and after preprocessed, respectively.

2.3. Input Patch Extraction. In our research work, compared with other DCNN-based detection problems, the DBT data sets available have a small number of image samples, so using the whole image directly is likely to result in overfitting. We split the entire DBT images into patches to address this issue, which increases data set dimension and complexity. As shown in Figure 3, we apply the sliding window method to scan the entire DBT image data and extract all possible input patches. All the patches are then classified according to the ground truth provided in the data sets. If the central pixel of an input patch is in the breast mass region, the input image patch is marked as positive (breast mass region candidate); Otherwise, it is designated as a negative (no mass region) label. Because the no mass regions can also provide valuable information for breast mass regions segmentation in DBT images, we extract image patches from breast mass regions and no breast mass region to augment the training image data. In other words, we use the image patches extracted from the no breast mass regions as the additional negative sample of dilated DCNN architecture training to help the proposed model distinguish the confounding regions and breast mass regions in the DBT images.

2.4. Dilated DCNN Architecture. This part will briefly introduce the architecture of the proposed dilated DCNN model and its application to our DBT mass regions segmentation framework. One of the problems of traditional typical CNN architectures using the max-pooling technique is that they will down-sample the image, resulting in segmented output with a resolution smaller than the input size. As shown in Figure 4 and Table 1, we use a new convolution network architecture, using dilated convolutions specially designed to get dense segmented output. The purpose of this model is to combine the multiscale context information systematically without losing the resolution, which is based on the dilated convolution to support the exponential

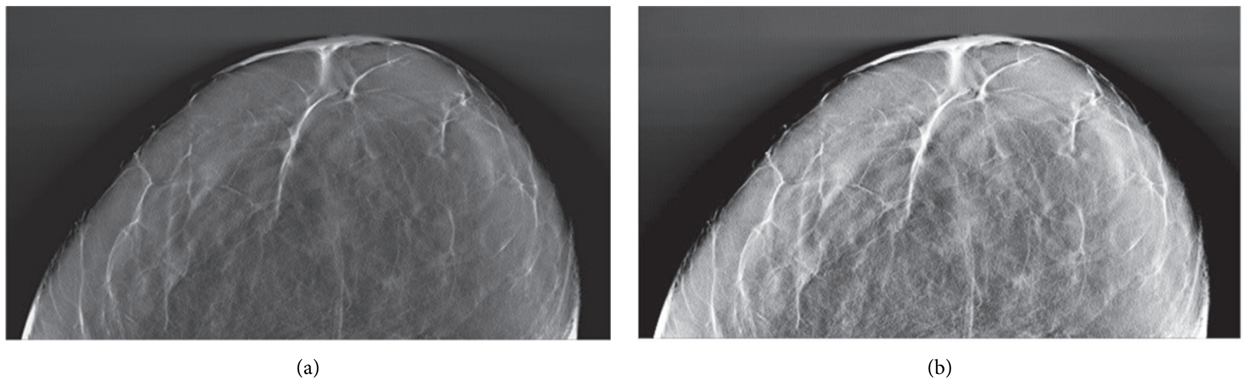

Figure 2: DBT image preprocessing results before and after preprocessing procedure. (a) DBT image before preprocessed. (b) DBT image after preprocessed.

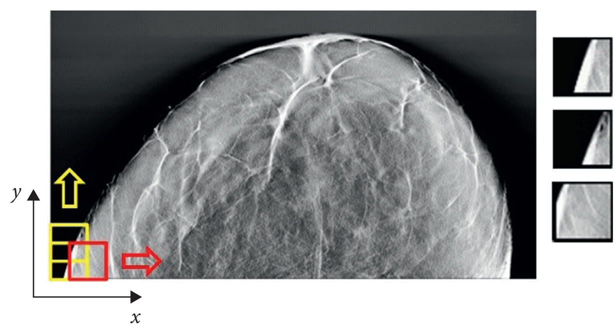

Figure 3: Sliding window method to scan the entire DBT image data and extract all possible input patches.

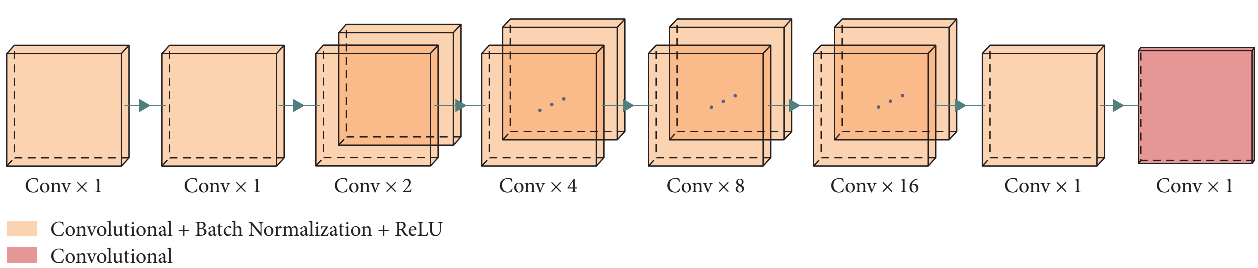

Figure 4: The proposed DCNN architecture.

expansion of the received field without losing the resolution or coverage.

Let f: Z^2 be a discrete function. Let $\Omega_k = [-k, k]^2 Z^2$, and let r: $\Omega_k \longrightarrow R$ be a discrete filter of size $(2k+1)^2$. The discrete convolution operator can be defined as

$$(f * r)(p) = \sum_{s+t=p} f(s) r(t). \tag{1}$$

We now generalize this operator. Let d be a dilation factor and let $*_d$ be defined as

$$(f *_d r)(p) = \sum_{s+dt=p} f(s) r(t). \tag{2}$$

We will refer $*_d$ as a dilated convolution or d-dilated convolution.

2.5. Patch-Based Training. The DBT image data sets used in our work exhibit serious class imbalance, i.e. the number of pixels in no breast mass regions is far more than that in breast mass regions. This brings a problem to the model's training because the pixels in the no breast mass regions influence the total loss function more than those in the breast mass regions. To settle this problem, we adopt an image patch-based training approach. In the training process, we balance the training image data by randomly resampling the same number of image patches of every class from all possible patches in each epoch. However, breast mass regions segmentation still has a similar problem of class imbalance. The number of positive samples is far less than the number of negative samples. Therefore, we adopt f_α-measure as cost function, which is also known as the Dice

Table 1: The proposed dilated DCNN configuration and parameters.

Layer	Type	Configuration	Dilation	Number of parameters
1	Convolutional Batch normalization ReLU	$3 \times 3 \times 1 \times 32$	1	2256
2	Convolutional Batch normalization ReLU	$3 \times 3 \times 32 \times 32$	1	18464
3	Convolutional Batch normalization ReLU	$3 \times 3 \times 32 \times 32$	2	36928
4	Convolutional Batch normalization ReLU	$3 \times 3 \times 32 \times 32$	4	73856
5	Convolutional Batch normalization ReLU	$3 \times 3 \times 32 \times 32$	8	147712
6	Convolutional Batch normalization ReLU	$3 \times 3 \times 32 \times 32$	16	295424
7	Convolutional Batch normalization ReLU	$3 \times 3 \times 32 \times 32$	1	295424
8	Convolutional	$1 \times 1 \times 32 \times 2$	1	16384

coefficient. Compared with conventional loss (e.g., mean square error), the f_α-measure enforces a better balance between performance on positive and negative regions, and thus is suitable for the task of mass regions in DBT images (having unbalanced samples in mass regions and nonmass regions).

Denote T and S as the ground truth heatmap and the predicted heatmap, respectively. Let M represent the number of elements (pixels) in T and S, and the f_α-measure-based loss function is defined in formula (3)

$$f_\alpha(S,T) = \frac{\left(1+\alpha^2\right)\sum_{i=1}^{M} s_i t_i}{\sum_{i=1}^{M} s_i + \sum_{i=1}^{M} t_i}, \tag{3}$$

where t_i is the ith element of the ground truth heatmap and s_i is the i-th element of the predicted heatmap. In this paper, we set $\alpha = 1$ based on the number of pixels in mass regions to the number of pixels in nonmass regions. If α is set to a higher value, the model loss mostly comes from the error of the mass regions, thus ignoring the error of the nonmass regions; otherwise, if setting to a smaller value, the model does not pay enough attention to the mass region because of the class imbalance, which reduces the segmentation accuracy.

2.6. DBT Image Data Augmentation. Extend the image data and generate more training data from the original image data to improve the performance of the proposed dilated DCNN model. Typical applications of the DCNN model for medical image analysis and computer vision tasks, rotations, and translations are often used to augment the data. In our work, the DBT image data consist entirely of 2D image patches. Hence, translation operation cannot augment the image data because it will cause a different image patch to have a possibly different class label. However, using rotation operations of the image patches might give some performance improvements. Therefore, we perform the rotation operation by using angles multiple of 90°.

2.7. Segmentation Postprocessing. In DBT images, some small clusters may be mistakenly classified as the breast mass regions. To deal with the problem, we impose a constraint by removing clusters in the segmentation output obtained by the proposed dilated DCNN-based system with less than 50 voxels in volumes.

2.8. Performance Analysis. To compare and analyze the performance with other classical CAD-based frameworks, the evaluation metrics used in this paper are (a) accuracy (ACC), sensitivity (SEN), and specificity (SPE) of the model; ACC refers to the ratio of the number of pixels correctly segmented to the number of total pixels in the image, SEN refers to the likelihood of a positive test among the subjects with the condition, and SPE refers to the probability of a negative test among the subjects without the condition. These three evaluation metrics are defined as follows:

$$\mathrm{ACC} = \frac{\mathrm{TP}+\mathrm{TN}}{\mathrm{TP}+\mathrm{TN}+\mathrm{FP}+\mathrm{FN}}, \tag{4}$$

$$\mathrm{SEN} = \frac{\mathrm{TP}}{\mathrm{TP}+\mathrm{FN}}, \tag{5}$$

$$\mathrm{SPE} = \frac{\mathrm{TN}}{\mathrm{TN} + \mathrm{FP}}. \quad (6)$$

TP, FP, TN, and FN denote true positive, false positive, true negative, and false negative, respectively, (b) free-response receiver operating characteristic curve (FROC), and (c) the area under the receiver operating curve (AUC). The FROC is used to evaluate the performance of the segmentation system on the DBT_gx and DBT_zcm data sets and is plotted between the fraction of correctly identified lesions as true-positive rate and the number of false-positive per volume (FPV) for all decision thresholds.

3. Results

3.1. Experimental Details. In this section, experiments with different training data sets are performed to evaluate the performance of the proposed dilated DCNN model. Note that in all cases, the original resolution of the processed DBT image is used. Patch-level data sets containing image patches of size 256×256 pixels are generated and used as the proposed dilated DCNN model inputs. In all experiments, a stride of 28×28 pixels is used to create the input image patches for training the dilated DCNN. The selection of the stride value is balanced according to the computational requirements and the number of training samples.

We apply the machine learning library Keras to implement the training and testing of the dilated DCNN model in Python 3.6. The training and testing experiments are performed on an NVIDIA Geforce Titan RTX 24G GPU with Intel Xeon Silver 4210 2.2 G GPU. The presented figures are generated using the plotting library matplotlib. To train the dilated DCNN, we used a batch size of 150 input image patches, 1000 batches per epoch, and 1000 epochs. We used an Adagrad optimizer [27] with a learning rate of 0.01.

3.2. Evaluation on Test Data sets. Given the limited data sets available in our study, mass regions segmentation in DBT images is performed using a ten-fold cross-validation strategy. Figure 5 presents FROC curves measuring the proposed dilated DCNN model trained on the DBT_gx and DBT_zcm data sets, respectively. Our dilated DCNN-based model's performance is substantially higher when the framework is tested on the DBT_gx data set with TPR = 0.971 ± 0.029 at 3.3 FPV, compared with that obtained on the DBT_zcm data set with TPR = 0.937 ± 0.008 at 4.0 FPV.

To further assess the mass regions segmentation performance in DBT images of our proposed method based on dilated DCNN, we evaluated the overlap between the proposed DBT mass labels and the ground truth maps. Figure 6 illustrates mass regions segmentation in DBT images on a few testing images using our proposed model. The 1st column shows individual segmentation results with our proposed dilated DCNN model for case #5, case #16, case #20, the 2nd column shows the corresponding ground truth maps, and a red arrow is used to indicate the lesion without obscuring the lesion in the 3rd column, respectively. The examples shown in Figure 5 indicate that the mass regions segmentation outputs predicted by our proposed dilated DCNN model are in high agreement with the manual annotations.

4. Discussion

In this study, a dilated DCNN architecture is specifically designed for the dense prediction of mass regions in DBT images, which systematically aggregates multiscale contextual information without losing resolution. Our proposed model adopts the f_{α}-measure as the cost function to suppress the influence of class imbalance. To generalize the applicability of the proposed dilated DCNN-based framework, we combine the two DBT image data sets into a larger data set, which is called the entire data set. In the experiments, we compare the performance of various typical automatic detection methods of breast mass regions in DBT images in terms of classifier used, DBT image data set size, SEN, ACC, and AUC. As can be seen in Table 2, our model based on dilated DCNN has achieved competitive results than some of them. Among these classic models, we will discuss the research work of Kim et al. [28], Fotin et al. [29], and Samara et al. [30] in detail. They applied deep learning to the detection and segmentation of breast mass regions in DBT images. Their research works evaluated the automated segmentation CAD frameworks for breast masses in DBT images using the hand-crafted feature- and DCNN-based models. The DCNN model proposed by Kim et al. [28] extracted low-level features from the regions of interest (ROIs) and corresponding ROIs, respectively, through the convolutional layers separately, which can recognize the latent bilateral feature representations of breast masses in the reconstructed DBT volumes. To represent the high-level bilateral features of breast masses in DBT images, they combined the low-level features into the fully connected layer. It was reported that the AUC of the latent bilateral feature representation model was 0.847. Fotin et al. [29] developed a DBT mass detection CAD framework using DCNN model. They trained the DCNN with the generated candidate ROIs, which included 1864 mammography breast lesions and 339 breast lesions from DBT images data. According to the report, 86.40% of ACC and 89% of SEN were obtained in their model. Samala et al. [30] proposed a DCNN framework composed of four convolutional layers and three fully connected layers. First, the DCNN model was trained on a large-scale two-dimensional mammography data set. The weights of the first three convolutional layers were frozen, and the rest weights continued to be trained and updated. Through the calculation results of the DCNN model, it can be seen that the AUC value was more than 0.8, and the SEN value was over 80%. As for the method proposed in our work, 87.1% ACC, 86.9% SEN, 88.2% SPE, and 0.859 AUC for the testing data set with 89 DBT volumes are obtained.

In other models not based on DCNN network, we select the studies of Chan et al. [17], van Schie et al. [16], Palma et al. [20], and Reiser et al. [31] for comparative analysis. Chan et al. [17] introduced three methods based on two-dimensional and three-dimensional, as well as the

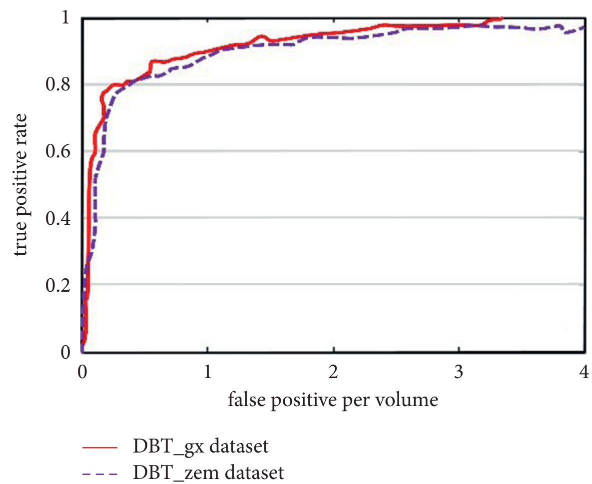

Figure 5: FROC curves for mass segmentation in DBT images on DBT_gx data set and DBT_zcm data set, respectively.

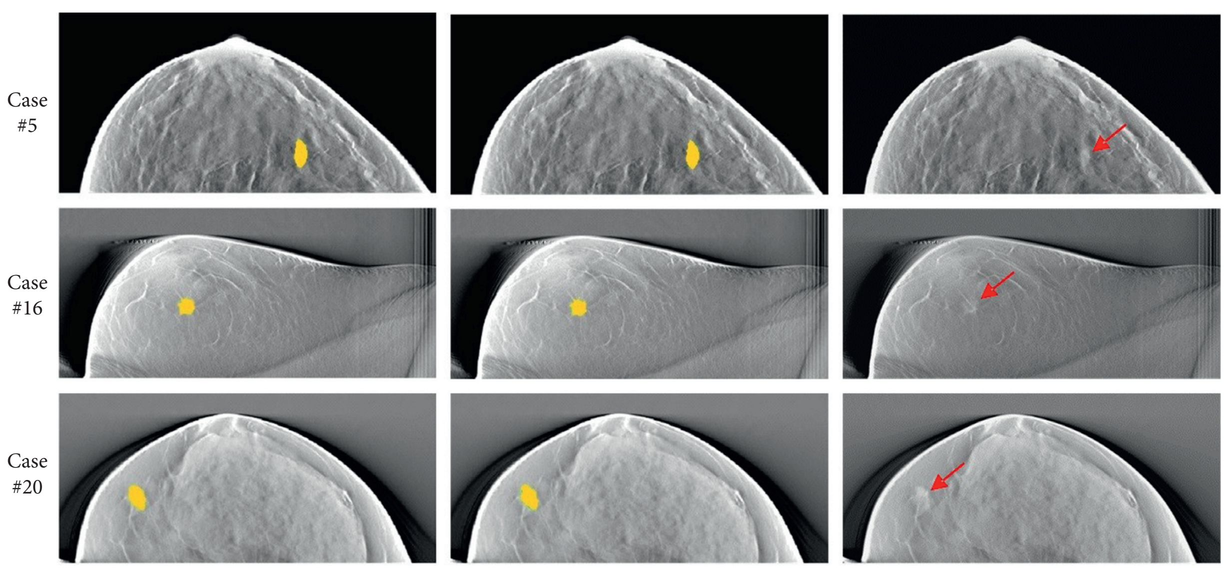

(a) Segmentation result (b) Ground truth map (c) Lesion location

combination of two-dimensional and three-dimensional methods. For the data set contained 100 DBT images from 69 patients with malignant patient cases, they obtained 80% SEN and 1.23 FPs/volume using the hybrid method. van Schie et al. [16] proposed a two-stage method, the first step was to locate ROIs in 2D slice images, and the second step was to locate 3D ROIs on DBT volumes combined with the extracted regions in 2D slice images. The results obtained from the DBT image data of 49 patients with one or more malignant tumours in 192 cases showed that 80% of the Sen was 3 FPs/volume. Palma et al. [20] developed a dual-channel DBT masses detection CAD framework in which each channel classified a type of DBT lesions. They combined discoveries and disjunction fusion methods from the channels. Their results showed that 90% SEN of the 101 DBT volumes contained 53 lesions. Reiser et al. [31] introduced a method of detecting DBT breast mass in two-dimensional projection views, and then reported 90% SEN for 36 DBT volumes using the visual angle range found in combination with detections.

Figure 7 shows examples of automatic segmentation of breast mass regions in DBT images by our dilated DCNN architecture and other typical CAD architectures, which is obtained by overlaying the breast mass regions in DBT images segmented by our proposed architecture and other typical CAD architectures to the original image, respectively. We carefully studied these methods presented by Kim et al. [28], Fontin et al. [29], Samala et al. [30], and Reiser et al. [31], then we configurated the frameworks and developed these models in Python 3.6 with the machine learning library Keras and applied the models to our own data set in our study. Otherwise, it is unfair to make a comparison of the

Table 2: Comparisons of typical studies in mass regions detection of the DBT images.

Method	Classifier	DBT image data set size	Sensitivity	Accuracy	AUC
Chan et al. [17]	LDA	100	80%	/	/

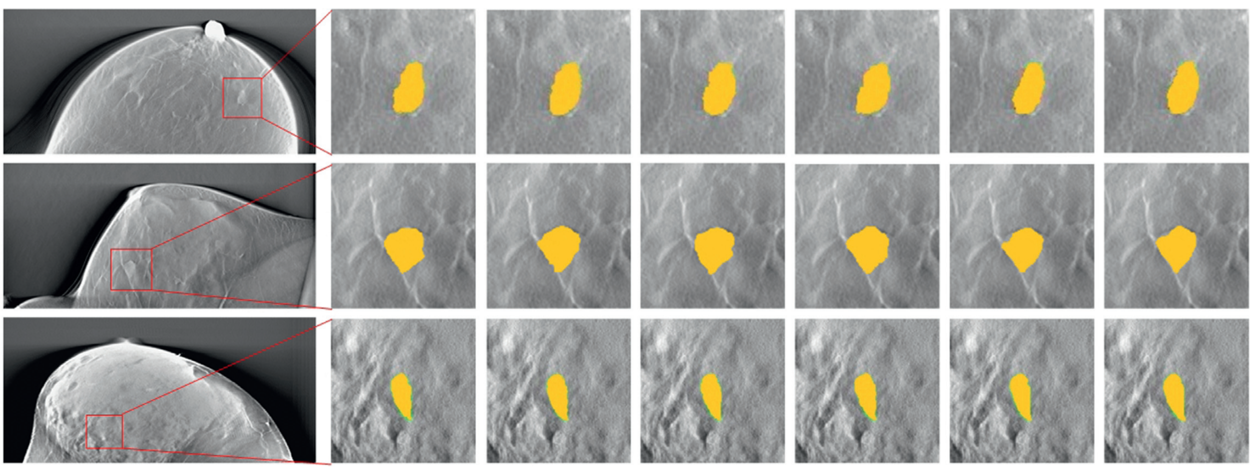

Figure 7: Examples of mass regions in DBT images segmented by our dilated DCNN framework and other typical CAD systems.

performance between our dilated DCNN model with other CAD models in automatic segmentation of breast masses in DBT images because other CAD models are trained and tested on different private data sets that are not available in public. Although the automatic segmentation model proposed in this paper cannot achieve the best overall DBT mass regions segmentation performance, our dilated DCNN framework achieves 86.3% ACC and 85.6% SEN with AUC of 0.852. The experimental results of this paper also indicate that our framework can get sound segmentation outputs on DBT image data set, and the dilated DCNN model is trained on the two-dimensional slice images of DBT volumes, not on the two-dimensional mammography data set. Although the proposed DCNN-based CAD framework has achieved promising results in automated segmentation of breast mass regions in DBT images, it can be further improved when there are more DBT image data. The main limitation of this study is the lack of sufficient DBT image data. To achieve satisfactory overall segmentation performance, our proposed automated segmentation framework for breast mass regions in DBT images needs more diverse data and structural distortion samples. Our proposed dilated DCNN-based approach can be applied to detect all early signs of breast tumour in DBT images, which is vital to decrease the review time for radiologists while maintaining or decreasing false positives.

5. Conclusions

This article presented a novel dilated DCNN-based architecture for mass regions segmentation in DBT images, performed experiments on an in-house collected DBT image data set, and obtained promising results. The constraint matrix is generated by using isotropic radial basis function and multiply with the DBT image to effectively improve the low contrast of candidate breast tumor regions and suppress the noise of background tissue regions. Our dilated DCNN architecture is specifically designed for dense prediction, systematically aggregating multiscale contextual information without losing resolution. Moreover, the proposed model adopts the f_α-measure as the cost function, further effectively suppresses the influence of class imbalance, and can improve the generalization ability of the segmentation. The average ACC, SEN, AUC obtained on the entire data set are promising and they are 86.3%, 85.6%, and 0.852, respectively. This study demonstrates that the presented dilated DCNN network has the potential to segment the mass regions in DBT Images accurately.

Academic Editor: Xin Ning

Research-based learning is a comprehensive practical course that requires students to identify research topics from their study life and social life and acquires knowledge and applied knowledge through independent inquiry in a way similar to scientific research. Under the framework of CT (constructivism theory), through the study of English research-based learning and its functions, starting from few-shot learning, a college English teaching model based on the integration of network and research-based learning is constructed to explore the realization method of this model in the teaching process. UCSR-EW (user context-aware semantic-aware recommendation for English words) algorithm is used to generate English word recommendation, and the English word records are represented by the semantic model. Then, the acceptance of English words is measured according to the learning stage and English word records, and then, the similar users are matched, and finally, the intelligent recommendation of English words is realized. CC (confidence coefficient) is introduced into the pronunciation error correction algorithm to improve the traditional pronunciation error correction algorithm, so as to improve the error correction effect.

1. Introduction

Research-based learning is a concept opposite to receptive learning. It has many important functions, which are mainly manifested in helping to cultivate students' scientific inquiry ability, scientific spirit, independence and cooperation, social responsibility, innovative spirit, and innovative ability, helping to develop students' awareness and habits of exploration, helping to turn the learning process into a process of independent exploration, stimulating and enhancing learning motivation, and helping to cultivate students' sustainable development ability [1]. Therefore, as the inevitable trend of the current university curriculum reform, research-based learning has also become the focus of attention in the English teaching circle [2, 3]. More and more researchers are discussing the connotation of research-based learning and its application in English courses from theoretical and practical perspectives [4, 5].

CT (constructivism theory) is an important branch of cognitive learning theory, which is the result of psychologists' in-depth research on the cognitive law of the human learning process, and the further development of learning theory from behaviorism to cognitivism [6]. Because the learning environment required by CT is strongly supported by the latest information technology achievements, CT is increasingly combined with the teaching practice of teachers, thus becoming the guiding ideology of deepening teaching reform in schools at home and abroad [7, 8]. In order to meet the needs of modern quality education, middle school English curriculum standards have been revised several times, requiring middle school teachers to teach with brand-new teaching concepts, teaching methods, and means, take students as the center, pay attention to students' emotional factors, intelligence development, learning methods training and ability training, and teach them how to learn [9]. To achieve this goal, educators should provide a beneficial environment for students to help them create their own opinions independently or collectively [10]. The popularity of multimedia and network technology also makes the student-centered teaching structure have the material conditions for realization.

The importance of students' participation in research-based learning activities cannot be overstated. A multiperson activity is more likely to generate this type of participation. Building a learning society [11] necessitates multiperson activities, which are not only required by learning content. User information and English word learning records are collected and uploaded to the recommendation system, and a new recommendation method based on user similarity, as well as the recommendation system's model and process under the group intelligence perception mode, is explored and designed. Detection algorithms are created for various types of errors. Finally, various error detection algorithms detect the pronunciation to be processed separately, and corresponding corrective suggestions are provided for the incorrect pronunciation based on the results of the detection.

2. Related Work

The development of cognitive psychology and metacognition research provides rich theoretical knowledge for the study of learning strategies. Especially, cognitive psychology uses the viewpoint of information processing to explore the psychological mechanism within cognition, which makes it possible for human beings to explore their own implicit learning [12, 13]. Literature [14] divides learning strategies into macrostrategies and microstrategies. The former has a wider range of applications, involving more factors of emotion and motivation; the latter involves more special knowledge and skills, has a closer relationship with the cognitive execution process, and is easily influenced by education. In Literature [15], according to the theory of information processing and metacognition, it is proposed that learning strategies include cognitive strategies and metacognitive strategies. The former is the related method and technology for directly processing information, while the latter is the related method and technology for monitoring and mediating the information processing process. Literature [16] divides learning strategies into eight categories: retelling strategies of simple and complex learning tasks and finishing strategies for simple and complex learning tasks, simple and finishing organizational strategies, comprehensive adjustment strategies, and emotional strategies. Literature [17] puts forward the importance and necessity of learning strategy training in English learning. Literature [18] pointed out that research-based learning is a learning activity in which students, under the guidance of teachers, choose and determine topics for research from nature, society, and life, and actively acquire knowledge, apply knowledge, and solve problems during the research process. Literature [19] also gives two types of research-based learning: project research and project design. It is considered that objective knowledge structure is internalized into the cognitive structure through individual interaction with it. The interaction between learners and the environment involves two basic processes: "assimilation" and "hue".

A recommendation system is a software tool and technology that suggests items to users based on their preferences. These recommendations cover a wide range of decision-making processes, including purchasing goods, listening to music, and reading online news [20]. Cinema recommendations are made to a virtual community of movie aficionados via e-mail and the Internet bibliography [21]. Bibliography literature [22] introduces eight attack strategies, which are mainly divided into four categories: basic attack, weak cognitive attack, nuclear attack, and informed attack. The challenges of modeling the simulated human score at the process and result levels are listed in literature [23], and it is noted that in the field of speech features and speech recognition, it is currently impossible to model the evaluation process comprehensively. Literature [24] evaluates the speaker's speech at the phoneme level, which has the benefits of accurately locating the speaker's pronunciation errors, evaluating the similarity between the speaker's speech and the target speech, and detecting systematic differences by comparing with a standard speech database. The user's voice data should be scored in segments at the phoneme level, and the overall score of this voice should be calculated by combining the scores of each phoneme, according to literature [25].

3. Research Method

3.1. English Research Study Based on CT. The key to English research study is students' activities. It is a tool of language communication, and any tool has one characteristic activity. If people want to learn a language, they must master the language through activities, learn to communicate, and achieve the purpose of communication through restricted and purposeful language activities. The development of research-based learning is mainly manifested in two aspects:

(1) The model of research-based learning gives students full freedom, makes students truly become the main body of learning, fully demonstrates students' autonomy, and creates a good space for students' individual development

(2) The evaluation of research-based learning is not to compare students horizontally but to make every student have a successful psychological experience through positive evaluation, and have enough self-confidence, so as to motivate every student to make new progress and achieve new success on the basis of the original, thus inspiring the internal needs and motives for improvement and improvement, and starting internal vitality and subjective initiative [5]

The teaching effect is determined by the design of the teaching model. In essence, research-based learning is a type of resource-based learning. In order to fully embody the characteristics of resource utilization learning, self-discovery learning, negotiation and cooperation learning, and practical and creative learning, the construction of a college English research-based learning mode in a network environment should take full advantage of the network platform's advantages, such as diversity, sharing, expansibility, and interactivity, and fully utilize the advantages of the network platform, such as diversity, sharing, expansibility, and interactivity. CT learning is emphasized as a process in which students actively construct meaning. In order to cultivate their autonomous, research-oriented, and cooperative learning abilities, students should actively explore, analyze, and discover the essence of things and their interrelationships using various methods, resources, and tools that are beneficial to the construction of meaning, from mastering little knowledge to constructing a complicated knowledge network.

CT teaching thought includes the following aspects: knowledge view, learning view, student view, evaluation view, the orientation and role of teachers and students, and learning environment (Figure 1).

Learning is always associated with a certain social and cultural background, that is, the “situation”. Learning in the actual situation can enable learners to assimilate and lead out the new knowledge that they have learned so as to endow the new knowledge with a certain meaning. If the original experience cannot assimilates the new knowledge, it will cause the process of “adaptation”, that is, the original cognitive structure will be reformed and reorganized. In a word, only by “assimilation” and “adaptation” can the meaning of new knowledge be constructed.

Whether it is the study of language knowledge such as phonetics, vocabulary, and grammar or the cultivation of basic skills such as listening, speaking, reading and writing, student-centered, aiming at how to guide students to learn and teach them to learn. Teachers should be good at creating situations, stimulating students’ interest and motivation, setting appropriate learning tasks, creating lively and diverse activity environments, providing ample opportunities for practical language communication, allowing students to explore and solve problems by using their knowledge and original abilities, and also using language knowledge to communicate in activities to complete various tasks.

Combining the dominance and operability of classroom teaching, this study constructs a college English classroom teaching model based on the integration of network and research-based learning (Figure 2).

Research-based learning mode relying on network technology is subject-oriented, which changes the teaching process from traditional inheritance to inquiry. Students use the Internet to do a lot of online reading and online audio-visual, get “information input”, accumulate materials, and then refine their own views, transfer the perceived information to oral, form materials for oral expression, and provide “speaking” with the contents and ways of oral communication through logical transformation of thinking.

Teachers use the Internet to create real problem situations, guide students to discover and put forward problems that need to be explored, and generate a strong desire for research based on the teaching objectives, based on the content of teaching materials, and based on the principles of creativity, practicality, and novelty. Because the information on the computer network is linked by hypertext, it is easy for students to become disoriented, making teacher guidance crucial. The author primarily provides advice to students when they are debating a topic that is off-topic or disorderly.

Figure 1: Teaching thought of CT.

However, affirming students’ primary role in learning does not negate teachers’ hegemony in the classroom. The essence of teaching is guidance, and the shift in teachers’ roles is more focused on the promotion of educational concepts and the innovation of teaching strategies, which is to set new and higher standards for teaching and educating people in the new situation, rather than on the transfer of teaching and educating responsibilities and status. In essence, student-centered education requires teachers to create favorable conditions for students’ development and fully recognizes teachers’ dominant position.

Teachers should provide topic-related language materials, such as video or audio, while also supplementing literature materials with orientation and the appropriate degree to integrate language learning and consolidation into the application. The task’s input materials primarily come from English resources on the Internet, which are directly from the front lines of application and have authentic, rich, and practical characteristics. Through research-based learning, students find, sort, and use them, resulting in language acquisition.

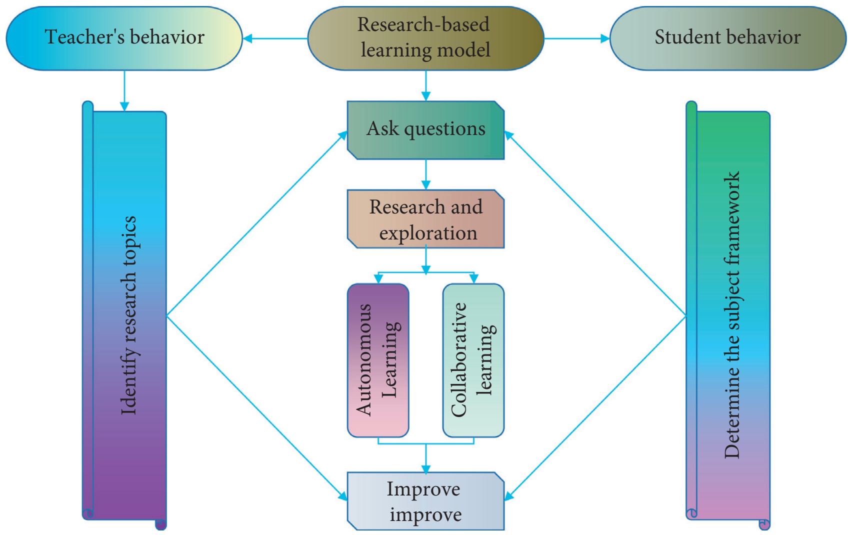

FIGURE 2: Web-based research-based learning model of college English.

3.2. UCSR-EW Algorithm. UCSR-EW (user context-aware semantic-aware recommendation for English words) algorithm uses word vectors to represent words, considers the relationship between English words from the semantic point of view, and, on this basis, introduces the context information of users, matches the words that users are interested in, and realizes intelligent recommendation of English words.

Word recommendation algorithm introduces the semantic model based on English word browsing records to calculate interest similarity among users. The context similarity between users is calculated by using the context information of users, and then, user similarity is calculated according to interest similarity and context similarity; the neighbor of the target user is selected according to the user similarity; neighbors generate neighbor recommendation lists according to their English word records; finally, all neighbor recommendation lists are merged to generate the final recommendation result. The specific algorithm framework is shown in Figure 3.

UCSR-EW algorithm first uses the trained semantic model to calculate the semantic similarity of words and then constructs the feature vector of English word browsing records.

Formula (1) is used to calculate the similarity between feature vector f_u and feature vector f_v, that is, the interest similarity of user u, v:

$$\mathrm{Sim}_{\mathrm{ic}}(u, v) = -\sqrt[2]{\frac{\sum_{i=1}^{k} (f_u)_i^2 - (f_v)_i^2}{k}}. \tag{1}$$

Feature vector f_v represents the semantic similarity of user v English word browsing records in user u word dimension, so the interest similarity of user u, v can be calculated by calculating the normalized Euclidean distance between feature vector f_u and feature vector f_v.

The age and geographical location of the user are used as context information, and the learning stage of the user is described by the context information of the user. The contextual similarity $\mathrm{Sim}_{\mathrm{sc}}$ of users will be calculated according to the age similarity $\mathrm{Sim}_{\mathrm{age}}$ and the regional similarity $\mathrm{Sim}_{\mathrm{location}}$, as shown in the following formula:

$$\mathrm{Sim}_{\mathrm{sc}} = \alpha \cdot \mathrm{Sim}_{\mathrm{age}} + \beta \cdot \mathrm{Sim}_{\mathrm{location}}. \tag{2}$$

Among them, α, β, respectively, represent the weight of age similarity $\mathrm{Sim}_{\mathrm{age}}$ and regional similarity $\mathrm{Sim}_{\mathrm{location}}$ in the calculation process of user context similarity $\mathrm{Sim}_{\mathrm{sc}}$, satisfying the condition $\alpha + \beta = 1$.

User-aware word semantic-aware recommendation algorithm is a recommendation method based on user similarity, which matches the neighborhood of the target user, and then generates recommendation results according to the neighbors of the target user (users in the neighborhood). User similarity $\mathrm{Sim}_{\mathrm{user}}$ can be calculated according to interest similarity and user context similarity, as shown in following formula:

$$\mathrm{Sim}_{\mathrm{user}} = W_{\mathrm{ic}} \cdot \mathrm{Sim}_{\mathrm{ic}} + W_{\mathrm{sc}} \cdot \mathrm{Sim}_{\mathrm{sc}}, \tag{3}$$

where $W_{\mathrm{ic}}, W_{\mathrm{sc}}$ represent the weights of interest similarity $\mathrm{Sim}_{\mathrm{ic}}$ and user context similarity $\mathrm{Sim}_{\mathrm{sc}}$, respectively.

After English words are duplicated and sorted, English words with large semantic similarity will always be ranked first, so that English words with small similarity but appearing in many neighbors' recommendation lists will never appear in the recommendation results. The word scoring model considering the frequency of English words is shown as follows:

$$\mathrm{score} = D_i \cdot \mathrm{Sim}_{\mathrm{word}}(w_i), \tag{4}$$

where D_i is the number of times the English word w_i appears in the neighbor recommendation list.

3.3. English Pronunciation Error Correction Algorithm. At present, the error correction evaluation of English pronunciation mainly focuses on the evaluation of acoustic characteristics, and the user's voice signal is cut into

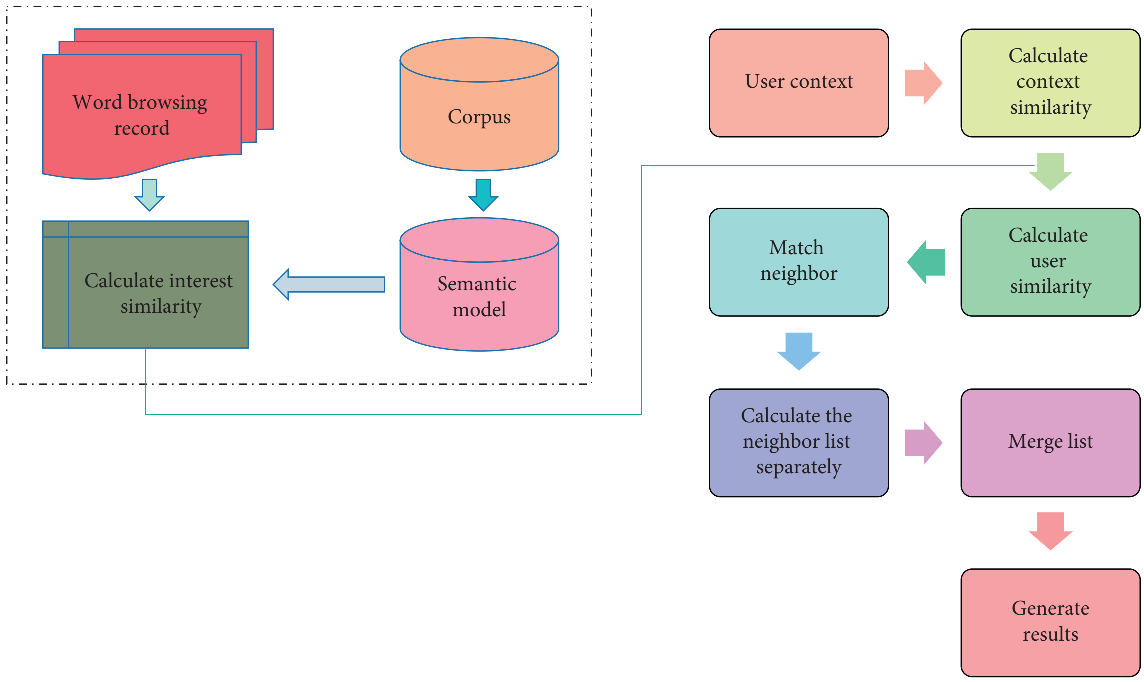

Figure 3: English word recommendation algorithm framework.

phoneme-level voice signals by forced alignment. Then, an evaluation score is obtained by calculating various similarities between the voice segments of each phoneme level and the standard phoneme acoustic model library.

This study develops a reasonable pronunciation error correction algorithm based on the above evaluation process and discusses and improves acoustic model training, phoneme segmentation, and similarity evaluation based on the characteristics of Chinese people speaking English. This study introduces the concept of CC (confidence coefficient), which calculates the confidence parameters such as likelihood ratio, likelihood ratio, and segment time to measure the similarity between this phoneme speech segment and the standard acoustic model, in order to correct users' pronunciation errors at the phoneme level and provide meaningful feedback information to users.

The pronunciation of this voice segment is the standard pronunciation. If the CC value of the observed sequence and the model of the standard phoneme is not within the range of the threshold value, the phoneme pronunciation of this speech segment is not standard, so as to further determine the wrong pronunciation of the user.

Assume that the phonetic sequence of word work is cut into three phoneme segments through a forced alignment network, corresponding to phoneme W, phoneme ER, and phoneme K, respectively. Let us take the phoneme ER as an example. First, let the observation sequence of the segmented ER be O_t, and the corresponding standard phoneme model be λ_{ER}.

The acoustic likelihood value of the frame corresponding to the standard phoneme model ER is defined as $l_i(o_t)$ where

$$l_i(o_t) = P(o_t|\lambda_{\mathrm{ER}}). \tag{5}$$

The likelihood of the inverse model corresponding to the phoneme ER is

$$l_i(o_t) = P\left(o_t|\lambda_{\overline{\mathrm{ER}}}\right), \tag{6}$$

where $\lambda_{\overline{\mathrm{ER}}}$ represents the inverse model of the phoneme ER.

Therefore, in the above formula, Ben multiplies the difference of ranking by the proportional difference of logarithmic probability, so that the reliability value of each phoneme will be influenced by ranking and logarithmic probability. The following is the set formula:

$$\mathrm{Confc} = \mathrm{PLLR}_{\mathrm{ER}}(o_t) * \mathrm{Confc}, \tag{7}$$

where Confc stands for the final CC.

The ratio of the number of phonemes whose error correction results are completely consistent with the expert labeling results to the total number of phonemes is known as the correct rate of phonemes. The algorithm's error correction rate is the ratio of the number of incorrect phonemes corrected by the algorithm to the total number of incorrect phonemes marked by all experts.

4. Results Analysis and Discussion

4.1. Analysis of English Word Recommendation Algorithm. In the process of research, using the method of group discussion, students are required to cooperate and help each other, which embodies the spirit of cooperation and mutual assistance among students. When the results are displayed between groups, they compete to show each other, hoping that their group is the best and the most perfect, which stimulates students' competitive consciousness. Pleasant cooperation and fair competition are two essential spirits for talent development today.

Students' ability to communicate correctly with pronunciation and intonation can only be cultivated in the real communication situation because changes in English stress, intonation, and rhythm are influenced by the actual communication environment and purpose. As a result, teachers should combine teaching materials to create language situations in which students can negotiate meanings and exchange emotions in communication and interaction, thereby assisting students in understanding the communicative function of pronunciation and intonation and forming an understanding of the English language. When speaking, students should be able to think clearly and express themselves using a variety of pronunciations and intonations.

The goal of the experiment of the word recommendation algorithm is to evaluate the word recommendation algorithm. The accuracy rate precision and recall are used to evaluate the effect of the recommendation algorithm. The higher the accuracy rate and recall rate, the better the recommendation effect.

The input of the UCSR-EW algorithm includes the user information file and English word record file. In addition, the algorithm also needs to input English word record length, English word number in the recommendation list, interest similarity weight W_{ic}, age similarity weight α, and user similarity threshold λ.

The key to learning a language is to imitate it. When students first learn how to pronounce vowels and consonants, it is critical that they imitate the pronunciation and practice it repeatedly in order to become proficient and accurate at it. Listening to the English pronunciations of many British and American people and imitating their pronunciation and intonation can help students to improve their English language skills.

The optimal value shown in Figure 4 is for the experimental data itself. When the experimental data change, the size of the optimal value and the value of the parameters may not be as shown in the experimental results.

In order to verify the performance of the English word recommendation algorithm proposed in this study, a comparative experiment was designed, and experiments of UCAR (user context-aware recommendation algorithm) algorithm and EWSAR (English word semantic awareness recommendation) algorithm were carried out on the same experimental data.

Without considering the browsing records of English words, the contextual similarity of users is the similarity of users, while the recommended English words will depend on the browsing records of other users with similar age and small city distance and have nothing to do with the English words browsed by the target users. Figure 5 shows the improved results of age similarity calculation, and Figure 6 shows the experimental results of the UCAR algorithm.

The communicative approach is helpful to improve students' communicative competence and enable them to learn to use correct and appropriate pronunciation and intonation. Teachers can provide students with various real communication situations and help students to correctly understand and choose the pronunciation and intonation suitable for the language environment, so as to achieve the purpose of communication.

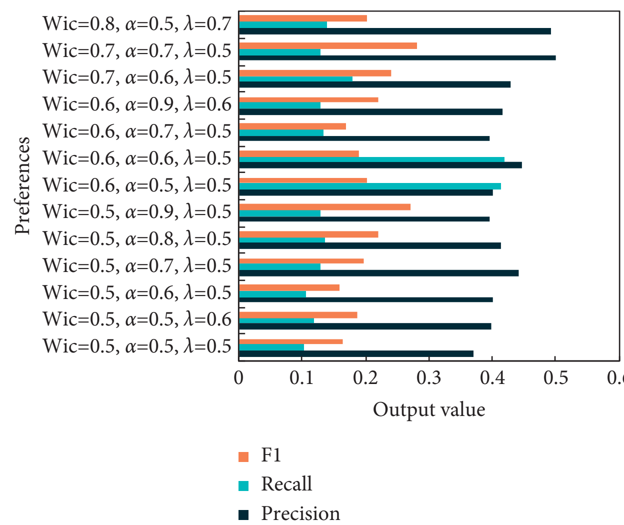

Figure 4: Experimental result.

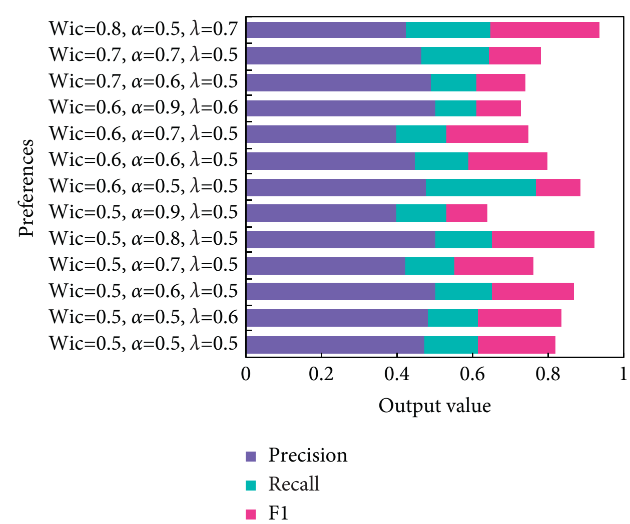

Figure 5: Improved results of age similarity calculation.

Comparison of performance between UCSR-EW algorithm, UCAR algorithm, and EWSAR algorithm is shown in Figure 7, and UCSR-EW algorithm is superior to UCAR algorithm and EWSAR algorithm in performance.

It replaced indoctrination with grammar instruction as the mainline of English instruction, and it transformed knowledge-imparting classroom instruction into ability-cultivating classroom instruction, improving students' interest in learning, assisting them in developing better learning strategies, improving their comprehensive English ability, cultivating their innovative spirit and practical ability, and improving teaching quality.

Of course, the single use of any kind of teaching method in teaching is not easy to get the best teaching effect. Teaching is an art in itself. Only by guiding teaching with advanced educational concepts, taking the best teaching

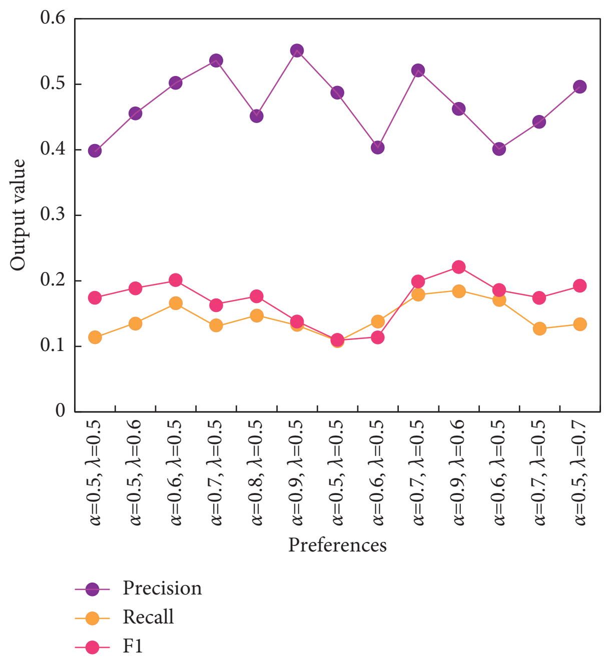

Figure 6: Experimental results of UCAR algorithm.

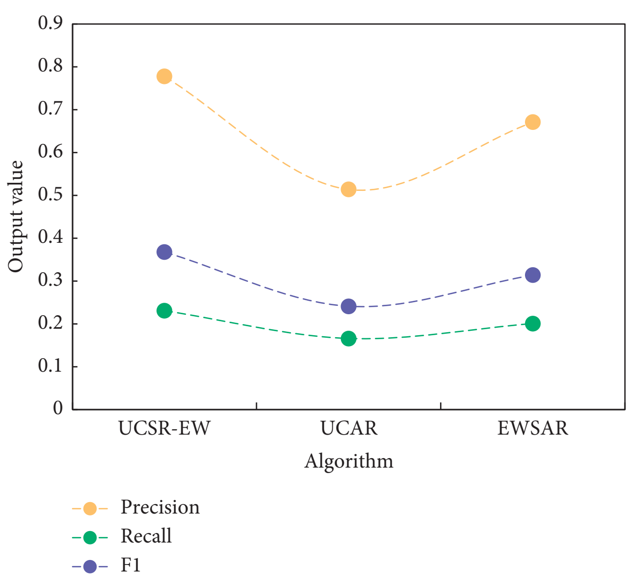

Figure 7: Algorithm performance comparison.

methods that meet the needs of the times, such as research-based learning as the leading factor, and combining all kinds of good teaching methods and creatively designing teaching can you get twice the result with half the effort.

The setting of learning objectives, the design of learning content, the provision of exercises, the transfer of adjacent knowledge, feedback, teaching assistance, learning evaluation, information organization, and other aspects should all well reflect the teaching nature. Teaching methods are not based on the learning content itself but attach importance to the creation of the learning environment. E-learning English does not just move the contents of English textbooks to the Internet intact but should combine learning theory and network characteristics to create a virtual learning environment for students and to pay attention to the organization of the teaching content, the richness, and the novelty of the content, so that students can find it worthwhile after browsing.

4.2. Analysis of Pronunciation Error Correction Algorithm. The main content of this section is to give the experimental results of adding the CC metric mentioned above to improve the traditional pronunciation error correction algorithm based on log likelihood. The experiment is designed and analyzed the experimental results in detail. The lower the threshold value, the more rigorous the algorithm is, the lower the phoneme accuracy rate, and the higher the threshold value, the looser the algorithm recognition, and the higher the phoneme accuracy rate. Figure 8 shows the phoneme accuracy of the traditional log-likelihood ratio and improved CC-based error correction algorithm.

The CC-based error correction algorithm outperforms the traditional log-likelihood algorithm in terms of phoneme accuracy, as shown in Figure 8. It is necessary to identify correctly pronounced phonemes in order to provide reliable feedback to users, but it is not sufficient to do so alone. The scale of phoneme recognition is relaxed as the ranking domain value increases, and the algorithm's error correction rate decreases. Although the user's pronunciation is assumed to be the same as the standard phoneme, experts have determined that the user's pronunciation is incorrect. At this time, the system missed a detection error, lowering the system's error correction rate.

The following experiment is designed to discuss the relationship between the correct rate of phonemes and the error correction rate of the algorithm. The experimental results are shown in Figure 9.

From the above experiments, it can be seen that with the increase of the threshold value, the limitation of the algorithm on phoneme ranking is relaxed, and the phoneme accuracy rate increases, but the phonemes that users send wrong may also be regarded as correct phonemes, so the error correction rate of the system will decrease accordingly.

In this way, by using the sigmoid function, the CC value relative to each phoneme model is limited between [0,1]. Figure 10 shows a discussion about the constant port and the relationship between CC value and rank when α takes different values.

English research-based learning evaluation is a type of evaluation that aims to fulfill the full scope of the evaluation. It emphasizes that the core of evaluation is students' absorption and mastery in the learning process, emphasizes the role of evaluation in students' development, and pays attention to positive encouragement and encouragement. It takes the promotion of students' development as the fundamental purpose, takes the promotion of students' development as the orientation, embodies the people-oriented thought, emphasizes that the core of evaluation is students' absorption and mastery in the learning process,

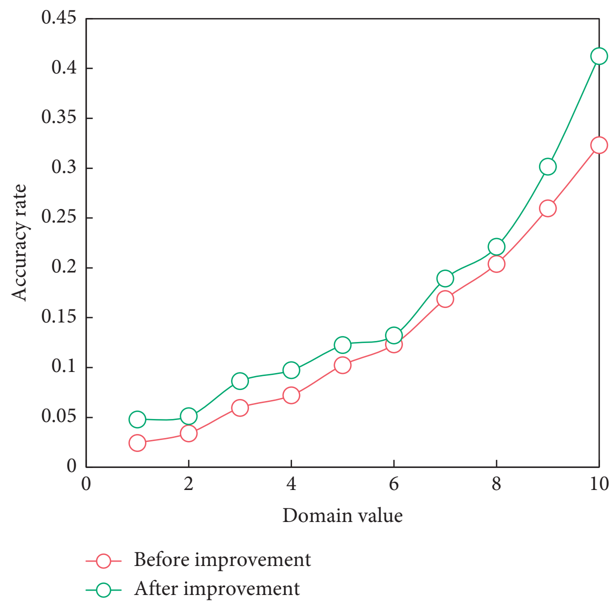

Figure 8: Comparison chart of phoneme accuracy before and after improvement.

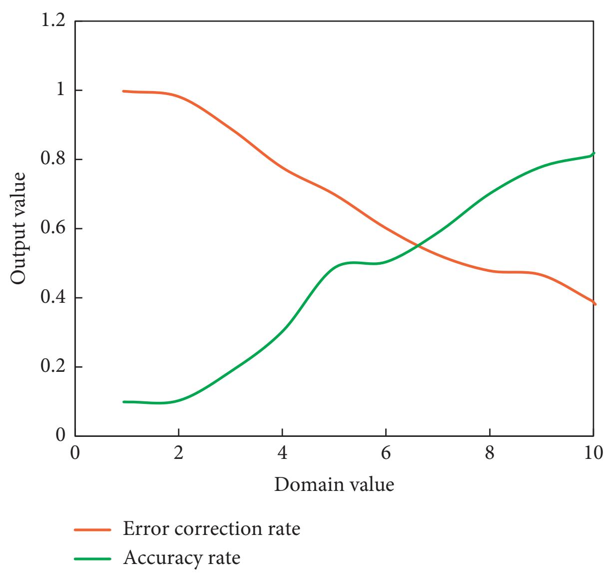

Figure 9: Relationship between error correction rate and phoneme accuracy rate of the algorithm.

emphasizes the role of evaluation in students' development, and pays attention to positive encouragement and to students' own interpretations of various phenomena, listen to their current perspectives, consider the origins of these ideas, and assist students in expanding or revising their own explanations, pay attention to students' personal development, and do not dismiss external guidance, such as teacher influence, pay attention to student inspiration and induction during teaching activities, and guide students through discussion activities and connection reasoning to explore and find problems, solve problems, and acquire knowledge.

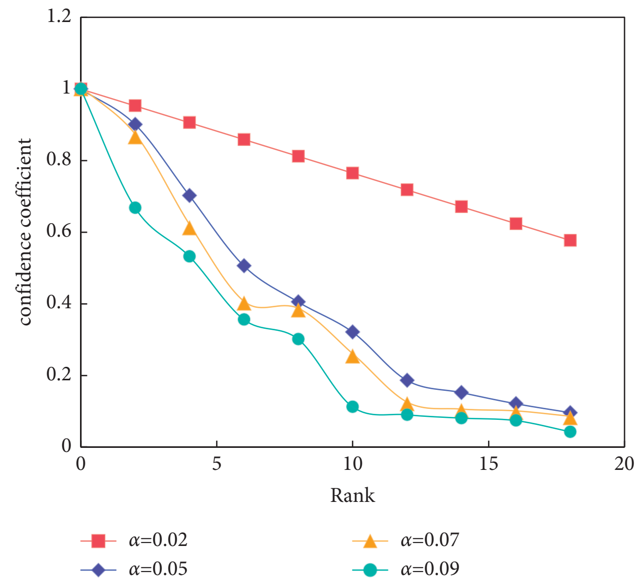

Figure 10: Relationship between α and rank rankings.

A colorful learning environment for students is created by creating situations that meet the requirements of teaching content and clues that suggest the relationship between old and new knowledge and help students to construct the meaning of what they are currently learning, to pay attention to the cultivation of cross-cultural awareness, method guidance, and strategy training, and to pay attention to guiding students to explore and discover the research-based learning style not only trains students' thinking but also cultivates their learning ability.

With the rapid development of multimedia computer and network education applications, CT is showing its strong vitality and expanding its influence in the world. Studying some learning theories of CT and carrying out teaching practice based on CT will carry out quality education with moral education as the core and cultivating students' spirit of exploration and innovation, active research and learning, cooperative learning, and practical ability as the focus, and promote the reform of teaching materials, which will have far-reaching influence and positive promotion.

5. Conclusion

Research-based learning is a teaching method in which subjects and objects are transformed and promoted by one another. This teaching model embodies the student-centered educational philosophy and emphasizes language acquisition and learning in the process and practice through the use of modern teaching methods. The central tenet of CT is that students are self-control knowledge builders. Teaching is primarily concerned with assisting students in improving their cognitive abilities. The UCSR-EW algorithm is proposed, which calculates an English word score based on semantic similarity and frequency of occurrence of English words and then recommends English words based on the score. In this study, we introduce CC into the phoneme error correction process and use it to calculate the CC rank of segmented phoneme segments and standard phoneme models to determine the accuracy of phoneme level in users' pronunciation. The results of the experiments show that including CC improves the correlation between system error correction and expert error correction significantly.

This study only looks at how phonemes are evaluated in spoken English, but there are many other aspects of spoken English that need to be highlighted for English learners, such as rhythm, and stress. Furthermore, the research and experiment in this study did not take into account the impact of regional dialects on English pronunciation. This will be the subject of more research in the future.

Data Availability

The data used to support the findings of this study are included within the article.

At present, China's population aging presents the characteristics of large base, fast aging process, and old age, but the research and development of product aging design in China is relatively late, which brings additional pressure to the daily life of the elderly. In such an environment, higher requirements are put forward for product aging design and service provision. Only products or services that timely meet the personalized and diversified needs of different customers can attract customers and improve customer satisfaction. How to design aging products with satisfactory appearance and humanized function is the focus of current research. Based on the product quality division of Kano model, this paper summarizes the domestic mainstream products and their functions. The designed questionnaire data are summarized; reliability and validity analysis, as well as descriptive statistical analysis, is performed on this basis for the constructed product service quality evaluation system. The service quality indicators are divided into three categories according to the Kano model: overall one-dimensional quality, charm quality, and necessary quality.

1. Introduction

With the refinement of management and the deepening of customer-centered management concept into enterprise management, the quality management of products and services has become a hot management issue [1]. Quality management methods and systems emerge one after another, and they have played an important role in different fields and contents. At the same time, with the deepening trend of aging in China, the number of elderly groups is increasing [1]. The educational needs of the elderly are also increasing. The popularity of smart phones and mobile Internet is affecting the daily life of the elderly. This paper collects and analyzes the relevant literature on product interactive aging design at home and abroad and finds that the current product interactive aging design in China is poor, and the product delivery design experience for the elderly needs to be improved [2]. Quality evaluation is a core part of quality management. Different quality management methods are permeated with corresponding quality evaluation methods. How to select scientific means to evaluate the service quality of enterprises in order to improve customer satisfaction and loyalty is a practical problem faced by enterprises [3]. At present, Kano model still has many limitations in practical application, and its quality evaluation method needs to be further supplemented and modified [4]. The Kano model is applied to the research of products for the elderly, mining the characteristics of products used by the elderly, and the corresponding design strategies are summarized, which is of great significance to guiding the aging design of products.

Today's environment faced by enterprises is not what it used to be. With the further interruption of monopoly industries, the market presents a strong competitive situation, which has played a significant role in promoting economic development, but at the same time, it poses severe challenges to competitive enterprises [5]. Population aging refers to the rising trend of the proportion of the elderly population in the total population under specific time and space conditions. With the increase of the number of the elderly in China, the educational needs of the elderly are becoming increasingly prominent [6]. In this environment, the interactive aging design of products is challenged. At present, many research contents focus on putting forward suggestions from the aspects of product interaction design and visual design, but there is lack of research on users' overall perception of product attributes. The overall perception research includes which attributes of the product are more important to users and which characteristics can better affect use satisfaction [7]. The introduction of Kano model into the design of aging interaction boundary of products can study the impact of different functions on user satisfaction and help designers reasonably allocate design resources. The service product itself has the characteristics of intangibility, which is more complex than the evaluation of physical products, which increases the risk in the process of consumer purchase [8]. Therefore, how to select scientific means to evaluate the service quality of enterprises in order to improve customer satisfaction and loyalty is a practical problem faced by enterprises. This paper constructs a service quality evaluation model of product interactive aging design, in order to help enterprises improve service quality and product interactive aging design.

The key to accelerating economic development is quality. There will be no real and tangible benefits unless quality is improved. Appropriate quality evaluation methods are essential for improving product quality and increasing enterprise international competitiveness [9]. To construct the nonlinear relationship between consumer satisfaction and product performance, a two-dimensional model can be used: on the one hand, it is the subjective feeling of consumers; on the other hand, it is the objective state of products. The Kano model converts specific attributes of products or services into customers' income, which is then divided into quality factors in order to analyze consumers' consumption intention and attitude [10]. As a result, the Kano model is widely used in quality control, new product development, and other areas. The rise in the number of elderly groups has heightened interest in their spiritual lives. Despite the fact that there are a lot of elderly products on the market, there are not many products specifically designed for them [11]. The current products are geared more toward teenagers, college students, and workers on the job. This paper examines the physiological and psychological characteristics, as well as the motivation and challenges of using a smartphone app by the elderly, and summarizes the pertinent information. This paper constructs a product interactive aging design quality evaluation model based on Kano model and uses Kano questionnaire to collect users' attitudes toward functions, so as to divide the functional attributes of products and rank the importance of each functional attribute. Combined with Kano model research results and interactive evaluation dimensions, the corresponding design strategies are obtained. The aging principle is verified by usability test and satisfaction evaluation, and the product interaction aging practice based on Kano model is completed.

2. Related Work

According to literature [12], quality means those characteristics in a product or service that can meet customer needs and make customers satisfied; it also means that a product or service is free of defects. According to literature [13], quality factors require not only a large category of judgment, but also a quantity that can effectively measure the category of quality factors in the Kano model's limitations. Only with this amount of data can a horizontal and comprehensive comparison of different products (or the same product) be made. Literature [14] proposed a Kano model-based system for evaluating personal online banking service quality and divided the service quality of personal online banking in China. According to the article, banks must improve the reliability and security of personal online banking; for one-dimensional quality, banks must improve the ease and speed of their operations and establish good communication with customers; and for charm quality, banks must improve innovation and market segmentation to improve service efficiency. According to the literature [15], customer satisfaction and perceived service quality have different relationships with expectations. A higher level of satisfaction does not imply a higher level of perceived quality. Expectations are divided into three categories: core attribute expectations, important attribute expectations, and other attribute expectations. Customers' perceived quality evaluation can be improved by meeting consumers' expectations of important attributes, and consumer satisfaction can be improved by meeting consumers' expectations of additional attributes. Customers' perceptions of service quality are multidimensional, according to literature [16], and service quality can be measured from five perspectives: reliability, responsiveness, assurance, empathy, and tangibility. Consumers' expected quality is determined by their personal needs and previous experience. A combination of four types of gaps can be used to express the gap between the quality of service and the quality expected by customers. Literature [17] believes that in the Kano model, a lot of information can be obtained by using sample data, which also plays an important supporting role for the dynamic changes of quality factors. Literature [18] proposed an I-Kano for customer satisfaction improvement decision-making, proposed Kano index and priority index, in order to use quantitative analysis methods, in the framework of the Kano model, combined with customer satisfaction, product, or service. The quality factors are judged and ranked by importance. Literature [19] applies the Kano model to engineering mechanics to determine the impact of various service qualities in the real estate industry on customer purchasing decisions. Literature [20] believes that perceived service quality includes two aspects: technical quality and functional quality. Literature [21] improved the calculation method of the Kano model and proposed a calculation method of the importance of the fuzzy Kano model. On the one hand, the fuzzy Kano questionnaire is used, and on the other hand, the demand importance adjustment function is introduced to calculate the importance of different quality attributes. This method is applied to the demand analysis of a company's combine harvester. Literature [22] proposed that customer expectation means the level expectation that customers can achieve for products or services, which is an exogenous variable. Perceived value is the perceived actual quality level, which is divided into two observation variables:

the price evaluation of relative quality and the quality evaluation of relative price. Literature [23] believes that the more sufficient the service quality is, the higher it is than consumers' expectations, the more satisfied consumers will be. Literature [24] proposed an analytical Kano model on the basis of analytical customer relationship management. The model realizes the objective classification of quality factors by constructing Kano satisfaction index and importance index. They integrate consumers' important perception of each product or attribute in the questionnaire design, and finally obtain the priority to improve the service quality attribute. Literature [25] holds that when incentive factors are available, they will increase people's job satisfaction, but when they are lacking, they will not lead to people's dissatisfaction. When health care factors are available, they will eliminate people's dissatisfaction, but will not increase people's satisfaction, while when they are lacking, they will cause people's dissatisfaction. Literature [26] uses the methods of fuzzy clustering and fuzzy transformation semantics to judge the quality attributes based on Kano model and puts forward a way to obtain product personalized requirements. In this paper, Kano model is used to explore the interactive aging design of products. And it explores the rules of consumers' judgment on the quality characteristics of products or services, find out the key quality factors such as charm quality, one-dimensional quality that affect consumers' satisfaction or attract consumers' attention, and explore the correlation degree between consumers' different personality characteristics and their judgment on quality factors, so as to provide suggestions for interactive aging design of products.

3. Methodology

3.1. The Design of Product Interaction Adaptive Aging Based on Kano Model. With the development of information age, China has entered a sub-deep aging society. In order to make the decline of old people's function and follow-up study of individual ability adapt to the rapid change of product interaction information, we should reconstruct the prototype of old people's interaction, optimize the interaction mechanism of old people's products, and build the design method system of product interaction suitable for aging [27]. Therefore, the interaction of products is more suitable for the physiological and psychological characteristics of the elderly group, the interaction of the elderly users is more accurate, natural, smooth, and relaxed, and the elderly products are safer, more comfortable, healthier, and more efficient.

Aging design is a design based on the physiological and psychological needs of the elderly and their experience, taking into account the security needs and belonging needs, and at the same time trying to realize the spiritual needs and self-realization needs of the elderly to improve their quality of life [28]. The research of product interaction aging design for aged care service with Chinese characteristics supports the scientific and reasonable generation of product aging interaction design system for social aged care service from the logical level. From the technical level, the interactive design of aging products for social pension services can be quickly and effectively transformed into an applied method system.

Product demand reflects the general requirements of users for enterprises and products and is the starting point of the whole life cycle of products. The process of product innovation and development largely depends on the understanding and analysis of product demand. Different personality consumers have different judgment results on quality factors [29]. Consumers with different personality types have different consumption preferences and habits, which makes it difficult to get satisfaction. According to the different influence modes of product attributes on consumer satisfaction, Kano model mainly classifies them into three different factors. They are charm factor, expectation factor, and necessary factor. Kano model divides users' demands into three categories: basic demands, normative demands, and interest demands. These three kinds of demands reflect the different levels of demands of users for products, and the demands will change with the changes of market and time. Interest will degenerate into normative demand, and normative demand will degenerate into basic demand. Aging products are designed and developed according to the needs of the elderly, so the products should reflect the needs of the elderly. The design elements of aging products include functional elements, aesthetic elements, safety elements, and ease of use elements. Figure 1 shows Kano model.

With the improvement of people's cultural level and living standard, the product system that carries the entertainment and life of the elderly has been popularized to some extent, which has also laid a certain foundation for aging products. Although the types of aged products on the market at present are very single, lacking in innovation and serious homogenization in design, they cannot bring rich product experience to the aged consumers. However, from the physiological characteristics, life and behavior of the elderly, the elderly products can be roughly divided into three categories:

(1) *Life Support Products*. Life support products are a common demand of the elderly. These products are designed by designers according to the specific life behavior needs of the elderly who need assistance. With these products and more professional medical care products, some elderly people can take care of themselves.

(2) *Fitness Products*. The improvement of the average life span of the elderly is closely related to the increase of leisure time, increasing attention to their healthy, happy, and full life. By participating in various ball games with friends, we can increase the fun of our later life, exercise our thinking system, and prevent inattention, memory decline, and slow response caused by aging and degeneration.

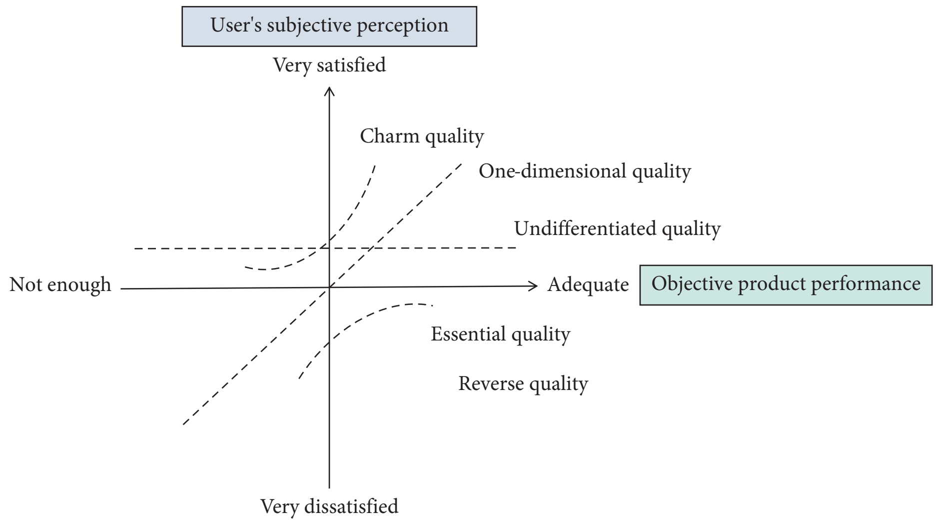

Figure 1: Kano model.

(3) *Leisure and Entertainment Products*. At ordinary times, the elderly will take part in some intellectual development projects because proper use of the brain can help to slow down brain degeneration and aging, prevent Alzheimer's disease, and maintain the vitality of thinking. These products are all aging products with the ultimate goal of developing the intelligence of the elderly, preventing brain degeneration by using the brain properly but not excessively, enhancing the interests and hobbies of the elderly, and increasing communication activities. To a certain extent, it can satisfy the spiritual needs of the elderly who are not satisfied with the old age, pursue health, hope to get attention and attention, and have their own hobbies.

There is a linear relationship between quality factors and customer satisfaction in the traditional quality model plough. To obtain the nonlinear relationship between customer satisfaction and product performance, the Kano model breaks through the previous one-dimensional model and uses the two-dimensional model of customer subjective feelings and objective performance of products and services. The Kano model can fully analyze product customized attributes and determine whether or not each customized attribute should be implemented and in what order. We should prioritize product customization attributes that can improve consumer satisfaction to a greater extent and make an appropriate trade-off between the manufacturer's production capacity and consumer satisfaction, in order to ensure that consumer satisfaction does not decline.

To implement the Kano model, the first step is to set up a questionnaire about product customization attributes. The results of the reliability analysis are not used to reflect the correctness of the results of the questionnaire, but to evaluate the reliability and stability of the questionnaire. Assuming that the result of the questionnaire is the algebraic sum of K items under investigation: $X = Y_1 + Y_2 + \cdots + Y_K$, then the Cronbach's a-reliability coefficient is defined as follows:

$$\alpha = \frac{K}{K-1}\left(1 - \frac{\sum_{i=1}^{K} \sigma_{Y_i}^2}{\sigma_Y^2}\right). \quad (1)$$

Among them, σ_Y^2 is the variance of the total score of the observed questionnaire test, and $\sigma_{Y_i}^2$ is the variance of all respondents' scores of the currently observed items.

Let domain $X = \{x_1, x_2, \ldots, x_k\}$, that is, the collection of all functional requirements. Fuzzy set $A = \{\mathrm{Br}, \mathrm{Pr}, \mathrm{Er}\}$, $A \in F(X)$.

There are n evaluation members, who are asked to independently give the estimated value $m_i\,(i = 1, 2, \ldots, n)$ of $\mu_A(x_0)$ and calculate its average $\overline{m}$ and deviation d:

$$\overline{m} = \frac{1}{n}\sum_{i=1}^{n} m_i,$$
$$d = \frac{1}{n}\sum_{i=1}^{n} \left|m_i - \overline{m}\right|. \quad (2)$$

For a given error $\varepsilon > 0$, $\mu_A(x_0)$ can be used as the approximate value of $\overline{m}$ if the deviation satisfies $d \leq \varepsilon$. If $d > \varepsilon$, repeat the above steps until satisfactory accuracy requirements are met.

When the evaluation experts estimate each membership degree, it is better to give the estimated value of $x_1, x_2, \ldots, x_k$ at a time than to estimate $a_i\,(i = 1, 2, \ldots, k)$ individually, because the overall estimation is carried out in comparison, which makes the decision easy to make and relatively reasonable.

3.2. Quality Evaluation Research. Intelligentization has become the Internet age's label, and the design of aging products is following suit, with many aging products already possessing some intelligence. As the elderly's functions deteriorate, they require more outside assistance. Intelligent aging products have a certain "wisdom" that can not only reduce the elderly's physical consumption, but also minimize the difficulty of use, and realize the operation and use of the products through systematic operation. Assume the elderly group is the research object, dynamically collect their living habits and behavior patterns, and build an elderly group behavior model. Data understanding, association reasoning, clustering analysis, and other algorithms are used to extract and deconstruct the typical behavior model of the elderly group, collect physiological signal information, and mine interactive information based on objects. The output interaction information is functionally reconstructed from the perspective of interaction mechanism, and the architecture forms are cognition, understanding, decision-making, implementation, and feedback, in order to construct the interaction prototype for observation and understanding, exploration and iterative design, and communication and evaluation, according to the interaction demand.

It is necessary for manufacturers to fully understand consumers' preferences and their information feedback on product satisfaction so as to formulate appropriate product optimization strategies and continuously improve product quality. The personality characteristics of consumers can be divided into three categories: introverted rational type, extroverted obedient type, and extroverted independent type. Among them, introverted rational consumers do not like to have too much interaction with others during the shopping process. Consumers with extroverted personality will show higher compliance with others. From the consumer's point of view, the quality of products is reflected in the degree of satisfaction of consumers. Figure 2 shows the structural model of customer satisfaction index.

Because consumers' own demand preferences are ambiguous and their cognitive process of demand preference is uncertain, it is often difficult for nonprofessional consumers to directly judge the quality of a product. However, from the standpoint of the product, the reasonable division of product attributes allows for the visualization of consumer demand, because consumer satisfaction with products can be measured by whether, how, and how these attributes are realized, and understanding the mapping relationship between consumer demand and product attributes is critical to the demand visualization process.

The attribution degree of quality elements is actually the problem of calculating the maximum leading degree of components in the distribution vector of quality elements. Therefore, the distribution vector is directly regarded as a set of numbers to calculate the maximum lead. The calculation method of the attribute degree of quality elements is as follows:

$$\eta\langle T\rangle = \eta\langle T(\mathrm{QE}, t)\rangle = (\eta' - \psi + 1)^{\arctan(N-1+\tan 1)}. \tag{3}$$

Among them, the determination of the value of ψ can use the half-number principle and can also be determined by means or other methods. The external advantage can be characterized by the discrete coefficient of a set of values other than the maximum value. The dispersion coefficient is a measure of the uniformity of the distribution between a group of numbers, which has the same points as the external advantages discussed in this article.

If we define a product attribute set $F = \{f_1, f_2, \ldots, f_i, \ldots, f_q\}$ that includes q product attributes, and a surveyed person set $E = \{e_1, e_2, \ldots, e_j, \ldots, e_p\}$ that includes p respondents, then, for each attribute, there are

$$\begin{aligned} &e_j \longrightarrow i = \left(a^+_{j\longrightarrow i}, a^-_{j\longrightarrow i}\right) \quad i = 1, 2, \ldots, q; \quad j = 1, 2, \ldots, p,\\ &a^+_{j\longrightarrow i}, a^-_{j\longrightarrow i} \in \{\text{"Like"}, \text{"Must} - \text{be"}, \text{"Neutral"}, \text{"Live with"}, \text{"Dislike"}\}. \end{aligned} \tag{4}$$

Among them, $a^+_{j\longrightarrow i}$ and $a^-_{j\longrightarrow i}$ are the answers to the positive and negative attribute questions, respectively.

Behavior mode is the foundation of product interaction mode, and product interaction mode is the result of behavior mode, which is interactive and interrelated. Different behavior mode information feedback determines different interaction modes, and different behavior mode information feedback determines different interaction modes. People-oriented user needs are prioritized in interactive design efforts to create and build meaningful relationships between people, products, and services. Interactive aging product design can improve elderly consumers' experiences with aging products, help them accept new things, and thus improve their quality of life. This paper investigates the relationship between elderly behavior patterns and product interaction based on a prototype of elderly interaction. The premise is that there is a mapping relationship between the physiological information of the elderly and product interactions, including the mapping content and structure. Its core is the old age behavior pattern's action mechanism on product interaction; its essence is the old age behavior pattern's support for product interaction and the reverse verification of old age behavior pattern by product interaction.

Define the transformation rule T and the frequency index $C_i(k)$:

$$\begin{aligned} &\mathrm{count}\left(T\left(e_{j\longrightarrow i}\right)\right) \equiv 1,\\ &C_i(k) = \sum_{j=1, T\left(e_{j\longrightarrow i}\right)=k}^{p} \mathrm{count}\left(T\left(e_{j\longrightarrow i}\right)\right),\\ &K(f_i) \in \left\{k' \mid C_i(k') = \max_{\forall k} C(k)\right\},\\ &T\left(e_{j\longrightarrow i}\right), k, k' \in \{A, O, M, I, R, Q\}. \end{aligned} \tag{5}$$

Among them, $K(f_i)$ is the Kano classification result of product attribute f_i. That is to say, by summing up the

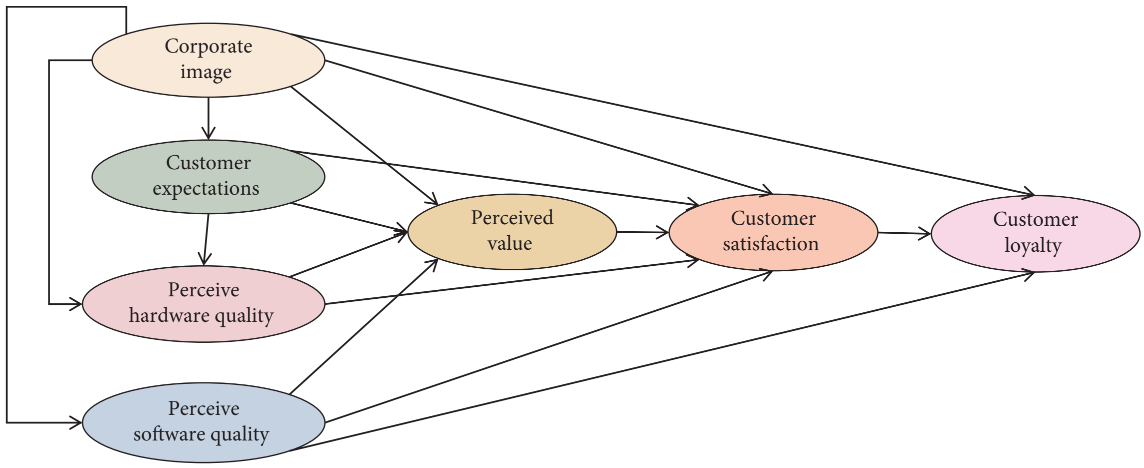

Figure 2: Customer satisfaction index structure model.

regional statistical percentages of each factor of a certain product attribute, the factor corresponding to the maximum value is the factor that the attribute is divided into.

The technology and environmental conditions provided by the mobile Internet make it possible to collect real-time and comprehensive data for the elderly. By using cloud processing and other means, it can not only reduce the functional burden of products, but also provide digital information services based on similar people. In the future, a big data information platform will be established for the elderly, which will provide conditions and entrances for the intervention of various comprehensive services. At the same time, the interactive experience based on communication will be realized through the construction of home or community networks, which will also provide the possibility for the optimization and upgrading of system services.

4. Results Analysis and Discussion

Kano model is based on customers' perceived quality. Kano model keeps approaching customers' expectations by developing charm quality characteristics, and its purpose is to maximize customers' potential needs. Kano model can be used to accurately find out the root causes of service quality problems, which is helpful for enterprises to prescribe the right medicine and formulate correct development strategies. Existing demand importance evaluation methods have obvious flaws when it comes to dealing with the importance issue. Because a large number of complicated and trivial needs of users are asked, it is easy to bore users and lead to incomplete and inaccurate inquiry results when using the user inquiry survey method. Although using the repetition frequency of users' requirements can avoid the drawbacks of the previous method, judging the importance solely on the basis of the repetition frequency of users' requirements is unreliable. Interest demand is a very rare occurrence in the Kano model's user demand acquisition process, but it is extremely important product demand information.

In the daily life of the elderly, cognitive ability is an important ability for the elderly to receive information about external things. The decline of cognitive ability of the elderly not only brings inconvenience to their own lives, but also troubles the lives of other family members. At the same time, the physiological function of the elderly is degraded due to the increase of age, as shown in Figure 3, it is physically and psychologically difficult to keep up with the fast-paced modern life.

The data of Kano questionnaire on product service quality are preliminarily summarized, and then the related quality characteristics are classified by Kano attributes. The priority order of attributes at the same level is determined by calculating the better-worse index. The value of better is usually positive, which means that if a certain attribute is provided, the user satisfaction will be improved. The larger the positive value, the stronger the effect of improving the user satisfaction, and the faster the increase. The value of worse is usually negative, which means that if a certain functional attribute is not provided, the user's satisfaction will decrease. The more negative the value is, the stronger the effect of decreasing the satisfaction will be and the faster it will decrease.

In this paper, the lowest threshold of hearing perception of elderly users is studied experimentally. The test mainly focuses on the sound threshold test of elderly users, and the sensitivity of elderly users to sound is found. When the elderly users are using the product, the sound prompt with appropriate volume can attract the attention of the elderly users so that the elderly users can grasp the state of the product. As shown in Figure 4, the sound threshold that the elderly users can distinguish is obtained, and the sound feelings that the elderly users hear are listed, which provides the data source for the research of product interactive hearing below.

The statistical data of sound threshold can be used to conclude that the elderly users' hearing loss is severe. The elderly users' auditory attention is hardly drawn to sound stimulation with a volume below 40 dB. The elderly users can only fully receive the sound stimulation and recognize the sound content when the volume is above 40 dB. As a result, in interactive aging product design, the sound feedback prompt of products must be above 40 dB in order for elderly users to recognize and master the product status.

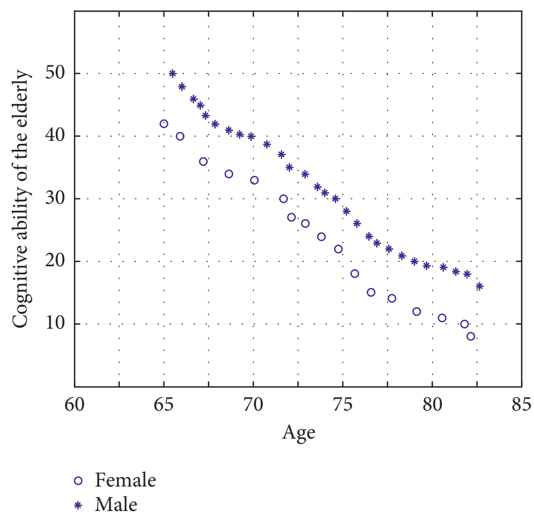

Figure 3: Trend of cognitive ability of the elderly with age.

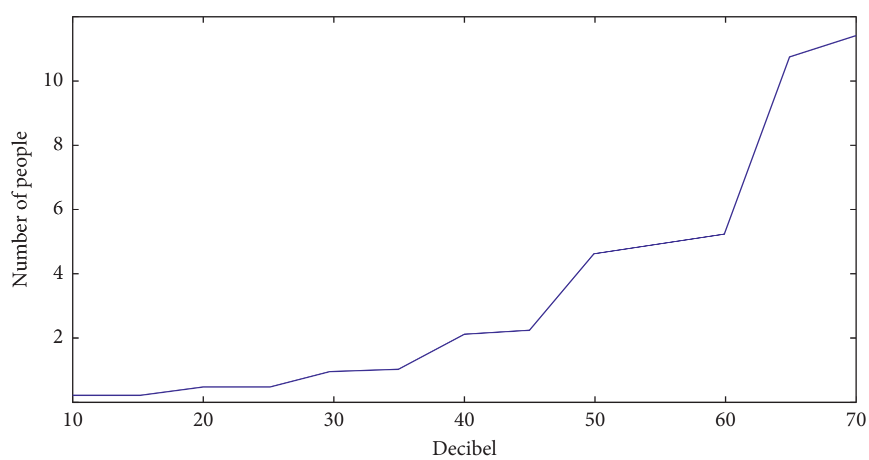

Figure 4: Minimum sound threshold statistical result.

On the one hand, the Kano model analysis results reflect the user's preference, which helps manufacturers gain a better understanding of their customers' individual needs and, ultimately, determine the customizable product attributes that must be entered into the aided design support system. On the other hand, it has the potential to improve the configuration process and efficiency. Consumers and manufacturers have formed a benign closed loop around their individual needs under this framework, from the perspective of consumers. Kano analysis, which improves the efficiency of product configuration in the CAD support system, fully reflects the collaborative value of consumer demand. He directly participates in the product configuration process as an individual consumer, efficiently obtains a personalized product design scheme through human-computer interaction, and fully satisfies his own preferences.

The visual effect and font size of the interface will affect the cognitive efficiency of the elderly users. In order to verify the feasibility of the operation interface of this scheme and whether it can meet the needs of the elderly users for easy identification and operation, the usability test of the operation interface is carried out. Using the software to make dynamic effects, key operation, feedback prompts, and so on, we simulate the operation mode of the old users' real use of the rice cooker and select an existing operation interface of the rice cooker in the market for comparative test. The experimental results are shown in Figure 5.

It can be seen from Figure 5 that the average time for the elderly users to operate the designed interface is less than that of the existing interface. The design scheme is obviously superior to the existing product scheme, benefiting from concise interface interaction, good human-machine dimension of parts, and appropriate feedback information. This also verifies the effectiveness of the aging design principle. The test of this design scheme relies on software to simulate the actual operation effect, and the final test result is convincing to a certain extent. The actual product interaction effect also needs real products as the evaluation object.

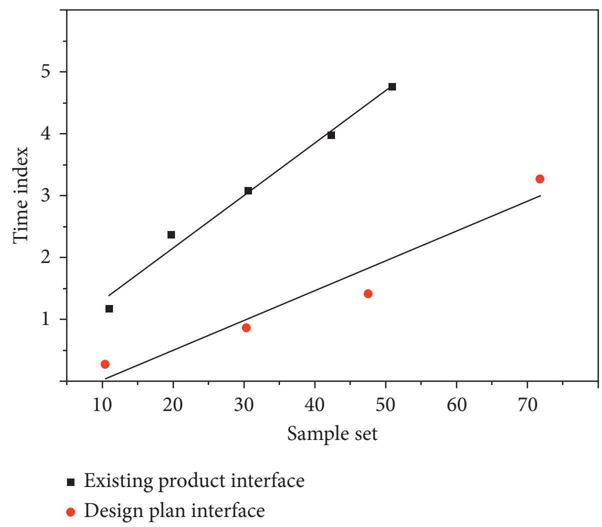

Figure 5: Average test time for two interfaces.

By refining the common factors that can represent the overall structure of the questionnaire, the cumulative explanatory quantity in the analysis results can explain to what extent the test questionnaire can reflect the true characteristics of the measured object; that is, it can test the structural validity of the questionnaire. Based on the two tests before and after the innovation activity, the transition matrix is constructed by analyzing the changes of a certain quality element among five categories of quality elements. Assuming that the innovation effect is stable, the stable state of Markov chain can indicate the degree of innovation. Figures 6 and 7 reflect the time taken by users to evaluate individual product design schemes in each generation population under the two methods.

According to the comparison results, the method proposed in this paper effectively reduces the user's operation time, and both the average time for evaluating each generation population and the total time for completing a product customization are less than the time required by traditional methods. Therefore, the method proposed in this paper can fully alleviate user fatigue in the process of product customization.

Although the importance analysis method for structural requirements is the same as for functional requirements, the distribution of weight values differs. Because of their complaints and dissatisfaction with the original product structure and behavior, users, for example, pay more attention to basic needs. If these factors are not adequately considered in the design of new products, user dissatisfaction will skyrocket, and the image of new products will suffer. As a result, businesses should adjust the criterion layer's weight set in accordance with their own product development strategies. Before the experiment, the data were set and recorded, and the behaviors and actions of the subjects using the products were coded to ensure the reliability and validity of the final data. The classification of behaviors should be complete and nonoverlapping, and behaviors should be clearly defined so that observation is not made more difficult or inconsistent. The behaviors in this experiment are grouped based on this requirement.

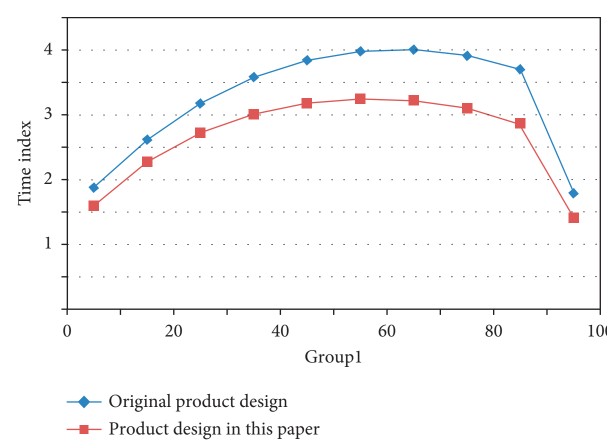

Figure 6: Time for single operation of the first group of users.

After the product design scheme is completed, in order to verify whether the design scheme can be accepted by the elderly users, the elderly users need to evaluate the product and obtain their satisfaction with the design scheme. This evaluation is mainly conducted from three aspects: product appearance, interface effect, and operation mode. Make Likert scale from the aspects of product appearance, usability, identifiability, interface layout, and operation mode. Figure 8 is a comparison of satisfaction evaluation between traditional product design and interactive aging product design for elderly users.

It can be seen from Figure 8 that typical elderly users are satisfied with the design scheme of this product. The average satisfaction of product appearance, usability, identifiability, interface layout, and operation mode is generally high. The scientific design of this paper is verified.

The characteristics of quality elements are examined in depth in this chapter. In terms of time characteristics, charm,

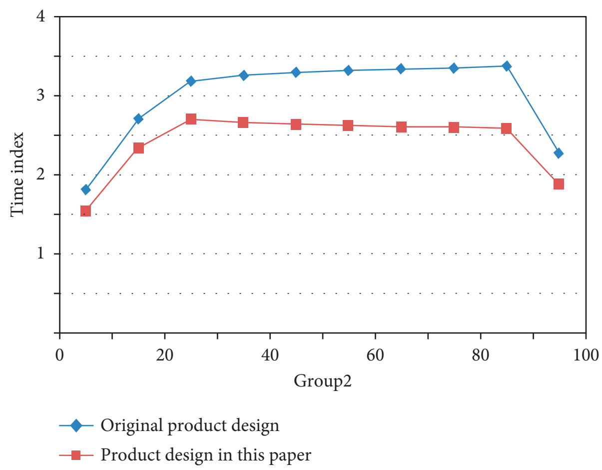

Figure 7: The second group of users' single operation time.

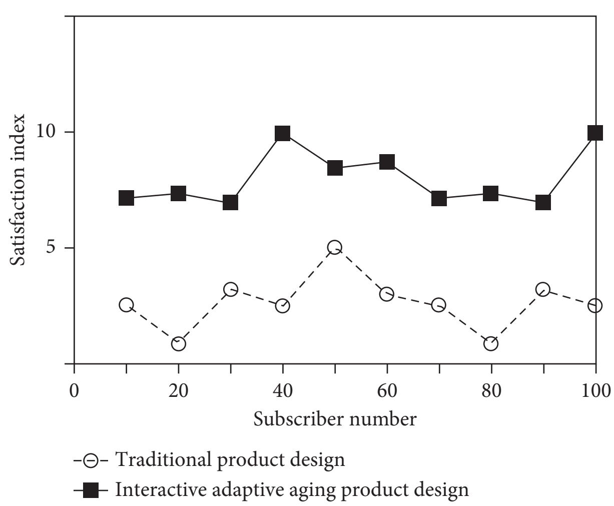

Figure 8: Comparison of product design satisfaction evaluation.

expected quality, and basic quality sink, from the perspective of enterprises, attractive quality is a pursuit goal, in which enterprises hope that the quality and physical characteristics of their products can become attractive quality to customers. The influencing factors of service quality are studied from the perspective of consumers' types, in combination with the characteristics of the elderly population and consumers' personality in the questionnaire survey results. To investigate the possible rules between different personality characteristics and Kano model quality judgment, summarize the consumers' Kano quality judgment results separately.

5. Conclusions

Fundamentally improving the interactive performance of the aged products, making the interaction between the aged users and the products more accurate and relaxed, and making the aged products safer, more comfortable, and more efficient, as well as improving the inclusiveness and interactivity of the hardware facilities for the aged groups under the aged care model with Chinese characteristics, and ensuring the level and quality of age care are of strategic and practical importance. The goal of designing products for the elderly is to provide a positive product experience based on barrier-free use so that product usage is more in line with the people-oriented concept and a high-quality user experience, promoting the stability and prosperity of a harmonious society. Product design, on the other hand, is an important aspect for businesses to remain evergreen. This paper develops a dynamic quality factor prediction model based on a thorough understanding of the characteristics of quality factors. It also introduces a brand-new method for assessing the impact of quality innovation activities. This paper proposes to evaluate the effect of interactive aging design of products using relevant Kano model theories from the perspective of the elderly. This method of assessment is more scientific and objective. At the same time, the evaluation model presented in this paper is straightforward and simple to implement.

Text makes up a large portion of network data because it is the vehicle for people's direct expression of emotions and opinions. How to analyze and mine these emotional text data has become a hot topic of concern in academia and industry in recent years. The online LDA (Latent Dirichlet Allocation) model is used in this paper to train the social hot topic data of professional migrant workers on the same time slice, and the subtopic evolution and intensity are obtained. The topic development is divided into four categories, and the classification model is created using SVM (Support Vector Machine). Instead of decision makers, a virtual human with sensibility and rationality is built using a hierarchical emotional cognitive model to solve multiobjective optimization problems interactively. It analyzes human body structure and emotional signals, and then combines them with visual and physiological signals to create multimodal emotional data. An example is used to demonstrate the effectiveness of the proposed model.

1. Introduction

Entrepreneurship of professional migrant workers can effectively alleviate social employment pressure, narrow the income gap between urban and rural areas, and promote new urbanization. In recent years, professional migrant workers' entrepreneurship has been paid more and more attention by the government and academia. However, at present, most professional migrant workers' new ventures are in a development dilemma due to lack of competitive advantages in the fierce market competition [1]. With the rapid spread of the Internet, its social effects are also rapidly expanding. These energies are positive and negative, while events with negative energy are more likely to cause large-scale discussions. At this time, local problems may become public topics in the country, causing huge social panic, and sometimes even requiring government intervention [2, 3]. The process of urbanization and the innovation of social system have increased farmers' enthusiasm to move to cities. They are eager to gain economic benefits in cities, but they are also eager to integrate into urban life, but the reality is not as they wish.

To deal with public opinion of professional migrant workers' social hotspots, it is necessary to improve the predictability of hotspots, which necessitates the analysis of professional migrant workers' social hotspots and trend prediction. The monitoring of professional migrant workers' social hot-spot public opinion requires the use of Weibo's hot-spot detection. It is necessary to understand the development trend of hot-spot in order to make the right decision and ensure the development of Weibo platform in the direction of health, freedom, and vitality in order to correctly guide public opinion and curb online rumors [4]. Different emotional themes focus on different aspects of emotional content in a subjective text and are also related to different emotional words in the text. As a result, the distribution of text themes can reflect the text's overall semantic structure. However, because the emotional content of the text is treated equally to other content in the theme modeling process, and the semantic strength of the emotional theme is determined by the proportion of emotional words in the text, it is still insufficient in highlighting the emotional semantics [5, 6]. Furthermore, traditional theme modeling ignores semantic relationship patterns such as text sequence and word context, instead treating the text as a word bag and determining the theme solely based on the word co-occurrence relationship, which limits the text representation ability.

This topic focuses on emotional analysis and topic trend prediction of social hot topics for professional migrant workers, which refers to the trend prediction of topic state change, that is, to predict the change of topic state in the next period of time [7]. Through human-computer interaction and fuzzy cognitive evaluation, the quantitative relationship among personality characteristics, mood state, and emotional state is described. On this basis, a virtual human integrating sensibility and rationality is proposed, and then a multiobjective decision-making problem-solving method based on hierarchical emotional cognitive model [8] is given. The visual signals are linearly fused with four physiological signals to obtain four groups of multimodal information [9]. The principle based on feedback information and the recognition rate of multimodal information to emotional state is introduced to design the weight determination method. On this basis, decision-level weighted fusion is introduced, and an emotion recognition model based on multimodal signal decision-level weighted fusion is established.

The innovation of this paper: This topic focuses on the emotional analysis of social hot topics of professional migrant workers on the Weibo platform. Based on the existing historical data, this paper deeply analyzes the characteristics of users and texts, extracts a series of characteristics such as emotions and users from them, and constructs a regression model combining with the time series model to describe the development trend of hot topics in the near future, and finally predicts the development trend of hot topics, and helps to realize the early warning of the development of hot topics.

2. Related Work

A research hotspot is using emotion classification technology to solve practical problems in social hot topics of professional migrant workers. The method of statistical emotion words is used in literature [10] to calculate emotions under fixed topics, which can be applied to trend prediction and yields good results. Hong et al. [11] calculate the emotional time series using the ratio of Weibo number to positive and negative emotional words obtained from Twitter data every day, and then use a self-organizing fuzzy neural network to predict the Dow Jones Industrial Average. To predict the movie box office, the emotional ratio is calculated using emotional analysis of social hot topic data, which is then combined with the movie box office using the Pearson correlation coefficient [12]. This paper uses statistics to conduct an emotional analysis on the topics of these mobile phones on Twitter, and then uses classified methods to predict users' satisfaction [13–15]. Zhou et al. [16] looked at opinion leader fans on Twitter, classified their emotional comments, and discovered that followers are influenced by their emotions, and that the change in this influence is consistent with reality. This study confirms that a user's emotions have an impact on his followers, particularly opinion leaders' emotional changes, and uses this relationship to predict user emotional changes.

The research on emotional modeling and application has been paid extensive attention [17, 18]. Especially, literature [19, 20] puts forward the emotional cognitive learning and decision-making model by applying Boltzmann selection mechanism, which takes emotional factors as internal influences and external environment as external influences, and realizes emotional cognitive learning and decision-making by calculating the internal and external influence probabilities after decision-making; Sosa and Rodríguez [21] realized the coordinated control of robot behavior on the basis of emotional cognitive learning and decision-making model. However, the application of emotional model was limited because it adopted symbolic cognitive state and decision-making behavior. In literature [22], the author proposed an improved emotional interaction model, but it still did not take into account the influence of individual personality characteristics on the emotional model, so it was still limited when it was used to solve decision-making problems. Khare and Bajaj [23] put forward a multimodal emotion recognition model based on visual signals and physiological signals, which combines facial expression features and ECG features in series at feature level to form multimodal features. Experiments show that the recognition rate of multimodal features is higher than that of one modal feature. Schmidt et al. [24] put forward the multistream fusion hidden Markov model for emotion recognition. The multistream fusion hidden Markov model is the generalization of the two-stream fusion hidden Markov model, which is a general model-level modal fusion method. Mohammed and Karim [25] use the principle of equal weight to weight and fuse the classification results of audio, video, and text at the decision level, which is equivalent to unweighted fusion at this time. Tao [26] uses grid traversal (0,1) to get the optimal weight, and at the decision level, the classification results of facial expression signals and ECG (electrocardiogram) signals are weighted and fused to get the final recognition result.

Based on the above research, aiming at the characteristics of multimodal information, linear fusion is introduced at the feature level to obtain multimodal features, and the expressive force of multimodal features on emotional state is analyzed. Combining with the principle based on feedback information, the weight determination method is designed. Linear weighted fusion is introduced at the decision level, and an emotion recognition model based on multimodal information two-level fusion is established. Therefore, combining with the characteristics of human multimodal emotional information, it is of great significance to study the weighted fusion of feature level and decision level to improve the model recognition rate.

3. Research Method

3.1. Research on Long-Term Topic Prediction Based on Subtopic Separation. LDA (Latent Dirichlet Allocation) topic model belongs to the document generation model, which assumes that the document has multiple hidden topics, all of which can be composed of the word distribution in the fixed vocabulary [27]. After the topic was put forward, it was widely used, especially in the direction of text clustering and similarity calculation. Figure 1 is the LDA model diagram.

Assume that the rectangular square at the top of LDA graph model is the theme, and K is the number of themes. The letter M in the figure represents the number of all documents in the model, while N is the number of words in the documents and Z is the number of words in the word list.

The inner and outer boxes in the figure also have specific meanings, in which the outer box is a document, while the inner box represents the choice of topics and words in the document. The superparameter in the graph is defined as follows:

α represents document-topic distribution, and β represents topic-word distribution, both of which are fixed values, which are specified by users in advance. W in the graph is observable data, which is a $M \times N$-dimensional matrix, and W_{ij} represents the word j in document i; Document-topic distribution θ and topic-word distribution ϕ are both implicit variables.

The process of using LDA model to generate documents is as follows:

(1) Selecting word distribution $\phi_k, k \in \{1, \cdots, K\}$ of topic k from Dir (β) of parameter β

(2) Select the theme distribution θ_i of document i from Dir (α) of parameter α, $i \in \{1, \cdots, M\}$

(3) For the word at the j position in document i, $i \in \{1, \cdots, M\}$, $j \in \{1, \cdots, N\}$:

(1) Generating the theme Z_{ij} of the word j in the document i according to the polynomial distribution with the parameter θ_i

(2) According to the polynomial distribution with parameter $\phi_{Z_{ij}}$, the word W_{ij} of word j in document i is generated

A topic will inevitably change with time, but no matter how it changes, the new data will still carry the information of the old data, that is, the topic is persistent and stable. However, the training process of LDA model is to train all documents directly and generate various topics at the same time, which cannot deal with online new texts. Therefore, online LDA model should be born. In online LDA model, the distribution of topic words in time slice t obeys the following Dirichlet distribution:

$$\phi_k^t \sim \text{Dirichlet}\left(\beta_k^t\right) \sim \text{Dirichlet}\left(w\beta_k^{t-1}\right). \tag{1}$$

Among them, the matrix β_k^{t-1} retains the words of the previous time slice, and w is a weight vector indicating the proportion of historical words retained.

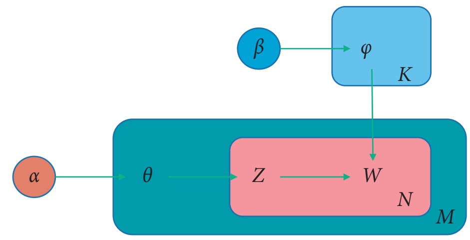

Figure 1: LDA model diagram.

Set the theme intensity of this article, that is, the document with clear theme tendency is regarded as high intensity, otherwise it is low. Calculate the intensity of each Weibo, finally get the total intensity of Weibo under the time slice, and calculate the theme intensity according to

$$T_S\left(Z_K\right) = \frac{\sum_{n=1}^{N} w_n^{\theta_{n,k}}}{\sum_{n=1}^{N} w_n}. \tag{2}$$

Among them, $\theta_{n,k}$ represents the estimated value of the distribution of the m-th Weibo on the k-th subtopic, and w_n represents the document weight. When the social hotspot is only related to this subtopic, the weight is set to 1. When social hotspots discuss multiple events at once, as shown in LDA, that is, when words with multiple topics appear in this social hot topic of professional migrant workers, and the weight is measured by the maximum value, the weight is measured by the maximum value.

When the theme evolves, the words change with it. The so-called variation is the dissimilarity. KL distance is generally used to measure the similarity. For the topics of $d-1$ time and d time, KL distance is

$$S_{\text{KL}} = \left(\phi_k^{d-1}, \phi_k^d\right) = \frac{1}{2}\left(\sum_{i=1}^{V} \phi_{k,i}^{d-1} \log \frac{\phi_{k,i}^{d-1}}{\phi_{k,i}^{d}}\right), \tag{3}$$

where ϕ_k^{d-1}, ϕ_k^d is the distribution of the same subtopic on the previous day and the next day, respectively, and the calculation result indicates the similarity between the two topics, then the topic variation rate is as shown in formula (4), which is

$$V = 1 - S_{\text{KL}}\left(\phi_k^{d-1}, \phi_k^d\right). \tag{4}$$

Considering that the ups and downs cannot reflect the overall change of the trend, according to the speed of topic trend change, the topic discussion degree is divided into four categories, and forecasts them separately. The specific division according to numerical values is shown in Figure 2.

These four categories are classified in this chapter based on subtopic intensity and subtopic variation rate, and the subtopic intensity and subtopic variation rate, as well as the classification results, are added as two features to each time slice, and the prediction is made using the GBDT method (gradient boosting decision tree).

3.2. Hierarchical Emotional Cognitive Model. Establish a hierarchical emotional cognitive model, which includes a personality characteristic layer, a mood state layer, an

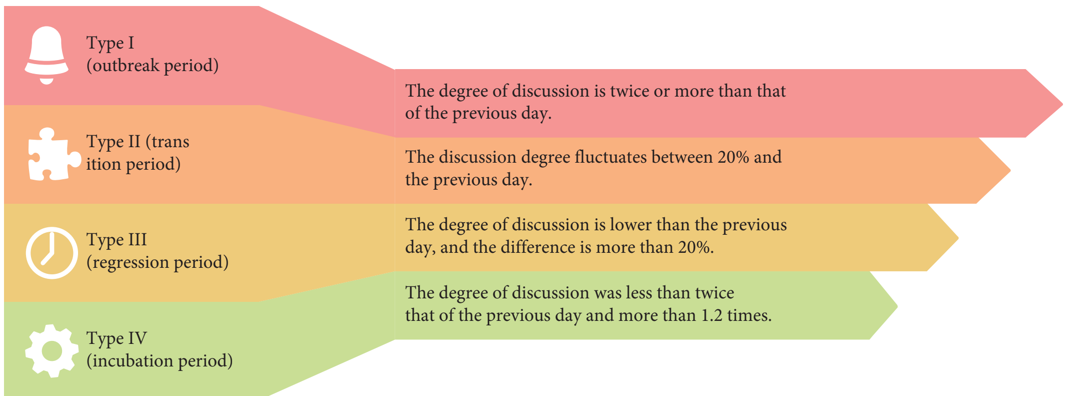

Figure 2: Classification table of long-term topic popularity value.

emotional state layer, and a cognitive evaluation module, as shown in Figure 3.

The personality layer realizes the acquisition of personality data through human-computer interaction, and influences the change process of the lower mood state through mapping and personality parameters; the cognitive module quantifies and evaluates the influence of external stimulus signals on the emotional model, and then transmits it to the mood layer of the emotional model.

In the process of emotion renewal, mood layer and emotion layer interact with each other, and the stability of personality layer, mood layer, and emotion layer decreases in turn, while personality layer is the most stable and emotion layer is the most prone to change.

Personality is a relatively stable parameter that can be used to describe a person's personality and is influenced by both heredity and acquired environment. Personality is an important parameter in the emotion model because it directly reflects the personality of the individual. Because personality has a direct impact on the size of each component of mood state and the speed with which states transition, emotion modeling requires accurate data on individual personalities.

The definite character characteristic vector is

$$\begin{aligned} &P_p = [P_N, P_E, P_O, P_C, P_A], \\ &P_X \in [0,1], \\ &X \in \{N, E, O, C, A\}. \end{aligned} \tag{5}$$

Among them, P_N, P_E, P_O, P_C, P_A represents neuroticism, extroversion, openness, conscientiousness, and agreeableness, respectively.

Mood level is used to represent people's mood state, which can be described by PAD (pleasure-arousal-dominance) model, where P represents the positive and negative characteristics of individual emotional state, A represents the individual's neurophysiological activation level, and D represents the individual's control over the situation and others. PAD model corresponds to a three-dimensional emotional space.

Define the mood state space as a three-dimensional PAD, and define the mood state vector as

$$M_{\text{ent}} = [m_P, m_A, m_D]. \tag{6}$$

Among them m_P, m_A, $m_D \in [-1,1]$, $M_{\text{ent}} = [0,0,0]$ corresponds to a calm state of mind.

In order to be suitable for multiobjective decision-making, two components, positive and negative characteristics of emotion and emotional intensity, are selected to represent the emotional state. The emotional state is defined as a two-dimensional vector:

$$E_e = [\chi, q], \chi\{-1, 0, 1\}, q \in (0, 1). \tag{7}$$

Among them χ represents the positive and negative characteristics of emotion, with a value of 1, 0, or 1, which respectively indicates that the current emotional state is negative, calm, and positive; q represents the current emotional intensity.

The cognitive evaluation of an emotion model for external stimulus signals should begin with the individual's intention and evaluation criteria for the evaluation subject, and then learn from the literature method [28]. Individuals' subjective wishes, preferences, and individual evaluation criteria determine their emotional expression, so the emotion model should pay attention to the design of wishes, preferences, and evaluation criteria for the cognition of stimulus signals.

The change of state of mind is influenced by personality characteristics and external stimuli, and at the same time, it will decay with time. Let M_t represent the state of mind corresponding to time t, then the updating process of state of mind space is as follows:

$$M_t = \varphi(M_{t-1}) + M_P + M(U) \tag{8}$$

Here, M_t, M_{t-1} is the state of mind of the current moment and the previous moment respectively; $\varphi(M_{t-1})$ is the mood state attenuation function; and $M(U)$ is the influence of external stimuli on mood, which is calculated by fuzzy cognitive evaluation module.

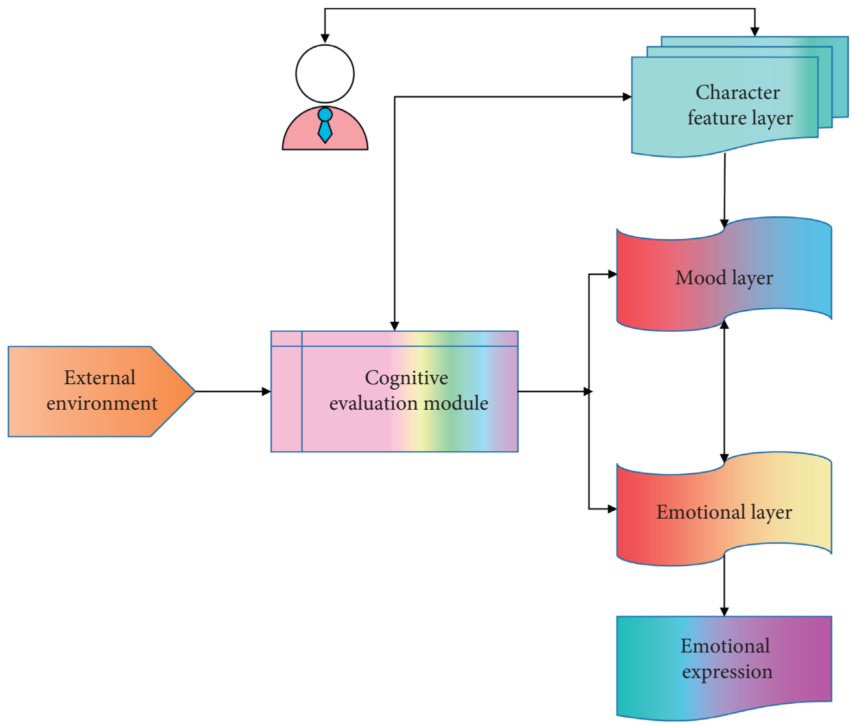

Figure 3: Hierarchical emotional cognitive model structure.

Normal multiobjective decision-making problem can be described as

$$\max M = \{f_1(x), f_2(x), \ldots, f_l(x)\}$$
$$s.t \begin{cases} g_i(x) \le 0, & i = 1, 2, \ldots, m, \\ X = (x_1, x_2, \ldots, x_n)^T, & x_* \in R, \end{cases} \quad (9)$$

where $g(x)$ is the constraint function.

Figure 4 shows an emotional interactive decision-making algorithm based on hierarchical emotional cognitive model. This algorithm takes goal achievement degree, priority of objective function and overall coordination degree as emotional cognitive evaluation factors, and combines rational decision-making with emotional decision-making to build a virtual human. After obtaining the cognitive model of decision-making experts through interaction, it can realize automatic emotional decision-making by computer.

Cognitive decision-making model consists of rational decision-making module and emotional decision-making module, which respectively give the adjustment range of goal attainment. The two parts of adjustment range of goal attainment represent external objective requirements and internal subjective desires, respectively.

3.3. Emotion Recognition Based on Multimodal Information Feature Level and Decision Level Fusion. Emotion can cause many changes such as external changes of facial expression and internal changes of human physiology at the same time, so it is imperative to study emotion recognition based on multimodal information [29]. Facial expression recognition based on visual signals, considering the dynamic feature information of facial expression changes, and using the temporal and spatial information of facial expression changes at the same time, can reflect the essence of facial expression changes more truly and has stronger practical applicability.

The process of expressing human emotions is a process in which various modal information complement each other comprehensively. Single-modal features can only show part of the attribute information of the object. In order to describe the target object more accurately, the integration of multimodal features is an inevitable trend. The emotional features involved in this chapter are visual signal features and four physiological signal features. After feature extraction [30–32], the visual signal features and four physiological signal features are combined in series to form four multimodal features.

SVM (Support Vector Machine) is a new learning algorithm developed on the basis of statistical learning theory. Support vector machine classifier has a good effect on small sample classification problem, and it is not necessary to take enough sample number as the theoretical condition. For the above reasons, this method has been widely used in pattern recognition.

This chapter chooses one-to-one method to solve the multiclassification problem of expressions based on support vector machine. For n expression categories, design a binary support vector machine classifier for every two expressions, that is, design $n(n-1)/2$ subsupport vector machine classifier, SVM_{ij}, $1 \le i < j \le k$. Among them, i, j is the expression category label.

In this chapter, the voting mechanism of multiple classifiers is adopted, and the complementary performance

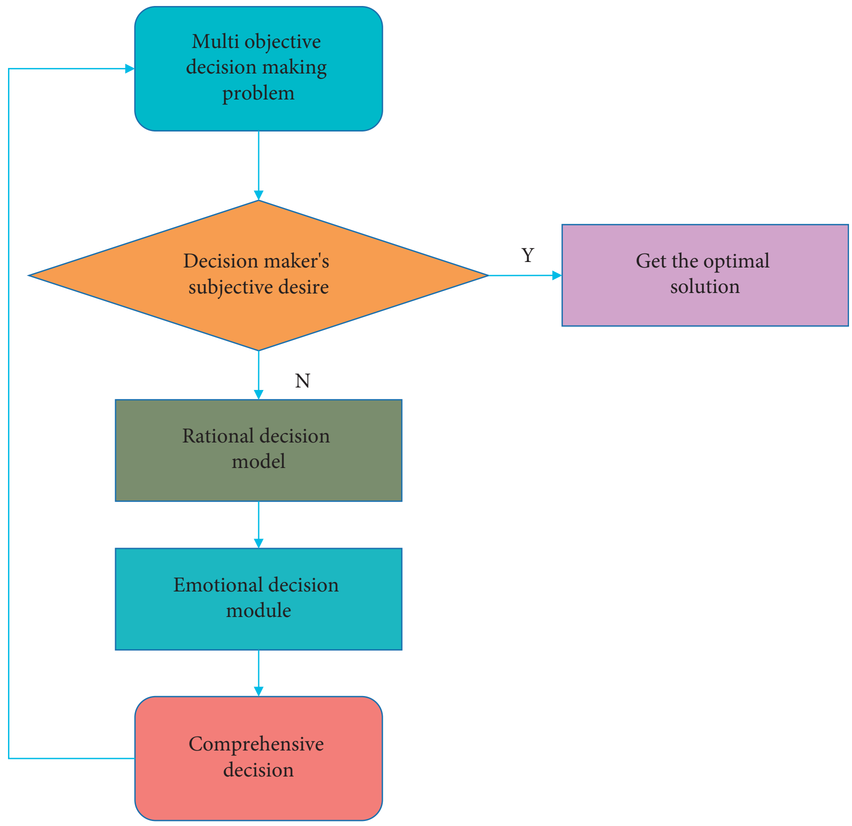

FIGURE 4: Cognitive decision-making process.

of multiple classifiers is used to improve the recognition effect. First, the recognition results of emotion state by emotion classifier based on multimodal signals are obtained. Then, for the experimental results of several subclassifiers, the final recognition results are obtained by weighted voting, and the specific calculation steps are as follows:

Get the weighting matrix of the multimodal signal, and then the weighting matrix $W_i\,(1 \le i \le 4)$ of the corresponding subclassifier is

$$W_i = \begin{bmatrix} p_{i1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & p_{im} \end{bmatrix}. \tag{10}$$

Let $\overrightarrow{C}_i = (c_{i1}, c_{\mathrm{im}})^T\,(1 \le i \le 4)$ be the result of the subclassifier, where $|\overrightarrow{C}_i| = 1, c_{\mathrm{ij}} \in \{0, 1\}\,(1 \le i \le 4, 1 \le j \le m)$.

$$\overrightarrow{C} = \sum_{i=1}^{4} W_i \overrightarrow{C}_i = \sum_{i=1}^{4} \begin{bmatrix} p_{i1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & p_{im} \end{bmatrix} \begin{bmatrix} c_{i1} \\ \vdots \\ c_{im} \end{bmatrix} = \begin{bmatrix} \sum\limits_{i=1}^{4} c_{i2} p_{i1} \\ \vdots \\ \sum\limits_{i=1}^{4} c_{im} p_{im} \end{bmatrix}. \tag{11}$$

Based on the maximum rule, the k-type emotional state with the highest score is the final recognition result, as shown below:

$$\mathrm{Max}_{j=1}^{m} \left\{ \sum_{i=1}^{4} c_{ij} p_{ij} \right\} = \sum_{i=1}^{4} c_{ik} p_{ik}. \tag{12}$$

For the emotion recognition model based on multimodal signals, because many modal signals are related to the emotional state, analyze the physiological structure of human body and the characteristics of emotion signals, and optimize the selection of visual signals (facial image signals) and four physiological signals (EEG (electroencephalogram) signals, ECG signals, respiratory signals and skin signals) that can be used for emotion recognition, as shown in Figure 5.

Four subclassifiers based on support vector machine are established, and four subclassifiers are trained and tested by using four multimodal emotion features, and the emotion recognition results are obtained. Finally, the model is trained and tested with four multimodal emotional features, and the final recognition result is obtained.

4. Analysis and Discussion

4.1. Long-Term Topic Prediction Analysis. Online LDA model trains data, using all data of the same topic every time, and dividing the data into different documents for each topic according to the daily time slice, and numbering the documents from 0 according to the date sequence. Compare the topic evolution and topic intensity with the topic discussion degree, as shown in Figure 6.

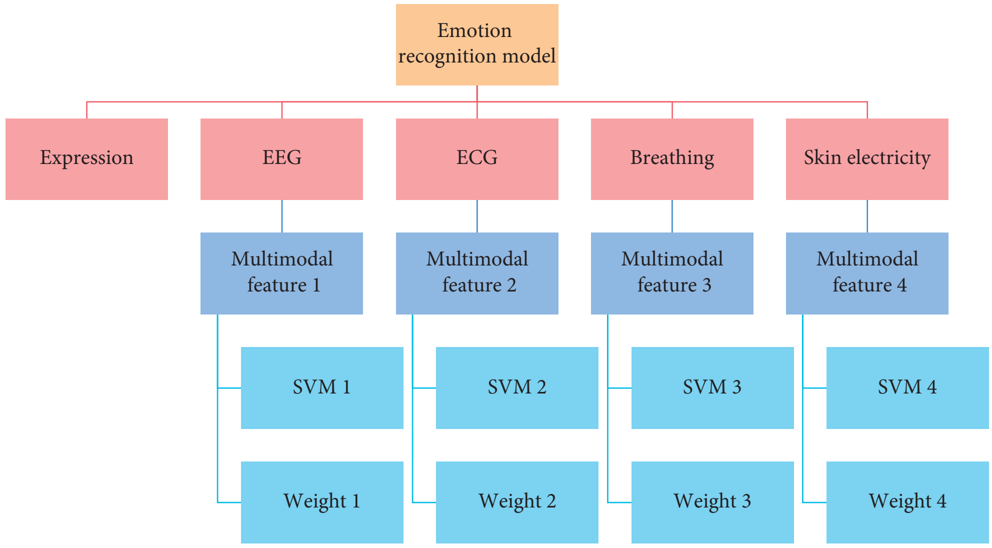

Figure 5: Emotion recognition model based on feature-level fusion and decision-level weighted fusion.

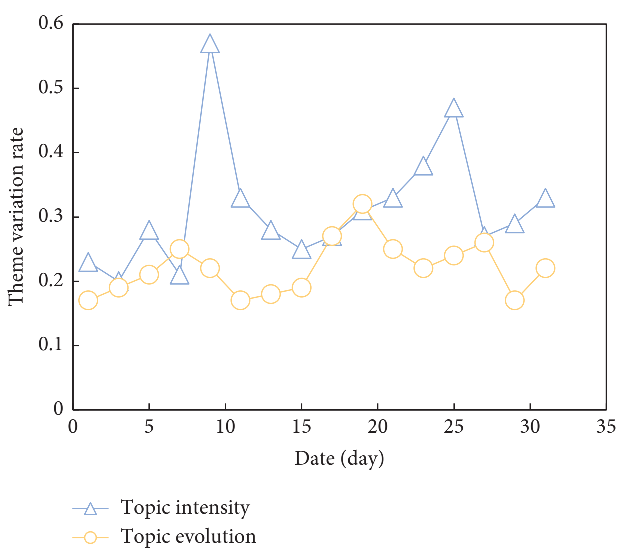

Figure 6: Topic intensity and topic evolution trend chart.

It can be found that when the topic variation rate and intensity are high, the topic discussion degree is also greatly improved, which shows that the topic discussion degree has a great relationship with the topic variation rate and the topic intensity. Careful observation shows that the trend chart between the topic variation rate and the topic intensity has the following relationship:

(1) The number of peaks is roughly the same, and they can all find the correspondence in the topic heat

(2) Theme enhancement lags behind the peak of theme evolution diagram

(3) The small peak of the topic is not closely related to the topic intensity and topic variation, but the big peak is closely related, and the peak of topic evolution is before the peak of the topic

SVM is widely used in classification and regression applications. In this section, SVM in sklearn Toolkit is used to classify forecast data into four categories, with the following characteristics:

(1) Subtopic intensity in the first four days

(2) Subtopic variation rate in the first four days

(3) The historical heat of the first four days

(4) Text features of the previous 4 days

After the features are normalized, SVM is used for training. SVM is very sensitive to the penalty factor c. gridsearchcv () in sklearn is used to automatically find the parameters by gridding. Figure 7 shows the subjective and objective classification error rates corresponding to four groups of feature combinations under several representative c values.

Theme evolution and theme intensity features are recorded as fea1, text content features as fea2 and data features as fea3.

After carefully adjusting the parameters again, the kernel function selects the linear kernel function, the parameter $c = 80$, $g = 0.03$. The final result is shown in Figure 8.

It can be found that the peak prediction rate is very high, which is very helpful for our future trend prediction, and the overall classification accuracy rate reaches 88%. In addition, it is found that these four stages usually occur in turn, so when the category is accurately predicted, this feature is added to the prediction feature to predict the data between two peaks.

In this section, four kinds of classification results are predicted in turn. Only the features of the previous day are used to predict the peak part, and all data before the arrival of the next peak are predicted by using the features of historical data of 4 days. If the calculation is less than 4 days from the peak, the previous features are filled with 0, and the GBDT regression method is used. Figure 9 shows the trend prediction results.

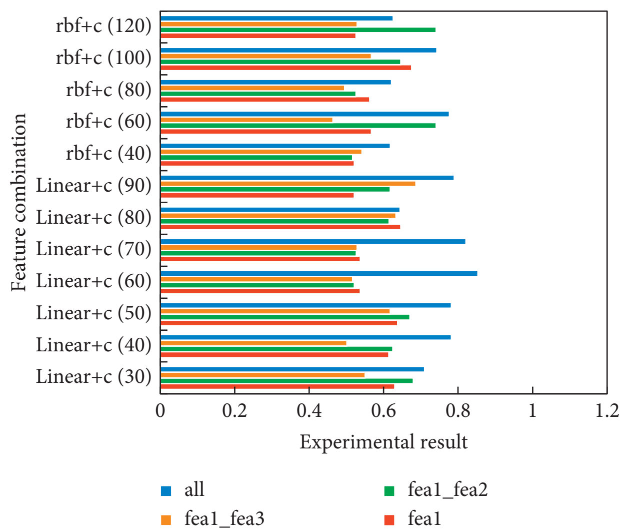

Figure 7: Comparison of experimental results with different characteristics.

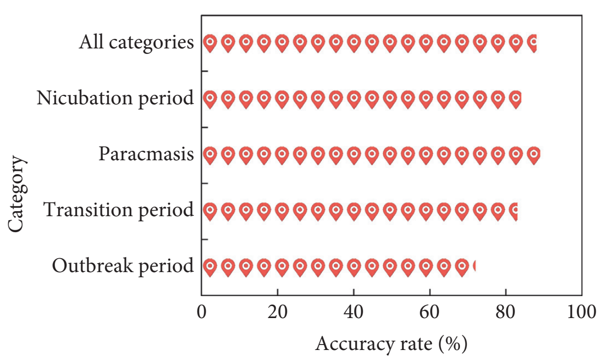

Figure 8: Four classification results.

From Figure 9, it can be seen that, after introducing online LDA model to separate subtopics, the mean square error dropped from 0.098 to 0.081, and the accuracy rate reached 0.77 from 0.74, both of which were better than the previous methods. Moreover, none of the previous forecast periods were accurate. After separation, most outbreak periods can be predicted accurately, but there is still a certain gap between the predicted values.

4.2. Cognitive Analysis. Firstly, the corresponding emotional cognitive model is established. By evaluating the decision makers' personality, the decision makers' personality parameters are $P_P = [\,0.33 \;\; 0.21 \;\; 0.56 \;\; 0.72 \;\; 0.83\,]$ and the influence component of mood is $M_P = [\,0.56 \;\; 0.12 \;\; 0.14\,]$.

When the optimal solution is $x^{*0} = (2.1, 3.1, 3.6)$, the goal achievement degree $\mu^0 = (0, 0, 0)$ and the overall coordination degree $\lambda^0 = 0.6$ are calculated. Then, the multi-objective decision-making is solved based on this emotional cognitive model.

On this basis, the third emotional cognitive decision was made, and the result obtained by the rational decision module was $\Delta\mu_1^3 = (0.233, -0.167, -0.332)$. The component transitions are shown in Figures 10–12.

Goal attainment: $\mu^3 = (0.778, 0.639, 0.507)$, overall achievement: $\lambda^3 = 0.778, s = \sqrt{\sum_{i=1}^{3} (\mu^3(i) - \mu^2(i))\wedge 2} = 0.063 < 0.1$, and satisfied $\mu(f_1(x^{*3})) > \mu(f_2(x^{*3})) > \mu(f_3(x^{*3}))$, Therefore, x^{*3} is the optimal solution to satisfy the subjective desire of decision makers.

4.3. Emotion Recognition. In this section, the experimental hardware devices are mostly desktop computers. The hardware configuration is as follows: inter (R) CORE (TM) i7-6700 CPU, 3.4 GHz, 4 GB memory, and 64 bit Windows 7 Ultimate operating system, which is primarily responsible for running various experimental tools and software, data processing, and result output. MATLAB and the EEG Lab toolbox are used to process a variety of physiological data, and the LibSVM software package is used to train and test the SVM classifier, with Python as the development environment.

The multimodal responses and self-emotional evaluations of 30 collected subjects were induced and recorded synchronously using 20 video clips from the database as stimuli. Emotional signals included peripheral/central nervous system physiological signals, image signals, audio signals, and eye tracking signals. The database's objects are of various ages, genders, races, cultures, and educational backgrounds, and the information coverage is extensive. Furthermore, the emotion-induced video is highly stimulating, the data collection environment is standard, and the emotion signals collected are of high quality.

First, the data set is divided into five types based on emotional tags using stratified random sampling. The training set is made up of a certain percentage of data samples extracted from each physiological signal's data set, while the test set is made up of the remaining data samples.

The emotion recognition model is trained and tested by using four kinds of multimodal signal emotion features, respectively, and the corresponding emotion recognition results are shown in Figure 13.

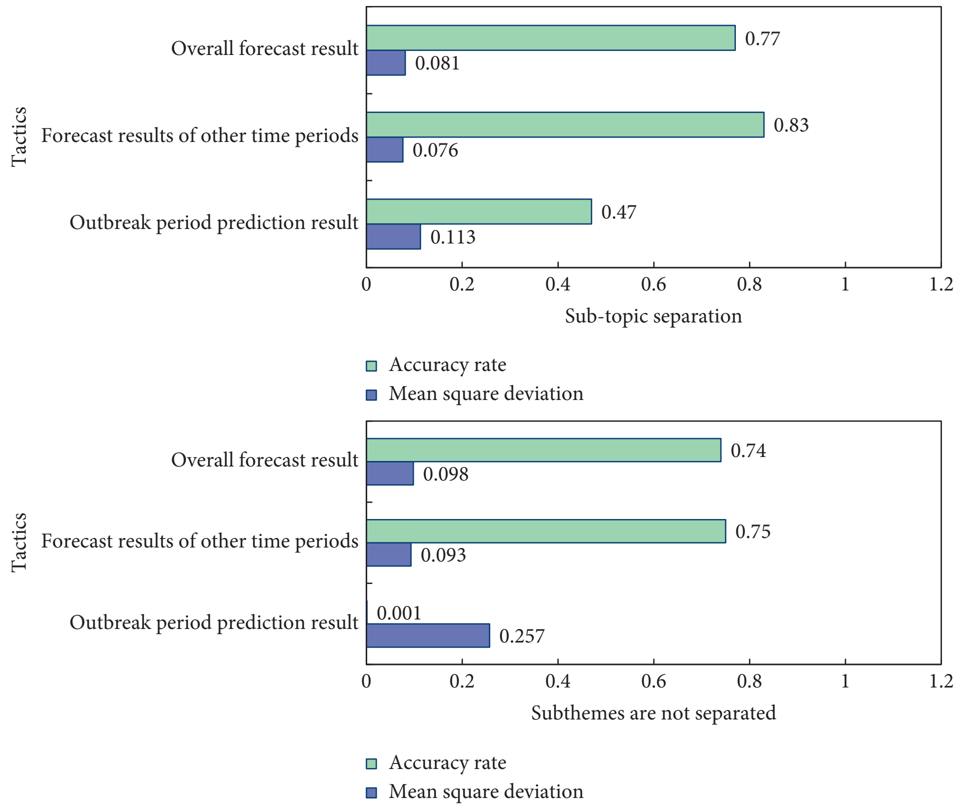

Figure 9: Trend prediction result.

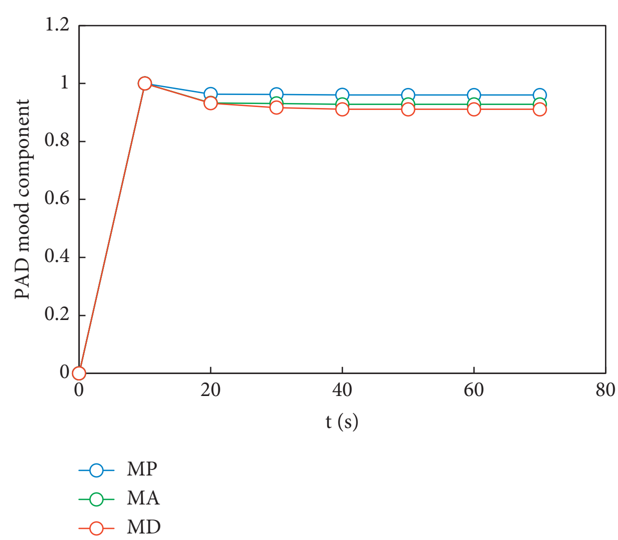

Figure 10: The transition process of each component of decision-making mood state of objective 1.

It can be found from Figure 13 that the local recognition rate of four emotional states is based on the multimodal signal 1 composed of visual signals and EEG signals, while the highest recognition rate of one emotional state "disgust" is based on the multimodal signal 2 composed of visual signals and ECG signals. In addition, the expressive power of four multimodal signals to five emotional states is different.

The types of emotional signals are analyzed in this chapter's research, and a feature-level fusion method is proposed that is universal and can be used for any multimodal emotional signal. This paper investigates the expressive power of multimodal emotional signals in identifying emotional states and proposes a universal weight determination method based on multimodal emotional signals for identifying emotional states. A universal decision-level weighted fusion modeling method is proposed, which can be applied to any multichannel emotional data. The modeling method based on two-level fusion can fully

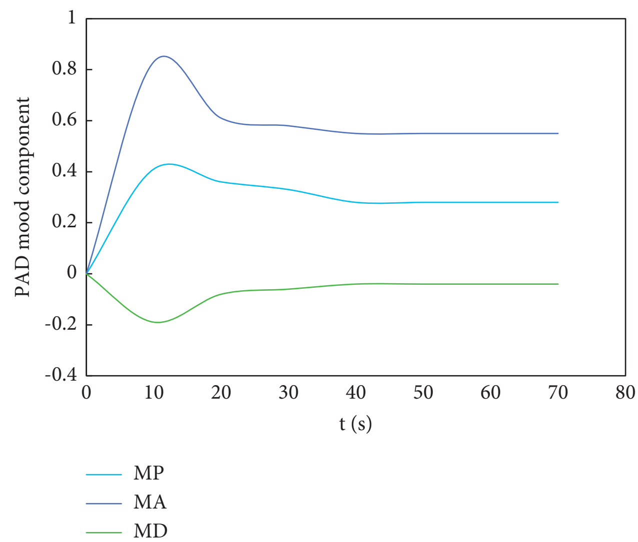

Figure 11: The transition process of each component of decision-making mood state of objective 2.

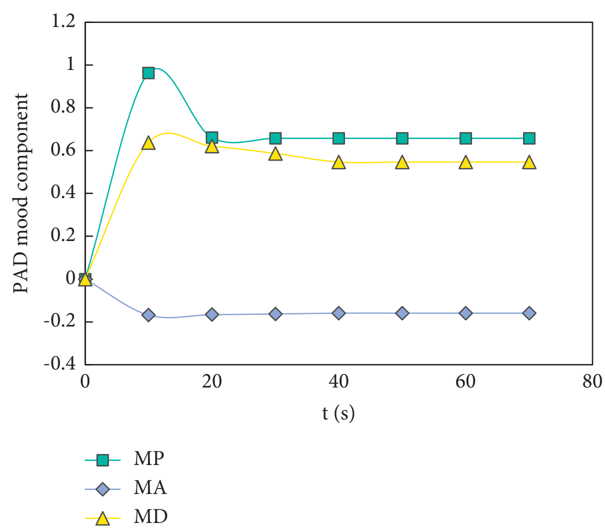

Figure 12: The transition process of each component of decision-making mood state of objective 3. At this point, $\Delta\mu^3 = (-0.186, 0.028, -0.034)$, the optimal solution of the third interactive decision is: $x^{*3} = (10.036, 8.875, 7.518)$, $f(x^{*3}) = (288.24, 241.28, 201.63)$.

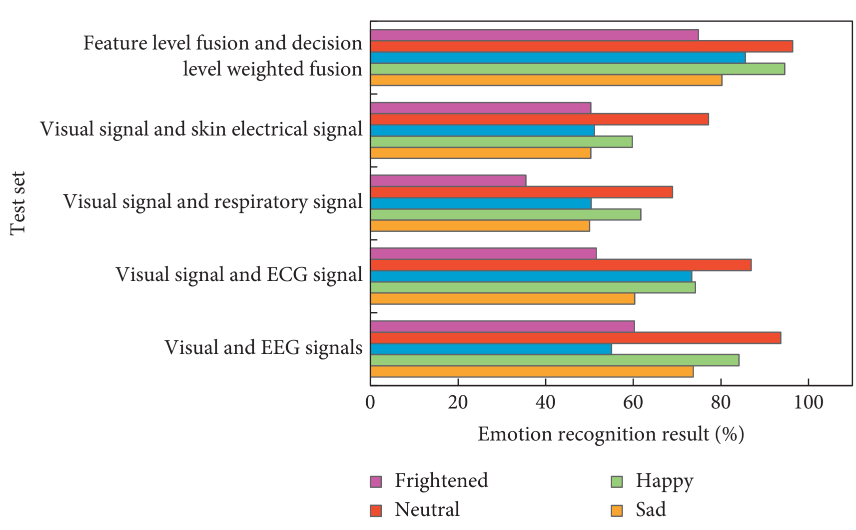

Figure 13: Emotion recognition results based on four multimodal emotion signals and two-level fusion.

exploit the benefits of each channel's emotional information, resulting in a higher model recognition rate.

5. Conclusion

Knowing the information trends of social events on the Weibo platform in real time, as well as tracking and predicting the social hot topics of professional migrant workers on a continuous basis, allows the government and enterprises to grasp public opinion trends in real time and guide public opinion, which is of great social importance to both the government and businesses. In this paper, the Weibo data is trained using an online LDA model on the same time slice, and the subtopic evolution and intensity are calculated. The development of the topic is divided into four categories. The classification model is built using SVM, and the data between two peaks is predicted using a short-term prediction model. The experimental results show that this method's topic popularity classification accuracy is 88 percent. A multiobjective emotional cognitive decision-making method is presented in this paper. This study lays the groundwork for implementing computer-assisted emotional decision-making in complex multiobjective problems. The classification results of four physiological signals are fused for decision-making according to the maximum rule, giving full play to the benefits of various physiological signals and thus improving the model recognition rate.

In this paper, an online LDA model is used to analyze the evolution of subtopics in long-term topics. However, due to the model's limitations, only the same number of subtopics can be fixed every day, which will need to be improved in future research. Various external factors, such as news media reports, public opinion climate, and so on, will influence the topic's trend.

Improving enterprises' independent innovation capability is critical to improving their competitive strength, industries' independent innovation capability, industries' international competitiveness, and countries' independent innovation capability, as well as building an innovative country. It is now the era of strategic innovation. Many growing businesses are focused on strategic innovation, but they overlook the issue of ensuring that strategic innovation is implemented. Management and innovation are perennial themes in the long-term development of businesses. The most pressing issue in enterprises' strategic innovation activities is how to combine their strategic direction with their superior ability and choose a strategic innovation path that is appropriate for their development. This paper uses data mining theory to establish the K-means clustering algorithm to identify the best strategic orientation of enterprise innovation strategic direction selection based on the existing advantages and capabilities of enterprises based on the analysis of the direction of enterprise strategic innovation.

1. Introduction

Nowadays, society is developing rapidly and the competitive environment is fierce. The key to how enterprises can grow reversely in this environment lies in innovation. From the enterprise level, the creative ability of Chinese enterprises is not high, and the subject status is difficult to establish. The innovation power is insufficient, and the institutional foundation and social and cultural foundation are still relatively weak [1]. There is a shortage of external and internal investment resources for innovation, and a market-oriented enterprise's independent innovation mechanism has yet to be formed. In order to gradually solve these problems, we must form a linkage mechanism between the government, industry associations, and enterprises and establish an institutional system and a policy system to promote enterprises' independent innovation [2]. Management innovation is driven by the internal and external motivation of enterprises. A specific analysis of the motivation of management innovation can enable us to have a scientific understanding of the causes and laws of management innovation so as to provide guidance for future management innovation activities [3]. From the perspective of enterprise innovation ability, enterprises must have the ability to ensure that innovation activities are carried out in the established direction, and the ability is reflected by a series of ability elements [4].

In the face of intense market competition, businesses have been put to the test in terms of both survival and development. As a result, businesses must innovate [5]. The majority of entrepreneurs believe that technology is at the center of innovation. They believe that the only way for businesses to increase profits and gain competitive advantages is through technological reform and innovation. In fact, without a strategy, innovation will fail [6]. In this era of technological homogeneity, strategic innovation can help businesses create more value. Only strategic innovation can truly realize an enterprise's value creation. Breaking the original survival strategy, paying attention to operating enterprises with new strategic thinking, and constantly identifying and cultivating strategic innovation ability are all things that businesses must do. Only in this way will we be able to effectively implement strategic innovation and, as a result, create a continuous competitive advantage, allowing businesses to grow sustainably in the market [7]. When a company discovers that its strategy is no longer generating value for customers, it has the ability to reidentify, acquire, and integrate the industry's internal and external environmental resources. The current profit situation is changed using the strategic innovation method, completing the enterprise's strategic innovation goal. It is based on the accumulation of knowledge and is linked by organizational learning. Its goal is to continuously add value to businesses and customers in order to ensure that businesses have a long-term competitive advantage in the market. The K-means algorithm is used to build a clustering mining model in this paper. It has been successfully used in practice to evaluate mining results, form knowledge, and promote the development of a company's strategic innovation capability.

Innovation is the soul of a nation's progress and the inexhaustible motive force of a country's prosperity. Nowadays, innovation has increasingly become an important symbol of the liberation and development of social productive forces, which is related to the development process of a nation. Management and innovation are the eternal themes of the sustainable development of enterprises [8]. Management innovation mainly includes management idea innovation, organization innovation, management method innovation, system innovation, and cultural innovation. In the original sense of innovation, technological innovation is the commercial application of scientific and technological achievements, and this process should be mainly completed by enterprises. It is not only the main body of the market economy but also the main body of technological innovation [9]. The strength of a country's independent innovation capability is mainly determined by enterprises, and the key to improving the independent innovation capability is to improve the independent innovation capability of enterprises [10]. Based on the analysis of the dynamic mechanism of enterprise strategic innovation capability formation and the K-means algorithm, this paper constructs and designs a clustering mining model of enterprise strategic innovation capability based on the K-means algorithm. The K-means algorithm has high computational performance. It is verified that the algorithm is suitable for the research of this paper, which can better reflect the characteristics of the data in this paper, and the model is successfully applied to the analysis of strategic innovation capability of enterprises.

2. Related Work

According to literature [11], trust, integration, and collaboration are three-dimensional mechanisms for enterprises to realize integrated innovation. When conducting independent innovation, literature [12] suggests that businesses should invest heavily in technology research and development. Empirical evidence supports the positive relationship between R&D spending and independent innovation. From the perspective of absorptive capacity, literature [13] studies believe that good technical resources and a strong capability foundation are prerequisites for enterprises to engage in integrated innovation and achieve technological leapfrogging. Endogenous innovation, as opposed to imitation innovation, external introduction, and cracking, is a spontaneous behavior in the system, according to literature [14]. Literature [15] investigates the technology-driven formation mechanism of integrated innovation capability and develops a theoretical framework for the action mechanism of enterprise technology integration capability based on the three dimensions of technology integration. From various perspectives, literature [16] discusses and analyzes the application process and some application status of data mining in E-government. According to literature [17], technology integration is a process of innovation based on an enterprise's existing technological processes and capabilities. Literature [18] introduces four analytical frameworks: global technology framework, organizational framework, active learning, and technology transfer at the enterprise level. Literature [19] puts forward that independent innovation is the breakthrough of technology explored by enterprises through their own efforts or joint research. Literature [20] introduced the idea of ontology to build a government data warehouse. The successful construction of enterprises' basic information data warehouse verified the feasibility of the construction method of the government data warehouse. Literature [21] provides a possible attempt to explain the changes of endogenous technology. Literature [22] established a long-term economic growth model based on innovation. Literature [23] puts forward endogenous innovation and imitation innovation in parallel when analyzing economic growth. Reference [24, 25] designed an implementation scheme of the system based on multilevel architecture. When analyzing the change process of European science and technology policy, literature [26] proposed an integrated innovation policy integrating "scientific innovation policy" and "industrial innovation policy." This view is actually an extension of the concept of the regional innovation system and the national innovation system. Literature [27] puts forward that independent innovation is an activity for innovation subjects to achieve scientific and technological breakthroughs by relying on their own strength so as to support and lead economic and social development and ensure national security. Literature [28] first incorporated technological progress into the economic growth model, analyzed the internal factors, and internalized a part of the role of technological progress. In the enterprise strategic innovation model studied in this paper, enterprises innovate on the basis of their own inherent strategies. Through the K-means algorithm, enterprises can find the best way for enterprise innovation, and through repeated iterations, they can find out the strategic innovation points gradually clear in the process of clustering so as to determine the optimal direction of enterprise strategic innovation.

3. Methodology

3.1. The Formation Mechanism of the Enterprise's Integrated Innovation Capability. A new idea, a new discovery, a new organizational form, a policy system, and an institutional framework are all examples of innovation. Although this is a broad definition, innovation in the economic sense is very specific. It refers to a commercially motivated production process that aims to capture or maintain market share and maximize profits. With society's rapid development, competition has never been more fierce. It is critical for developing businesses to recognize that, in the face of fierce social competition, their strategies must be adjusted or recustomized [29].

What is the strategic innovation capability of enterprises? It is considered that with the goal of continuously creating enterprise and customer value, in the process of successfully completing the cognition, formulation, implementation, and control of enterprise innovation strategy, the existing resources inside and outside the enterprise can be discovered, acquired, utilized, and integrated to improve the utilization rate of existing resources or create new resources. In this way, the system composed of various elements of strategic innovation ability needed by enterprises to gain sustainable market competitive advantage can be ensured. The independent innovation capability system of enterprises is shown in Figure 1.

The research on integrated innovation capability mainly focuses on its formation mechanism. Integrated innovation is a process in which the innovation subject optimizes and reorganizes the elements to form an organic whole with multiple functions and adaptability to evolution. Any enterprise system is not isolated and static. They are closely related to the external environment and change with the changes of the external environment to maintain their own balance [30]. It includes integration dimensions such as technology, strategy, knowledge, and organization. Different dimensions do not exist in isolation, but are interconnected and interdependent. The nonlinear interaction between various elements within each enterprise system forms a balanced system and ensures the dynamic mechanism.

The key to establishing a management innovation mechanism is to understand the fundamental elements of management innovation. Understanding management innovation mechanisms requires a thorough understanding of the subject of innovation, as well as innovation motivation, ability, and behavior. Entrepreneurs, managers, and employees with knowledge reserves are among the subjects of innovation. Entrepreneurs are at the forefront of managerial innovation. Its primary responsibility is to coordinate, manage, and guide the innovation activities of the subject and object of innovation. The key to management innovation is managers. The source and foundation of management innovation are knowledge workers. Figure 2 depicts the relationship between enterprise innovation and other topics.

Only with certain ability can the subject of enterprise management innovation complete the process of management innovation. This necessary ability is a synthesis of various abilities, mainly including innovation ability, transformation ability, organization and coordination ability, and learning ability. Under the action of linearity, there will be no way for enterprises' strategic innovation capabilities to correlate with each other, which will lead to the failure of functional coupling of innovation subjects. What is more serious is that the strategic innovation capability system cannot update and evolve, and the capability cannot be improved, which will eventually lead to the collapse of enterprises.

3.2. Evaluation Index of Creative Ability of Enterprises. Enterprise strategic innovation capability is a capability system aiming at providing strategic innovation. After selecting, analyzing, and distinguishing the ability factors, it finally forms organic polymerization. In this way, we can help enterprises to have the competitiveness of sustained advantages. Among them, the degree of coordination among various factors will affect the efficiency of the overall strategic innovation capability system. Therefore, enterprises must find suitable strategic innovation capabilities and implement them to adapt to the market environment. The supervision, examination, and revision of management innovation are the last stages of the process of enterprise management innovation. It refers to a series of activities to evaluate and scientifically summarize innovation achievements after a period of relatively stable operation. And it is an important link to promote enterprises to carry out a new round of innovation and bring the innovation achievements of enterprise management into play. The general process of management innovation is shown in Figure 3.

The establishment of an evaluation index system for an enterprise's creative ability is critical both in the theoretical research of independent enterprise innovation and in the practice of promoting the formation and development of an enterprise's creative ability. From the standpoint of the strategic innovation process and strategic innovation obstacles, companies must use their innovation capabilities as a foundation to ensure that the strategic innovation process runs smoothly and that strategic innovation obstacles are overcome. Organizational structure innovation, business process innovation, functional management innovation, and strategic management innovation are the different levels of management innovation. Each level of innovation has a distinct focus and set of procedures to follow. The evaluation index system of enterprises' independent innovation capability includes 4 first-level indicators. The first is the index of potential technological innovation resources, the second is the evaluation index of technological innovation activities, the third is the index of technological innovation output capacity, and the fourth is the index of technological innovation environment. There are two media between the external environment and the system. One is the boundary between the system and environment, and the other is the boundary domain between the system and environment. System boundaries absorb and release capacity, substances, and information to hinder the filtering of these contents. In this process, the boundary domain plays a buffer role in the communication between the system and the environment.

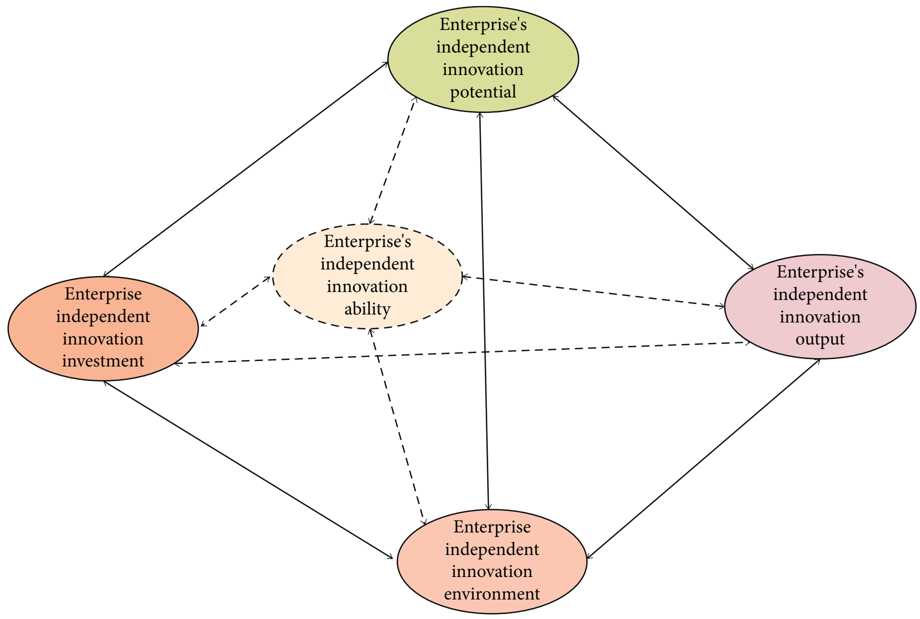

Figure 1: Enterprise's independent innovation capability system.

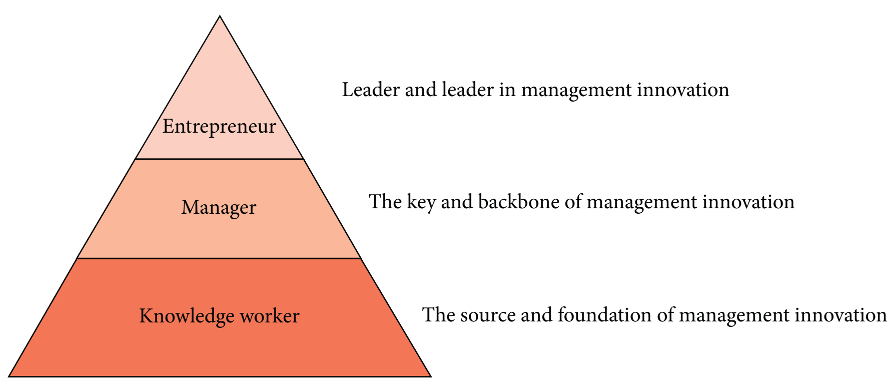

Figure 2: The relationship between innovation entities.

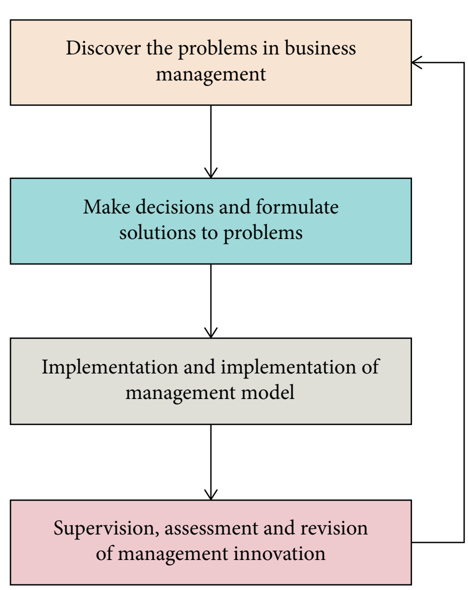

Figure 3: Process of management innovation.

With the emergence of information technology, the shortening of the product life cycle, product diversification, and the emergence of a large number of competitors, enterprises must timely adjust the organizational structure in order to seek survival and development in the market environment characterized by variability, uncertainty, and globalization. The evaluation of enterprises' creative ability should reflect the principles of scientificity, comprehensiveness and generality, feasibility and operability, representativeness and simplicity, and comparability and reliability. The enterprise strategic innovation ability itself is helping enterprises obtain a long-term competitive advantage. It explores what kind of ability enterprises should have from the perspective of enterprise strategic innovation so as to survive in a dynamic environment, seek long-term development, and form a sustainable competitive advantage.

The evaluation of the creative ability of enterprises is an important way for enterprises to know their own creative ability. The research on the evaluation of independent innovation capability of enterprises can not only discover the regular problems in the cultivation and improvement of independent innovation capability of enterprises but also provide reasonable evaluation tools for enterprises.

3.3. Enterprise Strategic Innovation Based on the K-Means Algorithm. K-means algorithm is one of the classical clustering algorithms, also known as K-means. The K-means clustering algorithm is the most traditional and classic clustering algorithm at present. By constantly adjusting and updating, it integrates the mean values of adjacent data from the central point and clusters the data. Its core idea is to find out a center point so as to minimize the deviation of each data point from its nearest center point, thus forming a "class." The algorithm has the advantages of high speed, good stability, and simple principle and is widely used in scientific research, industry and commerce, and other fields.

The K-means algorithm is based on the principle of minimizing the clustering performance index, and the commonly used clustering criterion function is the sum of the squares of the errors of each sample point in the dataset and minimizes it. The basic idea is that, firstly, k objects are randomly selected from n data objects as initial clustering centers; for that remaining other objects, according to their similarity with these cluster centers, they are, respectively, assigned to the cluster most similar to them; then, the cluster center of each new cluster is calculated; this process is repeated until the standard measure function begins to converge. The commonly used criterion function is the sum of the squared error (SSE). It is defined as follows:

$$\mathrm{SSE} = \sum_{i=1}^{k} \sum_{p \in c_j} \left\| p - m_i \right\|^2 . \tag{1}$$

Here, E is the sum of squared errors of all objects in the mining dataset, and p is a certain point in the space, which represents a given data object. m_i is the average value of cluster C. This criterion makes the generated clusters as compact as possible, and the clusters are separated as much as possible.

In the K-means algorithm, proximity, centroid, and objective function are the three key points of the algorithm. Usually, the proximity function is the squared Euclidean distance, the centroid is the mean, and the Euclidean distance calculation formula is as follows:

$$d_2^2 = \left| x_{i1} - x_{j1} \right|^2 + \left| x_{i2} - x_{j2} \right|^2 + \ldots + \left| x_{ip} - x_{jp} \right|^2 . \tag{2}$$

The selection of the initial cluster center has a greater impact on the clustering results. If the selection is not good, effective clustering results will not be obtained. We can compare the final calculation results by setting some different initial values. If the results have been stable, the selection is appropriate, but it is a waste of resources and time-consuming. Generally, the mean square error is used as the standard measurement function. The k clusters have the following characteristics: each cluster itself is as compact as possible, and each cluster is separated as much as possible.

The description object of cluster analysis can be expressed by a set of specific characteristics. The specific characteristic value can be a text, a numerical value, or a mixture of the two. For a given set of n objects, the possible ways to divide it into k clusters are

$$N(n,k) = \frac{1}{k!} \sum_{j=0}^{k} (-1)^j \binom{k}{j} (k-j)^n . \tag{3}$$

Therefore, n objects are divided into k clusters, and the number of possible cluster divisions is

$$\sum_{k=1}^{n} N(n,k). \tag{4}$$

The strategic convergence emphasizes that the strategic innovation capability of enterprises is a nonlinear organic aggregation through analyzing, selecting, and classifying various enterprise capability elements so as to help enterprises gain sustainable competitive advantages.

There are n objects to participate in the evaluation, and there are m quantitative evaluation indicators. The undetermined weight coefficient of each indicator is $b_j \, (j = 1, 2, 3, \ldots, m)$, the original data of each object on each indicator is $X_{ij} \, (i = 1, 2, 3, \ldots, n; \, j = 1, 2, 3, \ldots, m)$, and the standard data is $U_{ij} \, (i = 1, 2, 3, \ldots, n; \, j = 1, 2, 3, \ldots, m)$. Assuming that the data corresponding to the conversion of U_{ij} is Z_{ij}, the comprehensive evaluation index y_i for each object is

$$y_i = \sum_{j=1}^{m} b_j \cdot Z_{ij}, \quad i = 1, 2, 3, \ldots, n. \tag{5}$$

According to the size of y_i, the ranking of the comprehensive evaluation of each evaluation object can be given. The specific steps are as follows:

(1) Convert from standard data U_{ij} to Z_{ij}. The conversion formula is

$$Z_{ij} = \frac{x_{ij} - x_j}{S_j}. \tag{6}$$

Among them,

$$\begin{aligned} \overline{x_j} &= \sum_{i=1}^{n} x_{ij}, \\ S_j &= \sqrt{\frac{\sum_{i=1}^{n}\left(x_{ij} - \overline{x_j}\right)^2}{n}}. \end{aligned} \tag{7}$$

(2) Determination of index weight coefficient: the criterion for determining the weight coefficient b_j is to make y_i as dispersed as possible. Even if the sample variance σ^2 is the largest, the sum of squares of b_j is 1 at the same time. Such a set of weight coefficients is exactly the eigenvector corresponding to the largest eigenvalue of the matrix $W = ZT{\cdot}Z$. Iti is denoted as $B = [b_m]$. Among them,

$$\sigma^2 = \sum_{i=1}^{n} \frac{\left(y_i - \overline{y}\right)^2}{n} Z = \left[z_{ij}\right] = \begin{bmatrix} z_{11} \ldots z_{1m} \\ \ldots \\ z_{n1} \ldots z_{nm} \end{bmatrix}. \tag{8}$$

People are interested in using data mining methods to discover potential information and data patterns from large amounts of data, which have become a common demand. With the advancement of data mining, new mining methods emerge one after the other, the most basic of which is clustering. Among the clustering methods, the K-means algorithm is one of the most well-known and widely used partitioning methods. Cluster analysis is extremely useful in a wide range of situations. The K-means algorithm clustering result is better, and it can fully reflect the data's basic characteristics. Targeted management can be accomplished by analyzing system data. The algorithm played an important role in it and is very practical.

4. Result Analysis and Discussion

The level of enterprise management determines the survival of an enterprise to a certain extent. If an enterprise wants to survive and develop in a positive direction, it must strengthen management and improve its modernization level. Corporate strategic innovation capabilities are formed in the process of corporate strategic innovation, and the targeted discovery, acquisition, utilization, creation, and integration of their strategic innovation resources are emphasized. Fund management is the top priority of enterprise management. However, a considerable number of group companies have the problem of loose fund management due to the limitation of management modes and methods. The operating performance of a company from 2014 to 2020 is shown in Figure 4.

Enterprises' creative ability means that, over a period of time, in order to cultivate their own technical ability and market competitive advantage, they achieve major breakthroughs in key industrial technologies and cultivate their own brands by effectively integrating and applying internal and external resources, in order to master or affect the basic quality of the value distribution process. Some basic information about business development can be found in the enterprise's basic information base. The amount of information in an enterprise's basic information base is growing in tandem with the economy and the enterprise itself. The overall plan made by an enterprise for its long-term survival and development on the basis of analysis and research of the external environment and internal resource conditions is known as strategy. The process of an enterprise's independent innovation capability evolving from cultivation to promotion to a new level is referred to as the "evolution of independent innovation capability." Realize the improvement of the overall level of enterprises' creative ability and make enterprises' creative ability develop to a higher level on the basis of fully cultivating enterprises' creative ability. Figure 5 depicts the evolution of enterprise-wide innovation capability.

The study of management innovation mechanisms concentrates on the components of management innovation and their interactions. Enterprises that are arbitrarily closed and have no communication with external environmental resources are in the midst of a structural organization disintegration crisis and will eventually be isolated and destroyed. Cluster ecology is an important aspect of a company's ability to innovate strategically. This feature can help businesses transform and use resources more effectively, formulate new strategies more quickly, and take advantage of opportunities to implement enterprise strategic innovation. It is not only innovation essential for social and economic development, but it is also essential for business success. Figure 6 depicts the enterprise risk assessment.

For most of the risks, companies need to take certain actions to transfer or diversify the risks to reach an acceptable level for the company. The relationship between financial risk weight and sample evaluation is shown in Figure 7.

System evolution emphasizes that the strategic innovation capability of enterprises will go through a dynamic process from generation, cultivation, and promotion to maintenance with the passage of time so that enterprises can make better use of the environment to evolve their own capability systems and achieve their strategic goals. The preliminarily processed data are normalized. During this period, the three center points are constantly adjusted, and after three operations with the K-means algorithm, the customer value distribution map is obtained, as shown in Figure 8.

Promoting the development of enterprises with innovation is the latest topic that enterprises are facing today, and the key to the success of management innovation is to form an effective management innovation mechanism. Clustering is a common phenomenon in real society. Using the

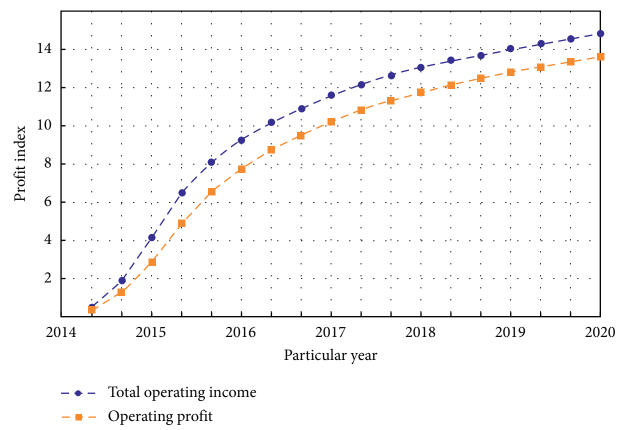

Figure 4: Operating performance.

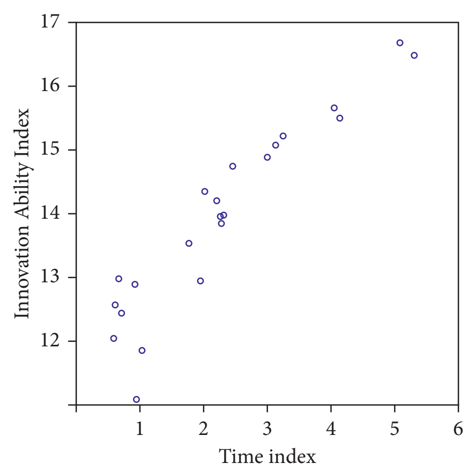

Figure 5: The evolution of independent innovation capabilities of enterprises.

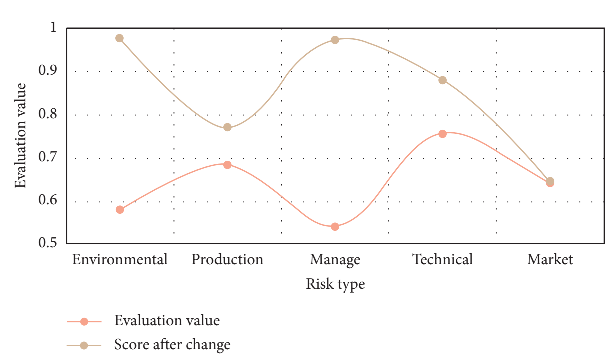

Figure 6: Enterprise risk evaluation.

optimized K-means algorithm, customers are divided into three parts. The red part is the most important customer, the blue part is the next most important customer, and the black part is the implied customer. From the graph, we can not only intuitively see the distribution of customer value but also get the number of customers in each value range, and the clustering effect is clear. The clustering effect diagram is shown in Figure 9.

Choosing an enterprise strategy is the primary choice of enterprise management innovation. Strategy is the soul of an enterprise. If an enterprise has no strategy, it will drift with the tide and always be in a passive position. The construction of the enterprise's creative ability evaluation index system includes the determination of element items and index items. It is inseparable from the definition of enterprise's creative ability. A correct understanding of the essence of

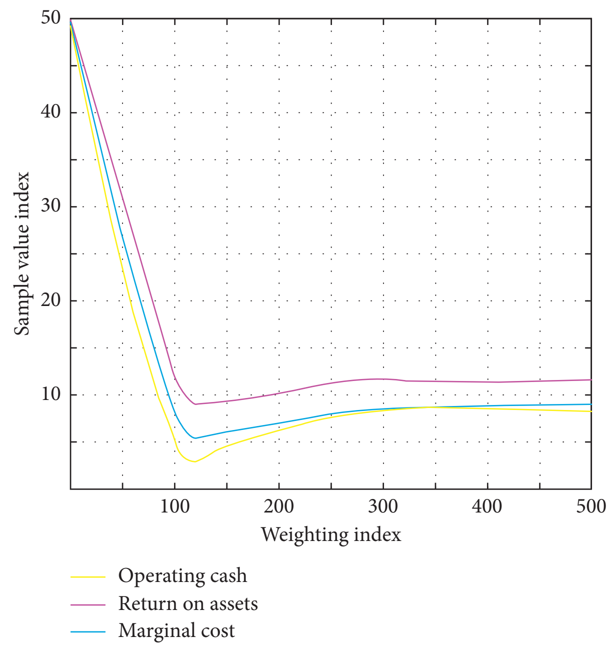

Figure 7: The relationship between financial risk weight and evaluation value.

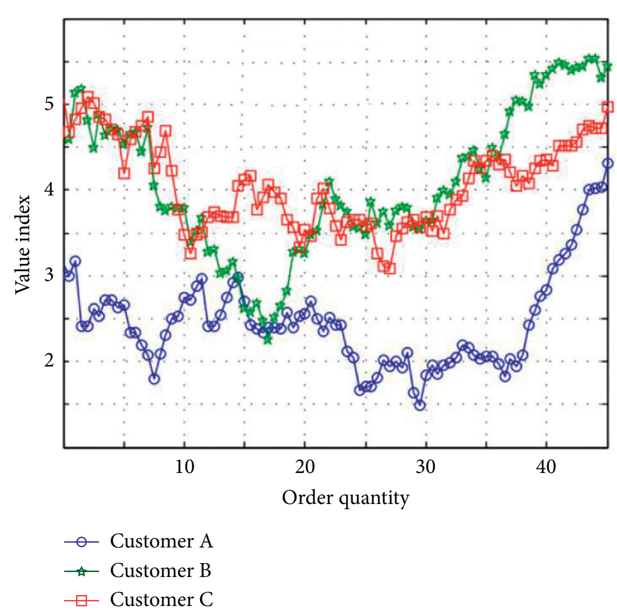

Figure 8: Distribution map of customer value.

enterprise's creative ability is the basic premise for the accurate evaluation of an enterprise's creative ability. Strategic innovation capability is a capability based on strategic innovation, which is a complex of strategic innovation and enterprise capability. Innovation guides the development direction, determines the development goal, and provides the development path for enterprise capabilities. Using the K-means algorithm in this paper, enterprises can find the best way for enterprise innovation, find out the strategic innovation points gradually clear in the process of clustering, and then determine the optimal direction of enterprise strategic innovation.

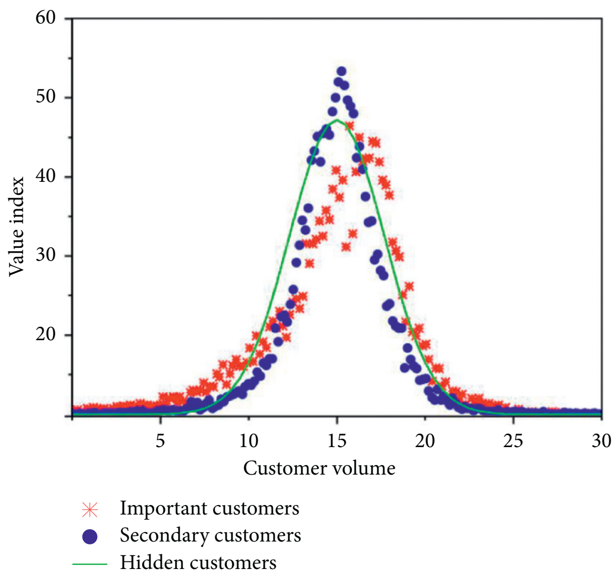

Figure 9: Clustering effect diagram based on K-means.

5. Conclusions

Enterprises must constantly carry out management innovation in order to survive and develop in the fierce market competition. Enterprises can only have flexibility and superiority in management mechanisms by implementing management innovation and thus remain invincible in the competition. All innovation must be strategic, and we must seize the strategic opportunity, highlighting the significance of strategic innovation. Strategic innovation underpins technological innovation. If a company has innovative technology but it does not fit into the company's overall innovation strategy, the company's technological innovation is pointless. The strategic innovation capability of a company cannot be created out of thin air, nor can it be born within a company. Through a dynamic mechanism, an enterprise's strategic innovation capability is formed during the process of strategic innovation. The openness, being far from equilibrium, nonlinear function, and fluctuation functions of the enterprise strategic innovation capability system cause the system information to self-replicate, stabilize, and generate a new order. The K-means algorithm studied in this paper can find the most suitable way for enterprise innovation, and through repeated iterations, find out the strategic innovation points gradually clear in the process of clustering. It can determine the optimal direction of enterprise strategic innovation.

To form a unified configuration and information management platform, FCCMS (financial center configuration management system) will integrate and sort information based on various configuration data and relationships as well as integrate processes and permissions. However, the most serious issue that data centers are currently facing is how to effectively manage these infrastructures. For various infrastructures, the data center currently uses a decentralized operation and maintenance management model. When an infrastructure fails due to inexperienced configuration management, this mode is not conducive to quickly locating and resolving the problem. A detection method of RFCO (random forest algorithm based on clustering optimization) is proposed, and an appropriate tree is selected from RF to integrate, so as to achieve the best effect. In this paper, the target matching algorithm based on FSL (few-shot learning) is deeply studied, and the target detection model is applied to the target matching and positioning task by using the ML method. The performance of the algorithm is tested by experiments on relevant datasets to verify the effectiveness of the algorithm in various scenarios.

1. Introduction

In China, the business volume of major commercial banks has increased significantly year after year as banking business has become more integrated with local market demand and with the global financial environment. At the same time, the banking industry's reliance on IT systems is becoming increasingly apparent [1]. Due to the large number of application systems and servers, as well as the large scale of supporting network rooms, it is often difficult to quickly locate the causes of emergencies, analyze the true root causes of problems, and influence related modules due to poor consideration in upgrading and changing, making it difficult to ensure the high availability and work efficiency of data center systems [2, 3].

Many excellent algorithms have appeared in the field of computer vision, and these algorithms have made remarkable achievements in the fields of image classification, target location, target detection, etc. However, the establishment of many algorithms depends on a large amount of training data, but it is difficult to get rich data in practical application scenarios [4–6]. Usually, the change of financial data reflects this gradual process information; therefore, some algorithms can be used to analyze financial data and design a system that can scientifically reflect the company's financial status, so as to guide enterprise decision makers to formulate correct guidelines, improve business activities, and prevent such problems in time [7]. DL (deep learning) has begun to rise. The related algorithms based on this have found a breakthrough for FSL (few-shot learning) [8, 9]. We establish a data center configuration management system in line with this practice standard and finely manage various infrastructures, so as to establish a long-term mechanism of production and operation with safety production as the core and effectively improve the service level of the data center.

Currently, each department's configuration information is primarily managed by hand. Because there is no unified configuration information maintenance window, there will be unnecessary redundancy when the configuration information is maintained by different departments. Furthermore, the data center's massive IT resources will result in high manual maintenance costs [10]. Although the trading platform system has an automatic monitoring platform, analyzing the impact of events is difficult due to the lack of a systematic relationship between configurations and the corresponding relationship between levels of technical business configuration units. The FCCMS (financial center configuration management system) uses the RF (random forest) algorithm and FSL as the guiding framework to design, classify, and model various infrastructures, abstract them into various configuration items, give them appropriate attributes and names, and establish the relationship between configuration items.

2. Related Work

The univariate analysis model takes a single indicator variable, compares financial data from businesses in various stages of crisis, eliminates insignificant financial indicators, and determines the financial indicators with the best discrimination ability [11]. After the analysis, the conclusions are not completely consistent due to the different research samples selected by different researchers. According to the literature [12], the three financial indicator pairs of shareholders' equity/assets and liabilities, working capital/total capital, and current assets/current liabilities have the best ability to predict financial crises. The results of a study [13] comparing and analyzing four financial ratio indicators show that the current ratio and debt ratio have the best early warning effect. The improved fruit fly optimization algorithm is combined with the Z-score model to create a financial early warning model in literature [14], and the results show that the model has good forecasting ability. The neural network model is used in literature [15] to study enterprise financial crisis early warning and is compared to the multivariate discriminant analysis model. The results show that the neural network model's prediction effect is clearly greater than that of the multivariate discriminant analysis model. The financial crisis prediction model based on moderate financial indicators and a genetic algorithm is studied in the literature [16], and the results show that this type of model has a high prediction accuracy. Literature [17] compares an SVM-based early warning model to a neural network model and a multivariate discriminant analysis model. The results show that SVM outperforms other models in terms of prediction accuracy. In [18], bagging and boosting methods were used to create a financial crisis early warning model. In [19], the dimension of the index system is reduced through PCA (principal component analysis), and the top three financial indicators in order of importance are turnover per share, asset turnover rate, and current ratio.

In the financial data center, when the number of equipment systems in an IT environment increases to a certain scale, the system management team will definitely consider enabling appropriate tools to assist management. Mihelcic et al. [20] studied an online regression algorithm of nondistributed sampling. Lee and Moon [21] put forward the idea of nonindependent identical distribution in data analysis and processing and other related fields and formed a set of nonindependent identical distribution learning framework. Zhu et al. [22] proposed a corner extraction algorithm, which realized corner detection. Panigrahy et al. [23] obtained a model that can accurately match complex scenes through a large amount of data. By introducing DenseNet, the number of parameters is reduced and the training complexity of target detection network is optimized.

3. Research Method

3.1. Overall System Design

3.1.1. Basic Architecture Design of the System. All data centers are attempting to reduce operating and maintenance costs, and service integration has proven to be effective in practice. Reduced energy consumption and the implementation of virtualization are two strategies that can effectively reduce the cost of operation and maintenance. The specific implementation of these measures, on the other hand, must be based on a clear understanding of how many servers are running and which servers are deployed, that is, by establishing a system to share information and data, reflecting data relationships, and forming a unified data center with configuration information. System function modules are shown in Figure 1.

In the design of CMDB (configuration management database) configuration items, the query function should be considered, and the additional functions developed according to the outstanding query requirements of customers should be customized, including the following specific functions: query the configuration item list according to the configuration item type and attribute conditions and search the target configuration item list according to the specific relationship between the configuration items. You can filter the attribute conditions in the target configuration item list and import and export the query configuration for any related level configuration item query to facilitate repeated query requirements in the future.

From the perspective of the system administrator, combined with blocky information, users can quickly enter the system and use and complete system functions, such as server administrator, which is concerned with service configuration, which application services are attached to the server, which storage is attached to the server, and how the server is maintained, among other things. The database administrator is concerned with the database's character section, which applications receive database services, which databases each application corresponds to, and which application databases offer cluster services.

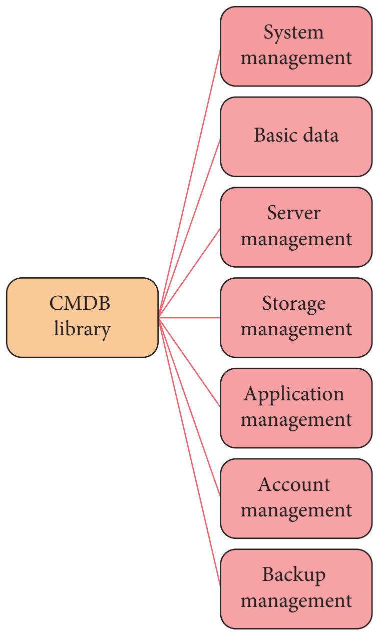

FIGURE 1: System function module diagram.

3.1.2. Hardware Architecture of the System. The configuration management system of the data center adopts the three-tier architecture of client, server, and NAS storage, in which the client is installed on the PC terminal that the operation and maintenance personnel use daily, and the operation and maintenance personnel of the data center can log in to the configuration management system by double-clicking the client, and the interface is intuitive and friendly and easy to operate.

As the core layer of the whole configuration management system, the web server is mainly responsible for responding to various requests submitted by clients, calling database services in the background by triggering events, and then the database server is responsible for data operation. All kinds of data information are finally stored in NAS storage. The hardware architecture of the configuration management system is shown in Figure 2.

The configuration management system uses 8 PC servers with high configuration of 48C96G as web servers, which are responsible for responding to requests from browsers, and 3 databases are installed with SQL Server 2005 database products. Client-server adopts B/S architecture which is widely used at present. The advantage of this architecture is that it is easy to operate and the client needs no maintenance.

3.1.3. System Security Architecture Design. Information security is the top priority for system construction. First of all, the most basic security measure is to establish an antivirus mechanism covering the whole network. In addition, a public four-tier security system model is proposed. In this four-layer model, the emphasis of each layer is different, as shown in Figure 3.

The first step of network security protection is planning. It is necessary to divide the trusted network and untrusted network from the business point of view, or the network area

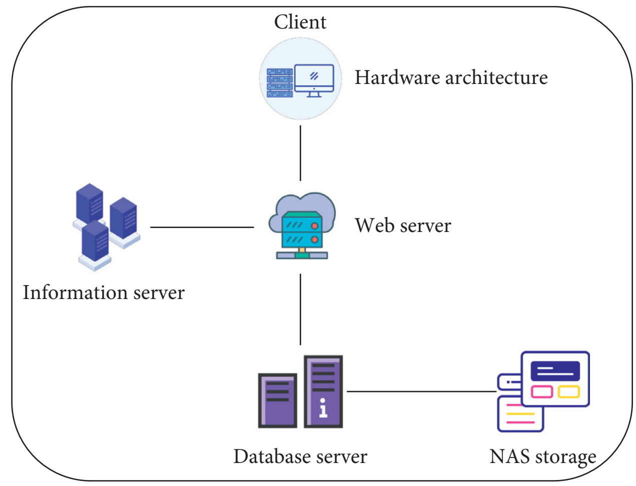

FIGURE 2: Configuration of the hardware architecture of the management system.

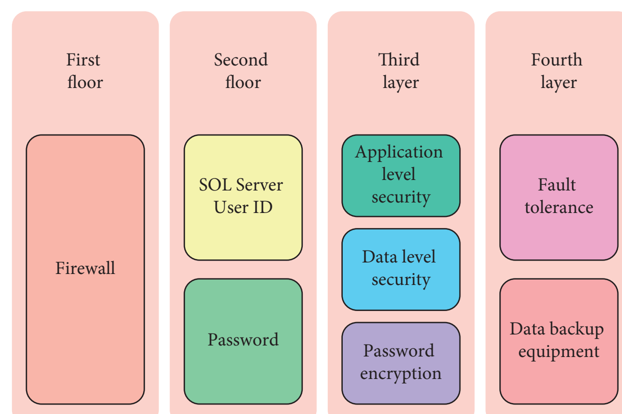

FIGURE 3: Deployment diagram of system architecture.

can be layered according to the distributed method, and each layer has different protection methods. Firewall devices are used to control or directly isolate users and services in different trust levels of network segments.

If users need access to the data center configuration library application system, they must first go through an identity authentication process. The most basic method is for the user to submit some identity authentication information to the application system in charge of identity authentication, and the application system compares that information to the correct data stored in the system. The user will be allowed to enter the configuration library application system if the verified information is legal and valid; otherwise, the user will be denied.

The creation, modification, deletion, and enabling and disabling of user accounts are all part of user management. Flexible operation and ease of use are required for user management. Grouping and authorizing user accounts, managing and maintaining permissions for user groups or roles, defining and maintaining permissions, and so on are all examples of permission management. Permission management necessitates a high level of security, accessibility, and hierarchical authorization.

3.2. Key Algorithm Design

3.2.1. Implementation of System Security Algorithm. The accuracy of member classifiers and the diversity of classifiers in classifier integration system are important issues that researchers have been paying attention to. Similarly, it is difficult to obtain satisfactory classification results by combining some classifiers with different distributions of classification errors but low performance.

RF algorithm is a classifier algorithm based on decision tree. RF has two kinds of important randomicity, the randomicity of training set extraction and the randomicity of node candidate segmentation feature set, which ensure the diversity of decision trees that make up RF. In addition, RF is a data-driven nonparametric classification method, which does not need prior knowledge, only needs to train and classify the given samples, and has a clear structure and is easy to understand.

The main idea of RF algorithm based on clustering optimization is to combine the two base classifiers with the highest correlation degree into a new cluster by using clustering algorithm based on correlation degree and then recalculate the correlation degree between the new clusters. By combining the base classifiers with high correlation, the RF model of aggregation based on correlation measure can be obtained. RFCO (random forest algorithm [25] based on clustering optimization) algorithm is mainly divided into three steps:

(1) Firstly, a large number of base classifiers are generated by RF algorithm, and these base classifiers are added to RF to prepare for the next clustering analysis.
(2) According to the similarity calculation rules between base classifiers, the similarity of base classifiers is calculated. Then, sort the similarity of all base classifiers to find out the two base classifiers with the greatest similarity.
(3) According to the results of clustering analysis, the algorithm will continue to merge the base classifiers, and when the predetermined termination condition is reached, the algorithm clustering will be terminated. Combining all cluster representatives, the RF model after cluster optimization is obtained.

According to the law of large numbers, when $m \longrightarrow \infty$, the function converges.

$$\frac{1}{m}\sum_{i=1}^{m}\alpha_i\left(H\left(x;\pi_i\right)=j\right),\quad j=1,2,\ldots,J. \tag{1}$$

Let the n-th base learning model not included in the m training sets be $H^n(x;\pi_i)$, $i = 1, 2, \ldots, m$; then, the strong learning model without included sample combination can be expressed as follows:

$$H_m^n(x)=\arg\max_j \frac{1}{M}\sum_{i=1}^{M}\alpha_i I\left(H^n\left(x;\pi_i\right)=j\right). \tag{2}$$

Therefore, the generalization error of RF algorithm based on clustering optimization can be estimated by test set. The generalization error of RF algorithm based on clustering optimization is constructed by training set as follows:

$$\frac{1}{N}\sum_{n=1}^{N}I\left(H_m^n\left(x_n\right)\neq y_n\right). \tag{3}$$

Therefore, network intrusion detection based on clustering optimized RF algorithm does not need to divide the collected network intrusion data into training set and test set. Furthermore, the optimized RF algorithm based on clustering and the optimal RF algorithm based on fruit fly are two separate algorithm implementation processes that do not clash, so they can be used together to improve the accuracy of network intrusion detection.

3.2.2. ML-Based Target Matching. With the development of machine learning, deep neural network is widely used. However, because deep neural network is easy to overfit in scenes with small sample size, some techniques to prevent overfitting in scenes with small sample size have been proposed. At present, among FSL methods in the field of computer vision, Bayesian learning, measurement network, ML (machine learning algorithm), and other methods are the mainstream methods.

For FSL problem, ML mainly uses the existing knowledge to solve the learning problem in the scene where there is only a small amount of data in the target field, and there have been many related technical achievements at present. For example, using self-learning technology, using a large number of unlabeled data in the source domain and samples in the target domain, and building an automatic sparse encoder to extract high-level features from samples, the task effect in the target domain is improved. According to the difference between the source domain and the target domain, the model structure is modified and different cost functions are set to get better results in the target domain. At present, the parameter migration method is widely used in image classification, target detection, and other tasks.

In this paper, a method of fast image transformation and solving the transformed target position is proposed. The specific affine matrix is generated according to the following formula:

$$M=M_{\text{scale}}M_{\text{rota}}M_{\text{shear}}M_{\text{trans}}=\begin{bmatrix}\theta_{11} & \theta_{12} & \theta_{13}\\ \theta_{21} & \theta_{22} & \theta_{23}\end{bmatrix}, \tag{4}$$

where M_{scale} is the scale transformation matrix, M_{rota} is the rotation matrix, M_{shear} is the staggered transformation matrix, and M_{trans} is the spatial translation matrix. By simulating the parameters of each matrix and then using the spatial transformation network transformation, the image can be simulated comprehensively by affine transformation.

At the same time, a row of $\begin{bmatrix}0 & 0 & 1\end{bmatrix}$ is filled under each spatial transformation matrix M, and the corresponding inverse matrix is generated for later calculation of the position of the transformed target, and the inverse matrix form is shown in the following formula:

$$M_{\text{inv}} = \begin{bmatrix} \theta'_{11} & \theta'_{12} & \theta'_{13} \\ \theta'_{21} & \theta'_{22} & \theta'_{23} \\ \theta'_{31} & \theta'_{32} & \theta'_{33} \end{bmatrix}. \tag{5}$$

When the input image is transformed by the spatial transformation network according to the matrix M, the target position in the new image will also change. The rectangular frame of the original target will become a parallelogram. The new target center position needs to be calculated. The calculation formula is shown in the following formula:

$$\begin{bmatrix} x_{gt'} \\ y_{gt'} \\ z_{gt'} \end{bmatrix} = \frac{\left(M_{\text{inv}} \begin{pmatrix} \left(x_{gt}/y_{gt}\right) \times 2 \\ 1 \end{pmatrix} + 1 \right)}{2}, \tag{6}$$

where $(x_{gt'}, y_{gt'})$ is the coordinate of the target center in the new image transformed by the spatial transformation network and $z_{gt'}$ represents irrelevant data. When calculating, first calculate the vector of diagonal vector after transformation, as shown in the following formula.

$$\begin{aligned} \begin{bmatrix} w^{tn}_{b1} \\ h^{tn}_{b1} \end{bmatrix} &= \begin{bmatrix} \theta'_{11} & \theta'_{12} \\ \theta'_{21} & \theta'_{22} \end{bmatrix} \begin{bmatrix} w_{gt} \\ -h_{gt} \end{bmatrix}, \\ \begin{bmatrix} w^{tn}_{b2} \\ h^{tn}_{b2} \end{bmatrix} &= \begin{bmatrix} \theta'_{11} & \theta'_{12} \\ \theta'_{21} & \theta'_{22} \end{bmatrix} \begin{bmatrix} w_{gt} \\ -h_{gt} \end{bmatrix}, \end{aligned} \tag{7}$$

where $(w^{tn}_{b1}, h^{tn}_{b1})$, $(w^{tn}_{b2}, h^{tn}_{b2})$ represents the vector of the diagonal vector of the target frame in the original image in the transformed image and $(\theta'_{11}, \theta'_{12}, \theta'_{21}, \theta'_{22})$ is the corresponding element in the inverse matrix M_{inv} of the affine matrix.

4. Result Analysis and Discussion

4.1. System Test Result Analysis. The configuration management system's main functions are data entry, data retrieval, and report generation. The developers will test the module's functionality after it has been developed. Submit the version control code after you have passed the test. Integrate and compile each branch code to form a complete system after all modules have been developed and tested. After the test is completed, the testers will create relevant reports based on the test cases formulated by the demanding personnel.

The configuration management system of an institution's interbank trading platform has been designed using the configuration management system design scheme. According to the actual test results of the system, the results fully show that the design and implementation scheme of the system can basically meet the requirements of configuration management and can significantly improve the work effect and efficiency in the financial data center, based on the measurement and comparison of the integrity of configuration information and timeliness of collecting configuration data, as well as the representativeness of configuration management requirements in the financial data center. The requirement compliance degree of the configuration management system is shown in Figure 4.

Managing related information of server hardware, configuration, maintenance, and so on is the core module of data center configuration library. All related software programs, services, applications, and so on are inseparable from servers, and the number of servers is often very large. One of the biggest features of the system, such as undeployed related services, supported specific applications, associated storage, change logs, maintenance support, and so on, can be quickly inquired through server links.

After the functional test, integration test, user test, and performance test are completed, and the related problems are solved, and they are finally reflected in the test report. After the test report is signed, it is regarded as an important document of system acceptance. The statistics of test results are shown in Figure 5.

After the configuration management system is put into use, in the quarterly assessment of key performance indicators, such as the variance rate of configuration management database audit, the variance rate of configuration information is always stable at around 1%, which is obviously improved compared with the variance rate of 25%–30% entered manually before.

Secondly, because the configuration management system integrates all kinds of basic information, the operation and maintenance personnel can query related configuration information in time, which saves a lot of precious time for solving incidents and problems and greatly improves the response and solving efficiency of emergencies.

The test results show that the system performs well in terms of scientific and automatic configuration management and IT service management, and the findings of this paper's research should be useful as a practical reference and application for similar data centers with a large number of application systems and infrastructures.

4.2. Algorithm Performance Analysis. This section mainly describes the intrusion detection capability of RFCO. The experimental results of SVM, MLP classifier algorithm, and RFCO in terms of accuracy are shown in Figure 6.

It can be seen from Figure 6 that the classification accuracy of network intrusion data by RFCO is higher than that of traditional MLP classifier and SVC model.

Storage management is the process of recording storage device configuration information, such as device number, model, supplier, basic configuration, current configuration, maintenance, and other configuration data, as well as the storage's division, use, server connection, and supported business systems. Storage device main table, storage device maintenance information table, storage device original configuration information table, and so on are some of the

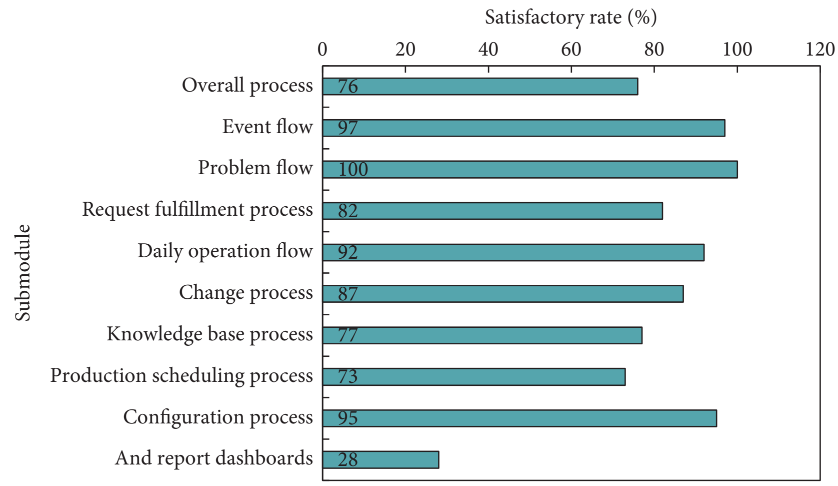

FIGURE 4: Management system requirements and configuration information integrity analysis table.

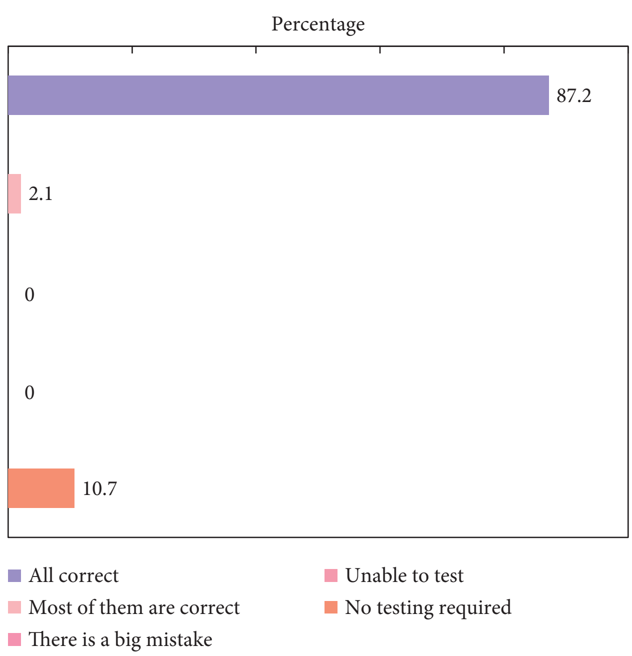

FIGURE 5: Test result statistics.

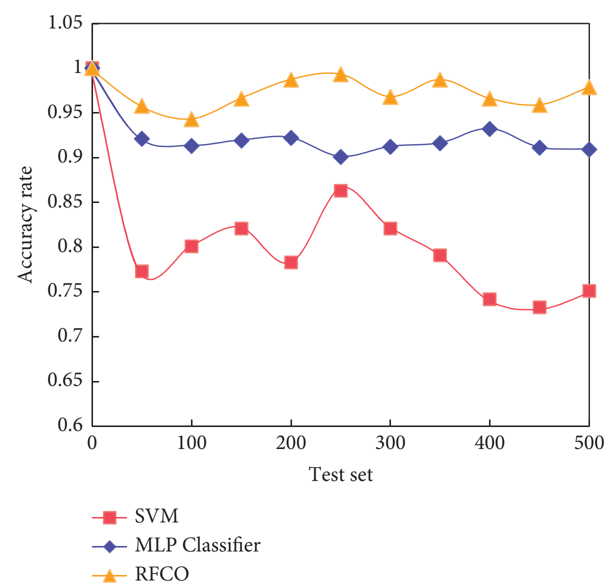

FIGURE 6: Accuracy comparison of algorithms.

main designed data tables. Storage device configuration information is kept in the main table, while storage device maintenance information is kept in the storage device maintenance information table.

Figure 7 compares MSE (mean square error) of three algorithms.

It can be seen from Figure 7 that the MSE value of RFCO for network intrusion detection model is very low. Therefore, the algorithm based on RFCO greatly reduces the MSE of network intrusion detection.

These evaluation parameters can reflect the accuracy, error, and various kinds of sample detection of various algorithms to a certain extent, but there are still some shortcomings in measuring the overall performance of the algorithms. Therefore, this section also uses F_1_score, precision, and recall parameters to measure the accuracy and robustness of the algorithms in combination with the relevant knowledge of machine learning algorithms. The experimental results are shown in Figure 8.

To sum up, compared with other algorithms, RFCO has a good classification effect, which can effectively solve the problem of various and complex features of network intrusion datasets. For other types of network intrusion data, RFCO also has a good detection effect.

Service management is the process of documenting the related service configuration information that is specifically supported by each application, such as software services, subservices, and the relationship configuration between a service and a specific application, among other things. Software service table, correspondence table between service and application, service relationship table, and so on are the main data tables involved in this module. The software service table primarily stores information about the service type, software name, patch configuration, and service type,

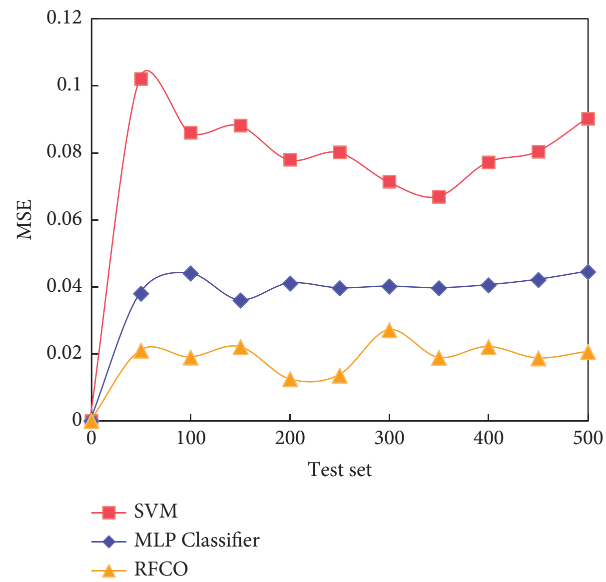

Figure 7: MSE comparison of three algorithms.

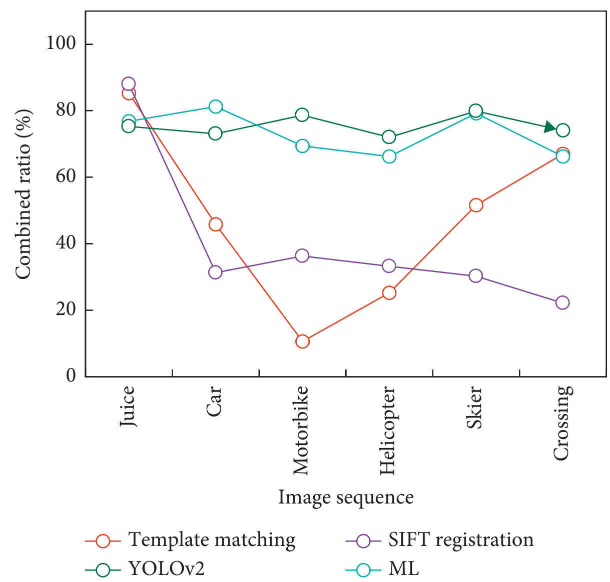

Figure 9: Cross-comparison experiment results.

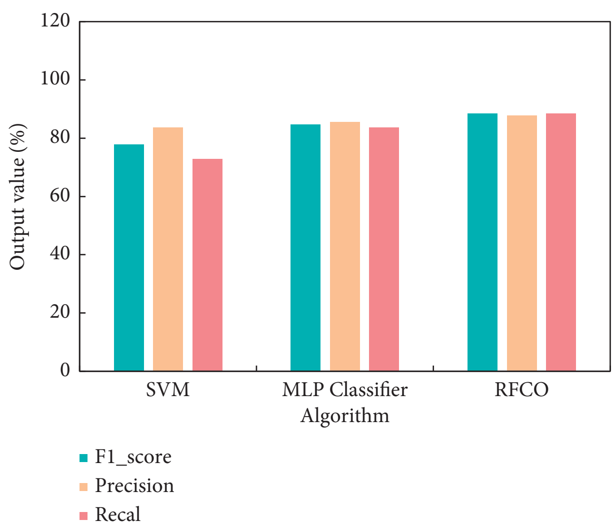

Figure 8: Experimental knot.

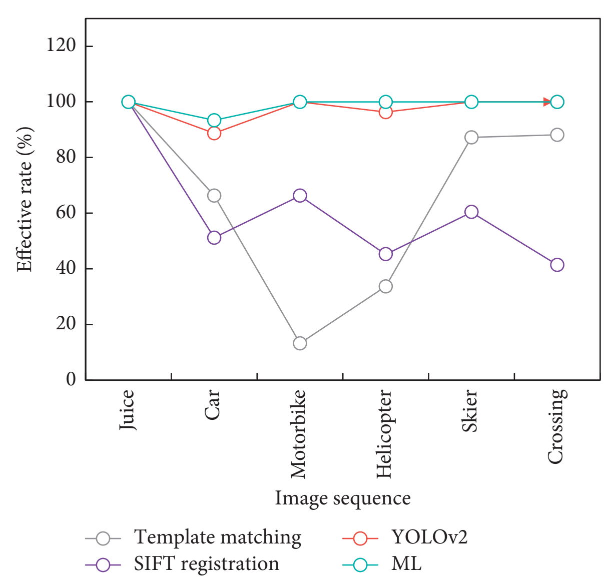

Figure 10: Effective experimental results.

among other things. The service and application correspondence table primarily records the relationship between the service and the corresponding application, as well as the service types that it supports, and the service relationship table is linked to related services.

Continue to verify image sequences using the VOT dataset and TempleColor128 dataset, including Juice, Car, and the other six groups. After manually removing the completely occluded and difficult-to-identify images from the above image sequences, about 10 images were chosen as training data and the remaining images were used as test data in the experiment. The intersection ratio results and the algorithm's efficiency results on six groups of image sequences are shown in Figures 9 and 10, respectively.

According to the above experimental data, it can be seen that the traditional algorithm has good effect only in some scenes, while the method based on DL has good generalization ability in all scenes.

In the daily operation of the data center, a series of changes, such as equipment replacement, system migration, project transformation, and so on, are often needed, and all these changes will cause the change of configuration information without exception, so it is necessary to maintain the configuration information to ensure that the currently recorded configuration information is consistent with the actual information in the production environment. Only when the configuration information is accurate can the normal operation of many processes such as service desk, event management, problem management, change management, and release management be supported.

If an existing configuration item template needs to be updated, the process loops back to the configuration item owner, who redesigns the template. The configuration management database administrator updates the configuration item template once the configuration process manager has approved it. The configuration information administrator is authorized to prepare relevant information in accordance with the modified new configuration item template in order to maintain the configuration item after the new configuration item template is established. The old value before the change and the new value after the change should be recorded in the maintenance record table. The name of the configuration item and all other configuration item names associated with the configuration item should be stored in the maintenance record table for a configuration item with the maintenance type "Delete."

The ML algorithm proposed in this paper maintains a high level of intersection ratio and efficiency. The ML-based target matching algorithm proposed in this paper keeps high efficiency in six scenes. At the same time, it is slightly worse than the previous twin network algorithm in the Car image sequence. The reason for analyzing similar scenes is that the target image and the target image with background are partially used in training, which affects the prediction results when the background changes drastically.

5. Conclusion

With the flourishing development of various businesses in the financial industry, particularly with the increasingly active transactions in the financial market and the increasing demand for regulatory statistics, the FCCMS design scheme in this paper has added new explorations and attempts, the theoretical basis and framework of the technical system have become clearer and more systematic, and the support for regulatory statistics has increased. Simultaneously, a large number of highly automated management software programs were chosen, enhancing IT management capability and level. RFCO synthesizes and optimizes the model's base classifiers, improving network intrusion detection accuracy. Finally, the target matching algorithm based on ML network proposed in this paper has significantly improved efficiency over traditional methods and has higher matching and positioning accuracy, according to the experimental results. The performance of small targets and scenes with spatial transformation has also been greatly improved when compared to the original YOLOv2 algorithm.

The FCCMS is currently unable to achieve full automation, and maintenance tasks such as establishing configuration item correlations and changing configuration item status and attributes still require manual intervention. We will strive to integrate the knowledge base, problem report, and other functions into the configuration management system in the future exploration so that the configuration management system can be more closely integrated with other processes and the data center's IT service quality can be improved further.

Deep learning has brought a rapid development in the aspect of molecular representation for various tasks, such as molecular property prediction. The prediction of molecular properties is a crucial task in the field of drug discovery for finding specific drugs with good pharmacological activity and pharmacokinetic properties. SMILES string is always used as a kind of character approach in deep neural network models, inspired by natural language processing techniques. However, the deep learning models are hindered by the nonunique nature of the SMILES string. To efficiently learn molecular features along all message paths, in this paper we encode multiple SMILES for every molecule as an automated data augmentation for the prediction of molecular properties, which alleviates the overfitting problem caused by the small amount of data in the datasets of molecular property prediction. As a result, by using the multiple SMILES-based augmentation, we obtained better molecular representation and showed superior performance in the tasks of predicting molecular properties.

1. Introduction

Traditionally, drug discovery is time-consuming and very expensive. For understanding the properties of a compound, many results of the simulations can be obtained via the experience of a chemist or pharmacist. The overall process is significantly complex, long, and always inefficient. Deep learning has brought a rapid development in the field of drug discovery and is expected to accelerate the process of drug discovery [1–8]. Nevertheless, deep learning methods still face some obstacles, such as small amount of data in molecular datasets, few label data [3], and label noise [5, 6], which leads to overfitting and poor model prediction performance.

Inspired by natural language processing techniques, many deep learning models use the simplified molecular input line entry system (SMILES) [9] as a line text representation of a molecule. SMILES string is in form of a 1D sequence of chemical structure that can be encoded using a one-hot vectorization form. A molecule may have multiple SMILES. Because SMILES are not unique, a molecule is often defined by canonical SMILES [10], which ensures that each molecule corresponds to a unique canonical SMILES. The SMILES-based methods [11–16] have shown great potential and have been widely used in the tasks of molecular property prediction [12–14] and molecular generation [15, 16]. The performances of the deep learning models are hindered by the nonunique nature of SMILES string, which affects the accuracy of molecular property prediction and the ability to explore the potential chemical space of molecules in molecular generation tasks [11]. Paul et al. proposed a mixed deep learning network architecture CheMixNet [12] to learn molecular representation by using several neural networks design (convolutional neural network (CNN), recurrent neural network (RNN), and multilayer perceptron (MLP)) for learning molecular SMILES sequences and molecular ACCess (MACCS) fingerprints, respectively. Then, concatenate the two parts of features and make the final prediction. Lin et al. learn molecular representation by using bidirectional gated recurrent unit (BiGRU) neural network architecture based on sequence manner [13], which is designed for solving the single- and multitask classification in the field of drug discovery. The methods input single SMILES sequence for a molecule to neural networks to learn representation. Therefore, the limited molecular representation affects the predictive performance of the neural network models. SMILES2vec [14] was proposed to train on SMILES for predicting chemical property using an RNN neural network via Bayesian optimization methods [17]. SMILES2vec was inspired by language translation using RNN in the field of natural language processing (NLP). SMILES2vec did not explicitly encode the grammar of SMILES specification. The LSTM-based [18] or GRU-based [19] recurrent neural network architecture is an effective neural network design for learning features from sequence or text data. The above neural network models based on SMILES have limitations because only the single SMILES of each molecule is considered, which cannot learn the grammatical features of SMILES well. Although SMILES enumeration [11] and all SMILES variational autoencoder [15] have considered multiple SMILES strings of single molecule to learn latent molecular representation. However, these methods are not used in the tasks of molecular property prediction. In this paper, we proposed a novel molecular representation method for molecular property prediction using multiple SMILES-based augmentation to alleviate the problem of a small amount of data and few labels in the molecular property prediction datasets , regardless of descriptors engineering and expert experience.

2. Related Work

A related method to this paper is the SMILES enumeration [11]. SMILES enumeration explored the fact that multiple SMILES represent the same molecule as a technique for data augmentation. The augmented dataset was bigger than the original. The neural network trained with the augmented dataset showed better performance on the test set than the original neural model trained with the unaugmented dataset. Another SMILES enumeration-based method is all SMILES variational autoencoder [15], which used multiple SMILES strings of single molecule to learn latent molecular representation for molecular generation. All SMILES variational autoencoder (VAE) encoded multiple SMILES by using several recurrent neural network layers and decoded them to molecular SMILES. All SMILES VAE learned a bijective mapping between molecules and the latent representations near the high-probability subspace of the prior. The result showed that all SMILES VAE obtained the state-of-the-art performance. However, these methods are not used in the tasks of molecular property prediction, recommended by MoleculeNet [8].

3. Methods

The key idea is that we focus on a multiple-SMILES representation learning as data augmentation for various downstream tasks. As we all know, the deep learning model must be fed with a large amount of data. Through learning a large amount of data, the model can find the law and obtain the potential knowledge of the data. Despite the presence of a large number of molecules, labeled datasets are scarce. In the task of molecular property prediction, the number of molecules in some datasets of property prediction is also very small. It leads to the problem of unstable prediction performance using the deep learning models due to overfitting and underfitting.

Inspired by the SMILES enumeration [11] and all SMILES VAE [15], we proposed a novel method of molecular property prediction using multiple SMILES-based augmentation to solve the overfitting and underfitting problem. The general framework is illustrated in Figure 1. Generally, before feeding the data into the deep neural network, the multiple SMILES-based augmentation must be completed (Figure 1(a)), which is related to whether the model can learn the potential knowledge in the datasets. It is a crucial step for the successful prediction of deep neural model. The process of data augmentation includes cleaning data and removing invalid molecules. Then multiple SMILES sequences are generated for each molecule, and further one-hot vectorization is carried out that can be fed to the neural network to learn molecular features. The deep neural network used in this paper is shown in Figure 1(b), which consists of stacked CNN and RNN. The "Gate" in Figure 1(b) is denoted as the gated recurrent unit (GRU) or long-short-term memory (LSTM). The final molecular representation can be used for a variety of downstream tasks, such as molecular property prediction.

In the following, we will describe technical details. We first give the mathematical definition of the problem (Section 3.1) and then propose a novel molecular representation method using multiple SMILES-based augmentation for molecular property prediction (Section 3.2).

3.1. Problem Definition. We define a feed-forward convolutional neural network as $\mathscr{CNN}_{(\text{kernel},\text{channel},\text{padding})}$, where kernel is the convolution kernel, channel denotes the convolution channel, and padding represents the type of padding. A recurrent neural network can be defined as $\mathscr{RNN}_{\text{gate}}$, where gate denotes the type of gate, such as LSTM and GRU. Let X_{os} be the original SMILES strings that have been cleaned and are valid molecules. Let mapping function of multiple SMILES be f_{ms}. X_{ms} is the multiple SMILES sequences. We define the vectorization function as f_{vect}. The problem is to learn the function f_{res} that maps the multiple SMILES vectors to molecular representation X_{mol}. The mapping relations are represented as follows:

$$\begin{aligned} X_{ms} &= f_{ms}(X_{os}), \\ &\left[f_{\text{vect}}(X_{ms}); \mathscr{CNN}_{(\text{kernel},\text{channel},\text{padding})}, \mathscr{RNN}_{\text{gate}}\right] \\ &\longrightarrow f_{\text{res}}\, X_{\text{mol}}. \end{aligned} \tag{1}$$

The whole process includes three mapping functions, namely, f_{ms}, f_{vect}, and f_{res}. The final molecular representation is what we want to get and can be further used in specific tasks such as molecular property prediction.

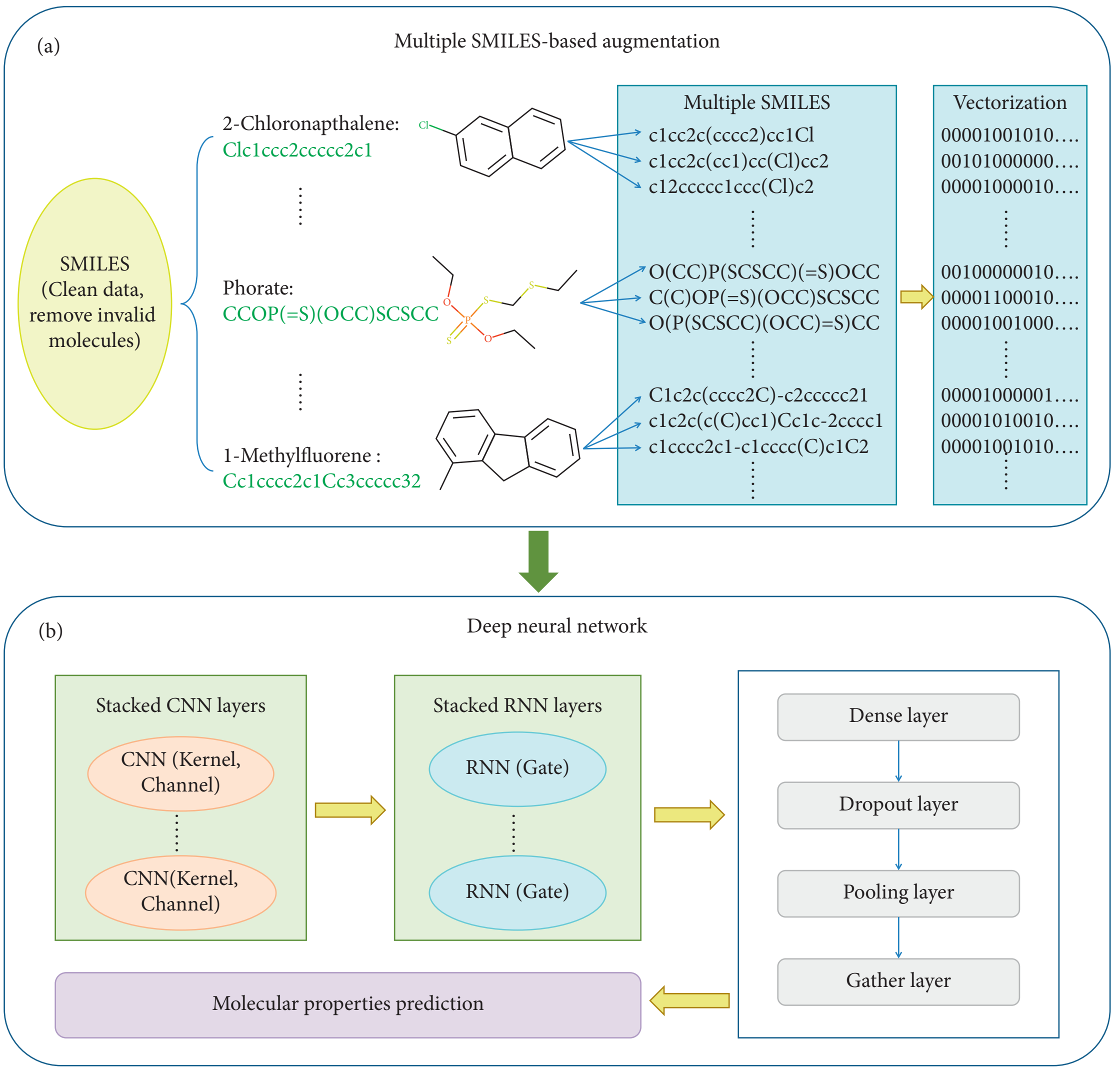

Figure 1: The architecture of molecular representation with a multiple SMILES-based augmentation for molecular property prediction. (a) The process of data augmentation using multiple SMILES. After cleaning and removing invalid molecules from the original datasets, multiple SMILES sequences are generated for each molecule, and further one-hot vectorization is carried out. (b) The stacked CNN and RNN neural networks. After passing through different layers (including dense layer, dropout layer, pooling layer, and gather layer), finally the characteristics such as molecular properties are predicted.

3.2. Multiple SMILES-Based Augmentation. The SMILES [9] is a popular specification for extracting the feature of molecular sequences that uses ASCII strings encoding molecular structures in the form of a line notation. The SMILES structure follows a certain grammar. The alphabets and numbers in SMILES denote atoms and rings, respectively. The special characters such as "=" and " ≡ " indicate the bond types, and the parentheses indicate side chains. The mapping function of multiple SMILES f_{ms} can be implemented using the method of renumbering atoms in RDKit [20] after performing randomization of a SMILES sequence and then regenerating a new SMILES sequence using the "MolToSmiles" method and setting canonical to be "False" in RDKit. Figure 2 takes estradiol as an example to randomly generate 10 multiple SMILES sequences. Estradiol is randomly selected from the ESOL dataset. Figure 3 demonstrates randomly generated 4 SMILES sequences with renumbered atoms in the molecular graph for estradiol. It is shown that atoms with different numbers in the molecule can generate different SMILES sequences. Therefore, the SMILES sequence of molecules is not unique, but canonical SMILES are unique for specific molecule.

The mapping function f_{vect} can be implemented using language translation technology in the field of natural language processing, which is an effective method for learning from text data. We need to construct a character set for all SMILES sequences in some datasets, which is similar to the corpus in natural language processing. Then randomization and vectorization to convert the SMILES array to a one-hot vector are performed. Figure 4 demonstrates the one-hot images of vectorization using multiple SMILES for estradiol. Each image of vectorization in Figure 4 highlights the one-hot vector for different SMILES sequences. The abscissa interval is [0, 9], and the 9 represents the number of

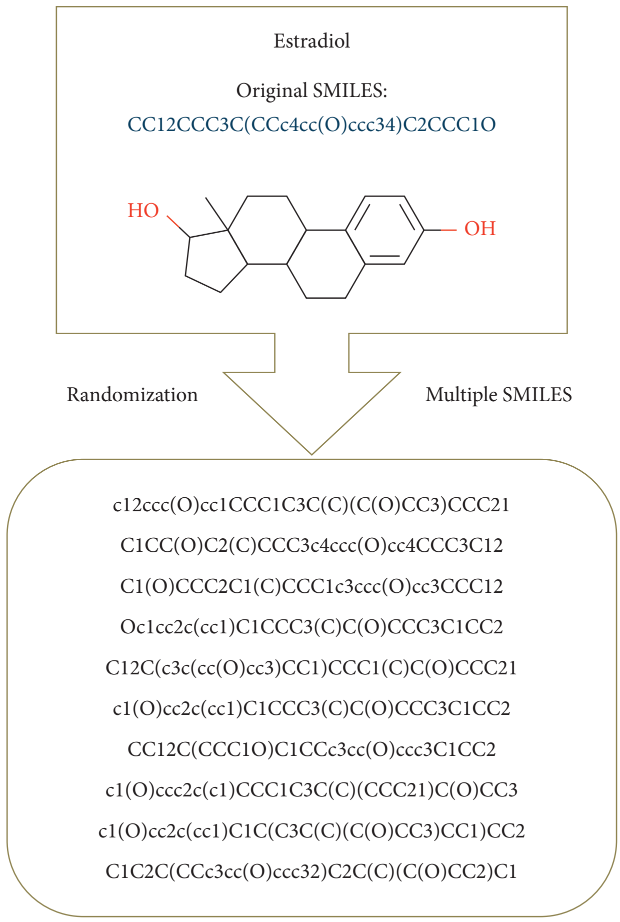

Figure 2: The generation of multiple SMILES for estradiol. The original SMILES is "CC12CCC3C(CCc4cc(O)ccc34)C2CCC1O" that is randomly selected from the ESOL dataset. Here, it is shown the randomly generated 10 SMILES sequences for estradiol molecule.

characters contained in the character set. The interval of the ordinate is [0, 37], and the 37 denotes the length of the SMILES string (including predefined extra padding).

The last mapping function f_{res} for obtaining molecular representation can be learned using stacked CNN and RNN mixed architecture. The RNN consists of an input layer, a

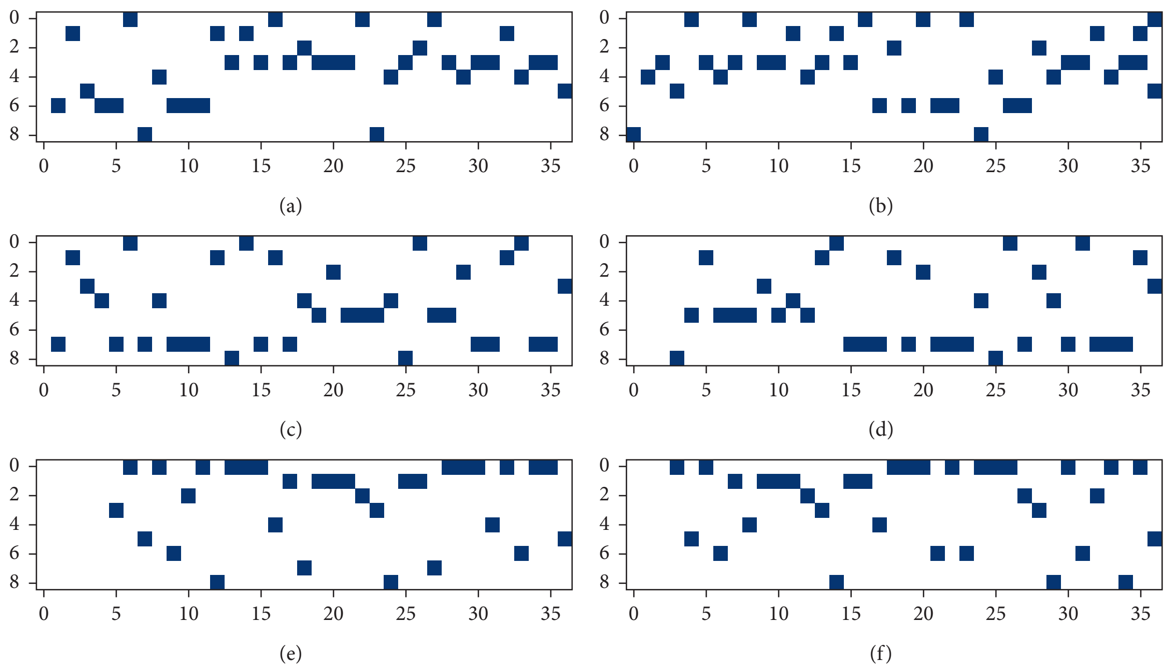

Figure 4: The images of one-hot vectorization using multiple SMILES for Estradiol molecule. It shows the vectorization of randomly generated 6 SMILES strings, using random order of the character set for Estradiol, which consists of 9 characters: "(", "3", "O", "c", "1", ")", "2", "4", "C". The length of padding is 37, that includes predefined extra padding. (a) c12cc(O)ccc1C1C(C3CCC(O)C3(C)CC1)CC2. (b) C1(O)C2(C)C(CC1)C1C(c3c(cc(O)cc3)CC1)CC2. (c) C12(C)C(CCC1O)C1C(c3ccc(O)cc3CC1)CC2. (d) Oc1ccc2c(c1)CCC1C3CCC(O)C3(C)CCC12. (e) OC1C2(C)CCC3c4ccc(O)cc4CCC3C2CC1. (f) C1C2c3ccc(O)cc3CCC2C2CCC(O)C2(C)C1.

hidden layer, and an output layer. Figure 5 shows the simple structure of RNN, where X is an input vector, H indicates the hidden vector of the hidden layer, O represents the output vector. W_{xh}, W_{ho}, and W_h denote the weight matrix from input layer to hidden layer from hidden layer to output layer, and hidden layer, respectively.

Figure 6 demonstrates the timeline structure of RNN. The output O_t of RNN at time t is related not only to the input x_t at time t but also to the hidden layer value h_{t-1} at time $t-1$. It is shown that RNN can better deal with sequence information, that is, the previous input is related to the subsequent input. SMILES string is precisely this sequence structure, which can extract features with designed RNN architecture.

The message passing process for stacked CNN and RNN mixed architecture can be found in Figure 7, which shows the message passing in the neural network at time t and time $t-1$. The result of the output layer at time t must be based on the input at time t and the result vector of the hidden layer at time $t-1$. The process can be summarized in the form of matrix as follows:

$$\begin{aligned} O_t &= \mathscr{P}\left(W_{\text{ho}} \cdot H_t\right), \\ H_t &= \mathscr{Q}\left(W_{xh} \cdot X_t + W_h \cdot H_{t-1}\right), \end{aligned} \tag{2}$$

where $\mathscr{P}$ and $\mathscr{Q}$ indicate some kind of neural network. Finally, the mapping function f_{res} for obtaining molecular representation can be represented using CNN and RNN as follows:

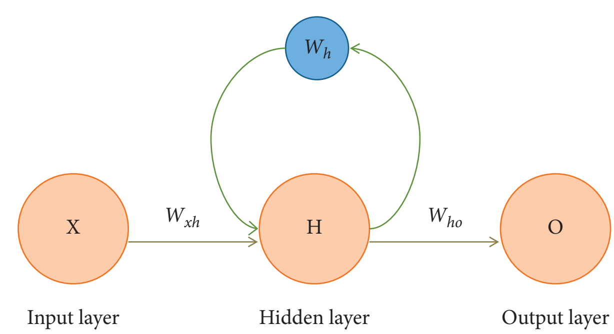

Figure 5: The structure of the recurrent neural network [21].

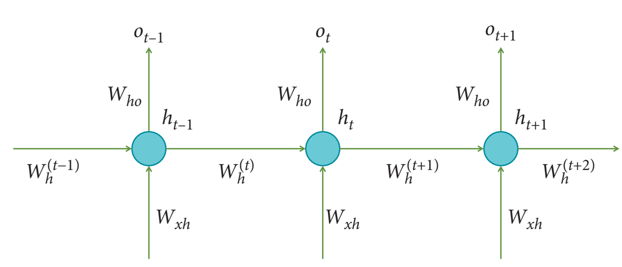

Figure 6: The timeline structure of the recurrent neural network [21].

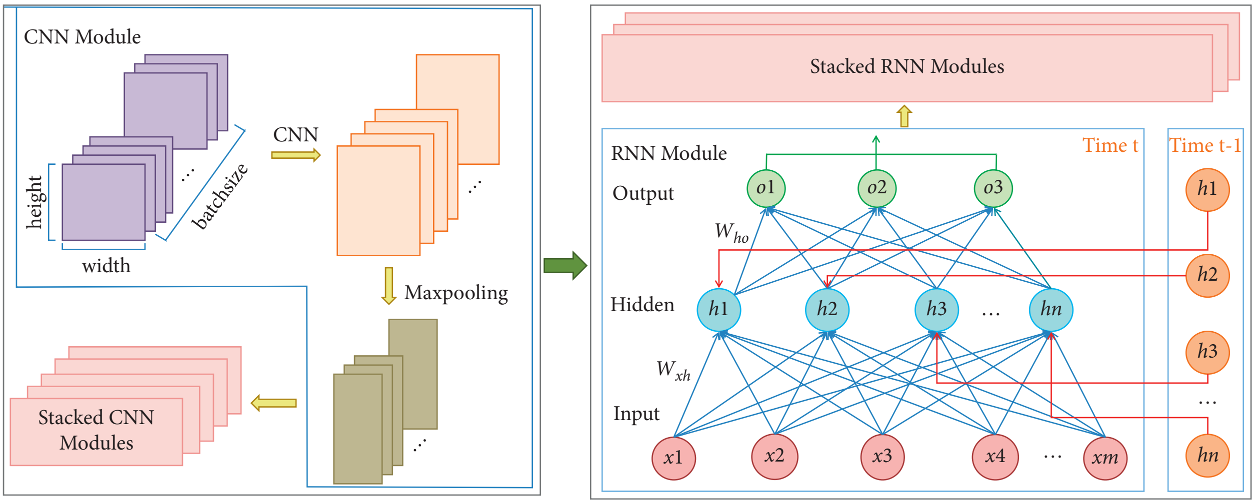

Figure 7: The message passing process for stacked CNN and RNN.

$$X_{cnn} = \mathscr{CNN}_{(\text{kernel,channel,padding})}\left(f_{\text{vect}}\left(X_{ms}\right)\right),$$
$$O_t = \mathscr{RNN}_{\text{gate}}\left(W_{ho}\cdot\left(\mathscr{Q}\left(W_{xh}\cdot X_{cnn}^{(t)} + W_h\cdot H^{(t-1)}\right)\right)\right),$$
$$X_{\text{mol}} = f_{(\text{Dense,Pooling,Gather})}\left(O_t\right), \tag{3}$$

where $f_{(\text{Dense,Pooling,Gather})}$ denotes the mapping of full-connection layer, pooling layer, and gather layer.

4. Experiments

Extensive experiments have been implemented to evaluate the performance of molecular representation using the multiple SMILES-based augmentation for the tasks of molecular property prediction. We will describe the datasets, baselines, and experimental results.

4.1. Dataset Description. We use five molecular property datasets recommended by MoleculeNet [8] for the experiments. Table 1 shows the information of five datasets.

The details of used datasets are shown as follows:

(i) ESOL: ESOL [22] contains the logarithmic aqueous solubility (mol/L) of 1,127 compounds, which is used as a regression task to predict water solubility in deep neural networks

(ii) Lipophilicity: lipophilicity [23] includes the octanol/water distribution coefficient (logD at pH 7.4) about 4,200 compounds, which is important in membrane permeability and solubility

(iii) FreeSolv: FreeSolv [24] provides the hydration free energy (kcal/mol) of 642 compounds in water

(iv) HIV: HIV [25] is used as a classification task in deep neural networks to predict the activity of inhibiting HIV replication, which contains 41,127 compounds

(v) BACE: BACE [26] is used as a classification task, which contains 1,513 molecules and provides quantitative and qualitative binding results for a set of inhibitors

The datasets must be cleaned before being input into the neural network. The cleaning and preprocessing process are shown in Figure 8. The original data are cleaned via five steps, namely, excluding invalid molecules, filtering organic molecules, removing salt and stereochemistry information, keeping the largest fragment, and converting to canonical SMILES. Then, we get the cleaned molecules that will be used to generate multiple SMILES sequences and vectorization. Finally, the feature of vectorization will be fed to the neural network to be trained.

4.2. Baselines. We compared our method with the following models:

(1) CheMixNet: CheMixNet [12] was proposed for predicting chemical properties using molecular SMILES sequences and fingerprints, which is a mixed deep neural network architecture. In this paper, we focus on the molecular SMILES sequence. Therefore, we do not consider computable characteristics, such as molecular fingerprints or physical descriptors. For a fair comparison with our method, we adopt the neural architecture of CNN and RNN in CheMixNet [12], which uses the SMILES as the sole input.

(2) Smi2Vec-BiGRU: Smi2Vec + BiGRU [13] was proposed for learning atoms and the single- and multitask classification tasks, which learns the low-dimensional representation for a molecule by transforming SMILES to vector based on bidirectional gated recurrent unit (GRU) [18] architectures.

(3) XGBoost: XGBoost [27] is an ensemble method to implement a gradient boosting decision tree (GBDT) for improving the speed and efficiency of the model.

Table 1: The description of public molecular datasets, including data type, task type, and the number of compounds before and after augmentation.

Dataset	Data type	Task type	Compound	Compound after augmentation
ESOL	SMILES	Regression	1127	6762
Lipophilicity	SMILES	Regression	4200	25200
FreeSolv	SMILES	Regression	642	3852
HIV	SMILES	Classification	41127	69987
BACE	SMILES	Classification	1513	9078

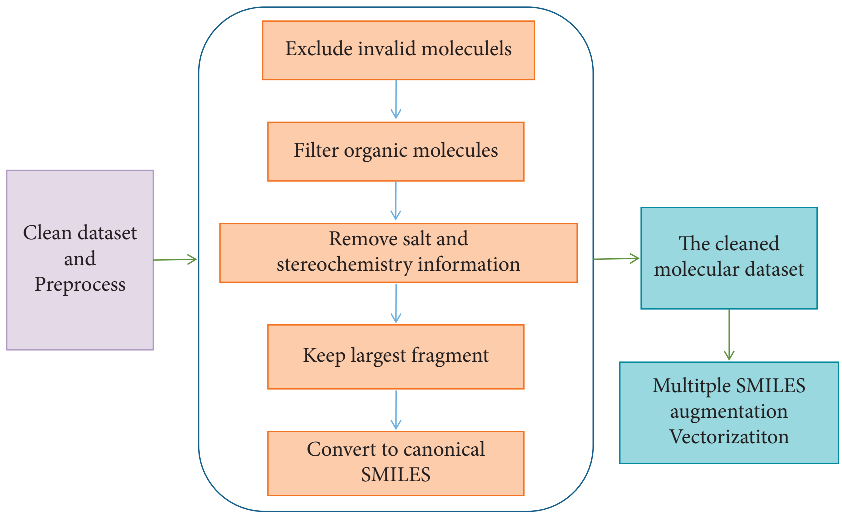

Figure 8: The process of data cleaning and preprocessing.

(4) Multitask: Multitask network [28] was proposed for sharing the processed input among all learning tasks in a dataset and then used separate linear classifiers or regressors for each different task.

(5) MPNN: Message Passing Neural Network (MPNN) is a generalized graph-based architecture [29], including the message passing phase and readout phase. The former phase is to learn the characteristics of the graph, and the latter phase is to obtain the full graph representation for predicting various tasks.

(6) GC: GC [30] is a standard feature extraction method for molecules based on circular fingerprints, which is a kind of graph convolutional model and operates directly on graphs with arbitrary size and shape.

(7) Weave: Weave [31] implemented graph convolutional operation on molecules using a simple encoding of the molecular graph including atoms, bonds, and distances.

(8) Pretraining GNN: pretraining GNN [32] proposed a new strategy and self-supervised methods for pretraining graph neural networks. In order to obtain useful local and global features, the strategy of pretraining GNN is to pretrain expressive graph neural networks by using individual nodes and entire graphs. Pretraining GNN achieved state-of-the-art performance on the tasks of molecular property prediction.

(9) Drug3D-Net: Drug3D-Net [2] is a grid-based 3D model for molecular representation using spatial-temporal gated attention, which uses the geometric information of molecules to extract the molecular characteristics.

(10) Multiple SMILES (RNN (one layer), RNN (two layers), CNN_RNN): this is the method presented in this article. The neural network architecture includes one layer RNN, two layers RNN, and the mixed networks of CNN and RNN.

4.3. Experimental Setup. In this experiment, we use root mean squared error (RMSE) and mean absolute error (MAE) to evaluate the performance of regression tasks. Similarly, we use the loss function of “binary_crossentropy” for classification datasets. We use the average area under the receiver operating characteristics curve (AUROC) and the area under the precision-recall curve (AUPRC) predicted from the test set to evaluate the performance of the model for classification tasks. Our experiment was trained based on the Keras framework and TensorFlow [33]. We used the Adam algorithm [34] for optimizing the parameters of the model. We set a total of 200 epochs, 64 batch sizes, and 5-fold cross-validation with checkpoint and early stopping. We set the learning rate as 0.001 with learning rate decay. We perform

Table 2: The RMSE and MAE values of various approaches in ESOL, lipophilicity, and FreeSolv datasets. The predictive values of the approaches are partly derived from the related references [2, 8].

Model		ESOL		Lipophilicity		FreeSolv	
		RMSE	MAE	RMSE	MAE	RMSE	MAE
CheMixNet	CNN_RNN	1.0419	0.8010	1.0513	0.8282	1.3553	1.0156
Conventional methods	XGBoost	0.9900	—	0.7990	—	1.7400	—
	Multitask	1.1200	—	0.8590	—	1.8700	—
Graph-based methods	MPNN	**0.5800**	—	0.7190	—	1.1500	—
	Weave	0.6100	—	0.7150	—	1.2200	—
3D-based models	Drug3D-Net	0.9683	0.7841	0.9930	0.8404	1.4709	1.1598
Our method (multiple SMILES)	RNN (one layer)	0.6585	0.5105	0.7929	0.6211	1.6051	1.2313
	RNN (two layers)	0.6394	0.4940	0.7960	0.6217	1.3575	1.0468
	CNN_RNN	0.5916	**0.4448**	**0.7054**	**0.5481**	**1.0033**	**0.7859**

The best results are highlighted in bold.

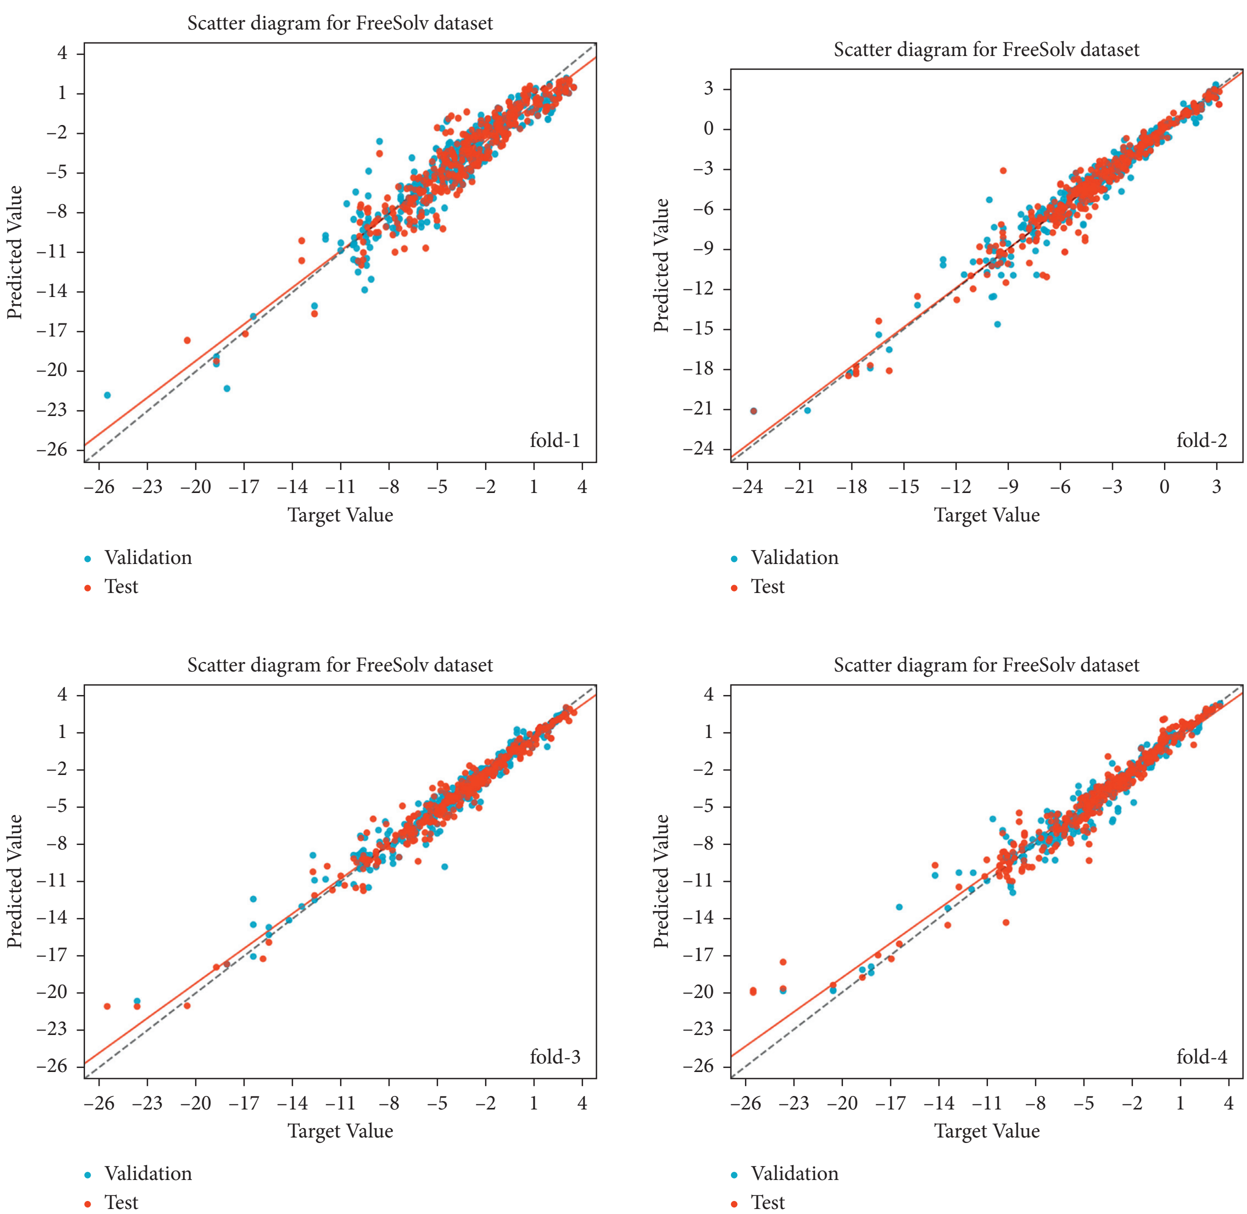

Figure 9: Scatter diagram of FreeSolv dataset for four training folds. The horizontal axis is the ground truth value, and the vertical axis is the predicted value by our model. The solid lines indicate the trend lines, and the dashed lines indicate the identity lines. The blue and red points represent the predicted values in the validation set and test set, respectively.

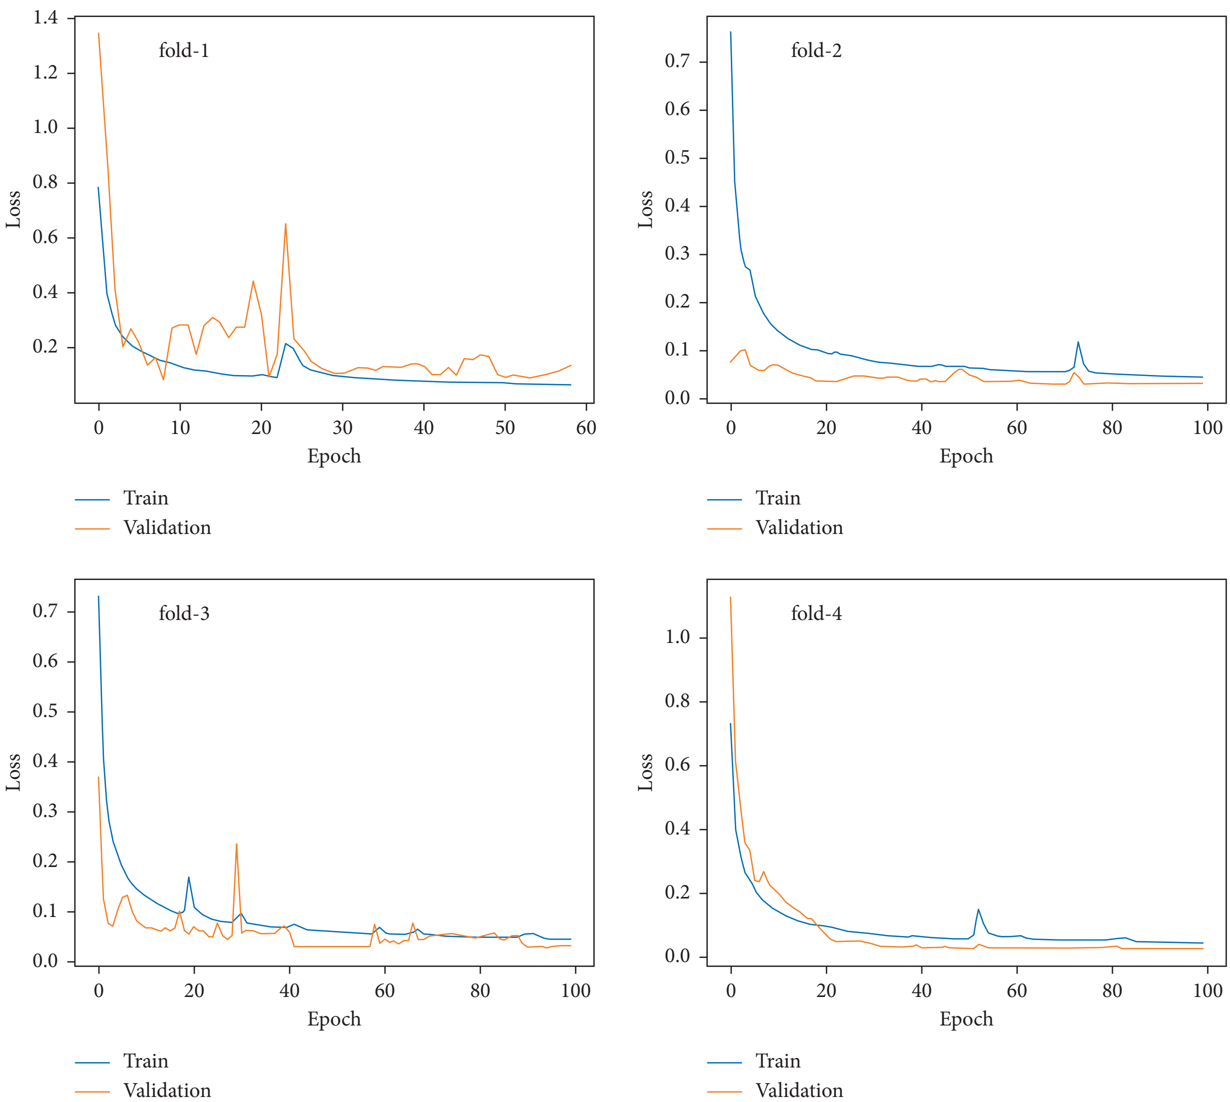

Figure 10: The loss curves during our model training for FreeSolv in the training set and validation set.

randomization of a SMILES string with the random number 5 for ESOL, lipophilicity, FreeSolv, and BACE datasets. As for the HIV dataset, we set random number 20 to implement multiple SMILES randomization only for positive samples so that we obtain a total of 30,303 positive examples compared with the original 39,684 negative samples.

4.4. Performance Comparison

4.4.1. Performance in Regressions. Solubility, lipophilicity, and free energy are very important physical chemistry properties, which are essential properties to understand molecular interaction with solvents. Table 2 demonstrates the predictive performances for water solubility (ESOL), octanol/water distribution coefficient (lipophilicity), and hydration free energy (FreeSolv). Our multiple SMILES-based model using mixed CNN and RNN architecture obtains the best performance. The smaller the value of RMSE and MAE, the better for ESOL, lipophilicity, and FreeSolv. As shown in Table 2, we obtain 0.4448 MAE and 0.5916 RMSE values for ESOL in the test set. The RMSE value of 0.5916 is slightly lower than the MPNN with the 0.5800 RMSE. However, as for lipophilicity and FreeSolv datasets, our method obtains superior performance on both RMSE and MAE values, which shows that the multiple SMILES-based data augmentation can alleviate the overfitting problem to a certain extent on a small amount of data, such as ESOL and FreeSolv datasets.

Figure 9 shows the scatter plots in the FreeSolv dataset for four training-folds, which indicates that the points on the test set closely surround the identity line, which shows that the prediction results in the test set are closer to the target value, although the trend lines deviate slightly from the identity lines in each training folds. In addition, Figure 10 shows the loss curves during our model training in the training set and validation set for the FreeSolv dataset. At the beginning of the training of the model, the loss on the training set and the validation set has a relatively large gap (training loss curve and validated loss curve are far away), indicating that the model is not stable. When the number of

Table 3: The AUROC and AUPRC scores of various approaches in HIV and BACE datasets. The predictive values of the approaches are partly derived from the related references [2, 8, 13, 32].

Model		HIV		BACE	
		AUROC	AUPRC	AUROC	AUPRC
CheMixNet	CNN_RNN	0.8204	0.8614	0.7429	0.7162
SMILES-based	Smi2Vec-BiGRU	0.9117	0.8963	0.8440	0.7872
Conventional methods	XGBoost	0.7560	—	0.8500	—
	Multitask	0.6980	—	0.8240	—
Graph-based methods	GC	0.7630	—	0.7830	—
	Weave	0.7030	—	0.8060	—
	Pretraining GNN	0.7990	0.7806	0.8450	0.7908
3D-based models	Drug3D-Net	0.9621	0.9617	0.7185	0.6397
Our method (multiple SMILES)	RNN (one layer)	0.9567	0.9525	0.7879	0.7577
	RNN (two layers)	0.9613	0.9636	0.8083	0.7665
	CNN_RNN	**0.9767**	**0.9798**	**0.8512**	**0.7919**

The best results are highlighted in bold.

training epochs increases, the loss curves on the training set and the validation set tends to be consistent and fit each other, indicating that the model tends to be stable and is slowly converging.

4.4.2. Performance in Classifications. Table 3 demonstrates the predictive performances for HIV activity (HIV) and inhibitors of human β-secretase 1 (BACE). The larger the AUROC and AUPRC score, the better for HIV and BACE. Our method based on mixed CNN and RNN architecture achieved the best performance on AUROC and AUPRC scores in the test set for HIV and BACE datasets. In HIV, we obtain 0.9767 AUROC and 0.9798 AUPRC scores compared with the 0.9621AUROC and 0.9617 AUPRC of the 3D-based method Drug3D-Net, although the Drug3D-Net considered the information of molecular geometry. In addition, the performance of our method exceeds that of the pretrained model pretraining GNN with a large margin.

In summary, our method shows superior performance in both regression datasets and classification datasets, which implies the good molecular representation ability of our proposed method.

4.5. Ablation Study. For different neural architectures of our multiple SMILES methods (shown in Tables 2 and 3), the mixed CNN_RNN architecture obtains the best performance among RNN (one layer), RNN (two layers), and CNN_RNN, which indicates that the CNN convolution in our model is essential and can improve the predictive performance for downstream tasks. Meanwhile, the performance of RNN (two layers) architecture is slightly better than that of RNN (one layer) architecture, which shows that the deeper neural networks can have better learning ability for extracting features. Therefore, it can show better performance in specific tasks, such as molecular property prediction.

5. Conclusion

In this study, we make full use of the nonunique nature of the SMILES string to perform randomization of a SMILES string multiple times for efficiently learning molecular features along all message paths. By encoding multiple SMILES for every molecule as an automated data augmentation, we obtain better molecular representation and the proposed method shows superior performance in the tasks of predicting molecular properties, which alleviates the overfitting problem caused by the small amount of data in the datasets of molecular property prediction.

Data Availability

All input data are publicly available and a detailed description for the same is mentioned in the Dataset Description.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

As an educational concept based on learning output, OBE (Outcome-Based Education) is student-centered and emphasizes students' personal progress and learning achievement. Based on BD (big data) analysis, this paper proposes a new talent training mode for the electronic information science and technology specialty. This model employs BD analysis technology to examine the correlation index between social demand and talent cultivation, based on the employment situation of students in the country in previous years. The teaching reform was carried out under the OBE concept, and a new training scheme was formed. Training objectives, graduation requirements, curriculum system, and continuous improvement mechanism were all determined. This paper proposes an algorithm for determining the degree of similarity between the knowledge required by the organization and the knowledge held by its employees. The person with the highest similarity is identified as the training candidate by the algorithm, and the training candidate is then trained according to the knowledge that the organization requires. Talent training in the field of electronic information science and technology has yielded positive results.

1. Introduction

The development of a talent training scheme is a crucial link in university talent training, as well as a vehicle for innovating talent training modes and improving talent training quality [1]. The key to developing a professional talent training plan is to establish talent training objectives, such as professional employment positions, professional skills and qualities that graduates should possess, etc., to create a talent training objective system with specific characteristics, and then to develop a professional talent training plan to enable graduates to acquire corresponding employment skills. Current teaching methods place an excessive amount of emphasis on book knowledge mastery, neglect practical application of knowledge, and are unable to guide students' creative thinking through engineering cases. Traditional examinations continue to dominate the assessment method, while process evaluation and formative evaluation are still in their infancy.

OBE (Outcome-Based Education) is a kind of educational concept oriented to students' learning outcomes, which emphasizes that engineering education must focus on students' achievement of expected learning outcomes. In the whole OBE teaching concept, students are always the center of education and highly involved, and all teaching links are carried out around students. Guiding the reform of engineering education with the concept of OBE education is conducive to solving the problem of mismatch between the current graduates' abilities and social needs and has practical significance [2]. Engineering talents, as the internal driving force of social development, have a profound impact on China's scientific and technological development level and people's quality of life [3, 4]. Engineering talents trained by local engineering colleges are of vital significance to local economic development and national engineering construction. At present, scholars' research on talent training quality evaluation mainly focuses on talent training quality standard, evaluation subject, evaluation index system, evaluation mechanism, evaluation system, and so on and has achieved certain research results [5]. However, there are still many problems, such as limited access to evaluation information and lack of in-depth analysis due to the single evaluation method, the lack of scientific evaluation index system, the inefficacy of fairness and authority of evaluation results in practice, and the lack of objectivity of evaluation, which leads to low reliability, insignificant validity, and the difficulty of practical results [6, 7].

The performance evaluation and information construction of education have become the driving force for the development of current university education as a result of the information age's impact. However, as university teaching levels improve, BD (big data) analysis is required to scientifically evaluate teaching performance in the practice of the training mode of talents majoring in electronic information science and technology, and how to improve the scientificity and effectiveness of performance evaluation through the digital network platform is the focus of this paper. A new talent training model for electronic information science and technology is proposed in this paper based on BD analysis. A more perfect talent training scheme is designed to provide a more scientific training mode for the training and output of national high-end technical talents by analyzing subjective and objective influencing factors.

The creative point of this research is as follows: this paper adopts the technical platform of big data analysis, based on the theory of constructing the evaluation index system of talent cultivation quality suitable for the collection and analysis of big data evaluation model, and then collects and analyzes data through the construction of functional modules, taking a university as an example to get the evaluation results. After repeated several times, a relatively perfect big data evaluation model can be formed, which is more widely used in the evaluation of talent cultivation quality in universities.

2. Related Work

Literature [8] discusses in detail the origin, essence, system, and principles of foreign OBE educational ideas and preliminarily realizes the advantages of OBE educational ideas in personnel training. Literature [9] pointed out that the results-oriented education should be reflected in the process of making clear the teaching purpose, making the teaching plan, implementing, and evaluating it. OBE, as a good belief, atmosphere, and method, is worth learning and learning from higher education in China. Literature [10] tries to learn from the American results-oriented education model, help you understand its theoretical composition, formation process, and manifestation, and promote the localization process of results-oriented education by analyzing the feasibility of learning from China. Literature [11] points out as follows: in the future, the development of a flexible, high-level, and sustainable OBE education concept should be promoted. Literature [12] focuses on the analysis of the problems existing in the training mode of applied talents and advocates the introduction of OBE education concept into the training process of applied talents from three aspects: students' expected learning outcomes, assessment system of learning outcomes, and practical teaching system of applied talents. Literature [13] emphasizes that local engineering colleges should take various forms to contribute to local development, train high-quality undergraduate students for local industrial development, and give full play to their advantages to run several influential disciplines in China. Literature [14] mainly discusses and studies how to define the training orientation in local engineering colleges. This paper defines the local engineering colleges from four aspects: the purpose of running a school, the type level, the scale of running a school, and the development goal. Literature [15] puts forward the idea of applying OBE concept to the curriculum system reform of local engineering colleges, but the particularity of this subject of local engineering colleges is not clear in the specific suggestions.

One of a university's main functions is talent cultivation, and the quality of talent cultivation is the focus of the university's overall quality. It does not exist in isolation at the university but is influenced by a variety of other factors. It has a lot of connotations and can react to the university's talent cultivation, so more research on the quality of talent cultivation is needed. According to literature [16], our universities have first experienced the quality concept of knowledge, then the quality concept of ability, and finally the diversified quality concept since the founding of the People's Republic of China. According to literature [17], the quality concept of university talent cultivation should be appropriate to meet students' continuous growth. According to the literature [18], talent training quality must be evaluated from a multidimensional and three-dimensional perspective. According to literature [19], in the evaluation process, the relationship between the university and society should be strengthened, and the appropriate evaluation mechanism and indicators should be established as a result. Literature [20] attaches importance to the use value of talents, and puts forward that evaluating the quality of talent training should meet the needs of the country and society, and should meet certain standards in the degree of conformity. According to literature [21], this paper evaluates the quality of talent training in universities from three aspects: training conditions, training process, and training effect, using analytic hierarchy process. According to literature [22], the fuzzy comprehensive evaluation method in the management model is used to analyze the quality of talent cultivation in universities. Literature [23] divides the evaluation modes of Chinese universities from the philosophical evaluation theory, the stakeholder theory of economics, and the diversified concept of evaluation subjects of pedagogy and puts forward the strategies of authentication mode, ranking mode, and evaluation mode for the construction of university evaluation modes.

3. Research Method

3.1. Design of a New Training Mode for Electronic Information Science and Technology Professionals Based on BD Analysis. OBE focuses on the training of professionals, which usually includes three stages (Figure 1).

The first step is to determine a graduate's professional postgraduation ability. To solve the problem of what kind of people the major trains, identify the target position of professional training, highlight professional characteristics, and analyze and refine the professional skills required by the

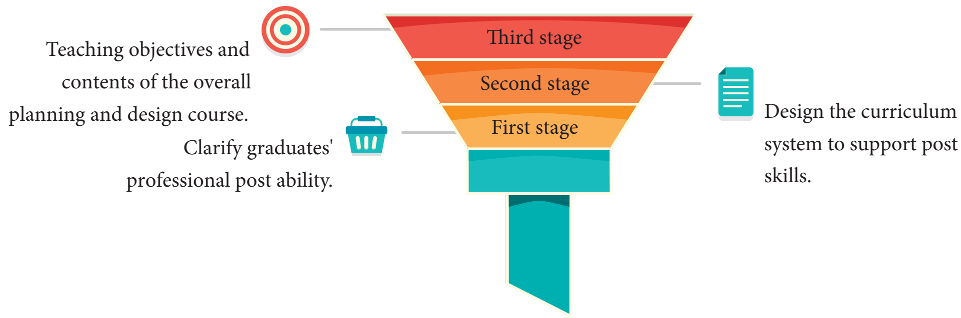

Figure 1: Three stages of personnel training of OBE concept.

major. The second step is to create a curriculum system that supports postsecondary skills. A reasonable curriculum system with ability expansion and extension is designed on the basis of clarifying job skills, guided by OBE education thought, focusing on the cultivation of students' ability literacy and quality literacy, in order to clarify the role of each course in achieving the training goal and solve problems such as why students should learn these contents. Third step is strong pertinence and adaptability in the overall planning and design of curriculum teaching objectives and teaching contents. The course teaching objectives are determined by the knowledge and skills needed to complete the work, in order to improve students' vocational skills and adaptability to the workplace, and to solve the problems of how to help students achieve these learning achievements, according to the needs of personnel training.

According to the training objectives and graduation requirements of computer electronic information science and technology specialty, combined with the general standard of engineering education certification and the supplementary standard of computer specialty, and according to the OBE education concept, the student-centered curriculum system is designed and constructed reversely.

Corresponding to the graduation requirements, build a modular curriculum system which is oriented by ability training, pays attention to knowledge application and quality training, and embodies interdisciplinary integration. The curriculum system consists of general education, professional education, quality development, and innovation and entrepreneurship [24], as shown in Figure 2.

In Figure 2, the general education module courses are set according to the relevant national requirements, general standards and supplementary standards of computer, and electronic information science and technology specialty of engineering education certification.

The module of engineering foundation and specialty foundation must conform to the "National Standard for the Teaching Quality of Computer Science and Technology in Ordinary Colleges and Universities" formulated by the Teaching Steering Committee of the Ministry of Education and cultivate students' professional basic abilities such as computational thinking, program design and implementation, algorithm analysis and design, system ability, etc., which can solve practical problems [25].

The major's optional module includes a number of hot technical courses as well as professional knowledge development courses. Students can choose a number of courses that satisfy the credit requirements based on their personal interests and development goals. Artificial intelligence, pattern recognition, Linux system operation and maintenance, information retrieval, digital image processing, and other topics are among the topics covered. To improve the integration between teaching and employment, talent education and training programs should be integrated with practical occupations, a "dual" education mechanism should be built, and new teaching and training programs should be set up according to actual occupational needs. Simultaneously, schools and businesses must improve their communication and collaborate to develop new education and training courses that meet the needs of talent development and businesses.

The essence of personnel training is to enable personnel to master new knowledge. Therefore, after analyzing the above problems from the perspective of knowledge, it is found that the content of personnel training should be the knowledge needed by the organization, and the identified candidates should be the personnel who are closest to the knowledge needed by the organization. Therefore, the process of organizing personnel training can be divided into as follows.

Firstly, the knowledge needed by the organization is determined, then the personnel closest to the knowledge needed by the organization are identified as training candidates, and then the training candidates are trained according to the determined knowledge needed by the organization. According to the relationship between the knowledge network and the personnel network, the knowledge easily lost by the organization can be determined by quantitative calculation. On this basis, the areas easily lost by the organization can be determined, and then the knowledge needed by the organization can be determined according to the actual situation of the organization.

Easy-to-lose knowledge refers to the knowledge owned by very few people in the organization. With the loss of people, this knowledge is easy to lose. The judgment formula of easy-to-lose knowledge is as follows:

$$L(ke) = \left\{ke_i \middle| \left|P(ke_i)\right| \leq \mathrm{thr}(\mathrm{elk})\right\}. \tag{1}$$

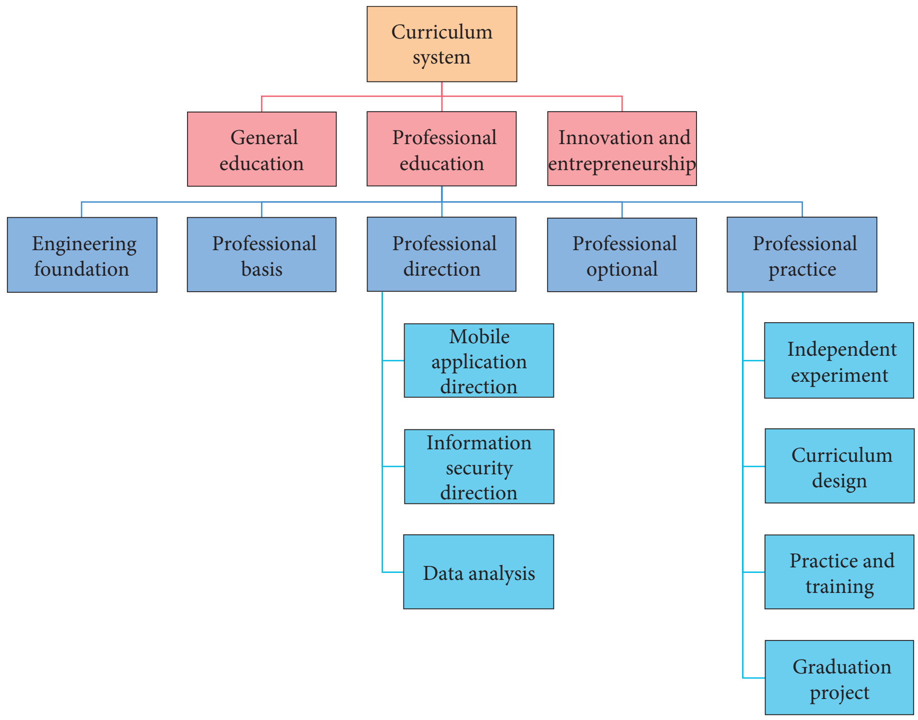

Figure 2: Curriculum system composition.

Among them, thr(elk) is the set threshold; when $|P(ke_i)| \leq \text{thr}(\text{elk})$, it is considered that ke_i is easy to lose knowledge. Ideally, $\text{thr}(\text{elk}) = 1$. Easy-to-lose knowledge needs to be repaired and stabilized in time, and its judgment is helpful to recognize the weak links of organizational knowledge.

After clustering $L(ke)$, a faction is formed, and the faction is regarded as a domain. Let $C_i(K)$ represent the set of knowledge elements that are easy to lose in domain C_i and judge whether C_i is a domain that is easy to lose according to the degree of domain knowledge loss.

The loss degree of domain knowledge is defined as follows: $C_i(L)/|C_i|$, where $|C_i(L)|, |C_i|$, respectively, represents the number of elements in their respective sets. Therefore, it means the proportion of the number of easily lost knowledge elements in C_i to the total number of knowledge elements. The judgment formula of easily lost domain can be expressed as follows:

$$Lc(C) = \left\{ C_i \middle| \frac{\|C_i(L)\|}{|C_i|} \geq \text{thr}(\text{eld}) \right\}. \tag{2}$$

Among them, thr(elk) is the set threshold, and when $|C_i(L)|/|C_i| \geq \text{thr}(\text{eld})$ is used, C_i is considered to be an easy-to-drain field, and ideally $\text{thr}(\text{eld}) = 100\%$.

To determine the knowledge that the organization requires, combine the knowledge that is easy to lose with the field that is easy to lose, and then combine the actual situation of the organization. Following the determination of the knowledge that the organization requires, the training candidates must be identified. The VSM (vector space model) is a traditional text-based calculation. The similarity between the organization needing knowledge and the personnel possessing knowledge represented by knowledge can be abstracted into the similarity between knowledge subjects if both the organization needing knowledge and the personnel possessing knowledge are regarded as knowledge subjects. Fields are formed after the knowledge network is clustered, and the similarity of knowledge subjects is investigated through the lens of fields.

In matrix T, rows represent knowledge subjects and columns represent fields, so the field vector of P_i is expressed as T_i, so the Sim calculation based on the similarity between P_i and P_j of the field vector is shown in formula (3).

$$\begin{aligned} \text{Sim}\left(P_i, P_j\right) &= \cos\left(\vec{T}_{\text{i}}, \vec{T}_{\text{j}}\right) \\ &= \frac{\vec{T}_{\text{i}} \cdot \vec{T}_{\text{j}}}{\left\|\vec{T}_{\text{i}}\right\| \cdot \left\|\vec{T}_{\text{j}}\right\|} \\ &= \frac{\sum_{k=1}^{m} c_{ik} \times c_{ji}}{\sqrt{\left[\left(\sum_{k=1}^{m} c_{ik}^2\right) \sum_{k=1}^{m} c_{jk}^2\right]}}. \end{aligned} \tag{3}$$

When calculating the similarity, it needs to be calculated first according to the similarity algorithm based on the domain, then calculate it according to the similarity algorithm based on the VSM, and then make a comprehensive judgment according to the results. The similarity algorithm based on the VSM is a classic algorithm, with guaranteed accuracy and recall rate.

3.2. BD Evaluation Model of Talent Cultivation. The BD evaluation model includes two aspects in the evaluation of talent training quality: one is the theoretical basis, that is, the index system and the second is the technical route, that is, the functional module. In the process of construction, it is necessary to write the theoretical basis, that is, the evaluation index system, into the background operation module of the model, which is reflected in the compilation of the underlying code.

From an intuitive point of view, the formation process of the evaluation model is a process of "conditional input, analysis tools, analysis methods, output results, result interpretation, model test, model correction and improvement."

In the process of building the concrete evaluation model, the main steps in the analysis mode are as follows: the first step, the acquisition scheme of evaluation data information, mainly through the crawler code to retrieve data and obtain evaluation information, and through the vertical search engine to trace the evaluation data layer by layer, obtain a certain amount of evaluation information and archive it to form the original database. The intuitive flow of BD model research is shown in Figure 3.

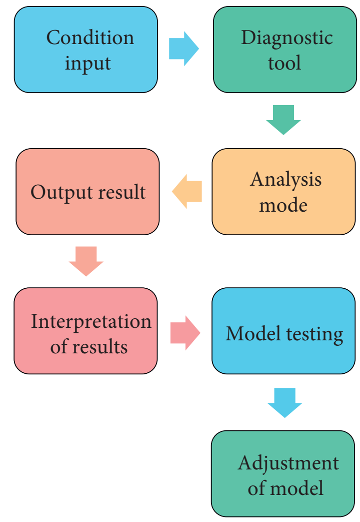

Figure 3: Flowchart of BD evaluation model construction.

To improve the integration between teaching and employment, talent education and training programs should be integrated with practical occupations, a "dual" education mechanism should be built, and new teaching and training programs should be set up according to actual occupational needs. Simultaneously, schools and businesses must improve their communication and collaborate to develop new education and training courses that meet the needs of talent development and businesses. Then, according to the training results, the school conducts secondary theoretical training for students' shortcomings to realize the cooperation between classroom and practice, and enterprises should provide training bases for students to enhance their practical operation ability; finally, the school conducts secondary theoretical training for students' shortcomings to realize the cooperation between classroom and practice.

According to the above-mentioned teaching mechanism, the calculation formula of students' training investment index under the new mechanism is as follows:

$$p = \frac{\lambda \cdot \mu f(p) - \Delta f}{\sqrt{m} \cdot (b_1 + b_2)}, \tag{4}$$

where p represents the investment index; λ represents the correlation index between social demand and talent cultivation; μ represents the deterioration index when learning engagement is low; F $f(p)$ represents a quantitative analysis function; Δf represents analysis error; m represents the index change value; b_1 said enterprise training investment parameters; and b_2 indicates the impact index of the improved educational mechanism.

Rebuild the talent cultivation teaching system based on the obtained indicators, which includes developing a modular curriculum system between schools and businesses; establish a task-based teaching and training procedure; and create training programs that are multichannel, multilevel, and multicategory. To achieve a diversified and systematic teaching system, create a centralized task-oriented training mode. Students' achievement is an important standard to measure students' mastery of knowledge in the process of cultivating talents in the electronic information science and technology specialty. Students with abnormal learning status are identified through outlier algorithm analysis of their scores, and managers provide personalized guidance to these students. At the same time, the neural network model is used to predict the scores of key subjects for these students with abnormal learning status, and targeted learning is carried out for the subjects with problems.

The Adagrad algorithm can obtain small learning updates for nonsparse features according to different learning rates for each parameter, and on the contrary, obtain large learning updates. So, this optimization algorithm is more suitable for dealing with sparse feature data. For the Adagrad algorithm, the update iteration method is as follows:

$$\theta_{t=1,i} = \theta_{t,i} - \frac{n}{\sqrt{G_t + \varepsilon}} \cdot g_{t,i}, \tag{5}$$

where $G_t \in R^{dd}$ is a diagonal matrix, where diagonal element e^{ii} represents the sum of squares of the gradient of the i-th parameter θ_i from the past to the present, and ε is the smoothing parameter.

Adam (Adaptive Moment Estimation) is also a method to determine the gradient descent at different rates according to different parameters. Its calculation is different from the historical gradient attenuation, and the historical square attenuation is not used. Its attenuation mode is similar to momentum, as follows:

$$\begin{aligned} m_t &= \beta_1 m_{t-1} + (1 - \beta_1) g_t, \\ v_t &= \beta_2 v_{t-1} + \left(1 - \beta_2 g_t^2\right), \end{aligned} \tag{6}$$

m_t, v_t is the weighted average and weighted deviation of gradient, respectively, and the initial value is 0 vector. Adam's researchers found that they are close to 0 vector, especially when the attenuation factor β_1, β_2 is close to 1. In order to solve this problem, the deviation of m_t, v_t is corrected:

$$\widehat{m}_t = \frac{m_t}{1-\beta_1^t},$$
$$\widehat{v}_t = \frac{v_t}{1-\beta_2^t}. \tag{7}$$

Finally, Adam's update equation is as follows:

$$\theta_{t+1} = \theta_t - \frac{\eta}{\sqrt{\widehat{v}_t + \varepsilon}}\widehat{m}_t. \tag{8}$$

In order to know the students' learning situation and find out the problems in the teaching process in time, some courses adopt the formative evaluation method of unit test. Teachers can get timely feedback in the teaching process, adjust teaching plans, and improve teaching methods at any time. Finally, at the end of each course, a questionnaire survey was conducted on the achievement of the course objectives of the course ε.

4. Results Analysis and Discussion

4.1. Evaluation Results of Talent Training Quality. The above contents of this paper have completed the theoretical and technical construction of BD evaluation model. Here, a case study of the actual utility of this evaluation model is made, that is, the application of BD evaluation model. By applying the evaluation model to practical cases, the corresponding evaluation results are obtained, and the availability of the evaluation model is evaluated reasonably by analyzing the evaluation results.

On the evaluation of personnel training quality by employers, the index scores are shown in Figure 4.

Through the analysis of Figure 4, it can be concluded that in terms of fairness, due to the lack of BD collection technology and scoring dictionary in this study, there may be some errors with the real situation, so the results presented in this figure are only a reference and partly reflect the objective truth of the talent training quality of this school. In the interpretation of the diagram, based on the knowledge and understanding of the major of electronic information science and technology, the specific interpretation conclusions are as follows.

The four subindicators have little difference in scores among the ideological and moral indicators, but the gap from the full score is still not a high score. The index design of this study played a role in the formation of this result. Because this study focuses on evaluating graduates' employability, social adaptability is primarily reflected in aspects of knowledge, ability, and other characteristics that are easy to examine and quantify, resulting in less evaluation information in ideological and moral aspects. This school's students excelled in terms of creativity and practical ability. As a student at this school, I can see election notices and good news about various innovation competitions on campus based on my knowledge of the school. This school has put in a lot of effort to develop innovative students. In terms of social practice, the school is the only university in the area with a bachelor's degree or higher, and it has a significant influence in the community. As a result, a variety of businesses, communities, and other institutions and organizations are willing to collaborate with the school to organize social practice activities that will enrich the lives of college students. In terms of social ability, this school's students' international ability was praised and scored highly. The social evaluation data show that the students in this school have a good work attitude, but there are some areas where employers criticize them. For example, despite students' short-term job-hopping behavior, their overall performance in this school is above average. On the one hand, this achievement is due to the balanced dilution of data in statistics; on the other hand, it also reflects students' lack of adaptability after work, or a lack of career education in this field in university talent development.

Specifically, in this study, because in the setting of the index system, in addition to the connotation of the index, there is also the consideration of the index weight; here, the product obtained by multiplying the scores of ten first-level indexes by their weights indicates the importance of the index in the whole evaluation system, as shown in Figure 5.

Through the analysis of Figure 5, it can be known that in the process of evaluating the quality of the training of electronic information science and technology professionals, the graduates of this school have received the most attention in terms of knowledge quality, social ability, and employment status, while the network evaluation has not paid much attention to students' entrepreneurship, students' source, further study, and ideological status. This result also enlightens us that in the evaluation of talent training quality, pay attention to the employability and employment status of talents, and explore the evaluation of talent training quality from the specific connotation of these indicators.

Take the employment statistics of students in the proposed talent training mode as the experimental group and the employment statistics of students in the traditional talent training mode as the control group. Figure 6 shows the test results.

By analyzing the above two groups of test results, it can be seen that under the application of the talent training model of BD analysis, students can improve their own technical level by strengthening practical training ability. At the same time, because this mode adjusts the teaching mode in time according to the market demand for talents, it makes the students' professional skills match with the social needs, thus increasing the number of employed people.

However, students who study under the traditional talent training mode are not fully trained in practical courses, and do not dig out the characteristics of correlation indexes between society and talent technology, which leads to the deviation between students' personal skills and social needs, which leads to poor matching effect, and then affects students' employment.

4.2. Neural Network Model Predicts the Scores of Outlier Students. Before designing the neural network model, the data need to be further preprocessed. Organize the course scores, classify the course scores according to students, and cut out unnecessary data fields and some courses in the

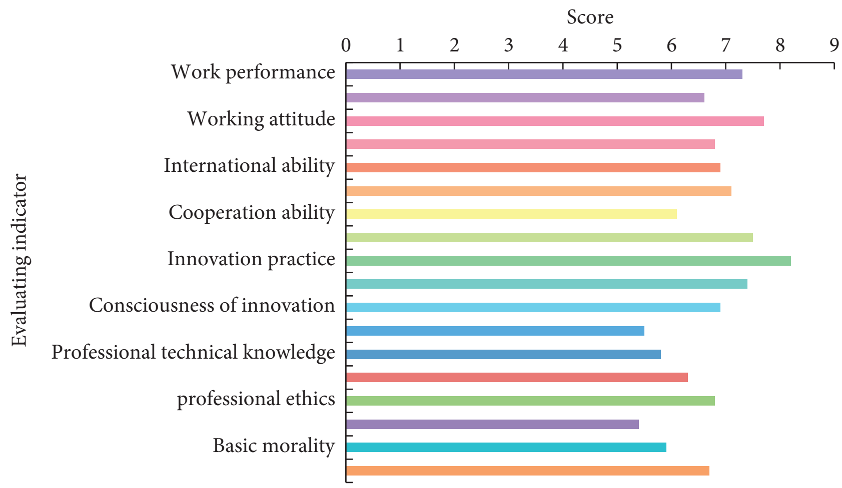

Figure 4: The evaluation index score of personnel training quality of employers.

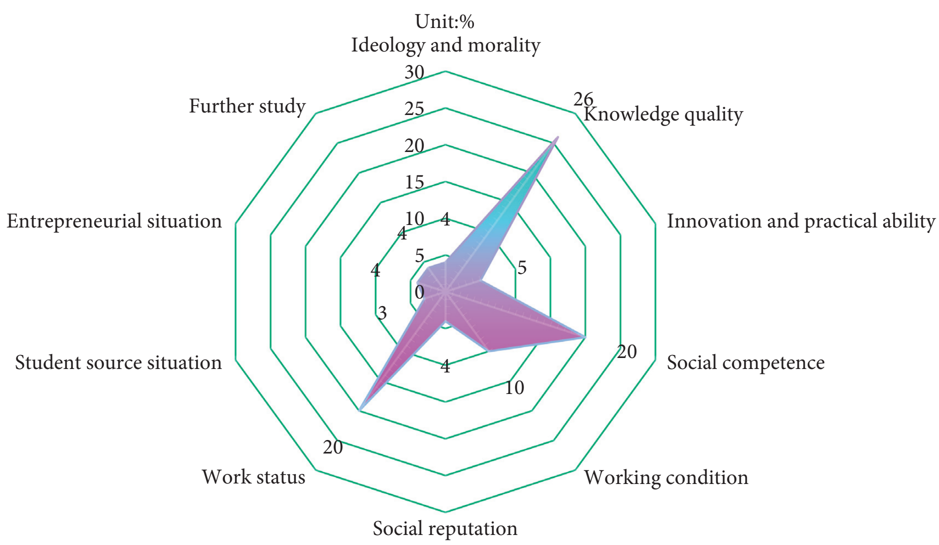

Figure 5: Proportion of indicators in importance.

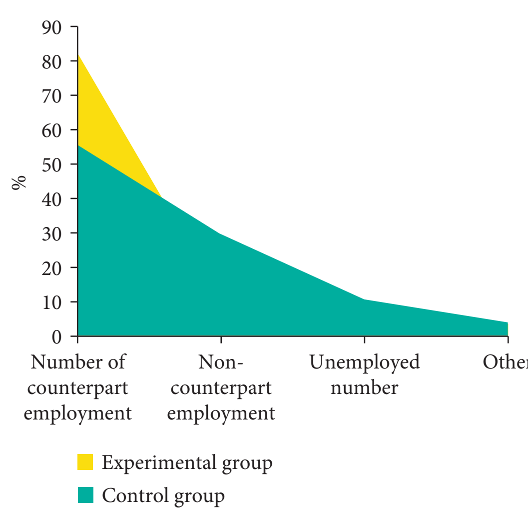

Figure 6: Test comparison results.

Table 1: Setting of neurons in each layer.

Number of experimental groups	First hidden layer	Second hidden layer	Third hidden layer
1	10	5	5
2	50	10	10
3	100	50	10

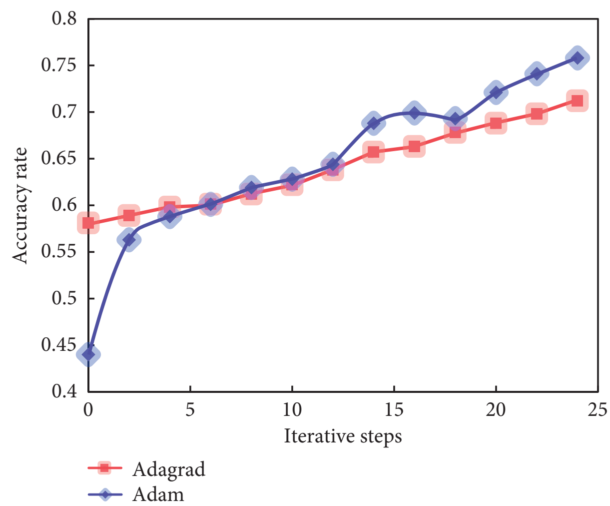

Figure 7: Algorithm comparison.

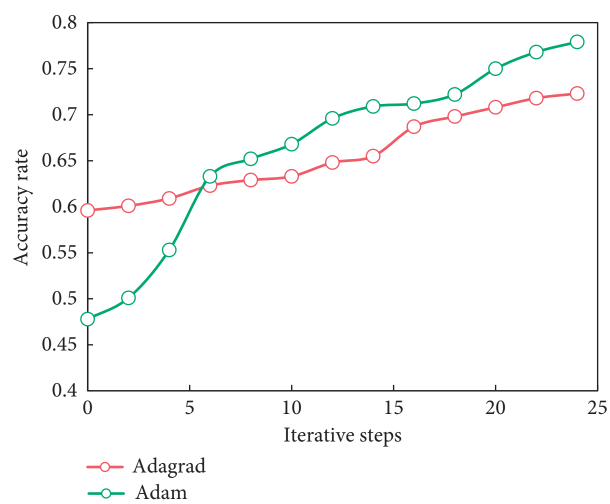

Figure 8: Algorithm comparison.

model design. Finally, the scores are processed, and the data are integrated according to three categories (the historical scores of the first five semesters of study courses, the name of target courses, and the category of target courses). When designing the neural network, the input layer inputs the scores of a certain student in the last semester, and the input dimension is 15. Finally, the probability of the category of the target course score is calculated through the Softmax layer. In the process of designing the neural network, three groups of experiments were designed. The number of neurons in each layer is shown in Table 1.

Through different optimizers, when the number of units in the first hidden layer is 10, the number of units in the second hidden layer is 5, and the number of units in the third hidden layer is 5, the accuracy of the classification results changes with the increase of iteration steps in the training process, as shown in Figure 7.

Similarly, when the number of the first hidden layer, the second hidden layer, and the third hidden layer are 50, 10, and 10, respectively, the change of the correct rate of the training set with the increase of the number of iterations is shown in Figure 8.

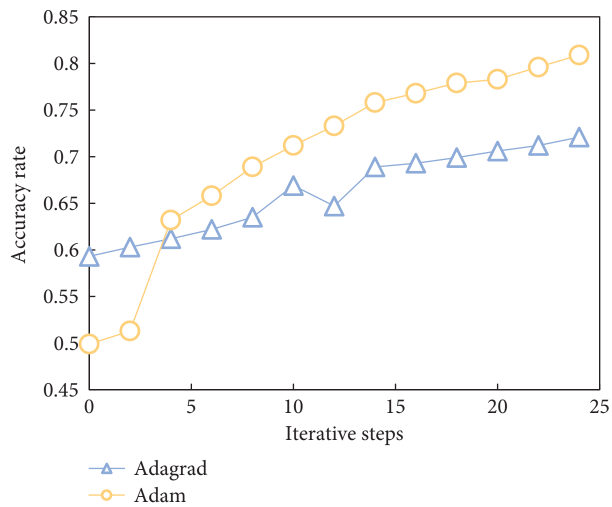

Figure 9: Algorithm comparison.

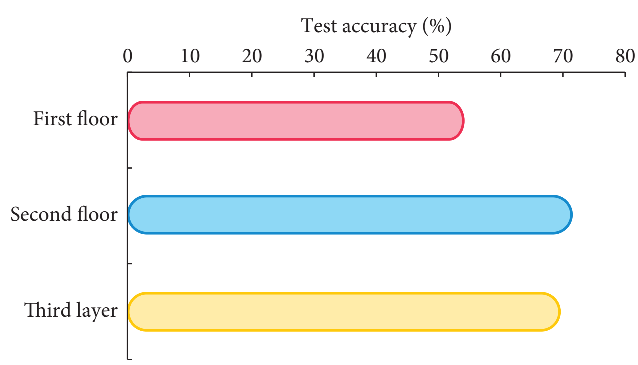

Figure 10: Test set accuracy rate.

Similarly, when the number of units in the first hidden layer, the second hidden layer, and the third hidden layer is 100, 50, and 10, the number of iterations increases, and the change of accuracy rate is shown in Figure 9.

It can be seen from these figures that with the increase of iteration times, the correct rate of training is constantly increasing, and the increasing trend is basically caused by different optimization algorithms. It is found that the Adam algorithm is better than the Adagrad algorithm in the training process.

When testing, the correct rate of Adam gradient update method is shown in Figure 10.

It is found that increasing the number of parameters will make the neural network model easier to over-fit, while too few parameters will make the model underfit. Finally, the Adam gradient updating method is used. The number of neurons in the first, second, and third hidden layers is 50, 10, and 10, respectively, as the final model.

5. Conclusion

The goal of OBE is to rebuild the curriculum system and update the curriculum training objectives to reflect changes in the industry, social needs, and the target orientation of skilled talent training. This paper examines the training model of electronic information science and technology professionals in universities with a BD background from various perspectives and performance evaluation frameworks, avoiding the blindness of university informatization decision-making, maximizing the scientific nature of large numbers, and laying a strong foundation for Chinese universities' modernization. In terms of data processing, the big data evaluation model is used to actively capture evaluation data on the network, and the importance of each index is scored using the emotion dictionary, after which the computer uses big data analysis technology to complete the comprehensive score of each index. Applying the OBE concept to BD technology and application talent training is a comprehensive reform of university talent training that also serves as a model for the training of professionals in electronic information science and technology.

The analysis of research status and specific application of OBE at home and abroad in this paper is not detailed enough, and some suggestions for improvement are too one-sided and general, and need to be further deepened and refined, due to the limited level of self-ability, which is limited by reference materials, number of articles, and writing time.

Received 14 December 2021; Revised 1 January 2022; Accepted 8 January 2022; Published 27 January 2022

Academic Editor: Xin Ning

For a long time, college English teaching in many Chinese universities has focused on cultivating students' reading abilities while ignoring the cultivation of students' speaking abilities, leaving many non-English majors unable to communicate in English even after years of English study. This paper outlines the entire design and development process for an intelligent correction system for spoken English, with a focus on the methods for implementing the functions of spoken English examination, question bank management, and marking. A multifeature fusion of SE (sample entropy) and MFCC (Mel frequency cepstrum coefficient) based speech emotion recognition method is proposed. It denotes the rate at which the SE nonlinear dynamic system generates new data. It can be used to describe the dynamic fluctuation of speech signals in response to various emotions. To process SE and its statistics, as well as MFCC, and calculate the probability that they belong to one of six emotions, the support vector machine is used. The spoken English recognition algorithm described in this paper has obvious performance improvements in many indicators, according to the experimental evaluation.

1. Introduction

At present, computer-aided evaluation system has gradually become one of the research hot spots [1]. Especially in large-scale examinations, it has begun to gradually replace teachers, which will become a major change in education. With the development of speech recognition technology, the speech evaluation system is also developing gradually. In spoken English recognition, the original phonetic training data is not accompanied by any language information. Therefore, the language information itself must be estimated during training [2, 3]. The method of discovering language categories is valuable for their potential application and theoretical insight. Therefore, spoken English has always been one of the main concerns in linguistics, rhetoric, discourse analysis, and corpus linguistics [4]. People study spoken English from many angles, including the description of the linguistic features of spoken English.

There are some features of pronunciation that Chinese English learners overlook, and there is no lack of neglect of some features in spoken English, which makes it the bottleneck for improving their spoken English level. It is uncommon to record the candidates' answers on the spot in a traditional oral exam [5, 6]. This makes it impossible to recreate the examinee's examination situation to other teachers or classmates at the time, as well as to comment on the examinee's answers at the time, and other candidates are unable to benefit from the examinee's experience and lessons [7]. For oral question-and-answer types, there are two methods of scoring: one is based on pronunciation, and the other is based on text. Pure speech scoring focuses on acoustic characteristics like pronunciation, frequency, and rhythm [8, 9]. This method, on the other hand, can be effective in limiting the types of speaking content. However, it is a little out of reach for open questions. The development of a multifeature fusion evaluation algorithm for spoken English based on speech recognition, natural language processing, and data fusion will pave the way for the development of an automatic spoken English evaluation system that can interact with users [10]. The learning efficiency of spoken English will be greatly improved by systematically imitating people's ways of thinking, evaluating users' spoken English, and providing suggestions.

This paper will look at audio processing, speech recognition, and intelligent English correction technology and design and implement a multifeature intelligent automatic correction model based on data from a college language training system. The automatic correction model aims to address the issue of automatic correction of open oral English questions, reduce teacher correction pressure, and provide effective oral English learning guidance for students.

2. Related Work

Spoken English is a language feature system that meets the needs of English users' oral communication. The immediacy, immediacy, and improvisation of oral communication determine that spoken English has its distinctive and unique linguistic features. In [11] through the research on the application of automatic speech recognition system to non-native language speech training, it is pointed out that if appropriate methods are used and mispronunciation detection is added, the evaluation system can provide the same evaluation results as human experts. In [12] pronunciation evaluation is divided into three parts: similarity of pronunciation content, similarity of pronunciation and intonation, and score adjustment based on nonlinear attenuation. Literature [13] proposed an algorithm to find similar speech sequences. This algorithm is also based on dynamic time planning algorithm. Compared with [14], the starting point and ending point are predefined, and then the similar phonetic sequences are found to be different in predefined areas. Literature [15] calculates all possible similarities and then determines the boundary of subsequences according to the similarity changes between adjacent elements. Literature [16] lists the challenges to be faced by modeling the simulated human score from the process and result levels and points out that it is impossible to model the evaluation process comprehensively in the field of speech features and speech recognition at present. In [17] evaluating what the interlocutor said at the phoneme level has the advantages that it can accurately locate where the speaker's pronunciation is wrong, evaluate the similarity between what the speaker said and the target pronunciation, and find the systematic difference by comparing it with the standard phonetic database.

Literature [18] divides pronunciation evaluation into three parts: similarity of pronunciation content, similarity of pronunciation and intonation, and score adjustment based on nonlinear attenuation. Based on the technology of speech recognition and accent adaptation based on hidden Markov model, this paper studies the accuracy and fluency of phoneme pronunciation, gives the pronunciation quality score at phoneme level, and further obtains the score result of the whole sentence. In [19] in the research of the same automatic composition correction system, it is pointed out that some composition correction systems have great deficiencies in content-based feedback and have certain limitations, such as being unable to identify whether students' compositions are irrelevant. Literature [20] studies an improved speech recognition method based on deep learning [21], which effectively improves the relevance of human-machine scoring in the spoken language scoring system based on speech recognition. Literature [22] discusses the significance of automatic correction system for online correction of English compositions, because automatic correction of compositions can not only reduce the burden of teachers, but also respond quickly, and the correction time is in seconds. Moreover, the automatic correction system has a profound influence on the role orientation of students and teachers and the teaching mode. Literature [23] expounds a working principle of automatic correction system. In [24] using the traditional machine learning model, Hidden Markov Model, to process audio files, directly extract sound features from audio, and then combine them with the rules of oral English scoring, an intelligent scoring system for oral English test was developed. Their research is very respectable. Not only is the model training of machine learning complicated, but the processing of audio files is extremely difficult. Voiceprint recognition has always been an important and difficult point for many scientists. Finding the rules of human voice has a very far-reaching impact on speech recognition and machine translation.

3. Research Method

3.1. Design of Intelligent Correction System for Spoken English. The connection mode of the campus LAN (local area network) is adopted between the student computer and the server. Because, after the exam, the student computer needs to upload a large number of audio data files to the server, it is required to get the maximum network transmission bandwidth between the student computer and the server as much as possible to reduce the delay caused by network transmission. Therefore, adopting the campus LAN can ensure the smooth progress of the examination process.

The application of this system will greatly improve the efficiency of oral examination, reduce the inequality caused by human factors in the course of oral examination, reproduce the candidates' answers at that time, improve students' oral English level, reduce the work intensity of teachers, and increase the safety and reliability of the examination.

The main function of the system is the learning and testing of spoken English. This requires the system administrator to set the learning mode or testing mode. The functional requirements of the system are shown in Figure 1.

In learning mode, the user first enters the system through a visual window, then selects the appropriate question bank, activates the demonstration voice, and follows and practices the instructions. The voice prompt and error correction functions are currently available. When a user enters the system in test mode, the system selects questions at random to ensure that the exam is fair. The voice prompt and error correction functions are currently disabled. The examinee's login, checking the examinee's information, auditioning before the exam, random selection of test questions, answering recording, and uploading the answering recording after the oral exam are the main functions of the oral exam. On the student test machine, the recording is completed, then packaged, and uploaded to the server. The server creates a corresponding folder based on the student's student ID and stores the received files in the folder for teachers to review and use after receiving the uploaded files.

The statistical subsystem is the feedback of candidates' achievements to teachers. Its main job is to help teachers make statistics after obtaining a large number of test scores.

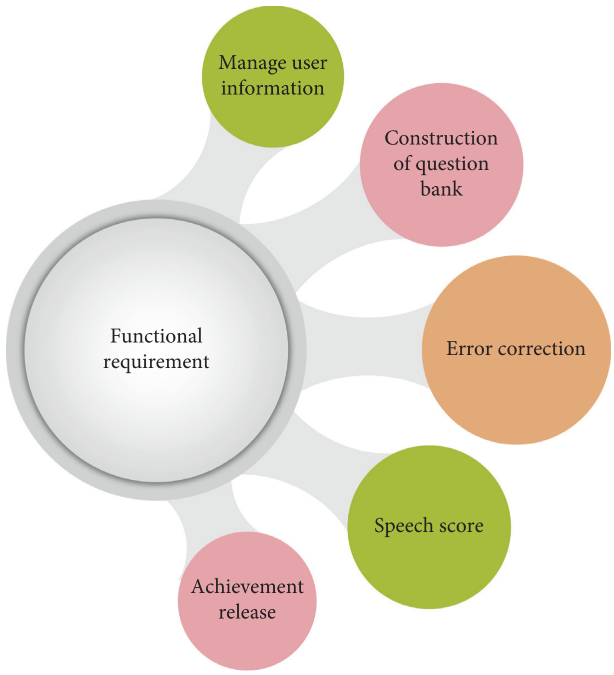

Figure 1: Functional requirements of the system.

Teachers will refer to the statistical results to better guide students to complete their studies and exams, so that they can achieve better results in future exams.

Computer-aided test system can help teachers or teaching administrators to design tests and generate test papers, implement tests under certain conditions, analyze tests, manage scores, and provide reports. Therefore, there are reasons to believe that we can design a computer-aided testing system specifically for spoken English testing.

A complete computer-aided test system not only has a question bank, but also has the functions of testing, evaluation, and analysis. The specific functional module structure is shown in Figure 2.

The computer can upload the results of students' answers to the server, and the server automatically judges objective questions such as multiple-choice and true-false questions, assigns scores based on whether they are correct or not, and records and saves the evaluation results of each student's test (generally including the question number, true or false information, waiting time for answers, and so on) for test analysis. For example, in the case of a balanced distribution of test difficulty, the majority of candidates can correctly answer the test's questions, while only those with poor academic performance can correctly answer fewer questions, indicating that this period of teaching was successful. For another example, if the candidates with excellent grades did not get it right but the candidates with poor grades did, this demonstrates that the topic cannot distinguish between excellent and poor students.

When the purpose of the test is to classify students and judge their level and ability, always hope that the test is fair and accurate. According to the requirements of educational evaluation, the test should have two necessary characteristics: evidence (validity) and reliability (reliability). Test paper analysis is the analysis of the reliability and validity of the test paper. The results of the analysis can reflect whether the test really checks the students' knowledge level and ability and whether the teaching process is successful or not. That is to say, it can be judged whether the test results can be used as the basis for evaluation.

3.2. Oral English Evaluation Algorithm Based on Multifeature Fusion

3.2.1. Feature Extraction. To evaluate the quality of a person's spoken English, usually give an overall evaluation first; for example, this person's spoken English is very good; then predict that the person's pronunciation is accurate and his intonation is well mastered, but his continuous reading is not good enough, and so on. The purpose of this study is to evaluate users' spoken English by computer and give the evaluation results. This requires a comprehensive evaluation algorithm, and an evaluation algorithm based on multifeature fusion is given in this paper.

This paper's proposed multifeature fusion evaluation algorithm is based on existing single-feature evaluation algorithms. At the very least, a multifeature comprehensive evaluation method should have the following characteristics: scalability, which means that the features chosen and the number of features chosen will have little impact on the system, and it should be simple to add and remove features. It has nothing to do with a single feature's evaluation algorithm; that is, changing the evaluation algorithm of a single feature has no effect on the system when the form of the evaluation result of a single feature remains unchanged.

As shown in Figure 3, the whole scoring system includes three parts: speech recognition, feature extraction, and linear regression.

The similarity features and syntactic features in feature extraction are extracted from the text after speech recognition, and the similarity features need to be compared with reference answers. Syntactic features are mainly used to measure the grammatical level of candidates' answers. The phonetic features, including pronunciation confidence and speaking fluency, are used to judge the accuracy of pronunciation and speaking fluency of candidates. These features are extracted from the preferred recognition results of speech recognition. Finally, score multiple features by using the trained linear regression model.

Firstly, multiple features are evaluated separately, and multiple evaluation results are obtained. Then quantify these evaluation results, the quantization standard is obtained through systematic training in advance, and the quantization result is $S_1, S_2, \ldots S_n$. Then, the weighted average of these quantized results is carried out to obtain the quantization result of comprehensive evaluation:

$$S = \sum_{i=1}^{n} a_i S_i, \tag{1}$$

where a_i is the weight of each feature, $\sum_{i=1}^{n} a_i = 1$; S_i is the quantified value of each evaluation result.

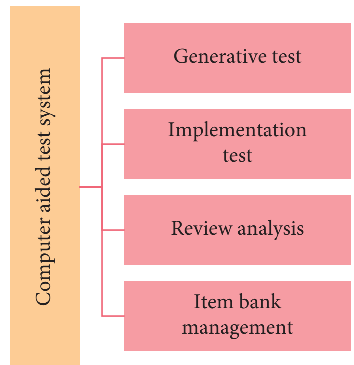

Figure 2: Functional module structure of computer-aided test system.

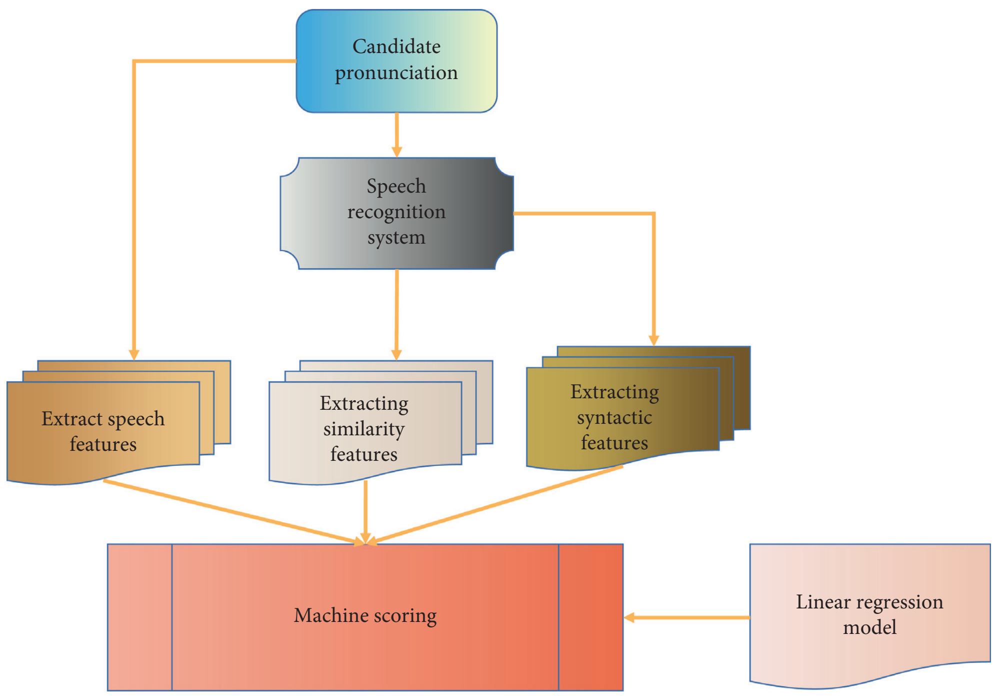

Figure 3: Scoring system framework.

Finally, based on the quantitative results, according to certain standards, the evaluation results are given. The evaluation results are divided into four grades, namely, "bad," "normal," "good," and "excellent".

SE (sample entropy) is a new method for measuring the complexity of time series, which is an improved statistic that does not count self-matching for the approximate algorithm.

It is defined as the conditional probability that the data vector will continue to maintain its similarity when it increases from m dimension to $m + 1$ dimension, and the SE of the original data with N points is expressed as

$$\begin{aligned} \mathrm{SampEn}(m, r, N) &= -\ln \frac{B^{m+1}(r)}{B^{m}(r)}, \\ SampEn(m, r, N) &= -\ln \frac{B^{m+1}(r)}{B^{m}(r)}. \end{aligned} \tag{2}$$

Traditional MFCC (Mel frequency cepstrum coefficient) only reflects the static features of speech signals, while SE can describe the dynamic changes of speech signals. The two features have different roles in distinguishing emotions. The two features of SE and MFCC are input into support vector machine, respectively, and the probabilities that they belong to six emotions are calculated. Then, the recognition results are obtained by combining addition rules and multiplication rules. This section concludes two kinds of fusion rules.

This paper uses two different fusion rules:

The addition rule is

$$F\left[P\left(\omega_i \mid f_1\right), \ldots, P\left(\omega_i \mid f_R\right)\right] = \sum_{j=1}^{R} P\left(\omega_i \mid f_j\right). \tag{3}$$

The multiplication rule is

$$F\left[P\left(\omega_i \mid f_1\right), \ldots, P\left(\omega_i \mid f_R\right)\right] = \prod_{j=1}^{R} P\left(\omega_i \mid f_j\right). \tag{4}$$

The algorithm steps of speech emotion recognition based on multifeature fusion of SE and MFCC are as follows:

Reading emotional speech signals and preemphasizing, framing, and windowing, with the frame length of 256 and the frame shift function of 128 as Hamming window;

Preprocessed speech signals of each frame are original data $x(1), x(2), \ldots, x(N)$, and this data is composed into a group of m-dimensional vectors in a continuous order:

$$x(i) = [x(i), x(i+1), x(i+m-1)], \quad i = 1 \sim N - m + 1. \tag{5}$$

Average $B_i^m(r)$:

$$B^m(r) = \frac{1}{N-m+1} \sum_{i=1}^{N-m+1} B_i^m(r). \tag{6}$$

According to the principle of addition and multiplication rules, the posterior probabilities of the two features are fused, and then the recognition rates of six emotions are calculated, respectively.

3.2.2. Semantic Discovery. When communicating in English, many Chinese college students rarely or never include nonverbal factors, such as lack of communicative competence in expression, body movements, and tone. Spoken English is the first step toward understanding a language and culture that is not one's own. When nonlanguage is combined with spoken English, one can gain a more comprehensive and in-depth understanding of the language, which will help students improve their practical ability to use English. Using dynamic programming technology, the semantic discovery algorithm detects the repeated parts of acoustic speech signals. In general, finding the shortest distance between sound input and a set of templates is used to recognize all duplicate parts. Local comparison [25] is used in this paper to reveal the repeated subparts of two acoustic signals using the cumulative quality scoring mechanism.

Input each spoken English as an acoustic feature vector U_m, and compare it with the stored feature vector V_n. The calculation method of cosine similarity is shown in formula (7).

$$D_{ij} = \frac{U_i \cdot V_j}{\left\|U_i\right\| \cdot \left\|V_j\right\|}. \tag{7}$$

For convenience of explanation, based on the above assumptions, in order to evaluate the reliability of system IP (indistinguishable phoneme) recognition, two relative measures are introduced, namely, the correct recognition rate $Q\ r$ and the false recognition rate e_i^j. The following are their exact definitions:

$$\begin{aligned} r &= \frac{N_{\text{right}}}{\left(N_{\text{right}} + N_{\text{error}}\right)}, \\ e_i^j &= \frac{N_c(i, j)}{n_t(i)}, \end{aligned} \tag{8}$$

where N_{right} is the number of phonemes correctly recognized by the system; N_{error} is the number of phonemes wrongly recognized by the system.

The normalization of input features refers to measuring the input feature values on the same standard. For example, the range of the output results of the grading network for vocabulary and grammar is [0.1]. The result of teacher's manual grading is 10 points. Therefore, it is necessary to normalize the teacher's manual score and the oral feature score mentioned earlier in this paper, so that the range of input features is uniform when training the multifeature correction model later. And after normalization, it can show candidates all the characteristics of spoken English. Namely:

$$x_i^{p^*} = \frac{x_i^p - x_i^{\min}}{x_i^{\max} - x_i^{\min}}. \tag{9}$$

In many spoken language scoring systems studied by predecessors, the scoring model is established by linear regression, which is a classic machine learning algorithm and can fit and predict data with linear characteristics. This paper will also use the method of linear regression to establish the scoring model. The definition of linear regression is as follows:

$$h_\theta(x) = \theta_0 + \theta_1 x_1 + \cdots + \theta_n x_n, \tag{10}$$

where n is the number of input features, and in this paper, $n = 5$. A linear regression model was also built using TensorFlow. Similarly, 80% of data sets are used as training sets and 20% as test sets.

4. Results Analysis and Discussion

4.1. Multifeature Recognition Results. In the simulation, all speech samples are divided into male, female, and mixed voice, and SE, fundamental frequency, energy, formant, and MFCC are extracted and their statistics are calculated. The mean and variance of SE are shown in Figure 4, and the average recognition rate of the three types of features and their statistics is shown in Figure 5.

Students have a strong desire for knowledge about the content of teachers' lectures, and their learning mentality is positive. Then, in the process of oral English practice, they

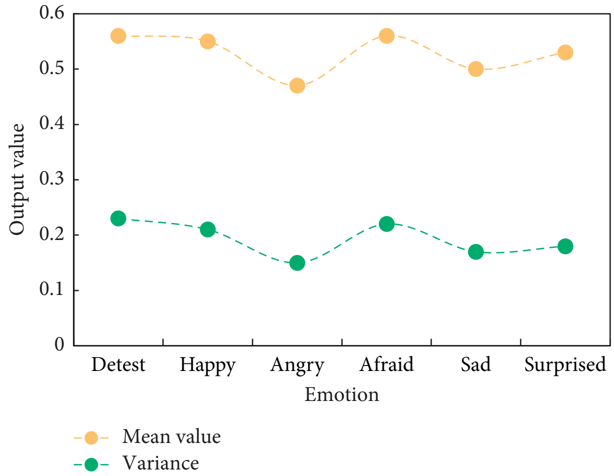

Figure 4: SE statistics of six kinds of emotions.

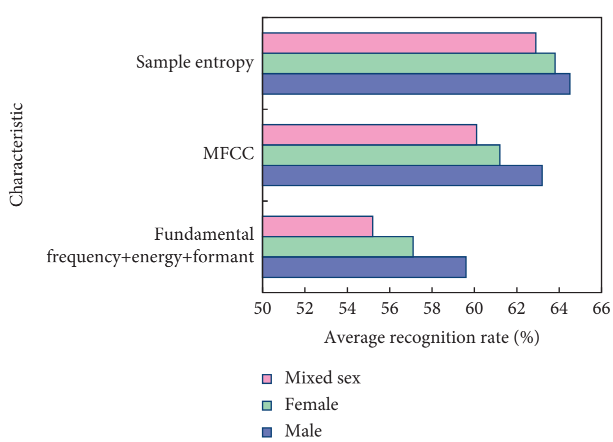

Figure 5: Average recognition rate of three kinds of features and their statistics.

need to be very careful and serious and will actively work to solve these problems and, at the same time, use a variety of oral English practice methods.

Their oral English ability is also different, but they are all studying hard, but their understanding of oral English can be summarized as repeated practice, and the content is mainly arranged by textbooks and teachers, while some English teachers are only teaching and emphasizing how students practice spoken English repeatedly; that is, they spend a lot of time repeatedly practicing reading every English word and sentence.

Figure 5 shows that the recognition rate of SE as a feature parameter is higher in male, female, and mixed voice samples than the other two feature parameters, with male voice samples having the highest recognition rate of 64.5 percent. Figure 6 shows the recognition results of six emotions of mixed male and female voice when SE is the feature parameter.

As can be seen from Figure 6, when SE and its statistics are used as feature parameters, the recognition rate of happy and surprised emotions is as high as 80%, the resolution of SE to happy and surprised emotions is high, and the emerging new information has a good distinction with other emotions.

Using the addition rule and multiplication rule in the previous section to fuse SE sum, respectively, the recognition result is shown in Figure 7.

From Figure 7, it can be seen that after SE and MFCC are merged, the recognition rate is obviously improved, and the highest recognition rate of multiplication rules is 68.8%. SE and MFCC have different emphasis on distinguishing emotions, and the recognition effect after fusion is ideal. The recognition rate of six emotions fused by multiplication rules is shown in Figure 8.

The recognition rate of happy emotions decreases after SE and MFCC are merged according to the multiplication rule, as the error rates of estimated probabilities of SE and MFCC accumulate, reducing the recognition rate of happy emotions. Fear and aversion emotion recognition rates improve dramatically after merging, and the average recognition rate of six emotions rises to 66.3 percent, up 3.9 percent from SE before merging. Various cultures found in the United States or English should be combined with a lot of oral English teaching. Because of the various users and environments, English will take on a variety of roles and meanings, particularly given the long-standing lifestyle differences between Westerners and Chinese. As a result, in the process of teaching oral English, teachers should not only pay attention to the pronunciation and grammatical accuracy of English words and phrases, but also teach students to understand the communication environment of characters and the relationships between characters in oral English, as well as analyzing the different meanings expressed by different words and phrases in different situations, because the change of tone directly affects the meanings expressed by different words and phrases in different situations.

4.2. Analysis of Intelligent Correction System for Spoken English. Creating a good atmosphere can help students get into the specific situation of the text faster and better and help students imagine abstract written words as concrete, vivid, and vivid pictures in their minds, so as to stimulate emotional resonance, enhance students' language perception ability, and finally let students enter the state of "reading aloud with affection." Reading forms can be arranged according to the classroom time, such as reading competitions among individuals, reading competitions among groups, reading by roles, etc. Individual reading forms are helpful for teachers to give targeted guidance and comment on students' reading effects, help students to correct shortcomings, and thus improve students' level of "emotional reading."

The training corpus C1 contains 1039 native natural oral recordings and scripts, while the test corpus C2 contains 128 IP clusters from native natural pronunciation recordings. Simultaneously, in order to complete the robustness testing, the author chose two students, one of whom graduated with a major in English and the other with a major in computer science. They have different levels of oral proficiency, so their recordings of the same corpus are labeled C3 and C4,

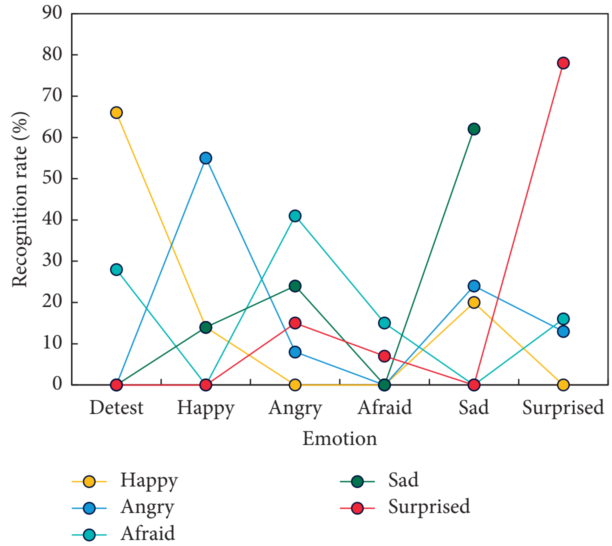

Figure 6: SE and its statistics on six kinds of emotion recognition rates.

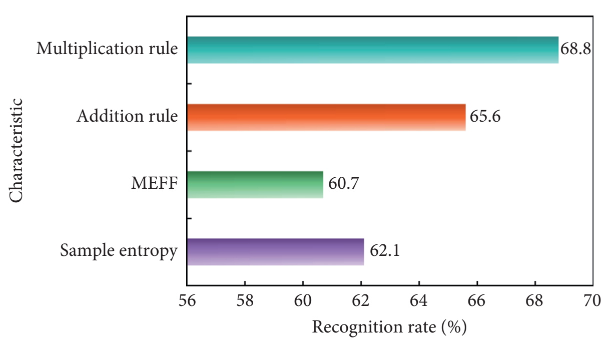

Figure 7: Average recognition rate of SE and MFCC and their fusion.

respectively. The results of voice evaluation for C2, C3, and C4 are shown in Figure 9.

These results show that our evaluation model can get reliable and robust evaluation results with the average phoneme recognition rate of the system.

In college, students are taught English orally. Schools have not paid much attention to English. Intensive reading and listening are two types of college English courses offered by many universities. While most listening courses are conducted in a centralized manner, which is limited by factors such as teachers, class size, and so on, the accuracy of the course accounts for nearly 3/4 of the total class hours. Furthermore, most universities do not include an oral exam in their English exams, resulting in students paying little attention to oral English learning.

The survey shows that 90% of teachers think that they mainly play the role of interpreter and demonstrator in English class, and 70% of teachers think that their role is mainly to guide students how to learn foreign languages and how to cultivate their foreign language learning ability. It can be seen that most English teachers can clearly understand how to effectively carry out teaching but rarely do this in actual teaching.

Figure 10 shows the size of training or test set; it reflects the performance of training or testing. The larger the performance, the better the performance.

From the above data, the integration method has the best stability, followed by the probability space distance method, and the probability mean method is the worst. In terms of performance, the method based on probability space distance is the best, followed by probability mean method, and the method based on Sugeno integral is the worst.

Teachers should create a positive learning environment for students, plan rich classroom activities, actively guide students to look at pictures and talk, intensify oral practice, and provide students with plenty of practical practice opportunities when teaching oral English. Their oral English level can only be improved to some extent through continued practice and practice. In order to improve one's language communication level, the process must be undertaken step by step, from easy to difficult, simple to tedious, and success cannot be rushed. Mechanical training can be done at the start of the training to gradually increase the level of fluent expression. Different ways of thinking exist in Chinese and foreign cultures, resulting in differences in language expression. The verbs in Chinese sentences are usually centered and spread horizontally, forming a flowing shape structure. The structure of Westerners' sentences is generally centered on subjects or predicates, and it is more complicated. As a result, students should use correct logical thinking to express themselves in the process of language expression, gain a deeper understanding of western culture, and improve the flexibility and smoothness of their oral expression.

Visual effects can make students more aware of the feelings attached to English that they have heard. In the practical use of English, when people communicate in English, they not only rely on their ears to listen, but also want to really understand what the other party wants to express, and they should combine their visual senses. In view of this, teachers can choose English movies that meet the

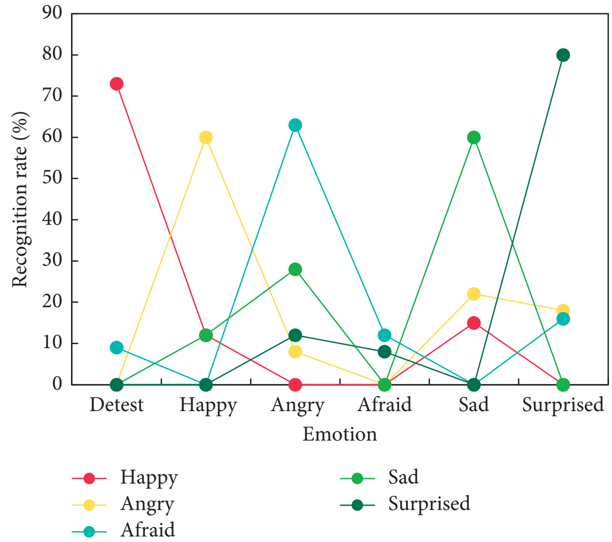

Figure 8: Six emotion recognition rates based on the fusion of SE and MFCC multiplication rules.

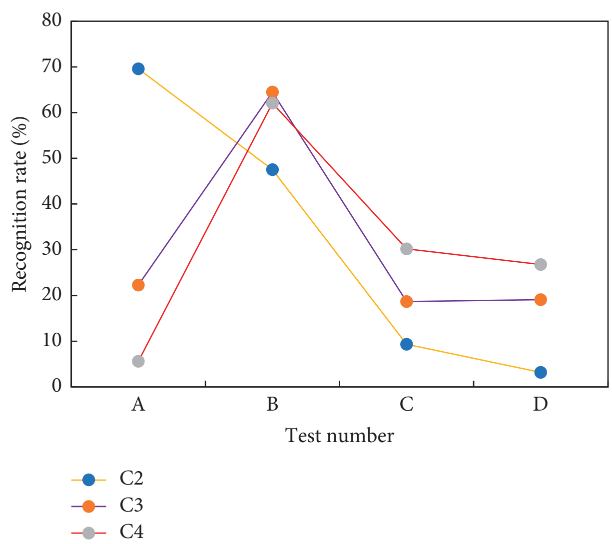

Figure 9: Comparison of open test results.

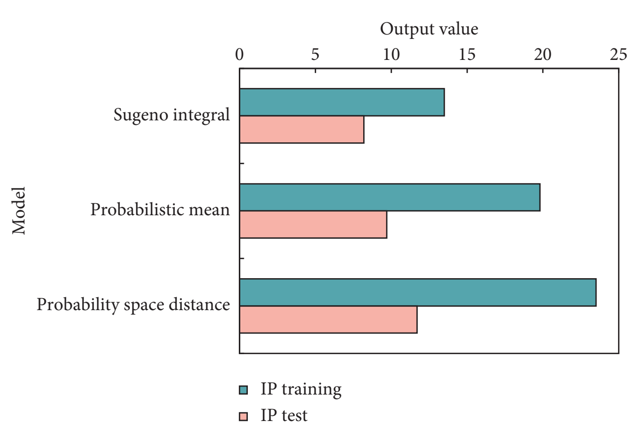

Figure 10: IP training and test results.

nonverbal communication factors for teaching. First, let students learn the nonverbal factors in the movies, because speaking English alone cannot effectively improve students' oral ability.

5. Conclusion

In college English classes, oral English instruction is a weak point. There are numerous issues that arise during the teaching process, such as a lack of a language environment, fewer class hours, and so on, and students' application ability is low. The analysis and design of the intelligent correction system for spoken English, as well as the specific implementation method, are detailed in this paper. The system greatly improves the efficiency of oral English tests while also reducing the difficulty of organizing them and teachers' workload. When SE is used alone as an emotion recognition feature, it outperforms MFCC and fundamental frequency. Finally, the MFCC and SE fusion recognition results are examined, and the fusion recognition rate is improved. Experiments show that the speech evaluation system presented in this paper is more in tune with people's subjective feelings and that the evaluation results can reflect the subjects' pronunciation level.

Due to the author's limited knowledge, there are still many flaws in the system's operation, and there are numerous areas for improvement and further research, such as expanding the question bank, improving system security, increasing system efficiency, and designing an analysis system for the data gathered during the examination process, among other things. In future research, the author will investigate and analyze the aforementioned issues in greater depth, with the goal of improving the system's functionality.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The author does not have any possible conflicts of interest.

Early childhood education in China has given stem education constant attention and study. On the one hand, it has introduced many foreign research findings on stem education, such as curriculum practice, evaluation systems, teacher training, and so on; on the other hand, this paper investigates the localization implementation path of stem education based on the realities of kindergartens. This paper investigates the development and implementation path of kindergarten stem education activities using data mining, analyzes how the kindergarten stem education monitoring index system is developed and further improved using data mining algorithm, and determines the function path and mode of data mining algorithm in kindergarten stem education. It is expected to be used as a reference in the development and implementation of stem education and teaching activities. The development and implementation path of kindergarten stem educational activities based on data mining algorithm using data technology to realize continuous audit can not only improve the audit means and scope but also provide new research ideas for the expansion and innovation of audit work, which is useful in building a path model of kindergarten stem educational activities development and implementation.

1. Introduction

In recent years, China has seen a surge in stem education, which has piqued the interest and support of a growing number of people. Through the organic integration of science, technology, engineering, and mathematics, stem education is a project-based learning and problem-solving oriented curriculum organization that aims to cultivate the activity development innovation consciousness and innovation ability of kindergartens [1]. The application of the stem education concept in kindergarten teaching not only meets the needs of the kindergarten population and development, but it also meets the requirements of activity development of teaching reform. Early childhood education in China has paid close attention to and studied stem education. On the one hand, it has introduced many foreign research findings on stem education, such as curriculum practice, evaluation systems, teacher training, and so on; on the other hand, the localization implementation path of stem education has been explored based on the reality of kindergartens [2]. Children's education concept of stem focuses on cultivating students' comprehensive learning and practical ability. The application of tools in kindergarten classroom teaching can not only effectively improve the comprehensive quality and ability of kindergarten but also improve the teaching efficiency to a certain extent [3]. These explorations have accumulated rich resources, implementation paths, and experience for the current stem education in kindergartens [4, 5].

As a potential resource of STEM education in kindergartens, related research is still lacking. This paper takes this as a starting point to explore the development and implementation path of STEM education activities in kindergartens based on data mining [6]. Generally speaking, China's preschool children's science education has gone through the process of germination, stagnation, development, reference, localization, and scientific transformation, forming the curriculum system that emphasizes localization and local growth, the development goal of educational activities for the country, the curriculum content closely related to children's life, and the implementation path organization form that focuses on "doing". At present, there are many theoretical researches on STEM educational concept in kindergartens in China, but the practical research on STEM educational activity development in kindergartens is not very rich [7]. Therefore, based on the data mining algorithm, this paper attempts to explore the science course "Make a paper plane" which is integrated with STEM concept, in order to provide more thoughts on the implementation path for front-line kindergarten teachers [8, 9]. The development and implementation path of STEM education activities in kindergartens is to comprehensively apply the techniques and methods of mathematical statistics, machine learning, and data mining to process and analyze STEM education data in kindergartens. Through data modeling, the correlation between learners' learning results and variables such as learning content, learning resources, and teaching behavior can be found to predict learners' future learning trends [10].

Under the background of the new era, education should pay attention to the cultivation of top-notch innovative strategic talents with international competitiveness, which is an effective way from "science and education" to "rejuvenating the country" and even "strengthening the country". The development of stem educational activities in kindergartens, implementation of scientific educational activities in kindergartens' aims, and quality improvement [11]. Therefore, the research on the implementation path of the development of stem education activities in kindergartens is the objective demand to promote the development of stem education in preschool kindergartens. Ideal data mining algorithm for kindergarten stem education activity development and implementation path using data technology to realize continuous audit can not only enhance audit means and broaden audit scope but also provide new research ideas for the expansion and innovation of audit work, and help to build a kindergarten stem education activity development and implementation path model based on Data Mining [12, 13]. We can obtain valuable information in a variety of complex data using the data mining algorithm, which not only allows us to grasp problems that arise in the development of kindergarten stem education activities at any time, but also allows us to adjust current kindergarten stem education construction methods and objectives according to data technology [14, 15]. This paper analyzes how the kindergarten stem education monitoring index system is developed and further improved by using data mining algorithm, in order to obtain the role path and mode of data mining algorithm in kindergarten stem education. It is expected to be used as a reference in the development and implementation of kindergarten stem education activities.

2. Related Work

Bonneton-Botté et al. [16] suggest that teachers should adopt constructivism teaching strategies and refer to the precursor model of shadow formation, which has a positive effect on children's understanding and identification of physical phenomena of shadows. Through the method of big data analysis, in recent two years, more and more researchers have paid attention to STEM education in preschool stage, and most of them are foreign researchers, but the overall quantity is still small [17]. The research contents mainly focus on early childhood STEM education policies, kindergarten STEM courses, and kindergarten STEM teachers. Research shows that children can learn scientific concepts and vocabulary better by adopting reactive teaching or combining reactive teaching with explicit teaching [18]. Mcgoey et al. [19] point out that the practice of early science education is an effective strategy for science teaching and learning, and it is the foundation for the future development of kindergarten children's scientific literacy. Whiting et al. [20], through big data analysis [21], show that STEM education is very good at solving practical problems in real life. Therefore, teachers should observe their behaviors through daily contact with children, and then explore their interests and needs. Research shows that scaffolding instruction can help kindergarten and primary school teachers, as well as researchers, analyze the science education activities in kindergartens, and judge whether the adopted strategies are effective, which strategies need to be eliminated, and what other strategies may be needed [22]. Scannell et al. [23] point out that STEM education plays a significant role in improving national quality, stimulating employment and balanced income distribution, promoting ethnic equality and gender equality, strengthening national economic strength and driving innovation, etc., and it is a booster of American national competitiveness. Through the method of big data analysis, in children's daily life, although some contents are not initiated by young children, they are initiated by adults, but they play a great role in children's growth and habit formation, which requires teachers to pay more attention [24]. Research shows that experimental basic education has a positive impact on the ability of 5-year-old children to solve scientific problems [25]. Experiment-based science education projects include experiments aimed at improving children's scientific process skills, independent thinking, decision-making, and problem-solving process. Literature [1] pointed out that the poor status of STEM education at the present stage is mainly influenced by the high cost of university education, poor academic preparation, demographic factors, lack of local core staff, and so on.

This paper studies the development and implementation path of kindergarten stem education activities based on data mining, and finds that kindergarten stem activities and project-based learning fit well, and project-based learning provides a good platform and opportunity for stem education.

3. Principle and Model of Data Mining Algorithm

Data Mining is a new discipline of "developing methods and exploring unique types of data in the educational environment, so as to better understand students and their learning environment through these methods." Data mining

(DM) is a process of discovering interesting knowledge from a large amount of data stored in databases, data warehouses, or other information bases, and it is a marginal discipline involving database management, artificial intelligence, machine learning, pattern recognition, data visualization, and other disciplines. If we can dig out this hidden pattern from the development of STEM education activities in kindergartens, its significance is self-evident. We can describe the general process of kindergarten data implementation path as shown in Figure 1.

3.1. Establish Data Mining Database. Analyze the data characteristics of the existing kindergarten information system, and establish the mining database.

3.2. Data Preprocessing. For the activity development and implementation path-related data of the existing stem education information in the kindergarten, the sequence mining method is used for standardized processing to ensure the integrity and consistency of the data, smooth the noise data, identify and delete outliers, so as to improve the data quality, improve the mining accuracy and performance, and store the processed data in the mining database.

3.3. Design Mining Algorithm. A general mining algorithm for a single disease can be designed by combining clustering analysis and ant colony algorithm in bionic algorithm. Clusters of related diseases can be obtained by clustering, and ant colony algorithm can be used to optimize the formation of clusters, so as to form an optimized single path.

3.4. Establish the Implementation Path Database. According to the related concepts of stem education in kindergartens, the adult attributes and their constraints are explained, and the content database storing the extracted values is established. Through the corresponding expression, it will be transformed into the familiar implementation path.

To construct the development and implementation path of STEM education activities in kindergartens from the perspective of data mining, it is necessary to realize it with the help of information active push technology. The basic activities of education are often divided into three categories: teaching, management and scientific research, because there are some differences in business processes and objects of concern in various fields. Therefore, the application of data mining in education should also be divided into three areas, as shown in Figure 2.

In the application of information active push technology, it is usually through SMS notification and server client connection, which is not only conducive to better let the majority of teachers and students know the school related teaching information and management information, but also make use of personalized data mining technology and information customization technology to continuously improve the efficiency of information personalized service. The stem education research model is summarized as the “win-win” model of stem education research, as shown in Figure 3.

STEM education research model is not only conducive to obtaining more extensive and effective data, but also indirectly promotes STEM education concept and its culture. At the same time, this method is also helpful to strengthen inter-regional cooperation, improve the imbalance of inter-regional education development, and improve the quality of education in underdeveloped areas.

Path informatization is realized on the basis of the development of existing business system in kindergarten STEM education activities. The implementation of path system does not change the operation of existing system in kindergarten, but seamlessly links with it to realize the interaction and sharing of information. The operation scheme of the implementation path system is shown in Figure 4.

In this paper, K-means, a data mining algorithm based on partition, is used for text data mining. The advantage of K-means is simple and fast. The basic principle of K-means algorithm is as follows: assuming that the extracted original data set is $X_i = (X_1, X_2, \ldots, X_{N-1}, X_n)$, the purpose of K-means is to segment the original data set X into k categories under the condition of given clustering number k ($K \leq n$). The k-means algorithm is described below.

Assume that the data set to be classified is $X_i = \{X_1, X_2, \ldots X_{N-1}, X_n\}$, the output clusters are $C_j = \{C_1, C_2, \ldots, C_K\}$ $(1 \leq J \leq K,\ K \leq N)$, and the center value of cluster CJ is $M_J = \{M_1, M_2, \ldots M_K\}$.

$$Mj = \frac{1}{n_j} \sum_{X_i \in C_j} X_i, \tag{1}$$

where N_J represents the number of input data X_i contained in the output cluster C_J. Euclidean distance is used to calculate the distance between a word vector and the centroid. Since X_i and M_J are n-dimensional vectors, it is necessary to use Σ to calculate the Euclidean distance between two n-dimensional vectors

$$\text{distance} = \sqrt{\sum_{i,j=1}^{n} \left\| X_i - M_j \right\|^2}. \tag{2}$$

It is mainly used to extract keywords and abstracts for text, and its core ideas are as follows:

$$\text{WS}(V_i) = (1-d) + d * \sum_{V_j \in In(V_i)} \frac{w_{ji}}{\sum_{V_k \in \text{Out}(V_j)} w_{jk}} \text{WS}(V_j). \tag{3}$$

Assuming that data mining has been completed, there are n clusters, in which there are m points in cluster I, then the calculation process of Silhouette index is as follows

Step 1. calculate the intracluster distance $a(i, j)$ for the J-th point in cluster I, where $a\ (i,\ j)$ is the average distance between any data object J in cluster I and other data objects in the cluster

$$a(i, j) = \frac{1}{M-1} \sum_{k=1, k \neq j}^{M} \text{Distance}(j, k). \tag{4}$$

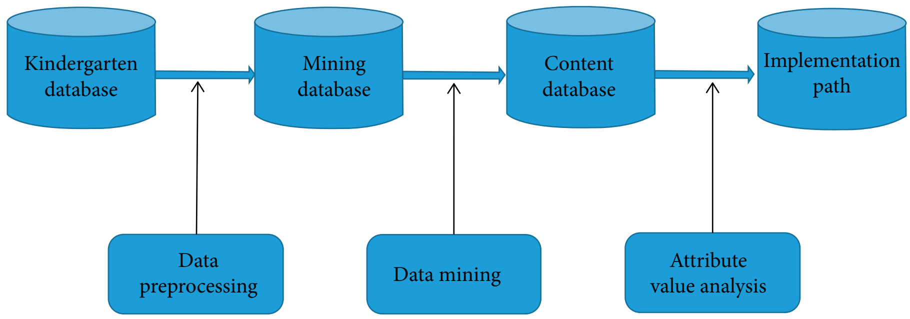

Figure 1: Data mining model.

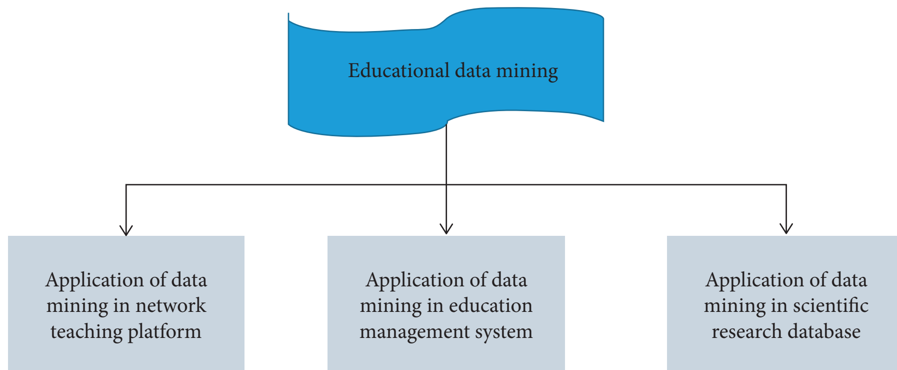

Figure 2: Distribution of educational data mining applications.

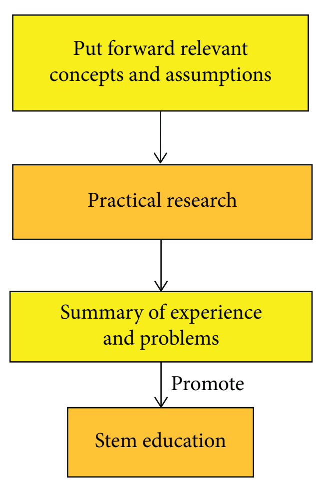

Figure 3: STEM educational research model.

Step 2. for the j-th point in cluster I, calculate the cluster spacing $b(i, j)$. $b(i, j)$ is the minimum of the average distance from any data object J in cluster I to any other data object in cluster I

$$b(i, j) = \min_{k=1 \longrightarrow N, k \neq i} (\text{Avg Distance}(j, k)). \tag{5}$$

Step 3. calculate the Silhouette index of point J in cluster I.

$$\text{Silhouette}(i, j) = \frac{b(i, j) - a(i, j)}{\max\{a(i, j), b(i, j)\}}. \tag{6}$$

Step 4. calculate the Silhouette index of cluster I.

$$avg\_\text{Silhouette}(i) = \frac{1}{M} \sum_{j=1}^{m} (\text{Silhouette}(i, j)). \tag{7}$$

Step 5. calculate the Silhouette index of the whole data set.

$$\text{avg\_SILHOUETTE} = \frac{1}{N} \sum_{i-1}^{N} (avg\_\text{Silhouette}(i)). \tag{8}$$

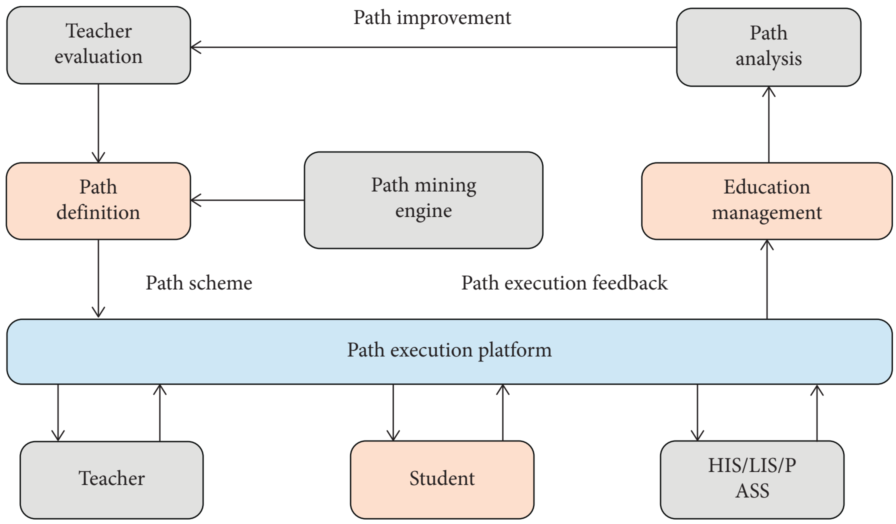

Figure 4: Implementation of route information system operation scheme.

The implementation path of the specified disease is excavated by the implementation path mining engine in this scheme, which is then put into teaching application after teacher evaluation and revision, resulting in a specific teaching scheme and teaching record. Then, to record the path's implementation, interact with the kindergarten systems. Finally, the feedback data is sent to the department in charge of handling abnormal alarms, abnormal monitoring, and statistics, as well as preparing for path analysis and optimization. The Data Mining Society defines educational data mining as "a new discipline that analyzes unique and growing large-scale data in the educational environment through development methods," which is similar to Baker's definition. Data mining is not only useful for improving the teaching and learning experiences of teachers and students, but it also has the potential to support scientific management decisions and strengthen school governance. In the data age, data mining meets the practical needs of mining the value of educational data and discovering the educational data implication law.

4. Development and Implementation Path of Stem Educational Activities in Kindergartens

4.1. Development and Implementation Path of Kindergarten Stem Education Activities Based on Data Mining. To carry out STEM education projects in kindergartens, first of all, teachers are required to have STEM concept and consciousness, and be able to guide their own specific practice by this, and to use STEM vision to discover the value contained in the projects, so as to effectively guide the activities. STEM education in kindergartens and educational research and practice activities are destined to be full of value, complexity, creativity, and uncertainty. In the research and practice of kindergarten STEM education, although data science or data mining can tell people what some phenomena and problems in kindergarten STEM education are, the present situation and state of kindergarten STEM education are, it cannot explain such valuable problems as "why is this so" and cannot put forward countermeasures and suggestions as "how to do" according to the characteristics and development rules of kindergarten STEM education activity development and kindergarten STEM education implementation path practice. The development and implementation path of STEM education activities in kindergartens has the characteristics of cross-domain, involving the study of science, technology, mathematics, and other fields of knowledge. Second, both of them pay attention to children's life experience. Based on the characteristics of children's thinking in concrete images, they emphasize the simplicity and interest of activities, and focus on exploration and operation, so that children can gain direct experience. Third, both of them often involve real problems in activities. Children need to communicate and discuss with peers and teachers in activities to form a small learning community, from which they can help each other to get useful experience and guidance, and then learn to solve real problems step by step.

Data mining is a novel situation and backdrop for the development and implementation of stem education activities in kindergartens, but it comes with its own set of challenges and shortcomings, including low data density, research ethics, personal privacy, and data security. While appreciating the value of data mining, we must also recognize its drawbacks and limitations. If children want to create a mental "primary school," they must first determine the construction project, then design and plan the school project in the form of painting, and finally construct the school. During the construction process, children must consider which materials to use, what to build first, what to build again, which method to use, how to solve balance and stability problems, and so on. All of these issues are related to engineering and technical education.

A series of practical researches on STEM project activities based on data mining algorithm were carried out. Under the guidance of the special research project "Research on STEM Education Practice in Kindergarten Based on Project Learning" of Shaanxi Academic Leaders Training

Plan, the exploration with project learning as the carrier was completed.

(1) Established the basis for the content selection of STEM education activities in kindergartens. Being close to children's life is a real problem that children are interested in and permeates all aspects of children's daily life.

(2) Summarize the implementation path of STEM education activities in kindergartens.

(3) Complete the compilation of Case Collection of STEM Education Activities, which contains 15 activity cases. The exploration at this stage helps us sort out the selection basis and implementation path of STEM education activities, and lays a solid foundation for the follow-up kindergarten STEM curriculum construction.

When screening children's interesting questions, teachers should be able to quickly judge whether the problem comes from children's life or impulse; judge whether the problem has the essence of science, mathematics, and technology; and judge whether the combination of children's teams can be used to solve problems. Stem education is a comprehensive science education based on constructivism, "learning by doing" and other theories. Developing stem education in early childhood has become a field of concern for researchers and early childhood educators at home and abroad. Integrating stem education concept into kindergarten education has become a new exploration direction. Generally speaking, data mining information collection is an organic combination of Official Statistical Organization database, daily management database of policy implementation department and field survey database. Therefore, through the data mining application path and method of developing and implementing the path monitoring index system in kindergarten stem education activities, China should strengthen the construction and analysis of data mining information in education monitoring, supervision, and evaluation; step up the construction of national education big data information center or database; and classify all kinds of Education data and information at all levels in China, improve the collection, analysis, and processing of relevant data of education monitoring index system at all levels, and build a data mining collection mechanism for kindergarten stem education activities in China. Real situations are often typical problem situations. After children experience complex and real problem situations, they will explore and understand knowledge and learn to transfer the understood knowledge to life. The development of stem educational activities in kindergartens often involves the real problems encountered by children. Children continue to push forward the process of activities through continuous problem exploration, solution, and implementation path.

The goal of the kindergarten STEM education activity based on data mining algorithm is to teach children how to effectively combine various disciplines to improve their problem-solving abilities. These various subject knowledge requirements are the foundation of STEM education activities in kindergartens and are required for solving problems. However, mathematics and science have distinct characteristics, and they can only be effectively integrated through engineering and design. As a result, we must focus on engineering and implementation path as the premise for STEM education activities in kindergartens. Garden A, with the support of the education administrative department and Shanghai Steiner Science Education Research Center, is implementing STEM project-based learning in kindergartens and, later, maker activities to broaden children's scientific and technological vision and cultivate their logical thinking, as part of the "Three-year Plan of Action for Preschool Education" and the second kindergarten curriculum reform. The development of kindergarten STEM education activities is a problem-solving activity, driven by the problems that children are most concerned about at the time, with a focus on the exploration and solution of practical problems in kindergarten STEM education, with an emphasis on children's understanding of knowledge and practical application on this basis.

4.2. Results and Analysis. Through the three-month investigation in kindergarten A, it is found that kindergarten A carries out activities in the form of themes, teaching around four theme activities in a semester, each theme lasts for two months, and each theme has about 50 collective activities, as shown in Figures 5–7.

The theme activity is "Visiting the Big Tree," as shown in Figures 5–7, with 11 collective activities accounting for about 24.5% of the total. The Kingdom of Paper has nine collective activities, which account for about 16% of all activities. Because the focus of teaching at the beginning of kindergarten is to guide children in adapting to their new environment and cultivating their basic life skills, the theme "Hello Friends" consists of ten collective activities, resulting in a lack of scientific education activities in the first theme. Color Kingdom has 20 collective activities, accounting for 18.5% of the total. The quantitative analysis of science education activities in kindergarten A reveals that the design of science education activities in kindergarten A is quantitatively balanced with the design of activities in other fields, taking into account the setting of courses in five fields, which is more beneficial to children's overall physical and mental development and also meets the Guide and Outline requirements. The key factor that determines the smooth progress of science education activities, as well as the effect of the entire activities and the direction of children's development, is whether the goal of science education activities is reasonable or not.

In this study, "overall observation situation" mainly refers to the main activity links of one-day life in kindergartens. The hypothesis of the study is: through action research, teachers' overall observation situations are becoming more and more diverse, and can infiltrate mathematics education and observation into all links of children's daily life. The following data shows the distribution of "overall observation situation" frequency of small class, middle class, and large class teachers, as shown in Figures 8–10.

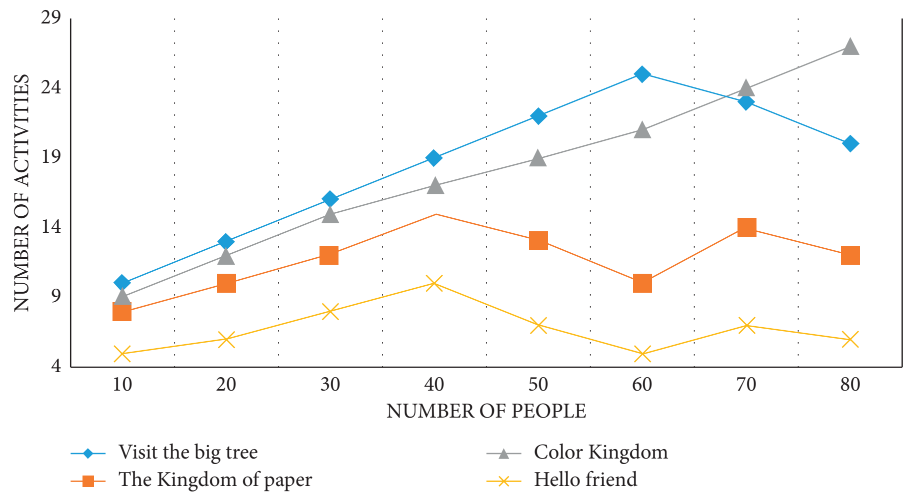

FIGURE 5: A number of theme activities in kindergarten during the first month.

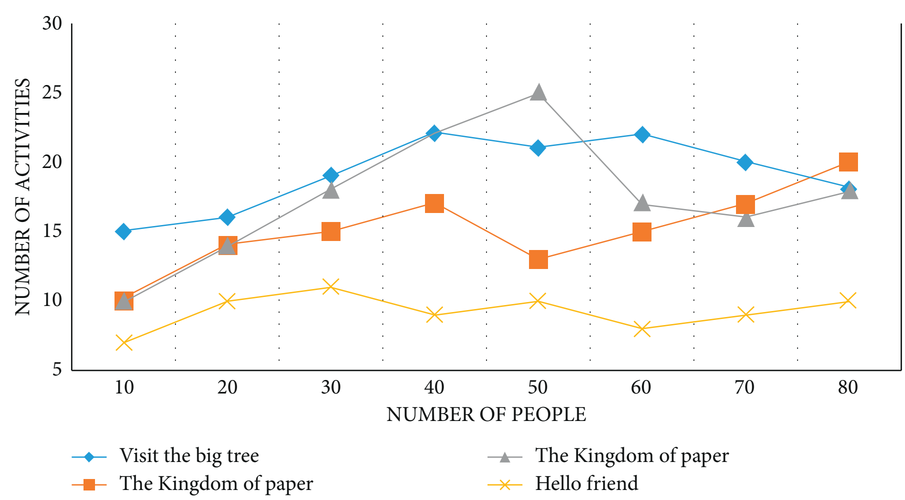

FIGURE 6: A number of theme activities in kindergarten for the second month.

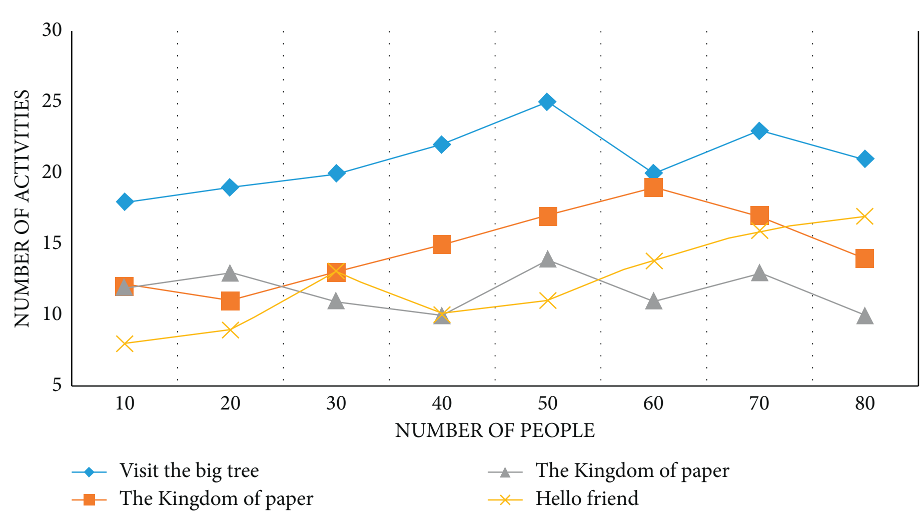

FIGURE 7: A number of theme activities in kindergarten for the third month.

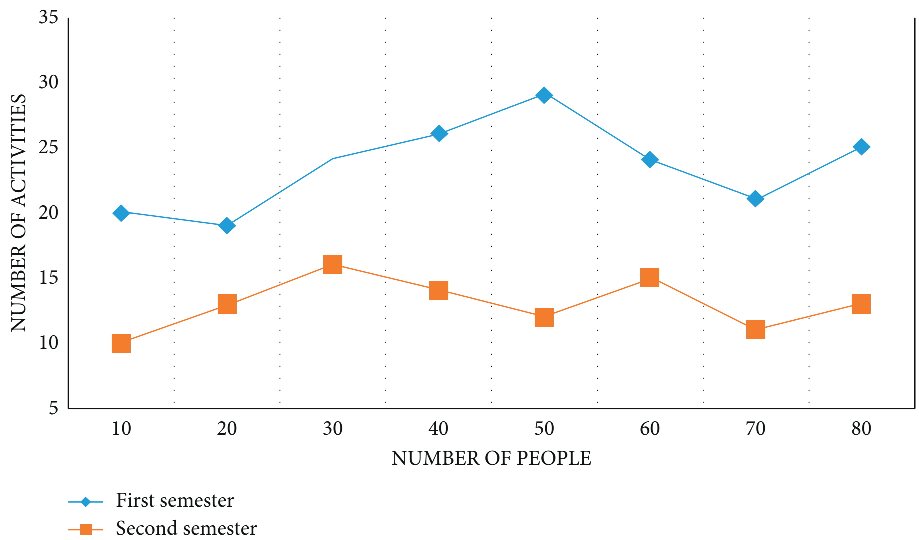

Figure 8: Distribution of “overall observation situation” frequency of small class teachers.

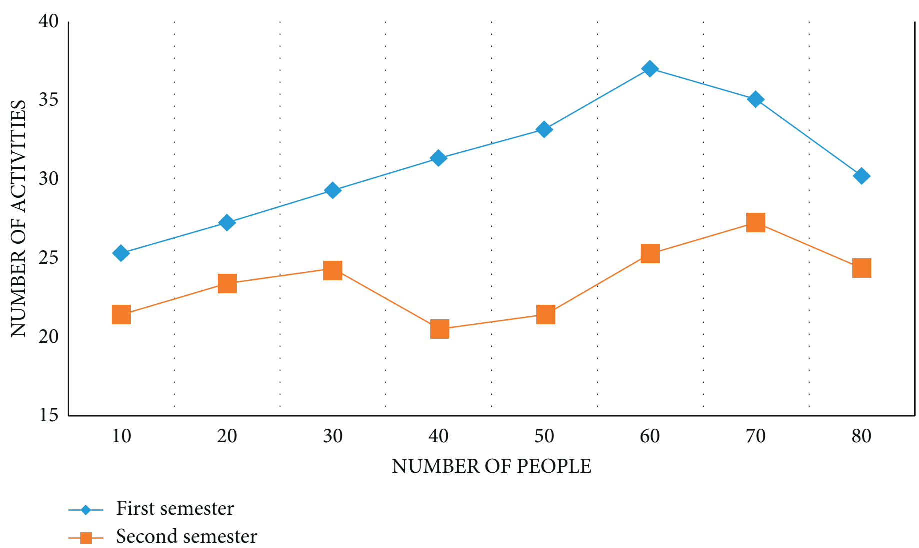

Figure 9: Distribution of “overall observation situation” frequency of middle-class teachers.

From the above data, it can be found that according to the chi-square test conditions, when comparing the composition ratio of two samples, this study needs to process the data and combine the frequencies in some columns to meet the test requirements. From the above data, we can see the main situations of observation in the first semester. The hypothesis of this study is that after action learning, teachers can naturally integrate the observation of children’s mathematics learning into various situations of daily life. In this study, observation situations are collectively referred to as “other situations,” and the data in these situations are combined to test whether the overall observation situation distribution of small class teachers has changed significantly.

According to the aforementioned data, the main situation observed by middle-class teachers in the first semester is “game activity.” The hypothesis of this study is that by incorporating observation of children’s mathematics learning into various situations in children’s day-to-day lives, preschool teachers can naturally integrate observation of children’s mathematics learning into various situations in children’s day-to-day lives. The observation situation is divided into “other situations” in this study, and the data from these situations are combined to see if the distribution of middle-class teachers’ observation situations has changed significantly. In other words, the composition ratio of middle school teachers’ “overall observation situation” did not change significantly from the first semester to the second semester. It is clear that, whether in the first or second semester, middle-class teachers’ observations are primarily focused on “game activities.”

From the above data, it can be found that from the first semester to the second semester, the “observation content” of large class teachers has changed significantly. Preschool teachers tend to “observe the learning results” in the first

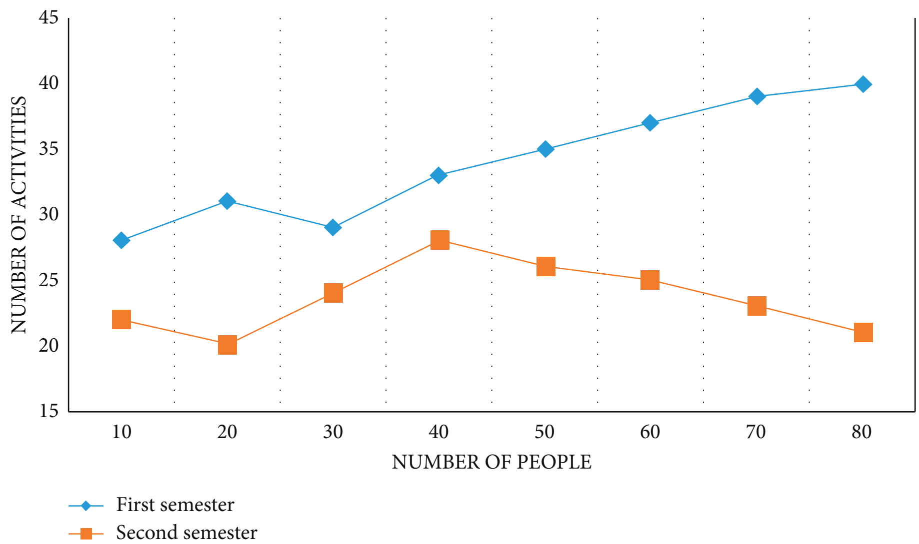

Figure 10: Distribution of “overall observation situation” frequency of large class teachers.

semester, which is related to observation habits developed over time; on the other hand, it is possible that the connotation of “evaluation of early childhood development” is not well understood, and there is no link between “evaluation” and “more effective early childhood learning support.” During the second semester, most teachers are able to observe the children’s mathematics learning process thoroughly and meticulously and record the important information learned. The details not only describe “what children learn” but also “how children learn,” according to the records. The research and implementation path for kindergarten STEM education is distinct. Data alone will not be able to solve all of the problems in kindergarten STEM education research and implementation. As a result, we should promote the reform and development of STEM education activities development and implementation path in kindergartens by using data mining as a new way of thinking and path, research paradigm and method, and practical tools and means based on STEM pedagogy.

5. Conclusions

To summarize, the article believes that correct ideas and reasonable methods are required for the actual implementation of stem education in kindergartens. Preschool teachers should also work on improving their professional quality in stem education. In the era of data mining, objectively analyzing the various paths and methods of data mining in the field of education is beneficial to our clearer and objective cognition of data mining, as well as thinking and using big data based on educational research and practice. As a result, China should strengthen the construction and analysis of data mining information in educational monitoring, supervision, and evaluation, as well as accelerate the construction of a national education big data information center or database, by developing stem educational activities in kindergartens and implementing data mining application paths and methods of path monitoring index system. The role and impact of data mining on education are discussed in this paper, which is based on data collection, acquisition, processing, and analysis. The stem education monitoring index system constructs the data hierarchy and category model of the index, analyzes the data collection mechanism of the index, and collects and obtains the data of each index of the index system, based on large-scale data investigation and database, using relevant ideas and methods of data mining. The development of stem educational activities in kindergartens frequently involves real-life issues that children face. Through a continuous problem exploration, solution, and implementation path, children continue to push the activity process forward.

Data Availability

The data used to support the findings of this study are included within the article.

Gross domestic product (GDP) is an important indicator for determining a country's or region's economic status and development level, and it is closely linked to inflation, unemployment, and economic growth rates. These basic indicators can comprehensively and effectively reflect a country's or region's future economic development. The center of radial basis function neural network and smoothing factor to take a uniform distribution of the random radial basis function artificial neural network will be the focus of this study. This stochastic learning method is a useful addition to the existing methods for determining the center and smoothing factors of radial basis function neural networks, and it can also help the network more efficiently train. GDP forecasting is aided by the genetic algorithm radial basis neural network, which allows the government to make timely and effective macrocontrol plans based on the forecast trend of GDP in the region. This study uses the genetic algorithm radial basis, neural network model, to make judgments on the relationships contained in this sequence and compare and analyze the prediction effect and generalization ability of the model to verify the applicability of the genetic algorithm radial basis, neural network model, based on the modeling of historical data, which may contain linear and nonlinear relationships by itself, so this study uses the genetic algorithm radial basis, neural network model, to make, compare, and analyze judgments on the relationships contained in this sequence.

1. Introduction

As economic policies become more relevant to people's lives, economic development has become a topic of discussion, and GDP, a measure of a country's or region's economic performance and level of development, has gradually become a national focus. The country's or region's future development trends are measured and evaluated. Shandong province's total GDP has ranked third among national economic provinces for many years, and according to the most recent data, its total GDP exceeded $7 trillion for the first time in 2017. Shandong province's economic development has a solid foundation. However, the gap between it and Guangdong and Jiangsu provinces, which are ranked first and second in terms of total GDP, is widening year by year [1]. Furthermore, Shandong province's total GDP ranking remains deficient when compared to its GDP per capita level; the level of GDP per capita indicates a region's level of development; for Shandong province, as a large population province, increasing GDP per capita is always a development goal. In terms of Shandong province's total GDP growth rate, it increased by 7.4 percent in 2020 compared to 2019, but the growth rate does not have an advantage over other provinces, and the economy of Shandong province still has a lot of room for development [2].

Based on the above background, it can be seen that the study of Shandong province's economic situation is very relevant and valuable, and the appropriate forecast of Shandong province's GDP can, to a certain extent, know the future economic development in advance, to be prepared in advance, and according to the forecast timely adjustment based on the existing situation. For the total economic volume of Shandong province, the situation of small per capita can explore the factors affecting the economic development of Shandong province and the interaction of Shandong province GDP and clarify the key to the economic development of Shandong province, based on the existing key transformation so that the economy of Shandong province attains healthy and stable development. Based on the development of the three major industries in Shandong province, there is still a lot of room for improvement, and the study and discussion of the GDP of each of the three major industries are conducive to further adjustment and optimization of the industrial structure and improvement of the economic development posture of Shandong province. Radial basis function (RBF) neural network is an efficient single-hidden layer forward network, which mimics the neural network structure of local regulation and mutual coverage of sensory domains in the human brain [3]. The gray forecasting model has unique advantages for forecasting with little data, missing data, or poor information, with low requirements for original data, high short-term forecasting accuracy, and ease of model testing; however, when data are scattered or the number of forecasting periods is long, the forecasting accuracy will significantly drop; the quadratic exponential smoothing method requires less historical data and has high short-term forecasting accuracy for forecasting with little data, missing data, or poor information; however, when the data are scattered or the number of RBF neural networks is a type of forward neural network that has global approximation capability and best approximation performance, it allows to approximate any nonlinear function. It differs from the BP (backpropagation) network in terms of network structure and learning algorithm, and it partially compensates for the BP network's shortcomings. In comparison to other types of forwarding neural networks, the RBF neural network has several advantages, including a simple network structure, a deep physiological foundation, fast learning ability, and good approximation performance [4]. The radial basis function combined with the genetic algorithm (RBFNN-GA) effectively avoids local minima and improves global retrieval ability by overcoming the overlearning phenomenon. The RBFNN-GA algorithm was used to conduct predictive analysis of the Shandong economic region, which provides useful information for future economic development strategy and policy.

2. Related Work

There are many research methods and empirical works on GDP forecasting in China and its provinces and cities, and the main methodological models are summarized as regression analysis, time series analysis, gray forecasting, artificial neural network, and a combination of these types of models. The literature [5] used five regression models to predict GDP and compared the prediction results and robustness; the literature [6] analyzed five influencing factors such as fiscal expenditure and residential consumption that affect China's GDP and built a linear regression model based on these five factors to predict China's GDP. The gray forecasting method has gained the attention of a huge amount of researchers with a smaller sample size to get higher prediction accuracy and is widely used in socioeconomic forecasting. The literature [7] used the time series data of the GDP of Jiangsu province from 1978 to 2009 and then used the GM model to forecast, and the test results showed that the model could provide accurate forecasts. Literature [8] established a gray GM model with different dimensions and an improved method of the gray model to forecast the GDP of Anhui province in 2015. Literature [9] used Lagrangian difference and segmented linear Newtonian difference methods and two orthogonalization methods to optimize the gray forecasting model to forecast the GDP growth of Xinjiang in 2018–2019. Due to their strong nonlinear fitting ability, artificial neural network models are frequently used to forecast GDP. The literature [10] used BP neural network models to forecast Guangxi GDP and found that BP networks are more informative. The literature [11] used the stepwise regression method to preprocess the data before applying the neural network method to predict the GDP of Jilin province, resulting in more accurate predictions. To build a GDP prediction model, the literature [12] combined the improved standard particle swarm algorithm with the dynamic Elman neural network with local memory function, which yielded GDP prediction values with higher accuracy. All of the above methods have produced positive results in predicting GDP, but as technology advances, the demand for accuracy and model stability grows. As a result, combined models for prediction are becoming more common, combining the benefits of each model to improve the model's applicability and prediction accuracy. To forecast GDP, literature [13] used the ARIMA model, exponential smoothing model, and a combined forecasting model with the residual inverse method, variance inverse method, and least-squares method. Literature [14] combined the time series model and regression analysis model to analyze and forecast the GDP of Anhui province. Literature [15] used gray forecasting GM and ARIMA models to separately forecast Chinese GDP and weighted average of the forecast values to get the final result to normalize. The literature [16] combined the ARIMA model with BP neural network method to form a new combined model to forecast the GDP of Shandong, studied its principle, and tested the generalization to derive the optimal forecasting model. The literature [17] empirically tests the impact of industrial structure on overall income and growth, and after discussing the detailed results of traditional shift-share analysis, it uses dynamic panel estimation to analyze a standard growth model extended by structural variables and, based on data from 28 OECD countries, concludes that industrial structure is a macroeconomic development and growth in the 1990s The conclusion that it is an important determinant of the literature [18], and others explored the link between public expenditure and economic growth, deriving conditions under which changes in the composition of expenditure lead to stable economic growth, and, using data from 43 developing countries, found that the current increase in the share of expenditure has a positive and significant growth effect, while in contrast, the relationship between the capital component of public expenditure and per capita growth is negative, with overuse of productive expenditures. There is no benefit to be derived from the excessive use of productive expenditures.

3. A Study on Regional GDP Forecasting Analysis of Shandong Economy in China Based on RBFNN-GA Algorithm

3.1. Radial Basis Function Neural Network Algorithm Combined with Genetic Algorithm. The basic idea of the RBFNN neural network is to transform the data from a low-dimensional space to a high-dimensional space so that the data can be linearly separated after the transformation. Both RBF and BP neural networks have a pretty nonlinear fitting ability. RBFNN contains only one hidden layer and computes the parameters by the idea of local approximation, which is computationally small and fast. RBF starts by choosing P basis functions, each of which will correspond to a training sample, and the individual basis functions are of the form $(\varphi\|X{-}X\|)$. Since the distances are radially identical, the radial basis functions get their name from this. Although both RBFNN and BP neural networks are universal approximators and belong to the same static feedforward neural network, they are always interchangeable in the same example. Figure 1 shows a radial basis function (RBF), whereas BP is a sigmoid function. Local minima in the parameter space, as shown in Figure 1, is a common problem with traditional neural network algorithms. Because any local minima is global minima if a function is convex, many models try to use convex optimization methods, such as the well-known support vector machine algorithm, which converts the problem into a dyadic problem using KKT conditions, and the dyadic problem is a convex optimization problem, allowing the global minima to be easily found. Because of their powerful nonlinear fitting ability, RBF neural networks can map a wide range of nonlinear relationships. In contrast, most loss functions, especially in deep learning, are nonconvex, and multiple local minima can be found [19]. In addition to the function's nonconvex nature, the spatial symmetry of the neural network's weights can result in a large number of local minima, emphasizing the importance of a good optimization algorithm. To find the existence of global minima, a genetic algorithm can be used to improve the traditional radial basis neural network algorithm.

The mathematical model of radial basis function neural network based on genetic algorithm (radial basis function neural network-genetic algorithm, RBFNN-GA) with three-layer network structure can be represented by the following:

$$T(i, j) = \frac{\overline{g}(i, j) + \overline{g}\max}{\overline{g}\max - \overline{g}\min} + |X - Y|^2, \tag{1}$$

where $X = (x_1, x_2, \ldots, x_n)$ is the input vector and $Y = (y_1, y_2, \ldots, y_n)$ denotes the center of the ith neuron node in the hidden layer; $|x{-}y|^2$ denotes the square of the Euclidean distance between the input vector and the centroid; g represents the activation function, which is usually Gaussian in radial basis function neural networks; σ denotes the smoothing factor of the activation function of the ith neural node, which is used to control the width of the activation function; A denotes the weight from the hidden layer to the output layer; and k and m denote the number of nodes of the hidden layer neurons and the dimension of the input vector, respectively. The structure of the three-layer radial basis function neural warp network in this study is shown in Figure 2.

A random radial basis function neural network differs from a general radial basis neural network, and in that the centers $y_i = (y_{i1}, y_{i2}, \ldots, y_{in})$ and the smoothing factor k of its hidden layer neuron nodes are generated in some way and need to be determined before the weights A of the output layer are derived by least squares. For any continuous function f and RBFNN-GA neural network, where $I \in [0, 1] \in R$, we define

$$Y = I_{nn} \cdot X_{nn} = \begin{pmatrix} I_{11} & \cdots & I_{1j} & \cdots & I_{1n} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ I_{i1} & \cdots & I_{ij} & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ I_{in} & \cdots & \cdots & \cdots & I_{nn} \end{pmatrix} \cdot \begin{pmatrix} x_{11} & \cdots & x_{1j} & \cdots & I_{1n} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ x_{i1} & \cdots & x_{ij} & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ x_{in} & \cdots & \cdots & \cdots & x_{nn} \end{pmatrix} = \begin{pmatrix} y_{11} & \cdots & y_{1j} & \cdots & y_{1n} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ y_{i1} & \cdots & y_{ij} & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ y_{in} & \cdots & \cdots & \cdots & y_{nn} \end{pmatrix}. \tag{2}$$

The parameter b denotes the output threshold. Then, based on the predicted output O and the expected output T_k, the prediction error can be determined as

$$b = (O_k - T_k) \cdot g(k). \tag{3}$$

The update formula for the weights and thresholds is as follows:

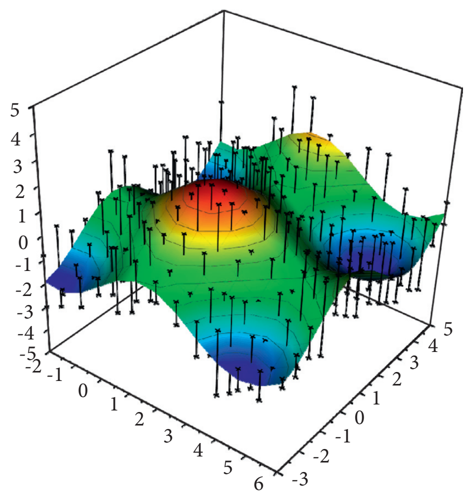

Figure 1: Schematic diagram of local minima.

$$\beta = \alpha_1 - \frac{(\alpha_2 + \alpha_1)\left(E_n^1 + \lambda_1\right)}{(\lambda_2 + \lambda_1)}. \tag{4}$$

When the input signal of the network is the kth training sample X_k, its output value of the jth neuron after the nonlinear transformation of the i-th hidden layer neuron is

$$X_k = T_k + b \sum_{i=1,j=1}^{n} X_{ij}^2, \tag{5}$$

where $j = 1,2, \ldots, J$. The basis function is generally chosen to be Green's function:

$$G(J) = j\frac{\partial \gamma}{\partial j} + \frac{1}{n}\sum_{i=1}^{n} X_i Y_i. \tag{6}$$

The core concept behind RBFNN networks is that the hidden layer transforms the input data, mapping the relatively low-dimensional input into a high-dimensional space, allowing the data to be transformed from indistinguishable in the low-dimensional space to divisible in the high-dimensional space. The division of the input space into several subspaces in hyperspherical form is the geometric core of RBFNN neural networks. Theoretically, it can be argued in this study that as long as there are enough hidden layer nodes, the RBF network can always achieve an infinite approximation to any arbitrary continuous function, regardless of how small the error is set. This study also shows that two-parameter weights in the formula and the center of the radial basis function have yet to be determined and will be determined through network training. The random selection of some parameters in radial basis function neural networks is a useful addition to the existing methods for determining the center and smoothing factor of these networks. The centers of radial basis functions are frequently calculated using clustering methods (K-means clustering, fuzzy C-means clustering, and principal component clustering methods) and other methods, similar to some fuzzy modeling technologies [20, 21]. The gradient descent method is frequently used to train the weights of the hidden layer to the output layer [22]. When the RBFNN-GA neural network has a very large number of hidden layers, it can be used to approximate any M-element continuous function with arbitrary accuracy, and the network can always be trained to find a corresponding set of weights to make the best approximation of the unknown nonlinear mapping relation $f(-)$ between the input and output. A regularized network is described in terms of the interpolation problem as complete interpolation, i.e., finding a hypersurface such that it passes through all sample points.

RBFNN-GA neural networks are nonlinear multilayer feedforward neural networks that have the same properties as multilayer perceptrons, with the exception that they are both general approximators, meaning that any multilayer perceptron can be replaced by an RBFNN-GA neural network, and any RBFNN-GA neural network can find a multilayer perceptron that performs the same function as it. However, there are some distinctions between the two networks.

(1) In terms of network structure, RBF neural networks have only one hidden layer, unlike multilayer perceptrons, which can have one or more hidden layers.

(2) In a multilayer perceptron, the implicit layer neuron model is identical to its output layer neuron model; in an RBFNN-GA neural network, the two models are quite different and the two models do not play the same role in the network.

(3) There can be linear or nonlinear implicit and output layers between multilayer perceptrons, and when they solve pattern classification problems, they generally choose nonlinear mapping relations, and if they are solving nonlinear regression problems, the output generally chooses linear relations, and it is different in RBFNN-GA neural networks, where the implicit layer is a nonlinear mapping relation while the output layer is a linear mapping relation.

(4) The excitation function of the RBFNN-GA neural network hidden layer neuron calculates the Euclidean distance between the input vector and the center, while the excitation function of the multilayer perceptron hidden layer neuron calculates the inner product between the input unit and its connection weights.

(5) The RBFNN-GA neural network uses a local exponentially decaying nonlinear function to make a local approximation of the nonlinear input-output mapping, while the multilayer perceptron is a global approximation of a nonlinear mapping. To put it another way, the multilayer perceptron requires many more parameters than the RBFNN-GA neural network in order to approximate the nonlinear input-output mapping with the same accuracy.

3.2. Application of RBFNN-GA Algorithm to GDP Forecasting and Analysis Studies. According to the literature and various theoretical proofs, the combined model's prediction effect can usually improve the single model to some extent.

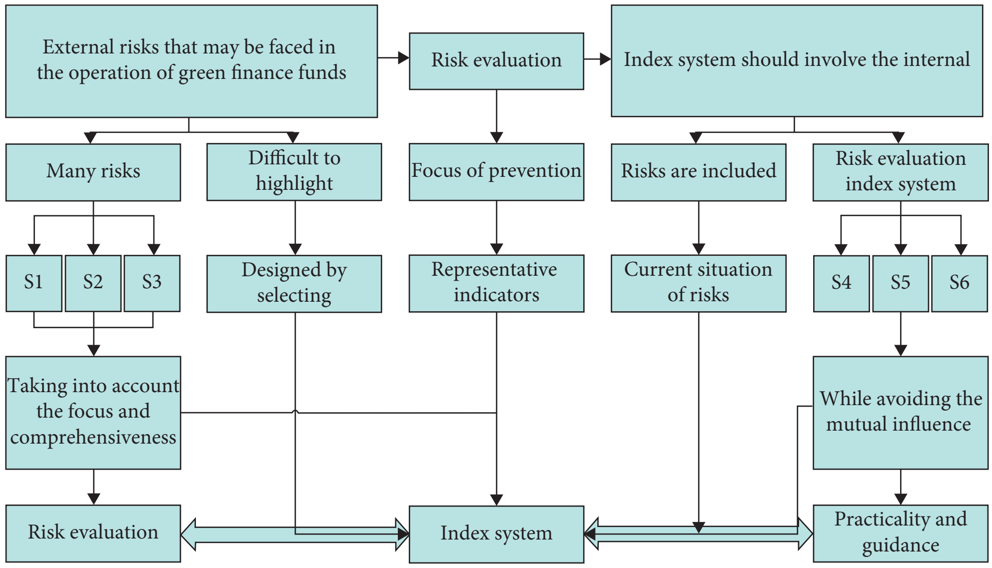

Figure 2: Structure of radial basis function neural network.

Because it is difficult to tell whether time series is linear or nonlinear in real-world applications based on time series modeling, a single model is often used for one of the mappings, whereas the combined forecasting method described in this study targets complex mapping relationships and can tap both linear and nonlinear features of the series. The rising trend of GDP in Shandong province is influenced by many factors and is a nonstationary series, so its series is judged to have both linear and nonlinear characteristics. The GA model is frequently used to model linear relationships, while the RBFNN neural network is used to mine the series' nonlinear relationships. Model compression techniques and scaling were combined with optimization goals to achieve an automatic selection of model compression techniques for various networks and task requirements. The combination of these two forecasting methods fully exploits their benefits and compensates for the single model's single mapping relationship flaw. Most of the data features of the GDP series in Shandong province can be mined using a combination of RBFNN and GA neural network, and the prediction accuracy of a single model can be improved.

The network structure of the RBFNN neural network algorithm is determined, and its training process is mainly divided into two parts: first is the forward propagation of information, which means that the information is input from the input layer, after the nonlinear mapping of neurons in the hidden layer, and passed into the output layer to output the result [23]. The second is error backward propagation, which refers to the error between the output result of the output layer and the true value by judging the error, and if it exceeds the range of the preset error, the error signal is gradually passed backward, while adjusting the weights and thresholds of each hidden layer passed through, so that the adjusted parameter model makes the output error decrease along the gradient direction. After repeatedly fixing the model after the parameters until the prediction error is controlled within the set range, the learning process of the network is ended and the weights and thresholds of each layer corresponding to the minimum mean square error are obtained, i.e., the nonlinear mapping relationship of the model is determined.

The compression algorithm is improved by studying three compression techniques, namely quantization, sparse, and cropping, to realize the compression of different models with different network structures at different scales of model compression. The experiments compare the models' load characteristics under various compression methods. The differences in performance between the various methods are tracked and analyzed. Finally, reasonable model compression and scaling techniques are demonstrated. By selecting a reasonable model compression technique and ratio, the model size, inference time, and energy consumption can be effectively reduced, and the performance of different compression methods in different network structures varies. The best compression method is determined by the target neural network's structure and the optimization constraints. The best compression method is determined by the target neural network's structure and the optimization constraints.

Combining the two algorithms of RBFNN and GA neural network, the main principles of the combined prediction model are as follows: (1) the GA model predicts the linear part of GDP in Shandong province; because the GA model builds a linear regression of the current data about its lagged data, so this study will apply the prediction result of the GA model as the linear part of the combined model prediction. The residual of the RBFNN model prediction, i.e., the white noise, as the part outside the linear part of the series, no longer has the value information of linear prediction, so it is hoped that the residual value of white noise can be extracted using nonlinear prediction. (2). RBFNN neural network model trains the white noise series and extracts the nonlinear features in the GDP series, mentions the residual series predicted by the GA model, and builds the RBFNN neural network model after the matrix transformation and normalization process. The predicted value of this model is used as the predicted value of the nonlinear part of the time series, i.e., the nonlinear information of the extracted time series. (3) The fitted value of the GA model is added to the predicted residual value of the RBFNN neural network and the obtained predicted value, which is the predicted value of the combined model proposed in this study. The specific steps are shown in Figure 3.

The variance of each variable in the model can be decomposed according to certain criteria, and the criterion of variance decomposition is to decompose the variance of the variable according to the proportional size of the influence of each random disturbance term on the variable, and the variance decomposition studies the proportion of the influence of the orthogonalized residuals on the mean squared error (MSE) of the prediction, so it can be seen that the variance decomposition studies the proportion of the influence of the orthogon. Because the variance decomposition yields the proportion of shocks' impact on variable change, the relative magnitude of each perturbation term's impact on the variables can be determined, and thus, the relative importance of each perturbation term on a variable can be determined. The sum of the percentage contributions of all orthogonalized disturbances to a variable's effect is 100 percent for its mean square error. The vast majority of time series in socioeconomic phenomena are nonstationary time series, as is well known. In order to convert the slowly varying trend terms, periodic seasonal terms, and smooth random noise terms in nonstationary time series into stationary time series, various data primitive transformations and more processing methods must be used in modeling. This can then be transformed into analysis modeling. As a result, transforming the time series into a smooth time series and ensuring that the trend information is extracted adequately become critical. When dealing with nonsmooth time series, a variety of treatments can be considered to smooth them out.

With the RBFNN algorithm, stochastic radial basis function neural networks have been shown to have fast learning ability and powerful function approximation capability, both in theory and practice. However, due to the random selection (uniform distribution) of the centers and smoothing factors of the radial basis functions in the network, it is easy to cause the output matrix of the hidden layer to be irreversible and even pathological. This leads to the instability of the solution when solving the output layer weights, which affects the stability of the RBFNN algorithm and the performance of the random radial basis function neural network. More importantly, the stochastic radial basis function neural network solving the output layer weights by the RBFNN algorithm does not avoid the overfitting phenomenon and usually performs very well in the training set but poorly in the test set. It is found that the above problem can be effectively avoided by model regularization, i.e., adding the l penalty term to the original model.

We need to preprocess the data before we can conduct the variable selection analysis, and the first step is to run a correlation test, as shown in Figure 4. The correlation coefficient between multiple sets of explanatory variables is above 0.8, and the multicollinearity between variables is serious, so it will lead to instability and difficulty in explaining the prediction model later, so in this step, we use the Lasso method to process for variable selection and solve the multicollinearity problem [24]. To free the model from the constraints of the explanatory variables' units and sizes, the data must be transformed into dimensionless, or normalized, form. Subsequently, we use the Glenmont package in R to implement the Lasso model for various X values. We can see how the model's coefficients change in the following diagram, and then, we use the cross-validation (CV) method to select the best parameter values and thus determine the variable selection results. Total energy supply and total disposable income per capita are the final economic explanatory variables we choose as the most relevant to Shandong province's GDP. This also demonstrates that Shandong province's GDP is highly correlated with agro-industry, indicating that the province's GDP is dominated by primary and secondary industries. Chemical, machinery, textile, metallurgy, and other energy-based industries account for the majority of Shandong province's main business income. Energy and raw material industries account for more than 40% of Shandong province's GDP, indicating that industrial agriculture remains the province's main contributor, and the development of tertiary industries, such as commerce, finance, and transportation and new industries such as the internet industry, is still in its infancy.

4. Experimental Verification and Conclusions

Figure 5 depicts the total economic volume of Shandong province over the next seven years, as predicted by the RBFNN-GA algorithm. It is expected that the total economic volume of Shandong province over the next seven years will continue to show an upward trend and grow at a high rate, with average annual growth rates of 3.98 percent, 5.63 percent, 6.39 percent, and 6.97 percent, respectively. GDP growth over the next five years is expected to be 7.63 percent on average, reaching 1,134.2 billion by 2025; GDP growth over the next five years is essentially the same as the growth rate in 2019–2020, is essentially consistent with the growth rate since 2015, and will remain at a higher level than in the previous 50 years. The average annual growth rate of total annual fixed-asset investment (FAI) over the next five years, 2022–2026, is forecasted to be 4.79 percent, reaching $801.95 billion in 2025; the growth rate of a total fixed-asset investment over the next five years is slightly higher than the growth rate in 2019–2020, but significantly lower than the growth rate since 2010, and will remain moderate and steady. Over the next five years, 2022–2026, the annual average growth rate of annual general public budget revenue (GBR) is expected to be 5.21 percent, reaching 947.8 billion by 2025. The general public budget revenue growth rate over the next five years is slightly higher than the rate in 2019–2020, which is largely consistent with the growth rate since 2010 and will annually increase. The initial individual's efficiency curve is the lowest, followed by the individual with the best head, and finally the individual with the best efficiency. The growth spokes of total fixed-asset investment

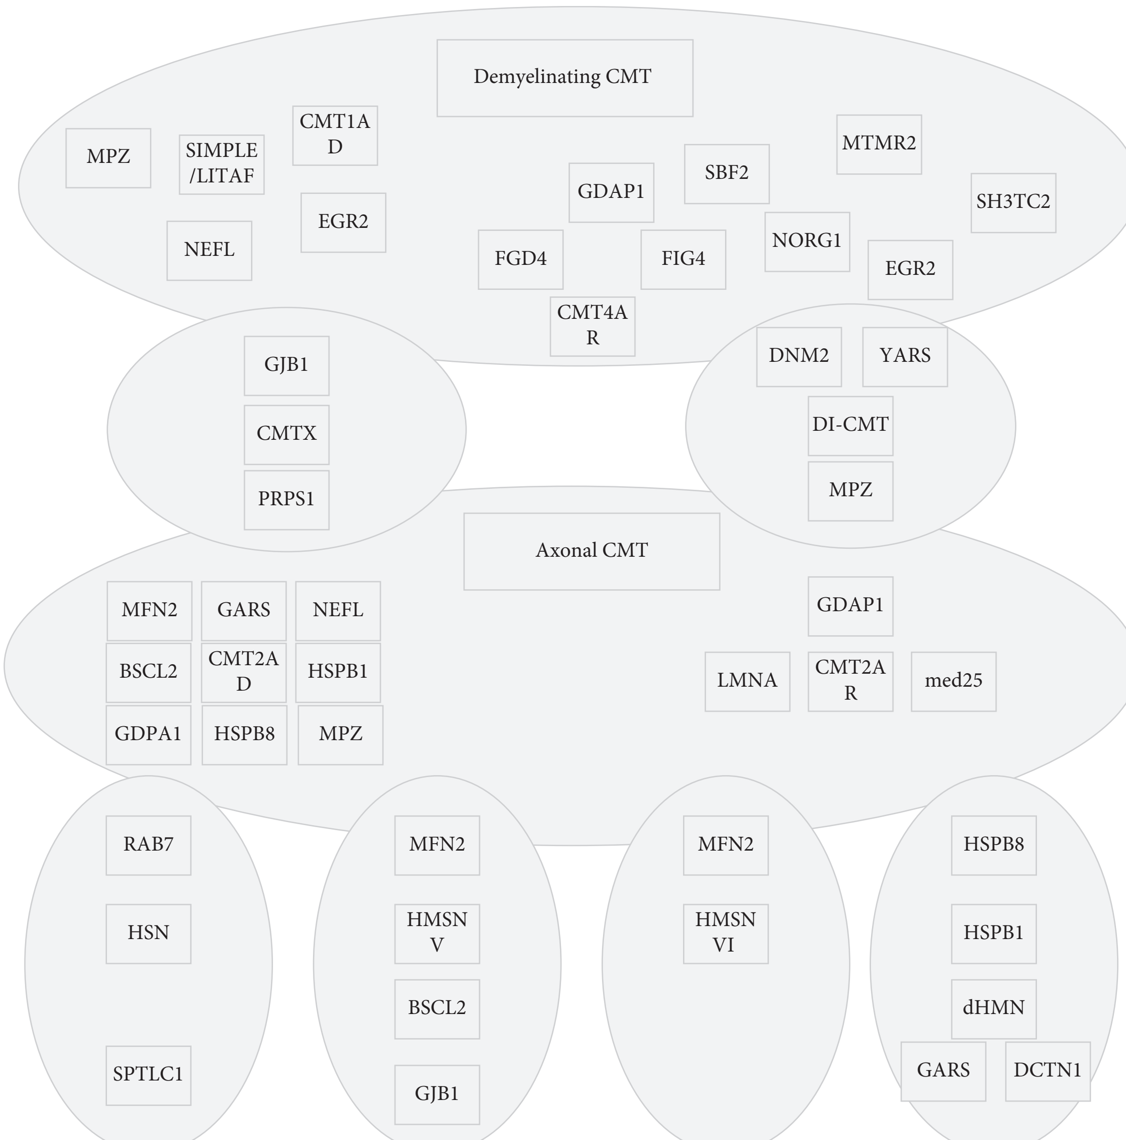

Figure 3: Flow chart of the combined model prediction.

and general public budget revenue are smaller when compared to GDP and total retail sales of consumer goods.

As shown in Figure 6, in the next five years, the regional GDP growth rate is expected to increase and then decrease, but the GDP growth rate does not change much, generally located in the range of 6.3%–6.8%. It can be seen that the economy of Shandong province has passed the stage of high growth, the growth rate has become slower and entered the stage of steady progress, the regional GDP will maintain moderate growth, at this time, the total regional production increased, not only the level of economic development but also the inflation rate is small, and this level of GDP growth rate is conducive to achieve high-quality economic development. Combined with the economic development history of Shandong province, Shandong province should implement a stable and progressive fiscal policy to improve the quality of economic development while stimulating the growth of economic aggregates.

Figure 7 shows the change in total energy production in Shandong province over the next five years as predicted by the RBFNN-GA model. The total energy production in Shandong province is expected to decline in the next five years, with an average annual growth rate of −3.98%. The average annual growth rate of total energy production in the five years of 2022–2026 is expected to be −3.25% and will drop to 103.52 million tons of standard coal by 2025; the growth rate of energy production in the next five years is slightly higher than that in 2019–2020, but it will remain negative. Insufficient energy supply will constrain the economy and reduce the rate of economic development.

The growth rate of disposable income per capita over the next five years in Figure 8 shows that urban disposable income per capita is increasing, with annual growth rates fluctuating between 5.7 and 6.5 percent, with an average annual growth rate of 6.13 percent; rural disposable income

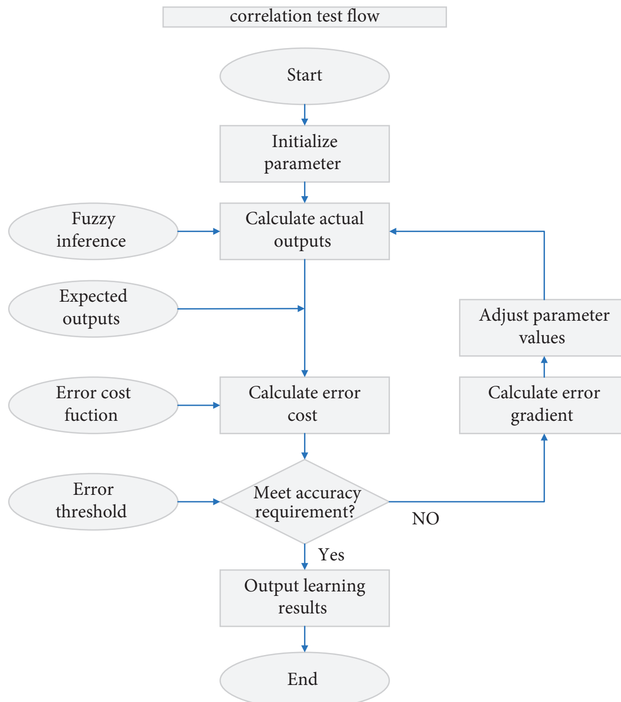

Figure 4: Flow chart of correlation test.

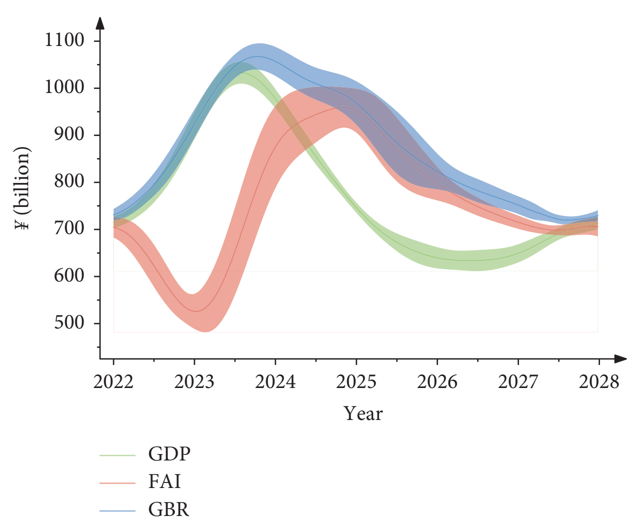

Figure 5: Economic aggregates projected by RBFNN-GA model for the next seven years in Shandong.

per capita is increasing, with annual growth rates fluctuating between 7.2 and 7.9 percent, with an average annual growth rate of 6.43 percent. Both growth rates are expected to be smaller than those seen since 2005, and the difference between the two is small and consistent. In terms of growth volume, although the difference between the growth rates of per capita disposable income of rural and urban residents is not large, or even slightly higher than that of urban areas, the average annual growth of per capita disposable income of urban residents is expected to be RMB 3,145 per person, while the average annual growth of per capita disposable income of rural residents is only RMB 1,403 per person, less than half of that of urban areas. The total economic volume of Shandong province is expected to continue to show an upward trend in the next seven years, maintaining steady growth at a high rate. In absolute terms, by 2025, the per capita disposable income of urban residents is expected to reach 63,146 yuan/person (a year), but only 27,893 yuan/person (a year) in rural areas, with the absolute difference in per capita disposable income increasing from 25,093 yuan/person to 35,253 yuan/person. In relative terms, the income ratio between urban and rural residents will decrease from 2.4873 in 2018 to 1.9758 in 2025, with a slight reduction in the relative gap.

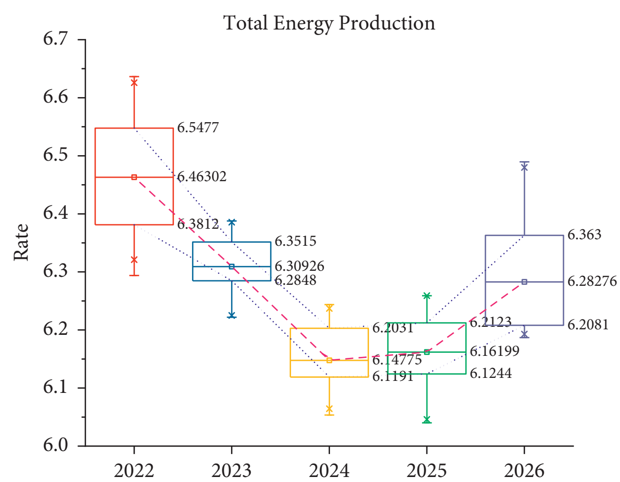

Figure 7: RBFNN-GA model projected changes in total energy production in Shandong over the next five years.

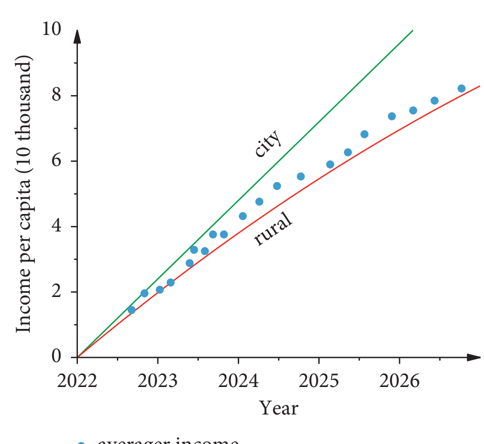

Figure 8: RBFNN-GA model forecasts disposable income per capita for the next five years in Shandong.

Currently, Shandong province's total economic output is at the forefront of the country, with total regional GDP in 2018 being the third highest in the country, GDP per capita the seventh highest in the country, and disposable income per capita in the first three quarters of 2019 ranked eighth in the country and will largely remain at this level over the next six years. In terms of growth, the projected GDP growth rate of 5.8% in Shandong province is not much different from the projected national GDP growth rate of about 4.7%, which is slightly lower in comparison; the per capita disposable income, especially the per capita disposable income of urban residents, will exceed the 50,000 yuan (/year) mark in 2022, and the per capita disposable income of rural residents will also exceed 20,000 yuan (/year) in the same year.

4.1. To Ensure Faster Economic Development and Improve the Quality of Economic Development. We should pursue progress while maintaining stability, improve the quality of economic development while stimulating economic output growth, and insist on promoting high-quality development as a general development strategy. To begin, we must vigorously develop high-tech industries and new industries, support the development of new services industries and promote development with "NEW," and take the early zone for the conversion of old and new dynamics and the pilot. We will also encourage the growth of innovation-driven digital intelligence, and new trade patterns, the development of marine industries, local economic cooperation between China, Japan, and Korea, and the rapid economic development of coastal cities. Second, sustained and steady growth should be ensured in total retail sales of consumer goods and fixed asset investment and growth should be promoted in line with demand by lowering fees and taxes and increasing government transfer payments. Finally, secondary energy conversion rates should be improved, new energy development should be accelerated, old kinetic energy should be replaced with new kinetic energy, and adequate energy supply should be ensured for industrial development.

4.2. Increase Agricultural Output and Promote Coordinated Urban and Rural Development. The data on per capita disposable income show that the gap between urban and rural residents' living standards is wide and unlikely to significantly narrow in the future. To begin, we should concentrate on the three rural areas, develop new agriculture, build new rural areas, and establish a model of rural revitalization in Qilu; second, we should promote village mergers and land transfers and develop large-scale agriculture and intensive agriculture; third, we should build high-standard farmland and develop green agriculture; fourth, we should establish agricultural science and technology companies, build high-tech agricultural demonstration parks, and accelerate the construction of high-tech agricultural demonstration parks. Second, in order to build beautiful villages, rural infrastructure should be strengthened, and the road hardening and toilet revolution should be accelerated. Finally, the urbanization of rural areas and the construction of small towns should be accelerated in two ways: first, the economic strength of counties, districts, and towns should be improved to close the gap between urban and rural areas in the province, and second, smart communities should be created and digital technology should be used to serve community management.

4.3. Pay Attention to the Spiritual Needs of the Masses and Enrich the Cultural Life of the Residents. The standard of living of the people has been greatly improved, and their concern for the world of design has been greatly increased. We should strengthen cultural construction, enrich cultural life, and improve the quality of life in the following ways: first, through building cultural communities, cultural squares, recreational clubs, and hosting cultural tours, to involve the masses and enrich the cultural life of the people; second, through activities such as culture in the community and culture in the countryside and through cultural storytelling and watching movies, etc., to promote local culture and positive mainstream culture to the masses, to improve the cultural literacy of the people, to promote the integration of culture and technology, to create a digital platform for cultural resources, a platform for the transformation of culture and technology, etc., to cultivate new cultural industries and enhance the people's sense of cultural access, to promote the development of culture and sports, such as hosting sports events, organizing national health games, sports, and cultural festivals, etc., and to find new ways to disseminate regional culture and popularize culture in daily exercise.

For future economic development, we recommend enhancing the development of the tertiary industry on the one hand and developing the service industry on the other hand. According to recent national economic data, the service industry's scale is growing, its quality and efficiency are greatly improved, and new industries and business models are emerging. Currently, the service industry in Shandong province requires further development. The service industry has the potential to bring a variety of new economic growth points, such as productive services, in the fine development of promising financial service industries of private fundraising, cultural tourism industry, internet economic industries such as big data, cloud computing, artificial intelligence, e-commerce, and so on. Simultaneously, the growth of the service sector can help to improve and support the current Shandong province economy, which is dominated by manufacturing and agriculture industries. In light of the new economic situation and the impact of the Sino-US trade war, it is more important than ever to fully tap domestic demand and to constantly activate the development of private enterprises, and small and microenterprises to generate new economic growth points. On the other hand, in light of the current economic situation and the escalation of difficulties, we cannot dismiss the importance of the state-owned economy, which has a significant impact on the economy of Shandong province. The Shandong economy state-owned system, which has a high starting point, high level, and high-quality state-owned enterprises, should be accelerated for further development. To stimulate market players and increase market-oriented reform, the upgrading and transformation of enterprises should be sped up that are not keeping up with market development. Simultaneously, increased support for scientific research undertakings is recommended; scientific and technological innovation can significantly improve productivity, more high speed, and high quality to enhance economic growth; not only the development of applied disciplines can be transformed into productivity, but also in the current situation, the development of basic disciplines is more important and can bring more critical core technological breakthroughs. It is suggested that spending on scientific research should be increased, that the construction of "double first-class" schools and disciplines should be strengthened, and that preferential policies for attracting talents, such as subsidies for settling talents and subsidies for high-end talents, should be increased.

5. Conclusions

This study completes the RBFNN-GA model's GDP prediction in Shandong province, and the results show that the RBFNN-GA model's prediction accuracy with input variables is higher than the univariate RBFNN model, and the RBFNN model's stability is also higher. To improve the accuracy of GDP prediction, this study combines the two algorithms of GA and RBFNN to create a combined model. Based on the assumption that the GA model mines the linear characteristics of the GDP series, the residual series predicted by the RBFNN model is taken as the part without linear information, and the RBFNN neural network model is built to extract the nonlinear information of this residual series. The linear part's predicted value is added to the nonlinear part's predicted value, and the resulting sum is the combined model's predicted value in this study. The way the residuals are predicted is the main difference between the improved combined model and the combinatorial model. By converting the genetic algorithm input information of both the fitted value sequence and the residual value sequence, the improved model predicts the residual value of the current period, and the value is added to the linear prediction result of the corresponding radial base model to obtain the prediction value of the improved model. After analyzing the experimental results, the improved combined model has the best prediction effect. The improved model predicts the current period's residual value by converting both the fitted and residual value sequences of the GA model into RBFNN neural network input information and then by adding the value to the linear prediction result of the corresponding RBFNN model to get the prediction value of the improved model. The improved combined model has the best forecasting effect, according to the experimental results. In this study, several more important economic indicators are chosen to provide reference opinions and strategies for Shandong's economic development policies in the next five years, including total economic volume and growth rate, energy supply, and people's living standards.

Shaanxi is one of China's most important cradles of civilization. The main vein of Chinese culture is rich history and culture, and brilliant red culture embodies the essence of socialist core values. It is still relatively weak to deeply analyze the related research of Shaanxi Province's cultural province construction on the basis of studying the achievements of cultural development in foreign countries and China and combining with the reality of Shaanxi Province. In this paper, a BPNN (BP neural network) model is selected to study the comprehensive evaluation of tourism competitiveness of smart tourism cities, and the software is used to realize the simulation of the comprehensive evaluation system of tourism competitiveness of smart tourism cities, which more comprehensively and objectively reflects the level of comprehensive competitiveness of each city. It is believed that there are some problems in Shaanxi regional cultural communication, such as insufficient exploration of content resources, insufficient communication channels, and low audience awareness, hoping to provide ideas and reference for further exploring the promotion of cultural communication power.

1. Introduction

Shaanxi is recognized as a province with rich cultural resources and is vigorously building Shaanxi as a province with rich historical culture, splendid revolutionary culture, distinctive folk culture, and modern culture with certain strength. How to develop Shaanxi's cultural undertakings with the help of rich cultural resources and develop a culturally rich province into a culturally strong province has become the direction of the joint efforts of provincial party committees and governments [1]. Although Shaanxi has made great achievements in the development of cultural undertakings and cultural industries in recent years, it is not commensurate with the requirements of being a big cultural province and building a strong cultural province. Compared with developed provinces, there is still a big gap, and the construction of a strong cultural province still faces some problems and difficulties [2, 3]. This is also the background of this topic.

Many cultural communication professionals began to actively study the internal relationship between the Internet and cultural communication content in the era of mobile Internet to better understand how to spread cultural content through the Internet. Cultural construction is an important aspect of socialist construction and a crucial component of the Chinese style socialist theoretical system. The classification and planning of historical and cultural cities, as well as the attention paid to implementation after the planning of famous city protection, are clearly inadequate. Protection planning should not be a one-size-fits-all approach [4, 5]. Protection planning should be evaluated in light of changes in implementation as protection work progresses, and this should be used as the basis for planning adjustments [6]. To enrich Shaanxi's cultural construction, it is critical to study the construction of Shaanxi Province as a strong cultural province. This paper examines the problems and reasons for the construction of a strong culture in Shaanxi Province, as well as the countermeasures and recommendations for the construction of a strong culture in Shaanxi Province, which is of reference value to the country's and other provinces' cultural construction.

Beginning with the scientific definition of culture, this paper examines the current state of Shaanxi's cultural province construction, highlighting the accomplishments and benefits of Shaanxi's cultural construction, and identifying the major issues that exist in Shaanxi's cultural construction. A transportation mode selection model based on the BPNN (back propagation neural network) algorithm is established after comprehensively considering the attribute variables and activity patterns of travelers, with a focus on the historical block, a special block. Using the protection of ancient cities as an example, it has been demonstrated that the BPNN evaluation model of the entire process of historic city protection planning can be used for historic city protection evaluation.

2. Related Work

The early research mainly focused on the background of cross-cultural generation, while the current research has already involved many disciplines of humanities and social sciences [7, 8]. Yang et al. [9] propose that some information is hidden in the context when people communicate with each other, and there are different levels of communication contexts among countries and ethnic groups. Countries such as Britain and the United States belong to the low-context society, while countries such as Japan and South Korea belong to the high-context society. By analyzing the current situation of foreign language education in China, Liu and Hu [10] pointed out that foreign language teaching in China attaches importance to language knowledge and language skills but neglects the cultivation of cultural factors, so that Chinese college students lack intercultural communication skills. Based on this, Hou [11] proposes to build a brand-new college English-teaching model based on intercultural communication. Wu and Ma et al. [12, 13] propose that to achieve effective communication across the gap of nationality, race, nationality, language, and culture, it is necessary to search for and think about the multidimensional interaction between self, people and society, people and culture, people and media, so as to find out the possible path of cross-cultural communication. Zhan [14] discusses smart tourism in depth and thinks that smart cities should have six dimensions: smart economy, smart environment, smart transportation space, smart people, smart families, and smart government. Through data analysis, it is found that innovation ability, attention to urban environmental quality, administrative management, and education level play an important role in the utilization of information technology and the intelligence of cities [15, 16].

The characteristics of artificial neural networks in terms of information processing are unique. It has been used successfully in a variety of fields. It has strong nonlinear mapping capabilities, as well as self-adaptation, self-learning, fault tolerance, and parallel processing capabilities. Neural networks have properties that make them ideal for studying chaotic sequence prediction. The use of neural networks [17] in multivariable time-series prediction and multivalue prediction has been studied in literature [18, 19], and Lu et al. [20] discuss the modeling mechanism and multivalue prediction of this method, as well as its application in stock price prediction. Tang and Yu [21] discuss the establishment mechanism of a time-series prediction model based on neural networks and then propose an adaptive time-series modeling and prediction by combining the time-difference method with BPNN. Sun and Lei [22] developed a radial basis function neural network model using cluster analysis, tested it using financial time series, and compared it to the radial basis function neural network model. Yuan et al. [23] established a time-delayed BPNN model and used the Bayesian regularization method to improve BPNN's generalization ability. Furthermore, many researchers used the search algorithm in optimization to improve the common BP learning method's convergence speed and network prediction performance.

3. Research Method

3.1. Communication Design of Shaanxi Regional History and Culture. The goal of Shaanxi Province as a strong cultural province is an indispensable part of the construction of "western province". Attaching great importance to cultural construction ideologically is an important prerequisite for building a strong cultural province. Shaanxi talents will have more sense of belonging and existence. Cultural construction is an important symbol of Shaanxi's comprehensive strength. A country pays attention to comprehensive national strength, and a province also pays attention to comprehensive labor saving, including not only material strength such as economic strength, scientific and technological strength, but also spiritual strength such as culture.

Culture, as a special component of comprehensive strength, is based on and backed by developed economy. Building a moderately prosperous society, to achieve the goal of building a culturally powerful province in the west also requires firm belief and guidance. Cultural construction provides intellectual support for the construction of a strong western province. China's modernization process, to a great extent, depends on the improvement of national quality and the development of human resources. Shaanxi should be highly aware of the importance of cultural construction ideologically, make full use of the advantages of efficient resources, train outstanding and high-quality talents, and provide backup forces for the construction of Shaanxi's strong cultural province.

As a kind of "soft power", culture is increasingly becoming an important factor of regional competitiveness and an important aspect of a region's comprehensive strength. Cultural background, cultural environment and atmosphere, and scientific and cultural quality of workers are increasingly becoming the important foundation and guarantee of economic development. The complex relationship between culture and economy is becoming more and more important. Therefore, the significance of cultural revival is not limited to simple economic development.

Thousands of years have passed since many cultural relics, historic sites, and cultural sites in historical and cultural cities were destroyed and rebuilt. They have remained tourist attractions for the time being, due to the cultural continuity and inheritance [24]. Aside from the continuation and inheritance of culture, the cultural sustainable development of famous historical and cultural cities is also very important for the innovation and development of culture, and it is an important index to measure the continuation of "context" of famous historical and cultural cities as well as the development of culture over time. It is a critical ally in the development of cultural tourism. Tourists are drawn to cultural relics and historic sites in well-known historical cities because they are diverse, have a long history, have a high taste, are valuable, and have a high ornamental value. At the same time, the material carriers of culture are the preservation of cultural relics and historic sites in well-known historical and cultural cities, the preservation of ancient architectural styles, and the preservation of cultural landscapes. The cultural evaluation index system of historical and cultural cities includes five major factors, which constitute an index system composed of three levels: target level, factor level, and index factor level, as shown in Figure 1.

The cultural industry in Shaanxi has more potential for economic growth. Shaanxi takes cultural tourism as a breaking point because of its diverse and colorful cultural resources, and labor drives many economic growth points throughout the industrial chain, including the cultural leisure industry, book publishing industry, and advertising exhibition industry. Culture is, at its core, a creative endeavor. Through the integration of various forms of cultural resources, various cultural products and services with fresh vitality can be continuously produced with the continuous input of creativity.

In the field investigation, the vast majority of tourists are in a positive and high emotional state, and a small number of tourists are mixed with negative emotions. In the specific tourism situation, this paper only selects tourists' positive tourism emotions as the focus of this paper. On the whole, the higher the tourists' positive tourism emotion, the stronger the tourists' sense of experience and identity to the tourist destination, and the greater the tourists' satisfaction. The structural model is shown in Figure 2.

Tourist satisfaction plays a part of intermediary role between positive tourism emotion and behavioral intention. As a senior creature, people's tourism emotion is complex in the process of tourism. The level of tourism emotion depends on tourists' experience and recognition of the tourism world, and its influence is far-reaching and extensive. On one hand, positive tourism emotion affects tourists' satisfaction with tourist destinations, on the other hand, it also has a direct effect on their behavior intention, but at the same time, tourists' positive tourism emotion also plays a role in behavior intention through overall satisfaction.

It is worth noting that while tourists' positive tourism emotion has a strong influence on behavior intention, the impact of positive tourism emotion on behavior intention is weakened when tourists' satisfaction factors are taken into account. As a result, the most important aspect of tourist destination management is to pay attention to tourist satisfaction. Xi'an tourists appreciate the ancient capital's incomparable charm because of its unique tourism resources and beautiful natural and cultural environment. As a result, Xi'an tourists' tourism emotion and satisfaction with tourism resources and culture, tourism environment, and facilities are related in the travel process, and there is a positive correlation. There is, however, no link between tourism emotion and tourism expectations, tourism service, or tourism price. The causal relationship between them cannot be determined using correlation analysis. The next step of regression analysis is required to investigate the relationship between tourists' tourism emotions and tourism resources and culture, tourism environment and facilities, and overall satisfaction.

3.2. BPNN Model Design

3.2.1. BPNN Structure. BPNN algorithm is a training algorithm based on the principle of error back propagation. It takes the minimum error mean square as the criterion and uses nonlinear differentiable function for weight training. BPNN is a multilayer forward anger network, which is composed of IL (Input layer), HL (hidden layer), and OL (Output layer). Usually, the number of layers of neural network does not include IL. Figure 3 is the BPNN structure diagram.

The HL transfer function of BPNN adopts the nonlinear function of continuously differentiable, usually Sigmoid function, while the transfer function of OL can adopt linear function or Sigmoid function, depending on the distribution range of OL vector.

Basic steps of algorithm: set the initial value of each weight or threshold: $w_{ji}(0), \theta_j(0)$ is a small random number.

Provide training samples: input vector $X_k, k = 1, 2, \ldots, P$; Expected output $d_k, k = 1, 2, \ldots, P$;

Calculate the actual output of the network and the state of HL unit:

$$o_{kj} = f_j\left(\sum_i w_{ji} o_{ki} - \theta_j\right). \quad (1)$$

Training error:

$$\begin{aligned} \delta_{kj} &= o_{kj}\left(1 - o_{kj}\right)\left(t_{kj} - o_{kj}\right), \\ \delta_{kj} &= o_{kj}\left(1 - o_{kj}\right)\sum_m o_{km} w_{mj}. \end{aligned} \quad (2)$$

Corrected weights and thresholds:

$$\begin{aligned} w_{ji}(t+1) &= w_{ji}(t) + \eta\delta_j o_{ki} + \alpha\left[w_{ji}(t) - w_{ji}(t-1)\right], \\ \theta_j(t+1) &= \theta_j(t) + \eta\delta_j + \alpha\left[\theta_j(t) - \theta_j(t-1)\right]. \end{aligned} \quad (3)$$

When k goes through 1 to P, judge whether the index meets the accuracy requirement.

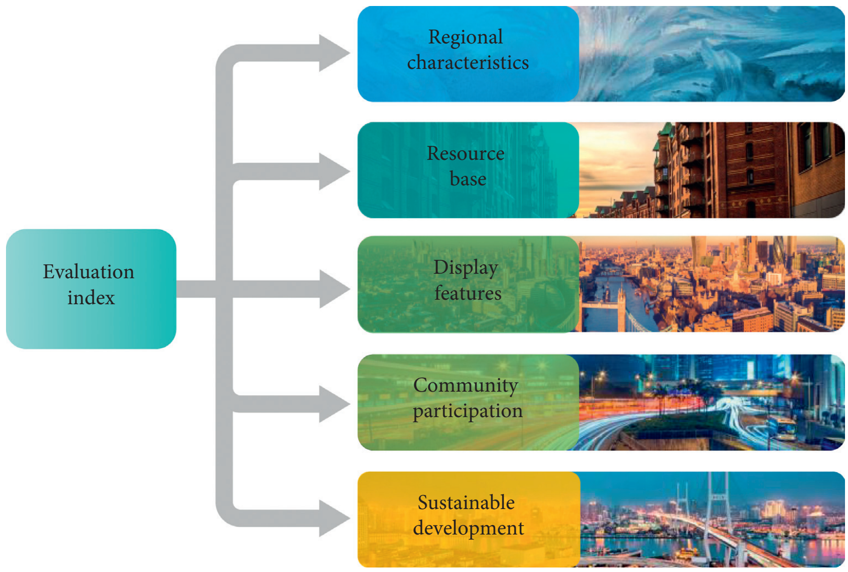

Figure 1: Cultural evaluation index system of famous historical cities.

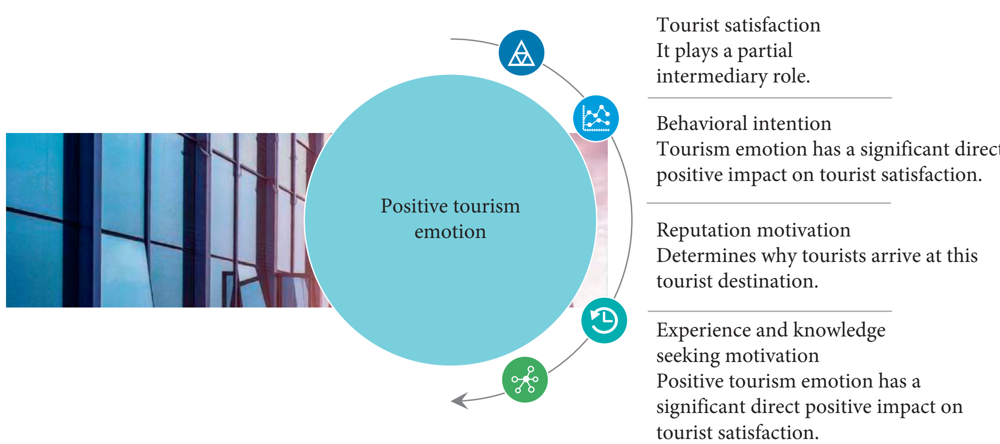

Figure 2: Structural equation model.

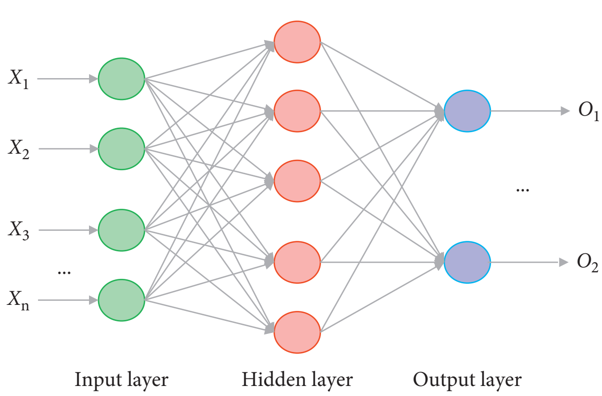

Figure 3: BPNN structure.

3.2.2. Establishment of the BPNN Evaluation Model. To meet the requirements of training error and prediction error, BPNN model training must include a series of constant comparisons between expected value and neural network output value, as well as repeated training and simulation operations. The comprehensive evaluation value of the implementation evaluation of historic city protection planning is obtained using the expert scoring method and is used as the expected value of BPNN model training samples.

The training samples come from 100 randomly generated sample evaluation values. According to the scores, the famous cities are evaluated and divided into five grades: (90–100) as good, (80–89) as good, (70–79) as good, (60–69) as fair and below 60 points as poor. The formula is as follows:

$$P = \sum C_i \times W_i, \tag{4}$$

where P is the comprehensive evaluation value for the protection planning of historic cities, C_i is the single score of evaluation index, and W_i is the weight of evaluation index.

3.2.3. Determination of the Number of HL Nodes. In the process of BPNN training, the weights and thresholds change randomly and change with the training times. The number of HL layers and the number of nodes in each layer will directly affect the training results. By setting the number of HL nodes, the training accuracy will be improved, and the error will be reduced. After debugging for many times, the number of HL nodes that reach the required accuracy and error is finally selected, and this number of HL nodes is the final required number of nodes.

There are many ways to determine the number of HL nodes, which are determined by empirical formula in this paper.

$$m = \sqrt{n + I} + a, \tag{5}$$

where n is the number of IL nodes, I is the number of OL nodes, and a is a constant from 1 to 10, so it is determined that the number of HL nodes is 13.

Each index has its own dimension. In the process of calculation, for the factors with different equivalent levels, dimensionless measures should be taken to make each factor in the same equivalent level. In this case, to make the input factors dimensionless, the actual travel time should be divided by 10 as the input of travel time, and the other seven factors should be converted into smaller values by stages, so as to avoid unnecessary errors caused by large data gaps and improve the training speed and accuracy.

3.2.4. Training Strategy. The sample data are usually divided into two parts when training the network: one part is used for training, and the other part is used to test the training effect. As BPNN is trained using the gradient descent method, the training set's error will decrease monotonically, while the average error on the test sample set will always be higher than the training sets, which will not decrease monotonically. The big trend is that after reaching a certain training level, the error on the training set decreases first, then increases again. As a result, rather than continuing to train until the error of the test set reaches the minimum point, the network usually stops training when the error of the test set reaches the minimum point.

4. Results Analysis and Discussion

4.1. Learning and Training Analysis of the BPNN Method. Shaanxi has a splendid red culture, in which the influence of Yan'an spirit radiates all over the country. Until now, the land of Sanqin has a large number of red cultural resources, including both material cultural resources and historical and cultural heritages, such as revolutionary documents, memorial sites, literary works, cultural relics, revolutionary war sites, and so on. In Shaanxi regional culture, there are many cultural resources rich in popular entertainment and expressive force, particularly some folk arts that are more suitable for media communication. These are priceless gems that must be thoroughly explored and exploited, and brands with distinct label value must be created to ensure strong and effective communication. Furthermore, the development of high-quality content in Shaanxi regional culture must be accelerated. There are some issues right now, such as a low level of innovation transformation, a lack of second creation, and a shallow interpretation.

In traffic mode division, the whole process of BPNN is divided into three steps. First, a suitable neural network must be established. Second, the network should be trained according to the existing input and output data to make the accuracy and error of the network as small as possible. Finally, the output prediction of other input data should be made according to the trained network. Train the network according to the nonlinear function, and get the output of the nonlinear function predicted by the trained network (Figure 4).

It can be seen from Figure 4 that on the basis of training, the remaining 15 pieces of data are used for prediction, and the predicted data basically accord with the expected data, which shows that BPNN algorithm has certain practicability in the research field of transportation mode selection.

Shaanxi's cultural market access conditions are constantly relaxed, but the cultural market order needs to be further standardized. A good cultural market environment is the foundation for the healthy development of the cultural industry. At present, the situation of fragmented, multihead management and fragmented cultural market in Shaanxi exists to a certain extent, which not only increases the difficulty of organizing capital operation but also causes waste and idleness of cultural resources. Cultural development is low and immature, and cultural products lack a standardized market trading environment and have not really formed a perfect market mechanism.

The above case proves that the BPNN algorithm is practical in the research field of transportation mode selection. The traffic sharing rates of Xi'an, Hanzhong, Luoyang and Baoji in Figure 1 are verified by BPNN method (Figures 5–7).

The verification results show that the predicted data of the traffic mode division model based on BPNN algorithm are basically consistent with the actual survey data.

The rich forms and contents of Shaanxi regional culture necessitate rich communication platforms or channels for all-around communication. In today's world, new media, in addition to traditional media, is a must-have communication channel. It is the audience's cultural communication's arrival terminal, so the effect of cultural communication power will eventually be reflected in the audience as the terminal. The investigation of the effect is primarily based on two levels of cultural awareness and recognition. It is necessary to divide the audience into groups, such as those who live in the province and those who live outside of it. Their understanding of Shaanxi regional culture differs, allowing them to communicate more effectively.

The cultural service system is sound. Public cultural facilities are scientifically planned, rationally laid out, and coordinated between urban and rural areas. Large and medium-sized cities have a number of modern symbolic cultural and entertainment facilities with high level, high standard, and unique style. Comprehensive cultural facilities and places for cultural activities at the grass-roots level are fully functional and basically can meet the needs of the masses to carry out regular cultural activities. The cultural service network is sound, with complete functions, wide coverage, and high service capacity and level.

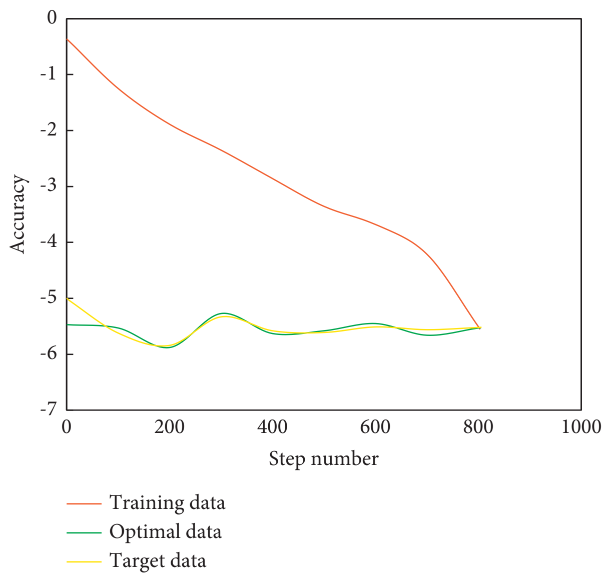

Figure 4: Schematic of BPNN training error.

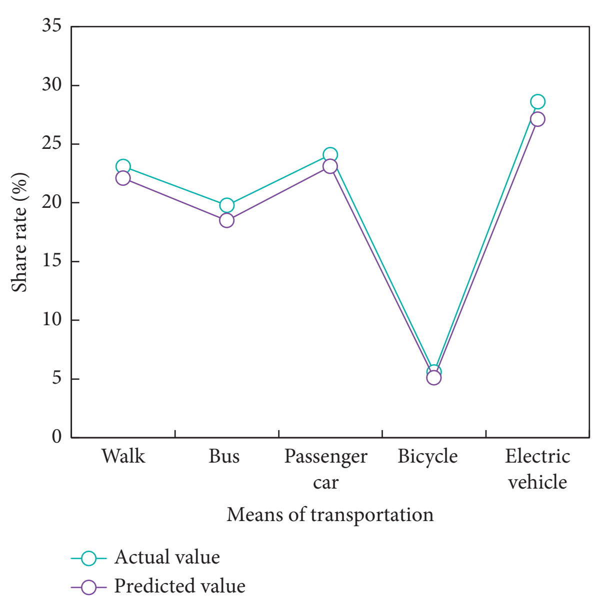

Figure 5: Comparison of Xi'an traffic mode sharing rate.

At present, the dissemination of Shaanxi regional culture is not accurate enough in audience segmentation, which leads to the loss of communication effect. Different audiences have uneven awareness of regional culture, and thus have different recognition of culture. In addition, the content, methods, channels, and skills of cultural communication all have an impact on the final communication effect, and these contents should be based on the accurate research of the audience.

4.2. Evaluation and Analysis of Shaanxi Regional Historical and Cultural Tourism. The research on the tourism competitiveness of smart tourism cities is a hot issue in the current tourism field. Under the development trend of modern tourism with the theme of science and technology and competition, the smart tourism city complex as a tourist destination has a comparative advantage with other smart tourism cities in the competition of tourism elements under the comprehensive action of tourism economic development, scientific and technological innovation, tourism resources, environmental support, geographical location, and other factors.

The tourism competitiveness of smart tourism cities is embodied in five aspects: economic development, scientific and technological innovation, potential competitiveness, environmental support, and development guarantee of smart tourism cities.

According to the established BPNN, relevant training comparison values can be obtained (as shown in Figure 8).

Figure 8 shows that the expected output value is very close to the value of neural network training output value. In other words, the BPNN model can accurately determine the general situation of tourism competitiveness of smart tourism cities according to various evaluation indexes. Therefore, the training of network model is over, and the evaluation model of tourism competitiveness of smart tourism cities based on BPNN has been constructed. When evaluating the tourism competitiveness of other smart tourism cities, only need to enter the normalized data of the evaluation sample index, and the required evaluation conclusion can be obtained.

Based on the results of BPNN evaluation on the competitiveness of smart tourism cities because the competitiveness of each city is different, by comparing other sample cities with those in an advantageous state, smart tourism cities can have an objective understanding of their own level of smart construction and the competitiveness of other cities, identify the gap and take corresponding measures to improve their competitiveness.

After BPNN training, the trained BPNN model is used for testing, and the index data of Xi'an and Shangluo test samples are input into the model, and the output results shown in Figure 9 are obtained.

The error of the test samples is close to the error of the training samples through the trained neural network, and it is assumed that the established network model can effectively approach the training samples based on the test samples in Figure 9. The relative and absolute error values of training and test samples in the BPNN model are also within acceptable bounds. As a result, the BPNN-based evaluation model of smart tourism city competitiveness developed in this paper is effective, and the directly trained neural network can be used to evaluate the competitiveness of other smart tourism cities.

Through the training results of BPNN, the evaluation results of 10 smart tourism city samples are compared and ranked, and the final competitiveness ranking is shown in Figure 10.

The core of culture is certain values and their concrete norms. Shaanxi is rich in cultural resources, but its influence is limited due to insufficient understanding and development. At the important stage of the transition period, it is necessary to fully understand and explore the spiritual

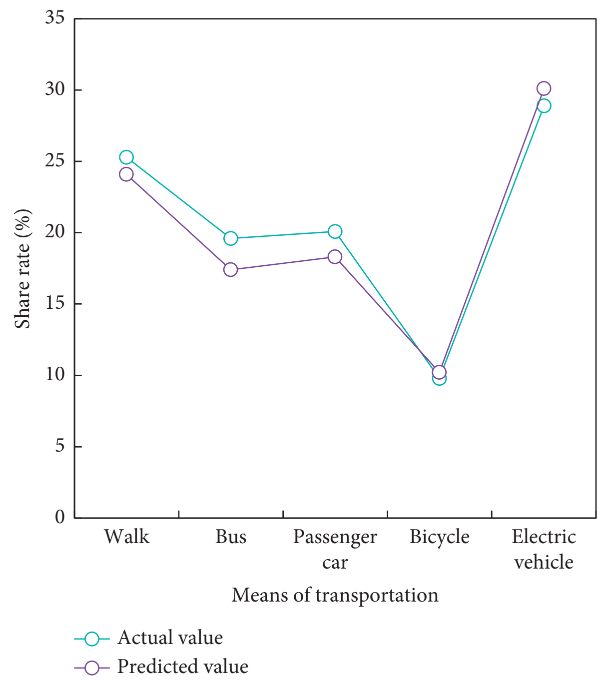

FIGURE 6: Comparison of traffic mode sharing rate in Hanzhong.

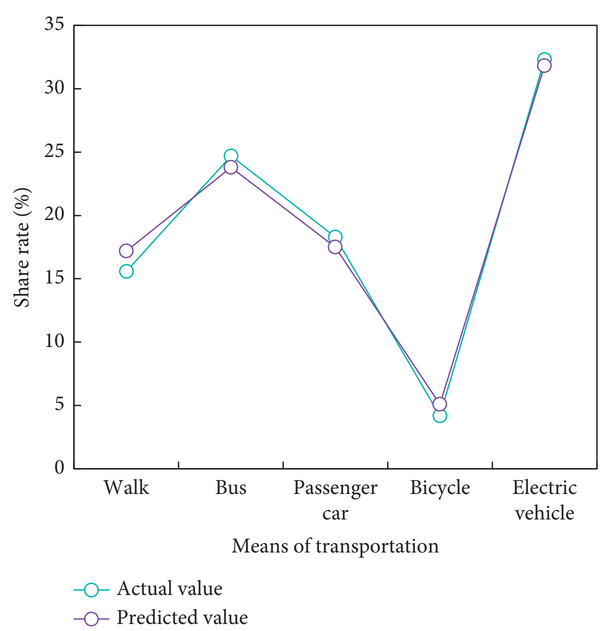

FIGURE 7: Comparison of traffic mode sharing rate in Baoji.

education value of Shaanxi's red cultural resources with Yan'an spirit and patriotism as the main connotation, so as to urge people to reflect on the spiritual emptiness and belief confusion that are prevalent now, draw positive energy from the values, outlook on life and spirit of life of revolutionary ancestors, establish correct value goals and value pursuits, shape social psychology of self-respect and self-improvement, and stimulate initiative and creativity.

Shaanxi is rich in science, education, and culture resources, and it is a big province of science and education, which provides intellectual support and powerful guarantee for the modernization of culture in terms of technology and manpower. The development of culture in the new period cannot be separated from scientific and technological innovation, such as animation industry, film, and television production industry, creative advertising industry and so on, which have highly accumulated scientific and technological content. Give full play to the advantages of Shaanxi education and the strength of science and technology, promote the integrated development of

Figure 8: Comparison chart of expected output and training output.

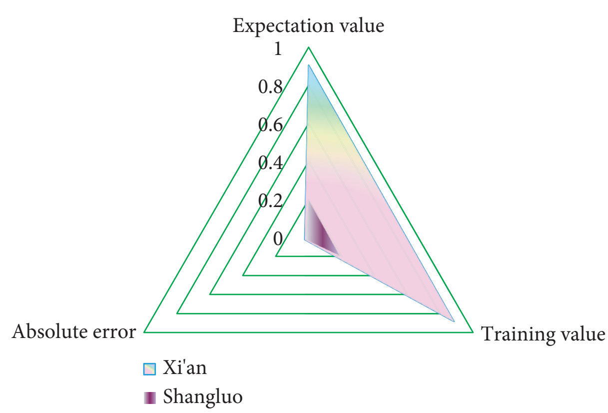

Figure 9: Comparison of output results of test sample expected value and training value.

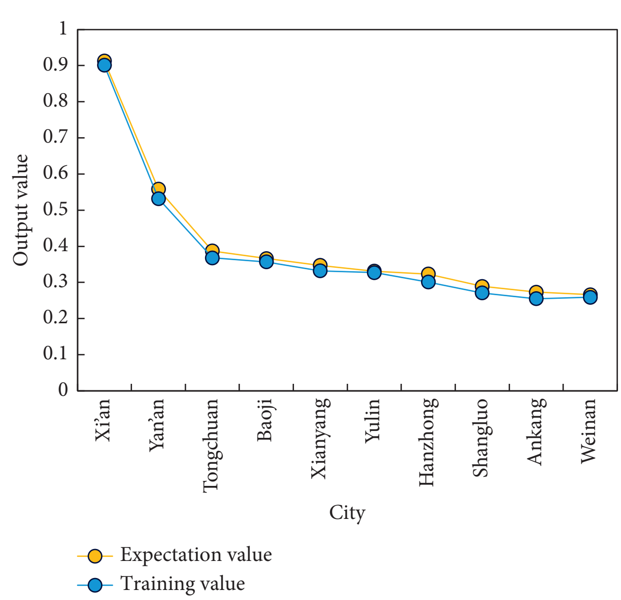

Figure 10: Ranking of evaluation results of tourism competitiveness of smart tourism cities.

enterprises in Industry-University-Research, realize the linkage between cultural industry capital and intellectual capital, and innovate and develop culture with high technology.

Culture and science and technology are the areas that need innovation most. If you plug in the wings of culture and technology, it will accelerate the transformation of culture and science and technology into real productive forces and maximize the cultural value. Shaanxi has both. As long as attach great importance to and develop reasonably, the resources of science and education will certainly promote the prosperity and development of Shaanxi culture.

5. Conclusion

At this new historical juncture, we must deeply comprehend the enormous significance and unavoidable requirements of building a socialist cultural power, adhere to a global and long-term vision, recognize the strategic importance of culture, strengthen the sense of mission and responsibility to promote cultural construction, and strive to realize the Chinese nation's cultural rejuvenation. As Shaanxi has unique and rich cultural resources, it is critical to explore and further revitalize these cultural resources as part of the province's overall economic and social development. The tourism competitiveness of smart tourism cities is evaluated using the BPNN model, and an empirical study is conducted in 10 smart tourism cities. The qualitative and quantitative index data are thoroughly investigated using the designed index system of tourism competitiveness of smart tourism cities. At the moment, audience segmentation for the dissemination of Shaanxi regional culture is insufficient, resulting in a loss of communication effect. Different audiences have varying levels of awareness of regional culture, and thus have varying levels of cultural recognition. Furthermore, cultural communication content, methods, channels, and skills all have an impact on the final communication effect, and these contents should be based on accurate audience research.

Although the BPNN model algorithm used in this paper is the most widely used algorithm in artificial neural networks, the samples chosen in this paper are somewhat fewer due to objective condition limitations, which reduces the accuracy and precision of BPNN model evaluation to some extent. It will be necessary to improve the sample data and the accuracy of data evaluation in future research.

In the fields of traffic management, traffic health, and vehicle safety, vehicle speed prediction is an important research topic. The greater the difference between vehicle speed and average vehicle speed, or the more discrete the vehicle speed distribution, the higher the accident rate. This paper proposes a vehicle speed prediction method based on adaptive KF (Kalman filtering) in the ARMA (Autoregressive Moving Average) environment to address the problem of high-speed moving vehicle speed prediction. The ARMA theory is used to model the prediction of speed time series. The contribution rate of each coefficient representing the original time series is different after fitting the original time series with the ARMA model, so each coefficient must be given a certain weight. Multisource traffic data fusion and interval speed prediction are carried out on the basis of few-shot data preprocessing and traffic state division, according to different traffic states. The speed prediction accuracy is very high, according to the algorithm verification results.

1. Introduction

According to statistics, intersections account for roughly 30% of all traffic accidents [1]. Even when traffic control lights are installed at intersections, deadly collisions caused by illegal activities such as speeding and running red lights still occur. At intersections, drivers must pay attention to influencing factors such as vehicles traveling in different directions, pedestrians, and nonmotor vehicles, as well as the relative positions of their own vehicles, and then make driving behavior decisions in a short amount of time [2, 3]. If the driver can be given some information about his own vehicle's operation ahead of time, it will greatly reduce the driver's driving difficulty at the intersection.

When driving on the road, drivers set their own speed based on the terrain and road conditions [4]. When the road's horizontal, vertical, and horizontal geometric elements exceed the minimum requirements for safe driving of automobiles on this grade of road, and external conditions such as traffic density, terrain, and climate are favorable, the actual driving speed of automobiles often approaches or exceeds the design speed [5, 6]. Entering the intersection and arranging them according to the time mark, according to existing research, can not only reflect the characteristics of drivers' individual driving behavior. Time series differ from ordinary series in that the data are organized in chronological order, and each numerical point has a corresponding time point [7]. These data are generated as part of the day-to-day operations of businesses, hospitals, schools, and other institutions, and they gradually accumulate into a large-scale time series database. The two types of data can be mutually supplemented and verified using data fusion. The accuracy of vehicle speed prediction across corresponding regions will be improved as well.

The above-mentioned contents are the focus of this paper. ARMA (Autoregressive Moving Average) predictive modeling was used [8]. The time series of vehicle speed generated when the object to be evaluated (own vehicle) and the vehicle in the direction of conflict (other vehicle) drive to the intersection at the same time serves as the evaluation basis and modeling data. The modeling data come from a real-world vehicle driving test. Multisource traffic data fusion and interval speed prediction are carried out according to different traffic states using data preprocessing and traffic state division.

2. Related Work

The purpose of travel time prediction is to use historical and real-time distance, speed, traffic flow, travel time, or some variables mathematically related to travel time to obtain the travel time of vehicles that will leave at a certain time in the future and whose starting and ending points are determined [9, 10]. These known variables can be obtained through equipment collection, estimation, or prediction [11]. In the process of predicting the travel time of expressway, combining the travel time of different sections in different time periods, the traffic operation conditions of different sections are obtained, and the results are extended to the whole section of expressway, and the final travel time prediction result is obtained, with a good result of about 10% error%. Literature [12] studies the daily travel time model and applies linear regression and tree model to travel time prediction. The input parameters include traffic flow information, occupancy data collected by single-loop detector, and historical travel time information (Literature [13]). Using the data collected by point traffic detectors, a short-term expressway travel time prediction method is mined. They took into account the spatial and temporal changes of traffic data and made use of the traffic measurement data collected from different places at the current moment and different places at the historical moment to do this [14]. Using the ARIMA model to determine the potential hot spots of taxis, in the process of research, they regard the demand of passengers for taxis as a simple linearly changing structure, so only linear models are used to predict. Literature [15] puts forward a model for forecasting service demand, which is suitable for a single taxi station. The use of traffic flow data in the forecasting process is a comprehensive place for them to consider, and the model can be used for real-time forecasting in online environment. However, according to their research ideas, different taxi stations in the same city must carry out different model training in order to achieve more accurate prediction results.

The speed information of vehicles before entering the intersection can be used as the basis of vehicle collision risk assessment at the intersection. Literature [16] studies the probability model between the speed of vehicles heading for the intersection and the occurrence of collision accidents, and there is a clear correlation between the speed and the acceptable gap in the workshop. Literature [17] puts forward a dynamic model and a communication model between vehicles after analyzing the characteristics and process of traffic conflicts at signalless intersections and sorts out a set of algorithms. Finally, the effectiveness of the algorithm is verified by computer programming simulation. Literature [18] developed a speed control device for vehicle turning left at intersection. Finally, the simulation results show that the device can really improve the safety of vehicle turning left at intersection. Literature [19] puts forward two strategies of setting left-turn phase and left-turn waiting area at intersections to improve the traffic quality at intersections. Literature [20] found that the intersection conflict simulated by software or model is very suitable for the actual intersection conflict research. Literature [21] holds that the occurrence of traffic accidents is mainly caused by the driver's mistakes, and the driver carries out a series of driving actions for a certain purpose, but the original driving intention cannot be realized due to the operation mistakes. Literature [22] establishes a hidden Markov model based on the pedal opening of the vehicle and the position information of the vehicle, so as to determine the intention that the driver really wants to achieve. Reference [23] establishes a hidden Markov model to infer the driver's intention when the vehicle deviates to different degrees. The final reasoning result is applied to the control device of the vehicle, which increases the safety of the vehicle when driving.

In order to determine the driver's driving intention, all types of state data must be collected, and an identification model must be established during the analysis of the driver's driving. The challenge is deciding what kind of data to collect, or choosing the feature vector for modeling. The difficulty of model building and the time it takes to identify a model can be reduced if the feature vector dimension is too small. However, the model's accuracy will deteriorate. Furthermore, collecting characteristic data in the actual driving environment of some vehicles is quite difficult. As a result, selecting the appropriate feature vector is critical in the study of predicting a driver's driving intention.

3. Research Method

3.1. Vehicle Speed Time Series Analysis. It is a critical variable in the field of speed traffic, and vehicle driving speed is a key index for reflecting traffic operations, and the driving state of floating vehicles can best reflect traffic operations over time. The traffic situation is constantly changing in real time, and the travel time of vehicles is directly influenced by the current traffic situation. As a result, understanding how to convert and correlate vehicle and traffic driving conditions, as well as how to display the short-term operation of traffic using appropriate variables, is critical. Under such conditions, road speed is generated.

In the research, this model is mainly used to calculate the traffic conditions before vehicles enter the expressway. When it is necessary to predict the travel time, the estimated travel time, the estimated starting point, and the expected ending point of the vehicle are all known. After getting the speed of the road section before the estimated travel time, then can know the traffic conditions during this period. At the same time, from the second 5 minutes to the first 5 minutes before the trip, one can get a general understanding of the changes in traffic operation. For the known estimated travel time, calculate the speed of each road segment within the first two 5 minutes of the trip, and arrange the speed of each road section according to the front and back position of the road section, so as to obtain the preliminary input characteristics.

In practical application, the complexity and unstructured degree of time series are very high, which forces the research to continuously improve the accuracy and applicability of time series mining algorithm. In reality, time series exists in all aspects. Finding the hidden rules and patterns from these complex data and finally serving for decision-making is the main purpose of data mining.

In the past research, the ARMA model was mostly used in forecasting. This paper mainly uses the ARMA model to extract features of time series. Determining the time series $\{X_t,\ t = 1, 2, \ldots, n\}$ can fit the ARMA model. We can find the basic model type judgment diagram in Figure 1.

If the accurate optimal value of (p, q) cannot be obtained by using autocorrelation function and partial autocorrelation function, AIC (Akaike information criterion) can be used to determine the order, which is a standard to measure the fitting effect of the model.

Increasing the parameter variables of the model will reduce the deviation between the estimated value of the model and the actual value, so that the model can better fit the original data. However, increasing the number of parameter variables will increase the complexity of the model, so the cost of increasing the variables should be punished.

The fitting ARMA model can be defined as follows:

$$\mathrm{AIC} = (p, q) = N \ln \sigma^2 (p, q) + 2 (p, q), \tag{1}$$

where N is the sample size, $k = p + q$ is the number of parameters in the ARMA model, and σ^2 is the estimation of noise variance.

BIC (Bayesian information criterion) is also a judgment criterion, which is expressed as follows:

$$\mathrm{BIC}(p, q) = N \ln \sigma^2 (p, q) + (p, q) \ln N. \tag{2}$$

The principle of this method is the same as that of AIC, but it increases the intensity of “punishment.” It can be seen that both of these criteria advocate the concise form of functions and use fewer variables to represent functions. When the number of samples is large, BIC principle is more effective, and AIC principle determines relatively many model parameters, so it is more suitable for small samples.

Check the autocorrelation and partial correlation between scattered data in time series data X_t. By observing the distribution of autocorrelation and partial correlation function values, if the distribution curve accords with the characteristics of “tailing” and “truncated,” it shows that the series is suitable for establishing the ARMA model. The calculation formulas of autocorrelation R_k and partial correlation function $\phi_{k,k}$ for correlation judgment are as follows:

$$\begin{cases} R_k = E\left[X_t, X_{t-k}\right], \\ \phi_{k,k} = \dfrac{E\left[X_t, X_{t-k}\right]}{\sqrt{E\left[X_t\right]^2, E\left[X_{t-1}\right]^2}}, \quad k = 1, 2, \ldots, n. \end{cases} \tag{3}$$

If the time series data do not meet the correlation requirements, it is necessary to perform differential, differential, or logarithmic operations on the data used for partial scatter points in X_t and then continue the subsequent steps when it becomes a stationary data series.

Select the appropriate p, q value to establish the analytical formula of ARMA model, and use the AIC rank criterion to determine the p, q value, even if the following formula is the minimum value:

$$\mathrm{AIC} = \min\left[N \cdot \ln \delta_k^2 + 2(p + q + 1)\right], \tag{4}$$

where N is the capacity of the selected speed sample and δ_k^2 is the residual variance of the model, that is,

$$\delta_k^2 = \sum_{k=1}^{N} \frac{\varepsilon_k^2}{N}. \tag{5}$$

If the absolute values of residual autocorrelation functions of the prediction results are less than $2/\sqrt{N}$, it indicates that the ARMA model meets the prediction requirements.

In general, data can be divided into numerical and nonnumerical types of characteristic attributes. These two types of filling are treated differently by the mean filling method. The missing values for numeric attributes will be filled using the average values of the attributes in other nonmissing samples. Fill in the values with the most frequent occurrences in the nonmissing samples, that is, the values with the highest frequency, for non-numeric attributes, according to the mode principle.

From the entire sample set, choose the road section speed that corresponds to the recorded road section and save it as the new adjacent road section sample set. Then, using a hierarchical clustering algorithm, this portion of the data is clustered, the centroid of each cluster is calculated, and the cluster centroid that is closest to the speed of the road section near the missing position is found. The values of data samples in the missing positions in the cluster are filled in the missing fields. This completes the missing item’s filling.

3.2. Vehicle Speed Prediction. At present, the prediction method generally uses the previous historical data, taking the day as the cycle, extracting the change rule of traffic parameters from it, and applying the extracted rule to the current time, thus obtaining the prediction result. According to the comprehensive evaluation of the previous traffic state dividing thresholds, the specific dividing standards are determined.

After dividing the continuous traffic data into traffic states, the traffic data belonging to different traffic states are classified. According to the historical traffic data of each traffic state, the state transition matrix required by the KF (Kalman filtering) method is trained by the artificial neural network, and then the interval speed prediction based on data fusion is carried out by the KF method.

In the ARMA environment, the dynamic performance of high-speed moving vehicles is very high. Therefore, when the parameters change little, we use a larger adaptive forgetting factor μ_k to increase the prediction strength. When the parameters change greatly, a small adaptive forgetting factor μ_k is used to enhance the identification accuracy. The

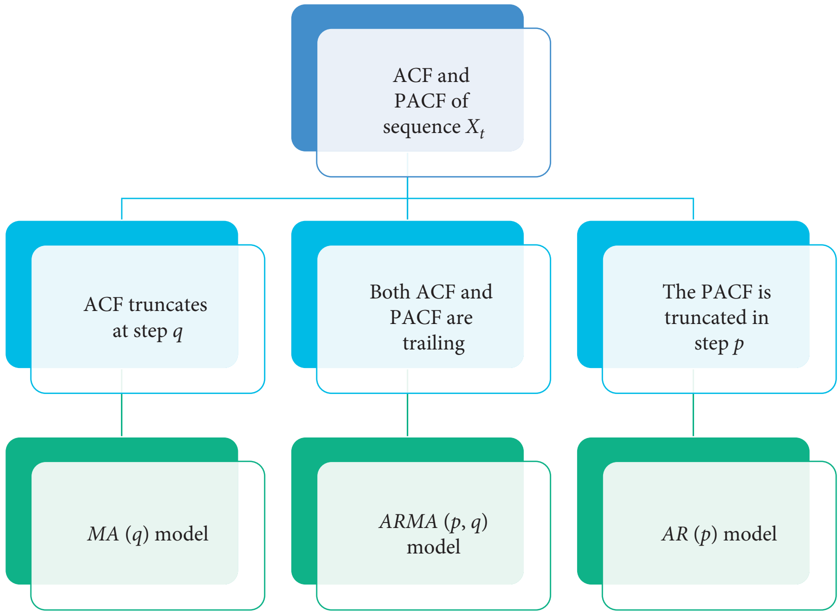

FIGURE 1: Basic model type judgment. ACF is autocorrelation function, PACF is partial autocorrelation function, MA is the moving average model, and AR is the autoregressive model.

formula of adaptive forgetting factor used in this paper is as follows:

$$\mu_k = \max\left\{1, \frac{tr(G_k)}{tr(H_k)}\right\}. \tag{6}$$

The core idea of memory decay is to apply a factor to the covariance matrix of prediction and increase the variance of prediction state vector, so as to make full use of the current measurement data.

$$G_k = M_k - CQC^T - R. \tag{7}$$

In equation (7), G_k and M_k represents the error variance at time k.

$$H_k = CAP_{k-1}A^T C^T. \tag{8}$$

In equation (8), H_k represents the error variance at time k, which ensures that the value of the error covariance matrix P_k is symmetric and positive, and improves the dynamic performance of the system.

In this paper, the flow of speed prediction operation of high-speed moving vehicles based on adaptive KF in ARMA environment is shown in Figure 2.

The contribution weight also plays a role in reducing dimension and simplifying operation to a certain extent. On this basis, this paper puts forward a new similarity measurement standard, and the process of clustering analysis becomes the following steps.

Using the ARMA model to fit the model, the time series will be represented by a set of coefficient vectors. Namely, the time series X, Y, and the parameter vectors of the fitting model are π_X, π_Y, respectively.

Find the contribution rate $(\alpha_1, \alpha_2, \ldots, \alpha_m)$ of the first m coefficients whose cumulative contribution rate reaches a certain percentage and then calculate the weight $\beta = (\beta_1, \beta_2, \ldots, \beta_m)$ of these m coefficients, where β is the weight vector and i represents the i th coefficient:

$$\beta_i = \frac{\alpha_i}{\sum_{i=1}^{m} \alpha_i}. \tag{9}$$

The newly obtained coefficient vectors are standardized, their Euclidean distance d_μ is used as similarity measure, and the corresponding clustering method is used to recluster, and finally the clustering result is obtained.

$$d_\mu = \sqrt{\sum_{k=1}^{m} (\mu_{Xk} - \mu_{Yk})^2}. \tag{10}$$

Due to the weekly similarity of traffic data, historical data with the same weather conditions in the same week as the forecast date in the last week were selected in the study. If the weather conditions are different, select the data of the same week last week. If the weather conditions are still different, select the data of the adjacent Sunday of last week.

Because the one-dimensional median filter is less affected by the contour of image samples, and the noise suppression effect of the two-dimensional median filter is obviously better than that of the one-dimensional median filter when the contour of image is not considered, one-dimensional and two-dimensional median filters can be used alternately when filtering. In addition, during filtering, the image can be iteratively filtered to get the optimal solution.

4. Results Analysis and Discussion

4.1. Modeling and Analysis of Time Series Prediction. Design the real vehicle driving data collection test according to the vehicle collision situation. The driving area is selected at the intersection of a newly built municipal road, and it is

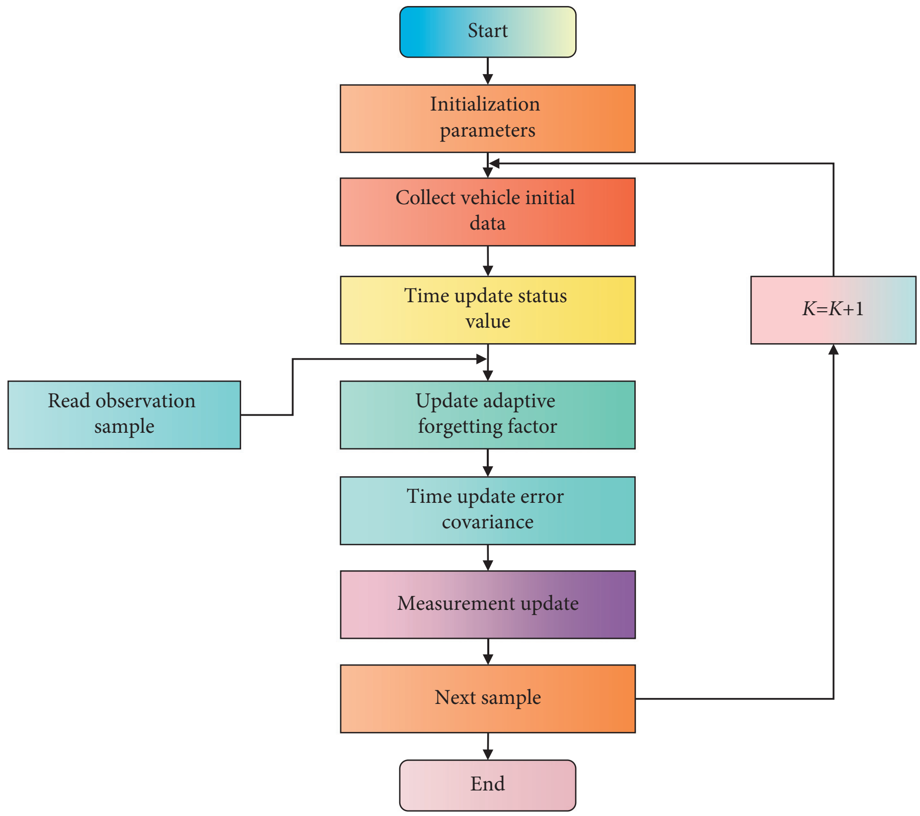

Figure 2: Adaptive KF speed prediction flow chart.

required that the road connecting the intersection should extend long enough, have a wide field of vision, and have small traffic flow. Motor vehicles 1 and 2 in the direction of conflict use the same type of small cars, and the vehicle speed is collected once every 1 s by the vehicle driving behavior test platform and stored in chronological order.

After the vehicle stops, determine the position of the collision point according to the traveling direction of the vehicle and measure the distance from the starting point to the collision point, as shown in Figure 3.

In straight-line sections, drivers will first choose between three types of traffic crossing options based on their destination and intersection design: straight, left, or right. The external information, such as traffic lights/signs, other vehicles, pedestrians, nonmotor vehicles, roads and obstacles at intersections, weather factors, and so on, is primarily received visually. The driver will adjust his speed to prepare for entering the intersection based on the above factors. The driver primarily uses the accelerator and brake pedals to adjust the speed of his own car on the straight road section.

The driving in the straight-line section and the driving in the intersection follow each other on the time axis. The purpose of driving on the straight road section is to prepare for driving in the intersection, so the speed fluctuation on the straight road section reflects the driver's turning preparations.

If you go straight through the intersection, the driver's main gaze targets are the vehicles and traffic lights ahead. Compared with the other two turning modes of crossing, the influencing factors of straight-through crossing are relatively simple. However, the change of traffic lights directly affects whether the vehicle stops or not. Therefore, the speed of straight-through traffic varies greatly.

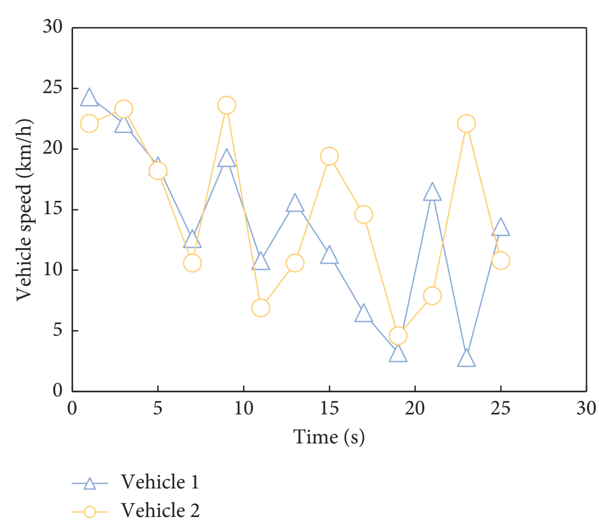

Figure 3: Time series of vehicle speeds 1 and 2 obtained from the real vehicle driving test.

Comparing the degree of difference between the curves in Figures 4 and 5, it can be seen that the prediction model [20] established by using the first 40 data in the vehicle speed series obtained from the experiment has a better prediction effect on the last 20 vehicle speeds.

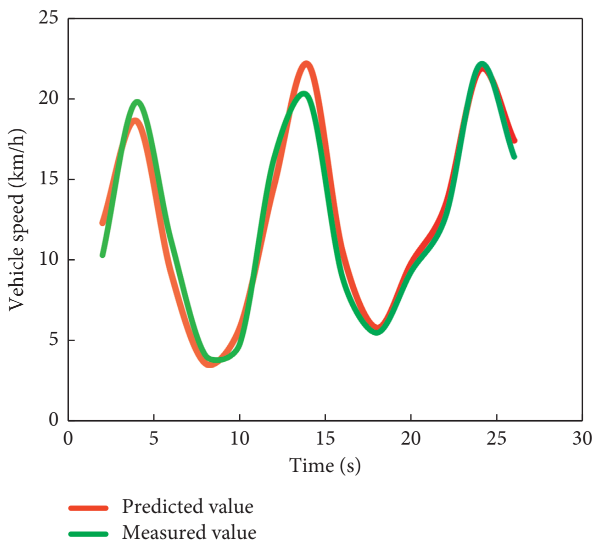

FIGURE 4: Comparison between predicted value and measured value of vehicle 1.

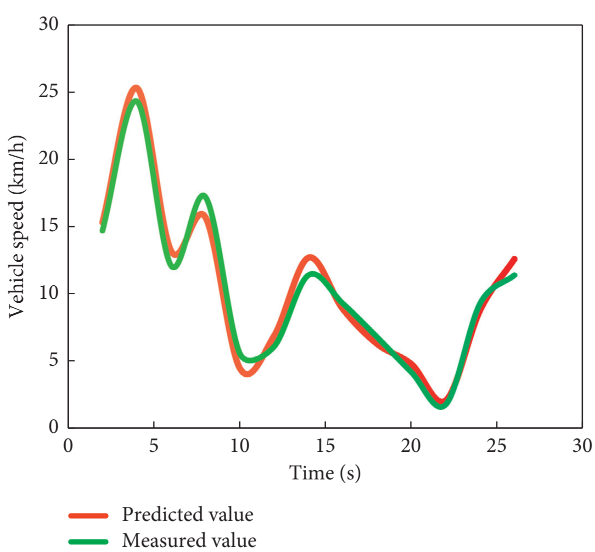

FIGURE 5: Comparison between vehicle 2 predicted value and measured value.

The vehicles run continuously in space, and the number and types of vehicles passing through different sections of each test section are basically the same in the same time period. However, for different observation points on the same section, the composition structure of vehicle types has spatial differences. In the process of driving on the expressway, certain drivers will frequently change lanes in order to choose the best route. This reflects the change of running speed in the direction.

By studying the speed change of different drivers when driving vehicles through the combination of curve and slope of the test section, the main influencing factors of drivers' driving behavior in the curve are found, so as to prepare for the later study of the running speed distribution characteristics of typical sections.

4.2. Verification and Analysis of Prediction Results. The vehicle will be acted on by centrifugal force pointing to the outside of the horizontal curve while driving on a curve. To improve the vehicle's lateral controllability, the driver typically slows down when entering the curve. The longitudinal stability of the vehicle is also involved in curve driving because the vehicle will decelerate when decelerating and the longitudinal stress will change. The safety of the entire route is largely determined by the quality of the curve's design, and curve speed characteristics have always been the focus of running speed research.

Because of the complexity and diversity of highway alignment composition, there are some differences in the running speed of entering the slope section, which affects the running speed of different sections on the slope section. Set at the longitudinal slope's beginning, middle, and end points, and increase the position section of the minimum sight distance point in the vertical curve section. You can track the vehicle to record the speed if the slope length is less than 800 meters. One person stands at the bottom of the slope or at the top of the slope, measuring the speed with a speed gun. Follow two people and keep track of their speed in two different directions. Because the speed measuring range of a radar speed measuring gun is limited when the slope is longer than 800 meters, more speed measuring personnel should be equipped. Record the relevant alignment and road surface parameters, roadside conditions, and road surface conditions of the point after the speed measurement test is completed, and take photos.

In the simulation experiment, three methods are used to predict the speed of high-speed vehicles. The predicted results of simulated vehicle speed are shown in Figures 6–8.

It can be seen from Figure 8 that during the whole iteration process, the maximum error between the actual running speed of the high-speed moving vehicle and the estimated speed based on the least square method is ±4 and fluctuates up and down here.

The original data obtained from the test include mileage, speed, and acceleration, which are continuously changing with the mileage. This paper mainly studies the distribution of running speed on curved slope sections, which are divided strictly according to the pile number. Therefore, the data obtained from the test should first be recalibrated according to the station number, so as to approximately get the continuous running state of vehicles on different sections.

The test shows that the mileage measured by the instrument is shorter than the actual pile number mileage. This is because the road pile number is based on the actual distance of the road centerline, and the instrument measures the actual mileage of the vehicle. However, when driving the vehicle, it is impossible for the driver to drive in strict accordance with the direction of the road centerline marking. Skilled drivers will often change lanes and choose shorter routes.

This kind of error caused by the driver's route selection is objective and inevitable in the test process, but the data can be recalibrated by setting special marking points, which are hereinafter referred to as "reference points." Data calibration is actually an artificial dispersion of experimental errors, and

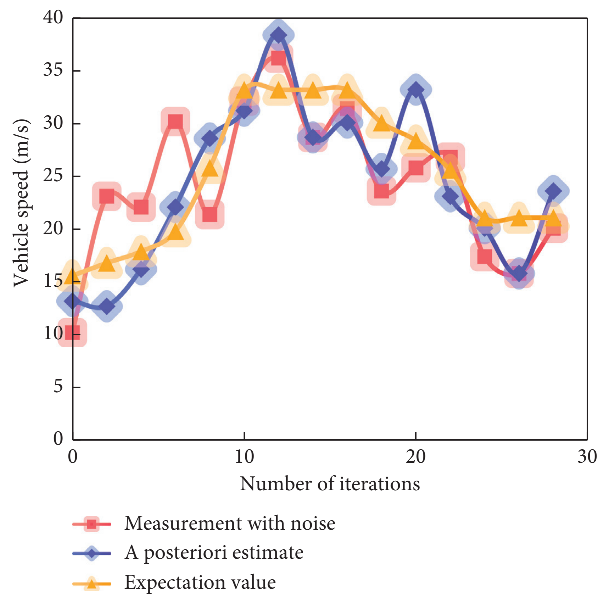

Figure 6: Speed prediction effect of the least square method.

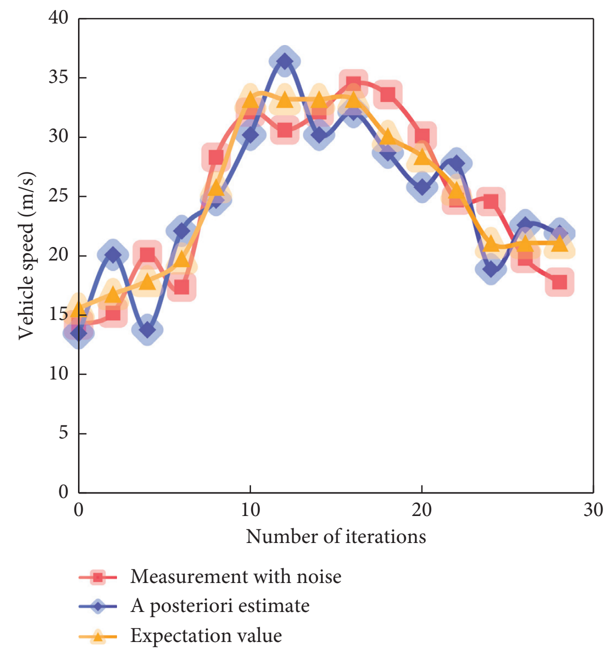

Figure 8: Speed prediction effect of adaptive KF.

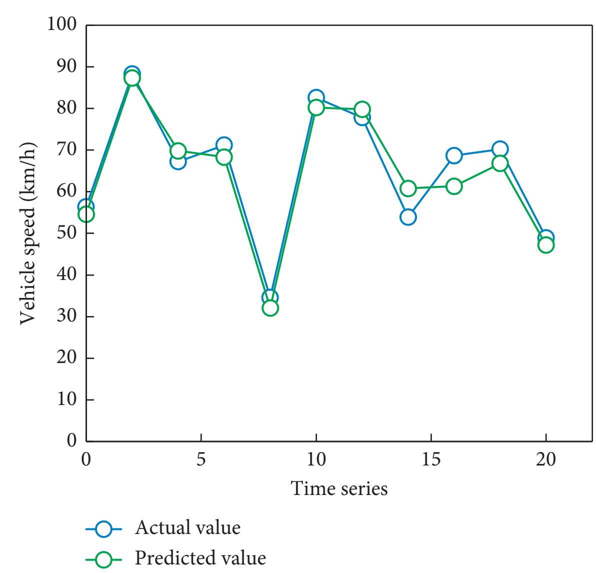

Figure 9: Comparison chart of data verification results.

the influence of this error can be reduced by increasing the number of "reference points" (Figures 9 and 10).

It can be seen from Figure 9 that the change trend of the predicted value is basically consistent with that of the real value. It can be seen from Figure 10 that the maximum relative error is 7.4, the error between the predicted result and the true value is small, and the predicted result is relatively accurate.

If you want to turn left through the intersection, the factors affecting the speed are more complicated than when you go straight through. Drivers should not only pay attention to the changes of traffic in intersections but also pay attention to the flow of people and nonmotor vehicles on crosswalks. According to the traffic rules, even if the traffic lights indicate that you can turn left, there are pedestrians and nonmotor vehicles crossing the street at the crosswalk.

The essence of the running speed method is to ensure the smooth and continuous running speed by controlling the gradual transition of the unit index values of adjacent road sections, thus improving the driving safety of the highway. In practice, the designer checks the consistency and coordination of technical indicators along the route direction through the running speed curve. If the vehicle speed curve under a certain set traffic volume is calculated, not only can you get the travel time between the start point and the end point, provide reference for road users' travel, but also

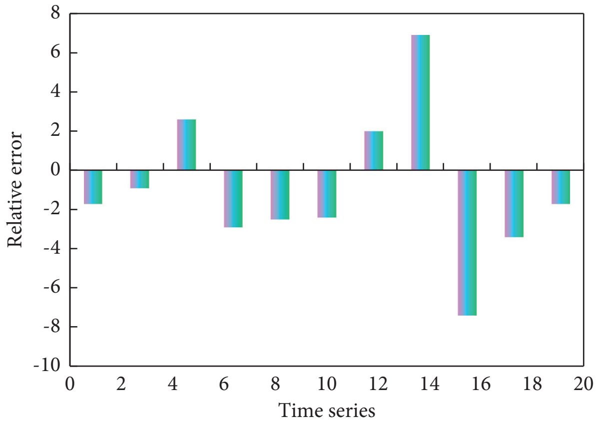

Figure 10: Relative error diagram of data.

measure the service level of the road, and then judge whether the design expectation is met and whether it is necessary to rebuild, expand, or build parallel lines.

5. Conclusion

This method improves KF's tracking ability by allowing it to record and predict the speed of high-speed moving vehicles in harsh environments, curves, uphill, and downhill. The predicted vehicle speed value is used to calculate vehicle displacement and distance between vehicles, which can be used to assess the risk of collisions in intersections between vehicles traveling in opposing directions. The research object is an ARMA model with a zero-mean random sequence. The simulation results show that the adaptive KF vehicle speed prediction method based on ARMA predicts values that are closer to reality, which improves the filter's convergence effect and reduces the fluctuation range, effectively overcomes the negative effects of process and measurement errors, and better reflects real-time effectiveness.

The vehicle speed prediction modeling and parameter tuning are done off-line, which is a flaw in this study. The ARMA modeling parameter self-tuning method and its implementation algorithm should be considered to help the prediction model adaptively adjust parameters to cope with changes in the driving environment, in order to improve the model's universality. The work described above will be continued in the follow-up study.
