Faced with the AI (artificial intelligence) era, it is both theoretically and practically important to examine the challenges and opportunities that vocational college education in China faces, as well as to actively explore how vocational college education can overcome the challenges and achieve a realistic path. This paper proposes and implements a wireless network-based vocational college talent management system. The main personnel management system primarily completes business operations related to daily personnel file management, while the data mining subsystem mines talent data using the DT (decision tree) classification algorithm to aid talent selection. At the same time, a new topology optimization algorithm based on the principle of minimum rigidity graph is proposed for talent management system wireless network optimization. The maximum-minimum balance criterion and the user-by-user optimization mechanism are designed to obtain the optimal relay selection and subchannel allocation strategy, ensuring the system's reliability and fairness. The optimized algorithm has a user security satisfaction of 0.93 in the range of 250 m, which is higher than other algorithms. It demonstrates that this algorithm's communication link is short, and it has good network connectivity and structural stability.

1. Introduction

The essence of the reform of vocational talents training education mode is to change the types of talents to meet the needs of different types of talents in different periods and societies. Talent training mode mainly includes training objectives, training norms, training methods, and finally what kind of people to train. In recent years, Internet giants have devoted themselves to the research and development of driverless technology, constantly exploring and innovating, realizing the integration of AI (artificial intelligence) [1] and traditional automobile technology, which has triggered people's endless reverie of future intelligence. From the perspective of the AI era, people gradually realize that innovative engineering and technical talents are more in line with the needs of this social and industrial transformation.

Only by deeply studying the basic theory of vocational college education can we formulate scientific policies and guidelines to guide the development of vocational college education. As the standard and requirement of training talents in schools at all levels, the goal of training talents is of great significance to the whole education and the development of specific majors in specific schools. Stukalina pointed out that the typical application of AI in education mainly includes intelligent tutors assisting individualized teaching and learning [2]. Ginsburg et al. studied AI as a course and pointed out that it is of great significance to carry out AI education courses in vocational colleges [3]. Leńko-Szymańska suggested that AI should also play a role in motor skill learning [4]. He pointed out that many learning tasks need to be completed through repeated movements, such as learning to write, draw, play musical instruments, practice motor skills, dance, and use sign language. Derosa et al. believe that "standardized work" is easily replaced by AI, while creative work and those with "emotional color and artistic creation" are difficult to replace, resulting in the phenomenon of "intermediate skills being squeezed" [5]. Filho et al. think that we should improve the combination of production and learning, combine "decentralized teaching" to innovate the classroom, and construct an effective interdisciplinary compound model [6].

AI is essentially a technological revolution. When artificial intelligence (AI) continues to profoundly influence and change human production and life, vocational college education, as one of the factors of production, will inevitably be forced to actively consider how to deal with AI's arrival [7, 8]. Although AI is not human intelligence, technology products that contain AI act as a "carrier" for human intelligence, allowing them to think like humans and even surpassing human intelligence. This paper discusses the causes of some problems that exist in the innovation and development of engineering and technical talents in reality and offers suggestions for cultivating innovative talents, based on the fact that a new generation AI technology has entered the application stage. The following two aspects of this paper's innovation: (1) this paper constructs a vocational college education talent management system with a wireless network by studying the application of DT technology in talent management and using wireless network technology, with the goal of assisting enterprises in making talent management decisions and (2) the topology optimization algorithm is used to design and optimize the system database objects during the development process. It increases the readability of system design documents and provides a solid foundation for the system's implementation.

2. Related Work

2.1. Talent Management Research. With the continuous development of science and technology, mankind has gradually entered the era of the knowledge economy. In the era of the knowledge economy, it means that the development and renewal of knowledge become more and more valuable. As an important factor of production in people's lives, it has been widely accepted by people. The goal of talent cultivation plays a very important role in the whole vocational college education system. It is not only the starting point of practical education activities but also the standard to evaluate the success of a school. Judging from the orientation of talent training objectives, talent training objectives can be divided into national, higher vocational, and professional training objectives.

Zheng et al., from the perspective of AI's development's demand for social talents and its impact on the employment of vocational college graduates, discussed how vocational colleges should innovate the talent training mode to promote the talent training of vocational college education to adapt to the new market demand as soon as possible [9]. Sun et al. defined the training goal of higher vocational talents as training knowledge-based skilled talents, who have both a high level of professional theoretical knowledge and a high level of operational skills [10]. Chen analyzed the factors influencing the change of talent training objectives from five aspects, namely [11], the change of social and economic development mode, the transformation and upgrading of industry and the changes and requirements of market demand, the basic law of higher vocational colleges' education, the value pursuit of higher vocational colleges' education, and the change of social talent view. Dong et al. put forward the strategies to improve the training objectives of educational talents in higher vocational colleges under the reform of the education supply side: strengthening specialty construction, strengthening the integration of production and education and school-enterprise integration and reforming the school-running mode [12]. Yang said that if education cannot make the workforce acquire new skills in time, the mismatch between the skills required by new technologies and those provided by the workforce will hinder the transformation [13]. Wei and others think that both teaching and practice should be devoted to innovation [14]. Jian believes that compound talents should be cultivated in the AI era [15].

2.2. Research on Wireless Network Optimization. Wireless network optimization is a series of processes to obtain relatively stable network coverage, capacity, and quality through certain economic investment so as to obtain better performance. For wireless sensor networks with limited power, topology optimization can reduce power consumption, prolong the life cycle of the network, improve the stability of communication link structure, and make the network better used in a complex environment.

Sagduyu et al. proposed a four-level clustering algorithm, which considered the problem of residual energy between nodes, built a hierarchical link structure, and improved the network load balance [16]. However, when more clusters are generated, the node degree of the head node will increase rapidly, which will affect the connectivity of the sensor. Xiao et al. proposed a robust control algorithm, which introduced the node scheduling adjustment factor and quantified the network node degree, sought the value rule of the node degree, obtained the optimal node degree of the network, and improved the balance of the network structure [17]. A method of network positioning based on stiffness matrix characteristics of the rigid graph is proposed. In the positioning process, the selection of positioning points and the construction of the network improve the eigenvalue of the stiffness matrix of the generated network, which improves the stability of the network structure on the premise of ensuring network connectivity. However, the influence of link weights on network lifetime is not considered in the algorithm.

Zhang et al. proposed a joint power tying and subchannel allocation algorithm, which can improve the capacity of the Femtocell network and protect the communication service quality of macrocell users [18]. Wang et al. have done relevant research on soft frequency reuse technology in home base station network [19]. This technology has improved the degree of reuse. Based on Wang's noncooperative game theory, the energy efficiency of a mobile communication network is maximized by appropriate power control strategies [20]. Singh et al. proposed a noncooperative game power control algorithm to optimize the network energy efficiency. In order to reduce the complexity, the author adopted distributed solution, which effectively reduced the algorithm complexity while improving the network energy efficiency [21]. Daniel et al. put forward an energy-saving subchannel allocation strategy, but this strategy does not consider the interference to neighboring cells and is not suitable for multicell scenarios, which has certain limitations [22]. Kakadia et al. put forward a medium-sized node selection strategy based on the principle of minimum outage probability, which improves the total capacity of the system and reduces the outage probability by selecting the relay with the minimum outage probability from end to end for forwarding service [23].

3. Methodology

3.1. Design of Educational Talent Management System in Vocational Colleges Based on Wireless Network. Workers in the AI era will most likely be product designers, producers, or sellers. Workers will learn how to not only understand technology but also how to maintain and debug products, as well as how to communicate with various customers to meet their needs. Many traditional industries are disappearing in the AI era, with the rapid development of science and technology, as well as the continuous application of industrial robots, while many new industries emerge. To adapt to changes in industry structure, vocational colleges should actively adjust their career scenes in response to changes in market talent supply and demand. The traditional management system falls short of meeting the modern talent management business needs. The new system, which is based on the old system, absorbs new user requirements and can meet those requirements in the workplace. As a result, the system's feasibility is strong, and it is critical to improve user satisfaction and employee productivity.

The requirement to adapt to the transformation of business forms in the AI era is to discover new technologies with creativity. Engineering and technical professionals with advanced technologies and a knack for technological innovation are unquestionably in demand. Only engineers with such abilities will be able to stand out in a sea of technological change and gain the first opportunity for personal growth. New tools, new applications, new methods, and so on will continue to emerge as new technologies inspire and support them. Engineers must make efforts in all aspects, whether in the chemical and pharmaceutical industry or in the construction and processing industry. Only in this manner can technical capability and business level meet real-world requirements. The SaaS (software-as-a-service) model is a new software application model that is gradually emerging against the backdrop of the continued maturation of application software and the in-depth development of Internet technology.

The SaaS model has the following advantages:

(1) Each unit does not need to be equipped with special professional technicians to maintain the system. At the same time, access to the latest technology applications to meet changing needs;

(2) There is no need for each unit to build its own management platform, and there is no need to consider issues such as cost depreciation and subsequent platform upgrade, which can effectively alleviate the pressure of insufficient funds.

In a word, building a talent management system using SaaS model can greatly reduce the burden of building and maintaining infrastructure and applications in each unit. All units can rely on the unified management platform of provinces, cities, and counties to use management software conveniently, without a large amount of hardware and software investment.

According to the concept of the SaaS model, the author initially constructed a talent management platform, and its architecture is shown in Figure 1:

The framework layer is responsible for data transmission and monitoring of the application service layer and the application integration layer, including security services, application monitoring, data backup, network control, operation management, and so on. It is the basic running environment of SaaS. The model provides application services provided by many software vendors, which ensures the high reliability, high security, and high scalability of the whole system. According to the needs for talent training in the AI era, the main modules of the designed system include talent information continuous maintenance module, business declaration module, declaration confirmation and audit module, talent and employee file management module, SMS sending and receiving module, system background management module, and so on. The system module structure is shown in Figure 2.

Compiling talent information maintenance is one of them, and it consists of two submodules: talent information registration and talent information editing. Professional title declaration and talent development special fund declaration are two submodules of the business declaration module. Two small modules are included in the application and audit module: professional title application and special fund for talent development application and audit. Six small modules make up the talent and personnel file management module: talent file transfer application, transfer application approval, file information record, transfer application file, transfer application approval, and file transfer.

DT (decision tree) module will automatically complete the whole data extraction process, and users can use the provided parameters to adjust DT so that the prediction results are more ideal. These parameters include confidence pruning and whether to merge discrete attributes. Pruning confidence determines the severity of the pruning operation and is the most important parameter. If the user makes a prediction according to the rule set when making a prediction, in the prediction module, the rule set is read from the rule file, and then its prediction data is read. In the process of prediction, a test case may predict different classification results according to different rules, and these results may contradict each other.

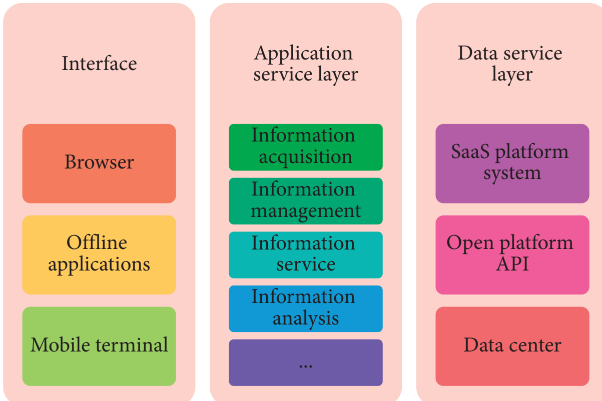

Figure 1: Talent management platform.

Considering the strong independence of this module, in order to reduce duplication of work, the system is changed to a web system, the codes of the DT generation module and prediction module are packaged in a DLL file independently, and the mining part is completed by calling dynamic link library system. In the stage of system design, DT module code design is the key and difficult point. As an independent subsystem of the talent management system, the data mining subsystem is mainly used by business decision-makers to support business talent management decisions. It includes three parts: the decision of outstanding talents, the decision of employee loyalty, and the decision of employee employment. Its structure is shown in Figure 3.

The model mainly selects the specific attributes according to the related contents of the talent index system established by the human resource management model. The indexes that reflect talent include education index, professional title index, age index, and industry index, and their credibility is proved by statistical methods.

According to business analysis, the conceptual database schema's common entity model structure, multivalued attributes, and entity relationships are transformed into a relational schema, which is then standardized. Every nonprimary attribute is functionally dependent on the relational schema code; the relationship ensures that each attribute's value range is a simple and indivisible data element. During the development process, staff not only can use out-of-the-box programme functions to operate the process but also can create many flexible processing links in the programme, and some functions and operation modules can be added, modified, and manually modified. This creates a good flexible space for system users, transforming the rigid programme into a living programme, and allowing them to experience the system's flexibility and humanized design ideas.

3.2. Wireless Network Optimization of Talent Management System. The era of AI is the era of machine revolution, and human-machine interaction is becoming more widespread. Many production processes necessitate the involvement of AI teams. Faced with the development situation in which start-up companies require a large number of AI talents, the talents trained by vocational colleges' original talent training objectives can no longer fully meet the new labor market demands. As a result, talent training objectives must be reset, and a new talent training plan must be developed, with the goal of meeting the new labor market demand for talents in the AI era and balancing the supply and demand of talents at the training end. All database access tasks are built in the database access class to improve the efficiency of project development and the speed of system execution. As a result, the database's public class is created and saved in the public class folder. The database control class can be called from the global module. A global file is configured in addition to the public class for accessing the database, in which the user name and password for accessing the database are stored in ciphertext form. This design method is adaptable and has a high rate of code reuse.

This paper presents a topology control algorithm for wireless sensor networks based on the optimization of algebraic stiffness characteristics of a minimum rigid body graph. The algorithm comprehensively considers the weight of communication links in the generated topological link graph and the rigidity of the generated rigid graph, which not only ensures the short communication links but also helps prolong the life cycle of the network, making the generated communication link graph more efficient and more stable in structure. The attenuation factor model is mainly used to predict the propagation loss in buildings and can deal with the influence of building types and the changes caused by obstacles. The model is flexible, and the standard deviation between the expected results and the measured values is small, while the deviation from the logarithmic distance model is much smaller. The attenuation model is

$$\overline{L}(d) = \overline{L}(d_0) + 10\gamma_{SE}\log_{10}\left(\frac{d}{d_0}\right) + ad + FAF, \tag{1}$$

where d_0 represents the standard reference distance, taking the empirical value of 1 m; d represents the distance between the signal transmitter and the signal receiver; a represents the channel attenuation index, in dB/m, and the typical apartment and office environment value is 0.2 m; γ_{SE} indicates the index value of the same building floor test. In different types of coverage areas, the value of γ_{SE} is different.

In the indoor environment, the attenuation factor model can be selected as the indoor wireless propagation model, and its expression is:

$$PL(d)[dB] = PL(d_0) + 10n\lg\left(\frac{d}{d_0}\right) + FAF. \tag{2}$$

The two-way relay transmission of the system is divided into two stages: multiple access stage (the first time slot) and transmission stage (the second time slot). In the multiaccess stage, all users send information to the relay station at the same time. In the transmission phase, the relay node amplifies the received information and sends it to the receiver. The two-way relay security network system model is shown in Figure 4.

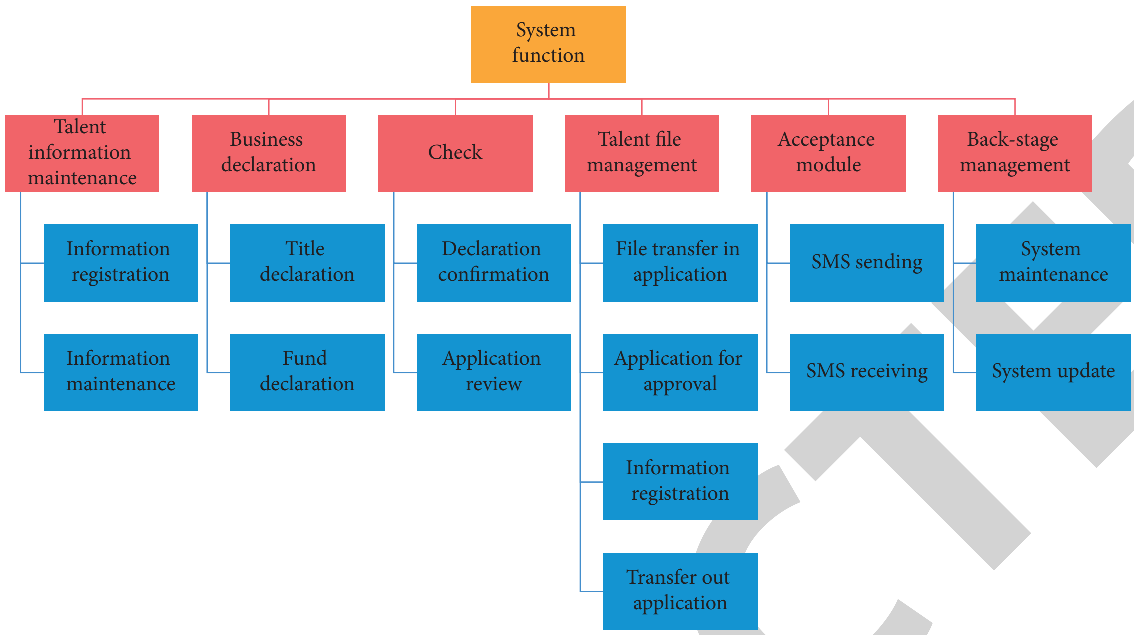

Figure 2: System function module structure.

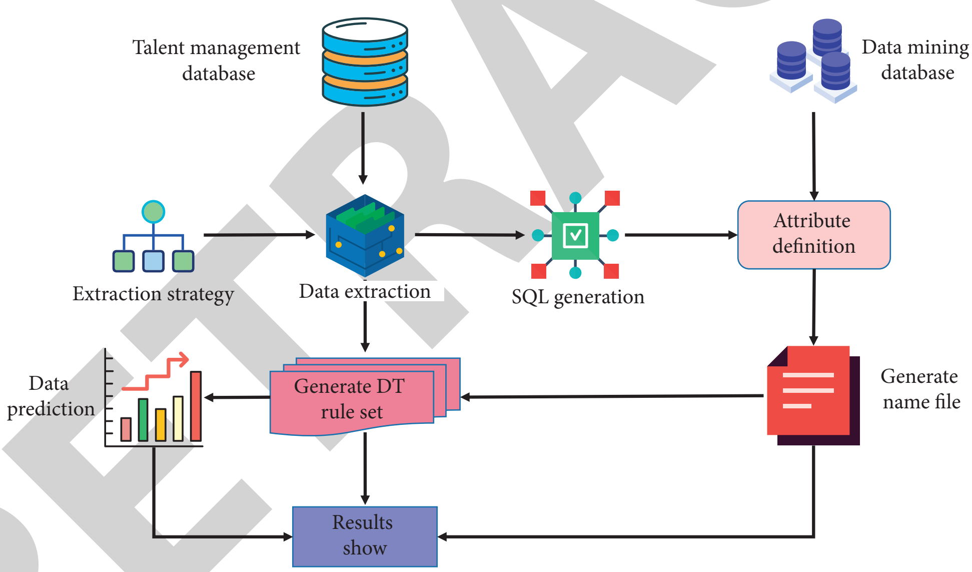

Figure 3: Overall structure diagram of data mining system.

Assume that each user group k is composed of A_k, B_k, and the bandwidth of each subchannel is B, and it is divided into N subchannels. Assume that in the multiple access stage, the user A_k, B_k occupies the subchannel i, and the signal received by the relay node is

$$Y^i_{EN} = \sqrt{p^i_{A_k} g^i_{A_k,RN}} X^i_{A_k} + \sqrt{p^i_{B_k} g^i_{B_k,RN}} X^i_{B_k} + Z^i_{RN}, \tag{3}$$

where $X^i_{A_k}, X^i_{B_k}$ are the transmission signal of A_k, B_k on subchannel i, $p^i_{A_k}, p^i_{B_k}$ are the emission power of A_k, B_k, $g^i_{A_k,RN}, g^i_{B_k,RN}$, respectively, represents the channel gain from A_k, B_k to relay station R on subchannel i, and Z^i_{RN} is that the average value of relay node RN on subchannel i is 0.

In the broadcast stage, the signals received by A_k, B_k and eavesdropper E on subchannel j are

$$\begin{aligned} Y^j_{A_{k,j}} &= \xi \sqrt{p^j_{RN}} h^j_{A_k} Y^i_{RN} + Z^j_{A_k}, \\ Y^j_{B_{k,j}} &= \xi \sqrt{p^j_{RN}} h^j_{B_k} Y^i_{RN} + Z^j_{B_k}, \\ Y^j_{E_j} &= \xi \sqrt{p^j_{RN}} h^j_{E} Y^i_{RN} + Z^j_{E}, \end{aligned} \tag{4}$$

where $j \in \{1, 2, \cdots, N\}$ is the subchannel occupied by the relay node in the broadcast stage; ξ is the forwarding amplification factor of the relay node; $h^j_{A_k}, h^j_{B_k}, h^j_E$ are the channel gain of relay node RN to A_k, B_k, E on subchannel j, respectively; p^j_{RN} is the transmitting power of the relay

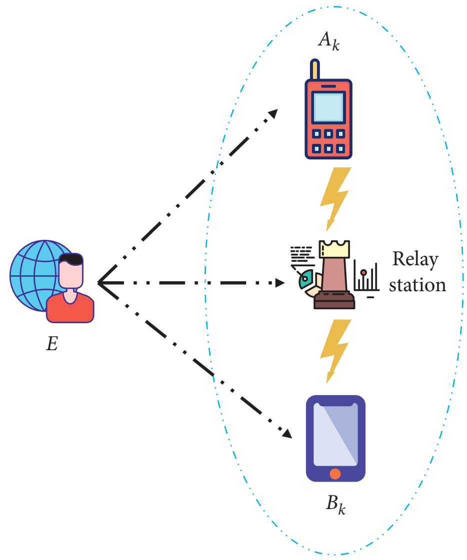

Figure 4: Two-way relay security network system.

node on the subchannel j in the broadcast stage; and $Z^j_{A_k}, Z^j_{B_k}, Z^j_E$ are the white Gaussian noise of A_k, B_k, E on subchannel j, respectively.

Each vertex in the minimum rigid graph has at least two adjacent edges [17], so the minimum rigid graph has less communication complexity and stronger robustness. Especially, the singular value of the stiffness matrix provides a method to measure the algebraic properties of the network [18]. Define the stiffness matrix of edges in the network as follows:

$$X_{(G,P)} = \overline{M}_{(G,P)}\overline{M}^T_{(G,P)} \in R^{|\varepsilon|\times|\varepsilon|}. \quad (5)$$

Among them, rigid graphs with larger determinant eigenvalue have better algebraic stiffness characteristics. Good stiffness characteristics can ensure that the network coverage positioning has a small error, thus improving the stability of the network.

Under the condition that the graph is the minimum stiffness graph, the trace value of the stiffness matrix can be maximized. This process can be transformed into an optimization problem:

$$\begin{aligned} &\underset{\varepsilon}{\text{maximize}}\ \text{trace}\left(\overline{M}_{G,P}\overline{M}^T_{G,P}\right),\\ &\text{subject to}\ \text{rank}\left(\overline{M}_{G,P}\right) = 2n - 3. \end{aligned} \quad (6)$$

This optimization problem can be solved by a classical greedy algorithm.

The coverage areas of base stations are not exactly the same. Therefore, a weight coefficient is introduced to correct it. This weight coefficient is determined by the ratio of user density to base station capacity. If the ratio is larger, the coverage radius will be smaller. On the contrary, it should be larger. Switching decision formula is

$$Mn + Ocn - Hys > Ms + Ocs + off, \quad (7)$$

where Mn represents the measurement result of the neighboring cell, Ocn represents the specific offset of the neighboring cell, Ms represents the measurement result of the serving cell, Ocs represents the specific offset of the serving cell, Hys represents the delay of the event, and off is the offset value of the event [21].

4. Experiment and Results

4.1. System Test Analysis. System performance testing is an important task in the testing task. When designing performance test cases, this system adopts the method of continuous iterative improvement, that is, the iterative process of testing, improvement, and retest. At the same time, when testing the performance of the system, it is not entirely based on test cases, but the test plan is adjusted in time according to the actual situation to meet the needs of the test system. Independent business performance test is actually the concurrent performance test of a business of the core business module, which can be understood as a unit performance test. Composite business performance testing is the concurrent performance testing of multiple services from one or more modules. The stress test scenario of concurrent user access is shown in Figure 5.

It can be seen from Figure 5 that when the number of users is less than 800, the response time of the system increases steadily with a slope. When the number of users is close to 1,000, the system drops obviously, and the drop is very serious, and a red line warning appears. Therefore, when less than 800 users access the system, the system performance may be in a stable state. If there are more than 1,000 users, there is a problem with the system performance. Try to keep it below 800. For the test of the improved system, the users who participated in the test of the existing management system before are still invited. The relevant data of six users who completed the usability task are shown in Table 1.

After completing the task, each user needs to fill out the scale. The number 1 stands for "very different," and 5 stands for "very much agree." The scores of the six user scales calculated are shown in Table 2.

The test results show that the improved user satisfaction is 62.23, and the user satisfaction has been improved to some extent. When users view a page, they do not need to think or spend a little time thinking to understand what the content on the page means and how to act. There is still a lot of attribute information in the real talent data, which can be gradually added in future applications. Keeping the attributes that have a great influence on outstanding talents' achievements and removing the attributes that have little influence will make the model more scientific and complete, and the prediction results will be more accurate.

Therefore, curriculum development must be based on a complete workflow, in-depth analysis of the workflow, and flawless integration of the entire production industry. Courses from various disciplines, occupations, and degrees should all be taken into account when creating a curriculum structure. Basic professional knowledge, interdisciplinary knowledge, professional ability, comprehensive application ability, and comprehensive ability should all be

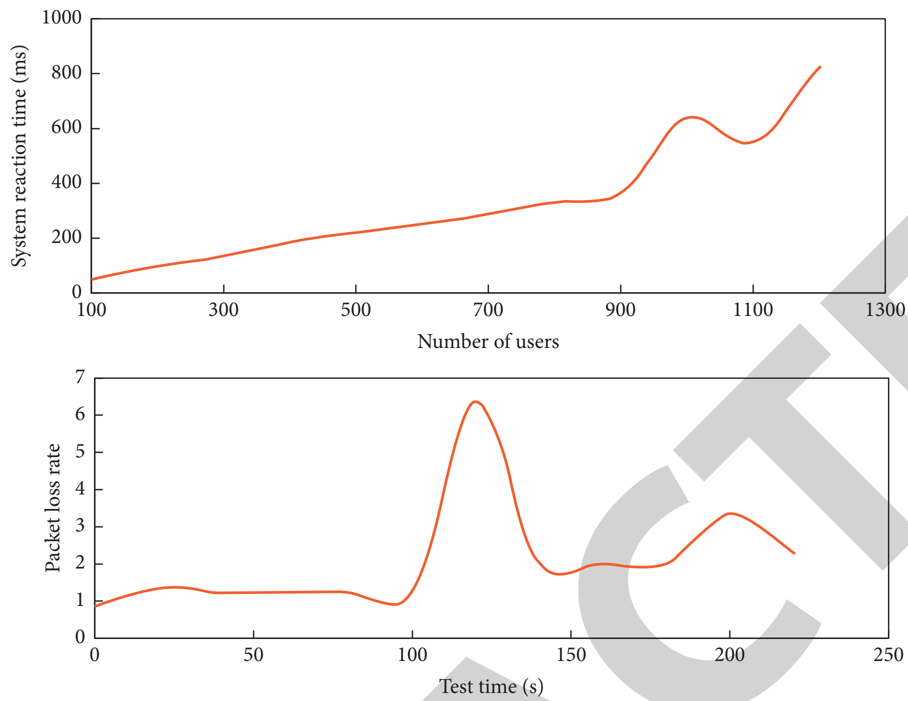

Figure 5: User concurrent access test.

Table 1: Completion rate and average time of tasks.

Task 1			Task 2		
Complete the task	After being prompted, the task is completed	Average completion time	Complete the task	After being prompted, the task is completed	Average completion time
100%	0	15 s	88.3%	9.6%	20 s

covered in the curriculum. The human society in the AI era is a complex multiparty coordination system, with real-world and virtual-world governance coexisting. This necessitates a re-examination of stakeholder relationships and a re-definition of governance scope in vocational college education. Continuous innovation and progress are required to strengthen the synergy of various stakeholders and to realize the Pareto optimal governance mechanism of vocational college education, such as restraint, encouragement, and guarantee.

Therefore, the professional training system in the AI era should no longer be limited to providing procedural training content for the workforce, such as computer science, data analysis, and so on, but should provide people-to-people training, machine training, and communication skills training between people and the world; provide training to deal with sudden problems; and provide training in critical cognition and thinking and cognition. The provision of these training contents will surely pave the way for the smooth transition of the labor force to the AI era.

4.2. Analysis of Wireless Network Optimization Algorithm. In order to verify the accuracy of the algorithm, this section uses MATLAB software to conduct simulation experiments to verify the effectiveness of the algorithm. The algorithm in this document is compared with other different algorithms, and the number of user groups is 18. In all simulations, the flat fading channel gain can be modeled by a unit random variable, which follows the average exponential distribution, and the path loss index is set to 3.

Table 2: User scale score.

User	Score
1	55
2	63
3	71
4	66
5	62.1
6	56.3

Figure 6 counts the traces of the stiffness matrix of the topological graph generated from the algorithm of reference [18] based on the topology of the least rigid graph and the least rigid graph constructed by the algorithm in this paper.

It can be seen from Figure 6 that in the same environment, the minimum rigid graph constructed by the algorithm in this paper has a large trace, which indicates that the minimum rigid graph generated by the algorithm has a good algebraic performance of stiffness, which is conducive to enhancing the stability of the network.

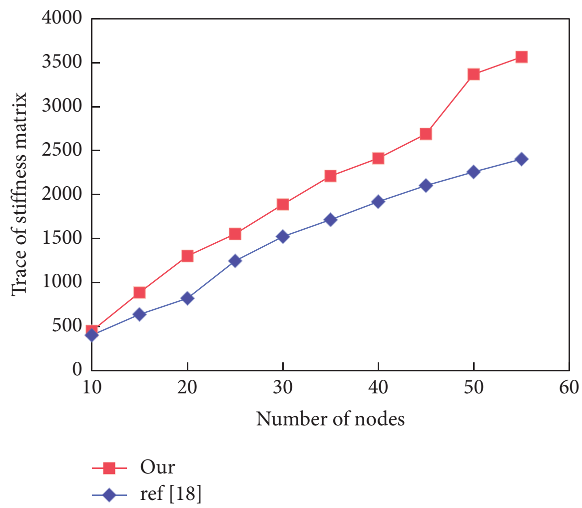

Figure 6: Trace of the stiffness matrix.

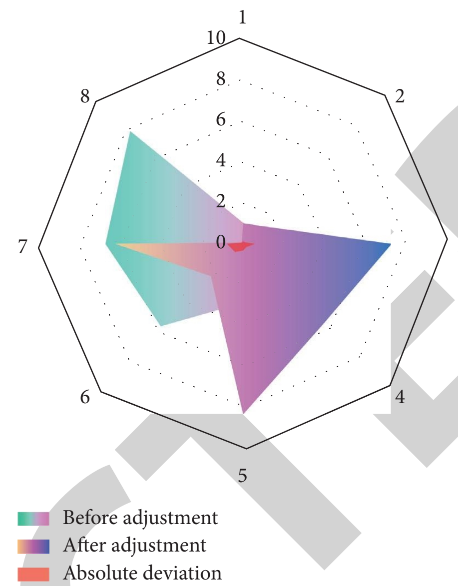

Figure 7: Relationship between the absolute deviation of different stations and deviation of handover success rate.

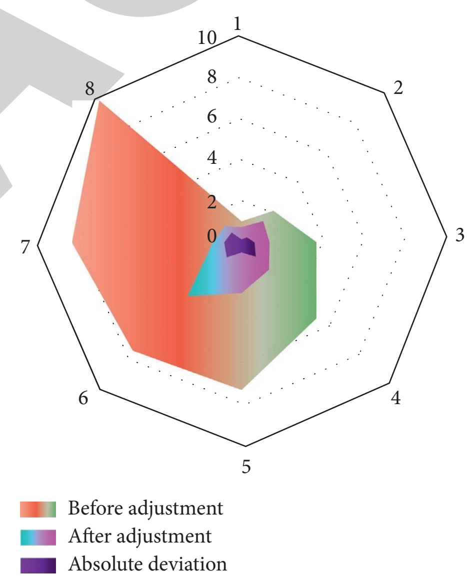

Figure 8: The relationship between the absolute deviation of different stations and the deviation of dropped call rate.

Drop call rate is an important indicator in mobile communication, which refers to the probability of unexpected interruption of communication in the process of mobile communication. Drop call rate reflects the communication quality of mobile networks to some extent. To illustrate the problem here, eight communities are selected from five sites. These five selected sites are macrosites, which are scattered and basically scattered in the whole cluster area. Then compare the relationship between your deviation and network indicators to guide optimization and replacement. The deviation here includes the absolute error between the physical site and the logical site and its replacement error. Figures 7 and 8 show the relationship between the adjusted wireless network index and polygon deviation.

According to the experimental data, it can be seen that the overlapping coverage deviation is obvious. When the absolute deviation is greater than 2, the network index fluctuates obviously, and the overall trend is upward, which increases with the increase of deviation. In the process of constructing the minimum stiffness graph, the edges are sorted in ascending order at first, and then the edge with the largest trace of the stiffness matrix is selected to join the stiffness matrix, that is, the communication link weight of the edge is further reduced while ensuring the algebraic performance of network stiffness. In the simulation, it is assumed that there is a relay node, an illegal E, and multiple legitimate users on the network. Users are randomly distributed in a circle with a radius of 50 meters centered on the relay node (all users are within the coverage of the relay node). Here, it is assumed that the distance between E and the relay node varies between 100 and 400 meters, and the total transmission power of the relay is set to 1,000 mW as shown in Figure 9.

It can be seen that when E is far away from the relay node, the average satisfaction of the user group shows an upward trend. When E is far away from the relay node, the signal-to-noise ratio it receives decreases, and the more and less communication information E can steal, the higher the security satisfaction of users will be. When E leaves the relay node within 250 meters, the average security satisfaction of all user groups increases rapidly. It is also found that within the range of 250 m, the user security satisfaction of the optimized algorithm in this paper is 0.93, and the user security satisfaction of the proposed optimized algorithm is higher than that of other algorithms. As E is far away from the relay node, this gap will become smaller and smaller.

5. Conclusions

The rise of AI has created a new demand for talent, requiring vocational colleges to adjust and reshape talent development goals in response to changing industry

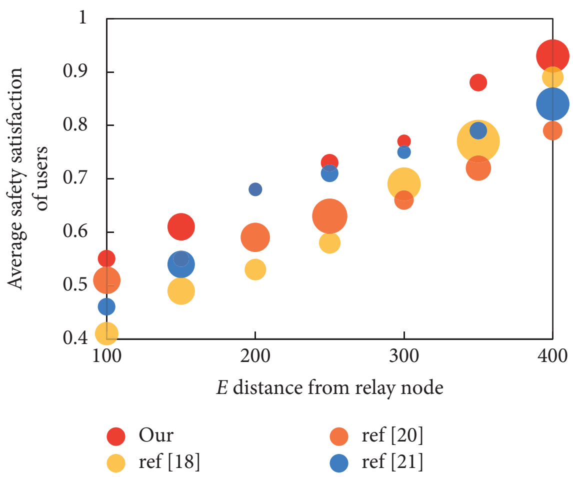

Figure 9: The relationship between the distance from E relay and users' safety satisfaction.

structures. As a result, establishing an educational talent training system in vocational colleges that incorporates AI technology can help mitigate the impact of AI on vocational college employees. The project developed a design scheme for a vocational college education talent management system based on a wireless network after conducting extensive field research to meet the needs of enterprise talent management in the AI era. The system essentially performs the expected system design function, and it has undergone a series of system tests. The results of the tests show that the system is functional and robust. The talent management system's wireless network optimization results show that within a range of 250 m, the optimized algorithm in this paper's user security satisfaction is 0.93, and the satisfaction of the optimized algorithm proposed by user security is higher than that of other algorithms. It demonstrates that the algorithm has good algebraic connectivity and stiffness properties.

Lung ultrasound has great application value in the differential diagnosis of pulmonary exudative lesions. It has good sensitivity and specificity for the diagnosis of various pulmonary diseases in neonates and children. It is believed that it can replace chest CT examination. It is routinely used for the diagnosis of pulmonary diseases in emergency critical care medicine. However, the interpretation of the impact of ultrasound on the human lungs relies heavily on experienced physicians, which greatly restricts the interpretation efficiency of the impact of ultrasound. In order to improve the efficiency of monitoring and interpretation of the impact of ultrasound, this paper proposes an intelligent detection algorithm for human lung clinical ultrasound images based on recurrent neural network. Transfer learning is used to replace the fully connected layer of the VGG16 model and improve the loss function, so that the same the Euclidean distance between category images can be reduced, and the Euclidean distance between different categories of images can be increased, enhancing the resolution of the entire model, thereby achieving better image feature extraction results. The experimental results show that the algorithm proposed in this paper can surpass the doctor's level in the identification of various lung diseases.

1. Introduction

The lungs are the main air-bearing organs of the body. Due to the physical characteristics of ultrasound itself, when the propagation path encounters gas, total reflection will occur, resulting in ultrasound not being able to capture the image of the normal lung tissue. In recent years, with the continuous development of ultrasound technology, ultrasound diagnosis of lung diseases has become an important means to check and monitor the treatment effect in the world, realizing the visualization of lung pathophysiology, known as the visual "stethoscope" [1].

With Lichtenstein's discovery of the value of pulmonary ultrasound, the establishment of perfect operating and scoring rules, and the formation of the imaging theory and procedure of LUS, LUS has become a simple and reliable means of diagnosing pulmonary diseases in recent years. The International Consortium of Lung Ultrasound has issued an international consensus on the diagnosis of lung diseases by ultrasound [2]. It is believed that lung ultrasound can not only accurately diagnose many lung diseases but also has higher accuracy and sensitivity than chest X-ray in the diagnosis of pneumothorax, pulmonary solids, and pleural effusion.

The determination of the type of lung disease relies mainly on the physician's subjective diagnosis of the patient's lung images. The accuracy of the diagnosis of lung diseases depends on the physician's personal condition and is highly subjective [3]. Moreover, the orientation of certain lung lesions varies from person to person, and the lung structure varies greatly from person to person. Therefore, it is also easy to create factors that may produce errors in this regard, thus failing to meet the requirements of precision medicine [4]. On the other hand, not all regions have good medical resources and medical conditions, and the medical conditions enjoyed by patients in different regions may be very different [5]. Computer-aided medical image recognition and diagnosis is able to overcome these difficulties and solve the current problems. Computer-aided medical image recognition and diagnosis aims to improve the accuracy of diagnosis by quickly and accurately detecting lesions.

This paper studies the theory of optimization on the one hand, will be conducive to the algorithm, On the other hand, it is beneficial to promote the efficiency of pulmonary ultrasound detection and has certain theoretical and application significance.

2. State of the Art

When it comes to image recognition, it is inseparable from the convolutional neural network of deep learning. Convolution neural network is a kind of feedforward neural network with convolution computation and depth structure. It is one of the representatives of the depth learning algorithm. It goes beyond the traditional learning tools and methods. Convolutional neural network, which is called neural network, plays a central role in the field of medical image recognition and image recognition. We have to mention the original convolutional neural network LeNet.

The proposal of LeNet marked the birth of CNN, and the 7-layer LeNet contains the basic modules of deep learning. The simple network is capable of automatic recognition of handwritten recognition numbers and automatic verification of CAPTCHA. AlexNet, designed by Hinton and his student Alex Krizhevsky, was the winner of the ILSVRC competition. Several technical breakthroughs and applications of new technologies were achieved in the AlexNet network. It is these techniques that take convolutional neural networks to new heights [6].

The innovations used in AlexNet include the following: (1) The use of the Relu activation function instead of the original Sigmoid activation function. When the number of layers of the neural network increases to a certain depth, if the Sigmoid activation function is used, the gradient will disappear and the whole network will converge too slowly, or there will be a gradient dispersion problem, using the Relu function is a good solution to this problem [7]. (2) The Dropout function is used during training, through which the parameters of some neurons can be randomly ignored, i.e., the activity of some neurons is suppressed, and this measure can also avoid overfitting of the model [8]. (3) Applying overlapping pooling layers to the convolutional neural network can not only significantly improve the computational speed compared with the previous average pooling layers but also—to a certain extent—reduce the overfitting of the model [9]. The overfitting of the model can be reduced to a certain extent. (4) The dataset expansion technique is used. (5) CUDA acceleration is used to reduce the computation time so that the number of layers of the neural network can be deepened to improve the overall model recognition accuracy. (6) The concept of LRU was introduced for the first time, adding LRU layer to CNN, the role of which is to filter the neurons in the network model layer, making the value of neurons with larger responses larger and the value of neurons with smaller responses smaller, which can well suggest the robustness and generalization ability of the model.

Since then, convolutional neural networks have developed rapidly and VGG series networks have emerged. The network structure of VGG16 is shown in Table 1. The advantage of VGG series is that the structure of the whole neural network is very simple, which can improve the calculation speed. Secondly, VGG series through the test of its own data, verified by deepening the depth of the neural network, improves the network identification performance, and can improve the accuracy of identification. Table 1 describes from top to bottom the number of neurons in VGG16 neural network layer, the arrangement of convolutional layer and pooling layer, and the size of the input and output image feature matrix of each neural network layer.

The core neural network representative of GoogLeNet is the Inception network, which is designed as a net-within-a-net structure, giving the model the ability to choose itself, with multiple choices for each layer, and the model automatically adjusts to choose the layer with higher recognition accuracy for training recognition. By adding 1×1 convolutional kernel layer, the whole Inception network can be designed to be deeper and the width can be expanded and adjusted, and the overall effect can reach 2–3 times of the original performance. The error rate of recognizing the top5 classified images was only 6.67%.

The biggest innovation highlight of Inception Net is the design of Module module. Module brings improvement not only in the overall model performance but also reduces the number of image data parameters. It provides the ability of the model to cross channels, improves the information transfer and expression ability of the network, and provides the model with more choices of linear transformation types. On the other hand, it is a regularization method that is first proposed and applied in the model for the whole network, which speeds up the convergence and improves the overall classification and recognition accuracy of the model [10]. The data are normalized in the implementation process to limit the range to $N(0, 1)$. The ResNets (residual networks) that emerged afterwards extend the depth of the network to several hundred layers by a special computational approach. This method is based on the idea of Highway Network, which opens up a "high speed channel" in the process of network propagation and is computed in an optimal fitting way [11].

Based on previous algorithm studies, the advantages of convolutional neural network in image recognition can be seen. Compared with other neural networks, the network has better fitting degree and higher accuracy rate of image recognition, so it can be better applied in intelligent detection of human lung clinical ultrasound images.

By combing the previous development context, we can see that the optimization of the past is a dark mass of optimization in the input layer. In order to take advantage of deep learning to interpret ultrasound images of lungs, we proposed a neural network algorithm based on VGG16, whose basic structure is shown in Figure 1. We replace the output layer of THE VGG16 neural network with the ultrasound image of the lung as the initial input, so as to improve the accuracy of the neural network results, and use

the transfer learning method to make the VGG16 neural network more suitable for lung ultrasound interpretation.

3. Methodology

3.1. Data Set. It is difficult to obtain medical images of lungs, and there are no datasets of lung medical images of the order of 10 million or millions at present. This is also a problem at present, and the solution is to expand the image dataset.

In order to ensure the integrity of the image data, ensure the scientific nature and authenticity of the experiment. The external library PIL in Python was used to realize the extension of lung medical image, and the image recognition and classification effects such as image rotation, mirror image, brightness adjustment, chroma adjustment, and random cropping were compared. Finally, image rotation and mirror were selected as the extension method of lung medical image dataset [12]. Because the whole model structure is divided into five branches, it is selected to use the original image to generate three image rotation directions, and then generate a mirror of a total of five pictures, that is to say, one original image will be extended to five, input different branches as the input images, the dataset expansion result is shown in Figure 2.

The purpose of dataset enhancement is mainly to perform some transformations on the input image data and train a model with better robustness, so that it can cope with various transformations and be more applicable to real scenes. For example, when taking pictures in life, the angle, brightness, stretching, etc., of the pictures obtained may be different due to different shooting locations or different cameramen, whether or not the different images can be recognized as the same structure. Again performing dataset enhancement is to train the model to be able to achieve excellent recognition accuracy with so many transformations [13]. AlexNet does a good job of dataset augmentation and eventually achieves good results.

There are many ways to enhance image datasets: one common method is to apply a bevel attribute to the image, and another is to add a shrink and expand factor.

The interface to the dataset enhancement algorithm is integrated in the Python external library Keras, which can be easily invoked by setting the corresponding parameters [14].

3.2. Recurrent Neural Network. Recursive neural network is an artificial neural network with tree-like hierarchical structure and the network nodes recurse the input information according to their connection order, which is one of the deep learning algorithms. Recursive neural networks can be trained using supervised and unsupervised learning theories. In supervised learning, recursive neural network uses back propagation algorithm to update weight parameters, and the calculation process can be similar to the back propagation algorithm over time of recurrent neural network. Unsupervised learning recursive neural networks are used for representational learning of structural information and the most common form of organization is recursive self-encoder.

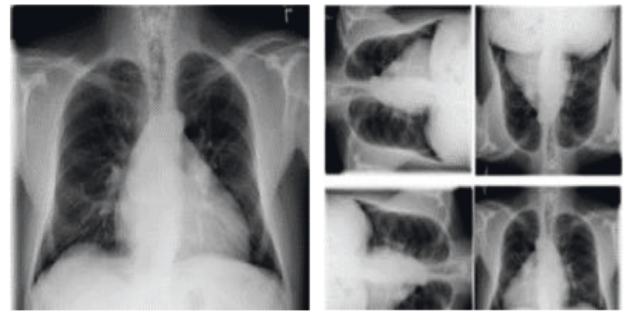

Figure 2: Lung image dataset expansion.

For a recurrent neural network, it is a network where the current output is related to the previous output as well. This means that the network remembers the last output result and then uses it in the calculation of this output, which makes the nodes between the intermediate layers transform from a connectionless one to a connected one, and the input given by the intermediate layers has both the output of the input layer and the output of the intermediate layer at the last moment.

Where X represents the input vector, U represents the weight matrix from the input to the intermediate layer, similarly W represents the weight matrix from the state to the intermediate layer, S is the state value of the node in the intermediate layer, V represents the weight matrix from the loop layer to the output layer, and Y represents the output. The value of state S is not only output to the output layer but also calculated by multiplying W and then used as input for the next calculation [15]. Figure 3 shows the expansion diagram of the recurrent neural network expanded along time in Figure 4.

Where the network input at time t is X_t, St denotes the value of the intermediate layer, and the output is Y_t. It is clear that the value of S_t depends not only on X_t but also on $S_t - 1$ as well. They can be expressed in equations as shown in (1) and (2), where g and f denote the activation functions.

$$Y_t = g(V_t S_t), \tag{1}$$

$$S_t = f(UX_i + W_t S_{t-1}). \tag{2}$$

Compared with other neural networks, the structure of recursive neural network can well introduce the concept of time into the neural network, which can make the input data at the previous moment directly affect the data calculation at that moment. St state can remember the information at the previous moment. Thus, it is beneficial for real-time image recognition. Therefore, this paper chose recursive neural network for pulmonary clinical image ultrasound detection. In practice, however, with the increase of depth of the model, the recursive neural network cannot handle well data dependency for a long time, so you can understand, the so-called back-propagation gradient disappeared and gradient caused by explosion problem, so this article think should optimize the recursive neural network so as to solve the data dependency problem for a long time. To solve these

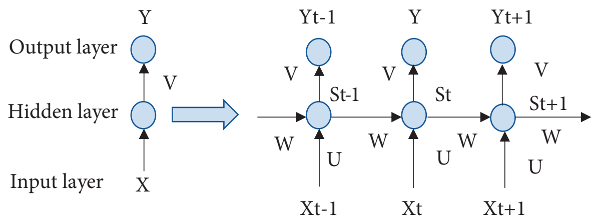

Figure 3: Structural diagram of recurrent neural network expansion.

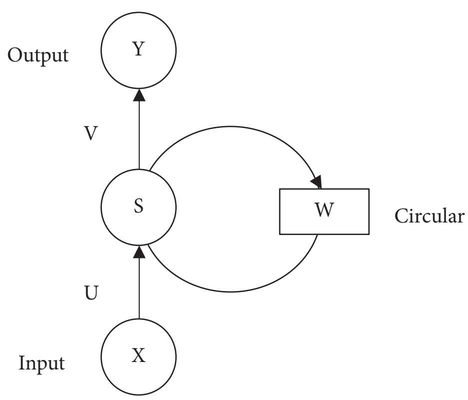

Figure 4: Recursive neural network structure.

problems, an improved recursive neural network, LSTM, is proposed.

LSTM adds three gate selection units in the recursive neural network, which solves the problems of gradient disappearance and gradient explosion of ordinary RNN (existing neural network), and forms an independent transmission mechanism for memory data and result data, so that information can be transmitted across regions. Overcomes the problem that standard RNN does not handle data dependency well over time. Deals with long time dependencies on data. Therefore, LSTM is one of the most popular recursive neural networks and has been widely used in several fields of artificial intelligence [16].

Figure 5 shows the structure of LSTM network, which has four network layers that make it different from the normal RNN network, LSTM stores the information selectively, while the normal RNN stores the information whether it is useful or not. The gates are sigmoid and tanh functions, and the process is implemented by multiplying the neural layers of the sigmoid or tanh functions with each point to make it possible [17]. The gates in this network are the forgetting gate and the input and output gates, respectively.

Where ⊗ denotes the dot product, f denotes the activation function, $C_t - 1$ denotes the cell state at the previous time step, $h_t - 1$ denotes the output value at the previous time step, ct is the cell state at this moment, and ht denotes the output value at this moment.

(1) forget gate is a judgment of what information is discarded by the cell state, and this judgment is done

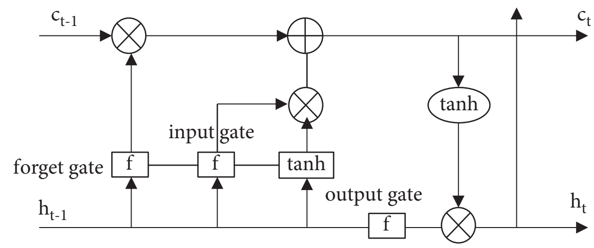

Figure 5: Structure of LSTM network.

by the sigmoid function, expressed as shown in the following equation:

$$f_t = \sigma\left(W_f\left[h_{t-1}, x_t\right] + b_f\right), \tag{3}$$

where $ht - 1$ denotes the last—moment output value, x_t denotes the input value at this moment, Wf denotes the weight matrix of this gate, b_t denotes the bias of this gate, and σ denotes the activation function.

(2) The input gate (input gatc) determines what information is stored in the cell state. First, the input gate is called a sigmoid layer, and second, a vector is created by calling the tanh layer as a new marquee value that can be added to the intermediate layer states [18]. Finally, the two parts are merged to create an update to the hidden layer state, which can replace the old memory information forgotten, then represented as shown in equations (4) and (5):

$$i_t = \sigma\left(W_i\left[h_{t-1}, x_t\right] + b_i\right), \tag{4}$$

$$\tilde{c}_t = \tanh\left(W_c\left[h_{t-1}, x_t\right] + b_c\right), \tag{5}$$

In this case, if we know the memories to be forgotten and those to be added, we can update the old cell state $c_t - 1$ to the new cell state ct. After that, the old m-server state will be multiplied by FT, which will determine the information to be forgotten, and then multiplied by the sum of the input gate of the current memory c_t [19]. After this series of operations, the new memory information will be derived, which is expressed as shown in the following equation (6):

$$c_t = f_t * c_{t-1} + i_t * \tilde{c}_t. \tag{6}$$

(3) The output gate is the information that needs to be decided for the output. Although the output is based on the cell state, it will be a post-selection value. This output gate needs to go through three steps to get the output information [20]. First, the output gate needs to go through a sigmoid layer, second, a partial selective output is performed for different parts of the cell state, and finally, the obtained cell state is fed into the tahn activation function so that it is multiplied with the sigmoid activation function to obtain a value that needs to be output, which is represented as shown in (7) and (8):

$$o_t = \sigma(W_o[h_{t-1}, x_t] + b_o), \tag{7}$$

$$h_t = o_t * \tanh(c_t), \tag{8}$$

where b_o denotes the output bias, W_o denotes the number of weights of the output, h_t denotes the output value of the cell state, and ot denotes the value of the output gate.

4. Result Analysis and Discussión

4.1. Principle of VGG16 Extraction of Image Features. Before introducing VGG16, it is necessary to introduce the general convolutional neural network computational rules and the important parts of it. The more important components of the convolutional neural network are the convolutional layer, the pooling layer, and the activation function, and the computational method is the BP back propagation algorithm.

The convolutional layer plays a crucial role in the whole neural network layer, which is equivalent to a filter, and consists of convolutional kernels, the number and size of which are set by the designer of the network, generally 3×3, 5×5, 7×7, 11×11. According to the set size of the convolution kernel, a weighted average calculation is performed on the corresponding size area of the input image. Depending on the step size, the size of the convolution kernel, and the setting of the convolution algorithm, the convolution process will extract different numbers of image features, and the final output matrix is the output of the convolution kernel on the image. The final convolution value is obtained by multiplying the convolution kernel parameters with the image pixel values in the matrix, and then the length of each convolution kernel move is determined by the convolution kernel step setting. After the convolution, kernel shift calculation will reduce the size of the whole image feature matrix, as seen in Figure 6.

The pooling layer is used to reduce the number of features extracted by the convolutional layer, i.e., to reduce the size of the feature matrix, thus reducing the system resources and time consumed during the model computation, and is also useful in preventing overfitting. This process can also be called “downsampling.” There are two main pooling layers: the maximum pooling layer, which extracts the largest value in the pooling matrix as the output, and the average pooling layer, which extracts the average value of the parameters in the pooling matrix as the output.

The activation function is set in each layer of the network, and each layer has input and output data. The input data are the parameter value transferred from the upper layer after the calculation, and the output value obtained after the calculation of the specific function is used as the input value for the lower layer of the network. The specific function in the middle refers to the activation function. There are many different types of activation functions. In order to make the values calculated by the activation function more nonlinear, the following activation functions are commonly used.

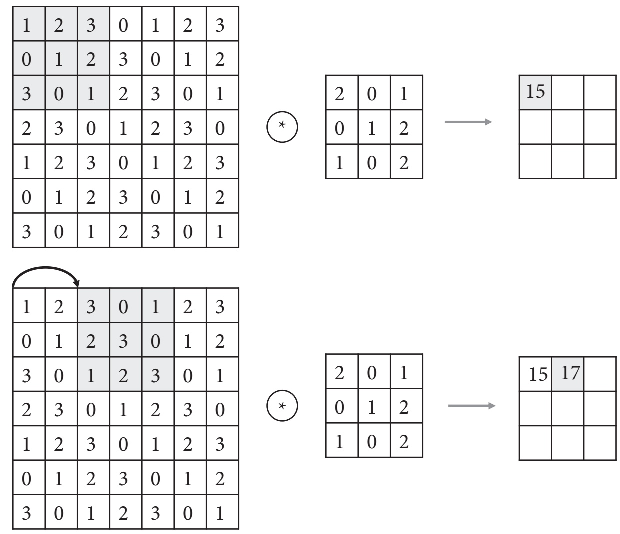

Figure 6: Convolution kernel to extract image features.

After the network reaches the last layer, the difference between the predicted result and the real result is calculated according to the corresponding loss function, according to which the BP back propagation algorithm goes forward to adjust the parameter values of the whole network model, so that the model can obtain better recognition and classification results.

The structure of the VGG16 model contains 13 convolutional layers, 3 fully connected layers, and 5 pooling layers. After training, the complete model is able to extract features from images.

4.2. Single-Branch Model Structure. In this paper, gradient advancing tree in traditional machine learning model is selected as the classification model of lung image recognition. The gradient advancing tree model is suitable for the classification and recognition scenes with small datasets. However, the traditional machine learning model requires manual extraction of image features on the one hand, and the upper limit of classification and recognition accuracy on the other hand is not very high. In order to solve these problems, the method commonly adopted abroad is to modify the classical model a lot, until it is applicable to the size of the corresponding dataset; using this method will cause a great loss of the ability of the VGG16 model to extract image features. Therefore, in the research method of this paper, we first use migration to adjust the parameters of the VGG16 model. Migration research is a machine learning method, which starts from a model in the development task. The model used in the development process is task B. The migration research method in this paper can improve the efficiency of model development. In this paper, the loss function of VGG16 is improved, the clustering effect is increased, and the ability of the whole model to extract image features is improved. Then, the function of the first half of the model is to extract the features of lung medical images, and then input the extracted features into the gradient enhanced tree model for recognition and classification.

In this paper, we modify the fully connected layer of the original VGG16 model by using the idea of migration learning, removing the fully connected layer, and replacing the fully connected layer with a fully connected network of our own design, and modifying the corresponding activation function and dropout parameters. The second and third layers are set to 256 neurons, respectively, reducing the number of neurons in each layer so that the training of the whole model can match the number of images in the training set and avoid the effect of overfitting the model. The loss function of the original classical model is innovatively improved to include clustering effect, so that the feature distance between images of the same category is reduced, while the feature distance between images of different categories is increased, thus improving the recognition and classification ability of the model. The image features extracted by the neural network are input to the gradient boost tree model for recognition and classification.

The first step of training the single-branch model is to obtain the lung medical image dataset and image preprocessing, after which the fully connected layer of VGG16 is replaced and the parameters are fine-tuned using migration learning, with the conflict of needing to extract image features manually. On the other hand, the single-branch model has certain advantages in terms of computational speed and computational efficiency because only one branch of training computation is required. However, the disadvantage of single-branch model is that the accuracy of recognition and classification may fluctuate greatly due to different scenes or different image datasets, which causes the stability and robustness of the model to be low and thus cannot be applied to the training recognition and classification of different scenes and different datasets; so we consider designing multiple-branch model structure and combining the recognition results of each branch through corresponding algorithms to finally complete the image. The model structure of multiple branches is considered, and the recognition results of each branch are combined by the corresponding algorithm to complete the classification of images.

4.3. Migration Learning of VGG16. The purpose of migration learning is to preserve the ability of VGG16 to extract features from images. Because of the small number of image datasets, the training cannot be done from scratch based on the original model, but rather fine-tuning the parameters for certain layers.

VGG16 consists of 13 convolutional layers, 5 pooling layers, and 3 fully connected layers. The changes in image size and number of channels per layer in the original and modified model structures are shown in Figure 6. The number of neurons in each of the three replacement layers is set to 4096, 256, and 256, respectively. The activation function uses the Relu function, which is called to splice the first 15 layers of the classical model with the fully connected layers designed by itself, and the parameters of the training layers can be adjusted so that the whole model is involved in the training, but only the parameters of the fully connected layers designed by itself are adjusted.

The first 15 layers of the VGG16 model have not been changed, but only the last three fully connected layers have been changed. The number of neurons in the fully connected layer is reduced and the corresponding activation function and dropout parameters are changed, the regularization coefficients are changed, and the training is performed using medical images of lungs. The training process only adjusts the three-layer model designed by ourselves, which can be set by the trainable parameter in the layer external library to avoid the participation of the first half of the VGG16 model in the training.

4.4. Model Accuracy and Robustness Verification and Analysis. The main objective of this research method is to solve the following problems: firstly, the VGG16 model is improved and fine-tuned by transfer learning to resolve the contradiction between the complex VGG16 model and insufficient lung images; secondly, the loss function in the VGG16 model is improved to include the judgment of inter-class similarity of lung images to make the model have the effect of clustering; after that, the VGG16 extracted image. Finally, the above model is used as a whole to combine multiple branches into a strong classifier by weighted voting or majority voting method to enhance the accuracy, precision, and recall of model recognition and improve the recognition ability and robustness of the model.

The data used in this study are from the publicly available ChestX-ray14 dataset, which is provided by https://www.kaggle.com/nih-chest-xrays/data. Images of five diseases (Atelectasis, Emphysema, Infiltration, Nodule, and Pneumonia) from the ChestX-ray14 dataset were selected. Some of the images in the dataset are shown in Figure 6. After that, the original images were rotated by 90°, 180°, and 270° and mirrored to obtain 4 patch images, thus expanding each 1 original image to 5. The number of images is then expanded by using data enhancement methods including image scaling, beveling, and panning. All images are converted to a uniform format and size and randomly divided into a training set and a test set (ratio 8 : 2). The recognition accuracy of the training set and the comparison results of the loss during training are shown in Figure 7.

From the accuracy graph, we can see that CheXNet starts to improve from 78%, while the model designed in this paper starts to improve from 65%, indicating that the dataset trained by CheXNet before is very similar to the lung images, while the initial dataset of the VGG16 model used in this paper is mostly images from daily life, which is different from the medical images.So the recognition accuracy of the model at the beginning will be improved. However, as the number of training iterations increases and the recognition accuracy of the model remains stable, the model designed in this paper clearly outperforms the recognition accuracy of CheXNet, and this conclusion can also be confirmed in the comparison of the loss results during training.

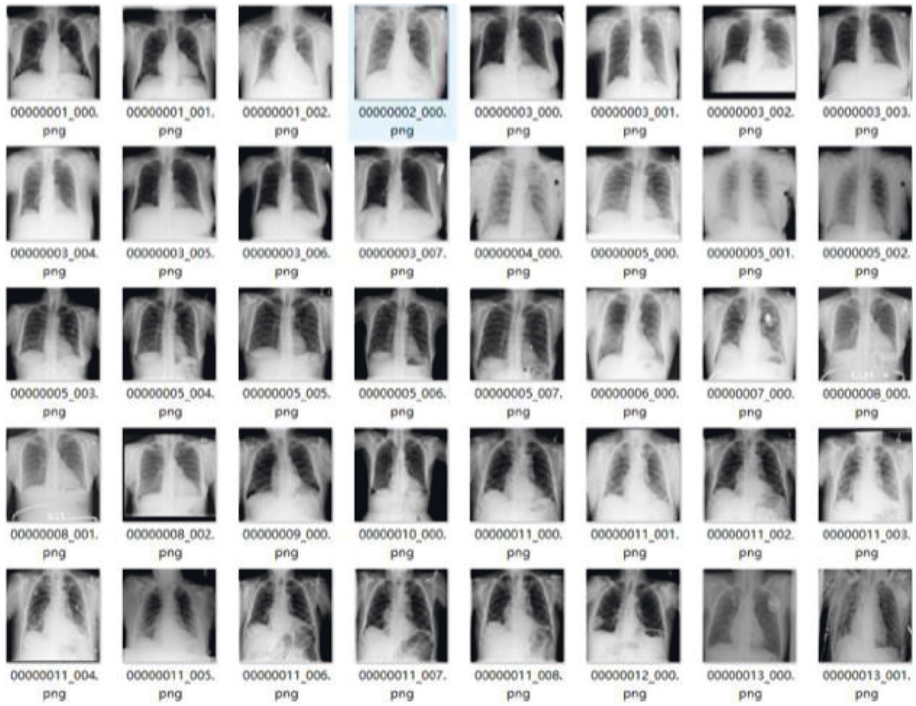

Figure 7: Partial dataset images.

In the comparison graph of model recognition accuracy, my_acc represents the recognition accuracy of the model designed in this paper, and standard_acc represents the recognition accuracy of CheXNet; in the comparison graph of loss during training, my_loss represents the change of loss during the iteration of the model designed in this paper, and standard_loss represents the change of loss during the iteration of the CheXNet model. my_loss represents the change of loss in the iterative process of the design model, and standard_loss represents the change of loss in the iterative process of the CheXNet model. In the comparison graph of recognition accuracy, when the recognition accuracy curve is close to smooth, the recognition accuracy of this design model is significantly better than that of CheXNet model; in the comparison graph of loss calculated during iteration, when the loss curve is close to smooth, the loss value calculated during iteration of this design model is lower than that calculated during iteration of CheXNet. The loss value calculated in the iterative process of the model designed in this paper is lower than that calculated in the iterative process of CheXNet when the loss curve is close to smooth. The loss here refers to the loss result value calculated by the loss function in each iteration of the model training process. By observing the loss value change graph, we can also analyze the advantages and disadvantages of different models in terms of recognition accuracy.

After the trained model is obtained, the recognition accuracy of the model is verified using the test set images obtained during image preprocessing, and the final accuracy verification conclusion is obtained by comparing the recognition accuracy of different models for the test set lung images, i.e., the model-assisted lung image disease classification accuracy.

Using the trained model for classification recognition on the test set, the test results are shown in Figure 8. In the comparison graph of recognition accuracy results, the CheXNet model and the model designed in this paper are tested and compared, and it is obvious that the model recognition accuracy is better or worse.

The blue curve in the figure shows the accuracy of the model designed in this paper in recognizing the test set data, and the red curve shows the accuracy of the CheXNet model in recognizing the test set images. It is obvious from the images that the model designed in this paper has better prediction effect than the current advanced CheXNet model.

In this paper, the different lung disease recognition accuracies were extracted separately and compared with the previous models. In this paper, the data from the original literature was selected and a row was added to include the data of the accuracy of the single lung disease recognized by the model designed in this paper for comparison with the previous models, as shown in Table 2. From the table, we can see the recognition accuracy of different models for each of the five lung images to be classified individually, which can also verify the advantages of the model designed in this paper in terms of recognition accuracy.

The robustness of the model designed in this paper was verified by comparing the accuracy and recall of the model designed in this paper with the CheXNet model and the F-values calculated by radiologists for image classification of

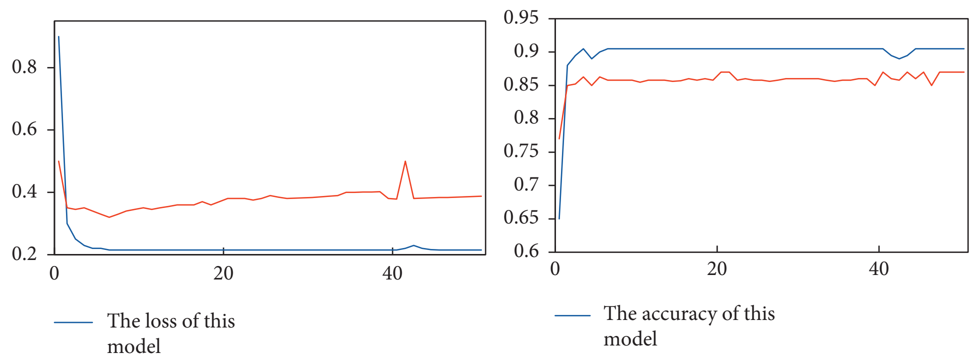

Figure 8: Comparison of training results.

Table 2: Comparison of accuracy rates of different models for lung diseases.

Disease type	Models			
	Wang et al., (2017)	Yao et al., (2017)	CheXNet models	Text model
Pulmonary atelectasis	0.716	0.772	0.8094	0.8243
Pulmonary emphysema	0.815	0.829	0.9371	0.9537
Pulmonary infiltration	0.609	0.695	0.7345	0.8211
Tuberculosis	0.671	0.717	0.7802	0.7981
Pneumonia	0.633	0.713	0.7680	0.7813

Table 3: Model robustness comparison.

Models	Standard		
	Accuracy rate	Recall rate	F-value
Physician average	0.330	0.442	0.378
CheXNet average	0.387	0.481	0.428
The model in this paper averages	0.415	0.496	0.452

five lung diseases, and the comparison results are shown in Table 3. It can be seen that the model in this paper has higher recognition accuracy.

5. Conclusion

In recent years, with the continuous development of ultrasound technology, ultrasound diagnosis of lung diseases has become an important means to check and monitor the treatment effect in the world, realizing the visualization of lung pathophysiology, known as the visual "stethoscope." In order to improve the recognition efficiency of lung ultrasound images, this paper proposed a lung image classification recognition method combining convolutional neural network VGG16 and gradient enhanced tree model. In order to improve the efficiency of model optimization, transfer learning is used to replace, train, and fine-tune the full connection layer of the VGG16 model. The original loss function is improved, and a new loss function is proposed, which reduces the Euclidean distance between the same category images and increases the Euclidean distance between different categories images, so as to enhance the recognition ability of the whole model and achieve better image feature extraction. Finally, multiple branches are designed and the classification results of these branches are combined by majority voting algorithm or weighted voting algorithm to obtain the detection results of lung images. It can be seen from the results that compared with the algorithm before optimization, the algorithm model designed in this paper has higher precision and accuracy.

The computer-aided language teaching system is maturing thanks to the advancement of few-shot learning technologies. In order to support teachers and increase students' learning efficiency, more computer-aided language teaching systems are being used in teaching and examinations. This study focuses on a multifeature fusion-based evaluation method for oral English learning, completely evaluating specific grammar, and assisting oral learners in improving their oral pronunciation skills. This study proposes an improved method based on HMM a posteriori probability scoring, in which the only standard reference model is no longer used as the basis for scoring and error determination, and instead, the average level of standard pronunciation in the entire corpus is introduced as another judgment basis, based on a preliminary study of speech recognition technology, scoring methods, and relevant theoretical knowledge of information feedback. This strategy can reduce the score limitation caused by standard pronunciation personal differences, lower the system's misjudgment rate in detecting pronunciation errors, and improve the usefulness of error correction information. An expert opinion database has been created based on the most prevalent forms of spoken pronunciation problems, which can successfully assist learners improve their spoken English level by combining the database's corrected information. Finally, this study proposes an artificial scoring system for spoken English that performs activities such as identification, scoring, error judgment, and correction opinion feedback, among others. Finally, it has been demonstrated through trials and tests that adding the average pronunciation level to the system improves the system's scoring performance and has a certain effect on increasing users' oral pronunciation level.

1. Introduction

In recent years, one of the hottest study topics in the domains of computer and education has been computer-assisted instruction systems. It has begun to gradually replace teachers to correct, particularly in large-scale language exams, which has become a significant change in the educational field. This type of technology is known as a computer-assisted language learning system [1]. Stress in English is a very essential prosody trait that affects rhythm and intonation, as well as having crucial grammatical and semantic implications. Mastering the stress rhythm correctly plays a crucial role in spoken English expression for language learners [2]. The oral English test now relies primarily on manual marking, which means that scoring is heavily impacted by the raters' psychological and physiological states, and objectivity and fairness of the scoring results cannot be guaranteed [3]. In the sphere of education, English is a critical topic. It will be extremely beneficial to boost students' enthusiasm in studying English, correct students' English pronunciation, evaluate students' academic achievement, and direct students' learning if artificial intelligence is combined with college English skill training [4]. The speech evaluation system is evolving in tandem with the advancement of voice recognition technology. It mostly uses a computer to assess people's pronunciation [5]. For example, the spoken Mandarin test system currently in use can not only score accurately, but it can also considerably enhance efficiency and save personnel [6]. Computer-assisted language learning has progressively begun to suit the diverse needs of language learners, thanks to the rapid development of speech recognition technology and other multimedia technologies. As a result, many researchers have been interested in a pronunciation evaluation system based on speech recognition technology.

Economic globalization has resulted in more regular exchanges between countries around the world today. The fact that English is an Esperanto has also sparked a lot of interest in learning English. People from non-native nations are increasingly keen to enhance their English abilities; in addition to understanding the necessary vocabulary and grammar, improving oral expression ability is also critical. As a result, in non-native countries, the methods of English education and learning have become a hot topic of discussion and research [7]. Oral English training is a crucial component of English instruction. It is difficult for teachers to provide one-on-one oral English instruction due to the large number of students in traditional classroom teaching. After class and examination, oral test questions have become an important link for students to assess their spoken English proficiency [8]. Fortunately, advances in voice processing technologies have made learning English easier and faster. In the realm of voice signal processing, the use of speech technology in language acquisition has become a major trend [9]. It is necessary to develop a system that can assist teachers in intelligently correcting subjective questions in language teaching in order to save time for teachers, save human and material resources for schools, and complete the correction requirements more accurately in order to save time for teachers, save human and material resources for schools, and complete the correction requirements more accurately [10]. Oral Q&A questions can be scored in two ways: from the perspective of pronunciation, and from the perspective of text. Acoustic variables like as pronunciation, frequency, and rhythm are typically used in pure speech scoring [11].

There are two factors to evaluating the level of spoken English in the CALL system based on speech technology. The core method entails identifying phoneme and word faults in learners' spoken language and providing appropriate feedback and solutions. Prosody judgment in spoken language is another factor to consider. For English learners, the latter is more challenging than the former [12]. It is now possible to obtain multidimensional automatic scoring for the open-ended oral language inquiry investigated in this research [13] because to advancements in speech recognition and artificial intelligence technology. This work will combine these mature new technologies with conventional automatic scoring-related technologies, with the goal of using text data after voice recognition as the research object and employing the multifeature fusion method to create a multifeature intelligent correction model. Make intelligent corrections from a variety of perspectives. Artificial intelligence can be used to grade oral expression questions, which appear to have no particular criteria and rely on teachers' subjective judgments. This is important for college English skill training guidance and correction [14]. The examinee's voice is used to do text recognition, with similarity and syntactic features taken from the text and phonetic features extracted from the speech. The automatic correction technology for closed-type oral exam questions cannot be directly transferred to open-type oral test questions due to the distinct principles of correction technology [15]. Because the traditional closed-type question type relies on known text to score speech, while open-type questions have nonunique responses, new text-independent technology is needed to overcome the challenge of open-type oral exam scoring [16]. Speech recognition technology has provided a solution for automatic scoring of large-scale Chinese-English oral translations. The automatic scoring approach not only ensures the correctness of Chinese-English oral translation scoring results, but it also considerably improves scoring efficiency and saves a lot of human, material, and financial resources.

2. Related Work

Document [17] examines the automatic correction of spoken language using an automatic composition correction system, and claims that it is possible to correct spoken language using speech recognition technology and a composition correction system. However, the spoken language correction approach suggested in this study has limits, and its scoring dimension is limited, therefore it does not allow for the evaluation of the pronunciation itself. Literature [18] pointed out that in the research of early stress recognition, the recognition system usually extracts some traditional phonetic features, such as sound length, energy, fundamental frequency, etc., and establishes a phonetic model by training linear discriminant function to recognize stressed syllables. Literature [19] puts forward that the functions of intelligent tutor system include building learning environment, communicating with students' emotions, and learning with students. Although the design of intelligent tutor system is called "intelligent" tutor system for evaluating students, it is not smart enough, and it still manages student information and arranges courses according to established rules, which canno't really replace tutors, and has certain limitations. Literature [20] lists the challenges faced by the modeling of simulated human scoring from the process and result levels, and points out that it is impossible to model the evaluation process comprehensively in the field of speech features and speech recognition at present. Literature [21] puts forward that under the dual influence of the abnormal needs of oral English learning and the development requirements of human computer interaction, the pronunciation evaluation system based on language lab recognition technology came into being. It fully integrates the two technologies of CALL and speech recognition to become a more intelligent English learning system, providing learners with opportunities for human computer interaction, and giving a lot of information feedback, completely changing the traditional English learning mode from "teacher teaching" to "student self-learning."

Literature [22] proposes that in the network environment, the automatic marking system plays a great role in the role orientation of teachers and students, because for non-English majors, their initiative in learning English is not high, and English learning is also very difficult for them. Literature [23] uses deep neural network to improve the robustness of the algorithm and retain the high discrimination of the algorithm, and obtains good experimental results. Although this algorithm is applied to reading questions, we can see that the application prospect of deep learning in oral automatic correction is very good. The combination of deep learning and automatic correction is an important direction for the development of automatic correction system in the future. Through the research on the application of automatic speech recognition system to non-native speech training, literature [24] pointed out that if appropriate methods are used and false pronunciation detection is added, the evaluation system can provide the same evaluation results as human experts. In terms of pronunciation quality evaluation, many studies at home and abroad have proposed various scoring algorithms, and the scoring performance produced by these algorithms has gradually approached the expert scoring level. However, in the research and implementation of pronunciation error detection and feedback information, many systems simply compare the phoneme recognition results with the phoneme correlation results of standard speech. Document [11] the automatic correction system is actually an upgrade of the intelligent tutor system. The intelligent tutor system guides students according to certain rules, and the automatic correction system also scores students' compositions according to the preset scoring rules. Automatic marking system is actually a combination of traditional intelligent tutor system and modern new technology.

3. Methodology

3.1. Multifeature English Spoken Scoring Algorithm. As one of the specific applications of computer-assisted language learning, the overall performance of spoken English scoring system largely depends on speech recognition technology. Multifeature fusion evaluation algorithm includes the evaluation algorithm of a single feature and the algorithm of fusing the evaluation results of multiple features. Because of the instability of the existing automatic speech recognition system, we can evaluate spoken English from this aspect. Multifeature comprehensive evaluation method should have at least the following characteristics: (1) scalability, that is, which features are selected and how many features are selected will not have great influence on the system, and it is easy to add or reduce features. (2) It has nothing to do with the evaluation algorithm of a single feature, that is, changing the evaluation algorithm of a single feature has no effect on the system when the evaluation result form of a single feature does not change. Speech signal analysis is the premise and foundation of speech signal processing. Only by analyzing the parameters that can represent the essential characteristics of speech signals can we use these parameters to process speech communication, speech synthesis, and speech recognition efficiently. And the quality of speech signal processing directly affects the effect of speech recognition. In the early speech recognition system, the isolated word recognition algorithm is the foundation, and its basic principle is to use template matching method for recognition. The fractal dimension characteristics of stressed syllables obtained by the polymorphic method are shown in Figure 1.

The following aspects are included in feature extraction: (1) energy features. The stationary process processing method and theory are incorporated into the short-term processing of speech signals, considerably simplifying speech signal analysis. (2) Characteristics of duration. The length of each syllable of a multisyllable English word is extracted and compared. Accents are defined as longer syllables. (3) The fundamental features of frequency. Fundamental tone detection is an important technology in speech processing that is frequently utilized in speech recognition, and fundamental frequency is one of the most important prosody parameters in the speech signal. (4) Prediction in linear form. Under the linear prediction technique, the LPC coefficient is a short-term measure of the speech signal. It is the foundation of speech processing and has been used in voice recognition, synthesis, coding, and other applications. The HMM-based scoring method requires pretraining a large number of acoustic models or reference models as a scoring standard, as well as combining the recognition and scoring mechanisms to determine the difference in phoneme pronunciation between the speech to be tested and the standard model and assigning a score. The scoring process based on HMM is shown in Figure 2.

In this method, the number of features can be increased or reduced as long as the weight a I is changed, which meets the first requirement of multifeature comprehensive evaluation method; changing the evaluation result form of a feature, as long as the corresponding quantitative method is changed, does not affect the whole algorithm, so it meets the second requirement of multifeature comprehensive evaluation method. In conclusion, this algorithm has strong scalability and independent of the evaluation model of single feature, and is suitable for comprehensive evaluation of spoken English. The similarity Manhattan distance formula is as follows:

$$D(A,B) = \sum_{k=1}^{n} |a_k - b_k|. \tag{1}$$

The formula for calculating the Dice coefficient is

$$D(A,B) = \frac{2 \cdot comm(A,B)}{leng(A) + leng(B)}. \tag{2}$$

Conditional probability mean of individual phonemes:

$$P = \frac{1}{n} \sum_{m=1}^{n} P(a_m \mid b_m). \tag{3}$$

The loss function is of the form

$$L(g_b, \hat{g}_b) = \left(g_b^{\gamma} - \hat{g}_b^{\gamma}\right)^2. \tag{4}$$

The multiscale shape distribution area is obtained as

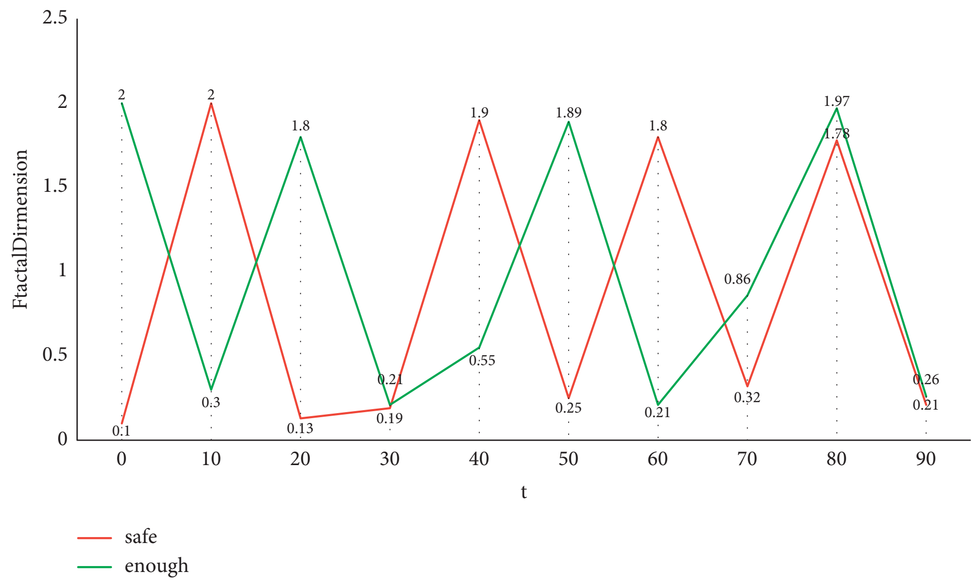

Figure 1: Fractal dimension characteristics of stressed syllables obtained by polymorphic coverage method.

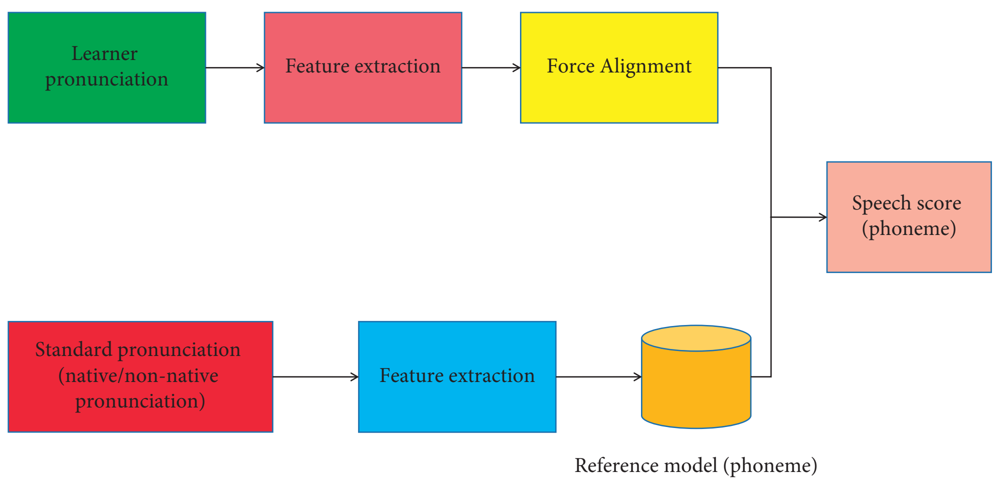

Figure 2: Scoring process based on HMM.

$$AB^{(\varepsilon)} = \text{area}\,(F \oplus \varepsilon B). \tag{5}$$

Linear rectification function of the formula is

$$f\,(x) = \max\,(0, x). \tag{6}$$

The log a posteriori probability scoring method based on HMM can not only better reflect the similarity between learners' pronunciation and standard pronunciation, but also reflect learners' pronunciation characteristics from pronunciation units such as phonemes and syllables, and has high stability. Therefore, this scoring method is widely used in relevant recognition systems or learning systems.

3.2. Design of Multifeature Intelligent Scoring Model. The whole scoring system includes three parts: speech recognition, feature extraction, and linear regression. The similarity features and syntactic features in feature extraction are extracted from the text after speech recognition, and the similarity features need to be compared with the reference answers. Automatic scoring of oral translation is mainly from two perspectives. One is to directly process the speech of oral translation and score oral translation directly; another point of view is to first convert the speech of oral translation into text, and indirectly score oral translation through text processing. The design purpose of the model does not focus on how to effectively recognize learners' speech, but how to improve the accuracy of system evaluation, reduce the misjudgment rate of pronunciation error detection, and whether the scoring accuracy of the system is improved when the average pronunciation scoring level is adopted under the same acoustic model. In the multifeature fusion evaluation system, the system only needs to recognize the input once, then evaluate the recognition results of multiple features respectively, and use the evaluation results of multiple features to give the final evaluation results. The multifeature intelligent scoring model is shown in Figure 3.

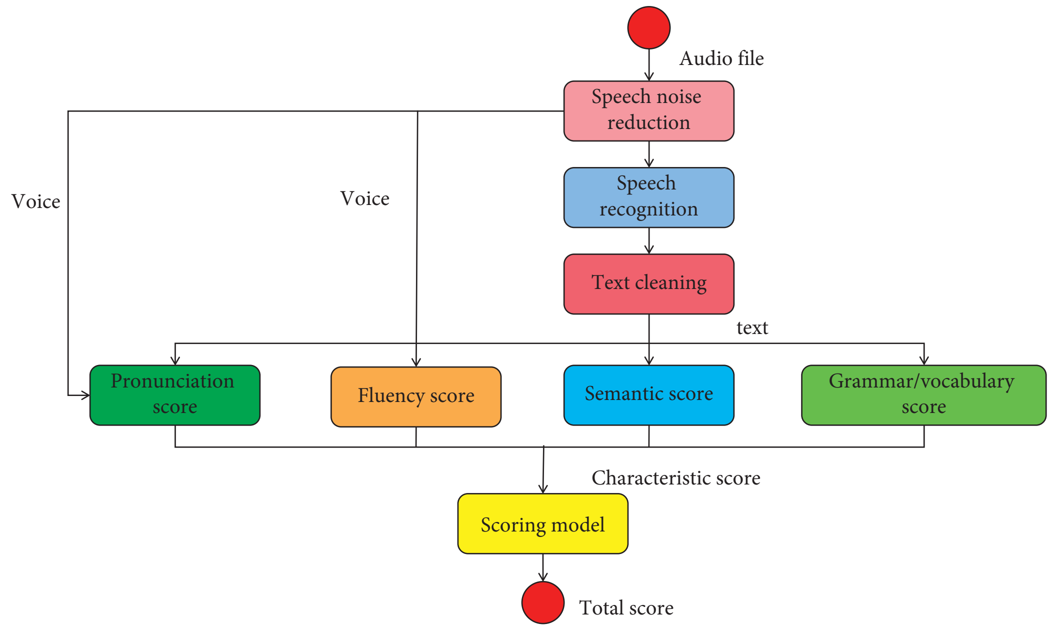

FIGURE 3: Multifeature intelligent scoring model.

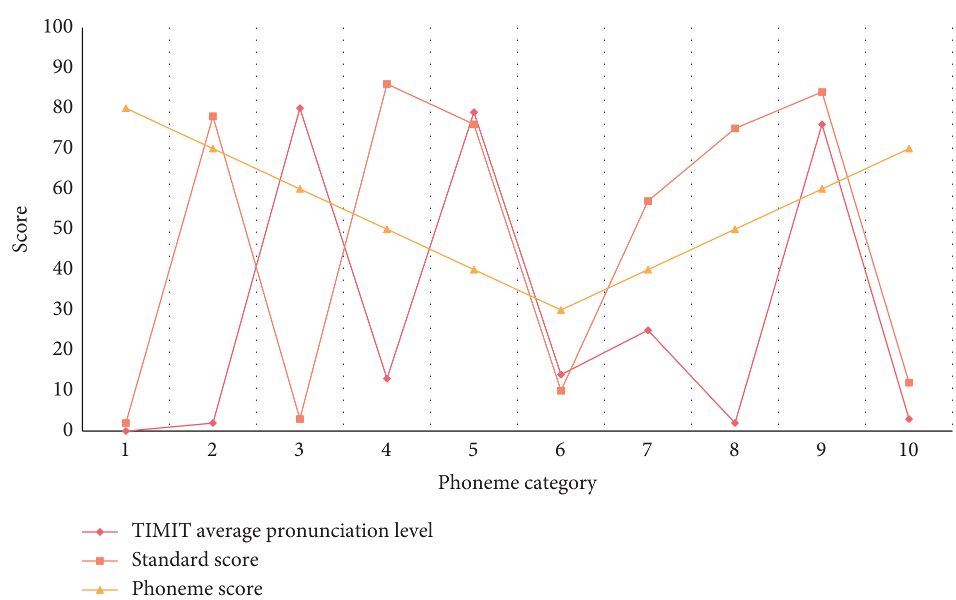

FIGURE 4: Comparison between score results and average pronunciation level.

Multifeature fusion evaluation system includes four parts: speech recognition, grammar expansion, single feature evaluation, and result processing. In order to make our feature extraction work smoothly and improve the accuracy, we also designed three data processing modules in the scoring model: (1) speech noise reduction module, (2) speech recognition module, and (3) text cleaning module. The training data is input into the neural network, and then the neural network is used for continuous training to train an intelligent scoring model. Then the test data is input into the intelligent scoring model to obtain the preliminary results of intelligent scoring, and the results are compared with the teacher's scores. Then, the model is feedback optimized, the model is improved, and finally the intelligent scoring model is determined. According to the statistical threshold of the corresponding phoneme, it is determined whether the learner's pronunciation is wrong, and the comparison between the score result and the average pronunciation level is shown in Figure 4.

Each extended new word's phonetic symbols are paired with the acoustic model and added to the system's lexicon. In this approach, the system can determine whether the oral practitioner pronounces the erroneous sound if the recognition result of the input speech is the expanded new word. When creating the system, the major design objectives should always be the system score, error

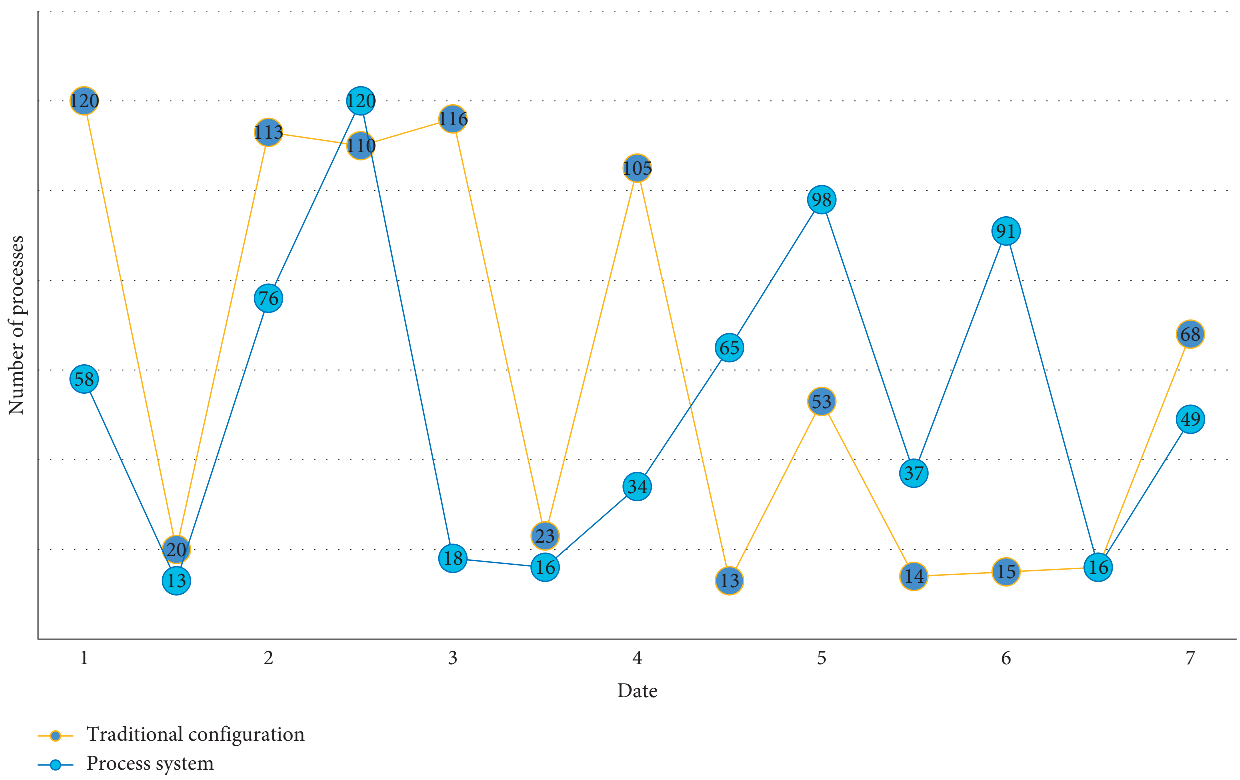

Figure 5: Comparison of the number of process runs.

prompt, and correction feedback. Simultaneously, we should consider the friendliness of the interactive interface between the system and users, as well as learning mode innovation, as additional objectives, in order to avoid reducing learning interest or efficiency due to boring learning forms or content, and to improve the system's operability. The statistical data of the operation process of the traditional configuration method and process system within one week are randomly intercepted, as shown in Figure 5.

First, feature extraction is performed on the dataset, and then these feature data together with the data labels are input into the neural network for supervised learning. After a period of learning and training, a classification model is finally generated, and we can use this model to extract features from the new spoken audio, and then input the features for scoring. The whole scoring process of the system is carried out from two aspects. On the one hand, the system itself needs to extract features and creates models for the selected standard corpus. At the same time, in order to eliminate the wrong scoring caused by the differences between standard pronunciation speakers, it also processes the standard pronunciation correspondingly, and selects the average of all phonemes as another reference factor to judge whether learners pronounce incorrectly or not. On the other hand, when learners input speech, the system will extract the features of their pronunciation through the speech recognizer, divide the feature values into phoneme-level scoring units, remove noises and noises, compare them with the standard reference model after forced alignment, and use the scoring algorithm in Chapter 3 to get the corresponding phoneme scores, thus completing the preliminary scoring of the system.

4. Result Analysis and Discussion

4.1. System Implementation. At first, the system will record the voice input by the user. After the user input is completed, the user input will be recognized by voice, and the result of the recognition will be expanded by grammar. Then, the linking and confusing sounds will be evaluated separately. Finally, the evaluation results of the two will be synthesized and the comprehensive evaluation results will be given. Automatic scoring performance is measured by correlation coefficient. The larger the correlation coefficient, the more consistent the scoring trend of experts on samples. The interface layout of English automatic scoring system is mainly divided into two parts. One is the selection and input of learners' pronunciation content, and the other is the feedback display of the system to users' pronunciation. Therefore, the realization of other main functions of the system, including speech recognition, is also realized in two parts. A linear criterion is used to distinguish the two categories optimally. The optimization criterion always increases the distance between classes and reduces the distance between classes. Most of the discriminant information can be obtained from the transferred feature space. The result processing part first quantifies the evaluation results of a single feature, and then synthesizes the quantized results to obtain the evaluation results of multifeature fusion. Finally, this chapter gives the realization method of the system. Users can choose the courses and exercises they want to learn. The

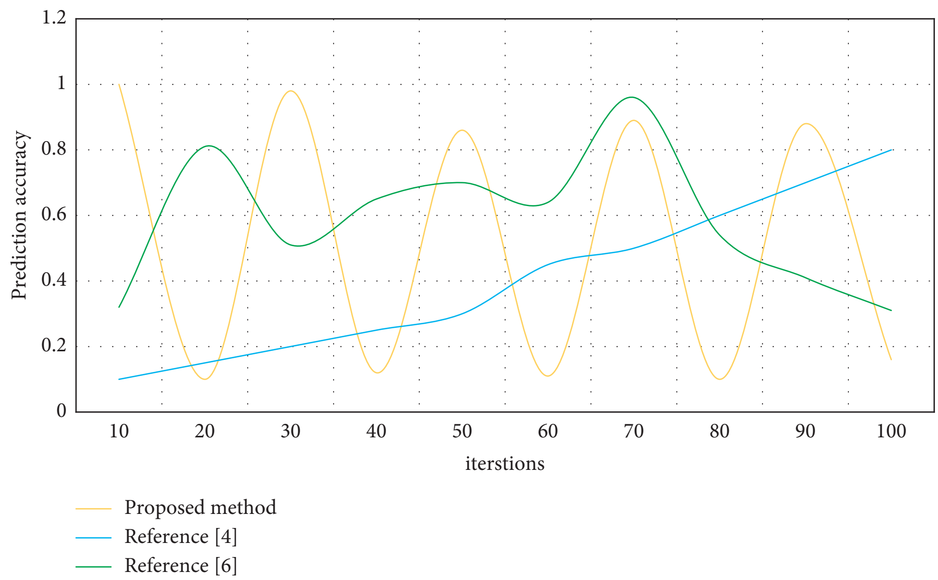

Figure 6: Comparison of detection performance.

system gives a comprehensive evaluation of the user's pronunciation, and marks the specific situation of the user's pronunciation and the areas that need improvement with special colors. Realize the pronunciation error detection of spoken English, test the detection performance, and get the results as shown in Figure 6.

Before comparing the scores, we must first segment the candidates' voice. Because the examinee has frustrations, repetitions, and other phenomena in oral expression, we are unable to 100% correspond the text and audio after speech recognition in the time dimension. Therefore, we need to segment the audio and try to align the pronunciation audio of standard words with the examinee's voice in the time series. If the user's pronunciation is not accurate enough, the system will refuse to evaluate and ask the user to learn again. After recording, learners can input their own pronunciation into the system, play back their previous pronunciation by using the user play function key, and get the score of previous pronunciation and corresponding correction opinions by using the scoring function key. Of course, if you cannot understand the problems of your pronunciation through scores and correction opinions, you can also compare the differences between your pronunciation and standard pronunciation to improve your pronunciation. You can only use standard playback. The whole process of system scoring mainly includes feature extraction, forced alignment, HMM-based posterior probability score calculation, mispronunciation judgment, correction feedback, and other processes. According to the needs of the system, the corresponding technical links are modified to realize the final scoring process. Learners can choose to play the standard pronunciation, and at the same time hear the pronunciation of the standard pronunciation, they can also see the score of the standard pronunciation in the right area of the scoring box, so that they can more intuitively see the differences between their own pronunciation and the standard pronunciation. At the same time, the expert opinion database will determine the final correction opinions according to learners' scores, standard pronunciation scores, and average pronunciation level of standard pronunciation.

4.2. Result Analysis. After using the average level as a reference, the judgment threshold has changed correspondingly, and the accuracy rate of wrong judgment of the system has been improved, which leads to the improvement of the accuracy rate and the reliability of feedback information. Figure 7 shows the results of comparing the accuracy of error capture of several approaches of spoken English pronunciation.

Because the learner's voice is first compared with the standard voice, the average level will be used for comparison when there is a large gap, so as to ensure that the learner's voice is infinitely close to the standard voice in terms of pronunciation level without pronunciation error and misjudgment, which also meets the design requirements of similar systems. The free English composition automatic correction online service based on corpus and cloud computing can instantly generate the scores, comments, and content analysis results of students' compositions by calculating the distance between students' compositions and standard corpora, which can provide multidimensional scoring results. Artificial intelligence can play the teaching role of constructivism, because artificial intelligence can analyze data in a short time, so it can find teaching resources that are conducive to learners' characteristics and in line with learners' cognitive style. Artificial intelligence can store and analyze a large amount of learner characteristic data. Through the analysis of learners' learning style and cognitive level, teachers can understand learners' advantages and disadvantages, make teachers timely and accurately adjust teaching strategies and teaching methods, and make learners more acceptable. Therefore, artificial intelligence can better guide teaching practice.

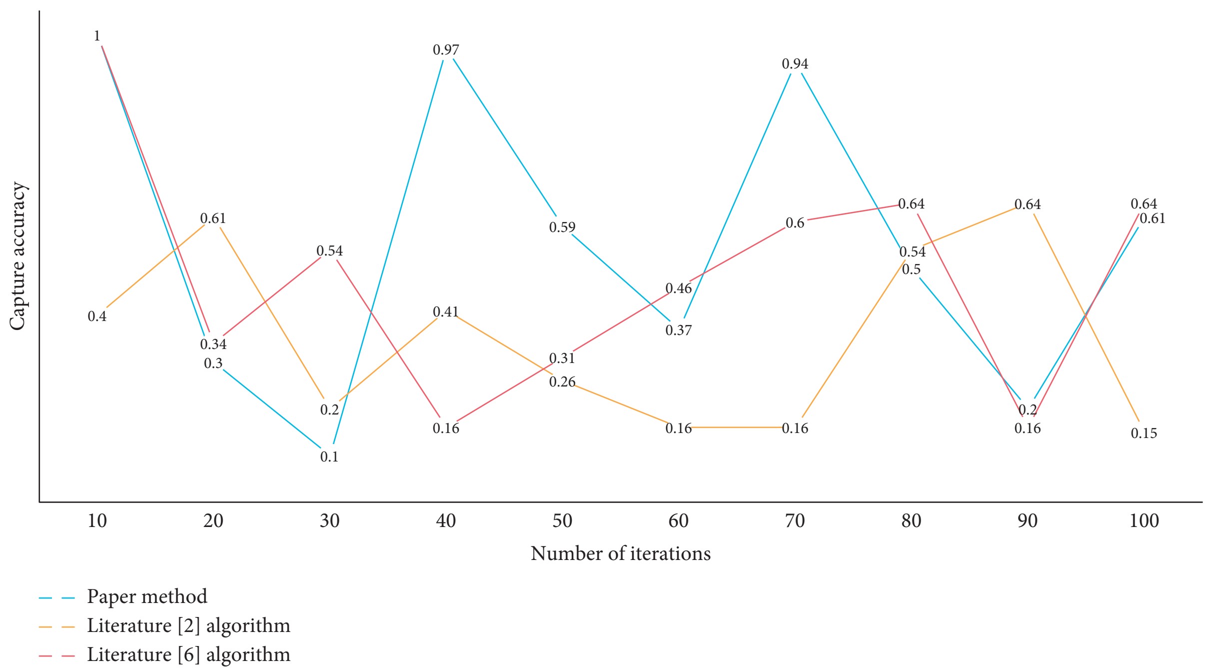

Figure 7: Comparison of capture accuracy.

After the system adopts an average pronunciation level based on standard speech as the error judgment standard, the accuracy of error detection has been improved to a certain extent. It is worth noting that since the system adopts the corpus of foreign pronunciation, it is possible to deviate from the normal value only from the score given to learners by the system, but when the same acoustic model is used as the system score. The verification of error detection accuracy is not affected, because the average pronunciation level used here is based on standard pronunciation as the source data. It is assumed that when the Chinese pronunciation corpus is used as the standard pronunciation for scoring and error judgment, the score is closer to the learners' real level, but the error and misjudgment caused by individual differences in standard pronunciation is still inevitable. Based on the multifeature fusion evaluation algorithm, the training and testing results show that the performance of the algorithm is good and the algorithm shows good stability under different weights. The automatic scoring system of spoken English is realized, with emphasis on the recording function, scoring process, and the realization process of expert correction feedback. The experimental data are analyzed by two error judgment methods: standard pronunciation score and average pronunciation level, and adding average pronunciation level to judge. The experiment shows that the method proposed in this study can effectively reduce the misjudgment rate, and the running performance of the system itself is stable, which basically meets the practical application standards of this kind of system.

5. Conclusion

The salient points of this study are: first, try to take speech recognition text as the research object to score the oral test; secondly, the similarity feature is improved, and a keyword coverage based on editing distance is proposed, and these two features are better than those obtained by traditional methods; thirdly, multiangle feature extraction and multifeature fusion in linear regression system. Fourth, select features and delete redundant features. Although the accuracy rate of speech recognition has been claimed to be over 95% in official documents, in the actual process, due to the test environment, the influence of students around and the noise nearby, the output result of speech recognition will be affected. The speech features are extracted by direct analysis of speech signals, the similarity features and syntactic features are extracted by analysis of the text after the speech signals are converted, and the automatic scoring system is obtained by using multiple regression analysis model. The corresponding evaluation algorithm is established, and features are added into the multifeature fusion evaluation system. Comprehensive evaluation system of spoken English, which integrates a large number of features, will be the future development direction. At present, the automatic scoring technology of open spoken questions is deeply studied and compared. Through feature fusion, Rank Net neural network maps the complex nonlinear relationship among features, and establishes the recognition model of stressed syllables in words and stressed sentences, which can accurately recognize stressed syllables in words and stressed sentences. This study summarizes the valuable experience of predecessors' work, innovatively applies and improves the key technologies, integrates and improves the latest technical schemes at present, puts forward and realizes a new open oral correction model, innovates the method of voice feature extraction, and improves the dimension of open oral scoring.

Geometric ability includes elements of identification, conceptualization, combination, drawing, and reasoning, and graphic perception is an important part of it. Kindergarten science education includes geometry instruction. Children are guided to perceive the relationship between shapes and figures through direct perception, first-hand experience, and practical operation through concentrated educational activities, and form image-concrete thinking over time, enhancing their perception and experience of the relationship between shapes in the objective world, and accumulating certain mathematical perceptual experience. Clustering is a branch of unsupervised pattern recognition that is very useful. Fuzzy clustering, which establishes the uncertainty description of samples to categories and can objectively reflect the real world, has become the mainstream of cluster analysis research. The graphics perception education of children is investigated using fuzzy clustering analysis. The main topic of this paper is how to apply children's graphics to the design of children's educational institutions and open up new creative perspectives for the design of children's educational institutions. The method of graphic perception education: perception education for preschool children is proposed based on the multichannel characteristics of preschool children's aesthetic perception and with reference to the theory of perception. The experimental results show that the improved algorithm reduces segmentation time by 171.48 s when compared to the traditional FCM algorithm for both noisy and high-quality images and that it is significantly faster than the FCM algorithm in terms of segmentation speed. As a result, the model construction of a set of children's graphic perception education for the cognitive characteristics of the age group children can provide corresponding references and references for related topic research.

1. Introduction

The abstraction and generalization of shape are known as geometry. In the process of human understanding of nature, it appeared as a symbolic system before language and words [1]. Children's geometry education is an important part of their mathematics education, and the living of geometry education encourages children's perception and experience of graphical relationships in the objective world, allowing them to accumulate perceptual experience in mathematics [2]. The ability to recognize and combine plane figures is reflected in two main areas in early childhood [3]. Learning graphics properly aids children in developing a correct understanding of life and the world around them, as well as their curiosity, curiosity, and interest in geometry and mathematics [4]. It also aids in the development of children's thinking abilities and qualities, which will aid in their future mathematics learning in elementary school [5]. Living conditions are improving, and parents are becoming more aware of the importance of having their children educated in graphics, indicating that children's art education is entering a new era [6].

People communicate with the outside world through their senses. Children, in comparison to adults, rely on their senses to gather information about the world around them [7]. People always try to find features that can describe a new object or phenomenon in order to compare it to known objects or phenomena to see if they are similar according to some fixed criteria and rules in order to recognize it or understand it [8]. Only certain parts or regions of an image are of interest in the study and application of images, and these parts are referred to as the target or foreground, whereas other parts are referred to as the background and generally correspond to specific and unique regions of the image [9, 10]. Perceptual design and graphic design are being studied together in order to integrate perceptual design and children's art educational spaces. The main goal is to bring children closer to the art education space, reflect the educational function of the environment, mobilize children's perceptions through their visual, tactile, olfactory, and auditory senses, and promote children's enthusiasm for knowledge exploration [11].

Geometric thinking skills, which include elements of identification, conceptualization, combination, drawing, judgment, reasoning, and presentation, are an important part of geometric abilities [12]. The targets in an image must be separated and extracted before they can be identified and analyzed. It is possible to further measure the targets and use the images on this basis. Cluster analysis [13] in kindergartens for geometric educational activities helps children perceive geometric features through seeing, touching, thinking, guessing, and trying and deepens and consolidates their knowledge of geometric figures [14]. Color images, on the other hand, have unquestionably assumed a dominant position in the new century, thanks to technological advancements and lower hardware costs. Color images play an important role in people's daily lives and technological applications because of their visual properties and rich color information. Young children learn inexhaustibly and can achieve great success in their future learning if they are equipped with the ability to transfer and construct knowledge. The following are the paper's unique features.

(1) Applying perceptual design to graphics, children's educational space embodies space can promote children's art education through children's sense of hearing, touch, smell, and vision to promote children's learning process.

(2) To find the inner connection between fuzzy cluster analysis and children's geometric graphic education activities, and to dig, filter, and refine the mathematical elements in the resources that are suitable for children's geometric graphic education activities.

(3) To address the shortcomings that the fuzzy C-mean clustering image segmentation [15] algorithm does not consider the different degrees of the contribution of each dimensional feature to the clustering and easily falls into local optimum, an improved fuzzy clustering algorithm based on kernel function is proposed.

This paper's research framework is divided into five major sections, which are listed below. The first section of this paper introduces the research background and significance before moving on to the paper's main work. The second section covers graphic perception training for young children as well as work on fuzzy clustering analysis. The third section of the paper introduces the conceptual direction of graphic perception education as well as the steps for implementing perceptual strategies in graphic education so that readers can gain a better understanding of the concepts of graphic perception education for young children using fuzzy cluster analysis. The thesis's fourth section concludes the description of fuzzy clustering analysis' application in early childhood graphic perception education by looking at two aspects: the analysis of fuzzy C-mean clustering image segmentation algorithm and the analysis of improved kernel function-based fuzzy clustering algorithm. The final section of the paper is a summary of the entire project.

2. Related Work

2.1. Children's Graphic Perception Education. Geometry is an important part of a child's development and is one of the fundamental components of their mathematics education. Geometry education activities in kindergarten refer to the geometry education activities that teachers plan and implement purposefully, planned, organized, and systematically within the time constraints of normal kindergarten teaching activities, in accordance with the rules of children's physical and mental development, as well as the characteristics of mathematical cognitive development. Through the transformation and application of geometric figures, as well as the use of symmetrical features to analyze mathematical situations, children can analyze the characteristics and properties of two- and three-dimensional geometric figures ad use visual and spatial reasoning, as well as geometric models, to solve problems.

The applications proposed by Tai and Ledai require teachers to arrange and organize the content in a way that integrates with other artistic activities such as music, dance, and literature, as well as with children's life experiences, in a way that helps children to generate "common experiences" and "complementary experiences" [16]. Li et al. proposed the five developmental levels for children, which became the most influential theory for the geometry curriculum in the United States and has been refined in subsequent developmental studies [17]. Feng and Chen argued that art appreciation works should be appreciated in a sequence from abstract to concrete and then from abstract to concrete. Works with strong emotional expression are the primary consideration in selecting works [18]. Rajkumar et al.'s developmental levels of graphic perception education describe the process of children's geometric thinking and the characteristics of children's geometric thinking at each stage, not just how much geometric knowledge children have mastered [19]. Shakeri et al. argue that preschool children's preferences for color and expressive style of artworks reflect their preference for aesthetic features [20].

Exploring the characteristics and patterns of children's graphic perception not only helps teachers to better understand the importance of teaching children's geometry but also helps them to grasp the characteristics and patterns of children's graphic perception and to gain a concrete and in-depth understanding of the developmental process of children's geometric thinking skills.

2.2. Fuzzy Cluster Analysis. In recent years, domestic research on children's graphic perception abilities has begun to emerge, primarily from the perspective of child psychology. Further research in the areas of fuzzy cluster analysis and multicultural perspectives is required. Children learning mathematical knowledge is only the surface manifestation of development in mathematics education; the key is to encourage the development of children's thinking structures through the learning process. The basis of target representation is image segmentation based on fuzzy cluster analysis, which has a significant impact on feature metrics. Image segmentation and goal representation, segmentation-based feature extraction, and parameter measurement, on the other hand, reduce the original image to a more compact form, allowing for higher-level image analysis and comprehension.

Goyal et al. proposed clustering algorithms for image segmentation because the subjective nature of human vision makes images more suitable for fuzzy processing [21]. Pham et al. used fuzzy entropy to analyze the homogeneity of images to obtain initial major homogeneous regions and then grouped pixels with similar colors in these regions to prevent oversegmentation [22]. Berikov proposed that fuzzy should be used in image segmentation processing. Also, the absence of patches in training sample images requires unsupervised analysis, and fuzzy clustering satisfies both requirements, thus becoming a powerful research and analysis tool in image processing [23]. Mlr et al. proposed a combination of the histogram and fuzzy C-mean clustering. This method obtains all possible uniform regions in a color image by histogram thresholding and then improves the tightness of the regions by fuzzy C-mean clustering [24]. Jia and Zhang used an automatic histogram analysis method to obtain the peaks and troughs of the histogram by automatic histogram analysis, then performed fuzzy clustering according to the determined number of clusters, and then used the distance between adjacent troughs in the histogram The mean value between adjacent troughs in the histogram is used as the initial clustering center.

Unsupervised classification, also known as cluster analysis, is the process of distinguishing and classifying things according to certain requirements and rules. In this process, there is no a priori knowledge about the classification [25], only the similarity between things as a criterion for class classification. Through education in recognizing geometric figures, combining and dividing geometric figures, and drawing geometric figures, children can get an initial understanding of the characteristics of shapes, learn to spell and draw them creatively, stimulate their interest in learning mathematics, and develop their ability to think about concrete images.

3. Thoughts on Education of Children's Graphic Perception Based on Fuzzy Cluster Analysis

3.1. Conception Direction of Graphic Education. Perception is an active process based on the relationship between a person and the outside world. From the day of birth, a person can spontaneously acquire knowledge about the inner self and the outer environment through the different senses of the body [26]. The education of graphic perception needs to be diffused and recorded, taking the text closest to the design focus to further deepen it. By splitting and reorganizing the various visual elements, the information and ideas that are wanted to be conveyed are translated into concrete graphics and then clearly communicated to the viewer [27]. For the given number of categories c, fuzzy weighted division matrix U, and weighted coefficient matrix W, the fuzzy division entropy of the sample set X is defined as

$$H(U;c) = -\frac{1}{N}\sum_{k=1}^{n}\sum_{i=1}^{c} w_k u_{ik} \ln(u_{ik}). \tag{1}$$

The activities were adjusted according to the specific practice, and educational activities were suggested to promote the cognitive development of children in mathematics. The specific flow of the study is shown in Figure 1.

First, depicting reality is a depiction and replication of what exists in reality, a reproduction of the real thing. Also, parents say that the teaching environment is most likely to make a first impression. Teachers select appropriate domestic and international paintings based on the age, preferences, and appreciation of children and the "principle of difference" in their aesthetic psychology. Therefore, the composite index value is not equal to the simple sum of the indicators but a weighted summation relationship, namely,

$$S = \sum_{i=1}^{n} w_i f_i(I_i), \quad i = 1, 2, \ldots, n, \tag{2}$$

where $f_i(I_i)$ is some measure of I_i, and w_i is the weight value of each index.

The integration of cluster analysis into geometry educational activities can make geometry vivid and visual, stimulate children's interest, bring them sensory stimulation from many aspects, and mobilize children's multiple senses to participate in activities [28]. For a given number of categories c, fuzzy weighted division matrix U, and weighted coefficient matrix W, the modified division fuzziness of the sample set X is defined as

$$\mathrm{MPF}(U;c) = \frac{PF(U;c)}{H(U;c)}. \tag{3}$$

Feature extraction [29] is the generation of useful new features from the original features through some transformations, whereas feature selection is the selection of features that help to distinguish different objects from a set of candidate features. Perception is the knowledge of various other elements of things and a complete, three-dimensional, and multidimensional overall grasp of the shape, color, space, light, tension, and texture of things [30]. Children's senses are generated through their senses as a process of representation of different stimuli of the external environment and a reflection of the individual characteristics of things. The designed activity program places children at the center of the activity, incorporates perceptual education into the teaching process, and encourages children to participate

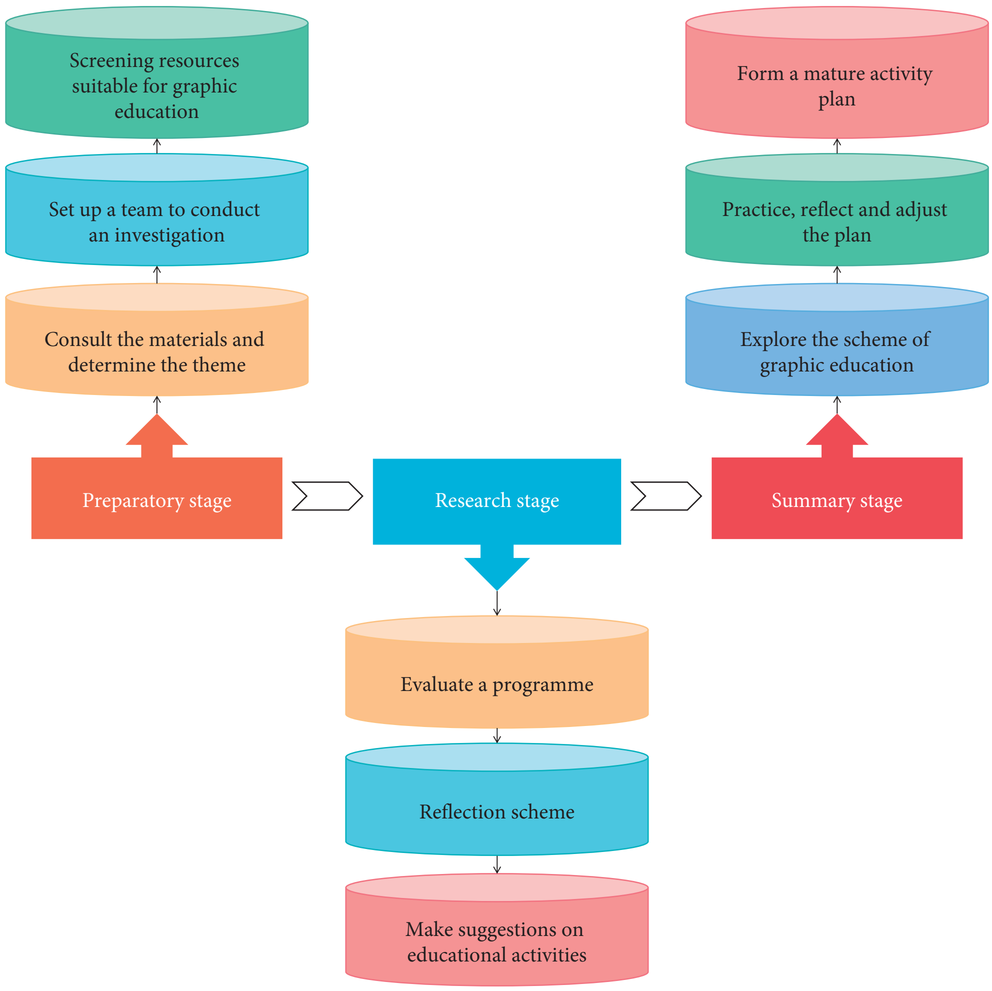

FIGURE 1: Research flow chart of kindergarten profit graph education activities.

in teaching activities in a fun way. The flowchart of teaching activities of geometric figures using kindergarten perceptual education is shown in Figure 2.

Secondly, artistic abstraction refers to the abstract expression of things; it is a kind of art form which is detached from the natural appearance. Generally speaking, artistic abstraction expresses subjective attitude through color and shape. The teacher needs to analyze the formal elements, spatial characteristics, and colors of the painting in a comprehensive, in-depth, and detailed manner in order to identify the forms that fit the definition of the "perception" strategy. This step is usually combined with the selection of the appropriate similarity measure and the establishment of a criterion function, followed by the grouping of samples according to whether they are similar to each other or not. For any sequence that iterates and eventually converges, the speed of convergence increases significantly and the number of iterations decreases significantly when the initial value of the iteration is close to the final convergence result. Children can understand the characteristics of graphs through experience, which is a favorable condition for teaching graphs. Also, this feature can explain the types of errors children make: similar graphs, similar objects, and confusing names. A higher affiliation is surrounded by a lower affiliation of the same category. Based on this understanding, a new objective function can be introduced:

$$J_m(U,V) = \sum_{k=1}^{n}\sum_{i=1}^{C}\left(u_{ik}\right)^m\left(d_{ik}\right)^2 + \frac{\beta}{N_R}\sum_{k=1}^{n}\sum_{i=1}^{C}\left(u_{ik}\right)^m\sum_{j\in Nk}\left(1-u_{ij}\right)^m. \tag{4}$$

Finally, spatial constructions were mostly made by stacking geometric shapes, and spatial constructions were made by matching the shapes and colors of geometric shapes. Compared to circles, squares, and triangles, circles accounted for the majority of children's scribbles, with a few concentrated in squares or triangles. Given a dataset, each clustering algorithm can generate a division regardless of the presence or absence of a clustering structure. Moreover, different methods usually produce different clustering results. Even for the same clustering algorithm, differences in parameters or the order of input samples may affect the final result. The urban kindergarten teacher did not teach the children geometry during this time, so the difference caused by the time factor is negligible.

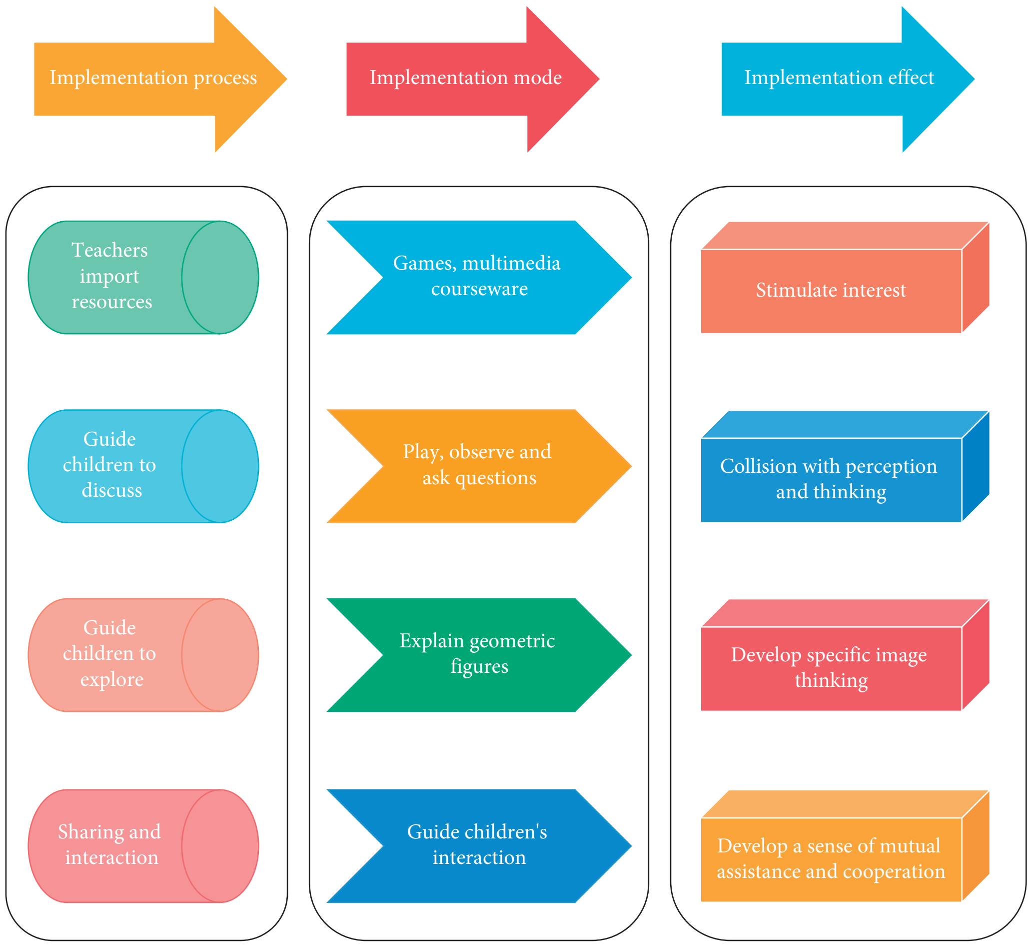

FIGURE 2: Flow chart of geometric figure teaching activities in kindergarten by using perceptual education.

3.2. Steps of Applying Perception Strategies in Graphic Education. When incorporating perceptual education in kindergarten geometry education activities, it is important to pay attention to the program design and the flow of activities according to the laws of kindergarten education and teaching activities and children's development. Children show disappointment in front of works with which they are very familiar, but they are indifferent when something completely unfamiliar is put in front of them. Only those things that are different from what they are familiar with, but can be seen to have some connection to them, are the ones that really appeal to them. The clustering method is to obtain homogeneous regions by manipulating the pixel features of images, while region growth is to divide regions by combining pixel features of the image domain and spatial information. The color image segmentation process in this paper is schematically shown in Figure 3.

First of all, choose paintings with strong musical expression. Geometry education activities applied to cluster analysis in kindergarten take the familiar living resources of young children as the carrier and the process of playing games as the main form of educational activities, so that children can increase their perception of geometric figures in the process of fun and education. Many masters of painting, both ancient and modern, have created numerous classic works, but not all of them are suitable for art appreciation activities using perceptual strategies. Because the unit used in each feature is incomparable, its size can represent the characteristics of the sample in that feature. Based on the principle of feature balance, that is, the contribution of each feature to the classification is essentially equally important, let the balance coefficient be r_j, which is calculated as follows:

$$r_j = \frac{\max\left\{\sum_{i=1}^{c} p_{il}, l = 1, 2, \ldots, s\right\}}{\sum_{i=1}^{c} p_{il}}, \quad j = 1, 2, \ldots, s. \tag{5}$$

The whole technique optimizes the points that may be pixels in the whole edge of the image, taking into account the overall variation of the large area, so as to obtain the most suitable set of edge points. The image is segmented using the standard FCM algorithm to obtain the best division matrix U and the objective function value J_{FCM}, and then the following function values corresponding to this division matrix U are calculated:

$$J_{\mathrm{add}} = \frac{1}{N_R} \sum_{k=1}^{n} \sum_{i=1}^{c} u_{ik}^{m} \sum_{j \in N_k} \left(1 - u_{ij}\right)^{m}. \tag{6}$$

Then use the following equation to calculate the coefficient β:

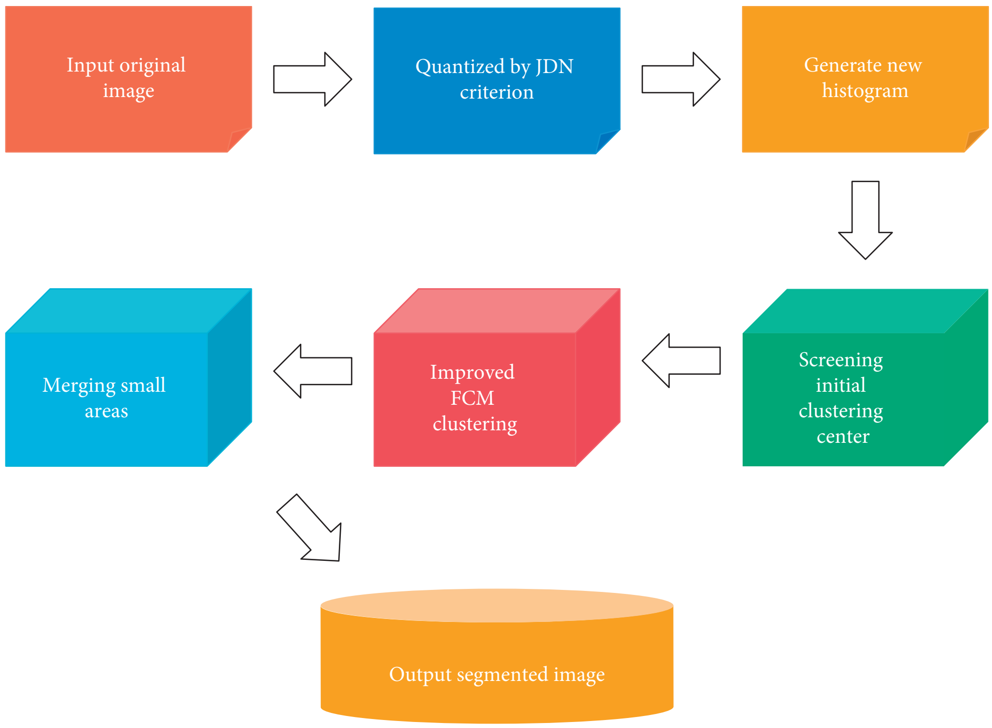

FIGURE 3: Schematic diagram of color image segmentation process.

$$\beta = \frac{J_{\mathrm{FCM}}}{J_{\mathrm{add}}}. \tag{7}$$

Children can master eight shapes in terms of difficulty. From easy to difficult, the order is circle, square, triangle, rectangle, semicircle, trapezoid, rhombus, and parallelogram. In the splitting phase, the homogeneity criterion is used to divide image regions into many homogeneous regions, and in the merging phase, adjacent similar regions are merged into one region. The instability of children's pattern recognition and the inattention to children's exams can affect the development of children's pattern recognition ability. As we know from the role of standard deviation in mathematical statistics, standard deviation describes the degree of concentration and dispersion of data. So the degree of class separation can be measured by the standard deviation of the clustering prototype, which is calculated as follows:

$$d_{ij} = \sqrt{\sum_{i=1}^{c} \left(p_{ij} - \overline{p_j}\right)^2}, \quad j = 1, 2, \ldots, s. \tag{8}$$

Second, timely and appropriate display of paintings is the second step in implementing the perception strategy. Based on the laws of children's physical and mental development, children are provided with objects, pictures, videos, etc. It is easy to use the surrounding life resources for visual observation and direct manipulation in educational activities and can be explained concisely in a language that children can understand to promote their correct perception of geometric figures. However, there is a mixture of nonestablishment and establishment in children's doodle investigations on a piece of paper, so it cannot be concluded that they are completely ignorant, but only that the degree of understanding of the investigation varies at this moment. Fuzzy clustering segmentation generally fails to effectively use the information of the spatial relationship between image pixels, which easily leads to discontinuity in the segmented region. In another segmentation, the number of categories may be incorrect, and there is often the possibility of oversegmentation. Let $X = \{x_1, x_2, \ldots, x_n\}$ be a collection of sample data mapped from the input pattern space R^s to the feature space R^p by a nonlinear transformation $\varphi(\bullet)$. The objective function for partitioning the data set into classes is

$$J_m = \sum_{i=1}^{c} \sum_{j=1}^{n} u_{ij}^m \left\| \varphi\left(x_j\right) - \varphi\left(v_i\right) \right\|^2. \tag{9}$$

Therefore, multiple clustering centers are selected as seed regions. Using these seeds as starting points, different strategies and methods are used to classify the neighboring pixels around them that satisfy their feature conditions. Generally, after the clustering is completed, the segmentation results need to be processed by some merging classes so that the final segmented regions are meaningful. Let K be the kernel function defined on the dataset, which is defined by an implicit mapping:

$$K(x, y) = \langle \varphi(x), \varphi(y) \rangle, \varphi\colon X \longrightarrow F. \tag{10}$$

Finally, mobilizing children's sensory systems such as hearing, smell, taste, and touch to improve the appreciation of drawing is the third step in implementing the perception

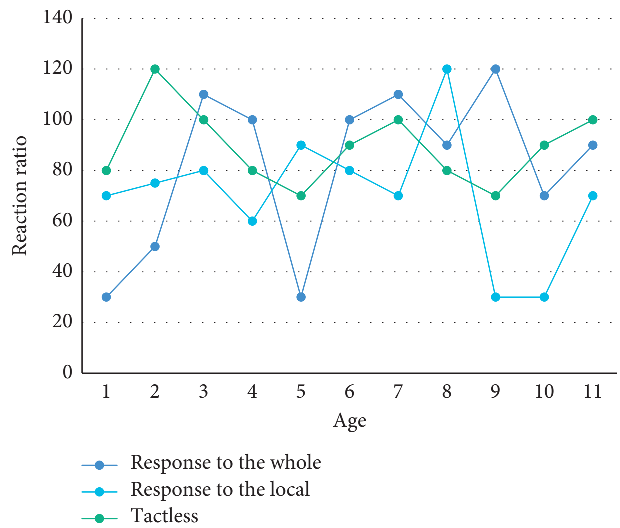

Figure 4: Ratio of responses of subjects of different age groups to global and local characteristics under the condition of free attention.

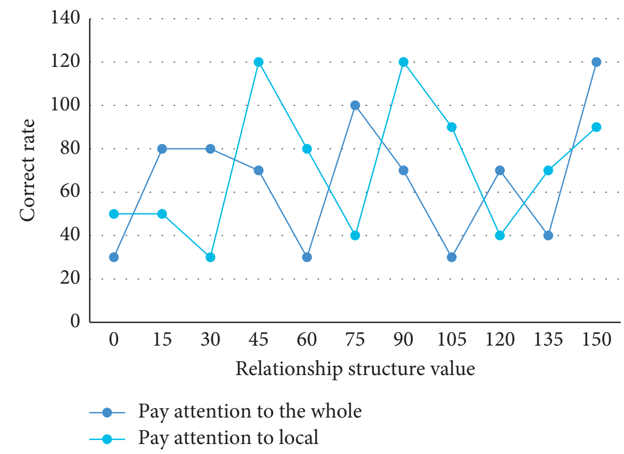

Figure 5: 5-year-old subjects' attention to the whole is influenced by the structural relationship.

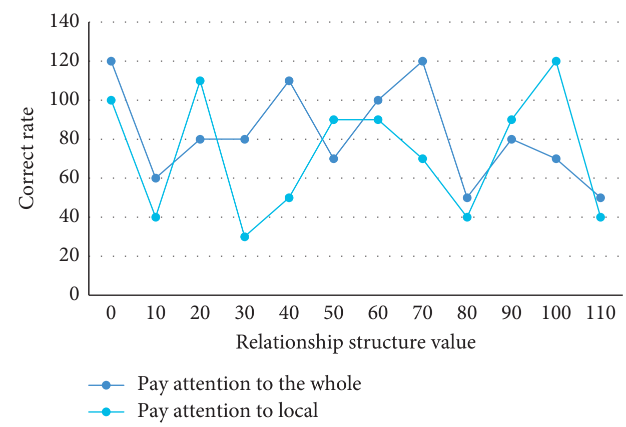

Figure 6: The 10-year-old group was influenced by the structural relationship when paying attention to the whole.

strategy. Children are fully guided to develop a strong interest in participating in geometric educational activities by creating contexts, providing manipulative materials, and designing games, with a focus on stimulating their interest in observation, thinking, and manipulation, making the process of educational activities vivid and interesting, and enhancing their desire to explore geometric shapes. The original histogram is recalculated using the JND color model with the minimum visible difference in human vision, and the three-dimensional axes of the original image histogram are sampled without affecting human vision to obtain new histogram pixel values, whether children's planar geometric figure recognition and combination abilities are positively or negatively correlated. Regardless of which research is conducted, the findings should ultimately guide practice, and the findings should assist kindergarten teachers in better understanding the characteristics and trends of young children's graphic perception.

4. Application Analysis of Fuzzy Cluster Analysis in Children's Graphic Perception Education

4.1. Analysis of Image Segmentation Algorithm Based on Fuzzy C-Means Clustering. The FCM algorithm is used for image segmentation by fuzzy clustering pixels with consistent attributes in an image and then calibrating the pixels in each class. In most cases, the given dataset consists of several samples. Each sample is multidimensional, and each dimension corresponds to a feature or attribute value. No matter how the objective function is defined in the FCM algorithm, there is a corresponding clustering prototype corresponding to it, so the convergence speed and even the clustering effect necessarily depend on the initial division. Since child subjects cannot respond as quickly as adult instructions, the response rates of subjects of different age groups to global and local features in the free attention condition are shown in Figure 4.

First, the pixels of the images are used as sample points of the data set, and the features of the pixels are the features of the grayscale images; i.e., the grayscale images are used as sample points. The test of children's planar geometry combination ability includes two parts. The characteristic of the combined audiovisual animation is that the animation content is a reproduction of the painting content, which gives life to the painting and makes the frozen moment flow. Since only the grayscale information of pixels is used in the grayscale threshold segmentation, the grayscale histogram can be used for clustering instead of the pixels of the image. However, because the statistical information of the original statistical histogram is scattered, the direction of the histogram curve may not be very clear and the peaks and valleys cannot be well selected for image segmentation. Therefore, the original histogram must be smoothed before it can be used in the subsequent segmentation center selection process. A further significance test was conducted to examine the difference between responses focusing on the whole and those focusing on the local. Setting up experiments in which

5- versus 10-year-old subjects were influenced by structural relations when paying attention to the whole, the experimental results are shown in Figure 5.

Second, the image is segmented using the difference between the background and the object as shown in Figure 6, taking a complete circle and dividing it into two semicircles, three obtuse sectors, and four right-angled sectors. To prepare for perceptual drawing, creatively recreate situations based on the teacher's picture composition using manipulable material materials, similar structural forms, and emotions. The number of samples in the grayscale domain is a fixed value independent of image size and equal to the number of grayscales in grayscale images once the grayscale of the image is known. If the image to be segmented has a clear difference between the background and the segmented object, i.e., if the histogram has a clear threshold that can segment the image into several separate parts, this method allows for quick and simple segmentation.

Finally, the pixel values of one or more image dimensions are counted to produce a histogram of pixel statistics for the image's dimensions. The histogram will show distinct peaks in homogeneous regions in an image with similar colors. The number of samples for clustering will be greatly reduced, the complexity of the computational matrix will be reduced, and the efficiency of the general-purpose algorithm for image segmentation will be increased if the pixels of an image are clustered with grayscale histograms instead. Geometry is vibrant, and so should the educational activities that accompany it. It is critical to fully explore children's interest in geometry and to allow them to enjoy geometry educational exploration activities through games. The juxtaposition of reality and imagination characterizes the combination of art appreciation and physical objects, with the same image highlighting the painting's unique color matching, form, and other artistic aesthetics. Set a color merging range after determining the central pixel values of several clusters. The color distance between all pixels in the image and these central pixels should then be calculated. The colors are merged if they are within the range; otherwise, they are identified as new cluster centers, and so on, until all pixels have been processed.

4.2. Analysis of Improved Fuzzy Clustering Algorithm Based on Kernel Function. Classical clustering algorithms directly use Euclidean distance as a similarity measure, and close samples in the sample space are clustered together. However, the commonly used edge operators are wide edges, so the obtained edges must be refined to ensure accurate color values are obtained. Therefore, the improved kernel function-based fuzzy clustering algorithm can map the samples in the input sample space to a high-dimensional feature space in which the nonlinear learning problem may become a linear learning problem. In this study, the mean scores and standard deviations of basic plane geometry figure recognition of 200 children in three age groups of elementary, middle, and large classes were statistically analyzed, as shown in Table 1.

Table 1: Average score and standard deviation of basic plane geometry recognition of children of all ages.

	Reception class	Middle class	Big class
Triangle average	3.24	5.98	10.54
Triangle standard deviation	0.45	1.65	2.77
Circular average	2.78	4.26	7.84
Circular standard deviation	0.27	1.27	1.85
Rectangle average	1.73	3.76	5.98
Rectangle standard deviation	0.17	0.94	1.26

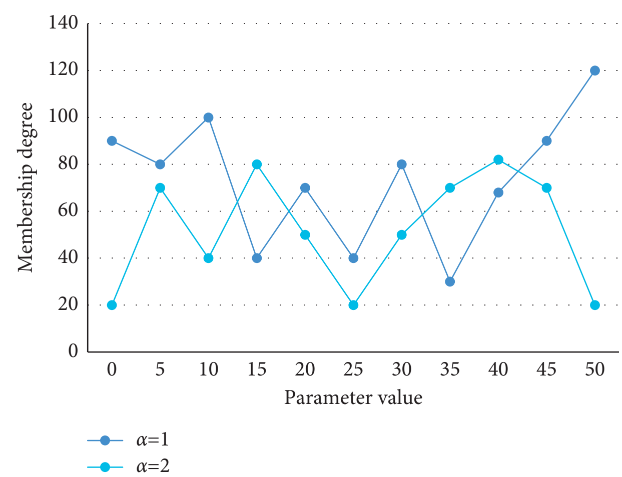

Figure 7: The membership histogram of each sample belonging to the first class when the α value takes some representative values.

The clustering process is guided by making the affiliation values of the labeled samples as close as possible to the labeled affiliation values, provided that the structure of the dataset is discovered in the unsupervised part of the previous section. The histogram of the affiliation of each sample belonging to class 1 when the α value is taken as some representative value is shown in Figure 7.

First, an image is viewed as a continuum of closely connected, interrelated pixels. Its individual features are part of the global features, affecting the values and features of other pixels on the edges, not in isolation. The cluster center values and affiliation of each sample to each cluster center value are corrected through iterative operations of the fuzzy classification matrix and the cluster center matrix to finally find the categorical features contained in the sample data set, thus classifying each sample into the category with the greatest affiliation. Children's understanding of geometric figures is significantly higher than their ability to name them correctly, and children's representations of figures are influenced by verbal expressions, which reveal inconsistencies between perception and expression. Subjects should be more accurate when paying attention to the whole than to the part, and the response to the whole should not vary with structural relations, whereas the part's response to contradictory structural relations should be worse than unrelated structural relations or even worse than consistent structural relations, and the response rate to the whole should be higher during free attention. The objective function is divided into two parts, similar to the improved kernel function-based fuzzy clustering algorithm FCM algorithm, but the latter part only contains labeled samples. The variation of the affiliation values of different supervised samples with increasing values of α is plotted in Figure 8.

Second, the color difference of each region to be segmented is small, but the difference between regions is large. From the concept of classification, the distance between classes is the smallest and the distance between classes is the largest. There is a positive transfer between children's perception of plane geometry and their perception of geometry. So the whole computational process is a process of iteratively modifying the clustering centers and classification matrix, which can converge from any given initial point along an iterative subsequence to the local minima or saddle points of its objective function. The inclusion of childlike graphics in the design of children's educational institutions helps children to acquire cognition, which in turn helps them to better understand their external environment. This proves that children can notice the front-back position and shading relationships of objects through visual perception and also want to represent them through drawing. Therefore, the difference between the gray value of the gray image and the gray value of the seed point is used as a criterion, and the rule for the end of growth is that all pixels grow completely and the distance between classes is greater than a certain threshold. In the improved algorithm, if both 2-DHs are from the original image, their binary groups will be distributed on the diagonal of the plane, so the segmentation of the improved algorithm is consistent with that of the standard FCM algorithm. The performance comparison of the two segmentation algorithms is shown in Table 2.

In summary, the segmentation time of the improved algorithm is significantly reduced by 171.48 s compared to the traditional FCM algorithm, whether it is used to segment noisy images or images with better quality, and thus significantly outperforms the FCM algorithm in terms of segmentation speed.

Finally, m sample instances are randomly selected from the training set. The correlation between each feature of each sample and the class is obtained by the difference between the selected samples and the two nearest neighbors belonging to the same class and different classes, and then the average value is taken as the weight of each feature. Children's perception of plane geometry and geometry goes through a process of pairing–identifying–naming from perceiving the external features of geometry to being able to name it. In order to get the best clustering results, the Lagrange multiplier method is used to obtain the affiliation function and the clustering prototype update formula, so as to obtain the alternatively optimized image segmentation results. The image is segmented into disjoint blocks, and then, the features of the blocks are judged to be consistent, and if they are consistent, they are merged, otherwise, the inconsistent blocks are segmented into blocks as parent blocks and judged again, and the process is repeated until all the features within the blocks are consistent, as well as the features between the blocks are different.

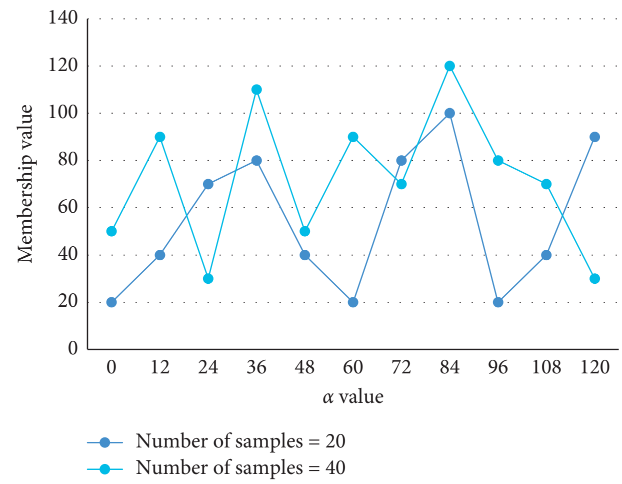

Figure 8: Changes in membership values of different supervised samples with the increase of α value.

Table 2: Comparison of segmentation results of Lena image polluted by the noise by two algorithms.

Algorithm	FCM	Improved algorithm
Split time (s)	189.26	17.78
Cluster center	24, 88, 137, 176	24, 90, 138, 177

5. Conclusions

Children's artworks reflect their perceptions of the outside world and express their inner feelings and thoughts. Art plays an essential role in preschool education as a fundamental subject. The ability of children to combine plane geometry is primarily at the fragmented combination and image stages, with some children at the precombination and shape combination stages. Preschoolers are in the early stages of self-awareness and understanding of the world, and their sense organs are rapidly developing. The development trend in children's thinking about the recognition of plane geometric figures is from visual to analytical, from focusing on the overall visual image to considering the figure's characteristics and concrete image thinking. Image segmentation is the problem of classifying the pixels of an image, and fuzzy theory has been found to have a good ability to describe image uncertainties. Graphics can help preschool children develop their visual system perceptual abilities by influencing their ability to perceive basic shapes, spatial relationships, colors, and visual memory. This research aims to improve children's perceptions of geometric figures, develop their unique figurative thinking, pique their interest in educational graphic perception activities, investigate the methods and paths of using fuzzy clustering analysis to develop educational geometric figure activities in kindergartens, and expand the ideas of developing garden-based curriculum resources in kindergarten science. As a result, the child-centered analysis of young children's graphic perception education proposed in this paper can combine the characteristics of preschool children's perceptual development and fuzzy cluster analysis to help graphic education implementers design a more popular curriculum for children and successfully carry out graphic perception teaching activities.

In order to solve the problem of athletes with lower limb movement injuries in table tennis footwork, with the increasing risk of sports, the incidence of acute injury also increased. The increase in athletic training, on the one hand, improves the skill level of the athlete; on the other hand, it increases the chances of more chronic injuries. Through the investigation of the injury site of 143 table tennis players, the researchers found that the lower limb injury accounted for 32% of the total injuries and the upper limb injury rate accounted for 33.14% of the trunk, accounting for 34.29%. The injury sites are mostly concentrated in the lumbar region, followed by the shoulders and knees. Through epidemiological research on the injuries of outstanding table tennis players, the survey results show that the probability of lower extremity injuries ranks in the top three, and most of them are acute sprains and chronic strain injuries. By applying the principles of sports biomechanics, a biomechanical analysis of the asynchronous foot movement in table tennis is proposed; from three aspects of kinematics, dynamics, and plantar pressure, it is found that the injury of table tennis is closely related to technical play connect. The risk of sports injury is inevitable in a sense, due to the long-term local overload, which causes the strain of the sports system. In order to avoid or reduce the occurrence of such sports injuries, coaches should standardize the technical movements of the players and arrange the exercise load reasonably according to the characteristics of the sports.

1. Introduction

Footwork refers to the movement method of footwork adopted by table tennis players in order to select the appropriate hitting position. Table tennis sports include technique and footwork, both of which are closely related and are indispensable. In training, especially in the early stage of youth enlightenment and basic training, due to the poor mobility of athletes, the main energy of coaches is often focused on cultivating correct techniques, while footwork training is often neglected. The result of this "hands first, footwork later" training results in athletes with good handwork and poor footwork. This affects the progress and improvement of children's sports technology level. Table tennis is a moderate-intensity sport, mainly aerobic metabolism, supplemented by anaerobic metabolism, seen as a healthy form of exercise; it has been accepted by more and more people in leisure and entertainment activities. The three elements of table tennis today are the following: The movement should be fast, the swing power should be strong, and the ball speed should be high. In order to meet the demand for physical fitness in multiround competitive competitions, this requires athletes to increase exercise load and improve motor units in their usual training. Moreover, in the physical training, the focus is on the strategic idea of "focusing on special physical training," effectively giving play to the physical fitness of athletes and making reasonable use of special endurance to improve competition performance. Scholars have found that, in the multiball practice of table tennis, the dynamic balance ability of the body will decline with the extension of training time, which will affect the performance level of players, and, compared with male table tennis players, female players will have an earlier decline in balance ability. Regarding the study of table tennis footwork, relevant scholars from various countries have actively integrated the advantages of various disciplines to analyze their in-depth mechanism. Athletes of different skill levels were selected to carry out systematic comparative research to reveal the internal laws and external connections of footwork itself. Using the improved letter notation method, the touchdown sequence of various footwork was analyzed from the perspective of footwork sequence, and the relationship between footwork, technique, and landing point was found. Sports biomechanics has become a powerful method for research in this field, modeling foot skeletal muscles based on software such as V3D, CAD, and finite element, and researchers can use a variety of measurement methods to obtain more detailed data on the foot and use computers for processing and analysis. The author aims to apply the principles of exercise biomechanics, from the three aspects of kinematics, dynamics, and plantar pressure, in addition to an in-depth study of the three footsteps in table tennis: the biomechanical laws of foot movement in stride, parallel step, and cross step; the following main conclusions are drawn: Forehand stride and forehand side-by-side strike have similar movement forms of the foot after the force foot hits the ground. There are similarities in the movement of the foot after the backhand step; the backhand side step and the backhand cross step hit the ball with the force foot on the ground. Among the three footwork movements, the movement form of the foot is similar when the pedal is extended off the ground when hitting the ball. Among the three footwork movements, the peak force of the vertical reaction force on the ground and the load rate of the force when the athlete completes the cross step are the largest; moreover, the flexion and extension range of the stepping joint of the force-generating foot and the change range of the heel angle are the largest; therefore, the frequent use of cross gait by athletes may increase the risk of foot fatigue injury. In the three kinds of footwork movements, when the peak force of the vertical reaction force of the ground on the hitting foot appears, the foot is in the flipping motion before and after the maximum valgus angle occurs; coupled with the maximum dorsiflexion state of stepping on the joint at this time, the probability of joint movement injury is increased. During the typical footwork of table tennis, the main bearing area of the plantar pressure of both feet is concentrated in the forefoot area, and the force in the midfoot area is not obvious. The peak value of plantar pressure in the rear area of the foot when hitting the ball was the largest, followed by the parallel gait, and the stride gait was the smallest. The middle area of the forefoot is a relatively stable main force area of the forefoot area, and the magnitude of the peak plantar pressure on the lateral area of the forefoot and the medial area of the forefoot is related to the action form of the gait, as shown in Figure 1.

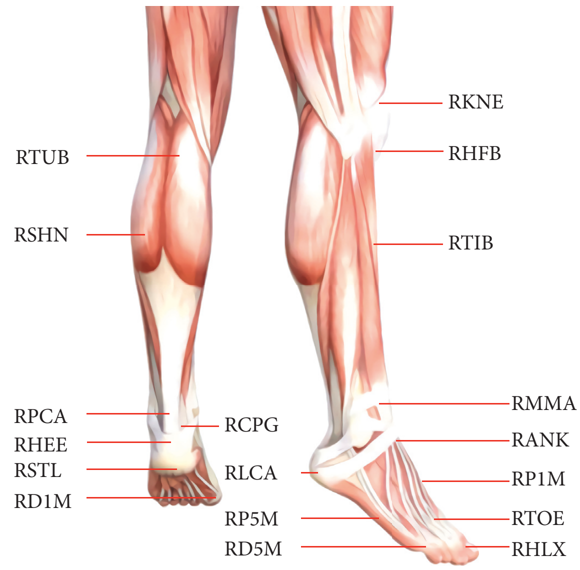

Figure 1: Biomechanical analysis of asynchronous foot movement in table tennis. The middle area of the forefoot is a relatively stable main force area of the forefoot area, and the magnitude of the peak plantar pressure on the lateral area of the forefoot and the medial area of the forefoot is related to the action form of the gait.

2. Literature Review

Since the beginning of the 21st century, Cf, A. et al. said that, with the fusion of various play styles, the sport of table tennis continues to develop in a fast and ferocious direction, requiring players to have outstanding expertise and comprehensive technology, be proactive, and be the first to get started [1]. In particular, the ITTF proposed three new rules in 2000: The sphere is changed from 38 mm to 40 mm; the 21-point system is changed to an 11-point system; the two-point rotation method and unobstructed serving are implemented in the serving rules. These rules place higher demands on table tennis players in various aspects. Shao et al. feel that as the competition becomes more and more confrontational and the ball turns more and more, the technical requirements for the movement range and direction of the athlete are also more refined, so that the athlete's footwork has become the decisive factor in the game [2]. Former Japanese world champion Nobuhiko Hasegawa had a famous quote: “Footwork is the life of table tennis.” It can be seen that table tennis footwork plays a vital role in the completion of the entire hitting action and the rationality, as well as effectiveness and scientificity of the completion of the action. Ardiyanto et al. felt that, in the study of table tennis footwork, the methods and theories of biomechanics provided a scientific means and basis for it [3]. The research scope of biomechanics includes the whole human body, and the research of foot biomechanics is an important part of it. The rise of foot biomechanical research is the result of several factors. Davide et al. said that, first, from a clinical point of view, with the continuous improvement of diabetes treatment methods, it has become possible to prolong the life of patients as much as possible, but, at the same time, the incidence of diabetic complications of diabetic foot is also increasing, medical workers are eager to know the causes of pathological phenomena such as diabetic foot, and biomechanics has begun to enter this field of research [4]. Second, in the work of Hong and Chao, from the perspective of the market, with the rapid development of competitive sports, the scientific scope of competitive sports has become more and more extensive, and the impact of sports shoes on sports has also received increasing attention; people have higher and higher requirements for the injury prevention ability and functional performance of special sports shoes, and it is particularly important to study the biomechanical characteristics of the foot in different special sports [5]. Finally, from a technical point of view, electronic measurement technology and computer technology provide a possibility for the study of foot biomechanics. Researchers can use a variety of measurement techniques to obtain plantar pressure and ground reaction force, process them with computers, and use CAD systems and professional finite element analysis software to model and analyze the foot. Bańkosz and Stefaniak said that “footwork is the soul of table tennis” and accurately summarized the importance of footwork movement in table tennis [6]. Footwork is an important part of table tennis batting and the beginning of each action, and the source of strength comes from the feet and legs. Wu et al. felt that when table tennis players take the initiative to attack the ball, in order to improve the quality of the shot, the movement of the upper limbs alone is not enough [7]. In other words, superb ball skills depend on precise footwork movement, and agile hitting awareness is achieved by flexible, fast, and stable footwork. Sports biomechanics is a common method used in table tennis footwork research; Li et al. felt that, using the theory of exercise biomechanics, in order to explore the biomechanical differences of the dominant foot between professional athletes and beginners in table tennis parallel gait and cross gait, the results and conclusions can improve the in-depth understanding of table tennis footwork for coaches and athletes and then promote the scientific development of table tennis footwork. Previous studies have mainly focused on the three-dimensional motion of human large joints, while the biomechanical characteristics of small foot joints in table tennis footwork have not yet been revealed [8]. Until the Oxford Foot Model (OFM) was discovered, the skeletal muscle model of the small joints of the foot was widely used. Tang et al. said that the Oxford Foot Model is improved on the basis of the traditional Plug-in-Gait model. This model provides more details of the foot and is a reliable multistage study of foot movement [9]. The research of this model mostly focuses on the motion analysis of the forefoot, hindfoot, and great toe, the three-dimensional motion of the forefoot relative to the hindfoot, and the hindfoot relative to the tibia, and the motion of the big toe on the sagittal plane is more detailed. In the analysis of a large number of movement patterns, the model can be widely used in foot analysis in sports and clinical medicine. Therefore, Tabrizi et al. think that using the Oxford Foot Model to study the foot biomechanical characteristics of table tennis footwork can find more movement patterns between the small joints of the foot and help us deeply understand its movement mechanism, which will be a brand new attempt [10].

3. Research Method

Based on the modeling and analysis of human kinematics, the author proposes a new marker point setting scheme and a gait motion measurement system composition scheme; research will be conducted on key techniques for gait motion measurement using established protocols, that is, to study how to obtain lower limb geometric parameters and gait kinematic parameters from gait measurement data. In the traditional gait motion measurement method, the position of the joint center (or axis) is calculated according to the coordinate position of a series of anatomical key points, combined with the manually measured geometric dimensions of the lower limbs. The positions of these anatomical key points are represented by physical measurement identification points on the skin surface or designated points (or virtual identification points) in the calibration process. Therefore, the accuracy of anatomical key point positioning in traditional measurement methods will directly affect the identification of joint positions; as a result, the accuracy and repeatability of gait motion measurement are affected, and the manual positioning process of anatomical key points is also a key factor affecting the pretest preparation time. Firstly, the fitting algorithm of joint position and model geometric parameters is established by analyzing the motion constraint relationship of lower limbs; then, the extraction algorithm of gait motion parameters is established by sampling inverse kinematics analysis method. For the implementation of this algorithm, algorithms and technical support are provided for marker point setting schemes and measurement methods, so that gait measurement does not depend on manual positioning of anatomical key points. Finally, through experiments and analysis of the experimental results, the feasibility of the gait measurement system and related algorithms proposed by the author is discussed [11]. When processing and analyzing the sampled data, it is often necessary to calculate the average posture of the lower limb movements, for example, attitude calculation of measuring rigid body under standard standing posture and attitude filtering. In the space three-dimensional coordinate system, the attitude description of the rigid body can take many forms, such as the direction cosine matrix, the finite rotation quaternion coordinate, the Euler quaternion coordinate, the Euler angle coordinate, and the Cardan angle coordinate. The general algorithm for the weighted average of vectors or matrices is shown in the following formula [12, 13]:

$$A = \frac{\sum_{i=1}^{n} w_i A_i}{\sum_{i=1}^{n} w_i}. \quad (1)$$

The Lifemod interface software of Python language is used to convert Motion’s 6 pieces of data and 2 pieces of kinematics data obtained from analysis and generate Slf files that Lifemod can recognize. The height, weight, and other information of the subjects were input, and the 19-link human model was established through Lifemod’s own human morphology database. The posture adjustment after data is given. The collected kinematic data is given to the model, and then, through posture adjustment and balance analysis, the floor pad model is established, and the contact between the human body model and the floor pad is established. The contact force between the human body model and the floor pad model, the force and moment of each link of the human body model, and the kinematic index of each link were simulated for 1 s to obtain 1000 pieces of data, which was the same as the acquisition frequency of the force table [14]. Formula (1) of inertia for strength training is shown below:

$$j\theta + k\theta = T(t), \tag{2}$$

where A is the weighted average matrix of matrix Ai ($i = 1, 2, \ldots, n$) and Wi is the weight of Ai. However, if the mean value calculation of the direction cosine matrix also adopts the above method, then the resulting matrix will no longer satisfy the constraints of the directional cosine matrix. Euler quaternion coordinates, Euler angle coordinates, and Cardan angle coordinates cannot use a simple weighted average to calculate the average attitude; this is mainly because these pose coordinates are essentially rotation vectors rather than ordinary vectors. Among the attitude coordinates, Euler quaternion is widely used because of its small calculation amount, nonsingularity, and full attitude work. Wahba proposed constructing the cost function to solve the Euler quaternion mean value problem in the 1960s; based on this idea, many researchers have proposed various algorithms. Among them, Markley et al. directly used the direction cosine matrix as the object to solve the weighted mean quaternion method, because the singular value decomposition of the matrix is not involved, making the algorithm relatively simple and widely used. The Euler quaternion n is a four-dimensional vector as shown in the following formula:

$$\underline{\Lambda = \left(\lambda_0, \underline{\lambda}^T\right)^T = \left(\lambda_0, \lambda_1, \lambda 2, \lambda_3\right)^T,} \tag{3}$$

where λ is the vector part and λ_0 is the scalar part. Since the Euler quaternion is essentially a rotation vector and its four variables are not independent, it must satisfy the normalization constraint as shown in the following formula:

$$\underline{\Lambda}^T\,\underline{\Lambda} = \|\underline{\Lambda}\|^2 = \lambda_0^2 + \lambda_1^2 + \lambda_2^2 + \lambda_3^2 = 1. \tag{4}$$

The direction cosine matrix corresponding to the Euler quaternion $\underline{\Lambda}$ is shown in the following formula:

$$\underline{A}(\underline{\Lambda}) = \left(2\lambda_0^2 - 1\right)\underline{I}_3 + \underline{\lambda}\,\overset{T}{\underline{\lambda}} + 2\lambda_0\underline{\tilde{\lambda}}, \tag{5}$$

In order to calculate the average Euler quaternion, construct the pose matrix cost function as shown in the following formula:

$$\overline{\underline{\Lambda}} = \arg\min \sum_i w_i \left\|\underline{A}(\underline{\Lambda}_i)\right\|_F^2. \tag{6}$$

From the definition of the Frobenius norm and the orthogonality of the directional cosine matrix, the following formula can be obtained:

$$\left\|\underline{A}(\underline{\Lambda}) - \underline{A}(\underline{\Lambda}_i)\right\|_F^2 = 6 - 2tr\left[\underline{A}(\underline{\Lambda}_i)\right]. \tag{7}$$

The time series of foot position coordinates and posture coordinates is the motion curve of the foot, and the position coordinates can be represented by the position coordinates of the stepping joints; the posture coordinates are represented by the direction cosine matrix of the foot conjoined base $e4$ with respect to the reference base or other posture coordinates. Corresponding to each sampling point, the changes in the position and posture of the foot in the pelvic conjoined base $e1$ are calculated; the following focuses on the motion curve of the foot in the overall base. For any sampling point, the direction cosine matrix $A04$ of the foot conjoined base $e4$ with respect to the overall base $e0$ is obtained. The position vector of the stepping joint in the overall base dream can be expressed as in the following formula:

$$r_{\text{ankle}} = r_{4b} - d. \tag{8}$$

Due to the influence of the model error, the actual lower limb joints are not truly pivoted, making it difficult to obtain accurate and consistent results for the fitting of the position of the joint rotation center (or rotation axis). For example, the movement pattern of the knee joint is not a simple flexion and extension movement; rather, it is a complex multi-DOF mode that combines flexion, roll, slide, lateral shift, and axial rotation. The flexion and extension movements do not revolve around the same center of rotation but generate multiple instantaneous centers of rotation according to the movement process. During the process of extending and flexing the knee joint, if the instantaneous center of rotation of each movement is continuously marked, the form one on the femoral bone, +*J*"-shaped trajectory, taking the lateral femoral skeleton as a reference, analyzing the electronic *X*-ray films at 9 different positions of the knee joint of 5 volunteers, and measuring the straight-line distance from the joint measurement axis to the lateral skeleton at each position, the measurement results are as follows: With flexion 40" as the center, the distance from the joint measurement axis to the lateral femoral skeleton gradually increases; the greater the flexion angle, the farther away from the lateral femoral skeleton, and the joint measurement axis in the entire range of motion is the same as that on the outer skeleton. The intraclass correlation coefficient (ICC) is often used to evaluate the reliability of a single measurement parameter, but it is not suitable for the repeatability evaluation of the entire curve or waveform; the evaluation index of the repeatability of the gait motion curve is called the adjusted coefficient of multiple correlation (CMC) or the adjusted coefficient of multiple determination (CMD). This method has been used by many researchers in related research. The CMC method is used to analyze the repetition reliability of joint motion parameters as shown in the following formula:

$$R_{wt}^2 = 1 - \frac{\sum_{i=1}^{M}\sum_{j=1}^{N}\sum_{t=1}^{T}\left(Y_{ijt} - \overline{Y}_{it}\right)^2 / MT(N-1)}{\sum_{i=1}^{M}\sum_{j=1}^{N}\sum_{t=1}^{T}\left(Y_{ijt} - \overline{Y}_{i}\right)^2 / MT(N-1)}. \tag{9}$$

The value of the curve is obtained by the *J*th test (trial) in the *i*th experiment in Y_{ijt} at the sampling point t; T is the total number of adopted points contained in the curve; N is the total number of trials for each subject in each experiment; in this experiment, $N = 3$; M is the total number of experiments (tests) for each subject, and $M = 4$ in this experiment; Y_{it} and Y_i are shown in the two following formulas:

$$Y_{it} = \frac{1}{N}\sum_{j=1}^{N} Y_{ijt}, \tag{10}$$

$$Y_i = \frac{1}{NT}\sum_{j=1}^{N}\sum_{t=1}^{T} Y_{ijt}. \tag{11}$$

The algorithm studied by the author is the key technology of the gait measurement system, which overcomes the limitations of the traditional gait measurement system. The realization of this technology makes the marking point layout of the gait measurement system independent of the manual positioning of anatomical key points, and the length of the lower limbs does not need manual measurement, so that the measurement method with fewer marking points can be realized, thus simplifying the measurement process, and, at the same time, it is helpful to reduce the influence of human error caused by the arrangement of marker points and improve the reliability of repeated measurement between experiments.

4. Experiments and Analysis

The stride method includes a forehand step and a backhand step. The experimental subjects all shoot with the right hand, move the right foot to the right for a forehand stride, and move the left foot to the left to perform a stride action during a backhand stride. Among them, the stride foot is the main moving foot that constitutes the stride gait, and it is also the main force-generating foot to complete the batting action, and, according to the research needs, the left foot (i.e., the supporting foot) in the forehand step is called the moving auxiliary foot, and the right foot (i.e., the stepping foot) is called the hitting force foot. The right foot in the backhand step is called the moving auxiliary foot, and the left foot is called the hitting force foot. Figure 2 shows the average-time curve of the flexion and extension angle, heel key angle, and toe extension angle during the forehand stride action of all subjects. As can be seen from Figure 2, when the subjects performed the forehand stride action, when the ball hit the ground, the foot basically did not turnover. However, after landing, the center of gravity of the body shifts to the foot where the ball is used, and the force on the foot increases and turns into a valgus state; when the calcaneal angle decreases and reaches the minimum value, that is, the maximum valgus angle, the stomping, flexion, and extension angle increases, and the restless joint performs hesitant movement. After the heel angle reaches the maximum valgus angle, it begins to increase; when the first peak force occurs, the foot is doing varus movement, the stomping joint is in the dorsiflexion movement, the toe extension angle decreases rapidly, and the foot that hits the ball with force enters the center of gravity adjustment stage of full-foot support.

The first stress stage is over, and the batting force foot enters the second stress stage. With the active push and extension of the hitting force foot, the force on the foot increases, the Achilles tendon angle begins to decrease, the

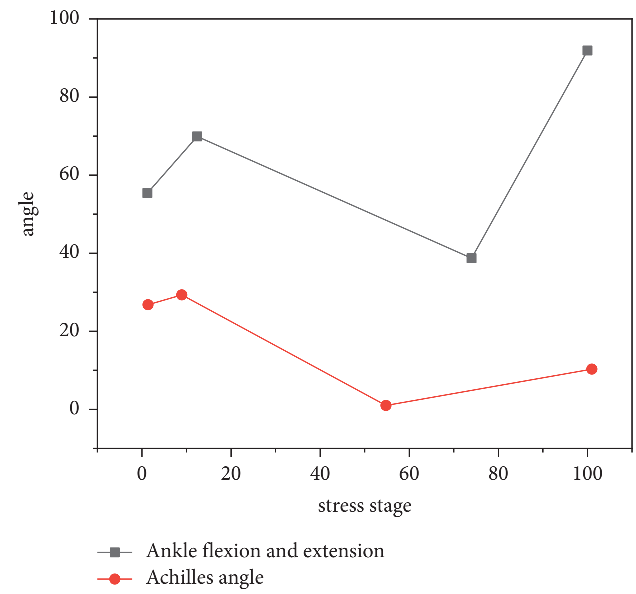

Figure 2: The average-time curve of each angle of the forehand stride strike. The right foot in the backhand step is called the moving auxiliary foot, and the left foot is called the hitting force foot.

foot performs valgus movement, and the restless joint continues to do dorsiflexion movement; when the foot reaches the maximum eversion of the second force stage and the manic joint reaches the maximum dorsiflexion angle, the second peak force appears. After hitting the ball, the force foot starts to push and extend off the ground, the stomping flexion and extension angle increases, and the restless joints do active flexion movement, and the maximum flexion angle is reached at the moment of lifting off the ground. In the stage of kicking off the ground, the toes and the toe joints land on the ground, and the heel is lifted; the toes begin to make the maximum toe extension movement around the toe extension joint, the calcaneal angle increases with the increase of the extension angle of the toe, and the foot performs a varus motion, which changes from the everted state to the initial state at the time of landing [15]. In the kinematic analysis of backhand stride action, all subjects performed backhand stride action when subjects performed backhand stride action, the force on the foot increased after hitting the ball with the force of the foot on the ground, and the foot turns into a valgus state and reaches the maximum valgus angle; at the same time, the stomping flexion and extension angle decreases. The manic joints do dorsiflexion movement; in the landing stage, the heel and toe joints land on the ground, and when the toes are off the ground, the toes begin to make the maximal toe extension movement around the toe joint; the toe extension angle increases first and then decreases before the toe hits the ground. When the first peak force appeared, the foot was in varus state and continued to do varus motion, and the pedal joint reached the maximum dorsiflexion angle. At this time, the extension angle of the toe decreases, and the hitting force foot enters the adjustment stage of the center of gravity supported by the full sole of the foot. Step on the joint to adjust the extension and flexion of a small angle, begin to do the valgus movement, and the toe extension angle enters the plateau phase of change. After the hitting force foot enters the second force stage, the force on the foot increases, the foot continues to do valgus movement, and the restless joint is adjusted in the form of dorsiflexion; when the second peak force occurs, the pedal joint reaches the maximum dorsiflexion angle of the second force stage, and the foot is in a valgus movement. After hitting the ball, the force foot starts to push and extend off the ground, the stomping flexion and extension angle increases, and the restless joints do active flexion and flexion, and the maximum kick angle at the moment of leaving the ground is reached. The toes begin to make the maximum toe extension movement around the toe joint, the extension angle of the toe increases, and the foot performs varus movement at the same time, from the eversion state to the initial varus state at the time of landing. It can be seen from the analysis of the plantar pressure of the stride gait that the main bearing area of the plantar pressure of both feet in the support stage is the forefoot area, and the pressure peak in the forefoot area is. The percentage reaches around 50% [16]. The stress on the midfoot area is not significant, the peak pressure is only about 30% of the body weight, and the peak pressure only accounts for about 15–18% of the total of the three areas. The peak pressure on the back of the foot during the support phase exceeds half of the body weight, but it is not as pronounced as that on the front of the foot. The step-step method is mostly used in the fast-break game near the table, counterattacking the ball from a large angle in the forehand position; when the subject moves to the forehand position with the forehand stride, in order to meet the near billiards, the body's center of gravity moves toward the near table; at this time, the force on the forefoot area is increased relative to the rear area, so the force on the forefoot area is the most obvious relative to each area during the forehand step; the same is true for the force on the sole of the backhand stride [17]. Comparing the mobile auxiliary foot with the batting force foot, there was no significant difference in the force in the midfoot area between the two, and the force in the forefoot area was greater when hitting the ball; the force of the auxiliary foot in the rear area of the foot is greater than that of the ball-hitting force [18, 19]. Because the batting force foot also undertakes the task of actively pushing and extending the force to participate in the batting action and returning to the original position, at this time, the forefoot area, which is the main force-bearing area of the kicking and stretching action, bears more pressure. However, the mobile auxiliary foot is in a state of full-foot support most of the time during the entire forehand step, and the force is relatively scattered; therefore, the difference between the force of the forefoot area and the rear area of the mobile auxiliary foot is small. Through the comparative analysis of the support time of the subjects' hitting power foot, it is found that the stride footwork action has more support time than the parallel footwork; this is because the movement speed and rhythm of the parallel footwork are faster than those of the stride footwork, and the ball-strengthening foot transitions to the active kick off the ground faster in the support phase. After the cross footwork action hits the ball with the force foot on the ground, wait until the mobile auxiliary foot moves the landing support and adjusts the body posture to the direction facing the initial position and then starts to actively push off the ground; therefore, the cross gait method is more complicated, and the support time of the hitting force foot is significantly longer than those of the stride gait method and the parallel gait method, and the difference is significant as shown in Figure 3.

As can be seen, the maximum load rate of the vertical reaction force on the ground after the strike force foot hits the ground in the cross-gait action is significantly larger than those of the stride gait and the parallel gait, and the difference is significant. This is because the first peak force after hitting the ball in the cross footwork is the largest among the three footwork movements, and its appearance time is also the earliest; the hitting force foot should reach the maximum first peak force in the shortest time as shown in Figure 4.

It can be seen that, among the three steps, after the cross footwork hits the ball with the power foot on the ground, the first peak force of the vertical reaction force from the ground is significantly larger than those of the other two footwork types. Due to the cross footwork, the batting force foot is in the single support stage for a period of time after landing, and the body weight is concentrated on the batting force foot, coupled with a large range of rapid movement, resulting in a high landing influenced by factors such as speed; as a result, in the action of the cross footwork, the first peak force of the hitting force foot in the first force stage is significantly greater than those of the other two footwork types. In the process of kicking off the ground after completing the hitting action, the distance back to the initial position of the cross footwork action is farther than those of the other two footwork types; compared with the other two types of footwork, the time left for the adjustment of the cross footwork between the two strokes is less, and the second peak force experienced is the largest [20], as shown in Figure 5.

The change range of the foot angle reflects the movement range of the subject's hitting force during the support force stage; with greater movement range of each link of the foot, especially in the state of continuous force, the risk of sports injuries increases accordingly. Athletes have the greatest flexion and extension of the restless joints during the cross-step process. The previous research on the change law of the angle of flexion and extension in the support stage of the hitting force has shown the maximum changes in the flexion and extension angles of the three footwork movements; they all appeared in the final stage of kicking and extending off the ground, reflecting the significant role of the kicking and flexing movement of stepping on the joint in the process of kicking and extending off the ground. In the action of cross footwork, the kicking foot is in the stage of kicking and extending off the ground, it is necessary to overcome greater resistance than the other two footsteps to return to a farther initial position, and the flexion movement of stepping on the joint is more important, and the range of motion is greater [21]. Therefore, the change range $\Delta\alpha$ of the angle of flexion and extension in the support stage of the impacting foot in the cross-footwork action is larger than those of the other

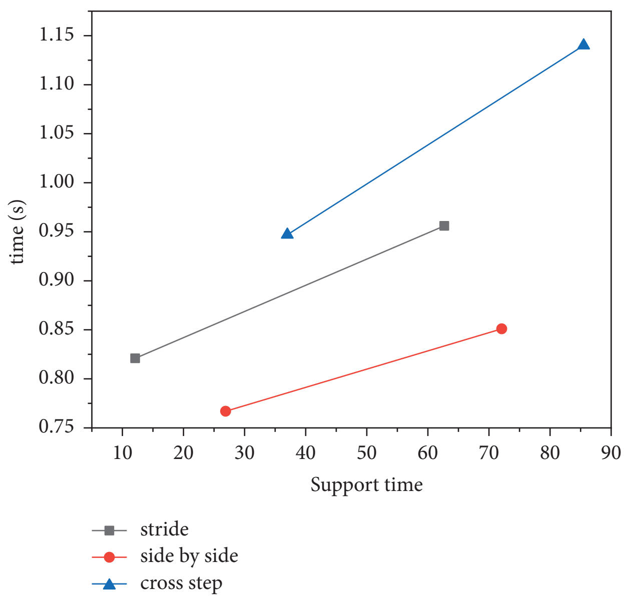

Figure 3: Comparison of the average support time at Farley corners. After the cross-footwork action hits the ball with the force foot on the ground.

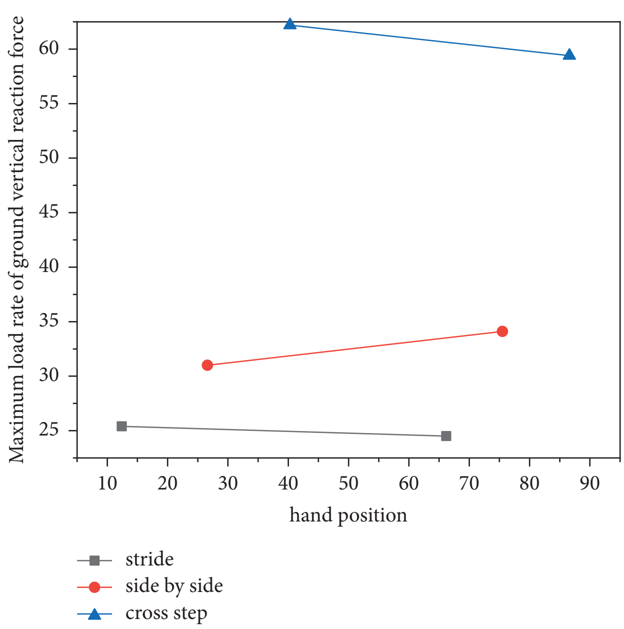

Figure 4: Comparison of the average value of the maximum load rate of the vertical reaction force on the ground of the hitting force. The difference is significant.

two footwork types, and the difference is significant. There was no significant difference in the change range $\Delta\gamma$ of the toe extension angle of the hitting foot when the subjects performed the three footwork movements, and the uniformity of the three footwork movements is not large, indicating that the toe extension movement of the hitting force foot in the process of supporting the force is not affected by the asynchronous movement, and the toe extension angle only changed within a small angle range, and there was no obvious movement of the toe extension. The heel angle is an

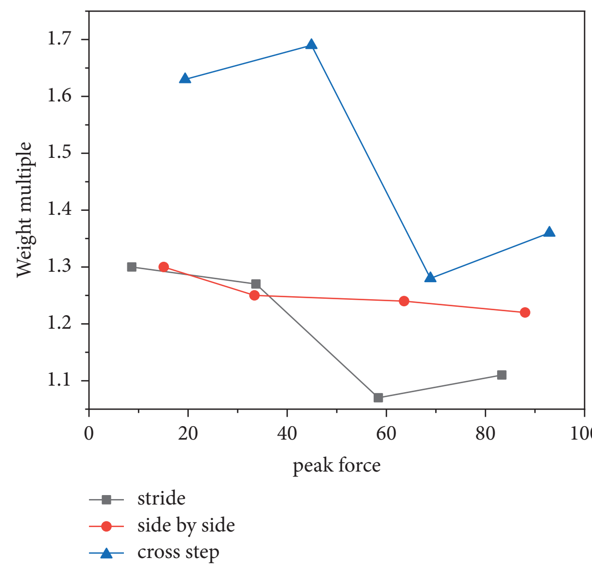

Figure 5: Comparison of the average value of the first peak force and the average value of the second peak force of the mana foot for three footwork strokes. Comparison with the other two types of footwork.

important index to reflect the flipping of the foot during exercise, and the magnitude of its variation $\Delta\beta$ is also an important reference index to evaluate the probability of sports injuries. As can be seen from Figure 6, the change amplitude $\Delta\beta$ of heel angle in the cross-gait action is significantly larger than those of the step-step and parallel gait, and the difference is significant. This may be because the cross footwork strikes the force foot away from the incoming ball, and the relative position of the strike force foot at the time of landing is beyond the body in the incoming ball direction, coupled with factors such as the faster initial speed before landing after a long moving distance; the results are shown in Figure 6.

From the previous results, it can be found that when the subjects perform the three footwork movements, there is a large change in the key angle in the support stage of the hitting force foot; most occur in the valgus movement of the first stress stage and the varus movement of the second stress stage. Comparing the kinetic data, it can be found that the maximum valgus angle of the heel angle mostly occurs near the time when the first peak force occurs in the first stress stage, which means that the foot is subjected to a large vertical force when the foot is in the valgus state, and the impact of the reaction force will increase the probability of foot sports injury [22, 23]. The maximum varus angle of the heel angle mostly occurs at the moment of kicking off the ground, with the appearance of the maximum extension angle of the restless joint; at this time, the hitting force foot is about to leave the ground, and the force is very small. As can be seen, the maximum varus/valgus angles of the power foot in the cross-footing action were larger than those in the other two footwork types, and the difference was significant. The results of the previous study also showed that, during the process of the subjects' performing, the three footwork movements and the peak force of the hitting force foot in the

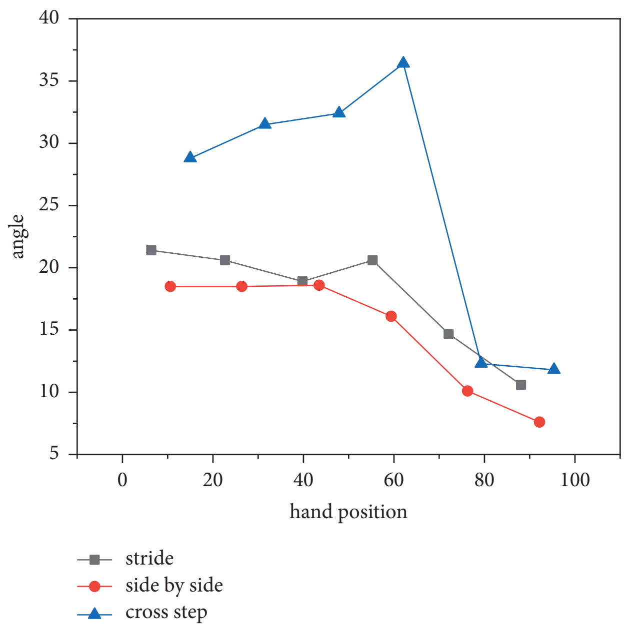

Figure 6: Comparison of the average value of the variation amplitude of the foot angles of the three gait styles, coupled with factors such as the faster initial speed before landing after a long moving distance.

support stage occur during the maximum dorsiflexion angle of the manic joint and the rapid turnover of the foot. In order to prevent sprains from stepping on joints, limit the force acting on the anterior ligament of the talus during stomping, the design of the shoe must strive to limit the varus and valgus forces acting on the restless joint, and this external twisting force is maximized during flexion. In addition, since the stomp joint has a certain degree of lateral flexibility when the stomp joint is flexed, this reduces its own stability; therefore, in order to provide support for sports shoes to resist the varus force that frequently causes sprains, sports shoes must provide stability to counteract the rotation of the pedal joints, especially in the flexion state. Based on the experimental results, the smaller joint range of motion of professional table tennis players when they complete the parallel footwork proves that professional athletes have better foot control and technical stereotypes [24]. For professional athletes, a larger internal rotation of the rear foot at the end of the lead can help the players to complete the gait better, and, with the larger abduction of the forefoot, it is beneficial to maintain the stability of the body's center of gravity. In addition, using V3D technology and high-speed cameras, we found that, during Phase I footwork movement, professional table tennis players are used to landing on the rear foot area, while beginners use the front corner area. This also explains why, during this process, the peak pressure of professional athletes occurs in three areas of the medial and lateral hindfoot and the lateral forefoot; for beginners, peak pressure occurs in three different areas: the big toe, the medial forefoot, and the middle. At the same time, this finding can illustrate that professional athletes can better distribute the body's center of gravity on the entire sole plane, providing a more stable swing foundation for the next stage [25, 26]. At the end of the lead-in period, professional athletes showed less hindfoot varus and forefoot valgus and greater extension of the big toe, which was beneficial to better maintain the balance of the center of gravity and adjust the posture for the rapid transition to be prepared to the next stage. From the results of the study, it was found that professional athletes have a more stable body weight transfer ability in the parallel gait. Professional athletes showed significantly greater dorsiflexion in the forefoot, relative to the hindfoot and relative to the tibial angle of the hindfoot than beginners. According to the systolic relaxation theory, the elastic potential energy previously stored in tendon extension can increase the concentric contraction of the muscle, which means that the professional table tennis player's greater dorsiflexion during the full lead phase can store more energy for the swing phase. The limitations of the author's study are manifested in the following aspects: First, the author's study lacked a gender-specific comparison of parallel gait and cross gait due to limitations in recruiting subjects [27]. Another potential limitation is that there are large differences in training years, although all professional table tennis players have the same level of skill level and are from the same university table tennis team, but this may limit the validity of the experiment to some extent [28]. In addition, beginners have different degrees of differences in their learning ability; this may affect the effectiveness of gait learning. Second, only the differences in the biomechanics of the dominant leg were compared. In fact, the nondominant leg also plays an important role in maintaining body stability during the swing phase. Finally, this experiment is to simulate the footwork movement process in actual combat, not in real competitive competitions. Considering a series of uncontrollable factors (athlete psychology, unfixed table tennis balls, etc.) will affect the results of the experiment.

5. Conclusion

Research shows the following: Compared to beginners, professional athletes spend less time performing side-step and cross-step footwork and show a smaller range of motion and faster angular velocity. This verifies that professional athletes have better ability to use foot drive and body balance in footwork movement techniques. At the end of the lead-up period, professional athletes in the gait show less forefoot valgus and hindfoot varus and greater flexion of the big toe, and the cross gait shows a smaller forefoot flexion and abduction angle, which is conducive to maintaining the stability of the body's center of gravity. For professional athletes, larger peak pressures and relative loads were found in the lateral forefoot and medial-lateral hindfoot regions in these two table tennis footwork styles. The results and analysis of this study are beneficial to provide more valuable theoretical reference for coaches and beginners in the process of footwork training and in the use of parallel and cross gait, how to use foot movement to improve the quality of technical movements and how to maintain body stability, and there are lessons to be learned. The author reveals in detail the kinematics and dynamics of the foot in the three footwork movements of table tennis, which provides data and theoretical basis for improving the effect of footwork movements and preventing foot injury in table tennis players. The movement forms of the foot after the forehand stride and the forehand parallel strike are similar. There are similarities in the movement of the foot after the backhand step, the backhand side step, and the backhand cross step hit the ball. In the three footwork movements, the motion forms of the feet when the pedals are extended and lifted off the ground are similar. The cross footwork is the longest, the stride footwork is the second, and the footwork is the shortest. In the cross-footwork method, the ball-strengthening foot is in the middle of the support stage, and the body posture and the center of gravity adjustment stage appear to be obviously unstressed or less stressed. Among the three footwork movements, the peak force of the vertical reaction force on the ground and the load rate of the force when the athlete completes the cross step are the largest; moreover, the flexion and extension range and calcaneal angle of the force-generating foot have the largest changes; therefore, the frequent use of cross gait by athletes may increase the probability of foot fatigue injury. In the three kinds of footwork movements, when the peak force of the vertical reaction force of the ground on the hitting foot appears, the foot is in a flipping motion before and after the maximum valgus angle occurs, coupled with the maximum dorsiflexion state of the stepping joint at this time, and the probability of injury of the stepping joint is increased. The main bearing area of the plantar pressure of the feet in the three gait movements is concentrated in the forefoot area, and the force in the midfoot area is not obvious. The peak value of plantar pressure in the rear area of the foot when hitting the ball was the largest, followed by the parallel gait, and the stride gait was the smallest. The middle area of the forefoot is the relatively stable main force area of the forefoot area, the peak size of the plantar pressure on the lateral area of the forefoot and the medial area of the forefoot is related to the action form of the footwork, the main force-bearing area of the forefoot area. The peak force of the ground reaction force received by the power foot in the buffering stage and the kicking stage of the three footwork movements is relatively large; therefore, special sports shoes for table tennis should have appropriate shock absorption and buffering functions, in order to relieve the load of frequent impact force on the feet of table tennis players during the game. The peak force of the three footwork movements hitting the power foot in the support stage appears in the maximum dorsiflexion angle of the restless joint and the rapid turnover of the foot. Therefore, special sports shoes for table tennis need to provide good stability support for the stepping joint to resist the foot in the support stage, especially in the state of stepping and bending, and the frequent torsional external force will reduce the probability of foot sports injury. Table tennis footwork action is the active and rapid exertion of the power foot in the stage of kicking off the ground; special sports shoes for table tennis are required to have good energy return performance, providing better conditions for table tennis players to move quickly.

This study proposes an optimized algorithm for the navigation of the mobile robot in the indoor and dynamic unknown environment based on the decision tree algorithm. Firstly, the error of the yaw value outputted from IMU sensor fusion module is analyzed in the indoor environment; then, the adaptive FAST SLAM is proposed to optimize the yaw value from the odometer; in the next, a decision tree algorithm is applied which predicts the correct moving direction of the mobile robot through the outputted yaw value from the IMU sensor fusion module and adaptive FAST SLAM of the odometer data in the indoor and dynamic environment; the following is the navigation algorithm proposed for the mobile robot in the dynamic and unknown environment; finally, a real mobile robot is designed to verify the proposed algorithm.The final result shows the proposed algorithms are valid and effective.

1. Introduction

There is a wide and extensive application of the mobile robot in many fields; it can fulfill the repeated, heavy, accurate, and complex work in many special environments; the navigation is important for the mobile robot because it is the basic function for the other actions of the mobile robot; it should move freely to the destination without colliding with the obstacles, just like people need to avoid colliding with the other people on the road. There are many navigation algorithms proposed which can be applied in many fields to fulfill the different requirement for human, so the optimization of the navigation is necessary to make the mobile robot moving more intelligently and effectively to the destination [1–3].

Different from the outside static known environment, if the mobile robot is running in the indoor dynamic unknown environment, more conflicts and limitations will be considered; the following is a comparison between them.

The first difference is the location and orientation function; the self-driving car is taken for example; all the cars are running in the outside environment where the GPS sensor can receive the satellite signals properly, so GPS can show the accurate position of the car on the roads, but if the car is running in the indoor environment where the satellite signal is weak or shielded, the GPS function will be unavailable and the corresponding GPS positioning function will be limited. It can only search few or no satellites and it cannot get the accurate position. The IMU sensors have the same problem, so the mobile robot cannot get its location and orientation through the IMU sensors in the indoor environment [4, 5].

The second difference is all environments are known for self-driving car because the map of all roads is provided for the car, but sometimes the mobile robot needs to work in the unknown environment where no map is provided, such as the environment of 24-hour lobby filled with moving people where it is not easy to build the map with SLAM technology [6]; otherwise, the mobile robot may need to fulfilling burrow adventure tasks where it is a totally unknown environment, so the mobile robot cannot locate its position on the map if it is running in an unknown environment.

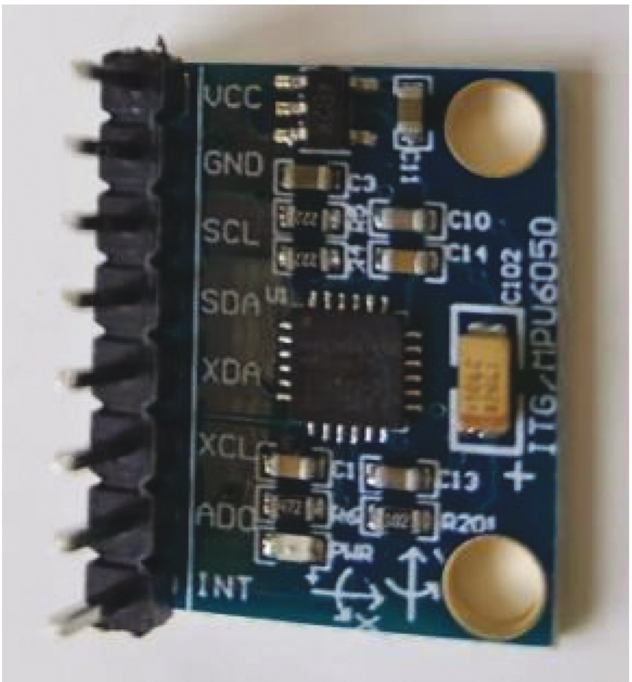

Figure 1: Gyroscope.

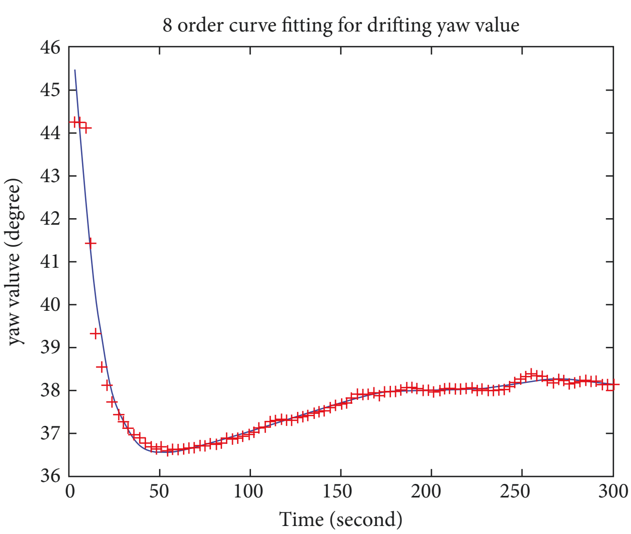

Figure 2: The 8-order curve fitting for the drifting yaw value.

The third difference is that sometimes mobile robot cannot be located in the dynamic environment; the home service mobile robot is taken for example; although it can build the map for the environment inside the house with SLAM, but people may move the position of the home appliance sometimes, so the mobile robot will recognize the wrong position through feature point matching whose data come from the laser sensor or the camera [7].

Based on the above comparisons, as well as considering the limited CPU and battery power for the mobile robot, the navigation algorithm in the indoor dynamic unknown environment should be improved.

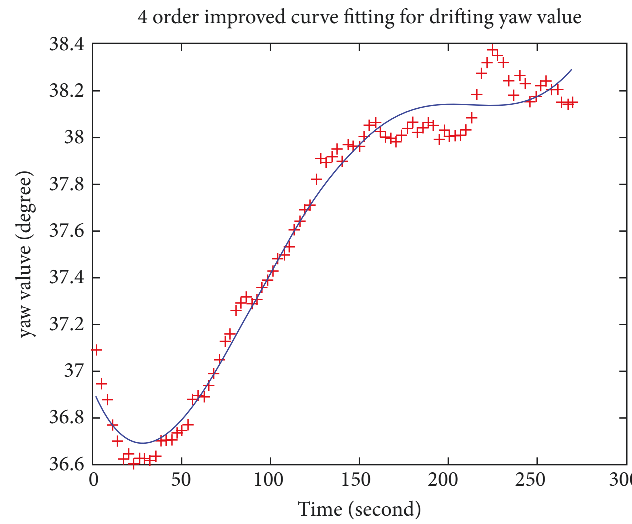

Figure 3: The 4-order improved curve fitting for the drifting yaw value.

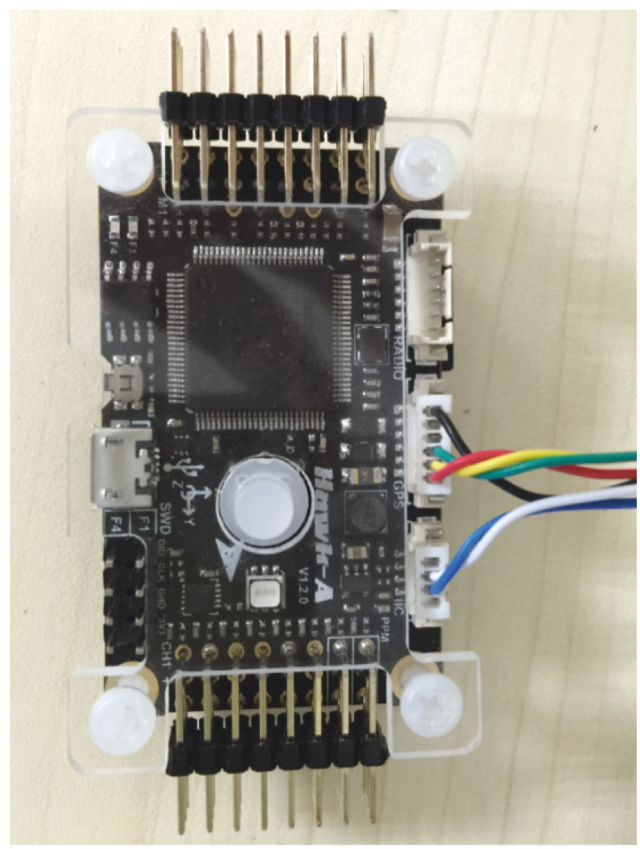

Figure 4: IMU sensor fusion module with GPS, gyroscope, electronic compass, magnetometer, and accelerometer.

2. Decision Tree Algorithm for the Yaw Value from IMU Sensor Fusion Module and Odometer

2.1. Yaw Value from IMU Sensor Fusion Module in the Indoor Environment. In the navigation process of the mobile robot,

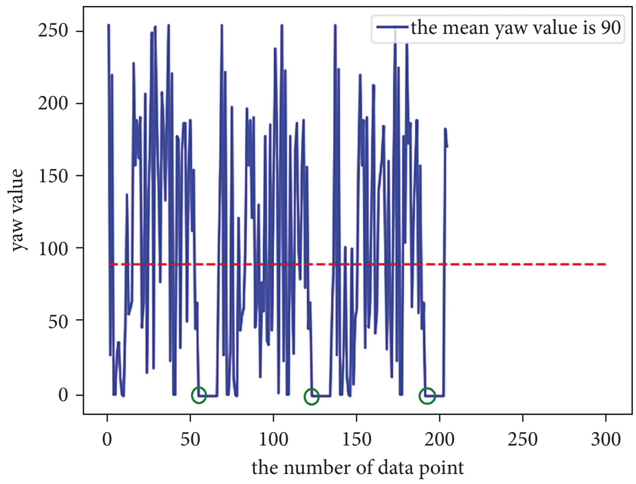

Figure 5: The output yaw value from multi-IMU sensor fusion module.

it is necessary to get the accurate current orientation of the mobile robot in every second, which can be obtained from gyroscope shown in Figure 1.

The output data of the gyroscope will be unavailable in the indoor environment; for example, when the mobile robot stops rotating and keeps static in the indoor environment, after the PID processing for gyroscope, the yaw value is collected and marked with the red cross as shown in Figure 2. It is obvious that the yaw value is still drifting and gradually maintains stability after 300 seconds (5 minutes); the blue line in Figure 2 shows the curve fitting for the yaw value during 300 seconds; the 1–7-order curve fitting is not perfect, but the 8 order can fit the curve more accurately as shown in Figure 2; the fitting function is

$$\begin{aligned} y = {} & 0.00000000000003 \times x^8 - 0.000000000000086 \times x^7 \\ & + 0.000000000049473 \times x^6 \\ & - 0.000000015493482 \times x^5 + 0.000002873185886 \times x^4 \\ & + 0.021422402741956 \times x^2 - 0.761774606869785 \times x \\ & + 47.571395698231385. \end{aligned} \tag{1}$$

Formula (1) is too complex and contains lots of double float data calculations which will consume lots of CPU resources and battery power, from the observation of Figure 2, that the data often drift dramatically in the first 30 seconds, which makes the curve complex and brings in lots of high-order term; if the data in the first 30 seconds can be deleted, it will simplify the curve fitting and polynomial formulas, compared with the other groups test data of yaw value; it is summarized that the yaw value will always drop 10%–20% in the first 30 seconds; the yaw value data at 30th second are often 80–90% of the initial yaw value, so it is often 85% of the initial yaw value for average.

Figure 3 shows the fourth-order improved curve fitting for drifting yaw value, and the yaw data in the first 30 seconds are deleted; the fitting formula is

$$\begin{aligned} y = {} & 0.000000003 \times x^4 - 0.000002660 \times x^3 + 0.000647 \times x^2 \\ & - 0.0514723 \times x + Y_i \times 0.85. \end{aligned} \tag{2}$$

It is clear that the 4-order curve fitting is more simple; if x has an assigned value as 270, the stable yaw value can be computed according to formula (2), but it is still not accurate because the yaw value comes from only one gyroscope in the indoor environment; if the cost of the device for the mobile robot is not considered, the multisensor fusion algorithm for GPS, gyroscope, electronic compass, magnetometer, and accelerometer is better than data processing for only one gyroscope as Figure 4 shows.

The multi-IMU sensor fusion module can be purchased on the market, which has downloaded the software of multi-IMU sensor fusion algorithm inside, so the output data of this module are more accurate [8]; when the mobile robot is rotating in the indoor environment and stops suddenly, the output yaw value is shown in Figure 5.

Figure 5 shows that the output yaw value is periodical which can be marked with green circle at the bottom of Figure 5; the baud rate is 115200; there are 90 data points in a period, and the output format is Byte, so the period is $10 * 90/115200 = 0.0078125$ second; in one period, the data still drift dramatically; it is needed to compute the mean yaw value in one period, which is 90 degree in Figure 5.

If the test is repeated for 10 times, when every time the mobile robot rotates and stops at a same direction, an object is placed to verify it is the same direction for 10 times' test, the result of 10 times test is shown in Figure 6.

From Figure 6, for the same direction in the indoor environment, the yaw value from one multi-IMU sensor fusion module is different every time and the range of value is between 87 to 94 in 10 times' test, so the yaw value from IMU sensors is not accurate in the indoor environment.

2.2. Odometer Data from the Processing of Adaptive FAST SLAM Algorithm. There is another method to obtain the yaw value, and the odometer can compute the yaw value [9]; generally, the reduction ratio of the gear motor is 1 : 50; the output pulses from the optical-electricity encoder is 500 when a DC motor rotate a circle; when gear motor connects to DC motor, the output pulse is 25000 when the wheel

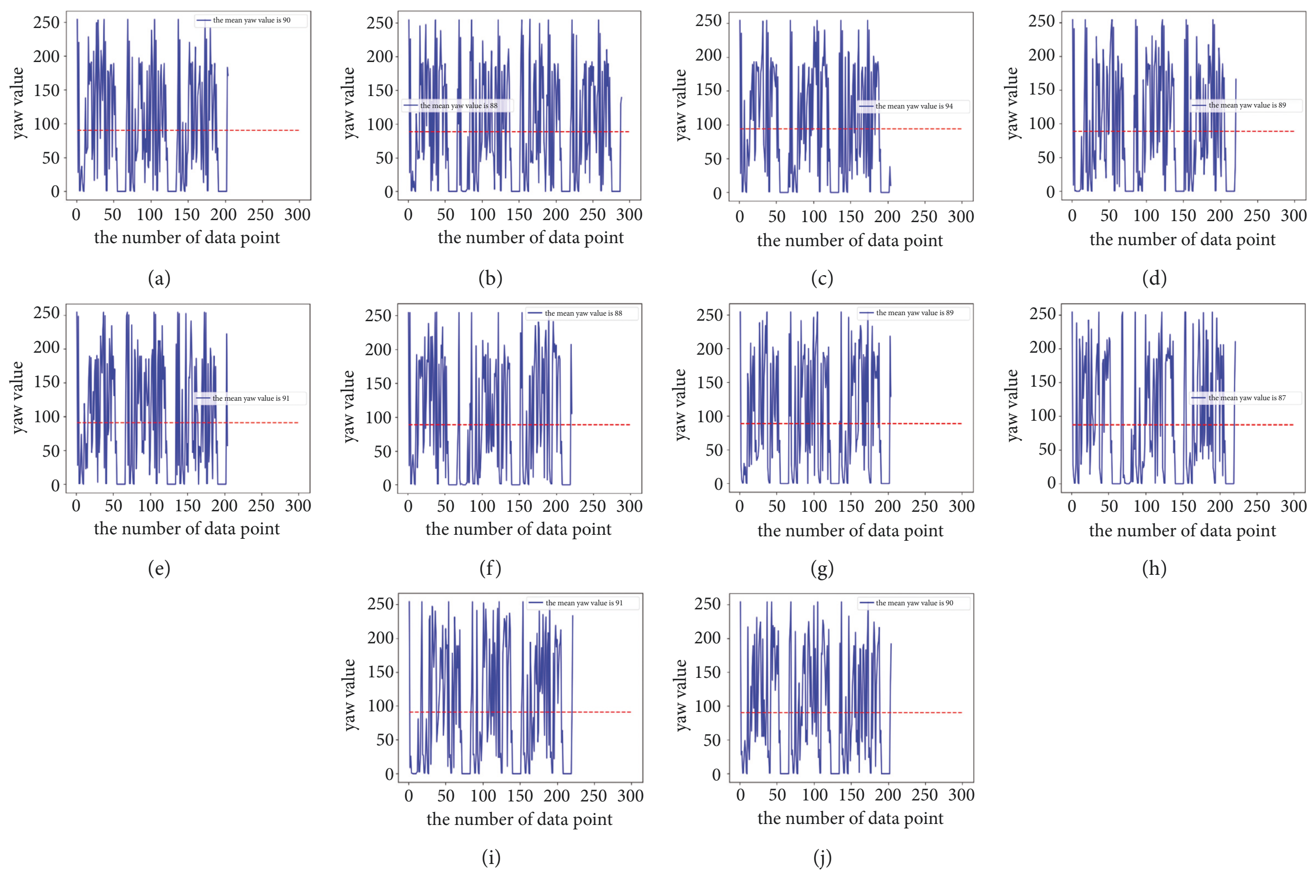

Figure 6: The 10 times' test of the output yaw value from multi-IMU sensor fusion module.

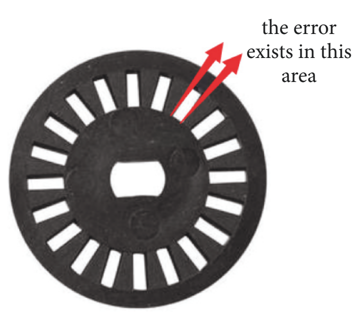

Figure 7: The error exists in each gap of grid of the optical-electricity encoder.

rotates in a circle; although the yaw value can reach a high accuracy when there is 25 KHz pulse outputted, there is still some error exists as shown in Figure 7.

The error is about 360/25000 = 0.0144 degree for a grid of optical-electricity encoder; when the mobile robot moves for a long time, the error will be accumulated to a large value; at the same time, ground friction is another source of error, especially when the mobile robot collides with a heavy obstacle and the wheel is slipping in the dynamic environment; in this status, the optical-electricity encoder is still computing, but the yaw value does not change; usually, the sensor error and observation error all can be accumulated, which is accumulated error. Because the true yaw value can

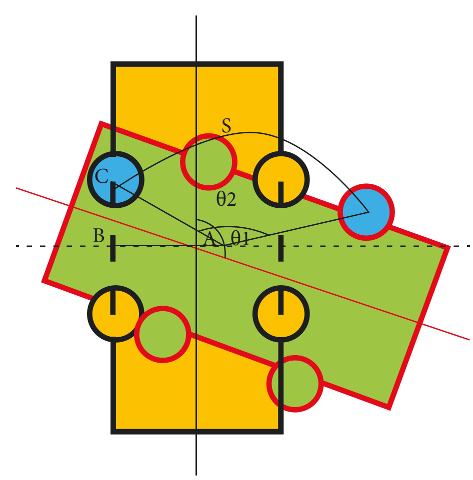

Figure 8: The yaw value of the mobile robot from the odometer.

be measured from round circle ruler in the indoor environment, so the accumulated error can be computed.

If the accumulated error is $v(k)$, the diameter of wheel is D, and the pulse from optical-electricity encoder is P, through analyzing the status of the mobile robot in Figures 8 and 9, the systematic observation model can be obtained from

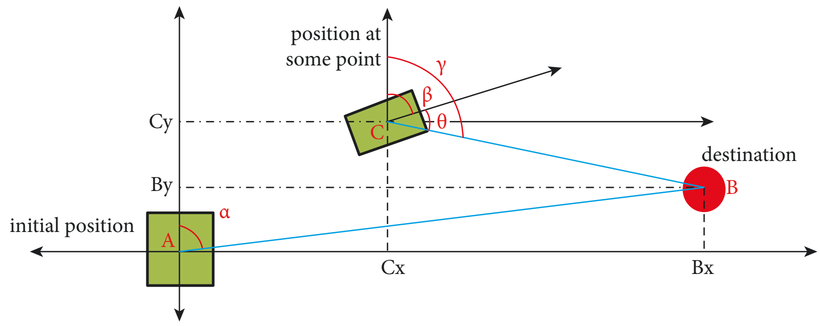

Figure 9: The simulation of the mobile robot moves in the indoor environment.

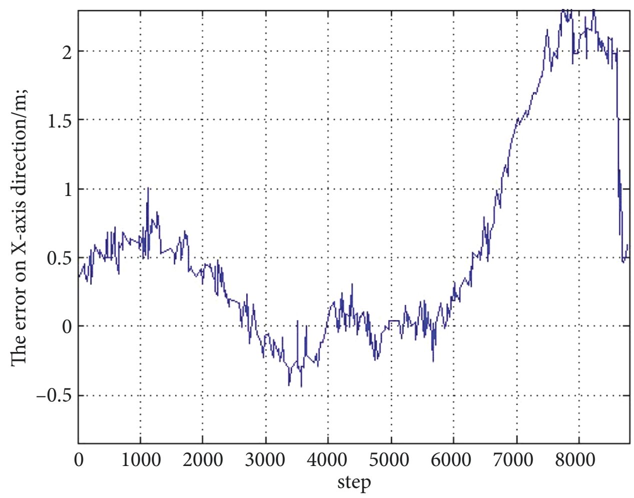

Figure 10: The error of EKF algorithm for the yaw value.

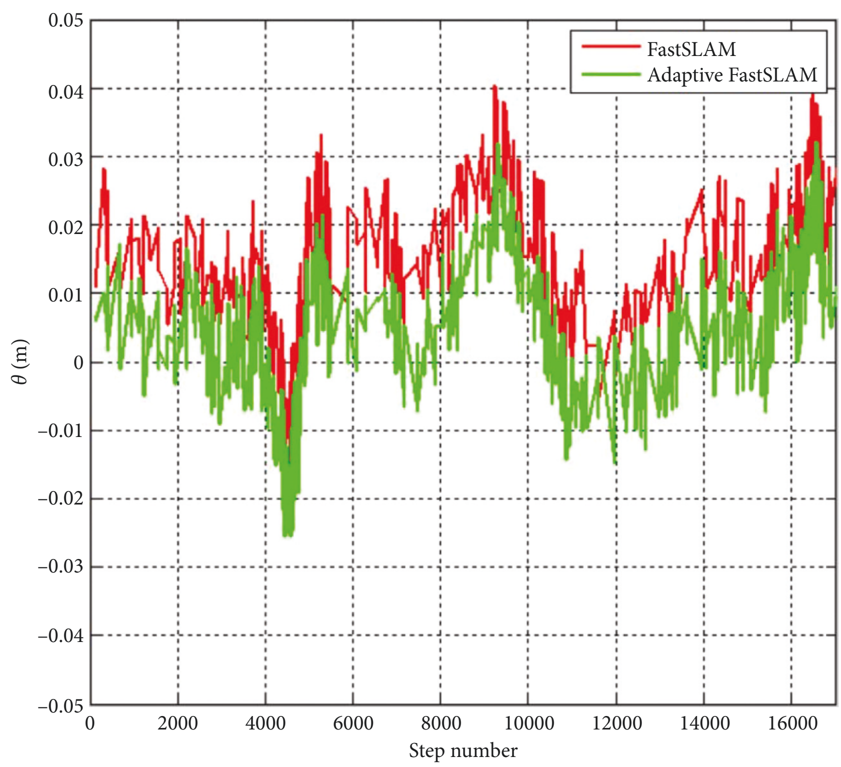

Figure 11: The comparison of yaw value error between Fast SLAM and Adaptive Fast SLAM.

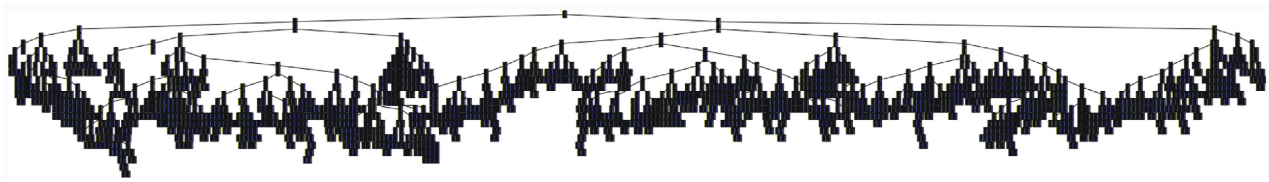

Figure 12: The 360 classifications of the decision tree.

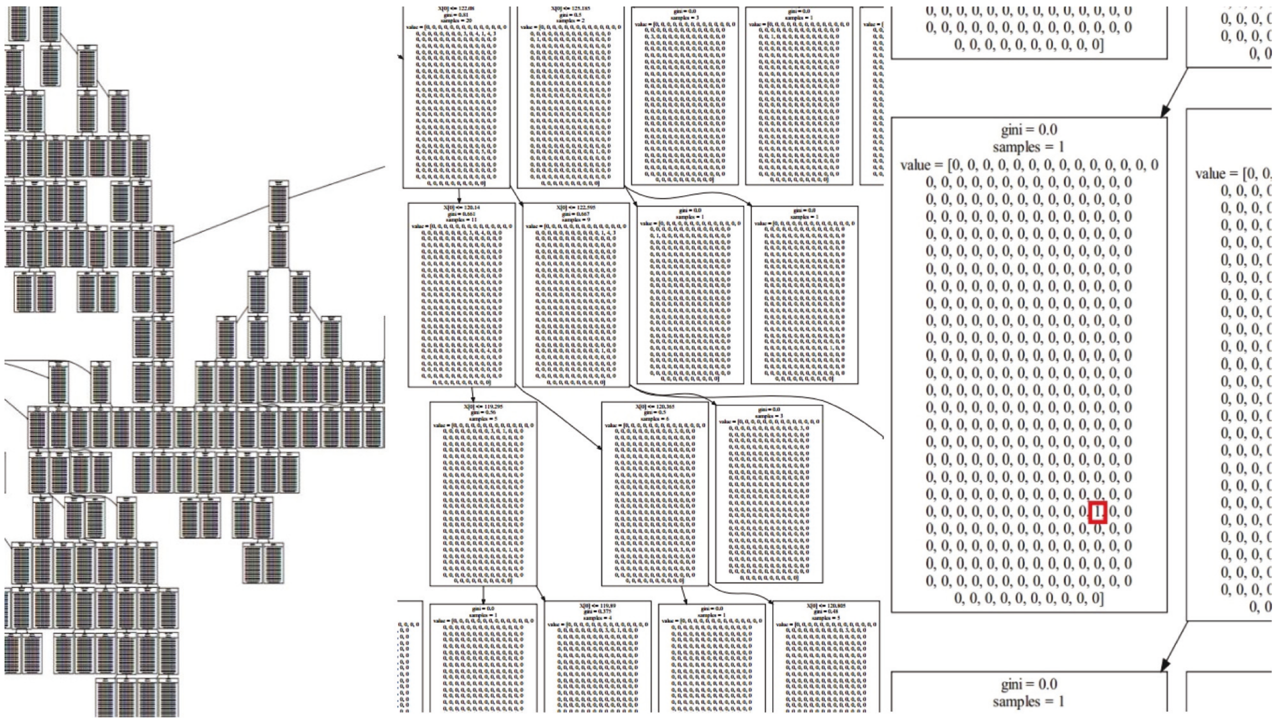

Figure 13: The detailed information of the decision tree.

$$Z(k) = \begin{bmatrix} \dfrac{r(k)}{\phi(k)} \end{bmatrix} + v(k) = \begin{bmatrix} \dfrac{BC}{\gamma - \beta} \end{bmatrix} + v(k) = \begin{bmatrix} \dfrac{\left((Bx - Cx)^2 + (By - Cy)^2\right)^{1/2}}{\tan^{-1}\left(\left(C_y - B_y\right)/\left(C_x - B_x\right)\right) + \pi/2 -} \\ \sum_{i=0}^{k} D \times P \times t_i / F \times \sqrt{AB^2 + BC^2} \end{bmatrix} + v(k). \quad (3)$$

The state estimation of the mobile robot is analyzed to get the method to eliminate the accumulated error; the purpose is to obtain the maximum probability of the state of the mobile robot:

$$\hat{x} = \arg \max_{x} p(x|v, y). \quad (4)$$

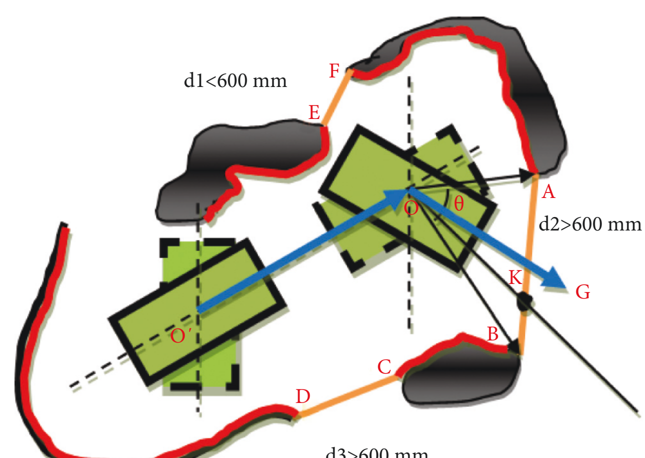

Figure 14: The movement of the mobile robot in the dynamic unknown environment.

Formula (4) can be decomposed by Bayes formulas, so the probability of pose under the condition of obtaining sensor value and observation value can be decomposed as the following formula:

Table 1: The relationship between angle of destination and turning direction.

The angle of destination compared the current orientation	Turning direction
If stop_forward = 0 and angle of destination is between 340° ~ 20°	Forward
If stop_forward > 0 and angle of destination is between 340° ~ 20°	Right
If angle of destination is between 20° ~ "160°"	Right
If stop_forward = 0 and angle of destination is between 160° ~ 200°	Backward
If stop_forward > 0 and angle of destination is between 160° ~ 200°	Right
If angle of destination is between 200° ~ "340°"	Left

$$\hat{x} = \arg \max_{x} \prod_{k=0}^{K} p(y_k|x_k) \cdot \left(p(x_0|\check{x}_0) \prod_{k=0}^{K} p(x_k|x_{k-1}, v_k) \right). \tag{5}$$

Usually, the distribution of the probability of the input value and observed value obeys Gauss distribution; in order to simplify the expression and computation, the maximum likelihood estimation is computed; for example, prior probability before the observation in each step can be expressed as the following:

$$\ln p(x_k|x_{k-1}, v_k) = -\frac{1}{2}(x_k - A_{k-1}x_{k-1} - v_k)^T Q_k^{-1}(x_k - A_{k-1}x_{k-1} - v_k) - \frac{1}{2}\ln\left((2\pi)^M \det Q_k\right)^T, \tag{6}$$

where Q_k is the noise in the moving process and A_{k-1} is the transfer matrix at time k-1 because the first part of the formula (6) is relative to the states x, which can be expressed as

$$J_{(v,k)}(x) = -\frac{1}{2}(x_k - A_{k-1}x_{k-1} - v_k)^T Q_k^{-1}(x_k - A_{k-1}x_{k-1} - v_k), \tag{7}$$

where $J_{(v,k)}(x)$ stands for the error from the real value to the estimated value, so it is necessary to get the minimum value of $J_{(v,k)}(x)$ as follows:

$$\frac{\partial J_{(v,k)}(x)}{\partial x^T} = 0, \tag{8}$$

where it means that when $J_{(v,k)}(x)$ get the minimum value, x can get the suitable estimated value whose probability is the maximum value; in this way, the EKF function can be deduced.

From Figure 10, it is obvious that, after the processing of EKF algorithm, the error of the yaw value is still large. EKF algorithm only considers the linear system; for the assessment of the nonlinear system, EKF algorithm will not be effective because it ignores Taylor's high-order term, which makes the big error of the status assessment. Because the particle filter algorithm has no limit for the system noise, it is taken as the good solution for the nonlinear Gaussian system [10–12].

However, as the number of particles increases, the computational complexity will also increase. In addition, due to the sequential importance sampling particle filter, the samples with bigger weight are chosen for many times, resulting in a decline in the diversity of the particle collection of samples, and thus, there will be sample depletion problems [13–15].

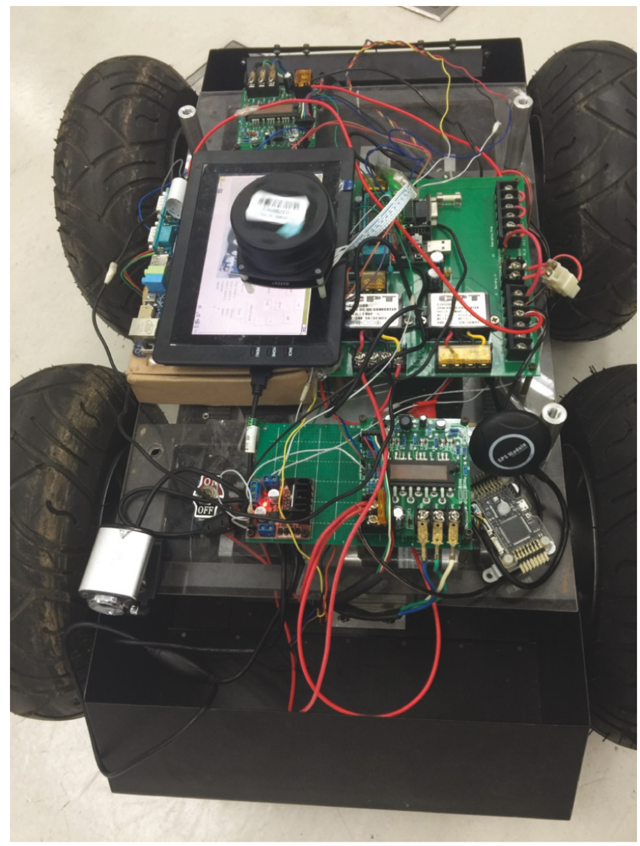

Figure 15: The designed mobile robot.

Fast SLAM is the universal SLAM technology, which can run the particle filter with few particles; similarly, low-dimensional KF is used to filter the surrounding features with known absolute position and consistency. Adaptive resampling algorithm can improve Fast SLAM algorithm; it sets the threshold number of resampling particles as 0.6 times of particles, which can take effective resampling operation by real time, computing effective particle number and particle degradation degree, to deal with the problem "sample degeneration" and "sample impoverishment" which is result in the frequent resampling [16].

The test between Fast SLAM and adaptive Fast SLAM is conducted on the mobile robot; in Figure 11, it is shown that when the mobile robot moves for a longer time, the yaw value error in adaptive FAST SLAM is much lower than it in FAST SLAM, so the yaw value which comes from odometer will be more accurate if they are processed by adaptive FAST SLAM [17].

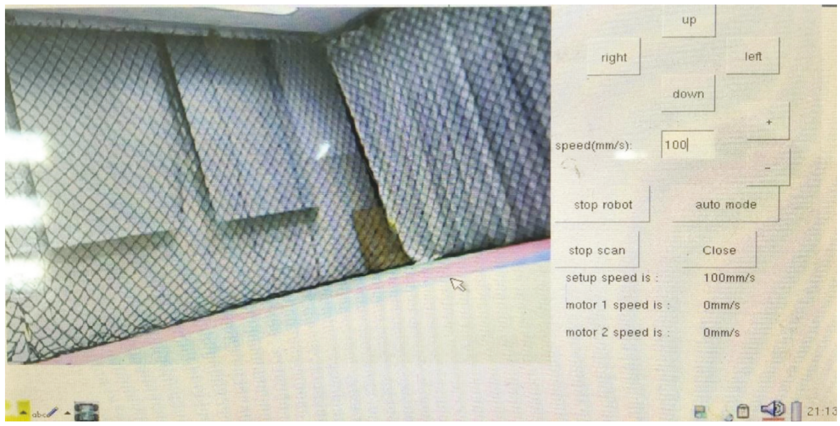

Figure 16: The LCD and touchscreen with camera video display in the embedded Linux system.

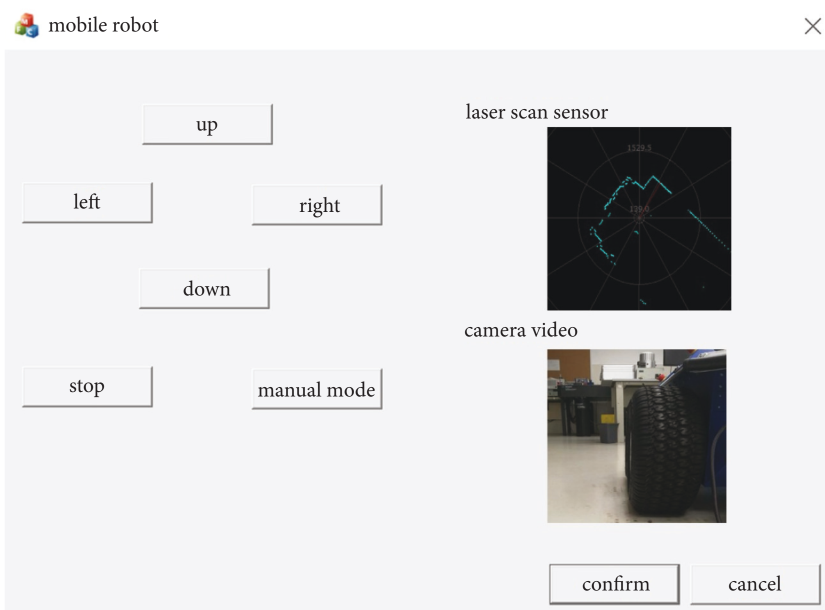

Figure 17: The software on the PC.

2.3. Decision Tree Algorithm. Lots of the data are obtained from the IMU sensor fusion module and the odometer every second, which can be analyzed through machine learning algorithms; considering the limited CPU and battery power of the mobile robot, the complex machine learning algorithms are not suitable for running on the mobile robot. For example, SVM algorithm can convert the data from low dimension to high dimension to classify the data into categories, but it will consume lots of hardware resource and take long time [18], so decision tree algorithm is suitable to run on the mobile robot to predict the yaw value every second because it runs fast and save CPU computation compared with the other machine learning algorithms.

Usually, decision tree algorithm can be used on the classification, but not prediction [19]; if the yaw value can be divided into 360 classifications, every classification stands for one degree; then, the classification can be converted into prediction.

The true yaw value can be measured by the round ruler, and there are only two attributes data, one is yaw value comes from the IMU sensor module and the other is the yaw value which comes from the odometer which is processed by adaptive FAST SLAM. The large number data can be divided into training set, test set, and validation set, with the K fold cross-validation method; then, the data can be trained to get a decision tree model [20]. It should be noted that the data should contain the yaw value when the mobile robot is in some special status, such as the wheel of the mobile robot slips when mobile robot collides with a heavy obstacle in the dynamic environment, or the mobile robot in the dense cluster of buildings where the Earth magnetic field is very weak and the outputted data from IMU sensor fusion module are vibrating dramatically; in this way, the overfitting ability of the model will be intensified.

In Figure 12, the yaw value can be classified into 360 classifications through the processing of decision tree algorithm, and each classification stands for the predicted yaw value in each second for the mobile robot; if Figure 12 is zoomed larger, some details can be visualized as shown in Figure 13.

In Figure 13, the each classification is distributed on the end point of the tree, the value in each end point is a matrix that contains 360 integers, in which one is 1 and others are 0, the position of integer 1 in the matrix stands for the corresponding yaw value. The outputted accuracy of the yaw value from the decision tree can reach 99%; it is very near the true yaw value which is measured by the round ruler, which provides a method to predict the true yaw value of the mobile robot in the indoor environment.

After the accurate yaw value is obtained in the indoor dynamic environment, the following is to judge the next step movement when mobile robot is in the dynamic unknown environment, as shown in Figure 14; the black object in Figure 14 is the dynamic moving object; the red line is the scanned environment from the laser scanning sensor. If the length of the mobile robot is 600 mm, it will go from the gap between moving objects whose length is larger than 600 mm while whose orientation is most near the angle of the destination. The distance and angle of the obstacles can be obtained from the laser scanning sensor, the location of the mobile robot can be computed from the odometer through adaptive FAST SLAM algorithm, and the orientation of the mobile robot can be computed through the decision tree algorithm. If there is an object appearing in the “320°” ~“40°” of the mobile robot, the mobile robot will stop move forward and start rotate left or right to move bypass the object; in this situation, the bit stop_forware is 1, else it is 0; based on the above analysis, the next step movement can be judged according to Table 1.

According to the above analysis, the mobile robot can move to the destination without colliding with moving obstacles in the indoor dynamic unknown environment.

3. Experiment

A mobile robot is designed by us; the CPU is S5PV210 CPU with ARM structure and OS is embedded Linux system, which is shown in Figure 15. On each side of the mobile robot, the belt connects 2 wheels that are driven by the DC motor and 1 : 50 reduction ratio gear motor, so the mobile robot can bear heavy object on it.

For hardware of the mobile robot, the first is the main board with “S5PV210” CPU and various connectors, which connecting the following IMU sensor fusion module, USB camera, LCD display, and touch screen operation, Serial port to Bluetooth module, USB to wifi module, and laser scan sensor. The second is the MCU board; it can send the speed of the motors to the serial port of mainboard and can receive the motor control command from the mainboard through the designed protocol. Because the Linux system is not the real-time operating system, the ARM board cannot read the high frequent pulse accurately, so the MCU board takes the task to read the 25 KHz motor speed pulse. The third part is the power board with SCM6716 chipset to supply the large current and power, and the peak current can reach 1.8 A, which is assurance that the mobile robot can carry the heavy objects.

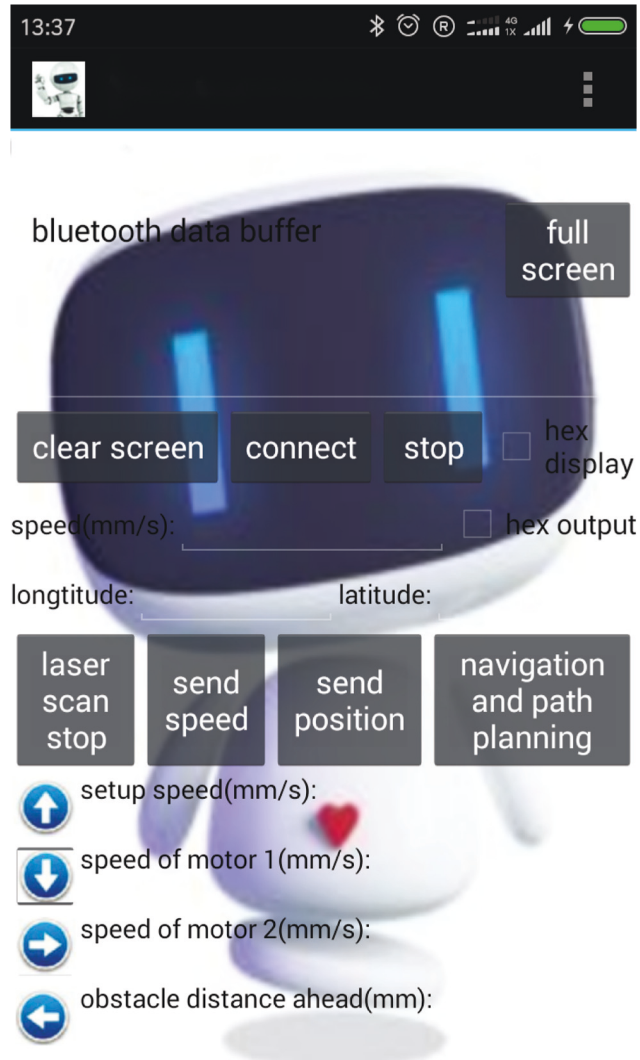

Figure 18: Android APP.

Various widgets on the LCD is designed with the embedded QT in the embedded Linux system, which is shown in Figure 16; through the signal and slot principle of QT, it can fulfill the LCD and touch screen functions. The software on the PC is designed to control the mobile robot and also to show the camera video and laser scanning environment, as shown in Figure 17. The Android APP is designed to communicate with the mainboard with Bluetooth protocol, which can send the value and command of the mobile robot to the Serial-Bluetooth module on the mainboard, as shown in Figure 18. The mjpeg-streamer is a universal tool for the remote monitoring in the B/S structure through the TCP/IP protocol, which can run on the mobile robot in the embedded Linux system; the camera video can be shown on Firefox browser in the Windows system with mjpeg-streamer as shown in Figure 19.

The map of the laboratory environment is not stored in the mobile robot; in order to test the navigation algorithm in the real world environment, the mobile robot is running in our laboratory environment which is the indoor dynamic

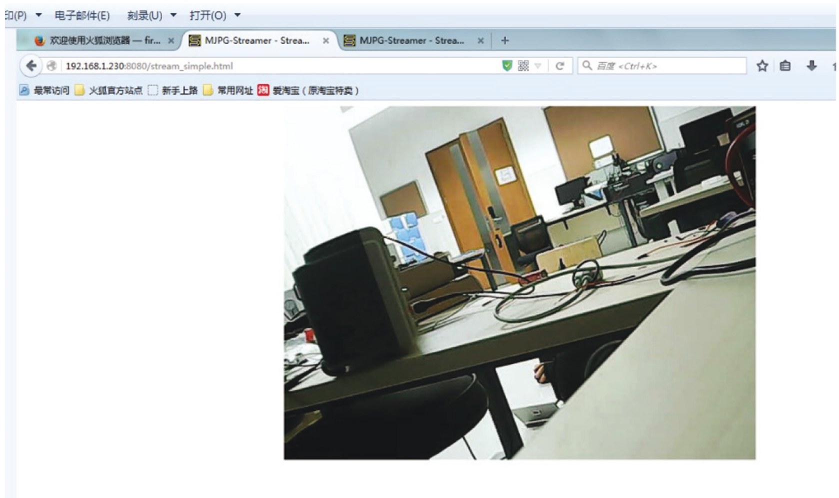

Figure 19: Remote monitoring on Firefox browser.

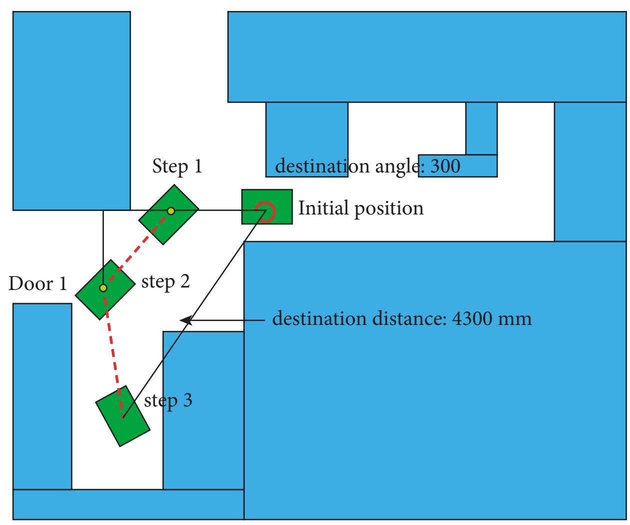

Figure 20: Navigation test of the mobile robot in the laboratory environment.

Figure 21: The navigation test on the designed mobile robot in the laboratory environment.

unknown environment just as shown in Figures 20 and 21; compared with initial position, the angle of destination is 300° and the distance of destination is 4300 mm which can be inputted in the Android APP; the orientation of the mobile robot can be computed according to the decision tree algorithm; the turning direction is judged according to Table 1 in every second; the angle of destination and distance is calculated and updated again in every second; finally, it can move to the destination without colliding with the obstacles on the path.

4. Conclusion

The testing result shows the proposed navigation algorithm is effective and real time responding in the indoor dynamic unknown environment. Compared with other algorithms, the mobile robot can obtain the accurate orientation through the decision tree algorithm in the indoor environment; it can obtain its location through the odometer data which are processed by adaptive FAST SLAM algorithm in the dynamic and unknown environment; it can scan the distance and angle of moving obstacles through the outputted data from the laser scanning sensor, which provide the data to judge the next step movement as shown in Table 1 in the dynamic and unknown environment.

There are some challenges in the navigation algorithm and realization of the mobile robot; one challenge is how to obtain the accurate orientation of the mobile robot in the indoor environment; through the decision tree algorithm, the predicted yaw value is much accurate especially when there is serious slipping of the wheels. The other challenge is that how to make the synchronization of the two threads; there is always errors when reading the outputted data from IMU sensor fusion module; finally, the problem detected that another thread is processing this data while this thread is reading this data; after adding the mutex lock on two threads, the none synchronous problem of two threads is solved and the reading and processing of the data from IMU sensor fusion module becomes normal.

The advantage of the proposed navigation algorithm is that it can be applied in the indoor dynamic unknown environment where there is the working environment for the home service robot; especially, this algorithm can save lots of CPU computation and battery power for the mobile robot which runs on the embedded platform. The next step work is to design and apply the deep learning algorithm on the mobile robot, which can recognize the human face and the appearance of home appliances, making the home service robot more stable and intelligent.

Academic Editor: Xin Ning

Since the existing music emotion classification researches focus on the single-modal analysis of audio or lyrics, the correlation among models are neglected, which lead to partial information loss. Therefore, a music emotion classification method based on deep learning and improved attention mechanism is proposed. First, the music lyrics features are extracted by Term Frequency-Inverse Document Frequency (TF-IDF) and Word2vec method, and the term frequency weight vector and word vector are obtained. Then, by using the feature extraction ability of Convolutional Neural Network (CNN) and the ability of Long Short-Term Memory (LSTM) network to process the serialized data, and integrating the matching attention mechanism, an emotion analysis model based on CNN-LSTM is constructed. Finally, the output results of the deep neural network and CNN-LSTM model are fused, and the emotion types are obtained by Softmax classifier. The experimental analysis based on the selected data sets shows that the average classification accuracy of the proposed method is 0.848, which is better than the other comparison methods, and the classification efficiency has been greatly improved.

1. Introduction

Due to the complexity of music duration and composition, the emotional features extracted from music show the characteristics of large quantity, multiple dimensions, and difficult to analyze [1]. The results of music emotion classification can be well applied to music recommendation function to reduce the disadvantages of collaborative filtering recommendation [2, 3]. At the same time, music can artistically express the emotional information contained therein, and listeners can also obtain emotional tendency through music audio and lyrics information [4]. Music emotion analysis can be well applied to the music recommendation function. Major online music applications have launched the music recommendation function to recommend suitable music and improve the user experience by analyzing the listening habits of different users [5, 6]. However, most of the applications recommend popular songs but ignore personalized works, which is difficult to meet the needs of listeners under different emotions. Therefore, the research on emotional classification of songs has a good application prospect [7].

Before the emergence of intelligent algorithms, the way of establishing classification labels mainly depended on manual work, and the songs with different music styles were established into corresponding song lists [8]. However, such methods are not only inefficient, but also have high requirements for manual experience, and the classification accuracy is also uneven [9, 10]. On the basis of manual classification, the traditional classification methods are gradually mature, which mainly include methods such as logistic regression, naive Bayes, random forest, and support vector machine [11]. For example, Rao Veeranki et al. [12] analyzed and compared the performances of four traditional methods in the process of music emotion classification: logical regression, naive Bayes, random forest, and support vector machine, and took the parameters such as mean, variance, kurtosis, and skewness as analysis indicators, which effectively improved the efficiency of music emotion classification [12]. However, the targeted feature extraction in mixed audio needs to be improved. Kumar and Vardhan [13] made full use of other emotional features according to the rule-based emotion classification algorithm, and obtained better classification accuracy by adding more words to the dictionary [13]. However, the granularity segmentation of music needs to be further improved. Tiple and Patwardhan [14] proposed a new emotion classification system through link preprocessing, feature extraction, and classification steps [14]. The proposed Spiking Neural Network (SNN) classifier based on gradient descent was used to process frames and extract the time, spectrum, and energy features related to music. Combined with the optimal weight value to reduce the training error, the gradient descent method was optimized. Chen and Li [15] proposed a multi-modal ensemble learning method based on stacking [15]. This method was different from the feature-level and decision-level fusion methods. However, this classification method is inefficient in the environment facing a large number of new music creation, and cannot flexibly meet the needs of category expansion in the later stage [16].

Nowadays, classification algorithms based on machine learning methods and deep neural network learning have carried out extensive research in the fields of audio, image and text, and achieved rich results [17, 18]. With the rise of artificial intelligence-related technologies, computers can realize complex emotion analysis and calculation, and automatically output emotion analysis results through algorithms. Scholars' researches on music emotion feature extraction and classification model are also gradually carried out. Hizlisoy et al. [19] proposed a music emotion recognition method based on CNN-LSTM [19]. The experimental evaluation on the constructed emotional music database effectively showed the good performance of the proposed method. However, this method ignores the timing features of audio itself. Sorussa et al. [20] proposed a digital music emotion classification system with different emotion categories, which used supervised machine learning technology to identify the acoustic features and create prediction models [20]. This method effectively improves the accuracy of the algorithm classification, but the efficiency of machine learning needs to be improved. Gan [21] proposed a recurrent neural network method with channel-attention mechanism to classify the music features [21]. The above machine learning methods have achieved good results in the field of music emotion classification, but in the process of dealing with lyrics and melody, the relationship between lyrics and melody emotions is separated in different ways, without considering the consistency of emotion between lyrics and melody [22], so there is room for further optimization of the detailed classification of music emotion.

Aiming at the problem that most existing classification methods are difficult to deal with multi-dimensional and complex music texts, a music emotion classification method based on deep learning and improved attention mechanism is proposed. Its innovations are summarized as follows:

(1) Aiming at the problem of high dimension and sparsity of word vector, the proposed method combines CNN and LSTM to construct emotion classification model, and integrates the matching attention mechanism to further improve the classification accuracy.

(2) In order to solve the problem of insufficient performance of single feature classification, the proposed method uses CNN-LSTM model and deep neural network to process word vector and word frequency weight vector, respectively, and carries out feature concatenation to ensure the reliability of emotion classification.

2. Lyrics Feature Extraction

2.1. TF-IDF Feature Extraction. Term Frequency-Inverse Document Frequency (TF-IDF) is a feature extraction method that represents the weights according to the frequency of word items in the text. TF-IDF can calculate the number of word occurrences by means of probability statistics, evaluate the proportion of word items in the text to determine the importance of the word, and use this to represent the emotional polarity of the lyric text. The more times an emotional representative word appears in a lyrics text, the higher the importance of the emotional word in the emotional classification evaluation. Integrating all word frequency information, the emotional tendency of the whole lyrics text can be evaluated [23].

TF is the word frequency of a word, indicating the number of times a word item appears in the text. TF is calculated as follows:

$$\mathrm{tf}(i, j) = \frac{n(i, j)}{\sum_k n(k, j)}, \tag{1}$$

where $n(i, j)$ represents the number of times that word w_i appears in document d_j, and its denominator represents the total number of words in the document.

IDF is the inverse text frequency. The fewer times the current text contains word items, the stronger the classification ability of the word items to the text. It can be obtained by dividing the total number of words in the data set by the number of samples containing word items and through logarithmic operation. IDF is calculated as follows:

$$\mathrm{idf}(i) = \log\frac{|D|}{\left\{j\colon t_i \in d_j\right\}}, \tag{2}$$

where |D| represents the number of all documents, and the denominator represents the number of documents containing the word w_i.

The TF-IDF calculation result is represented by the product of TF and IDF. If the current word item appears less in the current category and more in the overall sample, the larger the TF-IDF value, the higher the classification ability of the feature item. To sum up, the core of TF-IDF text feature extraction method is to remove the influence of common words and retain important features with text resolution.

TF-IDF is a simple and convenient text word frequency feature extraction method, but it also has some defects. The words in the text are regarded as independent feature items,

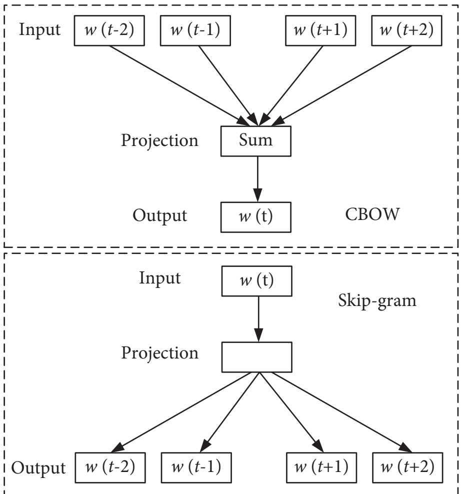

Figure 1: Word2vec training word vector model.

ignoring the relationship between words and ignoring the relationship between words and the whole article. This representation method has good statistical significance for local content, but ignores the integrity of the text, resulting in the loss of fine-grained emotional semantic content. For example, a certain emotion polar word only appears in the song lyrics text of this emotion, but less in other emotion types, which will lead to the error of emotion evaluation.

2.2. Word2vec Word Vector. Word2vec is a distributed text representation method, which maps each word item in the text to a word vector. Word2vec improves the shortcomings of the traditional deep learning word embedding model, with faster training speed and fewer vector dimensions. Word2vec usually includes two model structures: Continues Bag of Words (CBOW) and Skip-Gram, as shown in Figure 1.

The model includes input layer, projection layer, and output layer. In CBOW method, the surrounding words are used to predict the central word, so as to use the prediction results of the central word to represent the a priori probability; Skip-Gram uses the central word to predict the surrounding words, so as to predict the overall result and represent a posteriori probability. Therefore, CBOW will be faster than Skip-Gram in practical use. The parameter dimension of Word2vec-generated word vector is related to the number of hidden layer units in the network. The default value of the program is 100 dimensions.

Word2vec also has some defects: because words and vectors are one-to-one, the problem of polysemy cannot be solved; a static word vector representation, although it has strong universality, it cannot be dynamically optimized for specific tasks. For special text types such as lyrics, text information is different from evaluation text, which can be expressed directly through the emotion polar words. The implicit semantic expression in lyrics is often difficult to summarize emotion through separated word frequency information. The word vector method integrating context semantic information has better classification performance [24].

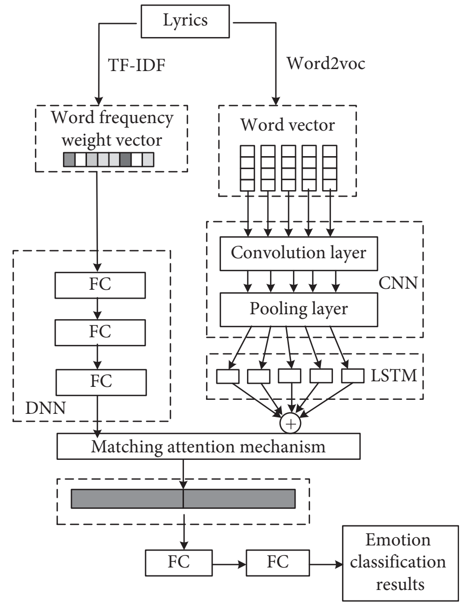

Figure 2: Emotion classification model of lyrics based on CNN-LSTM.

3. Proposed Lyrics Emotion Classification Model

3.1. Model Construction. After preprocessing the lyrics text, two emotion feature vectors, vector space model and distributed vector representation, can be extracted. Word2vec is extracted as word vector representation, which can be applied to deep learning methods, but it often has the characteristics of high dimension and sparsity. A single network model cannot deal with the features well. The architecture of CNN-LSTM not only has the advantage of CNN extracting local features, but also has the advantage of LSTM connecting the extracted features in sequences. Although TF-IDF representation method based on word frequency statistics has some defects in the semantic representation, it also has good distinguishing ability for text information with prominent keywords. In order to integrate the emotional feature representation of two kinds of text, a lyric emotion classification model based on CNN-LSTM is constructed. The model architecture is shown in Figure 2.

The proposed model is divided into two parts: word vector + CNN-LSTM and word frequency weight + Deep Neural Network (DNN). First, CNN is used to extract multiple sets of word vector features of the input text, and the extracted features are integrated into the input of LSTM neural network to output a new set of word vector feature representation. Then, the word bag model vector extracted by TF-IDF is processed by DNN. The features of the two categories are concatenated as the fusion representation of lyrics text, which is finally classified and output by Softmax to obtain the text emotion classification results.

The lyrics emotion classification model based on CNN-LSTM is similar to the audio emotion classification model in network structure. The inputs of the audio classification model are spectrogram and low-level descriptor features, respectively, while the inputs of the text classification model are word vector and word frequency weight vector, respectively [25]. The proposed model also has some performance differences when applied to audio features and text features. Because the audio feature dimension depends on the extracted spectrum description feature, the sequence length depends on the segmentation mode and frame interval of the original music; the text feature dimension depends on the distributed representation dimension set in the feature extraction stage, and the length of the text sequence is directly related to the number of word items. For the theme of song audio classification, CNN plays a leading role in the CNN-LSTM combined network. CNN is used to extract spectrum feature, which requires deeper convolution operation. The size of convolution kernel and stride will affect the classification performance. For the propose of lyrics text classification, the original serialized text feature word vector is difficult to train due to its high dimension and sparsity. CNN mainly provides feature compression ability. Bidirectional LSTM and matching attention mechanism have a greater impact on classification accuracy than convolution layer.

BiLSTM is a structure composed of forward LSTM and backward LSTM, which can well complete the extraction of data features. BiLSTM can well analyze bidirectional data information and provide more fine-grained calculation. The calculation process is as follows:

$$\begin{aligned}\overrightarrow{h}_t &= f\left(\overrightarrow{W}\cdot x_t + \overrightarrow{W}\cdot \overrightarrow{h}_{t-1} + \overrightarrow{b}\right),\\ \overleftarrow{h}_t &= f\left(\overleftarrow{W}\cdot x_t + \overleftarrow{W}\cdot \overleftarrow{h}_{t-1} + \overleftarrow{b}\right),\\ y_t &= g(U\cdot[\overleftarrow{h};\overrightarrow{h}] + c),\end{aligned} \tag{3}$$

where, one LSTM layer processes the sequence from left to right, and the other LSTM layer processes the sequence from right to left. $\overrightarrow{W}$ and $\overleftarrow{W}$ represent the network hidden layer parameters, x_t represents the input data, $\overleftarrow{h}_t$ and $\overrightarrow{h}_t$ represent the output results of the two LSTM layers at time t, $\overrightarrow{b}$ and $\overleftarrow{b}$ represent the offset value, and y_t represents the output of BiLSTM. The BiLSTM structure is shown in Figure 3.

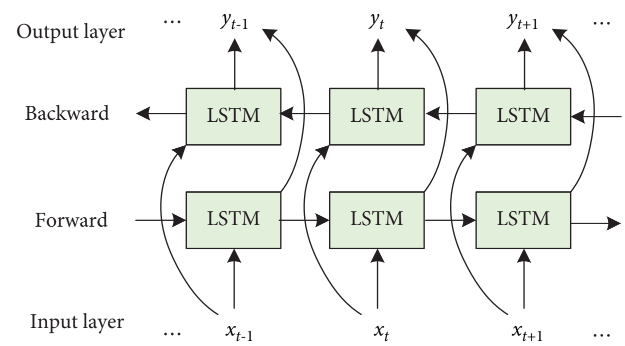

Figure 3: BiLSTM structure.

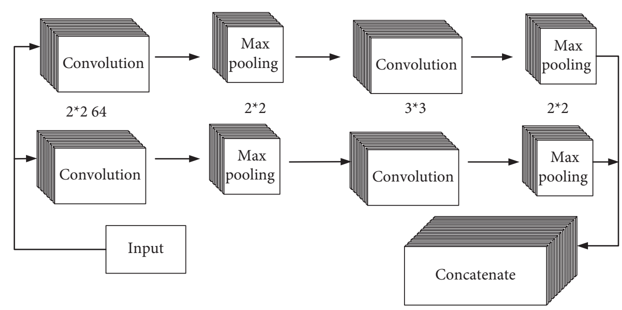

Figure 4: CNN model.

3.2. Model Description

3.2.1. Input Layer. The input of the model is audio feature data. The original music file is preprocessed, and the word vector and word frequency weight vector are obtained, respectively. The feature size of each spectrogram is normalized to $256\times256\times3$, where 256 is the width and height of the image, and 3 represents the number of channels (RGB) of the color spectrogram.

3.2.2. CNN Layer. The detailed view of the CNN layer model is shown in Figure 4. In the model implementation, CNN layer includes two convolution layers and two pooling layers. The input of first convolution is the word vector, the convolution operation is performed through 64 convolution kernels with size of 2×2 and step of 1, and Relu is used as the activation function [26].

The output vector size H of CNN depends on G (input size), κ (convolution kernel size), P (padding size), and τ (step size). The calculation is as follows:

$$H = \frac{(G-\kappa+2P)}{\tau+1}. \tag{4}$$

During the convolution feature extraction, first, use a single convolution kernel to calculate each local feature of the input. Then, concatenate the calculated features vertically, and finally perform nonlinear calculation on the concatenated features through the activation function to obtain the final convolution feature. The mathematical expression is as follows:

$$\begin{aligned}h_{1\kappa}(i) &= f\left(J_\kappa\cdot X(i\colon i+\kappa-1)+b\right),\\ h_{1\kappa} &= [h_{1\kappa}(1);h_{1\kappa}(2);\cdots;h_{1\kappa}(H);],\\ hr_{1\kappa} &= \mathrm{Relu}[h_{1\kappa}],\end{aligned} \tag{5}$$

where, J_κ represents the convolution kernel with height κ, H is the size of the output vector, $h_{1\kappa}(i)$ is the i-th local feature, $hr_{1\kappa}$ is the output c8onvolution feature, X is the input, and f is the tanh activation function.

3.2.3. LSTM Layer. In order to fuse different features to improve the classification accuracy, cascade is used to connect the merged results as the input of LSTM layer. The mathematical expression is as follows:

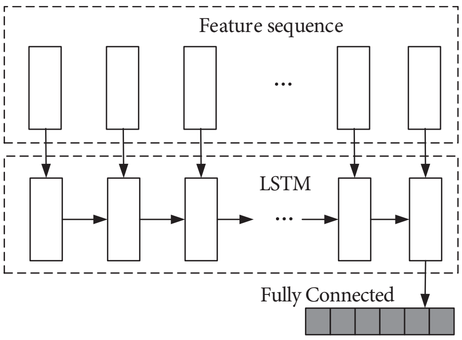

Figure 5: LSTM model.

$$\begin{aligned} hp_{1\kappa} &= \max[hr_{1\kappa}], \\ h_1 &= \varphi(hp_{1\kappa}, hp_{2\kappa}), \end{aligned} \tag{6}$$

where, $\mathrm{hp}_{1\kappa}$ is the result of pooling operation; φ is the merge connection function, and h_1 is the input of LSTM.

The word vectors generated from the sample set are further extracted by the CNN layer. Specifically, for the lyrics sample represented as $[v_{(1)}, v_{(2)}, \ldots, v_{(T)}]$, where T is the number of frames after lyrics segmentation. After passing through the CNN layer, a sequence vector $[c_{(1)}, c_{(2)}, \ldots, c_{(T)}]$ is obtained as the input of the LSTM layer. The detailed view of LSTM model is shown in Figure 5.

Input the vector output from the previous layer and selected by the feature into the bidirectional LSTM. The LSTM layer in the model has 128 units, and the output results can be expressed as $[l_{(1)}, l_{(2)}, \ldots, l_{(T)}]$.

3.2.4. Matching Attention Mechanism. For fine-grained emotion analysis, the ordinary attention mechanism cannot accurately extract the target words of fine-grained elements, resulting in the low accuracy of emotion analysis. Therefore, based on the original attention mechanism, a matching attention mechanism is built to improve this problem. The input of attention matching mechanism includes two parts. One part is the weighted word vector after the feature fusion of Word2vec word vector feature and TF-IDF feature based on word frequency statistics; the other part is the word vector generated after the fine-grained feature information in the data set is sent to Word2vec. First, these two parts of input are fed into the matching attention mechanism, and the context information and fine-grained element information q_s are captured at the same time. The calculation is as follows:

$$q_s = \mathrm{Average}\left(\frac{1}{m}\sum_{i=1}^{m} e_{a_i}, \frac{1}{n}\sum_{j=1}^{n} e_{\omega_j}\right), \tag{7}$$

where, Average represents the average value of the input vector, e_{a_i} is the word vector, e_{ω_j} is the weight word vector, and m and n are the numbers of word vectors and weight word vectors, respectively. In order to make the information of fine-grained elements meaningful, only the dimensions related to fine-grained elements will be retained in the Q_t, while other dimensions will be deleted. The calculation process is as follows:

$$Q_t = \omega_t \cdot q_s + b_t, \tag{8}$$

where Q_t is the weight vector of k fine-grained elements. It mainly looks for the dimensions related to fine-grained elements by looking at the words nearby in the word vector space. ω_t and b_t represents the weight matrix and offset vector, respectively. After the loss function is determined, the parameters in ω_t and b_t can be updated by gradient descent method. When the loss function converges, the optimal solution can be obtained. Then multiply Q_t by a randomly initialized matrix ψ to obtain the target word a_s matching the fine-grained elements identified by matching attention, which is expressed as follows:

$$a_s = \psi \cdot Q_t, \tag{9}$$

where, the dimension of ψ is $k \times d$. It can be updated by gradient descent method.

Finally, matching attention weight p_i is calculated according to a_s. The calculation is as follows:

$$p_i = \frac{\exp\left(\tanh\left(h_i^T \cdot \omega_0 \cdot a_s\right)\right)}{\sum_{j=1}^{n} \exp\left(\tanh\left(h_j^T \cdot \omega_0 \cdot a_s\right)\right)}, \tag{10}$$

where $\omega_0 \in \mathfrak{R}^{d\times d}$ is a trainable weight matrix, h is the output of LSTM hidden layer.

Finally, the weighted sum of the hidden vector h_i generated by the bidirectional LSTM and the matching attention weight p_i is used for the sentence representation Z_s of emotion classification, which is expressed as follows:

$$Z_s = \sum_{i=1}^{n} p_i h_i. \tag{11}$$

Take Z_s as the feature of the final emotion classification and put it into the fully connected layer for linear transformation, and Softmax classifier is used for emotion classification to obtain the final emotion ϕ. The mathematical expression is as follows:

$$\phi = \mathrm{softmax}\left(\omega_Z \cdot Z_s + b_Z\right). \tag{12}$$

3.2.5. DNN Layer. The input of DNN layer is the word frequency weight vector, which contains three hidden layers, also known as FC (fully connected layer). All nodes of FC in the network are connected with the nodes of the previous layer to achieve the purpose of integrating feature information and reducing dimension. The number of nodes of the three FCs in the model is 256, 128, and 64, respectively. The dimension of the input feature is further compressed after passing through the DNN layer.

3.2.6. Output Layer. The output layer consists of FC and Softmax. First, the output of word vector features through CNN layer, LSTM layer, and attention mechanism layer and the output of word frequency weight vector features through

DNN layer are concatenated as the final classification feature vector representation. Output classification is through FC and Softmax layers. The Softmax layer is a loss function, which is used to map the output to the probability interval to obtain the classification probability distribution, so as to output the classification results. The model is actually classified into four emotional categories: happy, sad, healing, and calm.

4. Experiments and Analysis

In order to build a parallel corpus of Chinese audio and lyrics, the data source is locked on the domestic music platform, and the data is collected based on the target of the task. In order to select the songs with higher quality, the songs with more credibility are selected, that is, the songs with a playback times of more than 2.5 million. In order to further carry out the task of music emotion classification, four kinds of emotion labels with happy, sad, healing, and calm were selected as candidates. A total of about 6000 music were collected. After further screening of song length, audio quality and language, 5286 music were finally retained as the candidate data set. On this data set, it is divided into two parts: training set and test set. The specific information of each data set is shown in Table 1.

In the experiment, the lyric text is preprocessed. First, the word segmentation is carried out to remove the invalid information related to music composition and stop words, and constructs a pure lyric text word item combination representation. Then, the text is transformed into a digital vector recognized by the computer through different feature extraction methods, and the feature dimension of the text vector is set to 100 dimensions. Finally, input them to the classifier to output the emotion classification results. The parameters of LSTM model are shown in Table 2.

4.1. Classification Accuracy of Different Text Features. The experiment adopts different word frequency weight vector feature extraction methods to verify the emotional classification performance of lyrics. First, the preprocessed text is represented by text vector through TF-IDF and Word2vec feature extraction methods, and then the same SVM classifier is used to output the emotion classification results. The classification accuracy of different text extraction methods is shown in Table 3.

As can be seen from Table 3, TF-IDF is completely based on the features of word frequency. When facing the sample data with implicit emotional semantics such as lyrics, the emotional classification performance is slightly insufficient, and the average classification accuracy is only 0.701. At the same time, the distributed word vector feature representation extracted by Word2vec tool has also achieved good accuracy in SVM classifier. The classification accuracy of happy emotion is as high as 0.801 and the average classification accuracy is 0.746. This distributed vector can be well used as the input of deep network method.

Table 1: The size of the data set and the number of songs contained in each type of emotion.

	Training set	Test set	Total
Happy	1078	194	1272
Sad	1267	317	1584
Calm	882	221	1103
Healing	1061	266	1327
Total	4288	998	5286

Table 2: Parameter setting of LSTM network model.

Parameter	Value
Loss function	Softmax
Optimizer	Adam
Learning rate	0.01
Activation function	Tanh
Dropout	0.03
Batch size	50
Epoch	30

Table 3: Classification accuracy results of different text features.

Text features	TF-IDF	Word2vec
Classification method	SVM	
Happy	0.762	0.801
Sad	0.735	0.779
Calm	0.647	0.698
Healing	0.661	0.703
Average	0.701	0.746

Table 4: Experimental results of three attention mechanisms.

Model	Classification accuracy
Traditional attention mechanism	0.753
Matching attention mechanism	0.826

4.2. Classification Accuracy of Different Attention Mechanisms. In order to study whether the matching attention mechanism can further improve the performance, it is compared with the traditional attention mechanism. The evaluation results of the joint training model on the selected data set are shown in Table 4, in which the average classification accuracy is used for performance evaluation.

It can be seen from Table 4 that the matching attention mechanism significantly improves the classification performance of the model, and its average classification accuracy is 0.826, which is 0.073 higher than that of the traditional attention mechanism. The traditional attention mechanism cannot accurately extract the target words of fine-grained elements, resulting in the low accuracy of emotion analysis. The matching attention mechanism can solve this problem, and greatly improve the classification accuracy combined with the context information.

4.3. Experimental Comparison and Analysis with Other Methods. In order to demonstrate the performance of the proposed method, it is experimentally analyzed with

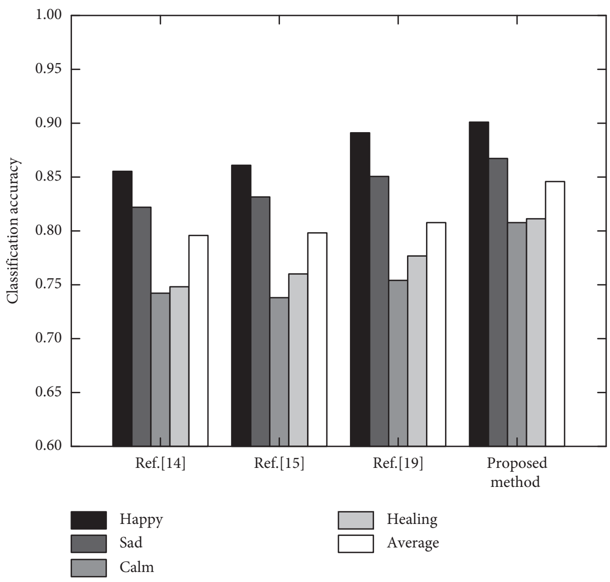

Figure 6: Classification accuracy of different methods.

Table 5: Classification results of different methods.

Method	Reference [14]	Reference [15]	Reference [19]	Proposed method
Happy	0.853	0.861	0.887	0.903
Sad	0.828	0.837	0.849	0.864
Calm	0.742	0.739	0.753	0.809
Healing	0.751	0.766	0.771	0.816
Average	0.794	0.801	0.815	0.848

Reference [14, 15, 19] on the selected data set. The classification accuracy of different emotions in lyrics is shown in Figure 6 and Table 5.

As can be seen from Figure 5 and Table 5, the proposed method combines the characteristics of CNN and LSTM, constructs an emotion analysis model based on CNN-LSTM, and combines DNN network learning to greatly improve the accuracy of music emotion classification, with an average classification accuracy of 0.848. The fusion processing of deep learning network improves the classification performance, especially integrates the matching attention mechanism, accurately extracts the target words of fine-grained elements, and significantly improves the classification accuracy of emotional types such as calm and healing, which are 0.056 and 0.045 higher than those in reference [19]. Reference [19] uses CNN-LSTM architecture to complete music emotion recognition. Although the average classification accuracy reaches 0.815, it is easy to confuse emotion types such as calm and healing, and the performance needs to be improved. Reference [14] classifies emotions based on gradient descent SNN classifier, and reference [15] classifies emotions based on stacking multi-modal ensemble learning method. Both of them are difficult to accurately distinguish massive and complex music types, and the average classification accuracy is about 0.800. In conclusion, the proposed method uses the comprehensive feature extraction ability of CNN and the ability of LSTM to process the serialized data to obtain better classification results, and has stable performance and high robustness under each subclassification.

5. Conclusion

Music contains rich human emotional information. The study of music emotional classification is helpful to organize and retrieve massive music data. Because of the large number and multiple dimensions of music, it is difficult and incomplete to extract emotional features. Therefore, a music emotion classification method based on deep learning and improved attention mechanism is proposed. The word frequency weight vector obtained based on TF-IDF is input into DNN for feature analysis, and the word vector obtained by Word2vec method is sent into the emotion analysis model based on CNN-LSTM. After the output of the two feature extraction channels are fused, the output layer outputs the emotion type. The experimental results based on the selected data set show that matching attention mechanism can more accurately extract the target words of fine-grained elements and improve the classification performance. Compared with the traditional attention mechanism, its average classification accuracy is improved by 0.073.

The processing of audio features in this paper is still a little rough. Only using the existing common features cannot fully reflect the relationship between music structured information and human emotion. Therefore, the feature extraction method with more music emotion classification ability can be further explored.

National dance is an important symbol of national spiritual culture, as it embodies each nation's unique history, living habits, ideology, and culture. Many Chinese ethnic groups have developed their own dance forms and styles, each with their own set of charms. Strengthening our understanding of its style and characteristics is critical to our understanding of the national dance. To begin with, this paper proposes a patch-based multiview stereo reconstruction scheme that can accurately reconstruct 3D character models. The movement capture system then collects national dance movement data and uses them to drive a three-dimensional character model that generates dance visual animation. In the human skeleton model, a spatial-temporal HMM (hidden Markov model) is proposed that not only studies the temporal information of human movements but also the spatial information of adjacent connection points. The recognition rate of this algorithm increases to 95.68 percent when the number of setting points is increased to ten and to 98.28 percent when the number of setting points is increased to twenty, according to the research. The experimental results show that the 3D reconstruction model of ethnic dance developed in this paper is capable of meeting the goal of ethnic dance digitalization while being simple to use, being low in cost, and with a good display effect.

1. Introduction

Three factors make up the essence of dance style: formal characteristics, thoughts, and images of dance works. They are concerned not only with the expression of the external form of dance works but also with the transmission of spiritual ideas. Many factors influence the formation and development of a dance style, including the social environment, history, and culture, as well as the personal preferences and aesthetics of the dancers. The styles and characteristics of different national dances are obviously different, influenced by regional, national psychology, culture, and other factors. People will gain a better understanding of ethnic dance style characteristics by comparing the style characteristics of different ethnic dances. National dancers use special costumes or auxiliary props such as a stage to assist dancers in performing and silk to express dance images, in addition to using body movements to express national dance culture. The effective arrangement of dance movements and efforts to use the arrangement and flexible design of shapes to form a good dance performance image share many similarities with national dance art and painting art. The lines produce products that satisfy the aesthetics, interesting dance steps, and emotional resonance of the audience.

National dance has a long and ancient history as a phenomenon of dance culture and embodies a specific style and a specific form, as well as historical changes and the development of the times in a specific period, i.e., the development of the times has a far-reaching impact on the national dance culture. To demonstrate the national dance, Piniés et al. used 3D modeling and human motion capture technology, and the model used in the dance was an animation model drawn by hand [1]. Ma et al. proposed a dance training system that combines motion capture and virtual reality by capturing imitation motion, projecting it on the screen using virtual reality technology, and providing feedback, but there occurred a large error in capturing motion [2]. Jones et al. proposed to perform three-dimensional convolution in the CNN (Convolutional Neural

Network) convolution layer, in order to capture the distinguishing features of spatial and temporal dimensions [3]. By extracting 16 joint points, Liu et al. were able to perform motion tracking and attitude analysis. Because the human body's movements are flexible, simply changing the joints will result in a large error in recognizing the movements of the human body [4]. Werner et al. used the metric learning algorithm twice during the time-consuming model training stage. This means that achieving the real-time recognition effect for an unfamiliar action is difficult for the algorithm [5]. Furthermore, because this type of algorithm must make complex decisions in order to eliminate a large number of false 3D graphics primitives, the search volume is too large and the efficiency is too low, making it unsuitable for widespread use. It is the most effective means of improving the efficiency of the bottom-up recognition algorithm by aligning it with engineers' drawing methods and starting from a higher level of graphic semantics.

Video technology research has become one of the hottest topics in academia in recent years. Video motion recognition is one of the most important video technologies for the application of video intelligence, and it is widely used in many fields [6, 7]. As a result, using 3D reconstruction technology to protect Chinese national dance art and culture is critical. The national dance artists are reconstructed using 3D reconstruction technology [8], their images are saved in digital form on the computer, and a model of national dance artists driven by dance scores is imported. The underlying data are selected and analyzed in the feature extraction stage, and the action information is modeled on the data to obtain the human action pattern. It is a crucial component of human motion recognition that has a direct impact on the accuracy and robustness of the system. It investigates not only the time series data of human movement but also the spatial data of adjacent connection points in the human skeleton model, in order to better reflect the fundamental law of feature distribution.

1.1. Main Research Contributions

(1) This document combines camera image array and Kinect principle to collect depth images and calculates the 3D point cloud coordinates and normal vectors of depth images. Then, this paper uses the camera pose matrix estimation method with edge feature points as the auxiliary relationship to realize point cloud matching, and the generated point cloud is triangulated to form a triangular surface model.

(2) People should not only judge the type of action according to the image when the action is still but also pay attention to the whole changing process of the action from the beginning to the end. In this paper, a human motion recognition algorithm based on 3D joint space-time information is proposed. The algorithm extends the one-dimensional hidden Markov model, which studies time series information, to spatial time series HMM, which not only studies the time series information of actions but also studies the spatial information of events.

1.2. Structural Arrangement. Section 1 introduces the research background and significance and then gives the main work of this paper. Section 2 mainly introduces the related technologies of 3D reconstruction. Section 3 puts forward the concrete methods and implementation of this research. Section 4 verifies the superiority and feasibility of this research model. Section 5 is the summary of the full text.

2. Related Work

2.1. Research on 3D Reconstruction Technology. 3D reconstruction is an important part of the field of artificial vision, in which the recovery of 3D structures of objects and scenes from 2D image sequences based on motion information has always been an important research content of 3D reconstruction. In order to get more detailed information from the model, it is necessary to reconstruct a dense point cloud. Therefore, it is very important to solve the problem of dense pixel matching in image sequences.

Ma et al. proposed an energy function, which contains not only a constant brightness term but also a regularization term, which can supplement the optical flow information of weak texture areas [9]. Hernando et al. adopted effective duality based on optimization scheme and extended it to video registration of multiframe optical streams by establishing a long-term temporal coherence model with subspace constraints [10]. Han et al. proposed that the subspace constraint should be regarded as an implicit long-term trajectory regularization term in the whole video, and the time-consistent optical flow can be obtained [11]. Lu et al. proposed using subspace constraints to build a multiframe optical flow model and made a clear reasoning on occlusion [12]. However, this method is limited by the hard subspace constraint of the known principal component analysis base, which is calculated by sparse feature tracking.

The method of model reconstruction through the software can provide abundant components and functions by the software itself, and it is convenient to construct the Wang Wei model, which provides convenience for the design of the article model. Kottkamp et al. proposed an automatic surface generation system [13]. The system uses a handheld camera to collect image sequences, and through multiview feature matching, it can automatically complete camera calibration and layered reconstruction of object surface. Boden et al. constructed the RGB-D mapping system by using the depth and color information collected by Kinect [14]. The system combines battery correction and visual feature matching and realizes the postregistration of three-dimensional point clouds. Then, through closed-loop detection and global optimization, the indoor scene can be reconstructed in real time. Chen et al. realized real-time 3D reconstruction by using mobile Kinect and studied the physical interaction and multitouch of the reconstructed scene [15].

2.2. Research on Human Motion Recognition Technology. The features of human motion recognition learned by traditional methods cannot cope with the troubles caused by complex scenes, and the problems to be solved are limited. The way of deep learning conforms to the mechanism of human perception of the world. When there are enough samples, the features learned through deep network often have certain semantic features.

Yin et al. divided the human skeleton into five parts, represented by five subnetworks, and then fused them at the high level. An end-to-end recurrent neural network method based on the skeleton is proposed for human body recognition [16]. Iosifidis et al. put forward a new cyclic attention neural network, which uses separated spatial attention to improve the accuracy in the data set [17]. Almazán et al. put forward a dance training method based on systematic desensitization, defined the function of systematic desensitization training, and concluded that this method can help athletes to master sports dance skills [18]. Wang applied support vector machine to motion recognition, and they classified the extracted local feature vectors linearly. Later, many researchers used support vector machine in the recognition process [19]. Wang et al. combined the features of skeleton and contour, considered the boundary of contour itself, and used the background removal method to obtain contour [20]. Then, the histogram of human body shape is calculated by a radial algorithm centered on silhouette, and the final descriptor is obtained by combining the two features. Chang et al. used inertial sensors and depth cameras to capture the actions of cooking food (such as cutting food, subpackaging food, and eating food) [21]. Referring to the acceleration measured with the wearable inertial sensor, the coordinates and displacements of the human wrist, elbow, and shoulder can be estimated according to the depth data.

3. Methodology

3.1. Three-Dimensional Reconstruction of the National Dance Style Characteristics

3.1.1. Overall Framework. The primary goal of the national dance deductive process is to use the image deductive process to allow the audience to truly experience and feel the allure of dance as an art form. Each nation's physical formation and dynamic characteristics are not only closely related to the nation's historical development but also the result of artistic creation. Dance is thus not only an artistic expression but also a symbol of traditional culture and customs. Every feature of each historical stage is reflected in national dance, which has always been the carrier of popular culture. In a unique way, it preserves and accumulates cultural factors at various historical stages. The model's accuracy is always inversely proportional to the amount of data stored. A portion of the storage space will be sacrificed in order to achieve high accuracy, and the compression of the storage space will inevitably result in a decrease in accuracy. As a result of the discrepancy between the amount of data and the model's accuracy, the strain reference template is chosen for the measured point cloud. The first box's point cloud template is arbitrary and can be a standard template. The previous frame's point cloud is used as the reference template for the next frame after nonrigid body registration, and then, the rigid body's point cloud registration method with two viewpoints is used for preregistration. This is to strike a balance between accuracy and data volume so that the final model can satisfy both computers and users.

Using the depth data collected by mobile Kinect, high-quality 3D models can be reconstructed in real time. The technical framework of the Kinect Fusion system is shown in Figure 1.

Firstly, the system collects the original depth data through Kinect and then calculates the unit coordinates and normal vectors from the spatial point cloud. Then, the absolute camera pose is calculated by iterative algorithm, and the point cloud registration operation is carried out. In the process of point cloud merging, different from the previous simple point cloud merging methods, the system uses truncated symbolic distance function to map the point cloud data into a global cube to realize the merging. Finally, the ray tracing method is used to model the surface according to the current camera pose.

Because the obtained depth map contains some holes, it is necessary to repair the depth map in order to improve the quality of subsequent reconstruction. In this paper, the method of joint bilateral filtering is used to draw depth data. Its basic idea is to use the RGB image as the guide map and fill the missing information in the depth map with its full-edge information.

The filtered depth map is expressed as

$$D'_x = \frac{\sum_{ij} w^s_{i,j} w^c_{i,j} w^z_{i,j}}{\sum_{ij} w_{i,j}}, \tag{1}$$

where $w^s_{i,j}$, $w^c_{i,j}$, and $w^z_{i,j}$ is the spatial weight, color weight, and depth weight, respectively.

The data processing flow of the system mainly includes three parts: calibration, acquisition, and registration, as shown in Figure 2.

After the system is started, first initialize the system parameters, setting the Kinect depth frame resolution to 650×460 and the frame rate to 20 frames per second, and initialize Kinect Fusion-related parameters. In the acquisition stage, Kinect Fusion integrates them into their global surface model system and uses the ICP (Iterative Closest Point) algorithm.

Estimation of the current position of Kinect: in the registration stage, two point clouds are fitted to the same coordinate system, which provides a good starting position for the subsequent ICP algorithm and improves the registration accuracy. In the calibration stage, the point clouds obtained by two Kinect cameras are adjusted to the same coordinate system. The calibration process only needs to be done once after the hardware platform of the system is built.

3.1.2. Point Cloud Registration. Point cloud registration is the key link of network reconfiguration technology, and the accuracy of point cloud registration directly affects the quality of the reconfiguration model. Because the accuracy of image processing is usually high, this step needs a lot of calculations, so the execution efficiency becomes one of the

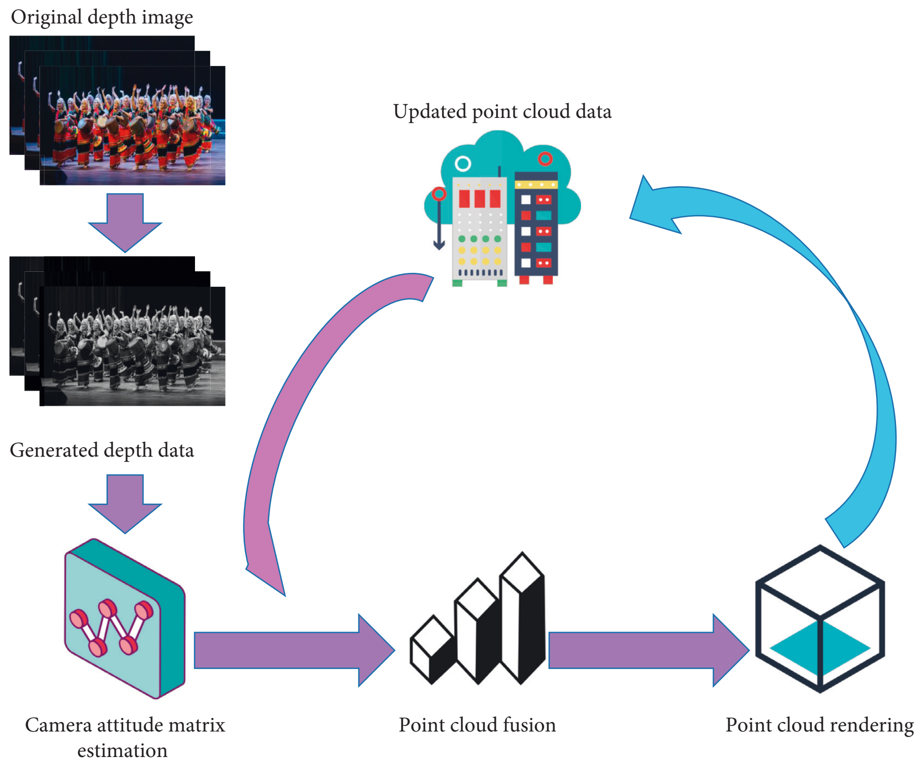

FIGURE 1: System framework.

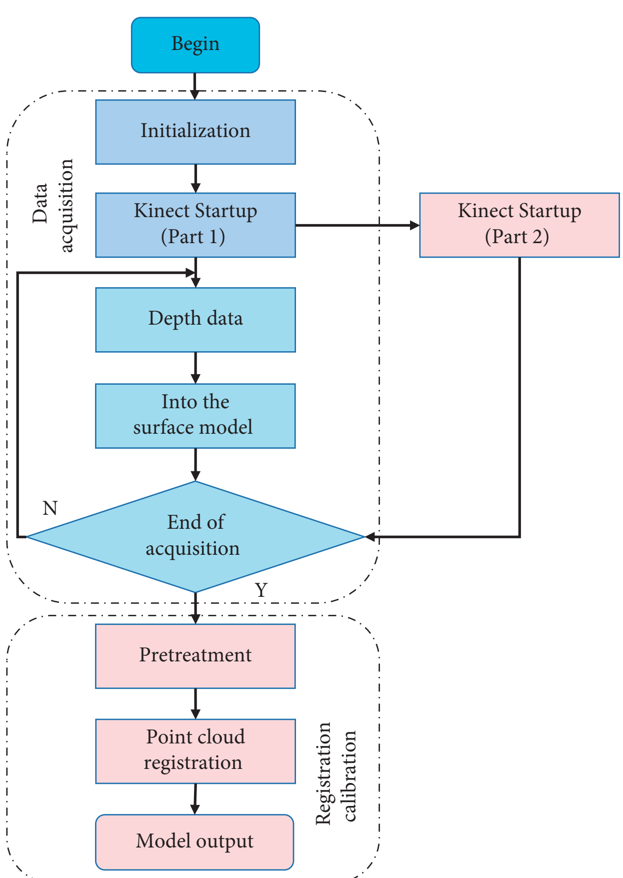

FIGURE 2: Data processing flow.

criteria to judge the algorithm. Besides efficiency, the accuracy and completeness of reconstruction must also be considered, because these factors determine the quality of the point cloud. In the process of recording consecutive frames, the body shape parameters of the same measured object must be the same. Firstly, the shape parameters of the standard model are selected as reference elements and then optimized according to the cost function, which is optimized frame by frame.

PMVS (Patch-Based Mufti View Stereo) algorithm is the best multiview stereo reconstruction algorithm at present. In addition, in order to distinguish between rendering and sparse reconstruction, this step is also called dense reconstruction. PMVS only reconstructs rigid structures. It will automatically ignore nonrigid structures, such as pedestrians in front of buildings. Given a set of oriented 3D points, the 3D coordinates and normal of each point are estimated. When the Kinect acquisition scene is mainly composed of walls and other planes, the ICP algorithm adopted by Kinect Fusion will terminate the iteration problem ahead of time, and the camera pose cannot be accurately estimated at this time, which will affect the results. It is not difficult to imagine that this problem can be solved by adding other corresponding nearest point pair selection methods. Therefore, this paper adopts the method of adding the edge features corresponding to the nearest points to avoid this problem.

Because the number of edge feature points in the registration process is much smaller than the number of nearest points corresponding to the original method, the error function between the nearest points of the edge is relatively weak. Here, the weight coefficient α is used to amplify the edge characteristic error function and increase its proportion in the total error function. So the final error function is shown in the following equation:

$$E'\left(T_{g,i}\right) = E_1 + \alpha E_2, \quad (2)$$

where it is the error function before modification, namely,

$$\begin{aligned} E_1 &= \sum_u \left\| \left(T_{g,i}\dot{V}_i(u) - \widehat{V}_{i-1}^g(\widehat{u})\right)^T \cdot N_{i-1}^g(\widehat{u}) \right\|_2, \\ E_2 &= \sum_q \left\| T_{g,i}\dot{V}_i(q) - \widehat{V}_{i-1}^g(\widehat{q}) \right\|_2. \end{aligned} \quad (3)$$

From the operations given above, we can get the final error function $E'(T_{g,i})$, which is consistent with the original error function of Kinect Fusion, and $E'(T_{g,i})$ can also be transformed into linear equations for least square optimization.

The center coordinate and normal vector of the patch are optimized to maximize the average correlation coefficient. In the optimization process, the center point of the patch is fixed on the ray of the reference image and the optimization degree of freedom is 3. The z coordinate of the center of the patch represents the two angles α and β of the normal vector. The equation of the slope is shown as follows:

$$a\left(X - X_c\right) + b\left(Y - Y_c\right) + c\left(Z - Z_c\right) = 0. \quad (4)$$

The relationship between normal and direction angle is $a = \cos\alpha\cos\beta, b = \sin\alpha\cos\beta,$ and $c = \sin\beta$.

3.1.3. Body Shape and Posture Estimation. The Poisson reconstruction method is used to reconstruct the surface of the recorded point cloud. Poisson reconstruction can consider all sampling points globally and has good robustness. After the surface is reconstructed, texture mapping is performed according to the vertices of the human mesh and the nearest neighbors of the human point cloud. For the vertex of each patch in the model, we find the nearest point in the point cloud, calculate the distance between the corresponding points, and assign the texture coordinates of that point to the vertex if it is less than the threshold. Considering the extensive research value and application prospect of the 3D human body model, this section proposes a method of human body model reconstruction combined with the human body model for nonrigid reconstruction of the dynamic human body. SMPL (Skinned Multiperson Linear) can accurately represent various postures and body shapes of the human body according to the deformation of skin apex, can simulate the bulge and depression of human muscles and other tissues during limb movement, so as to avoid surface deformation during movement, and can accurately describe the human body. Stretched and contracted muscles show the same soft tissue movement as real people.

Through rigid body registration, the two models are preregistered, and then the shape and posture parameters of SMPL are optimized to obtain the final model. The cost parameters are constructed as follows:

$$E(\beta,\theta) = \lambda_{m2s}E_{m2s} + \lambda_\beta E_\beta(\beta) + \lambda_\theta E_\theta(\theta). \quad (5)$$

Among them, E_β in the cost function is the prior constraint term of body shape and E_θ in the cost function is the constraint of posture, which helps to prevent unnatural posture. The obtained body shape parameters and posture parameters are input into the SMPL generation model, and a complete three-dimensional human body model is obtained.

The constraint term E_{m2s} represents the sum of the distances of the corresponding points between the reconstructed points and the standard model:

$$E_{m2s}(M,P) = \sum_{m_i\in vis(M)} \rho\left(\min\left\|m_i, v\right\|\right). \quad (6)$$

Here, M is the model surface, P is the scanning point cloud, function $vis(M)$ represents the effective visible model vertex, m_i is the effective point on P, ρ is the robust Geman–McClure function, and v is the point corresponding to m_i point on the SMPL model. λ_{m2s} is its weight term.

3.2. Dance Movement Recognition

3.2.1. Feature Extraction. National dance is a form of time and space coexistence art. It, like other straight tree arts, has cultural and individual characteristics that are connected through communication. The passage of time and space has brought about significant changes in people's lives and cultures. National dance should be based on current events. At the same time, folk dance follows the rhythm of the times and incorporates its characteristics. The theme and dance form were innovated and arranged in accordance with China's different revolutionary histories and modern opening periods, reflecting the characteristics of the times at the time. The goal of extracting local features in human motion recognition is to pique people's curiosity. In the part of a motion that changes significantly, there is no need to locate and track the entire human body. External environmental factors such as the change in human body shape, the change in shooting angle, the change in illumination, and the problem of occlusion have strong anti-interference properties.

In the experiment of this chapter, (x_i, y_i, z_i) is used to represent the three-dimensional coordinate of the ith bone joint and $J = [J_1, J_2, \ldots, J_M]$ represents the selected M bone joints. The calculation method of displacement vector features is as follows:

$$d_i^t = \frac{J_i^{t+1} - J_i^{t-1}}{\Delta T}, \quad t = 1,2,\ldots,N,\ i = 1,2,\ldots,M, \quad (7)$$

whereJ_i^t represents the coordinate of the ith bone joint in the t frame, N represents the serial number of the frame in which the bone joint is located, and M represents the corresponding label of the selected bone joint. ΔT represents the time interval between the $t+1$ frame and the $t-1$ frame.

Content-based retrieval technology has been proved to be very effective and fast in similarity search of large-scale data. Therefore, this section is devoted to extending the retrieval technology to real-time motion recognition.

General templates representing various categories can be used as template patterns to directly match and identify test actions.

Assume that x and y represent a frame of the test sample and the general template, respectively, to support the similarity calculation:

$$h_p(x, y) = \begin{cases} 1, & x_p \in y_p, \\ 0, & \text{otherwise}. \end{cases} \quad (8)$$

Here, if the two x and y do not match, $s(x, y)$ is no longer assigned to zero, but a negative value, and $h_p(x, y) - 5$ is given as punishment, thus enhancing the difference between different actions.

In the process of recognition, each part of it is searched in its corresponding key table in turn. The accumulated scores of these results can be used as the identification basis, and the specific identification process is shown in Figure 3.

After the previous steps, the key frame is represented by a five-dimensional vector, where each dimension represents the pose mapping of a part of the frame. For each dimension, we look for its match on its corresponding key. Therefore, five sets of search results are returned for these five dimensions. Therefore, we need to further analyze these search results and find the matching results from the intermediate frames. The input frame can always find as many matches as possible, which leads to the accurate classification of similar actions. Finally, input action recognition is determined by the general template with the highest performance score.

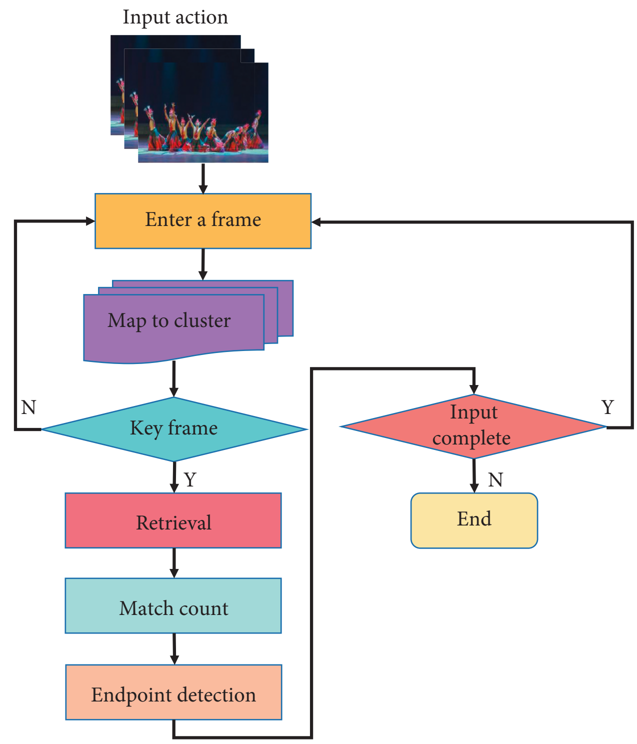

FIGURE 3: Real-time motion recognition process.

3.2.2. Action Classifier Design. HMM (hidden Markov model) is a dynamic model based on stochastic process and probabilistic observation. It is widely used in the recognition of various dynamic process systems involving state transition, such as speech recognition, handwriting recognition, and motion recognition. Its basic assumptions include the output independence hypothesis and the Markov hypothesis. The value is implicit, and it is one of some finite sequence of states. Markov hypothesis means that the current state completely depends on the state of the previous moment, and there is a fixed probability of this dependence between states.

Evaluation is the first problem to be solved in the motion recognition algorithm based on HMM, because given the observation sequence O and multiple HMMs, it is necessary to judge which HMM produced the observation sequence O according to the evaluation results.

There are two solutions to the evaluation problem: the forward algorithm and the backward algorithm. The Markov hypothesis is extended to the two-dimensional case. The state of the feature block depends on the state of the left feature block and the state of the upper feature block. There is a fixed probability between these states.

Both forward probability and backward probability can be calculated effectively by recursion. Unlike the new forward algorithm proposed in this paper, the iterative sequence of backward algorithm is from right to left and from bottom to top. The backward algorithm iteratively calculates $\phi_i^{w+1}(m, x)$ and $\beta_{i+1}^{w}(m, n)$, which represents the backward probability of the joint state of adjacent feature blocks. Their definitions are as follows:

$$\begin{aligned} \beta_{i+1}^{w}(m, n) &= p\left(o_{i+1}^{w+1,\ldots,W}, O_{t+2}, \ldots, O_T | q_i^w = s_m, q_{i+1}^w = s_n\right), \\ \phi_i^{w+1}(m, x) &= p\left(O_{i+1}, \ldots, O_T | q_i^w = s_m, q_i^w = s_x\right). \end{aligned} \quad (9)$$

4. Experiment and Results

In order to quantitatively compare the 3D SMPL human body models reconstructed by this method, this section uses the shadow recovery shape 3D reconstruction method to establish the standard 3D human body template and adds additional illumination constraints on the basis of this method. In order to optimize the depth value, this method integrates the illumination information of the object surface and the generated 3D model is smoother and contains more detailed information of the object surface.

Then, the three-dimensional human body model reconstructed by the first two methods is registered with the standard template, and the nearest geometric distance between the reconstructed model point and the standard template is calculated and represented by pseudo-color. By comparing the root mean square values of the generated model and template, the similarity between the model and template can be effectively reflected. The error comparison of the former two methods is shown in Figure 4.

According to the calculation of Figure 4, the average root mean square error of this method is 2.23 times that of this method and the reconstruction effect of this method is better.

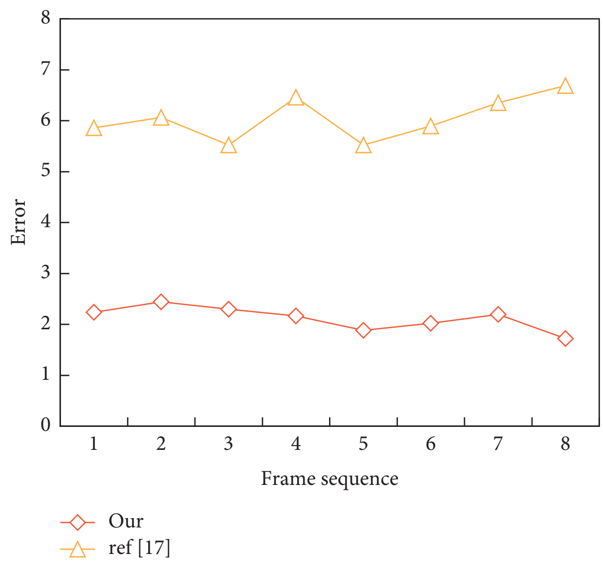

Figure 4: Error comparison of algorithms.

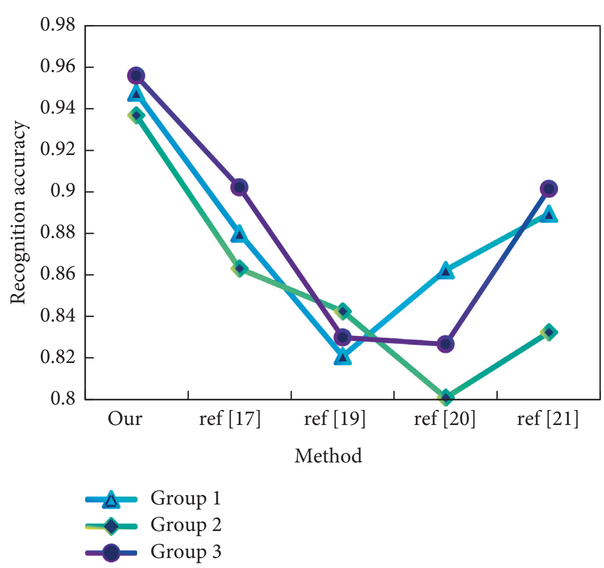

Figure 5: Recognition accuracy (data set 1).

For each group of data sets, we conduct a user-independent group action pattern recognition experiment, and we select three collected samples as training sets and the other two as test samples. As shown in Figures 5 and 6, for each action type, only the first two training samples are selected for each captured topic for training; that is, there are only 6 training samples for each action type.

It can be seen from the results that the recognition accuracy of this method is the highest among all methods. As far as human perception is concerned, they belong to the same action category, but due to different arm actions, the action data values may be quite different. Therefore, when these actions are calculated and recognized as a whole, the recognition accuracy will be seriously affected and our limb-based segmentation method can avoid this shortcoming.

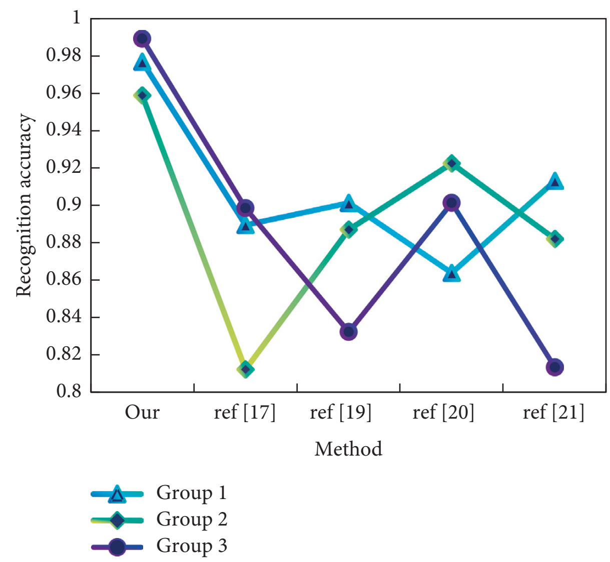

Figure 6: Recognition accuracy (data set 2).

In this section, on the basis of the above experiments, some extended experiments are made. Table 1 gives the comparison of the algorithm proposed in this paper and the training time of a single sample in each stage of reference [19–21].

It can be seen from Table 1 that the average training time of the model in [19] for a single sample is more than 20 times higher than that of the algorithm in this paper. The amount of data in this database is relatively small, so this time cannot be ignored for a database with a relatively large amount of data. It can be concluded that the algorithm in this paper can basically recognize human movements in real time. More importantly, the algorithm in this document does not need human intervention. According to different databases, the parameter values can be automatically adjusted according to the input data, and the adaptability is strong.

In order to reduce the randomness of the clustering process, nine people are used for training and one person is used for testing in the database, which is a one-time cross-validation method. Table 2 shows comparison with the other literature studies.

As can be seen from Table 2, the recognition rate of this algorithm basically exceeds that of all the current literature. It is easy for an algorithm to achieve a high recognition rate in the database, but it is very difficult to increase it by a few percentage points on the existing basis.

The auxiliary training method collects the coordinate points of each trainer's motion joints and compares them with the standard movements. The Kinect is used to collect the position of the trainer's motion coordinates, and the error values of the motion joint coordinates obtained by the three methods are compared to assist the dance method. Compared with the data collected by Kinect, the detailed analysis of joint angle capture in motion capture shows the experimental results in Figure 7.

In Figure 7, the method designed in this paper is more accurate in angle capture than other comparison methods. It can be known that the analysis method of folk dance style characteristics based on 3D reconstruction designed in this

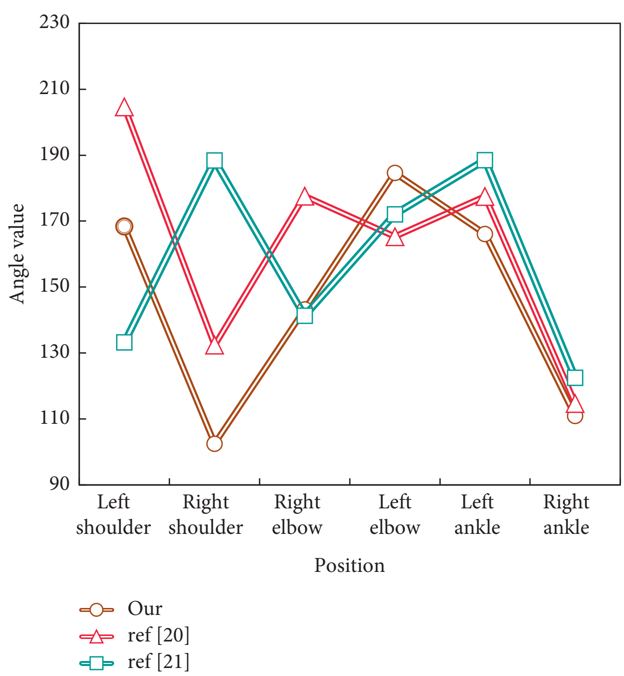

Figure 7: Comparison of joint angle values of trainers.

paper has higher accuracy in capturing the trainer's movement position and can form a more accurate contrast with the standard movement, thus realizing error correction in auxiliary training.

The experiment will investigate the influence of test sample noise on spatio-temporal HMM recognition performance. The test sample feature space is composed of Gaussian noise with different signal-to-noise ratios. At this time, the number of training samples is set to 50% of the total number of samples. In the experiment, feature information from different joint points is used to represent the features of the human body model and the influence of feature dimensions on the recognition rate of the model is tested. The results are shown in Figure 8.

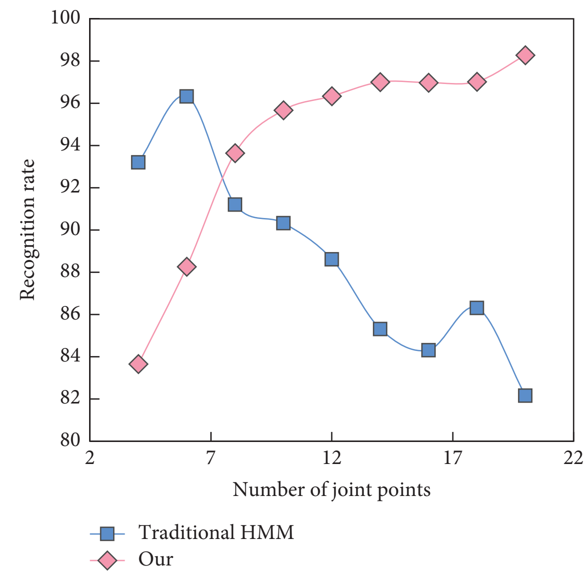

Figure 8: Influence of feature information of different number of joints on recognition rate of different algorithms.

The change of curve reflects the influence of the dimension change of skeleton model features on the recognition algorithm. The larger the dimension, the richer the skeleton model features. When the feature dimension increases, the recognition rate increases, while the recognition rate of one-dimensional Markov model algorithm decreases. When the number of joints increases to 10, the recognition rate of our algorithm increases to 95.68%, and when the number of joints increases to 20, the recognition rate of our algorithm increases to 98% and 28%. When the feature dimension is small, the reason for the low recognition rate of our algorithm in this paper is that the spatial dependency between low-dimensional feature blocks is fuzzy and the dependency is easily affected by noise in the training feature space, which will affect the performance of our algorithm. Experimental results show that the proposed algorithm is superior to the one-dimensional Markov model algorithm in recognition rate and robustness in solving high-dimensional human motion recognition problems.

5. Conclusions

Ethnic dance is a powerful reflection of a country's culture, national identity, and historical tradition. Dances of various nationalities have their own distinct styles as an important cultural card of a nation. It is necessary to understand the style characteristics of national dance in order to better understand its performance characteristics and improve its performance effect. This is done by first understanding its basic characteristics. The upper and lower parts of the human body are scanned with two Kinect depth cameras, and the two 3D point clouds obtained by scanning are spliced to create a complete 3D model of the human body. The one-dimensional hidden Markov model is extended to the spatial time series HMM in order to solve the dimension disaster caused by the three-dimensional representation of the human body. The recognition rate of this algorithm increases to 95.68 percent when the number of joints is increased to ten and to 98.28 percent when the number of joints is increased to twenty, according to the experimental results. This method is quick and simple to use, and it can be applied to augmented reality, ethnic dance style analysis, and other applications.

Physical education in middle school is very important for teenagers, so it is also crucial to understand the differences between PET (Physical Education Teaching) systems in middle schools at home and abroad. The frontier and hotspot of PET research in middle schools at home and abroad are examined in this paper using citation analysis, information visualization, and cluster analysis, as well as CiteSpace software. The findings show that PET method research in China is qualitative, whereas PET method research in middle schools around the world is quantitative evaluation and empirical research. Domestic research hotspots focus on classroom instructional design, whereas foreign countries focus on load identification theory's application in instructional design. Frontier research in the United States is dispersed and covers a wide range of topics, whereas research in other countries focuses on cognitive load theory. The classification time of this improved algorithm is reduced by 190.97 seconds when compared to the traditional KNN algorithm, and the total time is increased by more than 50%. According to the findings, nonsports or nonsports influencing factors should be given more consideration in the study of adolescent physical fitness decline in China.

1. Introduction

Physical education is one way for schools to implement comprehensive education, and physical education in all levels and types of schools plays an important role in sports development. The purpose of the physical education curriculum is to assist students in mastering the fundamental theoretical knowledge of physical education as well as the fundamental skills of scientific exercise, as well as to establish a correct view of physical education, in order to achieve the goal of improving physical fitness and health. It can help us understand and discuss the interaction of various factors and their various forms in the overall process of Physical Education Teaching, which is conducive to dynamically grasping the essence and law of the process [1]. In general, there are many PET (Physical Education Teaching) systems in middle schools that can help to develop the teaching system in middle schools. Physical education is an important part of our country's middle school education, with a focus on the combination of physical education and fitness, as well as the function of leisure and entertainment [2]. With China's middle school physical education reform progressing, developing a scientific and effective middle school physical education model is becoming more important in addressing the practical issues that the current social environment imposes on the development of school physical education in the country. It is critical to study the PET model abroad because it is at the forefront of the development of high-level theory of school physical education.

PET mode is a teaching program that encapsulates a set of teaching principles. It consists of a relatively stable teaching process structure and teaching method system, which is primarily reflected in the design and implementation of units and teaching courses [3]. Teaching, according to Xiong et al. [4], is a step toward transforming learning experiences into units, courses, and procedures. Alternatively, it is the process by which teachers teach students to absorb knowledge and skills [4]. Alves et al. [5] believe that education is a form of social power and that knowledge allows some people to control others [5]. Oliveira et al. [6] believe that the social environment plays an important role in the development of children and that social activities can explain cognitive changes in children [6]. Learning, according to Barker et al. [7], is a process of reorganizing the cognitive system as well as a series of processes of acquiring knowledge from the media, imitating knowledge, and incorporating it into the knowledge framework [7]. It is stated that classroom learning motivation is a natural characteristic of students, not a result of teacher manipulation. By drawing concept maps, Kim et al. [8] developed a teaching tool to help us check whether students truly integrate new knowledge into their cognitive structure [8]. This methodology and conceptual relationship framework are extremely useful. PET theory and practice are linked by the fact that the PET model is not only theoretical but also operable. A comparison of Chinese and foreign PET models will aid us in absorbing the positive aspects of foreign PET models and serve as a useful reference for China's PET model reform.

Sports and PET are both effective ways to encourage teenagers' healthy development. Excellent PE teachers play a critical role in assisting students in developing their physical fitness, competitiveness, and self-confidence. Physical education majors bear the burden of training future physical education teachers, and the quality of that training is directly related to whether or not the training plan for undergraduate talents of physical education majors is scientific, reasonable, and in line with national conditions. The main goal of comparing PET schemes in middle schools in the United States and other countries is to see if foreign models and experiences can help improve the quality of domestic physical education professionals.

The main creative points of this paper are as follows: (1) By using the method of citation analysis, the knowledge maps of the development of PE teaching design in middle schools at home and abroad were constructed, respectively, and the development of PET design in middle schools at home and abroad was comprehensively compared and analyzed. By looking for the key nodes in the process of cluster analysis of cocited documents, this paper compares the key documents that have changed the research field in the history of PET design in middle schools at home and abroad in recent ten years. (2) Through the comparative analysis of physical training research at home and abroad, this paper finds out the shortcomings of physical training research in China and the gap between China and foreign countries, then provides new ideas and methods for the development of physical training in China, and at the same time provides some references for theoretical research of physical training in China.

2. Related Work

2.1. Study on PET. Brian et al. started with the concept of curriculum, pedagogy, and evaluation as interrelated school information system, put forward and discussed "quality sports" with curriculum, pedagogy, and evaluation as basic dimensions and the meaning of sports quality in each dimension, and thought that to realize quality education in PET, it is necessary to pursue and demonstrate quality education within and between curriculum, pedagogy, and evaluation [9]. Roure and Pasco [10] believe that physical ability is the athletic ability of the human body through the nerve-muscle system based on the energy metabolism of the three energy supply systems [10]. Ayers and Woods [11] regarded citation network as a directed acyclic network formed by a series of events and papers in time series, used a search algorithm to explore the events that can represent the mainstream direction and the connection paths that play a key role in the formation of citation network, and put forward the critical path algorithm in citation network [11]. Giordano and Christopher [12] pointed out that British universities implement the training goal of "thick foundation and wide caliber." The training of sports talents in Japanese middle schools is adjusted and improved according to the social demand for sports talents [12].

Amatori et al. [13] pointed out that, with the change in social demand for sports talents, the training goal of physical education major in colleges and universities has changed from specialized training of physical education teachers to training comprehensive talents and applied talents with strong adaptability [13]. Li and Fan's [14] research focuses on the analysis of childhood feelings. It is necessary to carry out education, which is the way for every individual to feel the world [14]. Sui [15] thinks that the influence of social factors and cultural factors is very important in the personal learning process. It should be emphasized that people will internalize their social environment and their cultural expression in the process of learning [15]. Osborne et al. [16] have proved that physical education class is regarded as a secondary course in many middle schools, so it has not been highly valued, the teaching equipment of this course is backward, and the concern of leaders at all levels has not been fully implemented [16]. Garnham [17] believes that the rapid development of modern society has greatly improved people's living standards, people pay more and more attention to physical and mental health, and people's attention has gradually turned to physical exercise [17]. We should put the reform of physical education at the top of the government's education department and actively promote the reform of physical education.

2.2. Overview of Clustering Algorithm Research. Clustering algorithm [18, 19] has achieved remarkable results since it was applied to data mining analyzed some clustering methods from the perspective of data mining (such as strict distinction between similarity and distance measurement and relevant optimization criteria applied to clustering) put forward a method to determine the initial clustering center by using the neighbor information of data points, which also has a certain reference value. Chen and Qiu [20]used the multidimensional grid data structure of attribute space to divide the space into multiple cell grids [20]. According to different levels of resolution, it stores multiple levels of cell grids, which form a hierarchical structure, and each high-level cell grid is divided into multiple lower-level cell grids.

Qin et al. [21] proposed a method to automatically optimize parameters. Clustering algorithm based on a synchronous model can alleviate some difficult problems of clustering analysis and noise detection on traditional data and has the characteristics of dynamic, local, and multiscale analysis, which can solve the difficulties faced by clustering analysis of large-scale data to a certain extent [21]. Yang et al. [22] proposed a simple nearest neighbor clustering algorithm based on statistics, which can eliminate background noise and isolated points and detect clustering areas with different densities from some data sets [22]. Baracchini et al. [23] showed how to reduce the time cost of clustering algorithm by using the idea and method of nearest neighbor. This idea based on nearest neighbor can still be applied to the clustering method based on the synchronous model. Therefore, we think this problem has certain research significance [23].

3. Methodology

3.1. Design of Clustering. Data mining technology has been widely used in finance, commerce, medicine, and other fields. In recent years, educational informatization has been popularized continuously. It is an inevitable trend to develop data mining technology in the field of education, analyze these complicated educational data, study teachers' teaching methods, and improve students' learning effect. Applying data mining analysis technology to analyze and predict mixed teaching behavior in middle schools and providing powerful decision-making or guidance for teachers and learners is the focus of current research, and it is also a realistic problem to be solved urgently. Data mining is a process of extracting data information that meets different business objectives and feeding back the information to users based on massive data analysis. In order to obtain potentially effective information to meet the needs of users, it is necessary to fully tap the surface information, remove redundant data, and display key data to users intuitively. Prediction and description are two goals of data mining. Prediction refers to the use of some information fields and variables in the database to predict hidden useful information, and description refers to the description of data into understandable patterns.

Because clustering is done without knowing the data structure of data pattern, it is difficult to judge what is a good transformation of feature space and the selection of feature subset. In fact, for some data sets, one standard can produce good results, while other data sets show the opposite results. The problem of pooling high-dimensional data comes from different angles. Besides designing new dimensionality reduction algorithms, we should also study the integration method of dimensionality reduction of high-dimensional data. Figure 1 shows the general steps of this method.

Clustering consists of two parts: set constructor $\prod$ and consensus function Γ. For a given data set, the set constructor generates a set of clustering schemes, and the consensus function analyzes and processes multiple clustering schemes of the set and finally outputs an optimized clustering scheme.

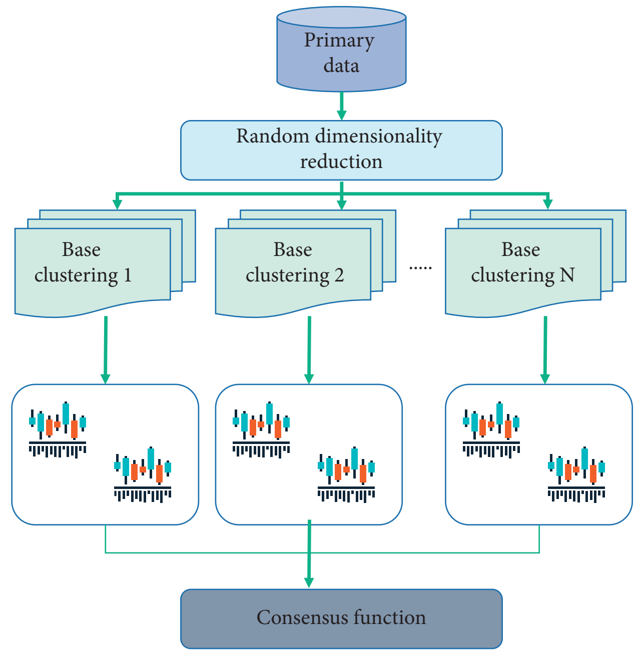

Figure 1: High-dimensional data clustering set process.

When there is a certain degree of linear correlation between variables in matrix X, the change of data X will be mainly reflected in the direction of the first few load vectors, and the projection of data matrix X on the last few load vectors will be very small, which is mainly caused by measurement noise. In this way, the matrix X_s can be written into the following formula after principal component decomposition:

$$X_s = t_1 p_1^T + t_2 p_2^T + \cdots + t_k p_k^T + E = \widehat{X}_s + E, \qquad (1)$$

where E is the residual matrix, which represents the change of X in the direction of p_{k+1} to p_m load vector, and it explains the measurement noise and model error factors. If only the reserved k principal component vectors $(k < m)$ are used to reconstruct the original data, the estimated data matrix $\widehat{X}_s$ and residual matrix E can be expressed as

$$\begin{aligned}\widehat{X}_s &= \sum_{i=1}^{k} t_i p_i^T,\\ E &= \sum_{i=k+1}^{m} t_i p_i^T.\end{aligned} \qquad (2)$$

The consensus function analyzes and processes according to the pooled set to generate the final pooled result. Because there is no clear correspondence between groups in a cluster and those supervised set combination methods cannot be directly applied, it is difficult to combine cluster sets.

There are two advantages of using the consensus function to partition graphs in this section:

(1) Graph division has a good learning area, and the algorithm of clustering to spectrum has been successfully applied in a large number of applications.

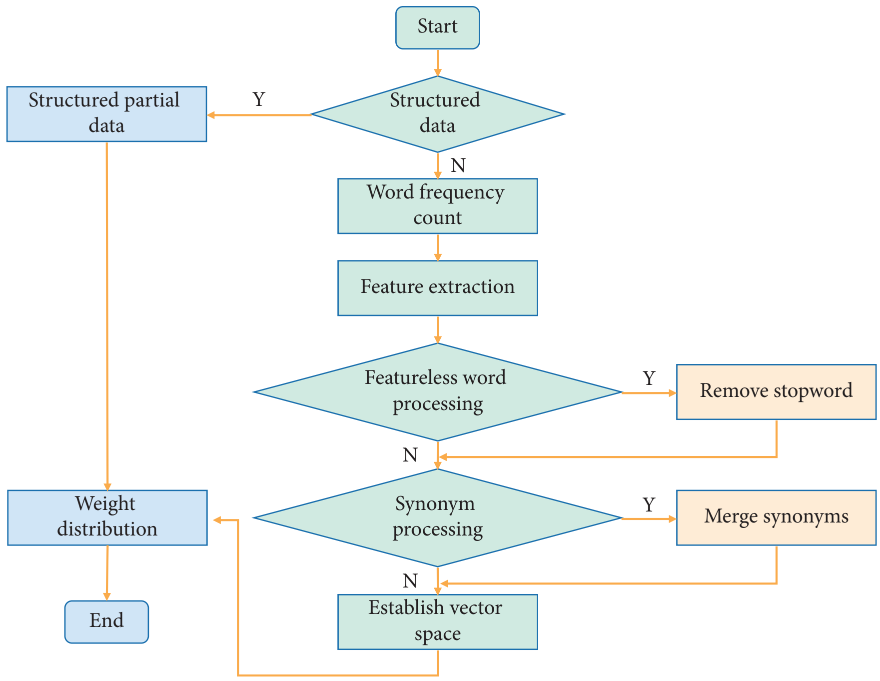

FIGURE 2: Text feature selection.

(2) When calculating the weight of edges in a graph, the clustering set gives a simple and effective measurement method to define similarity, which is a prerequisite for the success of graph division.

For simplicity, we only use the grouping set part of this method. In the process of building a cluster set, every time the base clustering algorithm is executed, a similarity matrix will be generated. Finally, all similarity matrices will be combined into a main similarity matrix to generate a similarity map. The graph is divided into several subgraphs, and each subgraph is connected and can be labeled as a group. The similarity matrix is constructed as follows according to the probability density function:

$$P\left(s_j \mid x_i\right) = \frac{p\left(x_i \mid s_j\right) \times P\left(s_j\right)}{\sum_{k=1}^{m} p\left(x_i \mid s_k\right) \times P\left(s_k\right)}, \tag{3}$$

where m is the number of clusters, Σ_j is the covariance matrix of relative cluster j, and u_j is the mean value of data objects in cluster j. The probability includes two parts: input data and clustering results. Therefore, the density vector is a good method for similarity measurement.

3.2. Feature Selection and Dimension Reduction. The general method of feature dimension reduction is to evaluate each original feature with an evaluation function, calculate its weight, and select features with high weight to form feature subsets. The basic process is as follows (Figure 2).

(1) Initially, the feature set includes all original features.

(2) Calculate the evaluation function value of each feature in the feature set.

(3) Sort features according to the value of the feature evaluation function.

(4) Select the first k features as feature subsets.

(5) According to the selected feature subset, the dimension of the text vector is compressed to simplify the representation of the text vector.

Generally speaking, the feature item set should have three characteristics: a complete feature item can truly represent the target content. According to the difference in feature vectors, objects can be distinguished from other documents. The dimension of the refined feature vector should be as small as possible.

The idea of possibility matching is to attach a membership function of the fuzzy set to each element in the sample based on the possibility theory so as to limit the evaluation values compatible with the elements, which represent the range values of attributes represented by atoms. The elements in the sample are described by a probability distribution, which indicates the inaccuracy and uncertainty of the data. The similarity of two samples is calculated by calculating the matching degree between sample objects.

Let the sample space be $U, p \in U, q \in U$, $\mu_p(u)$ as the membership function of p and $\pi(p)$ as the probability distribution of p, both of which are functions from U to [0,1]. In order to calculate the similarity between sample p and sample q, two measurement functions are introduced: possible similarity and necessary similarity.

The possible similarity of p to q is as follows:

$$\begin{aligned} f(p) &= \pi(p,q) \\ &= \operatorname*{Sup}_{u \in p} \min\left(\mu_p(u), \pi_q(u)\right). \end{aligned} \tag{4}$$

$f(p)$ gives the possible similarity between sample p and sample qq, that is, the degree of matching between the set tone of values compatible with sample p and the set of sample q values.

The necessary similarity between p and q is as follows:

$$g(p) = N(p,q) = \operatorname*{Inf}_{u\in p} \max\left(\mu_p(u), 1 - \pi_q(u)\right). \quad (5)$$

$g(p)$ gives the degree of certainty of $p-q$ compatible values, that is, the degree to which the set of possible values of q is contained by the set of p compatible values.

Probabilistic clustering analysis is the application of probabilistic matching in clustering analysis. Traditional fuzzy clustering analysis can be roughly divided into two categories: one is based on fuzzy equivalence relationships, and the other is based on fuzzy similarity relationships. A clustering method based on fuzzy equivalence relations is known as probabilistic clustering. When the sample space is a finite set, a fuzzy equivalence matrix represents the fuzzy equivalence relation, while a Boolean equivalence matrix represents the ordinary equivalence relation. The fuzzy equivalence matrix is then converted to a Boolean equivalence matrix, resulting in a clustering analysis process.

3.3. Text Classification of PET Research in Middle Schools at Home and Abroad. Because cluster analysis can aid in the exploration of unknown data structures, the results of its analysis can provide the best sample set for classification and other tasks and reduce the workload of empirical analysis such as manual annotation, and it has become the starting point for a series of data analyses. It is widely used in descriptive and predictive models to help analyze the known data structure. Clustering analysis and classification fall under the category of machine learning when it comes to developing a learning model. As a result, studying arbitrary family shape processing and large-scale text classification through clustering is extremely important from the perspective of machine learning.

Calculate the Euclidean distance or cosine similarity between the sample to be classified and the known training sample, find the K nearest neighbor texts with the closest distance or the greatest similarity to the text to be classified, and then judge the K nearest neighbor texts of the text to be classified according to the category of the text to be classified [19]. Considering the distance and angle between two vectors, the representative function is defined. The defined representative function is applied to KNN weight calculation instead of the category attribute function.

Let the known category of training text d_i be C_j, and define the importance of d_i to category C_j as the representative function $u(d_i, C_j)$, as shown in (6).

$$u\left(d_i, C_j\right) = \frac{1}{\operatorname{Dist}\left(d_i, \overline{C}_j\right)} \times \operatorname{Sim}\left(d_i, \overline{C}_j\right), \quad (6)$$

where $\overline{C}_j$ represents the center vector of category C_j, which is to add all the text vectors of category C_j and then average them. $\operatorname{Dist}(d_i, \overline{C}_j)$ represents the Euclidean distance from the training text d_i to the center of the category C_j to which it belongs, and $\operatorname{Sim}(d_i, \overline{C}_j)$ is the cosine similarity between the training text d_i and the center of the category C_j to which it belongs.

The value of K is determined by the spatial distribution of all points and can only be adjusted by the experimental results. Common methods for calculating distance include cos distance and Euclidean distance. In this paper, the cos distance formula is used to calculate the distance. Assuming there is a vector A, B, the cos distance between them is calculated by the following formula:

$$D_{\cos} = \frac{A \cdot B}{|A| \cdot |B|}. \quad (7)$$

A, B and the denominator is the product of the length of the vector A, B.

In this paper, the naive Bayes classifier is used for comparative experiments. It is a classification method based on the Bayes rule, which is expressed as follows:

$$P(h|D) = \frac{P(D\,|\,h)P(h)}{P(D)}. \quad (8)$$

$P(h)$ is the prior probability of assuming h, $P(D)$ represents the prior probability of training data D, $P(D\,|\,h)$ represents the probability of observing data D when h holds, and $P(h\,|\,D)$ is called the posterior probability of h.

The category attribute function $y(d_i, C_j)$ in the KNN algorithm will be replaced by the following formula:

$$y\left(d_i, C_j\right) = \begin{cases} u\left(d_i, C_j\right), & d_i \in C_j, \\ 0, & d_i \notin C_j. \end{cases} \quad (9)$$

In the KNN text classification algorithm, the improved K-medoids algorithm is applied to cut the training text. In the classification process of the KNN algorithm, the representative degree $u(d_i, C_j)$ is used to replace the category attribute function $y(d_i, C_j)$. The flow of this improved algorithm is shown in Figure 3.

4. Experiment and Results

4.1. Analysis and Comparison of PET Research Hotspots at Home and Abroad. In this paper, CiteSpace software is used to analyze the literature data with similar themes. Because the research methods used in this paper (word frequency analysis and cocitation analysis) have certain requirements for references and keywords in literature data, this index mainly checks literature data and CSSCI, and the database does not contain bibliographic data. During the operation, 15 items of bibliographic information and related information were counted, as shown in Figure 4. These 15 items reflect the most concerned hot topics in the field of PET research abroad.

Among these 15 papers, the papers involved the research of the combination of self-determination theory and PET. Therefore, the self-determination theory is also one of the hottest research points in the field of PET research abroad. Emphasis is placed on the influence of language and behavior of PE teachers on students and their professional development. Physical education courses are also studied according to the characteristics of girls. It can be seen that

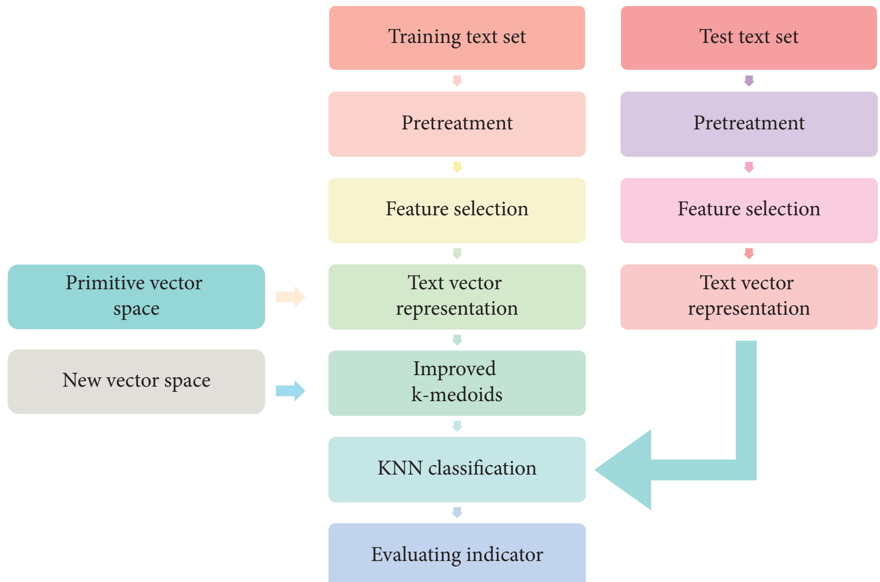

Figure 3: Improved algorithm flow.

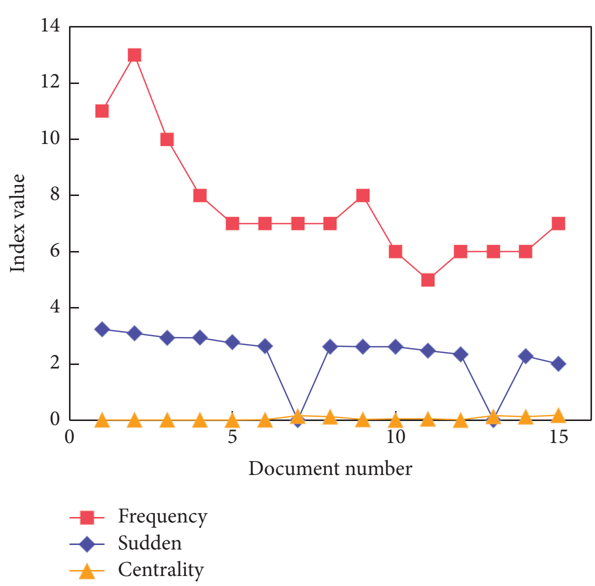

Figure 4: Literature of PET research hotspots abroad cocited network literature information.

the research field of PET abroad is biased toward women. The keyword frequency statistics in a specific period is the concentrated expression of the research focus in a specific field in that period. Therefore, keyword frequency is an important index to reveal research hotspots in specific fields. In this work, the information of 10 articles cited twice is counted, as shown in Figure 5. These 10 documents will reflect the most concerned hot topics in the field of PET research in China.

It can be seen that the research hotspots represented by keywords in the keyword cooccurrence network mainly focus on school physical education, physical education, physical education curriculum, middle school physical education, physical education teachers, PET methods, physical education concepts, traditional physical education, national physical education, physical education, and health curriculum standards and educational theories. This conclusion is generally consistent with the key research points reflected in the previous highly cited literature.

China's PET practice research should appropriately increase the research on sports from the perspective of public health. At present, the research on PET practice in China is mostly biased toward students' physical condition, and the research on sports from the perspective of public health should be appropriately increased. China's physical education curriculum survey should pay more attention to the details of the physical education class program. At present, China's physical education curriculum research tends to pay more attention to the standards or reforms of physical education and health curriculum and should appropriately increase the research on the details of physical education curriculum (such as students' physical activity level).

4.2. Comparative Analysis of Research Hotspots of PET Design in Middle Schools at Home and Abroad. Comparing the hot keywords at home and abroad, we can see that there are some similarities between them. The same hot field reflects the intersection of teaching design research at home and abroad, and it is also the mainstream research field at home and abroad. Due to the different degrees of attention paid to some hot keywords, the research enthusiasm and depth will be different (Figure 6).

From the ontology of instructional design, foreign countries pay more attention to the research of teaching strategies, while domestic countries pay more attention to the research of teaching methods and models. The frequency of attention to constructivism theory research in China is relatively high and central, while that in foreign countries is relatively low, which shows that the attention to constructivism theory in China is higher than that in foreign

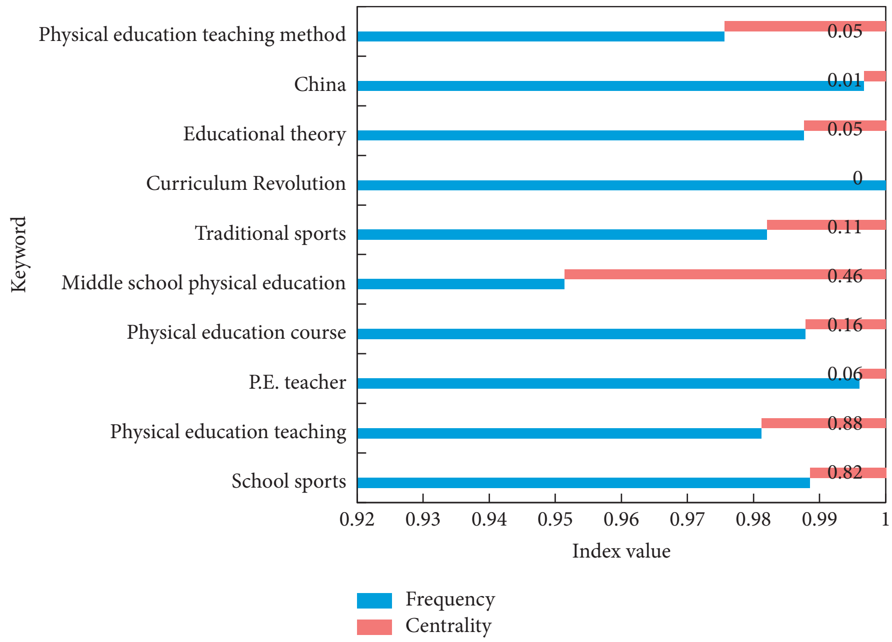

FIGURE 5: Keyword frequency in periodical cooccurrence network.

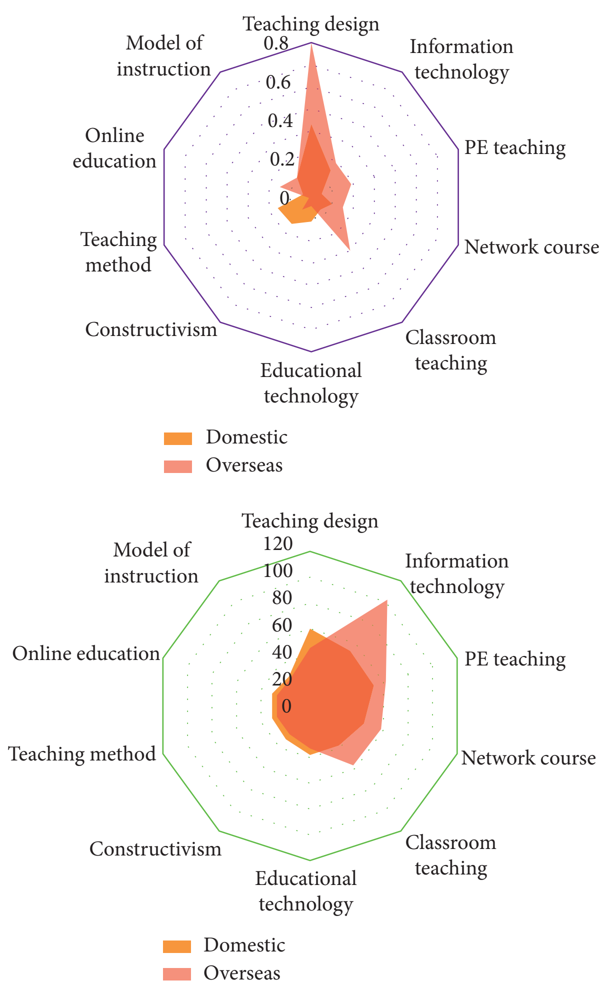

FIGURE 6: Hot keywords at home and abroad.

countries in the past decade. In addition, foreign countries gradually pay attention to the influence of emotional factors on students' learning effect, and the study of learning motivation is highly valued. However, the frequency of student-centered middle school students' hot words in China is only 7. In recent years, the domestic educational circles have vigorously advocated the design concept of constructivism, but in practice, the dominant position of students is often neglected.

Foreign countries focus on the research of teaching strategies, while domestic countries focus on the research of teaching methods and models. There are many discussions on the ontology of instructional design in China. At present, in the information age, informational instructional design and networked instructional design have become hot spots, while foreign countries focus on performance technology research.

Using the mutation word detection technology and CiteSpace software algorithm, combined with the time distribution characteristics of word frequency, keywords with high-frequency change rate are detected from subject words, which are called mutation words. Determine the frontier research and development trend of specific disciplines or fields. After importing the data into CiteSpace, 41 domestic variant words and 3 foreign variant words can be detected, and their time zone views can be obtained by running them separately. The statistics of variant words in domestic instructional design are shown in Figure 7. Statistics of variant words in foreign instructional design are shown in Table 1.

It is clear that domestic research has progressed in the area of exploration, which is consistent with the findings of other national researchers. Every year, hot research topics in

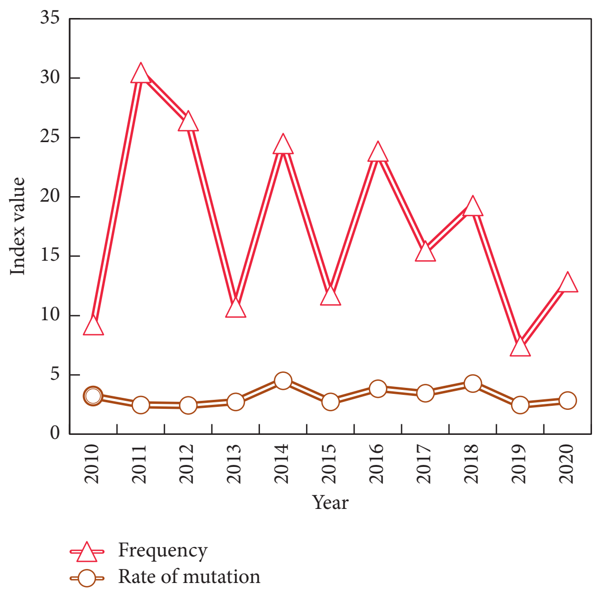

Figure 7: Statistics of abrupt words in domestic instructional design automation.

Table 1: Statistics of abrupt words in foreign instructional design.

Year	Rate of mutation	Frequency	Keyword
2011	2.36	13	Curriculum practice
2012	2.88	21	Information-based instructional design

instructional design are identified, but the research is not innovative. Since then, the focus of instructional design theory research has shifted to cognitive science, particularly distraction research, and no new research topics have emerged. When compared to domestic research, foreign boundary research, cognitive load, and distraction effect have not piqued domestic researchers' interest. More practical research closely related to national instructional design appears to be more important to national researchers. Localization of instructional design theory research entails combining foreign culture with traditional Chinese culture and social needs, as well as reconstructing and internalizing theoretical achievements in instructional design from other countries that do not meet China's needs. In reality, what exists is a theoretical system with Chinese characteristics. Teaching design research is inherently boring, and any research results necessitate the investment of time and energy by researchers, which can be exchanged through hard work. It is commendable that researchers pay attention to the latest trends, new theories, new models, and new technologies. The original research can be abandoned, and researchers must pay attention to the application of new hotspots.

Physical training is an important part of physical training. In recent years, some domestic scholars have conducted many valuable theoretical and empirical studies on the research status, existing problems, and future development trends of physical training, most of which are based on local conditions. There are relatively few researches

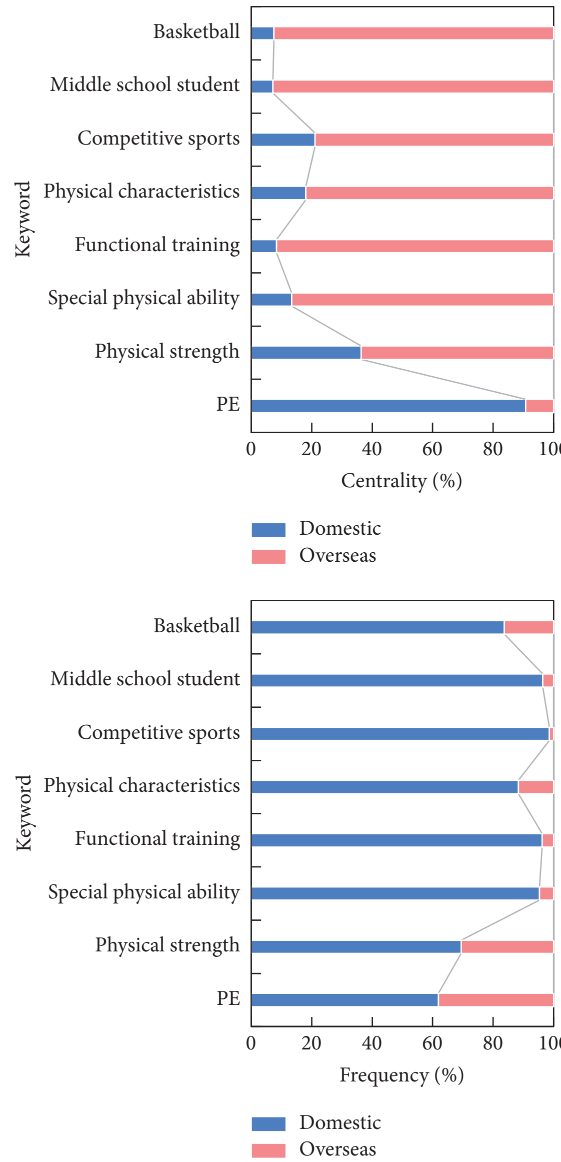

Figure 8: Distribution of keywords in physical training research at home and abroad.

on visual angle, subjective thinking, and qualitative analysis, as well as macroscopic understanding and quantitative analysis of physical exercise theory and practice at home and abroad. According to the visualization results, the keyword distribution of physical exercise research at home and abroad is drawn, as shown in Figure 8.

From the time distribution point of view, China's physical training research started late, but with the rapid development of modern competitive sports and the vigorous promotion of national fitness, China's physical training has undergone tremendous changes compared with the past. Foreign countries have a wide range of research objects on physical training, while China's research objects on physical training are relatively limited, mostly concentrated on a few elite athletes of various competitive sports.

The research field of physical exercise in China is mainly concentrated in the field of competitive sports. Compared

Table 2: Time performance.

Time/min	Before improvement	Before improvement
Training time	0	72.43
Classification time	346.58	155.61
Total time	346.58	228.04

with foreign countries, there is less research on physical training in other aspects such as mass fitness and national physique; that is, the development of physical training in competitive sports and mass fitness is uneven. Foreign countries pay more attention to the synchronous development of theory and practice, while domestic theoretical research of physical training lags behind practice, with competitive sports as the main theoretical research and certain repetitiveness of research contents. Pay attention to the physical health, mental health, and cognitive status of teenagers and the elderly in order to improve their physical health and quality of life. However, many empirical studies in China have the largest number of athletes among them, and their main purpose is to improve the recovery quality and achieve better quality of life and good results.

4.3. Performance Analysis of Clustering Algorithm. The experimental Chinese corpus is used, and the training set and the test set do not overlap. The selected text categories include 30 categories, like art, education, history, law, transportation, politics, and so on. The training text set contains 9809 texts, and the test text set contains 9813 texts. The comparison results of algorithm time performance are shown in Table 2.

It can be seen from Table 2 that, compared with the traditional KNN algorithm, the sorting time is reduced by 190.97, and the total time is increased by more than 50%. To sum up, compared with the traditional KNN algorithm, the improved KNN algorithm in this paper has a significant improvement in time performance.

5. Conclusions

In this study, the frontier and key points in the field of PET research in middle schools at home and abroad are investigated, scientometrics and clustering algorithms are comprehensively applied, and quantitative analysis and qualitative analysis are combined. Self-determination theory has been discovered to be one of the hottest research hotspots in the field of PET research in other countries. Physical education curriculum research in China has a tendency to focus on the standard or reform of physical education and health curriculum. The frequency and centrality of constructivism theoretical research in China are higher, whereas the frequency and centrality of constructivism research abroad are lower. Both at home and abroad, emphasis is placed on the methods, steps, and scheme design of the teaching process, with foreign countries placing a greater emphasis on teaching strategy research. Physical training research in China is primarily focused on competitive sports, and the development of physical training in competitive sports, mass fitness, and other areas is uneven. Foreign countries place a greater emphasis on the simultaneous development of theory and practice, whereas domestic physical training theoretical research lags behind practice. When compared to the traditional KNN algorithm, this algorithm reduces classification time by 190.97 seconds while increasing total time by more than 50%. Improving one's ability to face the educational world necessitates a large number of teaching resources in order to improve classroom teaching quality.

In order to explore the kinematics and muscle force characteristics of competitive Taijiquan arm manipulation, and solve the problems of arm trajectory and control in the process of manipulation, this study puts forward the sports biomechanical analysis of arm manipulation in competitive Taijiquan. The technical characteristics and muscle force characteristics of 15 athletes from the competitive Taijiquan team of Xi'an Institute of physical education were studied. Use Excel 2007 and SPSS17.0 to statistically analyze and process the original data. According to the actual needs, the data indicators are summarized. The combined movements of competitive Taijiquan arm manipulation are captured through high-speed photography, and the kinematic data are statistically analyzed, mainly from the two aspects of action amplitude change and action braking. The results show the action track length, relative track length, and action track length of each plane of the two combined hands. The order of the two combined action tracks is: combination 1 > combination 2, in which the action track in the sagittal plane is the longest in combination 1, and it can also be considered that the motion amplitude in the sagittal plane is the largest in combination 1. The average acceleration of group A in the first beat is 0.51 m/s^2 smaller than that of group B, and the value is 0.22 m/s^2 smaller. Therefore, the deceleration of group A is larger than that of group B, and the braking capacity of group A is slightly stronger than that of group B. In the second beat, the average acceleration of group B is 1.5722 m/s^2 larger than that of group A, and the value is 0.210 m/s^2 larger. The average acceleration of group A in the third, fourth, fifth, and sixth beats is 0.9, 3.728, 0.57, and 0.837 m/s^2 smaller than that of group B, and the values are 0.466, 0.174, 0.250, and 0.003 m/s^2 smaller, indicating that the braking capacity of group A in the third, fourth, fifth, sixth, and eighth beats is slightly stronger than that of group B. In the braking of each beat in combination 1 and combination 2 of group AB, the braking ability of arm manipulation of group A is stronger than that of group B. In competitive Taijiquan, the movement techniques of manipulation include: bouncing technology, braking technology, and control technology. For arm manipulation, athletes should have the ability of "braking" technology. In the correlation analysis of movement track length, RMS and I EMG, the score of athletes in group A is high, and there is no correlation between movement track length and RMS. There is a significant correlation between RMS and movement track length in group B, and the correlation degree is moderate. This shows that when the movement of group B athletes is completed, the muscles are in a state of tension, the movement skills are not mastered well, and the energy saving is not achieved. During training, we should pay more attention to the proprioception of muscles and form a correct way of muscle exertion.

1. Introduction

After years of experience in the field, the success rate of competitive Taijiquan difficult movements gradually tends to be stable. In the application of difficult movement training methods, professional teams in various provinces and cities are different, but they are developing towards scientific and systematic training. Because the difficult movement of competitive Taijiquan requires one foot landing support, and the connection difficulty coefficient is very large, so that when competitive Taijiquan competition is carried out in the competitive field, there will still be mistakes and points deducted in the difficult movement. Through the investigation on the selection and completion of difficult movements of competitive Taijiquan, this study explores the training methods of difficult movements, so as to contribute to the scientific and sustainable development of competitive Taijiquan in China [1]. From the situation of Chinese competitive Taijiquan competition, the problems of athletes in difficult movements mainly include jumping, shaking, foot rolling, incoherent connection between front and back movements, and so on [2]. Therefore, we should understand the basic characteristics of difficult movements and fully realize the significance of the success of difficult movements for athletes to achieve excellent results. On this basis, the training system of difficult movements of competitive Taijiquan is designed, which has high research value and practical significance for enriching the training methods of difficult movements of competitive Taijiquan. This study summarizes the influencing factors involved in the difficult movement training of competitive Taijiquan, scientifically summarizes and systematically summarizes the methods and steps of difficult movement training of competitive Taijiquan according to the results of questionnaire and interview survey, hoping to provide theoretical basis for improving the overall level of difficult movement completion, find and make up for the shortcomings of difficult movement training methods, and provide theoretical reference for the training practice of competitive Taijiquan [3, 4]. Dynamic analysis is not carried out independently, and it often needs kinematic means to assist it. Synchronous measurement of kinematics and dynamics will better and more scientifically collect and analyze experimental data. Generally, the force value on the body ground or the peak value of flexion and extension muscle group when overcoming resistance can be measured by means of force measuring platform, isokinetic muscle strength tester, and plantar pressure. It is generally used to study the force value at a certain time of a sports event and the explosive power of athletes. Figure 1 shows the biomechanical factors affecting the economy of running [5].

2. Literature Review

Ding et al. used Ariel kinematics video fast feedback analysis system to analyze the three-dimensional kinematics of the rotating shot put technology of two excellent male shot putters in China. The whole action process was divided into six space-time points, and each space-time point was quantitatively analyzed [6]. Acosta and others used the three-dimensional image analysis method to analyze the kinematic characteristics of Chinese professional football players throwing long-distance out of bounds, and came to the conclusion that they want to throw long-distance and high-quality out of bounds. Athletes need to mobilize their body muscles as much as possible for orderly swing from bottom to top, and can release the ball within a reasonable and effective angle range [7]. Lee and others used six optical cameras to obtain the lower limb technical action images of 10 men's volleyball players during the take-off period of front and rear buckle. Through the analysis and research on the kinematic characteristics of the obtained data, it is concluded that the rear spike has shorter take-off time and larger parallel distance than the front buckle. The technical requirements of the front and rear breasting are different in the take-off stage [8]. Peng and others used the biomechanical principle to study and analyze the volleyball spiking action, and concluded that the force order of spiking action [9]. Rodrigues and others believe that testing and analyzing the indexes of kinematics, dynamics, and biology is the main research method and means of sports biomechanics, and the kinematics research method is one of its main research methods [10]. Kim and others have summed up the mechanical principles and requirements of the Taijiquan push hand technical action of "its root is in the foot, hair is in the leg, dominates the waist and shape is in the finger" with mechanical common sense and empirical perception [11]. Sun and others define Taijiquan pushing hand as a competitive skill project that follows certain rules and uses techniques such as hugging, stroking, squeezing, pressing, picking, eight, elbow, and leaning. Both sides stick together, judge each other's strength through the feeling of muscles, and then push each other out with strength to determine the outcome [12]. Anderson and others interpreted Taiji pushing hand as: two people are opponents of each other. According to the principle of "sacrificing themselves to others, calling for smooth delivery, sticking to each other, and not losing the top", they use the methods of shed, stroking, squeezing, pressing, picking, eight, elbow, leaning, advancing, retreating, looking, looking, and fixing to find out each other's strength and intention through the feeling of their skin, and achieve the form of sports to win each other in an effective way when they have the opportunity and power [13]. Wampler and others described in detail the technical movements of Taijiquan hand pushing, and summarized that the four techniques of holding, stroking, squeezing, and pressing are the main technical movements of Taijiquan hand pushing, which also explains the importance of shed, stroking, squeezing, and pressing in the process of Taijiquan hand pushing [14]. Ahmed and others proposed that Taijiquan push hand is based on the principle of "stick with touch, do not lose, do not top, do not be too short, bend and stretch with bending", using eight techniques and strength of "shed, stroke, squeeze, press, pick, clear, elbow, and lean", to practice the sensitivity of skin touch and inner body feeling of limbs, and find out the changes of each other's strength, such as direction, size, rigidity, reality, length, speed, and so on [15].

Based on the current research, this study puts forward the sports biomechanical analysis of arm manipulation in competitive Taijiquan. Using the synchronous measurement method of three-dimensional high-speed camera (casio-fh25) and *s* EMG (megawin6000), this study studies the hand movements of 15 teams in a sports college, evaluates the quality of 15 athletes, and carries out two groups of combined movements. The scores were divided into AB group and statistically analyzed by Excel 2007 and spss170. The results show that in the braking of each beat in combination 1 and combination 2 of group AB, the braking ability of arm manipulation of group A is stronger than that of group B. In competitive Taijiquan, the movement techniques of manipulation include: bouncing technology, braking technology and control technology. For arm manipulation, athletes should have the ability of "braking" technology. In the correlation analysis of movement track length, RMS and *i* EMG, the score of athletes in group A is high, and there is no

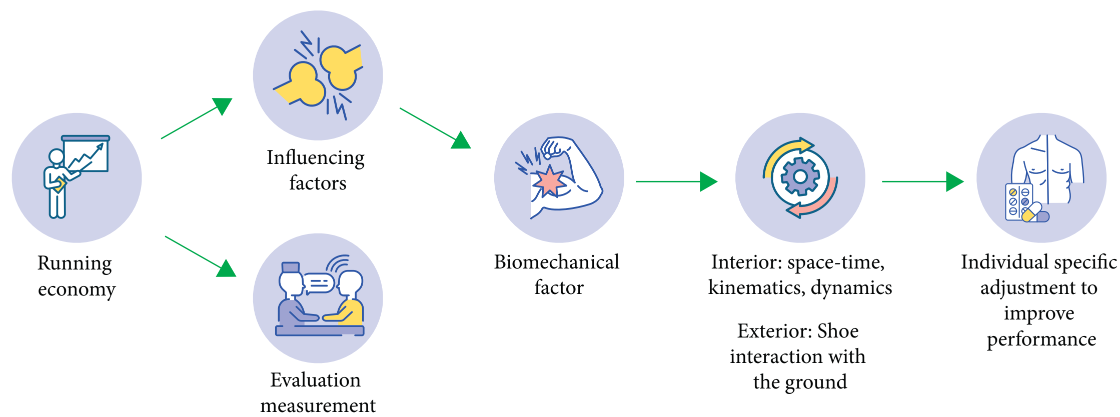

Figure 1: Biomechanical factors affecting running economy. It is generally used to study the force value at a certain time of a sports event and the explosive power of athletes.

correlation between movement track length and RMS. There is a significant correlation between RMS and movement track length in group B, and the correlation degree is moderate.

3. Method

3.1. Research Object. This study takes the technical characteristics and muscle force characteristics of 15 athletes from the competitive Taijiquan team of Xi'an Institute of Physical Education to complete the arm manipulation of competitive Taijiquan.

3.2. Research Methods

3.2.1. Subjects. About 15 athletes from the competitive Taijiquan team of a sports college were divided into 4 athletes with grade and 11 athletes without grade, including 10 males and 5 females. And the special years of the subjects were more than 3 years. The height of all subjects was 1.77 ± 0.09 m, the weight was 62.59 ± 8.85 kg, the age was 20.94 ± 1.44 years old, there was no medical history, and the test was in good condition without muscle fatigue. Finally, the athletes are grouped according to the scoring results of the athletes' arm manipulation.

3.2.2. Test Action. The exercise of competitive Taijiquan is complex and changeable, with certain innovation. In the competitive Taijiquan competition, they all appear in the form of combination, so the actions tested in this study are reflected in the form of combination. The arm manipulation of competitive Taijiquan can be divided into: take the shoulder joint as the axis, lift the arm in a certain direction and stop at a certain position, and the range of motion is no more than 180° [16, 17]. Flexion and extension: the upper arm is fixed and the elbow joint is the axis. The elbow joint is extended from straight to curved or from curved to straight. Winding/looping: arc movement of both arms or one arm with the shoulder as the axis or the forearm with the elbow joint as the axis. In the daily training of competitive Taijiquan, the basic arm manipulation movement combination will be practiced, and combined with the basic arm manipulation movement of competitive Taijiquan, so these basic movements are divided into two combination movements. Since the rhythm of the single action structure of winding/looping is not easy to control, the combined action test is not carried out for the action structure of winding. The main actions of combination 1 are: front lift, up lift, side lift, and down lift. The action of combination 2 is also a lift, including side up lift and side down lift. Among them, chest crossing is only a connecting action [18]. In the test, under the unified beat, the beat is 120 beats/minute, and the athletes complete two movements with heel lifting, and take the best group of movements for analysis.

3.2.3. Experimental Equipment. Equipment required for kinematics: 2 CASIO-FH25 high-speed cameras in Japan; Stereo calibration frame; lampstand; Tape measure; 1 synchronous lamp; American APAs image analysis system.

Equipment required by sEMG: Finland megawin6000 surface electromyography wireless remote tester, sampling frequency of 1000 Hz, 17 packs of electromyography, 1 bottle of 75% medical alcohol, 1 shaving knife, and 1 pack of medical tampon.

Equipment required for sEMG standardized test: use Lifefitness and purelength fitness equipment, including pastor chair biceps trainer; Gantry comprehensive trainer; Dumbbells; Sitting high tension back muscle trainer [19].

3.2.4. Experimental Content. Test of high-speed camera: in this test, two high-speed cameras are used for synchronous shooting, and the shooting frequency is 30 Hz to analyze the kinematics of the action image.

Test of actual action sEMG. sEMG test muscles include biceps brachii, triceps brachii, middle bundle of deltoid and latissimus dorsi on the left and right sides, with a total of 8 muscles.

sEMG standardized test.

The maximum random isometric contraction (MIVC) strength test was performed on the tested muscles, and the test results were taken as the standardized value (100%).

3.2.5. Indexes Selected in the Experiment. Kinematic indexes and *s* EMG indexes are selected in this study.

Kinematic index:

Original coordinates: in this study, the original coordinates of each athlete's hand on the X, y and Z axes are selected to calculate the athlete's action track length [20].

Linear speed, this study selects the linear speed from the upper arm to the forearm, and obtains the arm braking effect of each athlete through the change of linear speed.

sEMG indicators:

RMS index, RMS is selected in this study to explore the rhythmicity of motor unit recruitment and excitation of each muscle. The calculation formula of RMS is as follows:

$$RMS = \sqrt{\frac{1}{N}\sum_{i=1}^{N} X_i}. \tag{1}$$

I EMG index, this study selects iEMG to explore the participation of muscle fibers. The calculation formula is

$$iEMG = \int_{N2}^{N1} X(t)\mathrm{d}t, \tag{2}$$

$N2$ is the starting point of integration; $N1$ is the end point of integration; X(t) is the function value of EMG curve; DT is the sampling interval, in millivolts per second.

3.2.6. Mathematical Statistics. Use Excel 2007 and SPSS17.0 to statistically analyze and process the original data. Summarize various data indicators according to the actual needs. Excel 2007 makes statistics and summary of the data, and uses independent sample t-test and correlation analysis to analyze the correlation and difference of the data. If $P < 0.05$, there is significant difference between the mean values of the two samples; if $P < 0.01$, there is very significant difference between the mean values of the two samples [21, 22].

3.3. Experimental Process. Two high-speed cameras (casio-fh25, Japan) were used to shoot in the gymnasium of Xi'an Institute of Physical Education by using the method of three-dimensional fixed camera photography. The two cameras and the subjects were in an isosceles right triangle [23]. The shooting distance is 7 m, the machine height is 1.0 m, the focal length is 49 mm, and the shooting frequency is 30 Hz. Use the Finnish MegaWin6000 surface electromyography wireless telemetry system to test it synchronously, and carry out standardized test for each muscle tested.

3.3.1. Test the Main Muscles of the Movement. Analyze the participating muscles of the test action from human anatomy, and analyze the actions of the two combinations, respectively. The results are as follows.

The participating muscles of each action in combination 1: Front lift, up lift, and side lift: biceps brachii, triceps brachii, deltoid, latissimus dorsi, extensor digitorum, extensor ulnaris lateralis, and pectoralis major. Downward lift: biceps brachii, triceps brachii, deltoid, latissimus dorsi, extensor digitorum, and extensor ulnaris lateralis [24].

Participating muscles of each action in combination 2: Chest cross, side down lift: biceps brachii, triceps brachii, deltoid, latissimus dorsi, extensor digitorum, and extensor ulnaris lateralis. Side lift: biceps brachii, triceps brachii, deltoid, latissimus dorsi, extensor digitorum, extensor ulnaris lateralis, and pectoralis major.

3.3.2. Basis of Muscle Selection. The muscles selected in this study are selected according to the structure of human anatomy, muscle function, and the characteristics of surface electromyography wireless remote test system. The biceps brachii spans the shoulder joint, elbow joint, and proximal radioulnar joint, so it has an effect on these three joints. The biceps brachii is divided into long head and short head. The main function is to bend the elbow joint and turn the forearm back [25]. Triceps brachii is located behind the humerus. Its main function is to extend the elbow joint and help the shoulder joint extend back and adduct. The middle bundle of deltoid muscle is located at the shoulder joint, and its main functions are shoulder abduction, flexion and pronation, extension and pronation. Latissimus dorsi is located at the back of the waist and the posterolateral sternum. Its main functions are shoulder joint extension, adduction, and internal rotation.

4. Results and Analysis

4.1. Kinematic Characteristics of Arm Manipulation. Through high-speed photography, the combined movement of competitive Taijiquan arm manipulation is captured, analyzed by the American APAs image system, and the kinematic data are statistically analyzed, mainly from the two aspects of action amplitude change and action braking. The results are as follows.

4.1.1. Change of Arm Manipulation Range. In competitive Taijiquan, the range of movement is one of the standards to judge the quality of athletes' movement completion. Action trajectory refers to the spatial characteristics of the action composed of the route that a part of the body passes from the starting position to the end. In kinematics, the length of action trajectory can be used to reflect the size of action amplitude. In arm manipulation, there are "route" requirements for combined action. The "route" of an action is the trajectory from one action to another. If the combination of manipulation action is straight arm, it is required to take the farthest "route". If the arm action is from bending arm to straight arm, it is required to take the shortest "route". In this study, because the athletes have a long sports life and the action routes of combined actions meet the above requirements, the action amplitude of combined actions of groups A and B is analyzed by the length of action track in biomechanics. The calculation of the length of the action track is based on the original coordinates of the athlete's completion of the action. The length from the second coordinate point to the first coordinate point is obtained, then it is superimposed, and finally the sum is obtained to obtain the track length of the complete action. Available formula is as follows:

$$L = \sum \sqrt{(X_{n+1} + X_n)^2 + (Y_{n+1} - Y_n)^2 + (Z_{n+1} - Z_n)^2}, n = 1, 2, 3, \ldots, \quad (3)$$

where L is the length of action track.

The hand is the limb end of the arm, and the movement track of the hand can be regarded as the movement track of each combined action. The track length of an athlete can also represent the range of motion of the athlete. In this study, the movement trajectory of the hand is selected, the trajectory length of the left and right hands is calculated, respectively, and then the average value is taken to reflect the trajectory length of the athlete's movement in the combination. Due to the difference of gender and height, the relative track length is obtained by the ratio of action track length to height. In order to more intuitively understand the movement trajectory changes of each combined action, select the movement trajectory of Jiang's left and right hands in group A and Niu's left and right hands in group B.

It can be seen from Table 1 that there is no significant difference between the two groups from the results of t-test. According to the action structure, the combined actions include flexion, abduction, adduction, and so on. In terms of numerical value, group A was longer than group B in terms of track length in horizontal plane, sagittal plane, frontal plane, and relative track length. In terms of relative track length, group A is 19.2 cm longer than group B on the sagittal plane, 7.5 cm longer than group B on the frontal plane, and 13.5 cm longer than group B on the horizontal plane. The longest length of group A is in the sagittal plane, and the longest length of group B is in the frontal plane. In combination I, the action amplitude of group A is greater than that of group B. It can be considered that the combined action has a long trajectory in the frontal and sagittal planes.

This is due to the action structure. The first four beats and the last four beats of the combined action of combination I are symmetrical actions, in which the front lift (the first beat and the seventh beat) and the up lift (the second beat and the sixth beat) mainly move in the frontal plane and horizontal plane, and the side lift (the third beat and the fifth beat) and the down lift (the fourth beat and the eighth beat) mainly move in the sagittal plane and horizontal plane. Combined with the relative track length, the action amplitude of group A in front lift and up lift is greater than that in side lift and down lift. The range of side lift and down lift in group B was greater than that in front lift and side lift.

The action trajectories of the two groups of hands are different on each plane, so the statistical analysis of the trajectories of XY (horizontal plane), XZ (frontal plane), and YZ (sagittal plane) on each plane is shown in Table 2.

It can be seen from Table 2 that there is no significant difference between the two groups from the results of t-test. According to the action structure, the actions of combination 2 include flexion, external rotation, adduction, and so on. In terms of numerical value, group A was longer than group B in terms of track length in horizontal plane, sagittal plane, frontal plane, and relative track length. From the perspective of relative trajectory, the longest is in the horizontal plane. On the horizontal plane, group A is 34.8 cm longer than group B. Secondly, in the sagittal plane, group A was 11 cm longer than group B. The shortest length was on the frontal plane. Group A was 8.1 cm longer than group B. It can be considered that in combination 2, the trajectory of motion on the horizontal plane is the longest. This is due to the structure of the action. The combination two has four beats, in which the chest cross two beats (the first beat and the third beat) mainly move in the horizontal plane and sagittal plane. The action structure of side up lift and side down lift is the same, but the end position of the action is different. One is side up (45° inclined up) and the other is side down (45° inclined down). Its moving surface is the same. The two beat actions move on the frontal plane and horizontal plane. Combined with the action structure and research results, it shows that the combined action of combination 2 has the longest trajectory on the horizontal plane, that is, the maximum motion amplitude on the horizontal plane.

Based on the above, the action track length, relative track length, and action track length of each plane of the two combined hands. The order of the two combined action tracks is: combination 1 > combination 2, in which the action track in the sagittal plane is the longest in combination 1, and it can also be considered that the motion amplitude in the sagittal plane is the largest in combination 1. The action track of combination 2 is the longest on the horizontal plane, and it is considered that the movement amplitude of combination 2 is the largest on the horizontal plane. In the action trajectories of these two combinations, the action trajectories of group A are longer than those of group B, and the action range of group A is larger than that of group B in the three combinations, which is consistent with the score results of the referee. Therefore, the length of action trajectories can be used as one of the criteria for judging the arm manipulation of athletes. The reason for the difference between the action trajectories of the two combined actions is that the beat is inconsistent: among them, combination 1 is an eight beat action and combination 2 is a four beat action. Difference of action structure: because each combined action structure has its own characteristics, the motion trajectory of each combination is different. Combined with the height difference between the two groups of athletes, there is no significant difference. The difference between the mean values is only 0.94 cm, and the movement structure is consistent. The reason for the difference in the length of movement track between the two groups of AB is that the movement of group B athletes is not "in place". In particular, the action of lifting requires a certain angle of arm action. For example, the forward lift requires the arm to be parallel to the ground when the action is in place, and the upward lift requires the arm to be located on the ear side. In training, the coach requires the "arm to clamp the ear". The action route is not clear: in competitive Taijiquan, the action of lifting requires taking the "farthest route". For example, in combination 1, the "farthest route" should be taken from the front lift to the upper lift, and the same is true from the upper lift to the side lift. Some of these movements require the most

Table 1: Track length of group AB hand.

Group B relative track length	2.684 ± 0.299	2.548 ± 0.23	2.577 ± 0.318
Difference (A-B)	0.349	0.12	0.082

recent route. Flexibility of shoulder: from the results, the movement track length of group B is smaller than that of group A, indicating that the flexibility of group A's shoulder is better than that of group B. When athletes do movements, they shrug and pinch their shoulders, especially when their arms are up. Some athletes are used to shrugging their shoulders. For this phenomenon, athletes should strengthen the practice of proprioception, always remind when doing actions, and slowly correct this wrong habit.

4.1.2. Arm Action Braking Effect. In competitive Taijiquan, whether the arm manipulation action of a single action or the combined arm manipulation action, each beat action needs to have "braking". In the kinematic index, the change of midline speed can be reflected from the moment of maximum online speed to the end of the action or the moment when the speed drops to zero. The speed change during this period is the "braking" of the arm, which is expressed by Δv and the average acceleration $\overline{a}$, according to the formula

$$\overline{a} = \frac{\Delta v}{\Delta t}. \tag{4}$$

Through the index of linear speed, the Δv value and average acceleration of each athlete's left hand and right hand in each beat are calculated, and then the average value is taken. The mean value can be considered as the speed change during the braking of the athlete's arm movement. The results of Δv and average acceleration of each beat between the two groups are shown in Tables 3 and 4.

The arm braking changes and t-test results of each beat in combination I are shown in Table 3. It can be seen from Table 3 that in terms of speed change, the minus sign only represents the deceleration process. In terms of value, the change trend of the two groups of speeds is consistent with the acceleration. The average acceleration of group A in the first beat is $0.51\,\mathrm{m/s^2}$ smaller than that of group B, and the Δv value is $0.22\,\mathrm{m/s^2}$ smaller. Therefore, the deceleration of group A is larger than that of group B, and the braking capacity of group A is slightly stronger than that of group B. In the second beat, the average acceleration of group B is $1.5722\,\mathrm{m/s^2}$ greater than that of group A, and the Δv value is $0.210\,\mathrm{m/s^2}$ greater. The average acceleration of group A in the third, fourth, fifth, and sixth beats is 0.9, 3.728, 0.57, and $0.837\,\mathrm{m/s^2}$ smaller than that of group B, and the V value is 0.466, 0.174, 0.25,0 and $0.003\,\mathrm{m/s^2}$ smaller, indicating that the braking capacity of group A in the third, fourth, fifth, sixt,h and eighth beats is slightly stronger than that of group B. The Δv value and average acceleration of group B in the seventh beat are less than those of group A. It can be considered that the braking capacity of group B in the seventh beat is slightly stronger than that of group A. The Δv value and average acceleration of group A in the eighth beat are smaller than those of group B, the deceleration of group B in the eighth beat is larger than that of group A, and the braking capacity of group A is slightly stronger than that of group B. It can be seen from the above that in the eight beat action of combination 1, the braking ability of group A is stronger than that of group B in the six beat action, and the braking ability of group B in the two beat action is stronger than that of group A. It can be considered that in the combination action of combination 1, the braking ability of athletes in group A is stronger than that of group B. The braking action of the second and seventh beats is the change between the front lift and the up lift. The braking action of the second beat is the braking action from the front lift to the upper lift, and the braking action of the seventh beat is the braking action from the upper lift to the front lift. The changes between the two movements of the athletes in group A are not as good as those in group B. The braking capacity of other actions of group B is not as good as that of group A.

In combination 2, the braking changes of the arm at each beat are shown in Table 4. It can be seen from Table 4 that from the numerical point of view, the change trend of the two groups of speeds is consistent with the acceleration. The Δv value and average acceleration of the first, second, and

fourth beat actions of group A are less than those of group B. from the perspective of braking effect, the braking ability of the arm manipulation combination actions of group A of the first, second, and fourth beat is stronger than that of group B. The Δv value and average acceleration of group B in the third beat are less than that of group A. From the perspective of braking effect, the braking ability of group B in the third beat is better than that of group A. The braking of the third beat is the action of lifting from the side up to the chest cross. In this beat, the braking of group A is stronger than that of group B. On the whole, in combination 2, the braking ability of arm manipulation in group A is stronger than that in group B, and the arm manipulation braking technology in group A is better than that in group B.

Based on the above data results, from the results of t-test, there is no significant difference between AB and ab groups ($P > 0.05$). From the numerical point of view, in the braking of each beat in combination 1 and combination 2 of group AB, the braking ability of arm manipulation of group A is stronger than that of group B. In competitive Taijiquan, the movement techniques of manipulation include: bouncing technology, braking technology and control technology. For arm manipulation, athletes should have the ability of "braking" technology. Through the braking technology, we can see the athlete's control over the action, and through the action control ability, we can evaluate the athlete's ability and level. Generally speaking, athletes with good action braking ability also have a good grasp of action control and understanding. The braking ability of the movement also reflects the athlete's control of muscle tension and relaxation. From the formation process of motor skills, it shows that the inhibition of motor center in cerebral cortex has been established and the formation of motor skills is automatic. The braking ability of group B athletes is weaker than that of group A. the main reasons are: the muscle exertion mode is wrong: the main exerting muscles of group AB athletes may be different, so there are differences in the muscle parts of action exertion. There are differences in muscle tension and relaxation ability: in competitive Taijiquan, athletes need to exert force and brake quickly, and have high requirements for muscle tension and relaxation ability. The ability of muscle tension and relaxation can be called energy saving in physiology. The ability of excellent athletes in this aspect is greater than that of ordinary athletes. There are some wrong movements: because the sports years of the two groups of athletes are more than three years, the movements have been automated. The original wrong action has also become automatic and difficult to correct.

4.2. s EMG Analysis. The *s* EMG of this study was carried out simultaneously with high-speed photography to explore the muscle force characteristics of athletes in each combination. The main muscles tested are: left biceps brachii, left triceps brachii, left deltoid middle bundle, left latissimus dorsi, right biceps brachii, right triceps brachii, right deltoid middle bundle, and right latissimus dorsi. RMS and EMG were selected to judge the strength of each muscle activity. Considering the difference of sebum thickness among athletes, it is impossible to make a direct comparative analysis. In the process of the experiment, each muscle is standardized, and then the standardized value of each athlete is obtained, and of each athlete is compared and analyzed.

4.2.1. Combination 1 s EMG Feature. The standardized value of RMS of combination 1 is shown in Figure 2.

As can be seen from Figure 2, the maximum muscles of the two groups are different. Group A is 118.87% of the right latissimus dorsi, group B is 75.78% of the left triceps brachii, and the minimum muscles are the left biceps brachii, group A is 12.87%, and group B is 10.78%. From the above figure, we can see that the standardized values of the muscles and standardized actions on the right are larger than those on the left. In group A, the latissimus dorsi and triceps brachii on both sides and biceps brachii were larger than those in group B, and the RMS standardized values of other muscles in group B were larger than those in group A.

The *i* EMG features of the combination are shown in Figure 3.

It can be seen from Figure 3 that in the combined arm manipulation, the standardized values of latissimus dorsi on both sides of group A are larger than those of other muscles, and the standardized values of triceps brachii on the left and biceps brachii on the right in group B are larger than those of other muscles. The lowest standardized value of the two groups was the left biceps brachii.

Based on the above standardized values of RMS and I EMG, the muscle standardized values of the two groups changed, but the change trend of their standardized size was unchanged. In the exercise of combination 1, the arms on both sides start to act at the same time. It is found that the standardized value of athletes in group AB is greater on the right than on the left. This is because the dominant hand of most athletes is the right hand, which is related to personal sports habits. Combined with the standardized values of RMS and I EMG in Figures 3 and 4, it is found that the recruitment ability and excitation rhythm of motor units of latissimus dorsi muscle in group A are stronger than those of

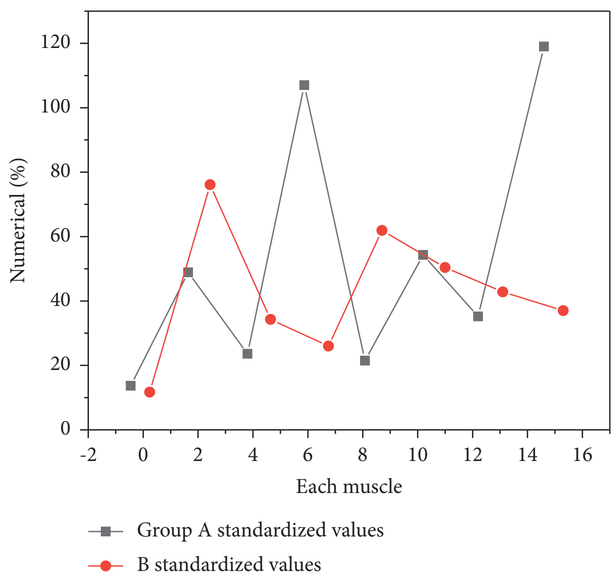

Figure 2: RMS standardized values of muscles in group AB. In group A the latissimus dorsi and triceps brachii on both sides and biceps brachii were larger than those in group B and the RMS standardized values of other muscles in group B were larger than those in group A.

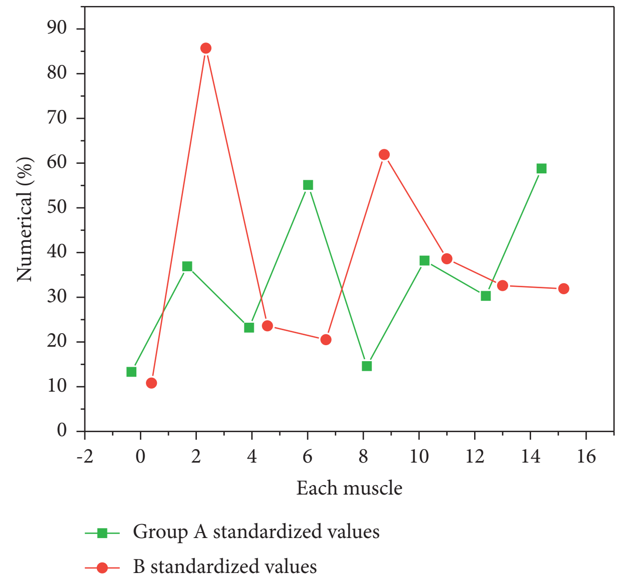

Figure 3: Standardized values of I EMG of muscles in groups B and AB. The lowest standardized value of the two groups was the left biceps brachii.

other muscles, and the participation of muscle fibers is also more than that of other muscles. It can be considered that the latissimus dorsi muscle is the main muscle involved in the arm manipulation of group A, and the triceps brachii on the left and biceps brachii on the right in group B have stronger recruitment ability and excitation rhythm of motor units than other muscles, and the participation of muscle fibers is also more than other muscles. It can be considered that the main muscles in group B are the triceps brachii on the left and the biceps brachii on the right. Combined with the scoring results of the referees on the athletes' arm manipulation movement, the athletes in group A are higher than those in group B, which shows that the action completion quality of group A is high, and it can be considered that the action force mode of this group of athletes is more correct than that of group B. Therefore, the main muscles of combined arm manipulation are latissimus dorsi on both sides. The athletes in group B should improve the way of exertion, no longer take the left triceps brachii and the right biceps brachii as the main exerting muscles, but change to latissimus dorsi.

4.2.2. sEMG Characteristics of Combination 2. The standardized value of RMS of combination 2 is shown in Figure 4.

As can be seen from Figure 4, among the standardized values of all muscles in group A, the maximum value is 89.61% of the latissimus dorsi on the right, and the minimum value is 11.32% of the biceps brachii on the left. Among the standardized values of all muscles in group B, the maximum value was 56.31% of the biceps brachii on the right and the minimum value was 17.69% of the latissimus dorsi on the left. The RMS standardized values of bilateral latissimus dorsi, right triceps brachii, and middle bundle of right deltoid in group A were higher than those in group B. In general, the standardized value of the right muscle in group A was greater than that in group B, and the standardized value of the left muscle in group B was greater than that in group A.

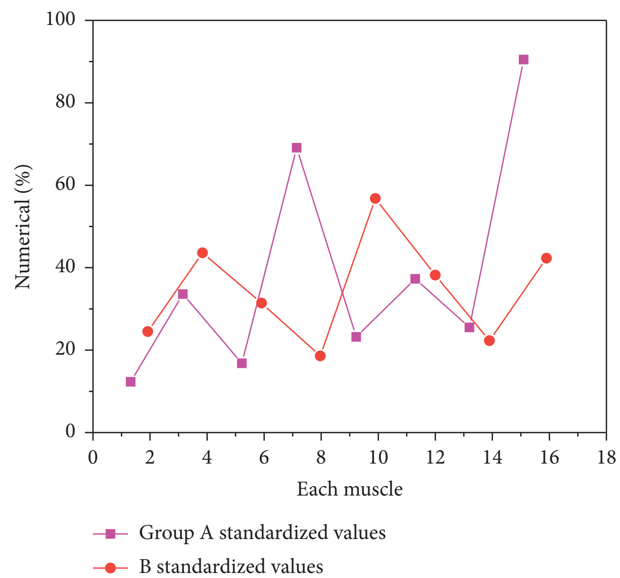

Figure 4: RMS standardized values of muscles in group AB. Among the standardized values of all muscles in group (B) the maximum value was 56.31% of the biceps brachii on the right and the minimum value was 17.69% of the latissimus dorsi on the left.

The *i* EMG characteristics of combination II are shown in Figure 5.

As shown in Figure 5, in the combined second-hand arm manipulation, the standardized value of latissimus dorsi on

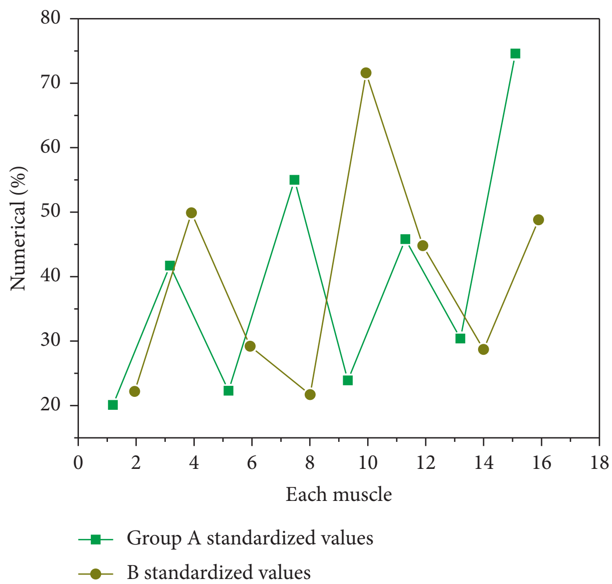

Figure 5: Standardized values of i EMG of muscles in group AB. In group B the standardized values of the left triceps brachii and the right biceps brachii were greater than those of other muscles, and the smallest value was the left latissimus dorsi.

both sides of group A is the largest, and the lowest standardized value is the left biceps brachii. In group B, the standardized values of the left triceps brachii and the right biceps brachii were greater than those of other muscles, and the smallest value was the left latissimus dorsi.

Based on the above standardized values of RMS and I EMG, the muscle standardized values of the two groups changed, but the change trend of their standardized size was unchanged. It is found that the muscle force on the right side of the athletes in group AB is greater than that on the left, indicating that the dominant hand of both groups is the right hand. This is because the dominant hand of most athletes is the right hand, which is related to personal sports habits. Combined with the standardized values of RMS and I EMG of latissimus dorsi in Figures 4 and 5, it is found that the recruitment ability and excitation rhythm of motor units of latissimus dorsi in group A are stronger than those of other muscles, and the participation of muscle fibers is also more than that of other muscles. It can be considered that in the arm manipulation of combination 2, the latissimus dorsi muscle is the main muscle involved in group A, and the recruitment ability and excitation rhythm of motor units of right biceps brachii and left triceps brachii in group B are stronger than those of other muscles, and the participation of muscle fibers is also more than that of other muscles. It can be considered that the main muscles in group B are the right biceps brachii and the left triceps brachii. Combined with the score results of the referee on the athletes' arm manipulation movement, it shows that the movement completion quality of group A is high, and it can be considered that the movement force mode of this group of athletes is more correct than that of group B. Therefore, the main muscles for the arm manipulation of combination 2 are the latissimus dorsi muscles on the left and right sides.

According to the characteristics of RMS and *i* EMG in these two combinations, the latissimus dorsi muscle is the main muscle in group A in the three combinations. The main muscles involved in group B in combinations 1 and 2 are the right triceps brachii and the left biceps brachii. In competitive Taijiquan, the basic form requirements for athletes are: lift the heels of both feet, clamp the legs and hips inward, clamp the shoulder blades backward, straighten the spine, sink the shoulders, center the head, open both hands, straighten the arms, put the five fingers together, and force to the fingertips. The control of athletes' basic posture also reflects the control ability of athletes to a certain extent. Combined with the structure and function of muscles and the research results, it can be considered that the basic shape of group A is better than group B, and the control ability of group A is stronger than group B. From the perspective of sports skills, the athletes in group A have a high degree of energy saving, good nerve control over muscles, and less redundant actions. It is suggested that athletes and coaches should mainly focus on the training of latissimus dorsi muscle in the training of arm manipulation, instead of the traditional arm muscle strength training.

In the correlation analysis of motion trajectory length, RMS and *i* EMG, there was no linear correlation in group A and moderate correlation in group B. The correlation between action track length and RMS and *i* EMG in group B was greater than that in group A. Combined with the referee's score results, the athletes in group A have high scores, and there is no correlation between the three indexes of action track length and RMS. There is a significant correlation between RMS and movement track length in group B, and the correlation degree is moderate. This shows that when the movement of group B athletes is completed, the muscles are in a state of tension, the movement skills are not mastered well, and the energy saving is not achieved. During training, we should pay more attention to the proprioception of muscles and form a correct way of muscle exertion.

5. Conclusion

This study provides a biomechanical analysis of the movements of Taijiquan hands. In this study, biomechanical research methods and tools were used to analyze the arm manipulation of competitive Taijiquan, and the problems of kinematics and muscle strength characteristics were solved. Pull and control arm movement during adjustment. Using the synchronous measurement method of three-dimensional high-speed camera (casio-fh25) and *s* EMG (megawin6000), this study studies the hand movements of 15 teams in a sports college, evaluates the quality of 15 athletes, and carries out two groups of combined movements. The scores were divided into AB group and statistically analyzed by Excel 2007 and spss170. The kinematic characteristics of arm exercise and the strength characteristics of eight muscles (biceps, triceps, middle deltoid, and major muscle) were studied in the two groups of athletes. The results show that in the competitive Taijiquan movement combining hand and chemistry, the movement of group a athletes is close to the music rhythm, and the movement coordination conforms to the rhythm of group A, which is more than that of group B. The larger the relative trajectory, the greater the motion amplitude and the higher the elongation. The length of track a is longer than that of group B, which is consistent with the scoring results. The "braking" method is very important. Comparing the normal values of RMS and I EMG during ab exercise between the two groups, the right muscle load was greater than the left. When combined with arm exercises, the core muscles use the left and right back muscles. The main muscles in group A are back muscles, and the main muscles in group B are triceps and biceps. In order to further brake the hand action, you can switch the hand action from two times to one blow, and feel the braking process. For athletes who have completed the action automation, special attention should be paid to the "in place" of the action.

In order to improve the quality of life of breast cancer patients, this paper will apply continuous early intervention to the nursing of breast cancer patients. The continuous early intervention nursing model can propose countermeasures for the health problems faced by patients with postoperative chemotherapy. In order to analyze the effect of continuous early intervention nursing on negative emotions and quality of life in breast cancer patients, the effect of continuous early intervention in improving the quality of life of breast cancer patients is analyzed by means of experimental research. The control group is given routine nursing, and the observation group is given continuous early intervention nursing intervention. Moreover, this paper obtains data statistics in combination with statistical analysis. Through the comparison of the test results, it can be seen that the implementation of continuous early intervention nursing intervention in breast cancer patients can improve the nursing effect, effectively relieve the negative emotions of patients, and improve the quality of life of patients.

1. Introduction

With the progress of modern medicine and the enhancement of people's awareness of health care, most breast cancer patients can get early diagnosis and early treatment and the long-term survival rate after surgery is also gradually improved. Therefore, how to improve the quality of life of breast cancer patients has attracted widespread attention in the medical community. Quality of life, a multidimensional concept, is people's subjective experience of goals, values, expectations, and living conditions. Clinically, quality of life is commonly used to evaluate the impact of disease and treatment on the physical, psychological, and social functions of patients. The quality of life of breast cancer patients is a dynamic indicator that changes with lifetime and is affected by many factors. Existing studies have shown that patients' physical symptoms, self-esteem, psychological stress, self-efficacy, and ability to cope with and adapt to diseases are all influencing factors of quality of life. First of all, the fact of having breast cancer is a serious stress and crisis event for both the patient and the family members. The diagnosis and surgical treatment of breast cancer is a process that most breast cancer patients have to go through. This process will have a huge impact on the patient's psychological, social, and family functions and then seriously affects the quality of life of breast cancer patients. Secondly, modified radical mastectomy for mastalgia can improve the cure rate of tumors, but it also damages the patient's skin, breast, fascia, muscle, and other tissue structures. This can easily lead to pathophysiological conditions such as soft tissue fibrosis, decreased muscle contractility, disruption of lymphatic pathways, and increased nerve sensitivity. After modified radical mastectomy for breast cancer, the skin lymphedema of the affected limb, the functional impairment of the loyal limb, and the movement disorder of the shoulder joint caused serious distress to the patient and seriously affected the quality of daily life of the patient. Third, the absence of breasts after surgery results in physical defects and changes in women's self-image, resulting in serious damage to the patient's self-esteem. At the same time, changes in self-efficacy and social adaptability affect the patient's normal work and life and reduce the patient's quality of life.

The perioperative period is a dangerous period in terms of the occurrence of negative emotions and abnormal adaptive behavior, which seriously affects the patient's compliance with surgical treatment and greatly affects the patient's prognosis, quality of life, and survival time. The perioperative period is a critical period for the treatment of breast cancer patients, and it is also a period of concentrated outbreaks of various physiological dysfunctions and psychological crises. Studies have shown that breast cancer patients have more psychological problems during the perioperative period and negative emotions such as anxiety are prominent, which is much higher than that of healthy people. However, at the same time, the perioperative period is also a critical period for functional exercise, prevention of complications, psychological adjustment, obtaining more social support, and establishing a good social adaptation function. The early postoperative period of breast cancer is the best time to start functional exercise, which can effectively prevent postoperative upper limb dysfunction. At the same time, family is the most important source of support for perioperative patients. The care, understanding, and support of family members, especially spouses, can enhance the patient's expectation of life, improve self-esteem, effectively enhance the patient's confidence in coping with difficulties, and better maintain their social adaptation function, thereby improving the quality of life of breast cancer patients.

2. Related Work

In [1], a survey of 200 breast cancer patients showed that a total of 14 symptoms were significantly negatively correlated with the quality of life of patients. Among them, the top five symptoms were lack of vitality, hair loss, mental stress, sweating, and anxiety. The top 5 most distressing symptoms for patients were hair loss, feeling "I do not look like myself," poor sleep, loss of appetite, and lack of energy. The research in literature [2] shows that the pain and edema of the affected limb after surgery have a certain degree of influence on the quality of life of loyal patients and the painful mouth maggots will also affect the quality of life of patients. In improving the quality of life of patients, the first thing to do is to maximize the control of symptoms [3]. Medical staff should pay enough attention, because these symptoms will accompany patients through every day; if these symptoms improve, the quality of life of patients will naturally improve. Literature [4] investigated the quality of life of 70 cancer patients before and after cancer pain treatment. The results showed that pain can comprehensively affect the quality of life of patients and effective analgesic treatment can significantly improve the quality of life of patients. Literature [5] systematically evaluated the effect of functional rehabilitation training in patients after breast cancer surgery, and the results showed that progressive limb rehabilitation training and whole body rehabilitation exercise in patients after breast cancer surgery can effectively improve the function of the affected limb and improve the quality of life. Relief of fatigue symptoms in patients with chemotherapy and radiotherapy has a certain effect. Individualized aerobic exercise can improve the patient's fatigue state and improve the patient's quality of life [6]. Postoperative breast cancer patients experience heaviness, swelling, tenderness, and numbness before developing upper extremity lymphedema, so early guidance and intervention are imperative. Clinical nurses should provide patients and their families with personal care guidance for lymphedema, so that patients and their families can master the correct long-term supportive treatment methods for the prevention of lymphedema [7]. Breast cancer patients have more psychological problems in the process of diagnosis, treatment, and rehabilitation, which has been proved by more and more studies [8]. Suffering from cancer is a strong stress stimulus for most people. Breast cancer and its surgical treatment can lead to obvious stress reactions in patients, such as anxiety, depression, anger, fear, and other negative emotions, which affect treatment and recovery. To a certain extent, the quality of life of patients and the whole family decreases [9]. Literature [10] studies have shown that systematic psychological intervention for breast cancer patients can effectively alleviate their negative emotions and improve their quality of life. Literature [11] believes that negative life events, social support, depression, and other psychosocial factors have a greater impact on the immune function of cancer patients. Most breast tumor patients have a strong stress response, and their immune function is significantly inhibited, and the stronger the stress response, the more severely inhibited their immune function. After timely psychological intervention, providing spiritual comfort, support, persuasion, and hints, the patient can quickly control the chaotic thinking and feelings and the psychological response and immune function can be effectively improved. Perioperative breast cancer patients have serious negative emotions, and psychological intervention can significantly improve the treatment of their physical diseases and their quality of life. The results of the study also showed that through psychological intervention, the negative emotions such as anxiety and depression in different cancer patients were significantly reduced and the quality of life was significantly improved. Yang Qiaoju's psychological intervention research confirmed that social psychological factors are closely related to the occurrence and development of malignant tumors, which is why the psychological intervention for patients with malignant tumors received better results. The main reason is that psychological intervention can better relieve some of the patients' psychological pressure and mental burden. It enables patients to receive treatment under a good emotional experience, and at the same time, a healthy psychological condition and a good mood can improve immunity and improve the quality of life through the role of the neuroendocrine immune system, forming a virtuous circle, which further enhances the patient's confidence in treatment. On the other hand, health education before and during chemotherapy enables patients to understand a lot of chemotherapy knowledge, eliminate patients' doubts and worries, help patients establish positive coping strategies, enhance self-care awareness, and actively help them cooperate with treatment. Finally, psychological intervention, such as one-on-one conversation and communication, enables patients to feel the greatest support and care from medical staff and helps patients adjust to problems caused by diagnosis and treatment [12]. The psychological intervention measures used in the study can effectively promote the improvement of the quality of life of patients with breast cancer after chemotherapy and contribute to the overall recovery of the patients. Clinical medical staff should understand the poor psychology of patients undergoing chemotherapy after breast cancer surgery, master the methods of psychological intervention, and actively carry out psychological intervention to improve the quality of life of patients undergoing chemotherapy after breast cancer surgery [13]. The results of literature [14] show that the psychological disorders of postoperative patients are closely related to age. The older they are, the lighter the psychological barrier, because they and their husbands have high hopes for quality of life and prolonging life and have little requirements for sex. The younger the age, the more severe the mental disorder. Improvement can be achieved to a large extent through psychological care. Unilateral mastectomy did not affect the postoperative quality of sexual life. In this process, medical staff's sense of responsibility and psychological communication ability and skills play a leading role. Correct psychological guidance has a significant effect on reducing postoperative sexual dissatisfaction. The main reasons for patients' anxiety and low self-esteem before and after surgery were concerns about affecting their sexual life. It is advised to inform the patient that postmastectomy will not affect the couple's sexual life. However, it should also be noted that the operation will bring inconvenience and embarrassment to the sexual life of the patient and her husband. The patient will be ashamed to expose herself due to physical defects, and at the same time, she will worry that sexual life will have adverse effects on her body. In response to this problem, patients and their husbands should be informed that this deficiency can be compensated by nonphysical love at this stage [15]. After a period of time, the psychology of both parties adapts to this reality and it will naturally get better. Psychological care can help patients adapt to the physical changes caused by mastectomy as soon as possible, influence patients to establish a correct understanding and evaluation of such changes, help them adjust to their psychological state in a timely manner, and help them to be confident in their future life. Psychological counseling and guiding intervention are very important to eliminate the anxiety and inferiority of patients through enlightenment. Psychological intervention can transform the spouse's sexual attitude and improve the quality of sexual life. Therefore, as long as the patients and their families are relieved of their ideological concerns, psychological intervention can reduce the occurrence of postoperative sexual life dissatisfaction [16].

Studies have shown that 30% of breast cancer patients show varying degrees of anxiety and depression and their quality of life is significantly lower than that of the normal population. Although the American Society of Clinical Oncology (ASCO) has developed assessments and measures to manage symptoms such as anxiety and depression in cancer patients, many breast cancer patients undergoing chemotherapy still report a high number of unmet needs, including physical, psychological, and social support and spiritual care [17]. A survey of support needs for breast cancer patients undergoing chemotherapy showed that younger patients had more information needs about the health care system and sexuality and that unmet needs were positively associated with patient symptom distress scores. The results of a survey on the quality of life of long-term breast cancer survivors in literature [18] show that the quality of life of breast cancer survivors is relatively satisfactory, but there are still physical and psychological diseases, and anxiety and depression are related to the reduction of quality of life. Literature [19] shows that the longer the breast cancer chemotherapy patients continue early care, the better their cognition, behavior, and status of the disease and the more confident they are to complete the treatment. During hospitalization, cancer patients can be cared for by medical staff, but their treatment time in the hospital is not long, and most of the patients recuperate at home during the intermittent period of treatment. Corresponding support and guidance are of great significance. Patients are eager to return to normal life after discharge, and they need to be managed to prevent tumor recurrence, symptom control, rehabilitation exercises, etc., to reduce physical and psychological discomfort. Rehabilitation will be of great benefit.

3. Materials and Methods

3.1. Research Object. In the experiment, breast patients who are admitted to the hospital were selected as the research objects. Inclusion criteria are as follows: female patients, who were conscious and normal, underwent pathological and imaging examinations, met the diagnostic criteria for breast cancer, received chemotherapy after surgery, had complete clinical data, provided informed consent, and obtained approval by the medical ethics committee. Exclusion criteria are as follows: showed poor active cooperation ability during treatment or withdrawal from the study for some reason; had systemic chronic disease or liver and kidney dysfunction; had nonprimary breast cancer; had speech, communication, audio-visual, behavioral, and other obstacles. They are equally divided into the observation group and control group completely by the random number table method. There is no significant difference in general data between the two groups ($P > 0.05$), which is comparable. There is no statistical difference in the age composition and educational level composition of the two groups of patients ($P > 0.05$), which are comparable. This study was approved by the hospital ethics committee.

3.2. Experiment Method. When the patients in the two groups are discharged from the hospital after the operation, the responsible nurses provided health guidance for discharge after the modified radical mastectomy for breast cancer. It includes dietary guidance, key points of limb protection, functional exercise of the affected limb, guidance on identifying flap necrosis and subcutaneous effusion, maintenance of drainage tubes, monitoring of drainage

12	54.46	41.98	27	48.29	34.58
13	57.91	39.14	28	52.59	47.44
14	43.61	47.36	29	49.47	37.11
15	52.22	44.63	30	56.12	38.84

fluid, and guidance on taking medicines for discharge. At the same time, the patients on every Monday afternoon (control group) or every Wednesday afternoon (observation group) made an appointment to return to the hospital to observe the wound. One month after the patients are discharged from the hospital, the recovery status of the skin flap and the functional recovery of the upper limb on the affected side were evaluated.

On this basis, the observation group implemented diversified continuous early interventions. (1) 1–3 days before discharge, the patients and their families will be evaluated for their psychosocial status, a personalized continuous early intervention plan will be developed, and hospital contact information will be issued. The specific methods and contents of continuous early intervention are shown in Table 1. (2) Composition and training of successive early intervention teams: The ward has 32 beds and 13 nurses. The continuous early intervention group consisted of 2 deputy chief physicians of breast surgery, 2 nurses in charge, and 5 nurses who had worked for more than 5 years. Among them, there is 1 lymphedema therapist and 1 psychological counselor. The training content includes breast cancer-related disease knowledge, wound management, physical function assessment, common complication assessment and coping strategies, listening and talking skills, guidance education on negative emotions, service awareness, nutrition, etc. (3) Establishment of a patient basic information table: the main contents of the control group information table include the patient's name, hospital number, age, admission date, operation date, discharge date, discharge diagnosis, phone number, diet, sleep, mood, flap recovery, incision suture removal time, amount of drainage fluid, upper limb swelling, and upper limb function recovery. On this basis, the observation group information table adds the follow-up date, follow-up content, and answers to difficult questions. (4) Items of continuous early care.

(1) Incision Management. ① It is necessary to observe the color, temperature, and tension of the wound flap to identify flap necrosis and subcutaneous effusion. If it is found that the incision is red and swollen, there is a sense of fluctuation under the skin, or if the color of the skin flap is purple, we should contact the management physician in time and deal with it in time. ② It is necessary to keep the incision dressing clean and dry, and it is advised not to scratch it with the hands to avoid infection.

(2) Drainage tube management. ① It is necessary to squeeze the drainage tube correctly to keep the drainage smooth. ② It is necessary to maintain the effective negative pressure suction of the negative pressure drainage bottle. ③ It is necessary to pour the drainage fluid regularly every day. If it is found that the drainage fluid suddenly decreases sharply, combined with chest wall pain or more fluid leakage from the drainage tube orifice, the patient needs to go to the hospital in time. At the same time, patients need to be informed of the dangers of not pouring the drainage fluid in time and the importance of recording the drainage fluid to improve their compliance.

(3) Process of Functional Exercise of the Affected Limb. It is necessary to formulate a personalized functional exercise plan for the affected limb for the patient according to the patient's description, postoperative days, and wound healing. At the same time, it is necessary to invite family members to participate in the plan and inform patients and family members of the purpose and significance of functional exercise of the affected limbs, so as to improve patients' compliance and family members' awareness of supervision.

(4) Guidance on Diet and Emotional State. It is necessary to distribute small prescriptions for breast cancer nutrition diets, instruct patients to arrange meals reasonably, and fast from greasy, estrogen-rich foods, or drugs.

(5) Psychosocial Support. It is necessary to assist patients in discovering social support resources around them, so that they can obtain support effectively, encourage family members, especially spouses, to provide psychological support, and maintain emotional stability. At the same time, patients need to be informed that they can consult follow-up

Table 2: Comparison of SDS of patients.

Number	Control group	Test group	Number	Control group	Test group
1	48.14	36.17	16	53.55	41.48

13	46.79	39.43	28	40.45	43.13
14	45.08	37.38	29	50.03	35.72
15	51.38	37.74	30	42.75	36.00

staff if they have anxiety, depression, and other emotions or poor sleep. In addition, it is necessary to encourage participation in the activities of the Pink Ribbon Club and the promotion of rehabilitation-themed salons to provide patients with more information and psychological support.

The adverse mood changes of the two groups of patients were recorded. Adverse mood changes were evaluated using the Self-Rating Anxiety Scale (SAS) and Self-Rating Depression Scale (SDS). They are performed before treatment and 3 months after patient care. The scales include 20 items, and the cutoff value is 50 points. The higher the score, the more severe the anxiety or depression. Changes in the quality of life of patients before and after nursing are recorded, and the European Organization for Cancer Treatment and Research is used to develop the RTC-QOL-C30 scoring scale. The higher the functional score, the better the quality of life of the patients. The nursing satisfaction of the two groups of patients is compared using a self-made questionnaire, which is divided into satisfied and dissatisfied levels. Before and after nursing, the health knowledge mastery of the two groups of patients is measured. In this experiment, we design a questionnaire on health knowledge of patients after chemotherapy, including five dimensions, representing the most basic chemotherapy support, skin reaction, and diet. The score adopts a three-level scoring method, and the patient never understands complete mastery of 3 points. The higher the score, the higher the patient's mastery of health knowledge.

4. Results

After nursing, the SAS and SDS scores of the two groups are significantly decreased (both $P < 0.05$). There are statistically significant differences in the SAS and SDS scores between the two groups (both $P < 0.05$), as shown in Tables 1 and 2. The corresponding statistical chart is shown in Figure 1 and 2.

After nursing, the quality of life scores of the two groups are improved (both $P < 0.05$). The quality of life scores of the observation group after intervention are significantly better than those of the control group (all $P < 0.05$), as shown in Tables 3–9. The corresponding statistical chart is shown in Figures 3–9.

5. Analysis and Discussion

In recent years, the incidence of breast cancer in China has shown a gradually increasing trend and the affected population is getting younger. Statistics show that breast cancer has acquired the third place among all malignant tumors. Although the diagnosis and treatment techniques have been improved, the functional rehabilitation of nurses

after surgery will inevitably lead to the loss of hope for many patients. Therefore, it is of great practical significance to study which nursing methods are used to improve patients' negative emotions and quality of life. The adverse reactions of breast cancer patients during treatment not only affect the patients' recovery but also affect their psychological status, resulting in a decline in the patients' quality of life. In the analysis of this group, the focus is on the application of

continuous early care in breast cancer. With the rapid development of nursing disciplines, a lot of efforts have been made in the nursing work of breast cancer chemotherapy at home and abroad. Continuous early care is given to implement discharge care on the basis of overall care, to ensure that patients can receive the same care as inpatient care after hospitalization, to effectively ensure the rehabilitation of patients with humerus, and to reduce the case fatality rate of patients. Continuous early care for breast cancer patients can effectively reduce CRF during chemotherapy and improve patient satisfaction. It shows that the implementation of continuous early nursing care for breast cancer patients is helpful for the mastery of patients' health knowledge and has an important effect on improving the relationship between nurses and patients, which is consistent with the results reported in previous studies. Moreover, various adverse reactions after breast cancer treatment seriously affect the quality of life of patients. As patients spend most of their time recovering at home, this prevents continuation of care. The implementation of continuous early care can ensure the continuity and integrity of nursing intervention and, at the same time, can improve the nursing ability of patients themselves and their families and improve the quality of life of patients. Before nursing, there is no significant difference in the SAS score and SDS score between the two groups ($P < 0.05$). After nursing, the SAS and SDS scores of the two groups are significantly decreased (both $P < 0.05$) and the SAS and SDS scores of the observation group are significantly lower than those of the control group at the same time after nursing (both $P < 0.05$). Moreover, the quality of life of the patients in the observation group after intervention is significantly better than those in the control group except for loss of appetite, constipation, diarrhea, economy, and other dimensions (all $P < 0.05$). The research results show that the implementation of continuous early care can improve the role function and emotional function of patients, indicating that the implementation of continuous early care can effectively reduce the adverse symptoms of patients and extend clinical intervention from the hospital to the family.

It is necessary to standardize the way of continuous early care and improve the professional quality of nursing staff. Moreover, continuous early care needs to organically combine the enthusiasm of patients for self-care and the enthusiasm of nurses by carrying out a variety of health education activities, which increases the trust of patients in nursing staff and makes the satisfaction of patients improve. In this study, continuous early care team members were trained once a week on breast cancer specialist knowledge, prevention and countermeasures for common complications after breast cancer surgery, identification of common psychological problems and emotional management, and other related subjects to improve their professional quality. At the same time, relevant guidelines and standards are formulated for the content and operation procedures of continuous early care, to standardize the professional behavior of nursing staff and to improve the quality of continuous early care. At the same time, it is necessary to use a convenient and economical network platform to provide consultation services, implement health guidance, and facilitate the implementation of continuous early care for patients in various places. Through face-to-face guidance and communication, the patients' compliance with treatment and functional rehabilitation of the affected limbs after discharge can be effectively improved and their emotions can be relieved in time. However, the disadvantage is that it is limited by time; through telephone follow-up, patients can feel the humanistic care of the hospital and improve nursing satisfaction. To sum up, continuous early nursing can effectively reduce postoperative complications of breast cancer and promote functional recovery of the upper limbs on the affected side. The establishment of a high-quality continuous early care team is the guarantee of continuous early care. Therefore, we need to develop a personalized continuous early care program and use a variety of continuous early care pathways. For example, carrying out continuous early care by means of appointment follow-up time, setting up QQ group, WeChat group, online consultation and answering questions, follow-up consultation, telephone follow-up, etc., is conducive to achieving good results.

Retracted: Probabilistic Statistics-Based Endurance Life Prediction of Bridge Structures

Computational Intelligence and Neuroscience

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

With the massive construction of bridge infrastructures, bridge health monitoring systems have gradually matured in application and research, but previous research has primarily focused on structural damage detection and bridge safety warnings based on valid data. The structural details of steel bridge panels and structural systems are determined by the coupling effects of many intrinsic and extrinsic uncertainties, such as material properties, structural characteristics, manufacturing processes, and random traffic loads. The evaluation of fatigue is a difficult task. This article first builds a big data platform, utilizing its high-efficiency parallel computing capability and highly fault-tolerant distributed file system to achieve second-level monitoring data processing; ensuring real-time data cleaning, data analysis, and safety warning; and building a big data analysis and processing platform with high reliability, high availability, high storage efficiency, and high scalability of bridge health monitoring. The big data platform chooses HDFS for offline data storage and Spark for data analysis and modelling after comparing and analysing the benefits and drawbacks of various big data technologies. Kafka is used for caching real-time data, and Spark-streaming is used for reading data and real-time processing. Finally, the platform's superiority and reliability in terms of offline computing performance, real-time online performance, scalability, and fault tolerance are confirmed through experimental analysis; the optimal data cleaning method is derived by comparing and analysing monitoring data noise, jump point, and drift phenomena. This part of the research is based on bridge temperature data with stable signals and bridge strain data with fluctuating signals, taking into account the influence of different data types; the corresponding data missing repair algorithms are proposed for different types of data to form a complete and general data patching method process. The probabilistic fracture mechanics theory, in comparison to the traditional deterministic fatigue assessment method, can better reflect the essential uncertainty of fatigue problems and is an effective way to assess the fatigue performance of orthotropic steel bridge decks. The goal of data patching is to ensure data recovery accuracy of over 90%, with no patching repair required for monitoring data with too much missing data. The endurance life of bridge structures is predicted using a big data probabilistic statistics approach based on a variety of factors such as material properties, construction characteristics, manufacturing processes, and random traffic loads.

1. Introduction

Bridges are the key nodes in the traffic lifeline project, and also show the strength of the country in social and economic development. In recent times, as the number of bridges increases and the age of bridges increases, the focus of bridgework is changing from "reconstruction rather than maintenance" to "construction and maintenance," and even "management and maintenance." However, compared with the breakthrough achievements in the fields of super flexible structure analysis, deep-water foundation design and construction, and super span bridge construction, there is a serious lack of research in bridge maintenance technology, and a weak reserve of bridge safety and health technology, resulting in the structural performance of bridges decaying before they get old, and the service life is generally much lower than the design life, and even safety accidents occur frequently. According to statistics, 60% of the actual life of the bridge is less than 25 years, nearly 800,000 highway bridges, the proportion of dangerous bridges is close to 15%, and the hidden danger is huge.

Large steel bridges are critical nodes and hubs in road traffic engineering, and orthotropic anisotropic steel bridge deck panels as the preferred deck structure for their main girders are required to ensure their safety and reliability in high-quality service during the design life. The fatigue cracking problem and secondary diseases such as deck pavement damage caused by the coupling influence of multiple factors such as structural characteristics and force system, material properties, environmental effects, and construction quality run through the entire process of application and development of orthotropic steel bridge panels, according to engineering application practice and research at home and abroad. It is difficult to repair and raise the overall cost of ownership, making it a management issue and a technical bottleneck that stymies the long-term development of steel bridges.

After large-scale new construction, developed countries have shifted their focus to the repair, reinforcement, and renovation of old buildings, and reconstruction is not only less expensive than new construction but also recovers the investment faster. Because of the current state of bridges, infrastructure investments should be directed toward the expansion and reconstruction of old and dangerous bridges. Durability assessment and life prediction are needed to develop scientifically developed repair, strengthening, and renovation plans for existing service structures. On the one hand, durability assessment and service life prediction can reveal the structure's potential hazards, and based on the results, the structure can be repaired and strengthened at an early stage of structural performance degradation, extending the structure's service life, reducing economic loss, and mitigating the serious energy and environmental problems caused by durability failure. On the other hand, it can reveal internal and external factors that affect the structure's life span. The existing deterministic methods are difficult to accurately consider the influence of the random characteristics of the abovementioned key factors and may obtain unsafe fatigue performance evaluation results. Aiming at the shortcomings of the existing deterministic evaluation methods, this article conducts systematic research on key issues such as fatigue load, crack growth, and fatigue reliability model and introduces the theory of random process and elastic-plastic fracture mechanics respectively to explore the effect of constant amplitude and random load. Based on the fatigue crack propagation characteristics, the probability and statistics theory and reliability theory are unified into the fatigue evaluation framework based on fracture mechanics, and a fatigue reliability evaluation method based on probabilistic fracture mechanics is proposed. Thus, targeted investments can be made according to the surrounding environment, usage, economic conditions, etc., which helps to improve the design level and construction quality of the project and improve the theory and method of new structural durability design.

2. Related Works

The research results of bridge health monitoring are becoming more mature, and some large bridges in the United States and abroad are equipped with various monitoring instruments and monitoring devices, as shown in Figure 1 for factors affecting bridge endurance life, primarily to monitor these factors. The first health monitoring systems were installed and researched in foreign countries in 1922 on the Ironton-Russell suspension bridge in the United States, which had undergone several repairs and reinforcements, so the relevant units installed health monitoring systems to monitor the stress changes of the bridge structure, and the bridge was operated safely for the next decades until it was demolished [1]. In addition to the installation of bridge health monitoring, research in the field of health monitoring has tended to be rich and mature, and bridge health monitoring has evolved in the direction of intelligence and digitalization in the current era of big data.

The material fracture prediction is closely related to the material type, chemical composition, and manufacturing process, and its magnitude is the key factor determining the fatigue crack propagation characteristics of the structural details of the steel bridge deck. The fracture parameter values of different steels are quite different and show significant random characteristics due to the influence of the inhomogeneity of the material microstructure. In foreign studies, literature [2] designed a bridge health monitoring system based on strain monitoring data, using the strain monitoring data collected to determine the stresses generated by live loads, to identify valuable parameters such as live load distribution factors and peaks, and to evaluate the structural health state of the bridge. Literature [3] investigated the improvement in the existing bridge monitoring system and proposed a method for information integration. The method uses a Bayesian probability model to obtain data and information from the structural health monitoring system to predict the probability of extreme values generation. This bridge health monitoring system has been applied to bridges in Wisconsin with good results. A method for adaptive identification of truss structures based on the Lyapunov method is proposed in the literature [4]. The Lyapunov method provides guaranteed convergence for parameter estimation in the identification. The finite element analysis method is used to identify the simulation model. The simulation results show that the adaptive estimation method can track the changes over time, thus providing monitoring of the degraded structure. Literature [5] utilized an enhanced structural health monitoring system using stream processing and artificial neural network techniques (SPAN Net) and applied it to a bridge in Bangkok. The system provides real-time monitoring and early warning mechanisms for bridge structures by applying wireless sensor networks, real-time data stream processing, and weighted attack maps based on measured bending strains.

Although Chinese bridge monitoring research is lagging behind that of other countries, bridge health monitoring researchers have conducted scientific research on health monitoring systems and practical research on various major bridge structures in China. Bridge health monitoring combined with machine learning and big data platforms are gradually emerging in today's wave of big data and artificial intelligence. Literature [6] proposed a method to evaluate the service status of bridge structures using a five-layer deep learning network and built an accurate finite element model of bridge structures based on bridge monitoring data. The pattern classification technique using neural networks was analysed using dynamic networks and genetic algorithms in literature [7], and its effectiveness in identifying structural damage of bridges was analysed in real tests, demonstrating the technique's feasibility.

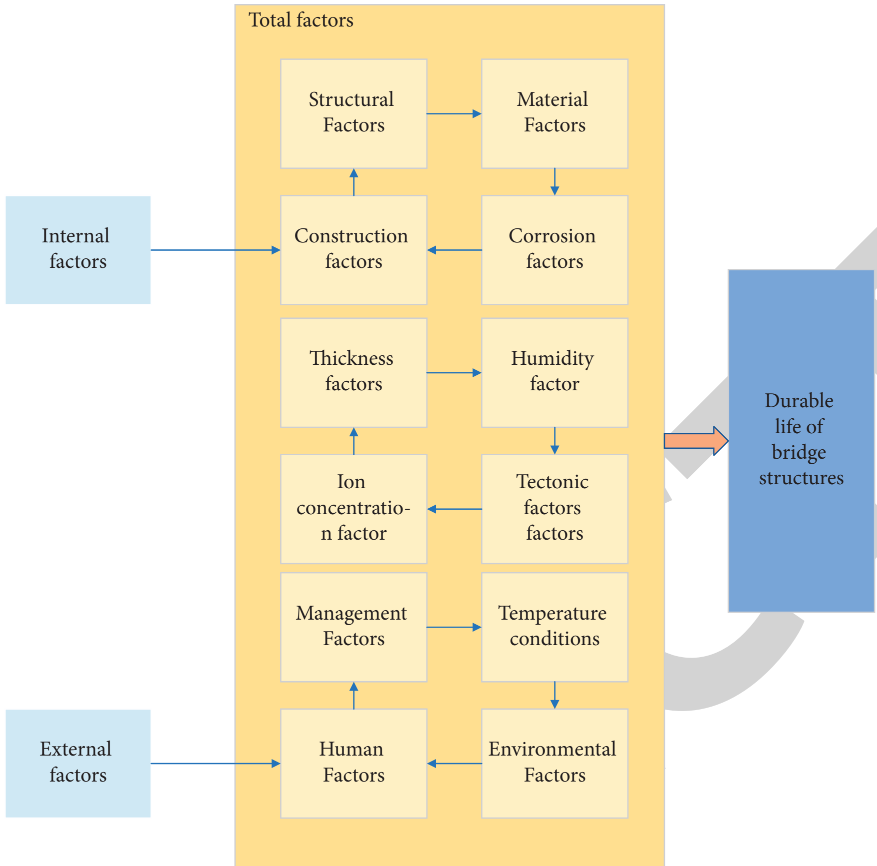

Figure 1: Factors affecting the durability life of bridges.

Literature [8] used radial basis function (RBF) neural networks to identify bridge damage and established guidelines for locating judged damage as well as an evaluation method for the identification effect. Literature [9] looked into a two-step method for damage detection based on a generalized regression neural network (GRNN), which is a variant of the radial basis (RBF) network with a faster training speed and a stronger nonlinear mapping capability, and network training can be completed instantly with high fitting accuracy. However, only a few typical simple bridge structures have been numerically simulated in the experimental validation stage, and there is still a significant gap in applying it to the damage identification of large bridge structures. The Korhonen clustering network was used in literature [10] to analyse isolated points of bridge monitoring data, as well as the analysis and early warning reference of bridge structure abnormalities based on this; the a priori model for bridge condition assessment was also established to explore the potential association rules among the attributes of bridge data, providing a data-supported basis for bridge condition assessment.

3. A Probabilistic Statistics-Based Approach to Bridge Life Prediction

3.1. Bridge Structure Durability Life Prediction Method. The service life of bridge structures has certain uncertainty due to the environment they are in and the level of corrosion stress. However, how to accurately predict the reliability of bridge structures during service; guide, overhaul, and improve their reliability; and ensure their service life under harsh environments is a concern for bridge durability researchers [11]. The establishment of a reliable theoretical relationship between the durability deterioration process and time, based on which the service life of bridge structures can be assessed qualitatively and quantitatively, is referred to as life prediction of bridge structures. Empirical prediction, comparative performance prediction, accelerated test prediction, mathematical model prediction, and probabilistic analysis (stochastic process) prediction are the main methods for life prediction of bridge structures in general, and these methods are often used interchangeably in practice, rather than just one. Due to the drawbacks of empirical and performance comparison prediction methods [12], such as low prediction reliability, large errors, and significant limitations in the application of new materials, three bridge structure durability prediction methods are widely used.

3.1.1. Accelerated Test Prediction Method. Accelerated testing is based on test simulations to increase the level of corrosion stress, such as increasing the temperature, humidity, and concentration of corrosive ions, to accelerate the deterioration process of bridge structure durability and shorten its actual service life. This method can predict the service life of reinforced concrete very well if the acceleration mechanism is reasonably designed, the test operation is reasonable, and the data collection method is correct [13]. But often in practice, due to the acceleration test mechanism and corrosion stress level and the actual engineering corrosion stress in the process of durable deterioration of reinforced concrete between the match to be clear, whether too high or too low scholars question the attitude, that is, the precise value of the acceleration factor (K) has ambiguity. According to the fatigue damage characteristics of orthotropic steel bridge decks, the effects of key factors such as materials, loads, and defects are comprehensively considered, and the fatigue reliability and time-varying laws of typical structural details during service as well as fatigue crack propagation characteristics are reasonably predicted. The evaluation method of the orthotropic steel bridge deck is the primary issue in fatigue evaluation. Figure 2 shows the accelerated experimental prediction method process.

3.1.2. Mathematical Model Prediction Method. The mathematical model prediction method is the most widely used in today's study of bridge structure life prediction, and it is primarily based on the steel corrosion model, which is embodied primarily through the carbonation and chloride ion diffusion theory and other calculation models, and it has now become an important life prediction tool. The accuracy and reliability of life prediction, on the other hand, are closely linked to the logic of mathematical models, the selection of material-related parameters, and the compatibility of environmental factors, and the results are somewhat absolute.

3.1.3. Probabilistic Analysis and Prediction Method. The probabilistic analysis prediction method expresses the relationship between the service life of bridge structures and time through the function of development evolution, and the prediction result is the non-mean service life (deterministic model), but the service life with a stochastic process, that is, the probability that the durability of bridge structures will fail at a certain service time point. The durability degradation of bridge structures is a changing process during the service life of bridge structures because it is the result of the coupling of various factors. For example, the hydration of $MgSO_4$ and cementitious materials has a double effect on bridge durability degradation. According to the need for durability assessment, the environment in which the structure is located should be investigated. Temperature, humidity, aggressive material gases, liquids and solids, freeze-thaw cycles and scouring, wear and tear, and other factors are all taken into account. The corresponding original design data and the survey of the completed acceptance data should both be completed at the same time. Meanwhile, the initial durability of the bridge structure is a continuous strengthening process with the addition of admixtures and dopants, and given this, the probabilistic analysis-based method of predicting the life of bridge structures is more reasonable than other methods. Furthermore, the service life prediction based on a deterministic model has certain ambiguity in the process of bridge structure life prediction, so it is necessary to use a probabilistic method to predict its service life. The probabilistic analysis prediction method is depicted in Figure 3.

The durability of bridge structures has always been the focus of scholars' attention. With the continuous research, scholars at home and abroad have a profound understanding of the durability degradation process and deterioration mechanism of bridge structures, and most of them adopt the methods related to accelerated corrosion and have achieved fruitful results [14]. However, the research on the durability of bridge structures is mostly concentrated in the field of general bridges, and relatively little research has been done on new construction materials. Along with the improvement in people's environmental awareness and the requirements of sustainable development, the research on the durability of green bridge structures and accelerated corrosion also needs to be further clarified, to lay a solid theoretical foundation for the promotion and application of green building materials.

Current methods of accelerated corrosion of bridge structures, particularly carbonation and chloride ions under the action of the accelerated corrosion mechanism, are more mature, and more research results based on the acceleration of steel corrosion method have also attracted more and more attention from scholars. However, the electrolyte used in the existing accelerated corrosion process is mostly an aggressive solution, but due to the lack of oxygen supply in the acceleration process, the deterioration mechanism of the reinforcing steel is distorted, and the model of reinforcing steel corrosion is questioned to some extent. There are many models for predicting the service life of bridge structures, but the majority of current research findings are based on a deterministic model, that is the service life under a specific corrosive environment or stress level. There is no denying that the erosion environment in which the bridge structure is situated changes over time, and that the corrosion stress level is also influenced by uncertainties. At the same time, the durability deterioration of the bridge structure is changing. For example, under the action of a single factor, durability is a gradual accumulation of the deterioration process, whereas under the action of multiple factors, the coupling of various factors sometimes slows down the deterioration rate, and sometimes accelerates it, both have a degree of uncertainty, so based on the deterministic model to predict the service life of the bridge, the use of the probabilistic analysis method as a reliability model for life prediction can better reflect the randomness of bridge structure durability deterioration due to various factors.

Overall, the main problems in the current study are as follows:

(1) At present, the research on the durability deterioration mechanism of bridge structures is mostly focused on ordinary silicate bridges, while there is little research based on green building materials, such as recycled bridge structures and magnesium chloride cement bridge structures to accelerate corrosion.

(2) In the accelerated corrosion study of bridge structures, especially based on the accelerated corrosion

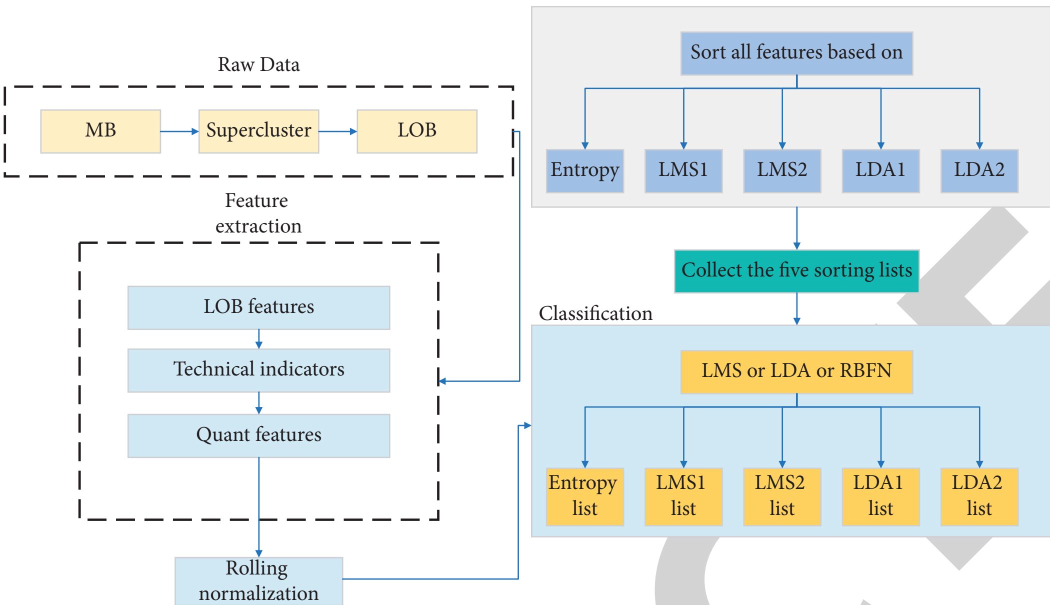

Figure 2: The flow of accelerated experimental prediction method.

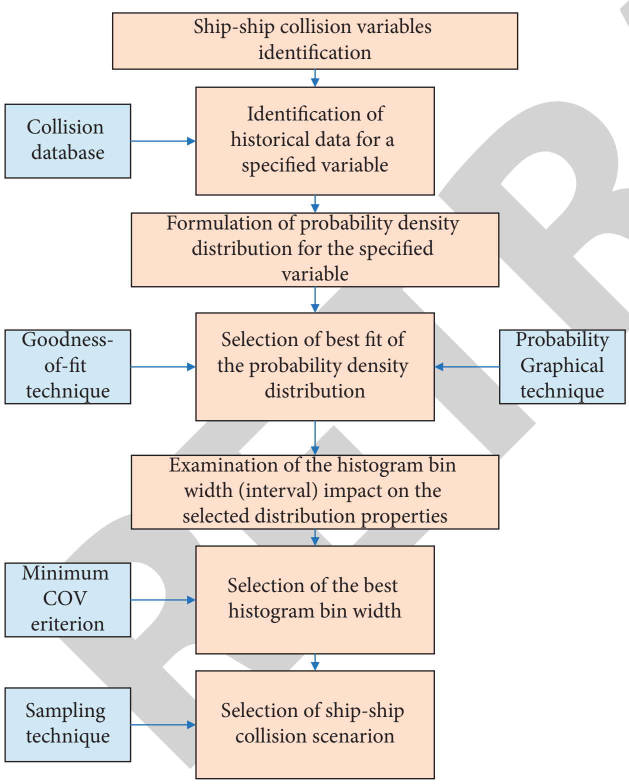

Figure 3: Probabilistic analysis prediction method flow.

test by electricity, the electrolyte mostly uses aggressive solutions; however, in the accelerated process with the bridge expansion and cracking, the solution is easy to penetrate the cracks resulting in the outflow of rust products, resulting in a certain ambiguity of the durability deterioration process of bridge structures under the effect of accelerated corrosion by electricity.

(3) There are many methods for life prediction of bridge structures, and the life prediction model based on stochastic analysis is practical, but the applicability of the probability function in the stochastic analysis method, the calculation of relevant parameters, and the accuracy of the prediction model need to be further determined.

(4) The model of the accelerated test prediction method has certain conditions of applicability, so under the premise of improving the accelerated corrosion mechanism, it will be more practical to explore the applicability and accuracy of life prediction of bridge structures based on the reliability analysis model.

Probabilistic statistical methods can reflect the factors affecting the durability life of bridge structures in a multi-level and all-around way; therefore, this article focuses on the application of probabilistic statistical methods in the durability prediction of bridge structures.

3.2. Probabilistic Statistical Methods. Considering the random nature of endurance life data, the correlation between before and after data, and the effectiveness of probabilistic statistics in the face of data and lack of theoretical models, this section will introduce models and methods based on probabilistic statistics used in the problem of predicting the endurance life of bridge structures. These include traditional probabilistic models, such as Bayesian classification models, conditional random field models, etc., and statistical learning theory, which is the basis of machine learning theory [15–17].

Based on the Bayesian formulation, numerous related theories have been developed. In this section, we introduce Bayesian decision theory in statistical pattern recognition and the Bayesian parameter estimation techniques [18] and

Bayesian learning techniques used to apply this decision theory in intrusion detection. The statistical decision theory with Bayesian decision-making as the core component is an important foundation of statistical pattern recognition, and the classifier designed based on it has the lowest classification error rate or risk, so it is often used as a criterion to measure the merits of other classifier design methods. When using this method to build a classification model, the following two prerequisites must be met: (1) the probability of the overall of each category of the sample needs to be known; and (2) the number of categories to be classified for decision-making needs to be known. The problem it solves is to determine the class to which the d-dimensional feature vector observed on the feature space $X = [x_1, x_2, x_3, ..., x_d]^T$ belongs, so it can be said that the Bayesian decision model-based intrusion detection technique combines both the feature space-based intrusion detection technique and the probabilistic statistics-based intrusion detection technique.

Bayesian decision-making based on the minimum error rate considers the posterior probability $P(x_i \mid X)$, which x_i denotes the category to which it belongs, and for the binary classification problem, $i = 1,\ 2$; then, based on the known probability of the overall of each category, this posterior probability is calculated by the Bayesian formula, to determine the category to which it belongs by the probability magnitude. The Bayesian formula is shown as follows:

$$P(x_i \mid X) = \frac{P(X \mid x_i)P(x_i)}{P(X)}, \tag{1}$$

where $P(x_i)$ is the prior probability x_i of the class, and $P(x_i \mid X)$ is the conditional probability of the observation X x_i under the class, $P(X)$ is a constant and generally need not be considered. In practice, the prior and conditional probabilities of each class are the premises of Bayesian decision theory. This requires estimation of the probability density function, that is, it requires the use of Bayesian parameter estimation or Bayesian learning to infer the overall distribution given a known sample set $P(x_i \mid D)$. Although the fuzzy-means clustering method based on soft partition can evaluate the durability of multiple samples to be evaluated and multiple evaluation indicators, due to the problem of data resources, although there are multiple samples, each sample has only two durability. The evaluation index can only show the durability of the component to a certain extent. Unlike traditional parameter estimation, which treats the parameter θ to be estimated as a constant, Bayesian parameter estimation treats θ as a random variable with a priori distribution. The basic idea is to use the past knowledge of θ to give a more realistic estimate of θ.

The Bayesian parameter estimation problem can be described as follows: first, the posterior probability density of the parameter θ under known data Y is calculated using the following Bayesian formula:

$$P(\theta \mid Y) = \frac{P(Y \mid \theta)P(\theta)}{P(Y)}, \tag{2}$$

where $P(\theta)$ is the known θ prior distribution and is the conditional probability of the sample Y under $P(Y \mid \theta)$ the parameters θ; then, the estimate $\theta = E(\theta \mid Y)$ is calculated according to the θ theorem.

Bayesian learning, on the other hand, solves directly for the overall distribution $P(x_i \mid Y)$ by finding the posterior probability of the parameter θ, which is expressed as follows:

$$P(x_i \mid Y) = \int P(x_i \mid X)P(X \mid Y)\mathrm{d}x_i. \tag{3}$$

Its learning process is roughly encapsulated as follows: for a fixed, it will completely determine the probability density of x; when the sample is observed; as the number of samples increases, the uncertainty of inference on will decrease. The basic theory of statistical pattern recognition is Bayesian decision theory, which has important implications for modelling and designing classifiers for bridge durability life prediction. Because Bayesian parameter estimation and Bayesian learning are both basic probabilistic statistical methods, they can be used in a variety of other durability life prediction models.

3.3. Experimental Design and Analysis of Results. For durability assessment of actual projects, the reliability of the current structural system should be evaluated not only from the system level but also considering the time effect and evaluating the reliability of the system at different moments [19]. The carbonization rate of different parts is different due to various factors, and considering the complexity of the carbonization process, if a single time-varying model is used to deal with the carbonization of the members, the results are too subjective and difficult to match with the specific actual project. Therefore, the Bayesian dynamic carbonation model can be used to make dynamic corrections to the respective carbonation based on the historical inspection data of each part of the real bridge and then calculate the reliability of the structural system based on the corrected carbonation depth (Figure 4).

In the figure $A_i(\alpha, \beta)$, it indicates the carbonation depth correction value of member i at the α moment after the moment update; $M_i(\alpha, \beta) = F[A_\mathrm{i}(k, k-1)]$ is the detection value of member i at the moment β; $N_i(\alpha, \beta)$ is the reliability index of member i at the moment α after the moment β update; $N(\alpha, \beta) = F[M_1(\alpha, \beta), \ldots, M_i(\alpha, \beta)]$ is the system reliability index at the moment α after the moment β update. From the flow chart, it can be seen that the Bayesian dynamic linear model completes the dynamic update correction of the carbonation depth, that is

$$A_i(\alpha, \beta) = F[A(k, k-1), M(i, k)]. \tag{4}$$

The component reliability calculation can be expressed as follows:

$$M_i(\alpha, \beta) = F[A_i(k, k-1)]. \tag{5}$$

And the differential equivalence recursive algorithm completes the calculation of the component reliability to the system reliability, that is

$$N(\alpha, \beta) = F[M_1(\alpha, \beta), \ldots, M_i(\alpha, \beta)]. \tag{6}$$

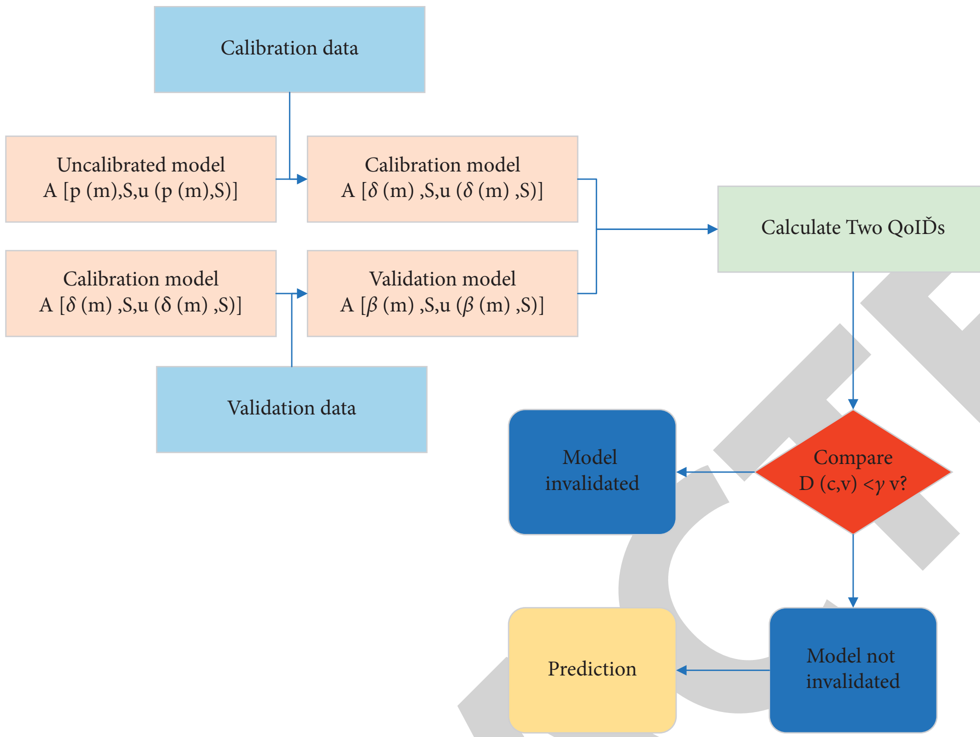

FIGURE 4: Flow chart of dynamic reliability assessment.

A top-bearing reinforced concrete box arch bridge with a calculated span of 81 m and a calculated vector height of 13.5 m was selected here. Due to the lack of bridge inspection data, it is difficult to collect the same bridge inspection data for the past years, so the rapid carbonation test of concrete was carried out in the laboratory to replace the actual measured data of the bridge with the test data. The stress state of the members in the test was determined according to the computational model, and Figure 5 shows the comparison of the carbonation depth of each specimen.

For reinforced concrete arch bridges, the main components can be divided into bridge tunnel system, arch column, main arch ring, etc. The carbonization model of different components is different due to different environments. The speed should be greater than the carbonization speed when there is no stress; while the main arch ring and the columns on the arch are mostly eccentric compression members, under appropriate compressive stress, the concrete is denser, which hinders the entry of carbon dioxide to a certain extent and slows down the carbonization speed. However, if the compressive stress is too large, cracks will occur inside, which may facilitate the entry of carbon dioxide and increase the carbonization rate instead.

The Bayesian dynamic linear model is used to correct and predict the carbonization depth. Taking the updated carbonization depth as the effect and the corresponding protective layer thickness as the resistance, according to the reliability calculation method, the reliability index of the component can be obtained at any time. The reliability index of the bridge system is obtained, and then the differential and equivalent recursive algorithm is used to obtain the reliability index of the bridge system after each update. It can be seen from Figure 6 that with the introduction of their respective test data, the reliability indicators of each component have been revised to different extents. On the one hand, some members become more reliable after the update, and some members become less reliable, which has little effect on the overall correction. It can also be seen from Figure 6 that the reliability changes of different components are different. If we use the reliability of components to evaluate the reliability of the system, not only because of the different selection of components, the evaluation results will also be

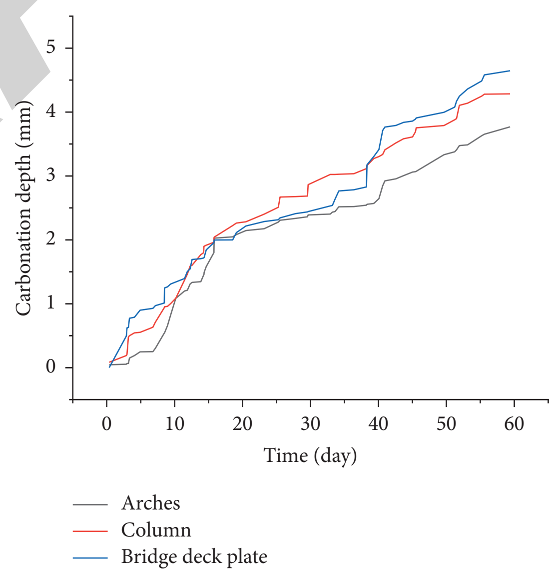

FIGURE 5: Comparison of the carbonization depth of specimens in each part.

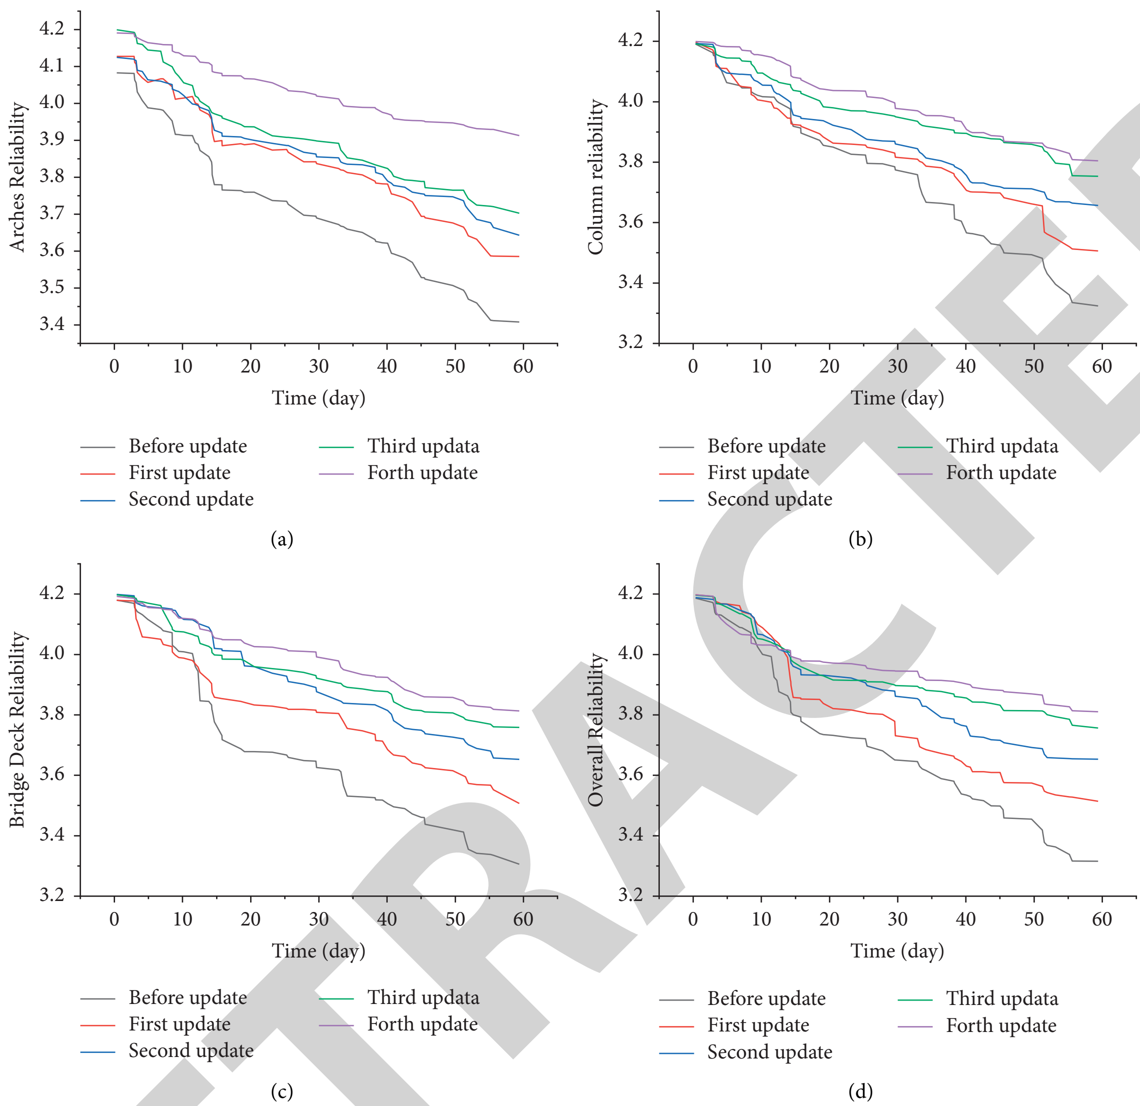

Figure 6: Comparison of the reliability of each component of the bridge.

different, and no matter how you choose, the reliability of components is always greater than the reliability of the system, which is dangerous to a certain extent.

Therefore, when evaluating the durability of bridge structures, it is not only necessary to start from the system level to solve the bias brought by replacing the system with the components, but also to reduce the subjective error by making comprehensive use of previous empirical models and engineering actual measurement data. In the absence of a large amount of statistical information on carbonation, this method can be effectively adapted to each specific project to make a more reliable assessment, and also has an important guiding role for the later maintenance and strengthening.

The reliability of the system is influenced by many factors, not only the reliability of each member, but also its correlation coefficient, which depends on the limit state equation of each member and is influenced by the thickness of the protective layer and the depth of carbonation. The influence of the reliability of each member on the reliability of the system is studied to determine the sensitivity of each member to the system and to provide guidance for the design and testing of reinforcement. The material fracture prediction is closely related to the material type, chemical composition, and manufacturing process, and its magnitude is the key factor determining the fatigue crack propagation characteristics of the structural details of the steel bridge deck. The fracture parameter values of different steels are quite different and show significant random characteristics due to the influence of the inhomogeneity of the material microstructure. The thickness of the protective layer of the members directly affects the reliability of the members. The thickness of the protective layer of each member is changed from 24 mm to 36 mm, and the thickness of the protective layer of one member is changed each time, and the reliability index is calculated on the 30th day after the fourth update. $\beta = 3.24$.

From Figure 7(a), it can be seen that when the thickness of the protective layer is 30 mm, the change in the thickness

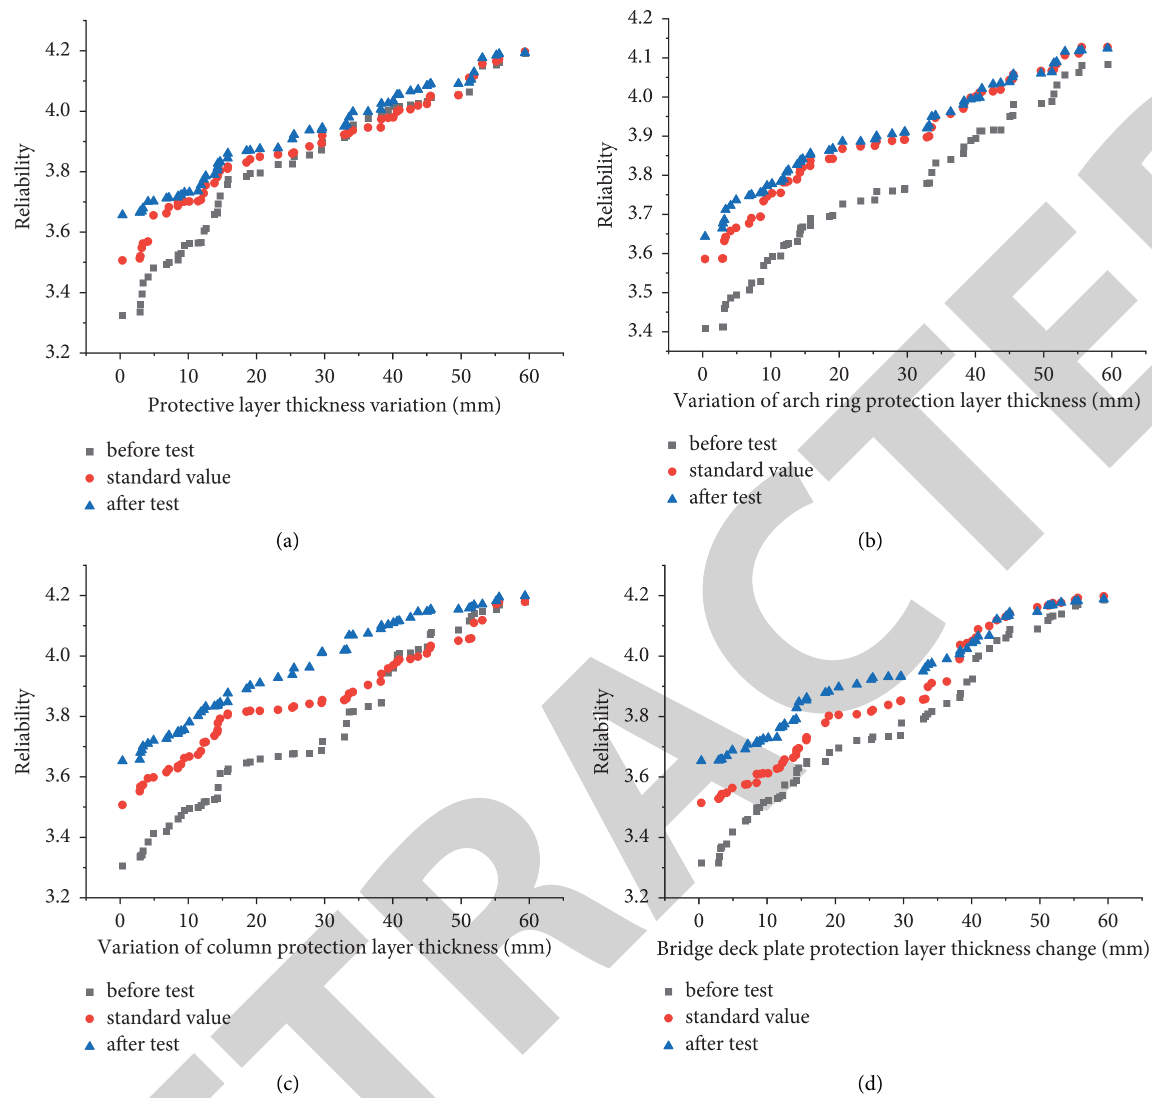

Figure 7: Effect of the thickness of the protective layer on the reliability of the system. (a) Protective layer thickness variation (mm), (b) variation of arch ring protection layer thickness (mm), (c) variation of column protective layer thickness (mm), and (d) bridge deck plate protection layer thickness change (mm).

of the protective layer of the bridge deck has the greatest influence on the reliability of the system and increasing the thickness of the protective layer of the bridge deck within a certain range can improve the reliability of the system, while increasing the thickness of the protective layer of the arch ring and column, the reliability of the system is not obvious; if the thickness of the protective layer of the bridge deck is reduced, the reliability of the system will be reduced immediately, while the thickness of the protective layer of the arch ring and column will be reduced by a certain amount before the reliability of the system decreases sharply. After a certain amount, the reliability of the system will drop sharply. When the thickness of the protective layer remains unchanged, the reliability index of the bridge deck is the lowest, and the reliability change of the bridge deck has the greatest influence on the reliability of the system, and the component with the greatest influence on the reliability of the system or the component with the lowest reliability, in order to further investigate the change law, makes the change of the reliability caused by the thickness of the respective protective layer and the change of the reliability of the corresponding system, as shown in Figures 7(b)–7(d), where Figures 7(b) and 7(c) make the auxiliary line $y =$. From the graph, it can be seen that the system reliability index is always lower than the reliability index of each member, according to the analysis of Figures 7(c) and 7(d), when the thickness of the protection layer of column or arch ring increases, the reliability index of the bridge deck remains unchanged, and the lowest reliability index is the bridge deck; therefore, when the thickness of the protection layer of column and arch ring increases, the system reliability can only be infinitely close to that of the bridge deck. The reliability of the system can only be infinitely close to the reliability index of the bridge deck; while the reliability of the

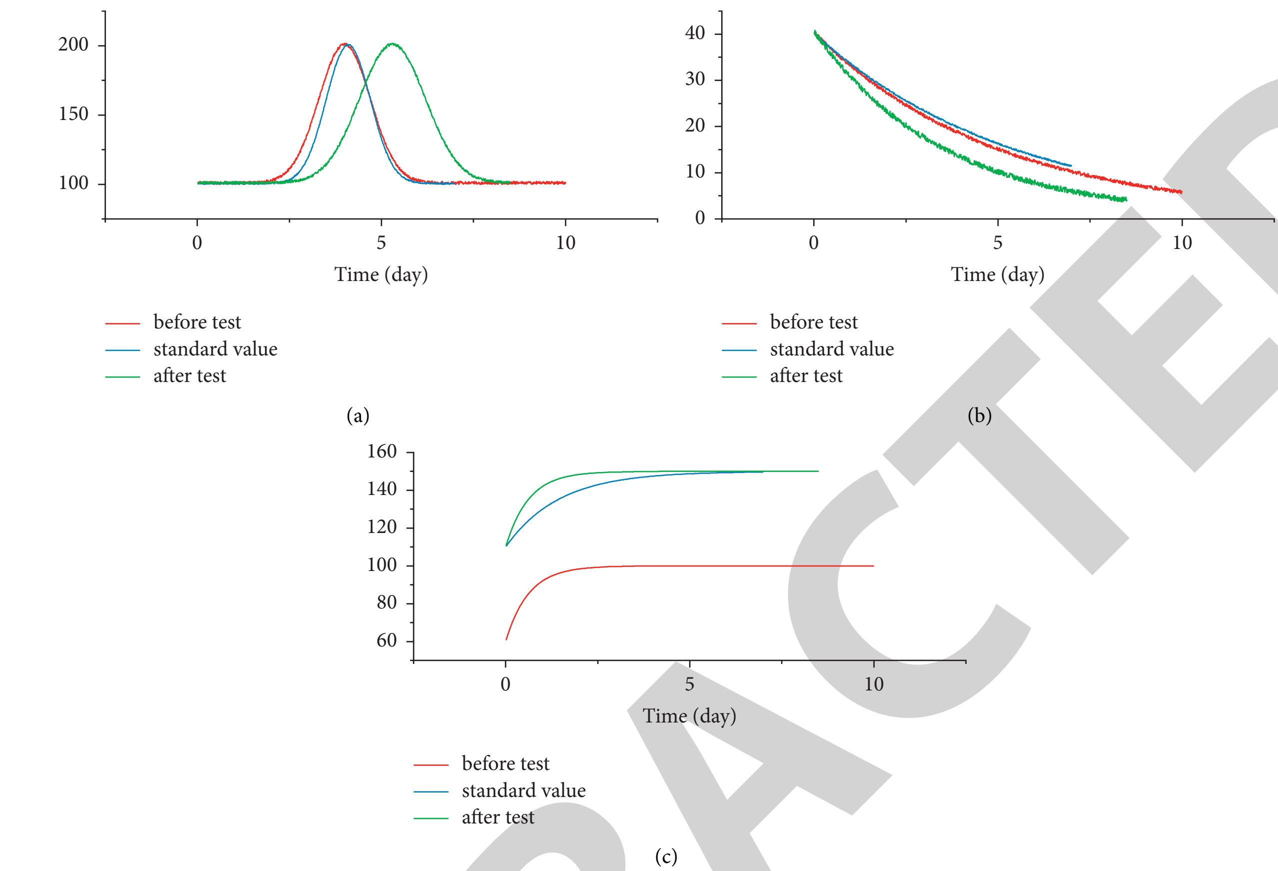

Figure 8: Comparison of reliability indicators after the maintenance of different components. (a) Maintenance of bridge deck, (b) maintenance of column, and (c) maintenance of arches.

bridge deck is still the lowest when the thickness of the protective layer of the column or the arch ring is reduced, and the change of the system reliability is not much when the thickness of the protective layer is reduced to the reliability index lower than that of the bridge deck, the system reliability index will be reduced with the reliability of the arch ring or the column; from Figure 7(d), it can be seen that for the bridge deck, the reliability is lower than that of the arch ring and the column because the reliability is lower than that of the bridge deck. Therefore, the change of protection layer thickness directly affects the system reliability index, and when the protection thickness increases to the extent that the reliability index of the deck plate is larger than that of the column, the change in system reliability gradually becomes smaller and lower than that of the column, which has the lowest member reliability at this time.

It can be seen from Figures 8(a) and 8(b) that when there is arch or column maintenance, although the member reliability can be temporarily stopped, the improvement in the system is not large, because at this time the system has the greatest impact on the components for the lowest reliability of the bridge deck, so the arch and column maintenance on the system is not much, and from Figure 8(c), it can be seen that when there is bridge deck maintenance, the system reliability decreases significantly slower, indicating that the maintenance of the bridge deck plate has a certain slowing effect on the system, but the system reliability is still decreasing at this time, which also shows that the members are only part of the system, and the influence of a single member on the system is limited. The maintenance of the deck slab has a more obvious improvement on the system's durability. According to the calculation results, the system reliability index is improved by 2.55% after the maintenance of the deck slab, while the arch ring and column are improved by 0.15% and 0.29%, respectively, after the maintenance. Therefore, when maintaining the bridge, the deck plate should be considered first, and if the reliability is no longer the lowest after the deck plate maintenance, the member with the lowest reliability at that moment should be considered for maintenance if maintenance is still needed.

Because the maintenance of the bridge deck plate has a more obvious impact on the system's reliability, the reliability index comparison is calculated separately when the bridge deck is maintained at different carbonation times, as shown in the experiment above, to investigate the impact of the maintenance time point on the change in reliability. The a priori model is modified by combining the testing data, based on the Bayesian dynamic linear model, so that the initial general a priori model can continuously incorporate the individual characteristics of the structure and the results are closer to the actual conditions. According to the analysis, the reliability index change curve shifts to the right after maintenance, and because the distance shifted is the same, the final effect of maintenance remains the same as long as maintenance is performed before the failure of the member; however, the system's reliability still decreases when maintenance is performed on a single member, so maintenance of the member before the system's failure does not guarantee.

4. Conclusion

The ability of a structure or member to maintain its safety and serviceability within the design life is reflected in its durability. In this article, a combination of experimental analysis, finite element simulation, and theoretical analysis is used to investigate how to incorporate the carbonation model of concrete members with individual characteristics, the durability and reliability of members and their time-varying properties, and the system durability and reliability dyads, all while considering the working conditions of concrete bridges in actual services, such as loading, cracking, and even acid rain erosion. The research looked into dynamic reliability assessment methods. The following are the main conclusions: (1) The carbonation rate of concrete decreases under compressive stress, and the degree of reduction is related to the ratio of compressive stress to ultimate compressive stress; tensile stress facilitates carbonation, and the higher the tensile stress, the faster the carbonation rate. (2) The similarity of the mechanism of action between the carbon dioxide diffusion model and the heat conduction equation is revealed by comparing the two, allowing a finite element model of concrete with cracks to be constructed and the effects of crack width and depth on the carbonation of concrete to be discussed. (3) The a priori model is modified based on the Bayesian dynamic linear model by combining the testing data, so that the initial general a priori model can continuously incorporate the individual characteristics of the structure, and the results are closer to the actual conditions; in the meantime, in response to the finding that the traditional Bayesian dynamic linear model may have a shortage of gradually increasing deviation between the predicted data and the measured data, the a priori model is modified by combining the testing data, so that the initial general idea of stepwise correction of the a priori model and prediction model is proposed, the error correction expression is given, and the idea's effectiveness is tested using the algorithm. (4) By combining the Bayesian dynamic model and the differential equivalence recursive algorithm, a dynamic assessment method for the bridge system's durability is presented, which can dynamically update the structure's durability condition at any time based on inspection data feedback. The algorithm's analysis reveals that there is a risk of replacing system evaluation with component evaluation, and that the components with the lowest reliability in tandem mode have the greatest influence on the system, which should be considered during inspection and maintenance.

The central issue in finance is how to select a portfolio in the financial market. The traditional artificial fish swarm algorithm (AFSA) is optimized in this paper, and the improved AFSA is used to solve the portfolio model. This model generates a uniform distribution operator using uniform distribution and combines it with the basic fish swarm algorithm. Uniform variation occurs when the variance of the optimal value of continuous convergence is within the allowable error. In this manner, the fish can escape the trap of the local extremum, obtaining the global optimal state. To validate the feasibility of improving AFSA, this paper conducts simulation experiments on portfolio problems using MATLAB tools. Experiments show that this model has an accuracy of 93.56 percent, which is 8.43 percent higher than that of the NSGA-II model and 3.76 percent higher than that of the multiobjective optimization model. The experiment shows that the algorithm in this paper can solve these types of problems well and that, using this model, the optimal portfolio investment decision scheme satisfying investors can be obtained. The optimized AFSA presented in this paper can serve as an important reference for investment portfolios and has a wide range of application possibilities in the investment market.

1. Introduction

With the increasing trend of economic globalization and financial integration, the regional economy has become more market-oriented and transparent. Market competition is all around us, and it is becoming more fierce and diverse [1]. While considering the enormous benefits that investment can bring, business should be prepared for the potential risks that come with it. During the capital investment process, rational investors will consider how to allocate a certain amount of capital to thousands of risky securities in order to spread the risk as widely as possible and obtain the greatest benefit [2]. The securities market, on the other hand, is a financial trading market where risks and interests coexist. Its risk changes are influenced by a variety of factors, including politics, economic fluctuations, policy regulation, and company development, making it difficult to grasp its essential characteristics [3]. Because of the volatile economic environment, the types of risks faced by investors in investment also exhibit diversification and variability, and the investment risk is increasing day by day. Individual investors and financial institutions face a central problem in determining how to allocate resources optimally in an uncertain environment in order to maximize income or minimize risk, that is, how to make portfolio selection in the financial market [4]. With the ongoing development of the market economy, investors from all walks of life are frequently confronted with the portfolio problem when engaging in asset investment activities. Portfolio optimization is extremely important in the financial field and has an incalculable impact on the growth of the market economy. Many scholars are currently concerned about it [5]. In today's volatile market, how to assist investors in effectively avoiding risks has gradually become the focus of portfolio research.

The central issue in finance is how to select an investment portfolio in the financial market. The goal of investors is to maximize benefits in a low-risk environment or to bear the least amount of risk while maximizing returns as much as possible. This establishes the need for investors to evaluate the benefits of securities investment and diversify asset risk as much as possible through portfolio model optimization [6]. Because of their high inspiration, effectiveness, and high matching with computer language, artificial intelligence algorithms have piqued the interest and application of researchers in recent years. AFSA (artificial fish swarm algorithm) is a swarm intelligence algorithm made up of many simple autonomous bodies. Each autonomous body is self-contained and can interact with information in its environment, utilizing a novel bottom-up search concept [7]. AFSA employs a novel concept that distinguishes it from other optimization algorithms. AFSA differs from traditional design and solution methods from the specific implementation of the algorithm to the overall design concept, but it can be well integrated with other traditional algorithms at the same time. AFSA's search process is divided into four stages: foraging behavior, tail chasing behavior, clustering behavior [8], and default behavior. The characteristics of AFSA, such as low initial requirements, strong robustness, strong ability to get rid of local extremum, and global optimization, can bring us an opportunity to solve the portfolio optimization problem. It is precisely because of the superior characteristics of AFSA that AFSA has attracted great interest and extensive attention of scholars from all walks of life at home and abroad since it was proposed. With the deepening of the research on this algorithm, many improved algorithms are applied, and the application field is gradually expanded. Therefore, this paper applies AFSA to the optimization of portfolio model. The innovations of this paper are as follows:

(1) The AFSA algorithm is applied to financial market portfolio optimization in this paper, and the original AFSA is improved. The adaptive improvement concept is used in this paper to improve the field of view and step size in the traditional AFSA. The field of view and step size gradually change from large to small to meet the needs of various states of algorithm optimization. Simultaneously, AFSA is integrated with a free search algorithm, allowing it to be applied to data in a portfolio problem to produce a better portfolio.

(2) In this paper, AFSA is used to solve the portfolio optimization problem in the investment field, and the algorithm can jump out of the trap of local extreme value in the optimization process, so as to achieve the optimal value. At the same time, the classical test function is used for simulation verification, and a variety of investment decision-making schemes that meet the requirements of investors are obtained. This study broadens the research field of portfolio and AFSA to a certain extent.

2. Related Work

As a nonlinear programming problem, the research goal of portfolio problem is to allocate the weight to the individuals of a specific asset set, so as to maximize the total return or minimize the total risk. Nowadays, many scholars use swarm intelligence method to solve this kind of problems. At present, the research and application of AFSA have penetrated into many disciplines and were used to solve practical problems. The algorithm has become a cutting-edge research topic with high research value. Some scholars have studied the application of AFSA in combinatorial optimization, but the research in this field needs to be further deepened.

For solving the nonlinear foreign exchange portfolio multiobjective optimization problem, Neumuller and Rothschild added liquidity conditions and proposed a unified method for solving portfolios [9]. Howton et al. carried out measurement research on the risk of investment portfolio, but there is still strong uncertainty in the measurement of investment return and risk [10]. Vikas et al. proposed the optimal portfolio model under the probability criterion. However, there is no explicit discussion on investment risk, and investment risk is implicitly described by the covariance of returns [5]. Au-Yeung and Chan used a compromise algorithm to solve portfolios with linear transaction costs [11]. Low et al. studied the relative effectiveness of proxy securities, the equilibrium and disequilibrium of portfolio investment, the interaction between investment decision-making and capital structure optimization, and portfolio selection under financing constraints [12]. Bekiros et al. studied a multiperiod portfolio optimization problem and algorithm with feedback control in a fuzzy environment [13]. Sabine finally established a multiobjective nonlinear programming model with transaction fees by adding another objective to generate a multiobjective function of nonlinear programming under the premise of including the objectives of rate of return, risk, liquidity, and so forth [14]. In order to improve the deficiencies of variance model, Eslamloueyan and Jafari introduced conditional value-at-risk to measure asset investment risk and established a multiobjective investment optimization model. Experiments show that the model can improve the ability of investors to manage investment risks [15]. Based on the subjective expected utility theory, Corradin constructed the dynamic prospect theory value objective function model by using the dynamic aversion coefficient and the wealth reference point; at the same time, considering the opportunity constraints to ensure the capital security of investors, the multifrequency vibration mutation particle swarm algorithm was used to analyze the model. Experiments have proved that it has good feasibility in the formulation of practical investment decisions [16]. In order to simplify the covariance matrix, Luque et al. introduced a multifactor tool. Experiments have verified that the method can effectively solve the large-scale investment portfolio problem [17]. Jappelli and Padula reviewed the evolution, improvement, integration with other algorithms, and applications of AFSA in various fields in recent years [18].

The research of these algorithms has played a positive role in promoting the solution of portfolio model. This paper makes a relatively in-depth study on the relevant literature and puts forward the financial market portfolio optimization model based on AFSA. In this paper, the field of vision and step size in traditional AFSA are improved by self-adaptation, and the field of vision and step size are gradually reduced from large to small, so that it can meet the different state needs of algorithm optimization. Try to use standardized and random selection behavior to add variation factors and improve the search strategy of foraging behavior, and then iterate through roulette to select the best of the whole fish school, so as to solve the problem of accuracy and stability. The simulation results show that the algorithm in this paper has good performance and can solve the problem of portfolio optimization.

3. Methodology

3.1. Financial Market Portfolio. The rational allocation of various assets to best meet the investors' trade-off between risks and benefits is referred to as portfolio management. In finance, portfolio theory is a key asset management theory. During the early stages of portfolio theory development, investors primarily used diversification as an investment strategy, making decisions based on their understanding of market information as well as their historical experience and skills [19]. According to this theory, the risks in portfolio problems decrease as the number of assets in the portfolio decision increases, and a diversified portfolio of assets with very low correlation can effectively reduce the risks. Investing behavior is frequently a long-term process for investors. In general, a portfolio is a research method that allows investors to correctly choose the distribution ratio of capital investment when confronted with multiple capital options in order to maximize profits while minimizing risks. Modern finance and modern portfolio theory are built around the portfolio problem [20]. This problem discusses how to rationally distribute an investor's wealth among various assets in order to achieve the goal of stable and rapid capital growth while also controlling investment risks. Effective portfolio must meet the two following conditions: ① Risk is minimized under the given expected rate of return. ② Under the condition of given risk, the expected rate of return is maximized. All efficient portfolios constitute efficient boundaries or efficient frontiers.

Investment risk is the possibility that the expected investment income will be lost due to the fluctuation of the invested assets as a result of objective factors such as the market environment. The manner in which an investment is made determines the risk of the investment. According to the causes of the risk, we can usually divide the risk into market risk, credit risk, liquidity risk, and operational risk. In a stochastic uncertain investment environment, the return on risky assets is typically assumed to be a random variable. Based on historical asset return data, investors can accurately predict the probability distribution of their future returns. The term "risk" refers to the fact that the rate of return on assets is uncertain [21]. The term "risk-free assets" refers to assets with a guaranteed rate of return. Risk-free assets have at least two characteristics: fixed income and no risk of default. In actual investment activities, portfolio investment, as opposed to single asset investment, can play a role in dispersing overall investment risk, so portfolio investment is a common problem in financial activities. The goal of an investor's investment is to realize consistent and rapid growth of their funds while effectively managing investment risks. During this time, investors must constantly readjust their wealth in order to realize their investment intention, that is, to minimize risks and maximize returns. Any investor wants to maximize his return on investment, but higher returns come with higher risks. The investment decision-making process is a trade-off between yield and risk, which is a decision-making problem with two objectives. The reason for building a portfolio is to reduce the investment risk to a certain extent. Investors can find a trade-off point between the investment income and the corresponding investment risk in the form of portfolio, so as to maximize the total income as much as possible when the investment risk is certain or minimize the investment risk as much as possible when the income is certain.

3.2. Portfolio Optimization. The so-called optimization algorithm, in fact, describes a search process or rule, and it is based on a certain idea or mechanism, and through certain search rules and ways, it can obtain the solution to the problem that users want. Combinatorial optimization is one of the optimization problems. It usually refers to the optimization process of finding the optimal arrangement, grouping, sequence, or screening of discrete events through the study of mathematical methods or finding the optimal solution of the objective function from a limited number of feasible solutions. When optimizing the objective function, the objective function with constraints is often involved, so the solution process is complicated. With the development of global economy, the risk of financial market is also increasing. At the same time, with the development of computer technology and the explosive growth of data in solving practical problems, the traditional mathematical solution has been unable to solve practical problems. Therefore, the use of artificial intelligence technology to solve combinatorial optimization problems arises at the historic moment. At present, AFSA has been widely used. In the research field of mathematical theory, some progress has been made in optimizing the objective function by AFSA, and people have paid attention to solving constrained combinatorial optimization problems. AFSA is a new swarm intelligence optimization algorithm based on simulating biological behavior. In the optimization algorithm, the concept of animal autonomy is introduced, and the bottom-up design idea is used, thus forming a new intelligent algorithm.

The intelligent algorithm not only reduces the labor of solving by hand but also lacks the precision of solving by hand. We can quickly find useful information hidden in a large number of data sets, including rules, concepts, patterns, and rules, by combining computer technology and a combinatorial optimization model. Traditional portfolio models are based on probability theory and treat problem uncertainty as a random phenomenon. However, there is a lot of uncertainty in the securities market. Fuzziness is more important than randomness in the field of subjective cognition. The modern portfolio invests in risk diversification and employs quantitative research methods to determine the optimal portfolio investment ratio. The risk of the portfolio decreases as the number of investment types in the portfolio increases. The primary goal of studying portfolio models is to learn how to control the distribution ratio of a portfolio in order to maximize its return. The algorithm is primarily used to rigorously describe a program's iterative steps to solve problems, and it is a generalized general program to solve problems step by step. For an arbitrary given problem, we say it can solve the example if there is such a method that can find the answer to the given problem after a certain step. During the investment process, investors must consider the expected return rate as well as the potential risk rate of purchasing securities. The portfolio model must be optimized in order to provide more objective and optimal decisions. The schematic diagram of optimization algorithm in this paper is shown in Figure 1.

In order to diversify the investment risk and obtain appropriate investment income, investors often use portfolio investment, that is, invest a sum of money in several different securities at the same time. The expression of mean-variance plays a very important role in the construction of portfolio model, providing an objective research tool for rational investors, and is the representative of current portfolio theory. In the mean-variance model, the expected return rate is the expected value of the return rate of the portfolio, and the expected risk refers to the variance of the return rate of the portfolio. Although the mean variance has laid the foundation of modern portfolio theory and has been widely recognized and applied, it still has some limitations. For example: ① Variance or standard deviation cannot determine the direction of income deviation and the possibility of future risks of investment, which are more concerned by investors. ② Generally, the return on assets in the actual market cannot meet the condition that it must conform to the normal distribution, which is a strict premise. ③ The investment portfolio model based on this theory has a large amount of calculation. The main innovation of the statistical analysis method of mean-variance probability is to quantify the income risk in the portfolio problem. Because the income and risk in the investment process are random and uncertain, it is better to use random variables in mathematical statistics for statistical analysis. The mean-variance model assumes that investors are risk-averse. Rational investors always hope to obtain the maximum expected return under the condition of restraining the risk and minimize the investment risk under the condition of restraining the expected return. A portfolio with this nature is called an effective portfolio. Compared with allowing short selling, when using Markowitz mean-variance model to select the optimal investment proportion vector under the condition of not allowing short selling, the opportunity space of portfolio will often be reduced. However, to a certain extent, not allowing short selling can reduce market risks and investors' risks. Therefore, short selling is often not allowed in underdeveloped markets.

3.3. Construction of Portfolio Optimization Model in Financial Market Based on AFSA. Artificial fish can realize the mutual conversion of these behaviors at different times through perception of the environment; that is, they can realize their own behavior through behavior evaluation. The food concentration and crowding distance are used to evaluate behavior. Artificial fish continue to move towards areas with high food concentration but are not overcrowded; then choose the best or better behavior, and finally realize the fish swarm convergence. Traditional AFSA has a number of flaws. For example, a fixed field of vision and step size may cause convergence speed to be slow or convergence accuracy to fail, and it may sometimes fall into the local extreme value and fail to reach the global optimum. Furthermore, the algorithm's mathematical foundation is lacking as is the corresponding theoretical analysis. Based on the shortcomings of the traditional AFSA, this section improves the financial market portfolio one by one. The basic strategy for artificial fish movement in this paper is no longer applicable. As a result, this paper proposes a normalization process to address the overflow problem of feasible solutions and employs dynamic vision and step size to improve the search ability of the fish swarm algorithm, avoiding local extremum and increasing optimization accuracy. When a typical transaction cost function is introduced, the model's constraint function becomes nonlinear, and the effective solution set becomes nonconvex and nonconcave, indicating that the search space is irregular. This necessitates using a highly robust algorithm that avoids falling into the local optimum. The flow chart of the improved free search algorithm of artificial fish swarm is shown in Figure 2.

The basic alternate behavior is foraging behavior. If you cannot find a better state than the current one in the process of clustering or rear-end collision, you will do foraging behavior. In foraging behavior, if you cannot find a better state than yourself, you will randomly select a location to update. This will lead to retrogression in the process of optimization. In view of this situation, the solution of this paper is to regard the current solution as a vector, and the next position is no longer obtained randomly, but offset the random angle based on the original direction. The point where AFSA triggers the uniform mutation of the fish school is that when the difference of the global optimal value in the bulletin board for several consecutive times is very small and the number of optimization iterations is not reached, the fish school begins to produce uniform mutation and generates a new fish school state. In this paper, the fitness of individuals is measured by an evaluation function based on ranking. Evaluation function is used to set a probability for each chromosome in the population, so that the probability of this chromosome being selected is proportional to its adaptability to other chromosomes in the population. That is, through roulette, the chromosome with strong adaptability is selected to have a greater chance of producing offspring. In the process of applying the algorithm, this paper tries to reduce the number of individuals and scale of the fish school as much as possible on the premise of ensuring the convergence of the stable algorithm. In this algorithm, with more fish swarm individuals set, the frequency of information exchange between artificial fish individuals will increase, and the convergence speed of the algorithm will be accelerated, so as to better jump out of the local extreme value. However, the amount of calculation and optimization

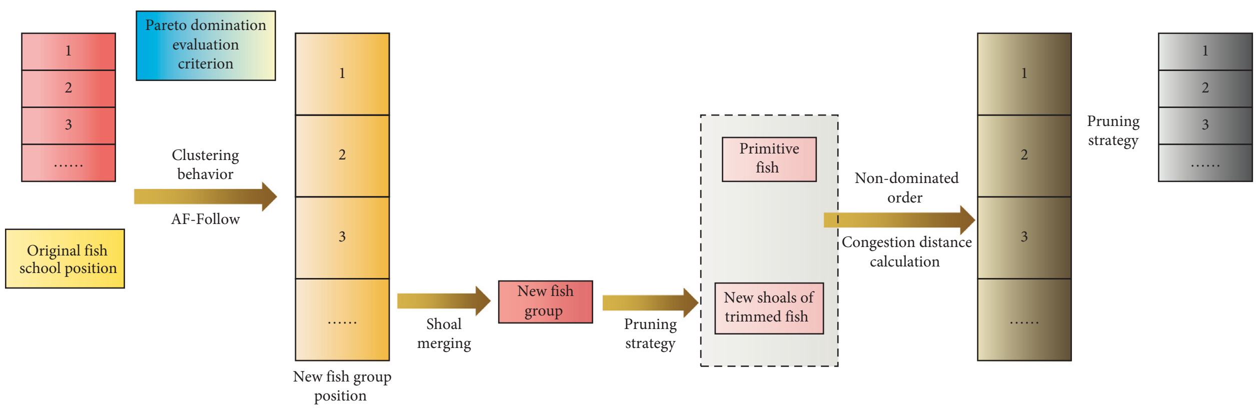

Figure 1: Schematic diagram of the optimization algorithm in this paper.

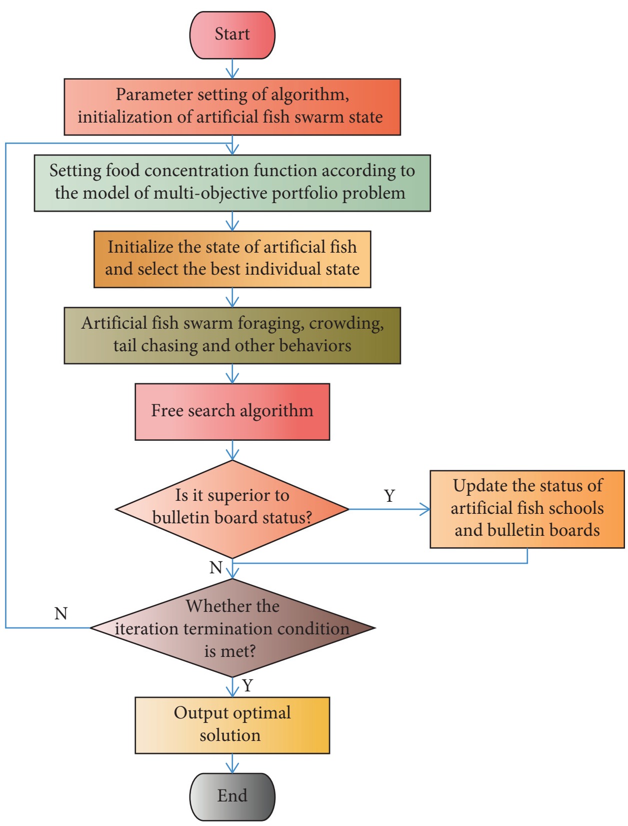

Figure 2: Process of the improved artificial fish free search algorithm.

time in each optimization iteration of the algorithm are also increased. Therefore, reasonably specifying the size of fish swarm is the key to improve the efficiency of the algorithm. In the past, artificial fish swarms did not consider individuals with poor search effect in the population. In this regard, this paper uses roulette to screen according to the fitness function value of each individual and seeks individuals with strong ability to iterate to the next generation with a large probability. AFSA embodies the natural law of survival of the fittest for all fish groups throughout the evolution of animals. Suppose that the i-th individual x_i in the artificial fish swarm is given a probability P_b of mutation; randomly select the subelement x_{ij} at position j in x_i to mutate it.

$$\begin{aligned} &\text{if } rand < P_b,\\ &x_{ij} = rand \\ &x_{i/\text{next}} = \text{norm}\left(x_{i/\text{next}}\right). \end{aligned} \tag{1}$$

The basic fish swarm algorithm selects and randomly generates a new solution after it is not optimized, which may lead to the regression of the solution. This paper uses the following formula to deal with it:

$$\begin{aligned} x_{i/\text{next}} &= \begin{cases} x_i + \left(x_v - x_i\right) * \text{dis}\left(x_v - x_i\right); & \text{if } Y_i > Y,\\ \text{ob}\left(x_i\right); & \text{else if } Y_{ob\left(x_i\right)} > Y,\\ x_i; & \text{else,} \end{cases}\\ x_{i/\text{next}} &= \text{norm}\left(x_{i/\text{next}}\right).. \end{aligned} \tag{2}$$

In the above formula, $ob\left(x_i\right)$ is the vector obtained by taking x_i as a direction vector and offsetting it by a certain angle. According to the fitness function value, the artificial fish individuals with strong optimization ability are screened out by roulette to enter the next generation.

$$\text{fish} - \text{swarm}_{i/\text{next}} = \text{roullete}\left(\text{fish} - \text{swarm}_i\right). \tag{3}$$

Suppose that investors consider four decision-making factors: wealth, risk, skewness, and kurtosis of the portfolio terminal. It is required to maximize the terminal wealth and cumulative skewness of the portfolio and minimize the cumulative risk and kurtosis of the portfolio. According to the uniform mutation operator in genetic algorithm, the mutation characteristics are combined with AFSA, so that the fish swarm algorithm has the same mutation ability, and it can avoid falling into local extremum, which is more conducive to the fish swarm reaching the global optimum in the shortest time. A single error index cannot fully evaluate the prediction effect of the model. Therefore, MAE (mean absolute error), RMSE (root mean square error), and CTR (correct trend rate) are introduced to evaluate the prediction accuracy, and the running time of the algorithm is used to evaluate the convergence speed. Its calculation formula is as follows:

$$\mathrm{MAE}=\frac{\sum_{i=1}^{n}\left|y_i'-y_i\right|}{n},$$
$$\mathrm{RMSE}=\sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(y_i'-y_i\right),n} \qquad (4)$$
$$\mathrm{CTR}=\frac{\sum_{i=1}^{n}\mathrm{CTR}_i}{n}.$$

In the above formula, y_i and R_i are the income of the asset on the current day and the previous day, respectively, and i is the return of the asset on the i day; namely,

$$R_i=\frac{y_i-y_i-1}{y_i-1}\quad i=2,\ldots,n=220. \qquad (5)$$

The expected rate of return is

$$\frac{y_i'-y_i-1}{y_i-1}. \qquad (6)$$

Combined with the portfolio model constraint function studied in this paper, an outlier penalty function is introduced:

$$\max F(x)=\delta\sum_{i=1}^{n}\left(Kx_iR_i-\prod_i\right)+(1-\delta)\left\{\max_{1\le i\le n}\{Kx_iS_i\}\right\}-\gamma\left(\sum_{i=1}^{n}x_i-1\right). \qquad (7)$$

In the above formula, $\gamma=8^k\,(k=1,2,3,\ldots)$.

The perception of artificial fish's range or distance is known as vision. The algorithm's convergence speed is generally determined by the value of the visual field. As a result, in order to observe the search space more thoroughly, the sensing range should be expanded, making it easier for artificial fish to locate and converge on the global extremum. For multiobjective decision-making problems, there is usually no optimal solution in the traditional sense due to the incommensurability and contradiction of objectives. A common method for resolving this type of problem is to convert the multiobjective decision-making problem into the corresponding single-objective decision-making problem. The traditional AFSA is limited in its search for the optimal solution of the objective function in the solution space of its research problem because the vision and step size of the fish swarm algorithm are typically fixed and artificially set before the experiment begins. In AFSA, each parameter's setting is not sensitive, and there is no strict theoretical basis for selecting the optimal parameter. The algorithm is extremely robust. However, because the algorithm is random, the value of each parameter has some influence on the algorithm's convergence process and optimization results. In this paper, adaptive field of vision and step size are used, which means that, in the early stage of convergence, a larger field of vision and step size are used so that it can be quickly positioned in the global optimal state; in the late stage of convergence, a smaller field of vision and step size are used to improve the algorithm's convergence accuracy.

4. Result Analysis and Discussion

The experimental data of this paper are the trading data of 25 stocks from the stock market for 450 trading days. The rate of return is the relative average rate of return. The data sent by the sample can minimize the interference caused by relevant errors in the experiment and can accurately demonstrate the performance of the algorithm. In this chapter, Matlab software is used for experiments. Run a 64-bit operating system with 16 GB of memory. Before the simulation, initialize the parameters. The experimental parameters for testing the performance of the algorithm are set as follows: the number of artificial fish school is 100; the initial visual field size is 1; the maximum number of attempts is 80; the mutation operator is 0.05; and the visual field distance is 1; the maximum number of iterations is 100. CTR, MAE, and RMSE experiments are carried out with different algorithms, and the results of three indexes are shown in Table 1.

It can be seen from the data in the table that the MAE and RMSE of the algorithm in this section are lower than those of other algorithms, and the CTR of the algorithm in this paper is the highest. In order to verify the effectiveness of this algorithm, we run the algorithm 100 times and test the influence of cardinality constraint and confidence value on the optimal value of this paper. The influence of cardinality constraint on the optimal value is shown in Figure 3. The influence of confidence on the optimal value is shown in Figure 4.

Figure 3 shows that the overall trend is that the value of conditional risk value decreases with the increase of base constraint. This is in line with the principle that diversified investment can reduce nonmarket risks. As can be seen from Figure 4, when the expected return is constant, with the increase of confidence value, the conditional risk value also increases correspondingly. This shows that investors' aversion to risks has increased. Figure 5 shows the comparison results of Pareto frontier distribution of different algorithms.

It can be seen from Figure 5 that the result obtained by the improved AFSA has the lowest risk under the same expected rate of return, and it approaches the optimal solution of linear programming well, and a group of Pareto optimal solutions are found. The improved AFSA and the traditional AFSA were tested by the test function, and the test was repeated 50 times in an independent environment. The test results are shown in Table 2.

Table 1: Comparison of the results of three indicators of different algorithms.

Algorithm	CTR	MAE	RMSE
Support vector machine algorithm	0.878	0.501	0.649
Multiobjective optimization algorithm	0.623	0.279	0.387
Particle swarm optimization	0.807	0.328	0.416
NSGA-II algorithm	0.745	0.496	0.485
Basic fish swarm algorithm	0.815	0.287	0.389
Algorithm in this paper	0.647	0.213	0.347

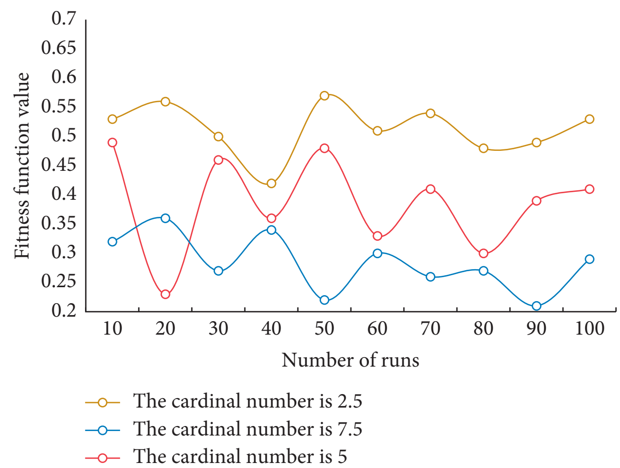

Figure 3: Influence of cardinality constraint on optimal value.

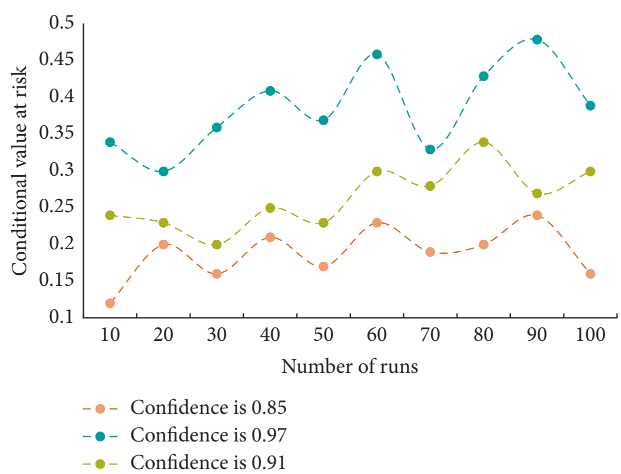

Figure 4: The effect of confidence on the optimal value.

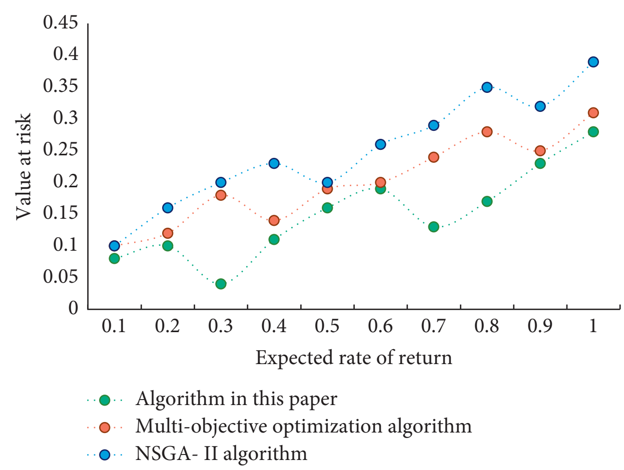

Figure 5: Comparison of pareto frontier distributions for different algorithms.

It can be seen from Table 2 that the improved AFSA has stronger overall optimization solution ability and better robustness than the traditional AFSA. The success rate of the improved algorithm in optimizing the test function has been greatly improved. To verify the effectiveness and reliability of the improved method, the precision experiment of the model is carried out, and the results are shown in Figure 6.

It can be seen that the accuracy of the improved model is obviously higher than those of the other two models. The accuracy of this model can reach 93.56%, which is 8.43% higher than that of NSGA-II model and 3.76% higher than that of multiobjective optimization model. This result verifies the effectiveness and reliability of the improved method in this paper. Using this model, NSGA-II model, and multiobjective optimization model to test the performance, the results are shown in Figure 7.

From the data analysis in Figure 7, it can be concluded that most of the total returns of the optimized portfolio model in this paper are higher than those of other models. It can obtain a better portfolio decision scheme, make the investment income as large as possible, and minimize the risk and provide investors with a certain investment direction. This shows that the portfolio model in this paper is

Table 2: Optimization results of test functions for different algorithms.

Index	Test 1		Test 2	
	Traditional AFSA	Improved AFSA	Traditional AFSA	Improved AFSA
Optimal solution	0.994	1	164.72	174.97
Worst solution	0.978	1	163.57	174.92
Average function value	0.983	1	163.98	174.96
Average number of convergence iterations	20	8	18	12
Success rate (%)	74.5	99.6	82.6	99.2

effective, and its optimal investment strategy can be applied to actual investment.

The improved AFSA shows more reliable convergence performance than the traditional AFSA because it refers to the solution strategy with strong theoretical basis in genetic algorithm. At the same time, due to the inherent advantages of AFSA, it also overcomes the problems such as the sensitivity of genetic algorithm to initial value. The experimental results show that it can eliminate the local extremum and finally obtain the global optimal state, which effectively solves the problem of low convergence accuracy of the algorithm optimization problem.

5. Conclusions

Market competition is prevalent at the moment, and it is becoming increasingly intense and diverse. Investors should be prepared for potential risks while also considering the numerous advantages that investment can provide. As a result, the current research focus is on how to select an investment strategy to maximize profits. The related literature are studied fairly thoroughly in this paper, and a financial market portfolio optimization model based on AFSA is built. Simultaneously, the corresponding improvement methods are proposed to address the shortcomings of traditional AFSA, such as low convergence accuracy, slow speed, and the tendency to fall into local extremum. Combining AFSA with a free search algorithm improves the optimization performance of traditional AFSA and, as a result, strengthens the overall algorithm's global ergodicity and local delicacy. According to empirical evidence, this model's accuracy can reach 93.56 percent, which is 8.43 percent higher than that of the NSGA-II model and 3.76 percent higher than that of the multiobjective optimization model. Simultaneously, the Pareto frontier obtained by improving AFSA is more uniform and diverse, indicating that the Pareto optimal solution is of higher quality. This demonstrates the improved algorithm's effectiveness and applicability. The optimal decision optimized by the improved fish swarm algorithm has a higher investment benefit, a higher expected return, and a lower risk of portfolio investment. This is beneficial to the prosperity and development of the securities trading market because it promotes investors' investment and trading activities. According to the findings of the preceding research, AFSA is a viable option for addressing the portfolio problem. AFSA has significant development potential, which merits our thorough and extensive investigation. By improving and perfecting it, AFSA is expected to have a better application prospect. The improved AFSA in this paper achieved good optimization results, but the index selection of the investment portfolio is not detailed and comprehensive enough, and how to improve the stability of AFSA performance without sacrificing efficiency will be researched further in the future.

In the huge number of online university education resources, it is difficult for learners to quickly locate the resources they need, which leads to "information trek." Traditional information recommendation methods tend to ignore the characteristics of learners, who are the main subjects of education. In order to improve the recommendation accuracy, a recommendation algorithm based on improved collaborative filtering model is proposed in this paper. Firstly, according to the student behavior data, consider the behavior order to create the behavior graph and behavior route. Then, the path of text type is vectorized by the Keras Tokenizer method. Finally, the similarity between multidimensional behavior path vectors is calculated, and path collaborative filtering recommendations are performed for each dimension separately. The MOOC data of a university in China are introduced to experimentally compare the algorithm of the article as well as the control group algorithm. The results show that the proposed algorithm takes better values in evaluation indexes, thus verifying that this algorithm can improve the effectiveness of innovation and entrepreneurship education resources recommendation in universities.

1. Introduction

In recent years, the use of online education platform is more and more accepted by learners [1]. Especially, after the outbreak of New Coronavirus, online learning is the preferred learning mode when offline learning cannot be carried out normally. Faced with the huge demand for online learning, online education institutions are providing free online courses and sharing online teaching resources, and the online education industry is showing an explosive growth trend. With the widespread use of online learning platforms, the number of educational resources for innovation and entrepreneurship in universities has also increased dramatically.

In the huge number of online college education resources, learners are difficult to quickly locate the resources they need, resulting in "information trek" [2]. Information recommendation is a method for students to quickly and effectively screen out the objects that meet their preference characteristics from the mass objects. At present, information recommendation technology is widely used in many fields [3]. It is an effective way to solve the problem of "information trek" to apply information recommendation technology to online education and realize personalized recommendation of innovation and entrepreneurship education resources in universities in the process of online education.

With the upgrading of Internet technology, the scale of online education services, represented by Massive Open Online Courses (MOOC), Net Ease Cloud Classroom, and innovation and entrepreneurship education resource platforms built by universities, continues to expand. Meanwhile, teaching data through social media such as Weibo, forum, and post bar also constitute a massive amount of online education resources [4]. These abundant online education service resources not only expand students' knowledge scope and supplement the deficiency of offline learning, but also bring a lot of inconvenience to students. First, complicated online education resources cause "information trek," and the quality of online education services is uneven, which makes it difficult for students to identify and compare, resulting in poor learning experience and effects. Second, faced with the same high-quality educational resources, students with high information literacy can easily obtain relevant information, while students with low information literacy can hardly access such resources, resulting in new educational inequities in the information environment. Third, all kinds of teaching resources are not pushed to students with the same probability. Mainstream education resources are pushed to students more frequently due to their high frequency of use, thus covering the minority and high-quality education resources. As a result, it is difficult for students to obtain such resources, resulting in "information cocoon."

How to help learners acquire the knowledge they are interested in quickly and accurately is an urgent problem to be solved by online education service platforms of universities [5]. Educational recommendation services are based on learners' personalized network information and learning behavior. The recommendation algorithm is used to quickly recommend precise college innovation and entrepreneurship education resources that meet students' potential learning needs from the massive educational information resources. It can enhance the experience and effectiveness of online learning [6].

The development of the Internet has broadened the channels for students to obtain information, but not all online information is valuable. Therefore, in the era of information overload, helping students efficiently and accurately screen out the resources they are interested in has become the key to the development of the Internet [7]. Collaborative filtering algorithm is the main technology to solve this problem [8]. As a widely recognized recommendation technology, collaborative filtering can effectively process structured information without studying the content and attributes of the recommendation information. At the same time, it can combine some concepts that are not easy to embody to complete information filtering, and the recommendation has a high degree of intelligence, which fully meets the requirements of personalized recommendation.

Relevant scholars further improve the collaborative filtering recommendation effect by using different methods. A personalized system filtering recommendation method based on coverage minimalism is proposed. According to the method of coverage reduction and student reduction in coverage rough set, the matching of redundant elements and redundant students is realized. Redundant students are removed from the target student set by reduction algorithm to ensure the effectiveness of collaborative filtering. Under the open data set, personalized recommendation services are provided for target students. The literature [9] proposed a method based on the clustering of student interest degree. Combining with the frequency of the target students scoring keywords, the degree of students' preference for keywords is obtained, and the student-keyword preference matrix is constructed, through which the clustering is realized. Logistic function is used to obtain students' interest in the project, determine students' preferences, find out students' similar students in the cluster, and collect some information about neighbours' hobbies to realize the recommendation of target students. However, the above recommendation method has some limitations, such as the serious problem of cold start, and it is difficult to accurately reflect the relationship between students and education resources.

In the era of big data, information overload is a huge problem we are faced with. It is extremely difficult for students to acquire the content they are interested in in time and accurately from massive data [10]. Recommendation system can alleviate the problem of information overload well and has been widely used in e-commerce, online news, and social networking sites.

Personalized recommendation system mainly uses the historical interaction information between students and projects to establish a model to predict students' evaluation of the project. In the traditional recommendation system, the recommendation based on collaborative filtering is the most classic [11]. An intuitive interpretation of collaborative filtering recommendations is that a student's rating of a project can be predicted by the rating of other students who are similar to him. Matrix decomposition is a common collaborative filtering method [12]. The idea of recommendation is to map the student vector and the project vector to a common vector representation space, in which the implicit vector is used to represent the student and the project, and then the score of the project can be directly obtained by calculating the similarity between the implicit vector of the student and the project. The successful application of matrix decomposition model in the recommendation field has led to the emergence of many improved methods based on matrix decomposition in the research field of recommendation system, such as the integration of neighbourhood model in matrix decomposition in the literature [13]. Factorization machine is used for feature interaction to generate more features and add them to model training. The literature [14] improves the effect of matrix decomposition by introducing auxiliary information such as project content. In recent years, the application of deep learning in image, natural language processing, and other fields has achieved good results, and many studies have begun to introduce deep learning into the field of the recommendation system [15]. Deep learning is usually introduced from two perspectives: (1) neural network is used to learn the representation vectors of students and projects, such as the deep matrix factorization (DMF) model proposed in the literature [16]. Dual-path neural network is used to replace the traditional matrix decomposition to learn the representation vectors of students and projects, and then score prediction is made. (2) The neural network is used as the matching function of the recommendation model, and the student vector and the project vector are fed into the matching function to directly obtain the scores of the students on the project, such as the neural collaborative filtering (NCF) model proposed in reference [17]. NeuMF in NCF simply concatenates the student vector and the project vector into a multilayer perceptron (MLP) to calculate the student's rating of the project. The literature [18] comprehensively considered the above two aspects and proposed a deep collaborative filtering model (DeepCF) combining representation learning and function learning. The above collaborative filtering recommendation model and deep learning recommendation model only extract the interaction features between students and projects from a single perspective, and the feature extraction is not comprehensive enough, which will limit the model's recommendation ability.

The essence of recommendation is a continuous decision-making process, and students' interest degree is not constant, so resource recommendation cannot be carried out from a static perspective. Therefore, this paper proposes a recommendation system of innovation and entrepreneurship education resources in universities based on the improved collaborative filtering model.

The innovations and contributions of this paper are listed as follows:

(1) According to the student behavior data, consider the behavior order to create the behavior graph and behavior route.
(2) Use Keras Tokenizer to vectorize the path of text type.
(3) The similarity between multidimensional behavior path vectors is calculated, and path collaborative filtering recommendations are performed for each dimension separately.

This paper consists of five main parts: the first part is the introduction, the second part is state of the art, the third part is methodology, the fourth part is result analysis and discussion, and the fifth part is the conclusion.

2. State of the Art

In order to improve the expansibility of the recommendation system, a scholar proposed Spark Hierarchical CF, which uses the student preference model and clustering algorithm to divide students into different student clusters according to different preference characteristics. And then it makes collaborative filtering recommendations for different student clusters. Compared with the algorithm based on MapReduce, the recommendation accuracy is improved and the operation time is saved, but the centre point of clustering is difficult to determine.

At present, there are four kinds of research on student behavior path, including methods based on reinforcement learning, methods based on statistical analysis, methods based on activity trajectory clustering, and methods based on the ant colony algorithm.

In order to improve the problem that the collaborative filtering algorithm ignores item attributes, a dynamic individual recommendation method based on reinforcement learning was proposed in the literature [19]. Firstly, students' attribute labels are mined from the operation behaviors, and then the reward and punishment models of attribute labels are adjusted according to the operate path and recall path to achieve dynamic adjustment of label weight. Finally, reinforcement learning is used to achieve label recommendation. The disadvantage of this method is that only recent behaviors are considered. Student preference information implied by behavioural pathways is not fully utilized.

The literature [20] proposed that students' experience perception can improve the recommendation effect. According to the behavioural data, analyse the student behavior path and create the student experience perception model. The behavioural path is defined as continuous indicators such as attracting attention, expressing interest, clicking intention, and watching video, which can better show the development trend of students' interest. However, this method has the problems of cold start and sparse data.

Considering the similarity between student visit and ant foraging, the ant colony algorithm was introduced in the literature [21] to realize recommendation, and the transition probability was calculated according to students' browsing behavior and preferred browsing path, so as to dynamically make recommendation. However, there are cold start problem and Matthew effect in this method, and there is occasional error in recommendation based on transfer probability. The literature [22] imitates the concept of pheromone in the ant colony algorithm and proposes pheromone-based algorithm to combine students' browsing behavior with reading behavior through commodity pheromone, and then recommend students according to their browsing trajectory. However, the properties of resource pheromones lead to the Matthew effect.

3. Methodology

This paper proposes a behavior path collaborative filtering recommendation algorithm based on knowledge graph. First, t behaviors in user behavior data are initialized to t nodes $= g_1, g_2, \ldots, g_t$, each node g stores the attribute of this behavior. And these nodes are constructed into a behavior knowledge map in Neo4j, which is referred to as the behavior map. Second, define the behavior path for the user against the same target entity in long weeks $\text{Route}_{\text{uid,iid}} = (h_1, h_2, \ldots, h_t)$, and construct it according to the behavior sequence in the behavior graph. Uid and iid indicate the student ID and education resource ID, respectively. Then, the behavior path is derived for vectorization. Finally, the similarity between multidimensional behavior paths is calculated. The flow of this algorithm is shown in Figure 1. This section describes the specific steps of the algorithm.

3.1. Construct Behavior Map. Taking each behavioural datum as a node, w genera of each behavior $(f_1, f_2, \ldots, f_w)$ is sealed as nodes and stored in the Neo4j data library. The construction algorithm is shown in

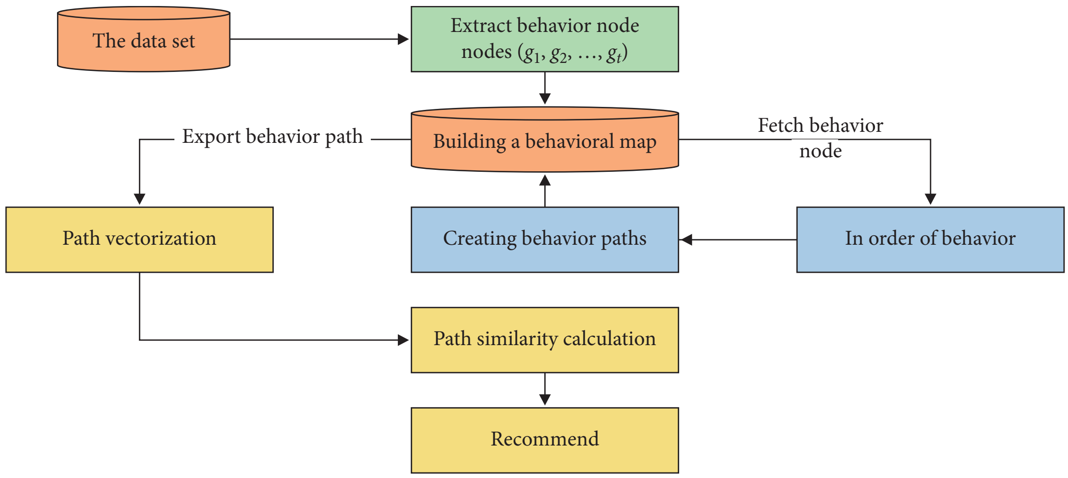

Figure 1: Flowchart of the BR-CF algorithm.

$$
\begin{aligned}
g &= \text{Graph}(\text{host}, \text{http\_port}, \text{user}, \text{password}),\\
\text{node} &= \text{Node}({}'f1' = f1, {}'f2' = f2, \ldots, {}'fm' = fm),\\
&\quad g.\text{create}(\text{node}),\\
&\quad g.\text{create}(\text{node}),
\end{aligned}
\tag{1}
$$

where host, http_ port, user, and password represent host address, port address, database user name, and password, respectively, which are used to connect to the neo4j database. Node encapsulates each behavior datum into a node, and the create (node) command stores each node in the neo4j database. The preliminarily constructed behavior map is shown in Figure 2.

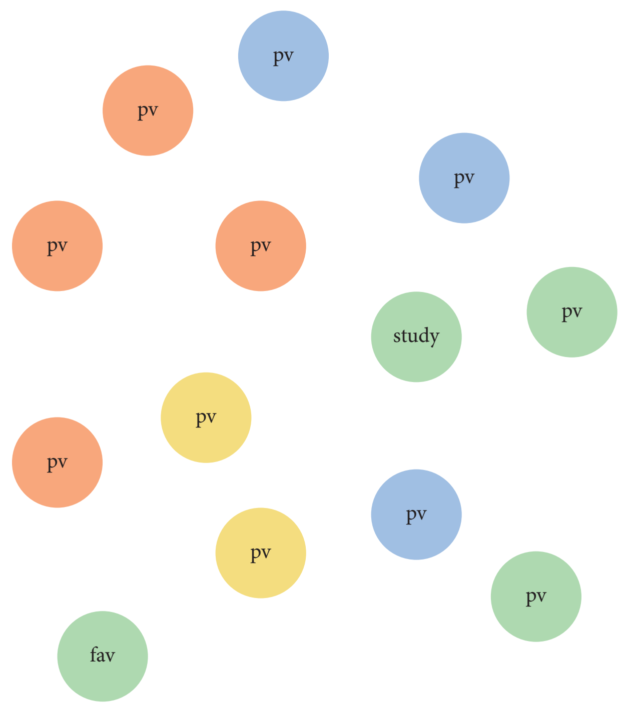

Figure 2: Preliminarily constructed behavior map.

3.2. Creating a Behavior Path. First, prioritize your actions. According to t behavior types contained in the behavior map, the behavior priority is defined $(h_1, h_2, h_3, \ldots, h_t)$, h represents a single behavior, h_1 has the lowest priority, and h_t has the highest priority.

Then, define the behavior path. This paper defines the behavior path as an ordered set of all behaviors generated by students for the same educational resource in a long period. $\text{Route}_{\text{uid,id}} = (h_1, h_2, \ldots, h_t)$. Uid and iid represent the student ID and education resource ID, respectively.

Finally, create a behavior path. According to the behavior sequence, traverse the behavior map, create a "continuous action" relationship for the continuous behavior made by the same student about the same educational resources, skip the single node that does not constitute a path, and get the $\text{Route}_{\text{uid, iid}}$ of all students about different educational resources after completing the traversal. The specific steps are shown in Figure 3. The created behavior path is shown in Figure 4.

3.3. Path Vectorization. Because the data type of the behavior path created in the previous step is text, and the similarity calculation requires digital data. The next is the vectorization and alignment of paths.

Firstly, classify the behavior paths by behavior priority, as listed in Table 1.

Secondly, vectorize each path in each class from text format to digital format. In this paper, Keras's Tokenizer class is used for vector transformation.

Finally, vector alignment is required. Because the path length is different, the length of each vector is also different, which means that the spatial dimension of the vector is not unified, and the similarity cannot be calculated. Calculate the maximum path length of all behavior paths and use Keras's kps.pad_sequences method to make the spatial dimension of each path the same as the maximum length, with the principle of complement 0. The data change process is listed in Table 2.

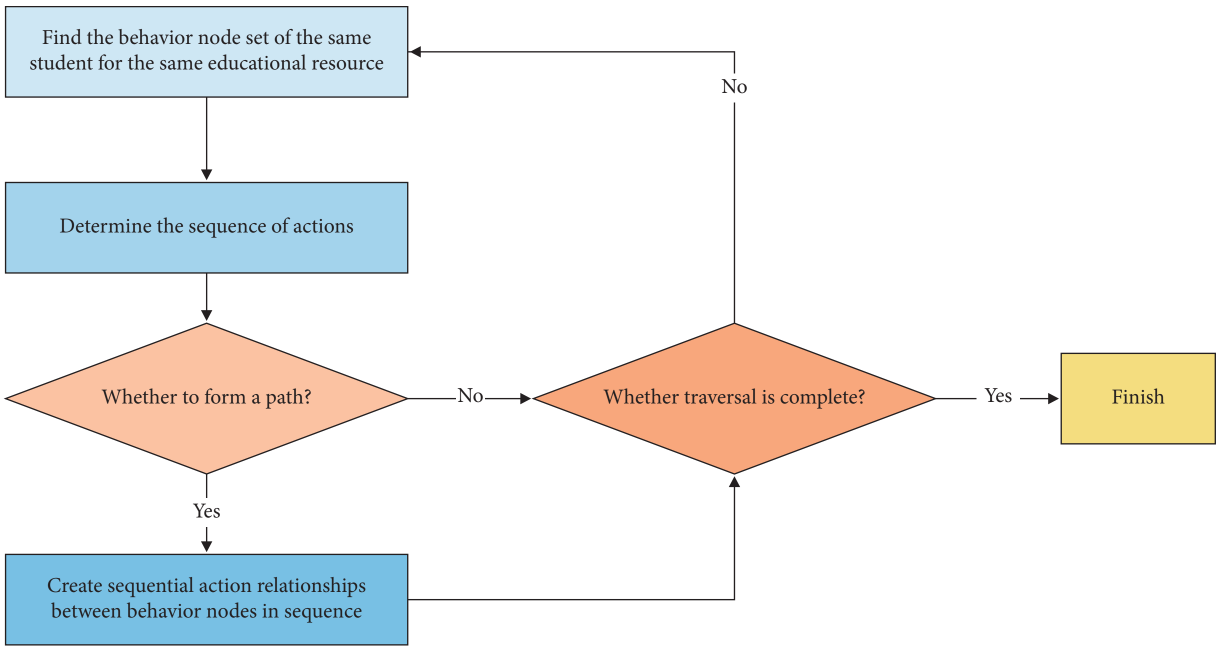

FIGURE 3: Steps to create a behavior path.

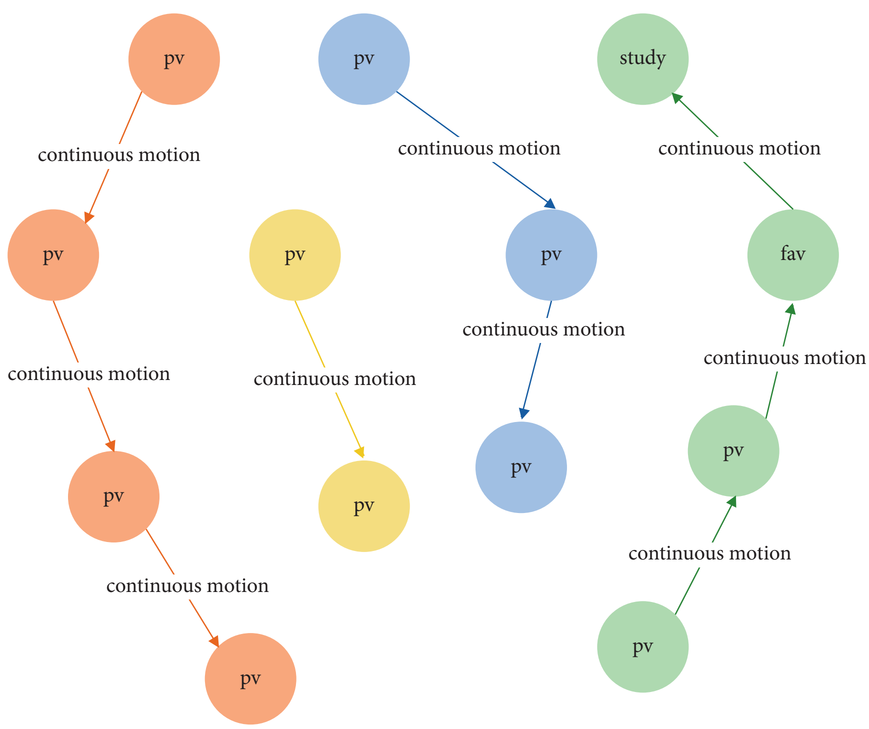

FIGURE 4: Behavior path diagram.

TABLE 1: Path classification.

Classification	Classification basis
Class h_1	The highest behavior priority in the path is h_1
Class h_2	The highest behavior priority in the path is h_2
...	...
Class h_t	The highest behavior priority in the path is h_t

3.4. Calculation of Path Similarity. Here, the path similarity is measured by the sum of the distances between a path in class G and each path in class H. As shown in equation (3), the smaller the total distance, the greater the similarity.

As shown in Table 2, the array of class h_2 and class h_3 is empty, it can be seen that there may be empty classes in the path classification. Direct calculation of similarity will lead

Table 2: Example of data change process.

Path status	Numerical value
Initial behavior path set	{"h_1–h_2–h_4–h_1–h_1" "h_1–h_1–h_1"} {h_1:["h_1–h_1–h_1"]
After path classification	h_2:[ ], h_3:[ ], h_4:["h_1–h_2–h_4–h_1–h_1"]} {h_1:[[1, 1, 1]]
After path steering	h_2:[ ], h_3:[ ], h_4:[[1, 2, 4, 1, 1]]} {h_1:[[1, 1, 1, 0, 0]],
After path alignment	h_2:[ ], h_3:[ ], h_4:[[1, 2, 4, 1, 1]]}

Table 3: Path category combination.

Possible combination of route categories	
1	(h_1)
2	(h_2)
3	(h_3)
4	(h_4)
5	(h_1, h_2)
6	(h_1, h_3)
7	(h_1, h_4)
8	(h_2, h_3)
9	(h_2, h_4)
10	(h_3, h_4)
11	(h_1, h_2, h_3)
12	(h_1, h_2, h_4)
13	(h_1, h_3, h_4)
14	(h_2, h_3, h_4)
15	(h_1, h_2, h_3, h_4)

to empty objects. Therefore, it is necessary to distinguish which classes are empty in the path classification and finally decide which behaviors can be recommended.

According to the permutation and combination principle, there are 2^T-1 types of classification for T types of behavior. For example, there are 15 types of classification for 4 types, as listed in Table 3, where combination (h_1) means that all classes except fot h_1 are empty, and combination (h_2, h_3, h_4) means that h_2, h_3, and h_4 are not empty. The h_1 class is empty, and so on.

After the path combination is determined, the path similarity is calculated. In this paper, Euclidean distance is used to calculate the similarity of paths. The calculation formula of Euclidean distance in t-dimensional space is shown in

$$d(i,j)=\sqrt{\sum_{x=1}^{t}\left(i_x-j_x\right)^2}. \tag{2}$$

Secondly, the sum of the distance between each path in class_1 and the path in class_2 is calculated, as shown in (3), where class_1 and class_2 represent two classes in the path subclass. The classification of other paths is similar:

$$\text{distances}=\sum_{i=1}^{t} d\left(i,j_x\right),\quad i\in\text{class}_1,\ j\in\text{class}_2. \tag{3}$$

Finally, the corresponding total distance list can be obtained for h_t class path, as shown in

$$\text{List\_distances\_}h_t=\left[\text{distances}_1,\text{distances}_2,\ldots\right],\quad t\in[1,t]. \tag{4}$$

If the combination is (h_2, h_3, h_4), the total distance list can be obtained by calculation, as shown in

$$\begin{aligned}\text{List\_distances\_}h_2&=\left[\text{distances}_1,\text{distances}_2,\ldots,\text{distances}_w\right],\\ \text{List\_distances\_}h_3&=\left[\text{distances}_1,\text{distances}_2,\ldots,\text{distances}_t\right],\end{aligned} \tag{5}$$

where w and t are the number of paths in h_2 and h_3, respectively. List_distances_h_2 represents the total distance list between each path in h_2 and all paths in h_3. And List_distances_h_3 represents the total distance list between each path in h_3 and all paths in h_4.

3.5. Multidimensional Recommendation. In this paper, the definition is derived from the multidimension $(d_1, d_2, d_3, \ldots, d_{t-1})$. D represents a set of recommendations that may be generated in line h. The d_1 pair should be able to generate the h_2 recommendation set. D_{t-1} corresponds to the possible recommendation set of h_t, which can be divided into possible_h_t table. D is the set of target entities corresponding to min (List_distances), that is, the set of target entities corresponding to the path with the minimum total distance. The results of recommendation obtained are shown in

$$\left\{d_1,d_2,\ldots,d_{n-1}\right\}=\left\{\text{possible\_}h_2{}'':\ [\cdots\cdots],{}''\text{possible\_}h_3{}'':\ [\cdots\cdots],\cdots\cdots{}''\text{possible\_}h_t{}'':\ [\cdots\cdots]\right\}. \tag{6}$$

According to the example results in equation (5), there are two recommendation dimensions d_2 and d_3. The returned recommendation results are shown in equation (7), which, respectively, represents the set of educational resources where the user recommended by this algorithm may have behaviors h_3 and h_4, and the value is the ID or other unique identification of the educational resource:

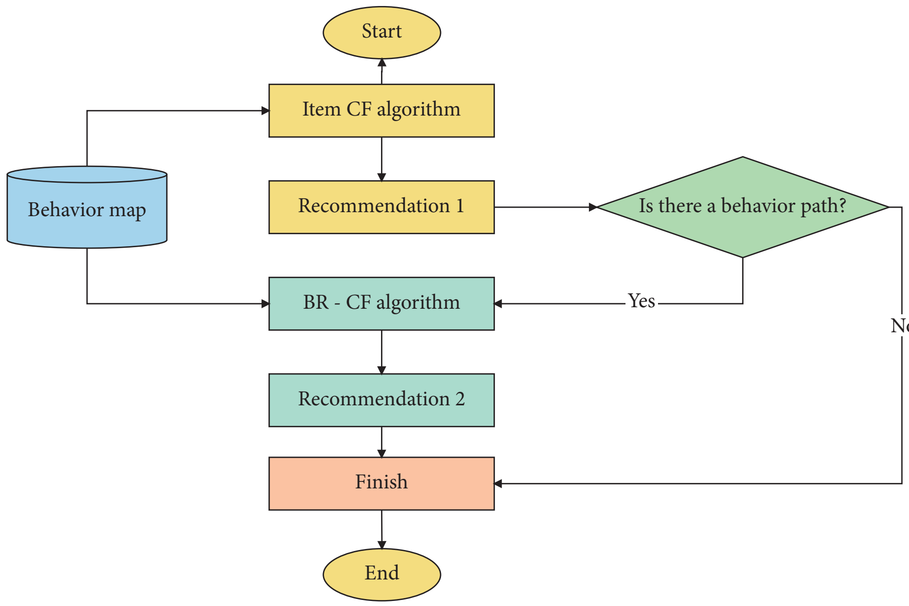

FIGURE 5: Flowchart of combine the item CF and BR-CF algorithm.

TABLE 4: Comparison of experimental results of four recommended algorithms with different TOP-N.

TOP-N	Index	Literature [23]	Literature [24]	Literature [25]	Proposed
5	Precision (%)	30.61	28.42	32.05	31.21
	Recall (%)	41.24	39.94	43.21	42.92
	RMSE	0.88	0.93	0.85	0.86
20	Precision (%)	28.16	26.96	28.08	29.98
	Recall (%)	44.37	43.65	46.78	47.58
	RMSE	0.79	0.91	0.78	0.72
35	Precision (%)	26.12	24.94	24.06	28.73
	Recall (%)	46.82	45.42	48.88	49.11
	RMSE	0.75	0.81	0.72	0.65
50	Precision (%)	23.24	22.25	21.78	25.97
	Recall (%)	50.16	48.9	51.34	51.79
	RMSE	0.68	0.72	0.61	0.57

$$\{d_3, d_4\} = \{"\text{possible\_}h_3" [\,2733371, 332733\,], "\text{possible\_}h_4": \ [124451]\}. \tag{7}$$

The item collaborative filtering recommendation algorithm, referred to as item CF, is used to recommend educational resources similar to those they liked before to college students.

In order to further analyse the recommendation performance of BR-CF, item CF and BR-CF are cascaded and mixed, respectively, in this section, and an improved algorithm based on the combination of item CF and BR-CF is proposed.

The cascade recommendation algorithm of item CF and BR-CF is referred to as Combine item CF and BR-CF. In the recommendation result of resource collaboration, the algorithm further calculates the set of target entities with behavior paths and the minimum total distance from the behavior paths of all target entities in the verification set. The flowchart is shown in Figure 5.

4. Result Analysis and Discussion

The experimental data in this paper are from a MOOC of a university in China bound by QQ account, and the crawler tool is used to directly obtain student information and innovation and entrepreneurship education resource data of universities. A total of 36,967 pieces of online learner information were obtained, including major, educational background, geographical location, friend relationship, learning time, course name, and evaluation content. After data screening, the dormant accounts and abandoned accounts whose monthly login times are less than 3 are excluded. Finally, the effective data set obtained contains 2400 students. The students were divided into two data sets in the ratio of 8 : 2. Among them, 1920 students' information constituted the training data set, and the other 480 students' information constituted the test data set.

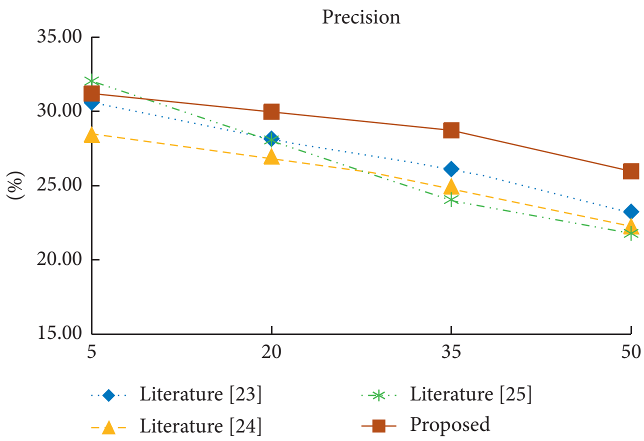

Figure 6: Accuracy of four recommendation algorithms under different recommendation numbers.

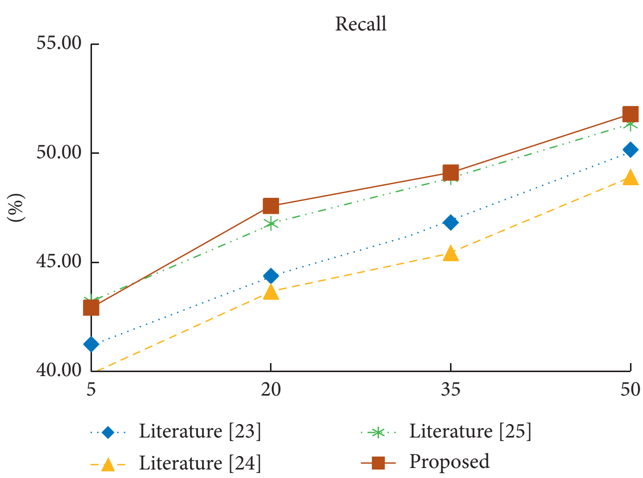

Figure 7: Recall rate of four recommendation algorithms under different recommendation numbers.

In order to test the quality of the proposed algorithm, the proposed algorithm based on the improved collaborative filtering model is compared with the literature [23], literature [24], and literature [25]. The number of adjacent recommendation students is set as 5, and the value is increased by 15 until it is 50. The Precision, Recall, and RMSE values of the four recommendation models under different number of recommendation students are listed, as shown in Table 4.

As shown in Figures 6–8, when the number of recommended students is greater than 20, the accuracy and root mean square error of the proposed algorithm in experimental data are better than those of the other three recommendation algorithms. In terms of recall rate, when the number of recommended students is greater than 35, there is not much difference between the proposed algorithm and the knowledge-based recommendation algorithm, but it is significantly better than the other two algorithms. Compared with the currently commonly used recommendation algorithm, the proposed algorithm takes into account student information, social relationship, and online learning behavior, so the recommendation quality is higher.

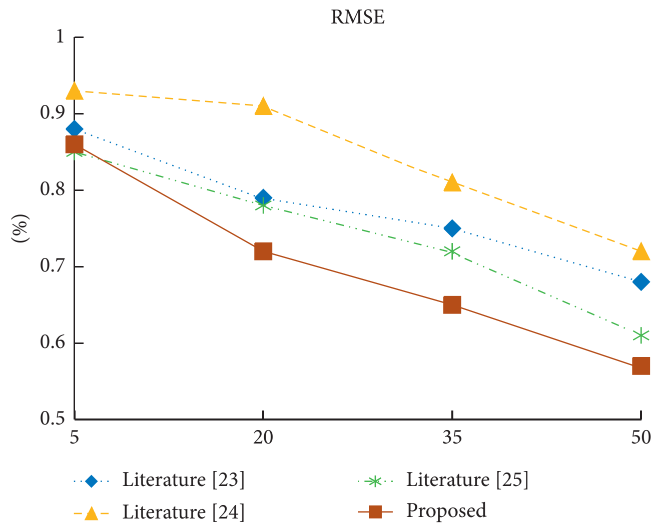

Figure 8: Root mean square error of four recommendation algorithms under different recommendation numbers.

5. Conclusion

At present, there are a lot of learning resources in online education learning platform, but the personalized service is not high. The target of online education services is learners. The commonly used personalized recommendation algorithm of education services only considers static information or dynamic characteristics of users, resulting in low recommendation quality. The collaborative filtering algorithm is the mainstream of information recommendation technology at present. However, the traditional recommendation system based on collaborative filtering algorithm has some limitations, such as low accuracy and cold start. And it is difficult to accurately reflect the relationship between students and educational resources. In order to improve the recommendation accuracy, this paper proposes a recommendation algorithm based on the improved collaborative filtering model for innovation and entrepreneurship education resources in universities. This paper uses 20,059 real behavior data and successfully creates 2,266 behavior paths according to the sequence of students' behaviors, which enriches the semantic information of the data. In addition, students' behavior data are fully used to make recommendations from three dimensions, which improves the data utilization rate and the diversity of recommendations. In particular, this paper puts forward the concept of behavior path, which can well represent the evolution and development process of students' behavior and better predict students' learning preferences by creating associations between behaviors. In order to test the quality of the recommendation algorithm, the proposed algorithm and other three recommendation algorithms were used as the control group in the experiment, and the Precision, Recall, and RMSE of these four recommendation algorithms were calculated under different recommended users. It shows the recommendation the proposed algorithm has more advantages in three evaluation indicators, and can be applied to online education services to better provide students with high-quality recommendation of college innovation and entrepreneurship education resources. Since the experimental platform and data in this paper are relatively single, in order to further verify and improve the personalized recommendation effect of the algorithm in this paper, other online education service platforms will be introduced in the future to verify the scalability and accuracy of this method.

Retracted: MOOC and Flipped Classroom Task-Based English Teaching Model for Colleges and Universities Using Data Mining and Few-Shot Learning Technology

Computational Intelligence and Neuroscience

Received 26 September 2023; Accepted 26 September 2023; Published 27 September 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

As a revolutionary education model, the flipped classroom teaching model has unique advantages over the traditional education model. How to change the teaching method of flipped classroom into a teaching method suitable for college English courses is a problem. The goal of this research is to investigate how to use data mining and few-shot learning technology to investigate the impact of MOOC and flipped classroom task-based college English teaching modes. This work provides a data mining-based decision tree algorithm and examines the enhanced decision tree method. The experimental results of this study demonstrate that two students in each of the two groups believe that the English teaching mode, which is mostly taught by traditional teachers, is very favorable to a thorough understanding of basic knowledge, accounting for 4% of the total. There are 17 students that believe the new teaching methodology is really beneficial, accounting for 34% of the total. This mode was determined to be effective for in-depth knowledge of the basics by a total of 25 students. It can be seen that the flipped classroom model is more popular with students.

1. Introduction

Since human beings entered the information society, with the rapid development of information technology, the amount of data generated by human society has also increased dramatically. However, how to turn complicated data into knowledge that people can easily accept and understand is a difficult problem for data researchers. Faced with the situation of "a large amount of data, but little knowledge," data mining technology came into being. This discipline, which originated in the field of database and artificial intelligence [1], has formed a system and has begun to play a huge role in practical applications.

At present, most mathematics classroom teaching is still not free from the shackles of traditional educational ideas. It has disadvantages such as dogmatization, unification, static, isolation, and separation from the real life of students. The dominant position of students in classroom teaching has not yet been established, lacking due freedom and choice, and there is still a large market for indoctrination education. In recent years, MOOCs and flipped classrooms have entered people's field of vision, which is a new form of educational resources and educational models, which has aroused strong repercussions in the education community around the world. MOOCs mainly use online platforms to display the main educational content in the form of microcourses. The flipped classroom is an innovative and personalized education model. The flipped classroom teaching mode based on MOOC mainly uses network technology and resources to reverse the educational purpose and educational form, educational subjects, and the role of teachers, which has attracted great attention in the field of education.

The innovations of this paper are as follows: (1) It introduces the relevant theoretical knowledge of data mining technology and MOOC and flipped classroom task-based college English teaching mode. It also uses decision tree algorithm based on data mining technology to analyze how data mining plays a role in MOOC and flipped classroom task-based college English teaching mode. (2) Based on the decision tree algorithm, it carried out experiments and analysis on MOOC and flipped classroom task-based college English teaching mode. Through investigation and analysis, it found that the task-based college English teaching model based on MOOCs and flipped classrooms can stimulate students' more interest in learning and enthusiasm for learning.

2. Related Work

The rapid development of information technology has brought people a convenient life that was unimaginable before and also impacted the traditional way of cognition of knowledge and information. Jovanovic found that learning strategies are related to flipped classrooms, and he also found that students tend to change the strategies that they employ and switch to less effective strategies. Although the scholar used clustering to discover the problems that students have in learning, he did not propose corresponding solutions based on the students' problems. Yilmaz found that the flipped classroom (FC) teaching model was associated with student satisfaction and motivation. The purpose of his research was to investigate the impact of students' e-learning readiness on student satisfaction and motivation in the FC teaching model. Research was conducted among 20 undergraduate students. They learn using the FC teaching model. The results show that the more satisfied students are, the more active they will be in preparing for the preclass preview. Although the scholar has specific experimental objects, he did not analyze the experimental data [2]. Baytiyeh tried to find out whether the flipped classroom model works in teaching and whether students can acquire skills in this model. Using a qualitative case study design, he found that this type of teaching enriches students' learning experience and helps them develop the skills they need. The scholar proposed a qualitative case study design, but he does not address an actual case [3]. Mcnally et al. found that although the flipped classroom is widely used, it lacks experience and is not easy to be accepted. He surveyed 5 students under the flipped classroom model and the results showed that students can have positive attitudes towards flipped classroom elements according to them. But the scholar came to the result directly, without explaining the whole process [4]. Kostaris et al. found that the emerging flipped classroom method has been widely used in teaching practice and achieved many good results. His main purpose is to design and implement an action study to study the effect of flipped classroom approach in teaching and learning. The scholar did not introduce what this action research is for [5]. Jin et al. found that body recognition is crucial in a variety of applications, including pursuit, defense, and more. Traditional human recognition methods are usually based on vision, biometrics, etc. They proposed a recognition method based on radar micro-Doppler features. The method uses deep convolutional neural networks (DCNNs) [6–8] and can recognize people in contactless, remote, and unilluminated states. But the scholar did not explain why he chose this method.

3. Decision Tree Algorithm before and after Improvement Based on Data Mining

3.1. The Process and Tasks of Data Mining. Network courses have steadily become an important teaching method in remote education due to the rapid growth of network technology. Students generate a tremendous amount of data about education and learning while taking online courses. Because the knowledge concealed behind the data cannot be mined, the linkages and laws that exist in the data cannot be uncovered when confronted with such a vast data collection. Teachers are unable to comprehend the impact of students' online learning, and studying diverse information points does not enable students to make judgments for themselves. Teachers are unable to improve the content of online courses or the effect of distant education due to their incapacity to alter targeted assistance and the pedagogical structure of online courses in a short amount of time.

Data mining, also known as knowledge discovery in databases, is a hot research topic in the field of artificial intelligence and databases. The so-called data mining refers to the nontrivial process of revealing implicit, previously unknown, and potentially valuable information from a large amount of data in the database. Data mining technology [9] provides an excellent solution to this problem. Data mining is the extraction of hidden data from practical application data that many people do not know in advance and are incomplete and ambiguous. However, it is also a potentially useful information process. Its application of data mining for online course learning is undoubtedly practical. The unearthed knowledge helps teachers to complete higher-level decision-making, adjust the educational structure of online courses in time, and improve the content and educational effects of online courses. The data mining architecture is shown in Figure 1.

As shown in Figure 1: Data mining is the process of mining interesting patterns and knowledge from large amounts of data. The data source is generally a database, data warehouse, Web, etc., and the obtained data is called a data set. Data mining is not a simple job. It does not mean that, with data, using a certain method and building several models, it can get the desired information. Data mining should be a multistep process. Before its implementation, a detailed plan should be made to determine what needs to be done at each step and how to do it. Only in this way can data mining be carried out in an orderly manner and be successful. Different environments and different projects may have different data mining processes [10].

In general, the data mining process goes through the following steps, as shown in Figure 2.

As shown in Figure 2: Knowledge is discovered for application. Now people are using knowledge of the following two methods. One is to look only at the relationships or results described by the knowledge itself to support decision-making, and the other is to analyze knowledge. The knowledge gained will be integrated into the organizational structure of information systems to guide practice. The data

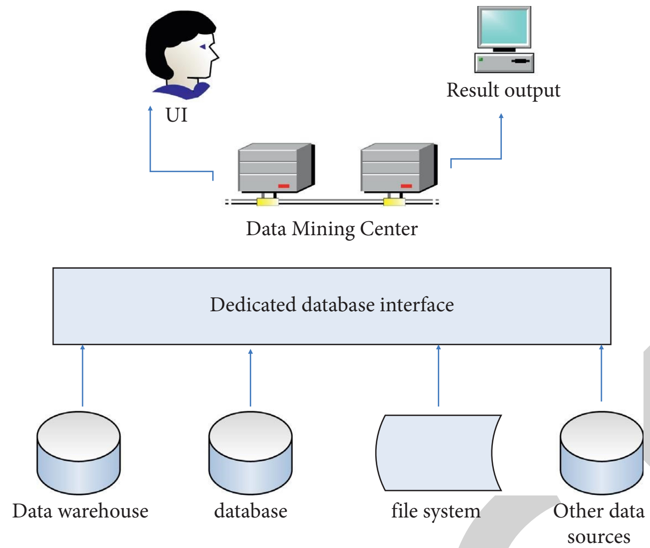

Figure 1: Data mining architecture.

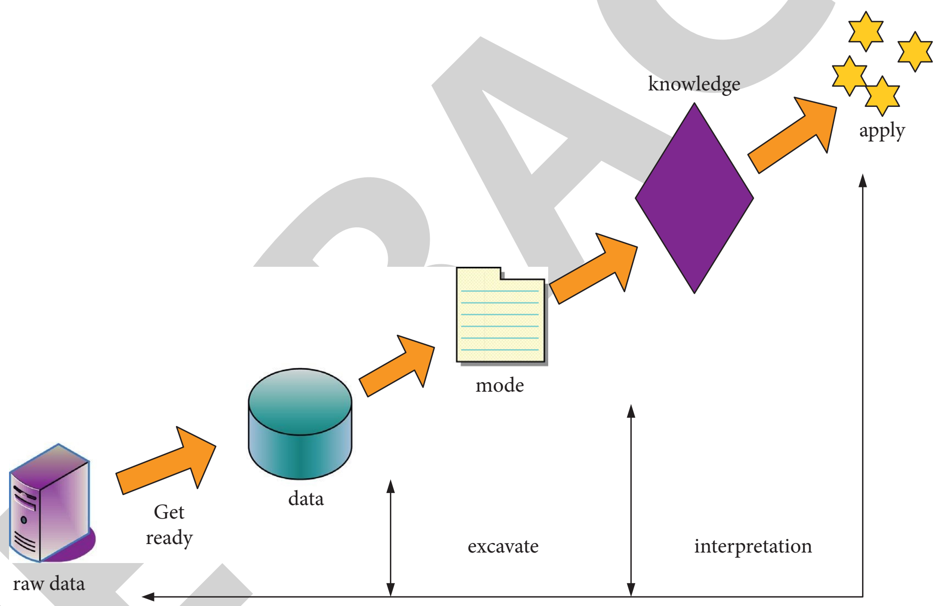

Figure 2: Steps of data mining.

mining process is a cyclic process. It will constantly approach the essence of things and achieve the purpose of optimizing and solving problems. It turns useful data into information, information into action, and action into value.

3.2. Decision Tree and Related Algorithm Theory. Decision tree is one of the classic methods of data mining. It clearly and completely shows the decision and classification process in a tree structure. The algorithm is simple and intuitive. Decision tree is a decision analysis method to obtain the probability that the expected value of the net present value is greater than or equal to zero by forming a decision tree based on the known probability of occurrence of various situations, to evaluate the project risk, and to judge its feasibility. It is a graphical method that uses probability analysis intuitively. Since this decision branch is drawn as a graph like the branches of a tree, it is called a decision tree.

The properties of a decision tree are that it has a clear hierarchy and logic. The entire decision-making process is straightforward, intuitive, and simple to comprehend, with a good classification effect. However, because the data mining technique involves so many association rules, it is not ideal for clustering [11, 12] and is instead employed for classification. The decision tree method is well suited to processing nonnumeric data, particularly on a large scale. This article is primarily concerned with the use of information such as enrollment sources and college entrance examination results in college and university enrollment. As a result, it primarily describes the information theory-based decision tree classification technique. The schematic diagram of decision tree generation is shown in Figure 3.

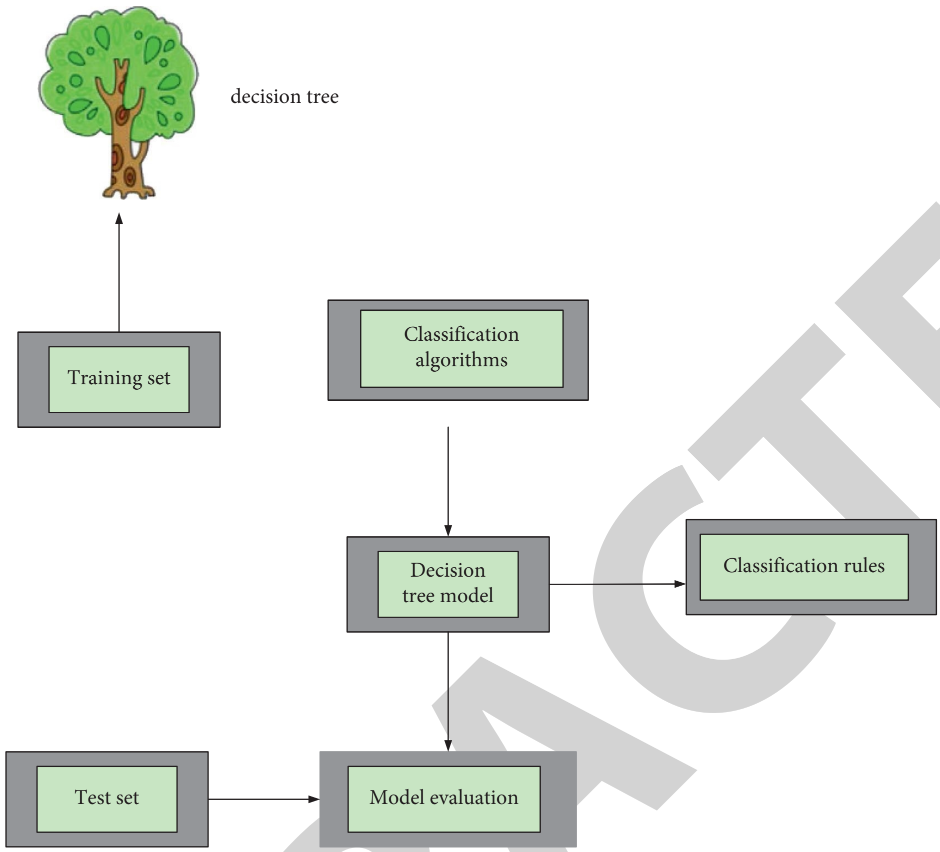

FIGURE 3: Schematic diagram of decision tree generation.

As shown in Figure 3: The related concepts in decision tree correlation information theory are as follows:

Information gain reflects the characteristics of the sample [13], and there is a close relationship between the two and a proportional relationship. In probability theory and information theory, information gain is asymmetric, which is used to measure the difference between two probability distributions P and Q. Information gain describes the difference between coding with Q and coding with P. Usually P represents the distribution of samples or observations, or it may be a theoretical distribution that is precisely calculated. Q represents a theory, model, description, or approximation to P. The entropy $\mathrm{Info}(D)$ of data D is as formula (1):

$$\mathrm{Info}(D) = -\sum_{i=1}^{m} P_i \log(P_i), \tag{1}$$

P_i is the nonzero probability that any information in D is contained in class C_i.

Attribute A is divided into D and contains n different attribute values 1. From this, it can be obtained that the attribute A is divided into D into a branch node with $A = \{a_1, a_2, \ldots, a_n\}$, $A = \{d_1, d_2, \ldots, d_n\}$ is a tuple in D, and its value in A is a_i, so the calculation formula of entropy can be obtained as

$$E(A) = -\sum_{i=1}^{m} \frac{|d_i|}{D} \times \mathrm{Info}(d_i). \tag{2}$$

The information gain is the difference between the amount of information before and after, and the calculation formula is

$$\mathrm{Gain}(A) = \mathrm{Info}(D) - E(A). \tag{3}$$

The information gain rate regulates the information gain through the parameter value, and the calculation formula is

$$\mathrm{SplitInfo}(D) = -\sum_{i=1}^{n} \frac{|S_i|}{S} \times \log\left(\frac{|d_i|}{D}\right). \tag{4}$$

It divides the n partitions corresponding to each subset in attribute A into the corresponding D. The calculation formula of the gain rate can be obtained as

$$\mathrm{GainRation}(A) = \frac{\mathrm{Gain}(A)}{\mathrm{SplitInfo}(A)}. \tag{5}$$

There are many algorithms for generating decision trees in data mining. The following focuses on several typical decision tree generation algorithms.

ID3 algorithm is the most influential and typical in decision tree mining [14]. Decision trees classify data for prediction purposes. The decision tree method first forms a decision tree according to the training set data. If the tree cannot give the correct classification for all objects, it selects some exceptions to add to the training set data and repeats the process until the correct decision set is formed. A decision tree represents the tree structure of a decision set.

It sets G to be a collection of training instance samples. It assumes that there are m classes in G; then the expected information to classify a given sample is

$$\operatorname{Inf}\left(g_1, g_2, \ldots, g_m\right) = -\sum_{i=1}^{m} \frac{g_i}{g} \log_2 \frac{g_i}{g}. \quad (6)$$

The expected information obtained by dividing according to the B attribute is called the entropy $E(B)$ of the B attribute, which is defined as

$$E(B) = \sum_{j=1}^{n} \left[\frac{\left(g_{1j} + g_{2j} + \cdots + g_{mj}\right)}{g} \right] \times \operatorname{Inf}\left(g_{1j,\ldots,}g_{mj}\right). \quad (7)$$

The obtained information gain for this partition on the B attribute is defined as

$$\operatorname{Gain}(B) = \operatorname{Inf}\left(g_1, g_2, \ldots, g_m\right). \quad (8)$$

The ID3 algorithm has the attribute of high information gain, which is the attribute with the highest partition purity in the given attribute set. Therefore, it can calculate the information gain of each attribute of the sample in G and obtain the attribute with the maximum information gain as the division attribute [15].

The ID3 algorithm is powerful and easy to use. It seems that this algorithm has been able to cope with most cases of classification applications, but a careful study can find that ID3 is more inclined to generate multibranched attributes when selecting split attributes. In extreme cases, the classification of ID3 algorithm becomes very unreasonable [16]. To this end, some scholars have introduced an extended parameter called segmentation information. It uses this parameter mainly to correct the information gain in the ID3 algorithm. The definition of the extended parameter is as

$$\operatorname{ExInf}_B(G) = -\sum_{i=1}^{v} \frac{\left|G_i\right|}{|G|} \log_2 \frac{\left|G_i\right|}{|G|}. \quad (9)$$

It also introduces the gain ratio metric to replace the information gain metric in the ID3 algorithm. It is defined as

$$\operatorname{GainRatio}(B) = \frac{\operatorname{Gain}(B)}{\operatorname{ExInf}_B(G)}. \quad (10)$$

It can be seen that the gain rate not only considers the information gain of the training samples in attribute B, but also considers the amount of information generated by the v branches generated by the v attribute values of attribute B [17]. So in the above example, due to the existence of extended parameters, its gain rate tends to be reasonable. The improved algorithm uses the highest gain rate as the splitting attribute, which is more scientific and reasonable [18, 19].

3.3. C4.5 Algorithm. C4.5 is a classification decision tree algorithm in machine learning [20]. It combines the advantages of the ID3 algorithm and is continuously improved to better realize the construction of decision trees. C4.5 is a family of algorithms used in classification problems in machine learning and data mining. Its goal is supervised learning. The goal of C4.5 is to learn to find a mapping from attribute values to categories, and this mapping can be used to classify new entities with unknown categories.

It gets the minimum value of the continuity property and stores it in MIN. It also stores the maximum value in MAX and divides the breakpoints A_i in [MIN, MAX] in the continuous attribute:

$$A_i = \mathrm{MIN} + \frac{\mathrm{MAX} = \mathrm{MIN}}{N} \times i. \quad (11)$$

Assuming that each variable in the database has two distinct values A and B, the uncertainty assessment of the optimal amount of data, i.e., the information entropy is as

$$S = -\sum_{I} \left(p_i \times \lg\left(p_i\right)\right). \quad (12)$$

There are V different data values in the attribute A in the set S, and A is used to divide S into v subsets, and the information gain rate is calculated during the division as

$$\operatorname{Gain}\left(A_i\right) = \operatorname{Gain}(A) \times \sum_{j \in [1, v]} p_i \log_2 p_i. \quad (13)$$

In the data mining algorithm, in order to improve the enthusiasm of the students in class and the learning efficiency, the students' learning progress data set is taken as the research object. This can scientifically apply these potential relevant influencing factors to provide key decision-making basis for future college English teaching [21].

The advantages of the decision tree method include a simple and straightforward analysis, high classification accuracy, and high execution efficiency. As a result, the decision tree technique is highly suited for data mining on a wide scale. ID3 chooses the classification standard for the data it collects. The ID3 algorithm can only mine nonlinear data; hence it chooses split attributes based on the number of attribute values. The C4.5 assessment classification criteria are used to determine the rate of information gain. By gradually increasing the information according to the information gain formula, C4.5 effectively eliminates the issues that emerge in ID3.

3.4. C4.5 Algorithm Improvement. The C4.5 decision algorithm has better advantages for mining massive data, and the improved algorithm of the classic C4.5 decision algorithm in the decision tree construction will better construct the decision tree. It places some restrictions on the rules and conventions of data: First, it performs classification based on the constructed new attributes, so it is necessary to centrally process and manage the classification attributes in the dataset. Second, it uses the last generated new attribute to classify, so it needs to pay attention to the approximate accurate rule management with high attribute degree.

The core step of the C4.5 decision tree size algorithm is the attribute selection metric calculation. It needs to compare the information gain of each attribute and select the attribute with the largest value to split the tree. Unfortunately, the logarithmic function is used a lot in entropy calculation, and the calculation of the logarithmic function in almost all programming languages requires a lot of computer computing time. Therefore, the computational efficiency of the algorithm is greatly reduced in each attribute selection. Therefore, the key to solving the problem of computing efficiency is how to optimize the entropy value operation and shorten its operation time. To solve this problem, this paper introduces Taylor's mean value theorem and McLaughlin expansion.

Using the Taylor expansion as a substitution to find the limit of the function is the most widely used. At this time, the Taylor formula containing the Peano remainder is generally used. Other equivalent infinitesimals can also be found using Taylor's formula. Taylor's mean value theorem is

$$f(n) = f(n_0) + f'(n_0)(n - n_0) + \cdots + \theta_t(n). \tag{14}$$

It assumes that function $f(n)$ has a derivative value of order $t + 1$ in a narrow interval around n_0, and $\theta_t(n)$ is Tay's remainder.

Maclaurin's expansion: when $n_0 = 0$, Tay's mean value theorem can be converted into Maclaurin's formula, which is

$$f(n) = f(n_0) + f'(n_0) + \cdots + \theta_t(n). \tag{15}$$

Among them, when $\theta_t(n)$ is negligible, the following approximate expression is obtained, which is

$$f(n) \approx f(n_0) + f'(0)m + \cdots + f'(0)\frac{m^t}{t}!. \tag{16}$$

McLaughlin's formula is a special form of Taylor's formula. It can be seen that, for the logarithmic operation in the entropy value, one can use the approximate expression of McFarland's formula instead. Since there is only the logarithmic operation on the base e in the java language, the logarithmic operation in the entropy value needs to be transformed as follows, that is,

$$\mathrm{Log}_2(n) = \frac{Ln(n)}{Ln(2)}, \tag{17}$$

$Ln(2)$ is a constant and only needs to be calculated once, while $Ln(n)$ needs to be improved.

Because $Ln0 = \infty$, function $Ln(n)$ cannot be directly expanded by McFarland's formula, so people set

$$f(n) = Ln(1 + n). \tag{18}$$

Formula (19) is expanded by the approximate expression 18 of McFarland's formula:

$$f(n) = Ln(1 + n) \approx \frac{n - n^2}{2 + n^3} + \cdots + \frac{(-1)^t n^{t+1}}{(t + 1)}. \tag{19}$$

Further approximately, the polynomial $(-1)^t n^{t+1}/(t + 1)$ can be used to replace the $Ln(n)$ operation, so as to reduce the computational complexity of the entropy value in the C4.5 algorithm.

3.5. The Flipped Classroom Teaching Mode Based on MOOC. With the continuous deepening of reform and opening up, the demand for foreign languages, especially international talents proficient in English, from various industries in society continues to increase. Although the proportion of English in various exams is decreasing, the requirement of English proficiency in the actual fierce competition has not decreased. According to the actual situation, China's college English education reform is being implemented.

In this mode, teachers will use screen recording software to create 10-minute video teaching points and upload them to the Internet. Students can watch in their free time and discover their own problems in time. The video contains a simple class review to deepen students' understanding of the knowledge. The unique method of "students study by themselves before class and practice together in class" is contrary to the previous "teacher lectures in class, students practice after class," so it is called flipped classroom, as shown in Figure 4.

As shown in Figure 4: The biggest difference between the flipped classroom education model and the previous classroom education model is that, in the flipped classroom, students complete knowledge learning outside the classroom, and the classroom becomes an interactive place between teachers and students. The flipped classroom teaching mode means that students watch teachers' video explanations before or outside of class, and they learn independently, and teachers no longer occupy classroom time to teach knowledge. The classroom becomes a place for teacher-student and student-to-student interaction. It includes answering questions and doubts, cooperative exploration, completing studies, etc., so as to achieve better educational effects. With the support of the network, students can use high-quality educational resources to learn knowledge without relying on teachers. The learning mode of the MOOC is shown in Figure 5.

As shown in Figure 5, a MOOC is a newly imported online course learning medium. It integrates a variety of educational resources, learning management systems, and open network resources, but it differs in several respects from previous online courses. MOOC platforms are open to the general public for free learning as well as formal learners in specialized schools and educational institutions. The construction of curricula and the organization of events are both examples of openness. Anyone can take part in a variety of learning and exchange activities, as well as providing educational resources and themes to the MOOC.

Traditional online course video software is frequently recorded with reference to the classroom teaching form, and the length of the video generally increases. Learners in MOOCs do not receive information passively.

3.6. Construction Model of Flipped Classroom Based on MOOC. In a typical flipped classroom teaching mode, preclass activities and in-class activities are the main sections, but these two sections are not separated by the flipped classroom teaching mode. Each section contains specific implementation links. These links reasonably connect the preclass activities with the in-class activities to form a complete and smooth teaching mode. The flipped classroom teaching mode based on MOOC is shown in Figure 6.

As shown in Figure 6, MOOC, a large-scale open online course, is the product of "Internet + education." It is a newly

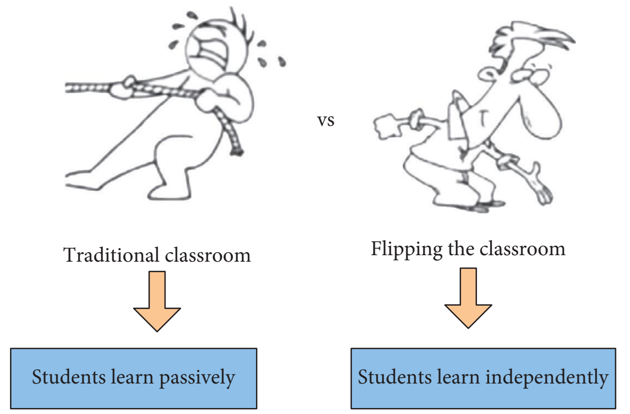

Figure 4: The difference between the flipped classroom education model and the previous classroom education model.

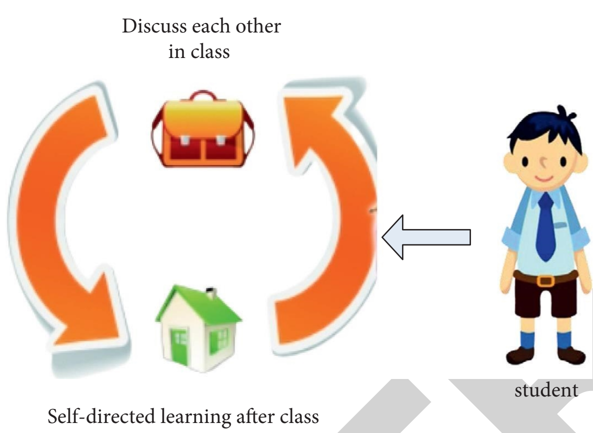

Figure 5: The learning model of MOOCs.

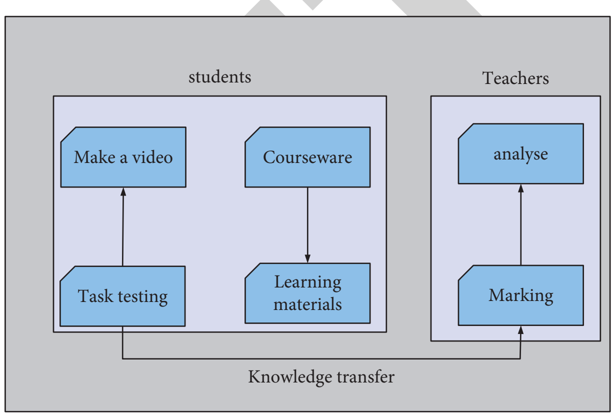

Figure 6: The flipped classroom teaching mode based on MOOC.

emerging online course development model. In a typical flipped classroom teaching model, the activities before class and the activities during class are the main parts. These two parts are not separated by the flipped classroom teaching mode. The autonomous learning based on the MOOC platform before class is mainly composed of task bar guided learning module, autonomous learning module, and group module. In the classroom, teachers create appropriate instructional situations based on instructional content, and students complete knowledge internalization through coinvestigation and interaction.

4. Decision Tree Algorithm and Experiment and Analysis of Flipped Classroom

4.1. Experimental Analysis of Improved Decision Tree Algorithm. In order to simplify the operation, this experiment chooses the first method. It uses the C4.5 original algorithm improved by the previously described improvement scheme. The data used in the experiment comes from the information of 50 students in college English teaching, and the total number of sample instances is 50. In this experiment, the original algorithm and the improved algorithm are compared and analyzed for 5 divisions of the sample instance set, namely, 10, 20, 30, 40, and 50 sample instances. The experimental results are shown in Figure 7.

As shown in Figure 7: It can be seen that, with the increase of the number of data sample instances, the execution efficiency of the improved algorithm is higher. At the same time, in the case of large data sample instance sets, the classification accuracy of the improved algorithm has also been improved to a certain extent. The practice of data mining itself is often faced with the mining of large data set instances. Therefore, using this improved C4.5 algorithm can greatly shorten the waiting time of data analysis and improve work efficiency without sacrificing the classification accuracy. The improved C4.5 algorithm overcomes the deficiencies of choosing attributes with many values when using information gain to select attributes and can complete the discretization processing of continuous attributes.

By comparing the decision trees generated by the two algorithms, it can be known that the improved decision tree shortens the attributes far from the root node by the balance coefficient. This increases the importance of teaching information and makes the classification results more accurate and reasonable. Only a partial decision tree is shown here. The final displayed results are shown in Table 1.

The revised C4.5 method is employed in the subsequent decision tree construction since the improved approach is more reasonable and accurate, as shown in Table 1. The average proportion of leaf node samples of the C4.5 algorithm is 6.6%. The average proportion of leaf node samples of the improved C4.5 algorithm is 7.7%. Because the data used to determine the training set is so tiny, the resulting mining model may have certain flaws. It then validates the training set model against the test set to see if it is accurate. This enables the mining model to be refined and revised further. The decision tree analysis function module of the system module analysis will be used to investigate this.

4.2. Experiment and Analysis of Traditional Teaching Mode and MOOC-Based Flipped Church Teaching Mode. This paper analyzes the development trend of English learning in recent years, as shown in Figure 8.

As shown in Figure 8: The study of college English is very important for expanding students' international horizons.

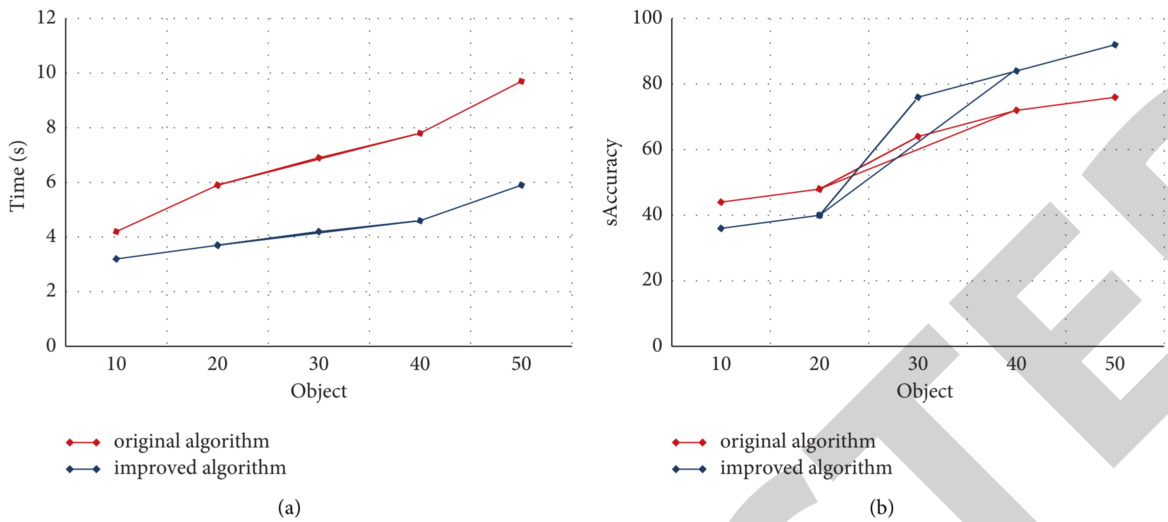

Figure 7: Comparison of algorithms before and after improvement. (a) Comparison of the efficiency of the C4.5 algorithm before and after the improvement. (b) Comparison statistics of C4.5 algorithm classification accuracy before and after improvement.

Table 1: Advantages of the improved decision tree.

Model	C4.5 algorithms	Improved C4.5 algorithm
Tree level	5	5
Number of leaf nodes	15	13
Leaf node sample proportion average	$(20/15)/20 * 100\% = 6.6\%$	$(18/13)/18 * 100\% = 7.7\%$

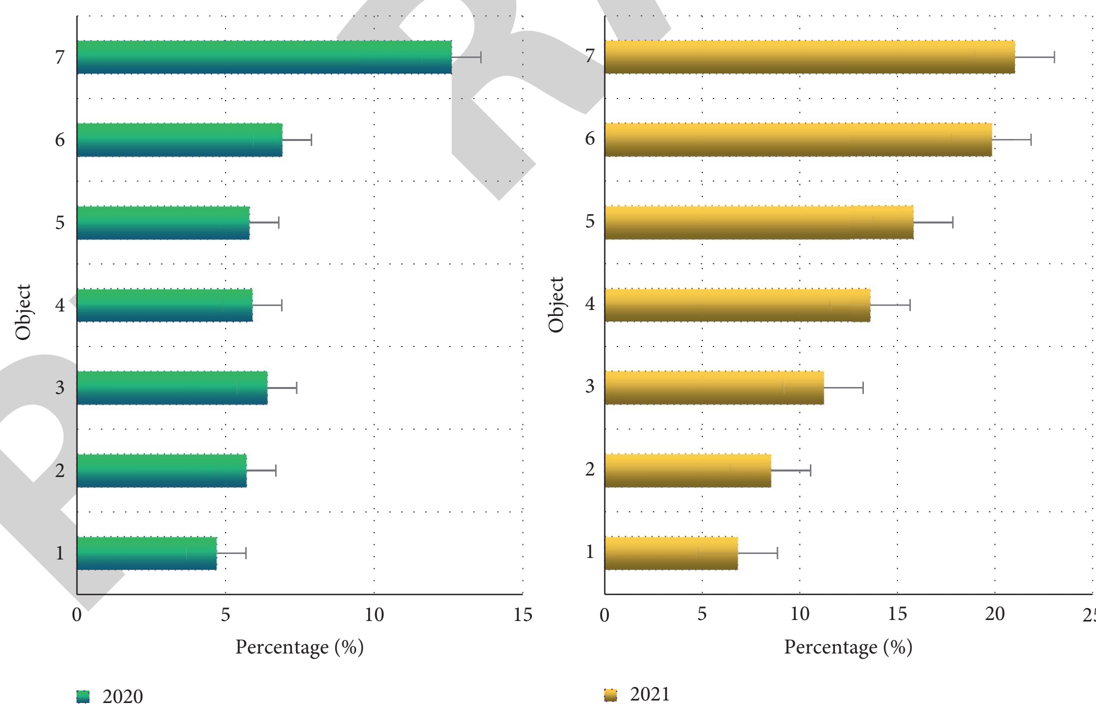

Figure 8: The development trend of learning English from 2020 to 2021.

The traditional education mode of college English education faces the problems of students' participation and educational effects.

The experimental subjects selected in this experiment are students majoring in English in a university, with a total of 50 people. There are 15 boys and 35 girls. It is divided into two groups, one group is conducted in the traditional teaching mode, which is group A, and the other group is conducted in the flipped classroom teaching mode based on MOOC, which is group B. There are 20 people in each group,

Table 2: Popularity of traditional teaching mode.

Object of investigation	Number of people	Percentage (%)	Effective percentage (%)
Like very much	2	10	10
Generally like	3	15	15
Neither like nor hate	5	25	25
Dissatisfied	8	32	32
Dislike very much	2	10	10

Table 3: Popularity of traditional teaching mode.

Object of investigation	Number of people	Percentage (%)	Effective percentage (%)
Like very much	9	45	45
Generally like	8	40	40
Neither like nor hate	2	10	10
Dissatisfied	1	5	5
Dislike very much	0	0	0

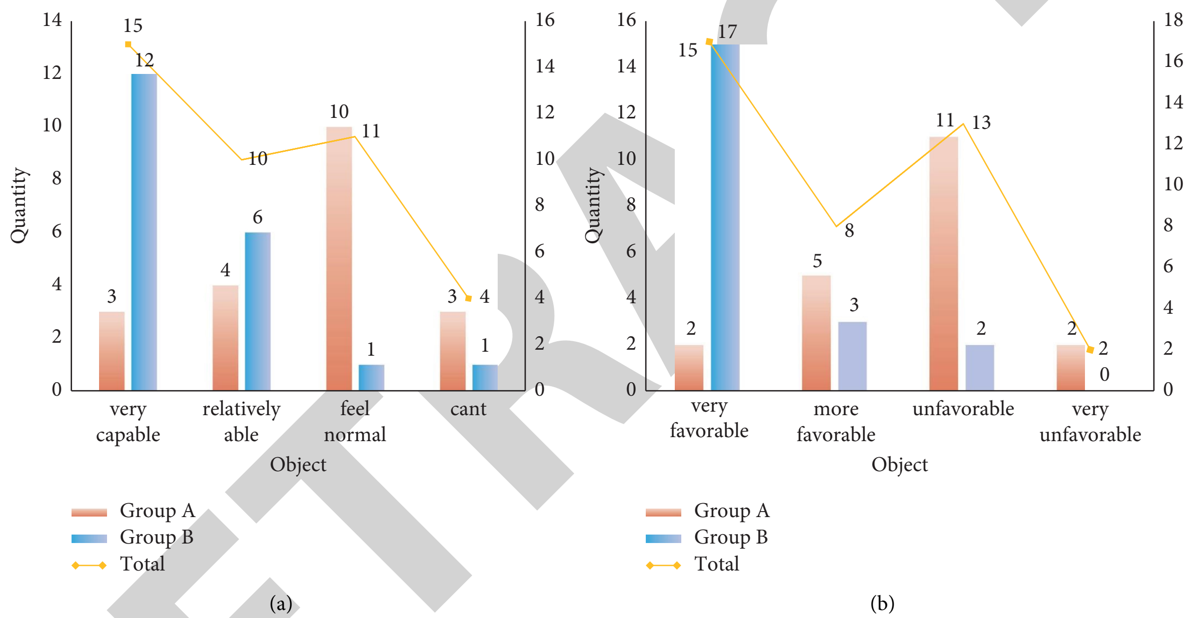

Figure 9: Statistical chart of pre- and posttests of the benefits of the two modes to the mastery of basic knowledge. (a) The traditional teaching mode can stimulate interest in learning. (b) Statistical graph of whether the MOOC-based flipped classroom teaching model can stimulate interest in learning.

and the purpose of this experiment is to change the students' learning attitude and improve the learning enthusiasm of the students in the college English classroom by applying the MOOC-based flipped classroom education model in the college English classroom. After a week of teaching, it first analyzes the students in the traditional teaching mode, as shown in Table 2.

As demonstrated in Table 2, the current teaching mode, which is mostly dependent on instructors' instruction, is unable to pique students' interest in learning, and the majority of students believe that this mode will not improve their learning efficiency or autonomy. Second, the students in group B, who are in the flipped classroom teaching style based on MOOC, are analyzed, as shown in Table 3.

As can be seen from Table 3, there are 9 people who like the MOOC-based flipped classroom teaching model very much, accounting for 45%. Generally, there are 8 people who like it, accounting for 40%. There are 2 people who neither like nor dislike, accounting for 10%. This paper investigates and analyzes two groups of students, as shown in Figure 9.

As shown in Figure 9: Through the summary of the results of the student interview survey, it can be known that the students are more accepting of the new teaching model and have higher satisfaction. This model has improved the overall teaching effect. After the teaching experiment, it tested 2 groups. The weekly test scores of the 2 groups are shown in Tables 4 and 5.

As shown in Tables 4 and 5, the students whose weekly scores in group B were higher than 70 points were significantly higher than those in group A. It can be seen that the new teaching mode has a good teaching effect compared with the traditional teaching mode. The learning ability of

Table 4: Weekly test scores of group A.

Fraction	Number of people	Percentage (%)	Effective percentage (%)
50–60	3	15	15
60–70	9	45	45
70–80	4	20	20
80–90	3	15	15
90–100	1	5	5

Table 5: Weekly test scores of group B.

Fraction	Number of people	Percentage (%)	Effective percentage (%)
50–60	0	0	0
60–70	1	5	5
70–80	7	35	35
80–90	7	35	35
90–100	5	25	25

group B students has been improved. At the same time, it can also indicate that the students in group B have a significant improvement in the application of knowledge compared with the students in group A.

5. Conclusion

Information is becoming a more important driver of humanity's progress in the natural and social sciences. Data mining is a technique for extracting information from seemingly unrelated data that is strongly related to people's lives. The fine-tuning teaching mode is a combination of computer-aided education and network platform technology that compensates for some of the deficiencies of the traditional teaching mode's teacher education mode. The importance of English in worldwide communication is growing, as is the importance of English teaching. MOOCs and flipped classroom task-based college English teaching modes have begun to appear as the traditional teaching mode can no longer match the needs of students. The main focus of this study is on the fundamental concepts of data mining technology, as well as the usefulness of MOOCs and flipped classroom task-based college English teaching modes for future local investigation. It offers a decision tree method based on data mining technology and discovers that decision trees are useful for mining and classifying students' information, resulting in improved English instruction. It conducts experiments on students using various teaching methods in the experimental section. The findings reveal that students prefer the task-oriented collegiate English education strategy based on MOOCs and flipped classrooms. This teaching method boosts students' learning initiative and excitement, as well as their English proficiency.

Texture has strong expressiveness in picture art, and color texture features play an important role in composition. Together with texture, they can convey the artistic connotation of portrait, especially in oil painting. Therefore, in order to make the picture form oil painting style and oil painting schema, we need to study the texture and color texture in combination with the previous oil painting art images. But now, there are few samples of good oil paintings, so it is difficult to study the texture and color texture in oil paintings. Therefore, in order to form a unique artistic style of modern oil painting and promote the development of modern oil painting art, this paper studies the texture and color texture characteristics in the environment of few oil painting works. This paper establishes a model through deep neural network to extract the image incentive and color texture of oil painting art works, which provides guidance for promoting the development of oil painting art. The experiments in this paper show that the depth neural network has high definition for the extraction of texture and color texture of small sample oil painting images, which can reach more than 85%. It has high guiding significance for the research and creation of oil painting art.

1. Introduction

For artistic creation, the first thing is to be based on the shoulders of predecessors. Therefore, it is very necessary to study the works created by predecessors, but it is also a difficult problem to fully study the previous works of art, especially the development of oil painting art. From the perspective of iconography, the texture that can best reflect the artistic language in oil painting art can deeply convey the painter's creative thought and emotion [1]. The second is the color texture, which can reflect the beauty of oil paintings, especially the combination of color can give people a visual impact. But at present, there are not many excellent oil painting works left by predecessors. In order to carefully extract the incentive and color texture in the image in a few works and play its role in oil painting art creation, it is necessary to establish the recognition model of image texture and color texture in a small sample environment, study the internal structure and formation elements of texture and color texture, and promote the formation and schema analysis of oil painting style in modern art.

In this paper, the extraction and analysis of texture and color texture features in the image can not only promote the development and creation of modern art, but also promote the development of modern art education. It makes the development of art more rapid but also has internal meaning. Furthermore, the study of texture and color texture features can help to integrate modern and traditional oil painting art, transforming modern painting into an oil painting style. It is more vibrant and creative. The importance of exploring texture in contemporary oil painting is enormous. The texture composition can reflect the creator's style and spirit while also increasing the aesthetic value of the work. From previous people's oil paintings, the logical relationship between texture, color, and texture features is examined. In their respective systems, they create styles. It can aid students in their exploration and creation of oil painting art. It allows people who practise painting to self-diagnose problems with their work and improve their aesthetic ability after viewing the article.

In order to make modern art images from oil painting style, many people have studied the texture, color, and texture of images. Liu's image oil painting style transfer reconstruction algorithm based on generative countermeasure network was difficult to train. He proposed an improved generative countermeasure network based on gradient punishment and constructed the total variance loss function to study the migration and reconstruction of image oil painting style. The experimental results show that the algorithm has better performance of image oil painting style migration and reconstruction and better effect of image oil painting style migration and reconstruction [2]. However, his research does not specifically explain how the oil painting style is transferred. Yang had proposed a joint domain image stylization method for portrait oil painting. From the perspective of art appreciation, a large number of oil painting works have been analyzed. Three key factors are summarized: texture, structure, and other image. Based on this, a sample-based color adjustment method is proposed. A large number of experimental results show that this method has achieved good results in maintaining the consistency of given image content [3]. His research only studied the color of the image, and the research has a certain one sidedness. El Mehdi et al. proposed a fast and efficient image indexing and search system based on color and texture features in content-based image retrieval system. The experimental results show that the combination of color features and texture features of brightness components can obtain similar results, and the efficiency is higher [4]. His research lacks experimental data and cannot reflect the accuracy of his conclusions. Do et al. proposed a CBIR system based on semantic features to retrieve images from databases. Their method divides the query image into 100 regions and uses K-means clustering algorithm and KNN classification algorithm for semiautomatic annotation. The experimental results showed that the image retrieval efficiency of the system is more than 98% [5]. His research has no specific theoretical support and is not convincing. In order to improve the efficiency of oil painting creation, the pyramid reference image sequence was established by using bilateral reference filtering and mathematical morphology operations by Chen. The experimental results show that the new reference image sequence has clearer texture direction, clear boundary, and is easy to draw. At the same time, this method can be well applied to oil painting teaching [6]. His research has studied the texture features of images, but the construction process of pyramid reference image sequence is not very systematic. Based on the research of these people, this paper reconstructs the recognition model of texture and color texture features in the image under a few samples so as to promote the formation of image oil painting style and graphic analysis.

In this paper, the research on the formation of oil painting style and graphic analysis has the following innovations: (1) this paper applies deep neural network to how to analyze the texture and color texture features in the image, and constructs a model system based on neural network, which can recognize more accurate texture and color texture features in the case of few samples. (2) In this paper, the texture and color texture of the image are analyzed with the help of neural network model, and then the image schema is analyzed with the algorithm. It enables the oil painting style to be transmitted and promotes the formation of oil painting style. (3) In this paper, a series of experiments are carried out on the research of color texture features. It proves that the model of this paper can promote the development of art biography and the formation of oil painting style.

2. Methods of Oil Painting Style Formation and Schema

2.1. Texture, Color, and Texture Characteristics of Oil Painting. No matter how a painting is handled, it will produce brush texture, so texture is one of the important formal elements of constructing portraits. With its rich artistic expression, it plays an important role in the field of painting and exists in oil painting in a unique form. Through the expression form of its own unique attributes, it shows the aesthetic feeling of vision and form in oil paintings [7]. The texture of different materials can show the characteristics of artistic language and image on the picture. In oil painting texture, texture can be said to be a kind of texture. Texture refers to the aesthetic feeling caused by the real expression of texture in the image of plastic arts. It is not only the texture of oil painting materials themselves but also the formation of new image texture after integration with texture materials. It is the combination of oil painting materials and texture materials [8]. In addition, the combination of texture materials and optimized materials will inevitably produce new different visual effects, so it will make people who look at images form different visual or tactile feelings. Texture characteristics refer to the special properties of all actual object surfaces, such as clouds, trees, bricks, hair, and buildings. People are used to some local disordered features in the image, but the whole has regular features, which are also called textures. It also contains important information about the arrangement of surface structure and its relationship with the environment. Texture is also a very important but difficult feature in the image, as shown in Figure 1.

In Figure 1, it can be seen that the Figure on the left is visually different from the Figure on the right. The Figure on the left is visually a water vortex image. The picture on the right is a water grain image, which has different visual effects. And from the perspective of feeling, the picture on the left will be more fresher, while the picture on the right will be heavier. In terms of feeling, in addition to the different effects of texture, we can also see the direction of the painter from the texture. It shows the traces left intentionally and unintentionally in the process of painting. These painting traces can obviously feel the emotional changes in the process of painter's creation. The rich and strong collocation of colors will make people form a completely different vision. Therefore, the color feature is not only the most direct and prominent feature of the image but also one of the most important sensory features of graphic vision [9, 10], as shown in Figure 2.

The contrast before and after colouring can be seen clearly in Figure 2. The portrait in the picture does not match the real human image when it is not painted, but after painting, it can see the skin color and hair color clearly and has a better sense of hierarchy. As a result, texture can reflect

Figure 1: Oil painting texture.

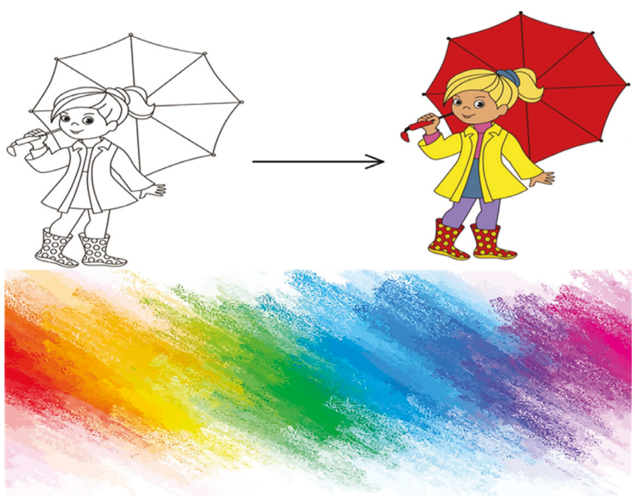

Figure 2: Image color.

the painter's emotional changes, and texture and color features can provide people with visual effects. At the same time, the painter's thoughts and feelings will be conveyed through color intensity. Its bright, warm color expresses the painter's inner love. Texture composition is how you express texture. Its concave, thick, and light surface will evoke a variety of emotions in those who view it. The introduction and creation of texture effects in painting art have opened up a whole new world for the expression of form and color. It has a natural, fresh, and flexible appearance, as well as the ability to be skillfully borrowed. It has evolved into a one-of-a-kind language for artists to express their emotions. It makes natural beauty and subjective feelings blend harmoniously in artistic creation [11]. Therefore, in order to make a breakthrough in modern art creation, we need to analyze the texture and color texture of previous art works.

2.2. Oil Painting Style Formation and Schema. Schema is to serve the formal beauty in painting. Schemata can be divided from time, regional environment, cultural background, personal artistic language, and so on. In all paintings, personal artistic language is to combine the things to be painted in the picture according to their feelings, and strengthen their feelings by using the basic rules of composition [12]. Painting is to match dots, lines, faces, black, white, gray, color blocks, etc. It uses the feeling to mix the elements such as points, lines, and surfaces with scattered, size, rhythm, straightness, cold, and warm. The art of painting must fully understand a pair of contradictions such as virtual reality, square and round, black and white, density, rhythm and charm, and experience the aesthetic principles contained here.

The three-dimensional characteristics [13] of natural objects should be transformed into two-dimensional through both eyes, and the painter's composition ability is fully reflected in this sensitivity. The position of the object image in the picture and the size proportion of the object image will have different visual and psychological feelings. How to form the characteristics of the image in the composition on the basis of clarifying the modeling system and color system becomes very important [14]. There is also an important portrait skill in the image, that is, the placement of portrait modeling. Modeling is how the painter deals with the placement of objects in the painting. Modeling system refers to a unique way formed by the painter's unique treatment of various factors constituting the picture. Modeling is not a single visual grasp, simple object reproduction. Graphic appearance writing is the active pursuit of perceptual psychology and an activity of the interaction between subject consciousness and object spiritual essence [15]. The establishment and improvement of the modeling system is a sign of the maturity of a painter. The modeling system does not take whether the picture has an image as the judgment basis of whether there is a modeling system. Conceptualizing the image is by no means the establishment of a modeling system. Because the painter's quality and taste determine his aesthetic ability and artistic appreciation. The establishment of modeling system requires painters to have high quality and taste, and they can also take this as a breakthrough point to form their own artistic style. The arrangement of composition and shape is shown in Figure 3.

The oil painting style is both traditional and contemporary. We must first understand the oil painting style in order to form it in the transmission of modern art. Oil painting styles and genres are diverse, and there have been countless styles since its inception [16]. Every painter will absorb the essence of the classic paradigm in order to create something new. It defies convention by employing open

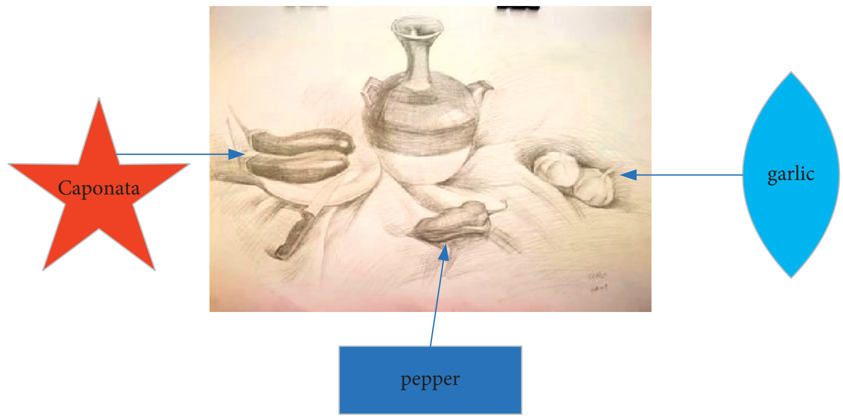

Figure 3: Placement of composition and shape.

reading and its own oil painting creation style, discussing new artistic connotations and expression forms, and attempting to establish its own independent painting style. As a result, when creating modern art, we must consider the style of classic oil paintings. It defies convention by incorporating practical research into the composition, color treatment, and texture effect of the image during the creative process. It attempts to learn from and integrate the schema in order to create modern works in a modern style and oil painting style [17].

2.3. Oil Painting Texture and Color Texture Feature Extraction and Principle. In the previous article, we know the importance of texture and color texture to the image, so if we want to form the oil painting style, we need to extract the texture and color texture features of the classic oil paintings. The specific process of extraction is shown in Figure 4.

As shown in Figure 4, the feature extraction process first inputs the pictures into the gallery, then compares the similarity of the oil paintings in the gallery, extracts the places with low similarity, and then improves it.

For the extraction of color texture features in the image, the histogram method of RGB space is generally adopted. The RGB model is the most commonly used color representation method in the computer, and the statistical histogram of the image is a function, which is usually expressed as

$$G(v) = \frac{A_v}{m}, \quad v = 0, 1, 2, \ldots, N. \tag{1}$$

In the upper form, v represents the color texture features that need to be extracted in the image, and m is the feature dimension of the feature in the RGB model. In order to make the size change of the picture not affect the image feature recognition, this paper normalizes the function. For the color of the image, the RGB model will obtain the statistical histogram of three different colors: R, G, and B, as shown in Figure 5.

If the histograms intersect, the horizontal axis is generally used to classify each color. The level depends on the depth of the color, and the vertical axis represents the proportion of the color in the Figure. If AG (v) and AW (v) are similar features of the two pictures, then the color similarity of the two images is calculated as follows: G and the characteristic histogram of the image W in the image library.

$$S(G, W) = \frac{\sum_{v=0}^{l-1} \min\left[A_G(v), A_W(v)\right]}{\sum_{v=0}^{l-1} H_Q(v)}. \tag{2}$$

In the query matching system, the efficient and accurate similarity matching degree of the query system makes the two methods restrict each other. At the same time, in order to improve efficiency, it also needs to reduce the cost of calculating the same distance. The original search method based on color features filters out the pictures with completely different colors and then introduces the similarity with the texture features of the image. It realizes the search based on texture characteristics, which further improves the accuracy of the search [18]. The fastest matching method is the distance between objects of different colors in the same picture, which roughly represents the color features on the three axes of R, G, and B. Then, the image color features can be represented by vectors:

$$F = \left[\kappa_R, \kappa_G, \kappa_B\right]. \tag{3}$$

At this time, the matching degree between image G and image W is as follows:

$$\begin{gathered} S(G, W) = \sqrt{\left(F_G - F_W\right)^2}, \\ \sqrt{\left(F_G - F_W\right)^2} = \sqrt{\sum_{R,G,B} \left(\kappa_G - \kappa_W\right)^2}. \end{gathered} \tag{4}$$

However, the RGB model histogram cannot effectively measure the fuzziness of people's perception of color features. In order to accurately measure the similarity of two different images, it is necessary to retrieve people's visual color similarity so as to integrate modern art creation into oil painting style. Therefore, it is necessary to refer to the color Table [19]. Assuming that people can feel the same reference color visually, and the number of this group of reference colors is more than the color features of the image to be

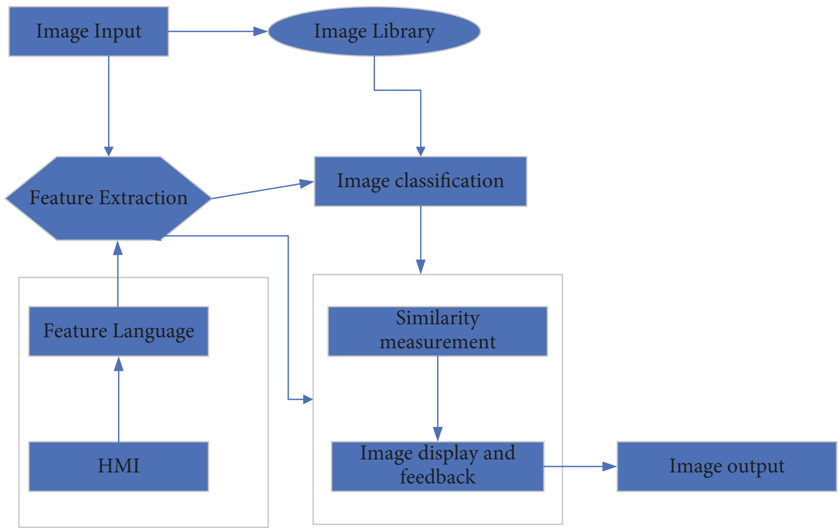

Figure 4: Flowchart of feature extraction.

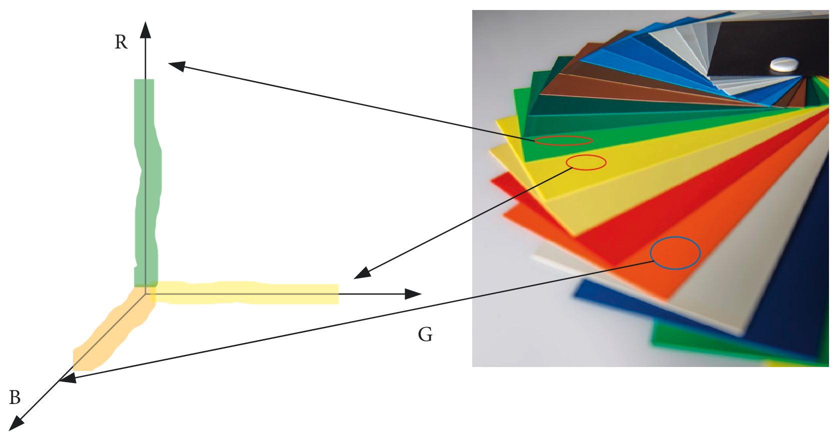

Figure 5: Statistical histogram.

retrieved, the matched feature vector in the cumulative histogram is

$$F = [e_1, e_2, \sigma, e_N]^T. \tag{5}$$

Among them, e_1 represents the frequency of the reference color in the image, and N is the dimension coefficient of the color reference Table, then the similarity matching degree between the test image A and the image W in the image library is

$$\begin{aligned} S(G,W) &= \sqrt[N]{(F_G - F_W)^2}, \\ \sqrt[N]{(F_G - F_W)^2} &= \sqrt{\sum_{i=1}^{N} N_1 (e_{iG} - e_{iW})^2}. \end{aligned} \tag{6}$$

In modern art creation, we need to match the similarity between the newly created image and the color of classic oil painting in the gallery step by step. The closer the similarity is, the deeper the integration of color and texture in classical oil painting is, and the oil painting style is forming [20]. Of course, in order to form the more perfect oil painting style, it is necessary to extract and recognize the texture features in classical oil painting [21]. At present, the commonly used texture analysis methods are statistical analysis method and spectrum analysis method. The measurement of texture has four feature quantities, namely contrast, energy, entropy, and correlation [22].

The so-called contrast refers to the moment of inertia of the main diagonal. The calculation method is generally as follows:

$$CON = \sum_G \sum_W (G - W)^2 d_{GW}. \tag{7}$$

Texture is divided into thickness. For coarse texture, the value of d_{GW} is a value concentrated on the diagonal of the image. If the value of $(G\text{-}W)$ is smaller, the value of image contrast is smaller, otherwise, it is larger. The calculation of energy will be affected by the gray value of the image, so assuming that the energy is t, the formula is

$$T = \sum_G \sum_W (d_{GW})^2. \tag{8}$$

Because the gray value of the image will affect the recognition of the texture features of the image, it is necessary to measure the uniformity of the gray value distribution of the image. When d_{GW} is more concentrated on the diagonal of the image, the value of T will be larger, and vice versa. When the dispersion degree of d_{GW} value distribution in the gray level co-occurrence matrix is different, the entropy value will change. The more dispersed d_{GW} is, the greater the entropy value will be. The calculation formula is as follows:

$$C = -\sum_{G}\sum_{W} d_{GM} \log d_{GM}. \tag{9}$$

The correlation is a measure of the linear relationship between image gray levels. Assuming that the mean value in matrix d_{GW} is λ_a and λ_b, and the standard deviation is χ_a and χ_b, the formula for calculating the correlation is

$$COR = \frac{\left[\sum_G \sum_W GW d_{GM} - \lambda_a \lambda_b\right]}{\chi_a \chi_b}. \tag{10}$$

Therefore, as an example, features can be basically extracted, and then roughness is the measurement of texture granularity, fine or rough. The finer the texture, the finer the image, and the grain size is the size of the basic grain of the texture [23], which can be defined as

$$R = \left[\left(\frac{1}{X_{ps}} \sum_{l,v\in N_t} [\vartheta(R,l,j)]^2\right) > Y\right]. \tag{11}$$

In the above formula, $\vartheta(R,l,j)$ represents the window with coordinates (I, J) as the center, R as the radius, Npt represents the clarity of the image, and Y is the threshold, so the image texture features can be extracted through granularity. Therefore, the extraction principles of color texture features and texture texture features are integrated into the depth neural network model. It integrates the color texture features and texture features of the image into the depth neural network model. Through the autonomous learning ability of the model, it no longer needs to extract step by step according to the above principle. It can not only improve the extraction efficiency of image features but also improve the accuracy of similarity and texture roughness. In the depth neural network model, the image contrast is defined as

$$CTS = \left(\frac{H}{a_4}\right)^{1/4}. \tag{12}$$

Among them, A4 = λ_a / H^4, H is the standard deviation, and the calculation method is as follows:

$$\begin{aligned} H &= \sqrt{\left(\lambda_b - \chi_b^2\right)}, \\ &= \sum_{i=0}^{U} p, \\ H_4 &= \sum_{i=0}^{U} p_4. \end{aligned} \tag{13}$$

In the upper form, H is the intensity of image brightness, and P represents the probability of texture appearing in the image with the same roughness. Therefore, in the deep neural network model, the classical oil painting is put into the neural network model, and then the modern works are transmitted to the deep neural network model for comparison. Then, the similarity between color texture and texture characteristics is obtained, and modern works are constantly adjusted to form oil painting style.

3. Experiment of Oil Painting Texture and Color Texture Feature Extraction

3.1. Experiment of Texture Feature Extraction and Recognition. This experiment will take two pictures as samples and use the depth neural network model constructed in this paper to recognize the texture of the two pictures. One of the samples is a classic oil painting in the model, while the other is a work of modern art. The sample picture is shown in Figure 6.

The specific data of each picture in Figure 6 is shown in Table 1.

Therefore, the texture of the picture is recognized and extracted in this experiment, and the texture is shown in Figure 7.

Figure 7 shows that the sample picture's texture is delicate, and it is clear that the painter is attempting to depict a peaceful landscape. The painter is very light when it comes to texture in the painting process. The image on the left is a classic gallery piece, while the image on the right is a contemporary art piece. Because the picture on the right cannot reflects the painter's emotion during the painting process, the similarity in texture should be around 85 percent. The image on the left is more delicate, particularly the texture of the waterfall, which will convey more vivid thoughts and feelings downstream.

3.2. Color Texture Feature Extraction Experiment. Taking the pictures in the above experiment as samples, the above A, B, C, and D pictures have different brightness. Therefore, this experiment first identifies the color similarity of the same picture under different brightness. Taking the diagonal of the picture as the benchmark, the measurement data record of similarity is shown in Figure 8.

In Figure 8, seven color points are tested from the diagonal of the picture, and the color similarity of the same picture under different brightness is identified. It can be found that the color similarity of the color taking points of the same diagonal in the picture is basically the same. In particular, although the same picture has different clarity, the color similarity is very similar and basically the same. Therefore, the model constructed in this paper has high accuracy for the extraction of color similarity, and it is of great help to the formation of oil painting style. Therefore, we extract and recognize the texture features and color features in the sample image, as shown in Figure 9.

In order to better measure the recognition of color features and texture features in this model, this experiment also makes similarity statistics on the color and texture

Figure 6: Experimental sample.

Table 1: Picture data.

Picture	Luminance (%)	Pixel
a	85	128 * 138
b	80	192 * 192
c	90	384 * 384
d	95	640 * 640

features of the same picture of different pixels in the sample, as shown in Table 2.

In combination with Figure 9 and Table 2, the pixels of the image will affect the similarity of the image, so it is necessary to ensure the clarity of the image during image comparison. In addition, from Figure 9, there will be some gaps between the color and texture of classic oil paintings and modern art works. However, it can be constantly revised according to the gap to guide the final formation of oil painting style.

3.3. Experimental Summary. Through the experiment of this paper, the model constructed in this paper plays a very important role in the formation of oil painting style. The texture extraction of oil painting is in place, which can clearly see how the painter writes in the process of painting. This model can find out the gap between classical oil paintings and modern art works by comparing the color characteristics, texture, and texture characteristics. It can help painters approach the oil painting style purposefully and promote the formation of oil painting style in modern art creation. At the same time, the analysis of the texture and other characteristics of the image is the analysis of the schema, and the model in this paper has a good effect on the schema analysis.

4. Discussion

This paper understands the texture characteristics of oil painting. The texture of oil painting can clearly see the trend of painters' brushes in their creation. A careful study of the texture of classic paintings can be of great help to artistic creation. The artistic expression of oil painting is very strong, especially in the matching of colors. The collocation is very strong, and some have a great visual impact. In the painting materials of oil painting, the roughness of texture produced by the thickness of pigment is different. Therefore, some that need to be distinguished can be reflected by the thickness of the pigment. Therefore, the integration and development of oil painting style and modern art can promote the development of modern art. Schema is very important in portrait, and point, line, and surface lighting constitute the basic structure of portrait. In addition, illustration is essential to the art of painting, especially in the modeling and placement of things in the portrait. This reflects the overall artistic effect of the portrait, so the schema can also be carefully analyzed to promote the development of modern art. Through the experiment of this paper, it can extract and recognize the texture and color texture features in oil paintings, and analyze the schema composition in oil paintings. This model can further compare the gap between classical oil painting and modern art works, and automatically make modern works close to oil painting style and promote the formation of oil painting style. It can also make a very detailed analysis of the schema.

Figure 7: Sample picture texture.

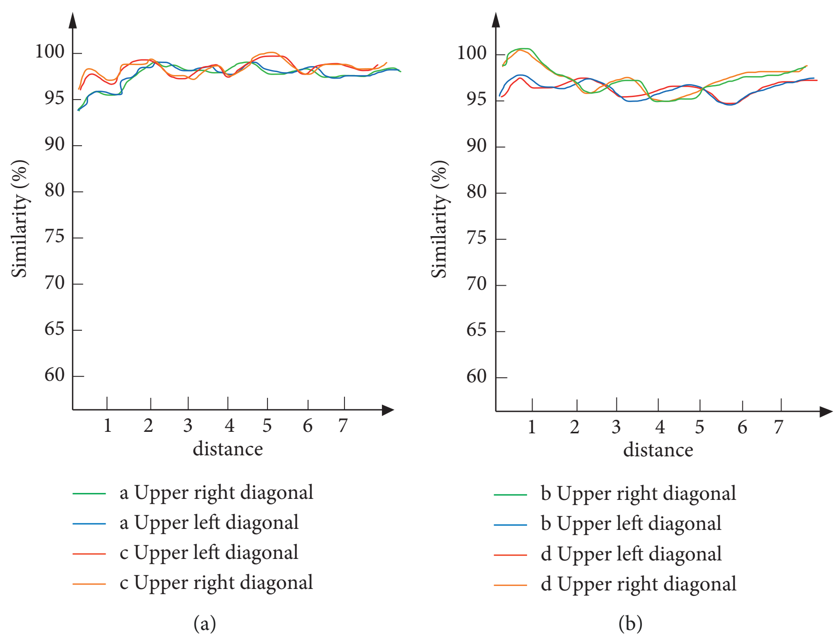

Figure 8: Diagonal color similarity. (a) Similarity between A and C. (b) Similarity between B and D.

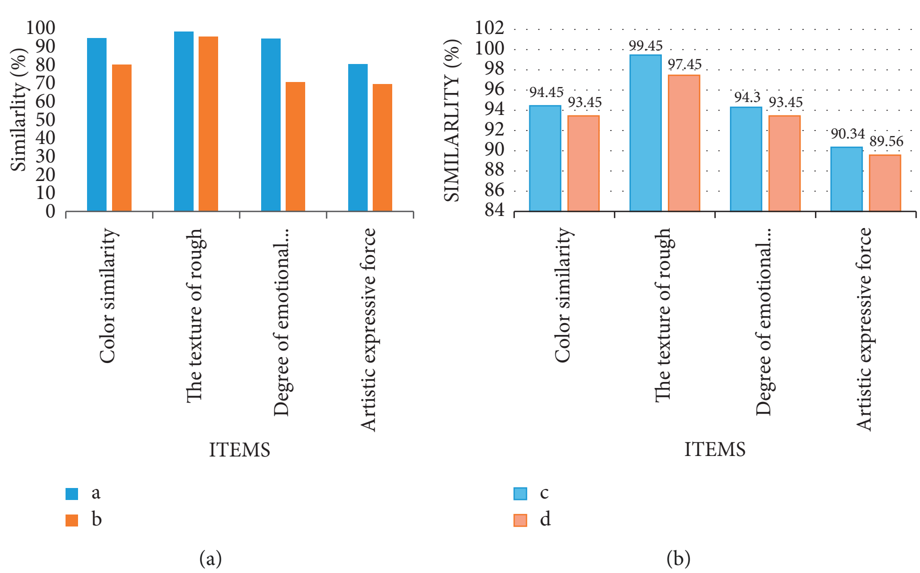

Figure 9: Similarity of different pictures. (a) Comparison of A and B. (b) Comparison of C and D.

Table 2: Similarity of color and texture features of the same image with different pixels.

	Gallery images		Image	
	a	*c*	*b*	*d*
Color similarity	99.45	97.45	89.45	94.45
The texture of rough	94.5	94.5	84.45	95.67
Degree of emotional communication	93.23	98.34	93.45	96.45
Artistic expressive force	94.56	95.45	94.34	98.45

5. Conclusion

This paper explores the role of texture and color texture in the portrait. Texture is the most direct way for oil painting to convey the painter's thoughts and feelings, and it is also the best way to convey the artistic effect of portrait. Color texture can bring great visual impact to people. Therefore, this paper makes a theoretical reasoning on how to form oil painting style and graphic analysis. This paper also constructs a deep neural network model to facilitate the extraction of image texture and color texture features so as to facilitate the graphic analysis in modern creative art and the formation of oil painting style. And the experiment of this paper proves that through the combination of the recognition principle of image color and texture features and the depth neural network model, we can well compare the gap of modern art in oil painting style and promote the formation of oil painting style. However, the research on oil painting texture and color texture features in this paper will still be affected by many uncertain factors. It is hoped that future research can overcome the influence of uncertain factors.

Under the background of intelligent education, the study chairs of intelligent classrooms in colleges and universities should reflect humanistic care and design and guide students to establish a healthy learning style. To realize the intelligent classroom learning, the intelligent seat can be applied to different sitting positions or different heights and weights. This paper designs a control system based on MC9S08DZ60 and realizes the communication between the control system and the mobile app by combining the Bluetooth module based on CSR8670. At the same time, this paper proposes an intelligent design that can adjust the seat height by voice. LD3320 speech recognition module is used for voice control, and a push rod motor with a rising speed of 7 mm/s is used to complete the lifting to meet the requirements of different sitting positions and different heights and weights. Then, the folding design of the intelligent seat for classroom learning is carried out. Infrared detectors are used at the armrests on both sides of the seat. When people have a tendency to sit down, they will speed up deployment. When a person leaves the seat, the seat will automatically retract. Finally, the objective evaluation method of pressure distribution test experiment is compared with the subjective scale evaluation of students, which verifies the effectiveness of the shape design of the chair in keeping students' healthy sitting posture for a long time.

1. Introduction

Under the background of intelligent education, it presents new opportunities and challenges for university education informationization. Universities must actively promote the development of educational management informationization, deepen the integration of information technology and education and teaching, innovate educational concepts and teaching models, promote the integration and sharing of educational management data, and improve fine management and scientific decision-making capability. Learning in the context of intelligent education is characterized by an autonomous learning process, interconnected learning methods, and intelligent learning support [1], resulting in a new intelligent learning paradigm. The premise and guarantee for achieving intelligent learning is to create a good intelligent learning environment. The main research contents of intelligent learning environment [2, 3] are how to fully utilize the new generation of information technology to support the realization of the core features of intelligent learning and how to design intelligent learning environment according to different learning occasions to support different activity modes.

Teaching smothering chair, also known as class chair, refers to the chair used by students in class, which is the most frequently used seat in campus life. It is not only the main category of school chairs but also the focus of educational furniture. It also reflects the related characteristics of smothering products and public services. A healthy chair is one that can ensure students' healthy sitting posture, and a healthy chair can maintain the health of lumbar vertebrae. In design, the shape of the chair is very important because a reasonable shape can maintain the normal physiological curve of lumbar vertebrae [4]. Literature [5] pointed out that if you keep sitting forward for a long time, it will cause great physiological pressure on the intervertebral disc, muscles, and ligaments. In general, it is generally believed that a good sitting position means sitting very straight, and the back support can make the back muscles support the trunk. If there is no back support, the time for the back muscles to support the trunk will be greatly shortened. Therefore, few people can keep their backs straight for a long time. There are two ways to solve this problem: either by providing a backrest or by increasing the angle between the torso and thighs. Literature [6–8] evaluates and analyzes the differences between the current human body sitting posture and healthy sitting posture, and then according to the relevant principles of sitting posture, discriminates six common sitting postures, which are: leaning right (left), leaning head, bending spine, leaning forward, and leaning back. These contents provide a theoretical basis for the study of sitting behavior. The algorithm of face, eyes, mouth, and shoulder detection has been improved, however, no specific product design scheme has been put forward, and the detection of the most sitting positions has been explored theoretically and experimentally. Literature [7], from the perspective of ergonomics, summarizes the main parameters of a healthy sitting posture for students. The angle of the body in a better sitting posture is 4 at 90 degrees, and the angle of the body in the best sitting posture is 2 at 90 degrees and 2 at 135 degrees. Literature [8] found that when the neck of human body bends more than 20 degrees, it will cause different degrees of musculoskeletal diseases.

In the case that the chairs in the modern market cannot meet the needs of students, the study has improved the design of the learning chairs in the intelligent classrooms of colleges and universities from the perspective of health. After repeated tests and experiments, various scientific and reasonable design indexes are constantly explored, and the design ideas and methods of intelligent structure of learning chairs in intelligent classrooms of colleges and universities based on human factors engineering are put forward.

2. Learning Seat Design Principles in Smart Classroom

2.1. Comfort Principle. In the intelligent classroom, the comfort of the chair has an impact on the learning experience. Human factors, seat factors, and human-seat interaction are the three types of factors that affect comfort. Gender, height, weight, and BMI are just a few examples of human factors. Individual preferences influence seat comfort [9]. Size, material, and appearance are all factors to consider when choosing a seat. The pressure distribution on the seat surface is related to seat factors, and the seat back should conform to the human spine curve [10]. Table and chair height ratios, as well as color matching, are important factors to consider. The height ratio of tables and chairs varies according to the user. The height of seats should be easily adjustable to meet the needs of the majority of users. Colors used in moderation can help reduce visual fatigue and provide a pleasant visual experience [11, 12].

2.2. Functional Principle. To cater to the intelligent classroom, tables and chairs should not be limited to the basic functions of sitting, writing, and receiving. The functional design of seats can be improved in many aspects, such as material, size, function, and color. In addition to the conventional physical improvement means, such as height adjustment, desktop tilt, roller addition, folding, or deformation of tables and chairs, we can also focus on technical improvement means, such as classroom interaction and resource sharing. For example, the application of Bluetooth transmission, virtual desktop technology, VR (Virtual Reality), AR (Augmented Reality), and other information technologies can optimize management, improve efficiency, facilitate data transmission, help students better integrate into the classroom, and improve students' participation and experience [13].

2.3. Interaction Principle. Wisdom class deviates from the traditional teaching model by emphasizing teacher-student interaction. We can consider the teaching mode and the realization of interactivity when designing seats for interactivity. There are four different types of teaching modes: the traditional teaching method, in which the teacher speaks and the students listen, is the first. The second type of discussion is group discussion, in which students are divided into groups of varying sizes. Thirdly, there are class meetings or other group gatherings that require everyone to sit together for deliberation, voting, and other activities [14, 15]. Fourth, to conduct activities in the classroom, tables and chairs must be removed. The implementation of interactivity in the smart classroom necessitates more technical means. Seats should be placed in a convenient and uniform manner, and they should be able to be adjusted as the class mode changes.

3. Intelligent Structure Design of Seat

3.1. Seat Shape Deduction. The design of the seat surface is based on the principle that different parts of the buttocks bear different pressures. The pressure is the greatest at the ischial tuberosity of the human body, gradually decreases to the periphery, and the pressure is the lowest at the thigh of the human body. The body pressure of the seat back is mainly distributed in the scapula and lumbar vertebrae of the back of the human body [16]. The supporting positions of these two parts are called "shoulder rest" and "waist rest." The seat "lumbar support" is approximately between the third and fourth lumbar vertebrae, and the seat "shoulder support" is approximately between the fifth and sixth thoracic vertebrae. In the design of seats, "lumbar support" is very important.

This paper mainly focuses on the medium-sized seats. As the design of a seat cushion is the key part of the seat to maintain students' healthy sitting posture, three types of seat cushion are designed: I, II, and III. The edge of the I seat cushion is raised, and the ischial tuberosity is raised with emphasis, and the legs have certain support. The overall shape of the B seat cushion is sleek, mainly heightening the hips and thighs. Type III cushion is relatively square, only heightening the rear side of the buttocks. The purpose of heightening the two sides and the rear edge of the cushion is to fix and limit the buttocks and thighs of the user and to correct the sitting posture of the user using the above methods.

As the cushion part is the key design part of the whole seat, firstly, the three preliminary designs are verified, and the most suitable cushion is selected. Then, the subsequent shape design and verification test are continued. Figure 1 below shows the hot zone diagram of the sitting and pressing comparative experiment of the three seat cushions I, II, and III.

As shown in the comparison of the hot zone diagrams of the three seat cushions in the above figure, the hot zone of the thigh part of the II seat cushion is red, which indicates that the pressure value here is too high, the pressure on the thigh is relatively large, and the stress on the sitting surface is uneven, which is not conducive for maintaining a healthy sitting posture. There are many red areas on the rear side of the buttocks of Type III seat cushion, and the red area at the ischial tuberosity is large and mainly concentrated on the right side, which shows that the above areas exert great pressure on the human surface and are unevenly stressed, and the curved surface design of the sitting surface is reasonable, which does not meet the requirements of maintaining sitting posture. Although the pressure distribution of type I cushion is not ideal, the pressure distribution of type I cushion is relatively balanced among the three cushions. Therefore, type I cushion is selected as the initial seat shape, which provides a basis for the subsequent shape deduction and verification test.

3.2. Design and Composition of the Mechanical Structure of Intelligent Seat in Intelligent Classrooms. The mechanical structure of the intelligent seat for learning in the intelligent classroom is shown in Figure 2. The design inspiration comes from the seats with high utilization rate in the market, which mainly includes the floor bracket part, the control armrest part, the reversible seat cushion, the locking part, and the chair back part [17].

The floor support part is used to support the seat cushion, connect the seat cushion with the chair back, and make the whole chair be placed on the ground completely and reliably.

Back part: the design of the back part is made of wooden strips and is polished. Considering ergonomics and according to the data provided by references, the backrest and waist are designed [18] to make users have perfect riding experience as much as possible. At the same time, the main control board is placed at the back of the fixed backrest, which makes reasonable use of the space and facilitates the later program debugging and maintenance.

Control handrail part: used for placing fingerprint reading module, LED lights for displaying the status of attendees, and interactive buttons. It is connected with the main control board at the back of the backrest through the slot on the armrest, which ensures the stability of the flat cable and makes rational use of the space. Armrests allow users to place their arms to adjust their sitting posture, relieve fatigue, and improve their riding experience and comfort [19].

This part is inspired by the common reversible seat cushion and locking mechanism. This part, however, is equipped with a controlled electromagnetic locking device, unlike ordinary seats. The iron core in the locking device is in a pop-up state before the fingerprint signal is input. The iron core is inserted into the pin hole of the rotary seat cushion at this point, preventing the seat from being turned over, achieving the function of one person and one seat. The electromagnet is electrified after receiving the fingerprint unlocking signal, the iron core is adsorbed, the pin hole is unlocked, and the seat cushion can be turned over [20], completing the intelligent unlocking function.

3.3. Design of Intelligent Seat Control System in Intelligent Classroom

3.3.1. Circuit Design. To realize that the intelligent classroom learning intelligent seat can be used for different sitting positions or different heights and weights, this paper designs a control system for intelligent classroom learning intelligent seat, which realizes the above functions by controlling two stepping motors and one steering gear in the adjusting mechanism. There are many integrated circuits in the control system, which need to be powered by 24 V, 5 V, 3.3 V, and 1.5 V. TPS54386 is a converter with dual voltage outputs and nonstep down, with the maximum output current reaching 3 A, and the output voltage range can be selected between 0.8 V and 90% of the input voltage [21]. Therefore, TPS54386 is selected in this paper to step down 12 V to 5 V for position detection sensor, operational amplifier BA4558F, power amplifier NS4150, and steering gear and step down to 3.3 V for main processor MC9S08DZ60 and Bluetooth module CSR8670. The circuit diagram is shown in Figure 3.

To facilitate the operation, the control system adopts the way of mobile phone APP to realize the automatic adjustment of the intelligent seat in the intelligent classroom, and the mobile phone APP communicates with the control circuit board through the Bluetooth module [22]. With reference to the power consumption, transmission distance, transmission speed, and chip cost of different versions of Bluetooth, this paper uses the Bluetooth molding set BT86 based on CSR8670, which has a power rate equal to Class2 10, and it is packaged with the size of 20 mm (L) $*$ 10 mm (W) $*$ 1.8 mm (H). Its main features are as follows:

(1) It fully supports Bluetooth V4.0 technical specification and is compatible with Bluetooth V5.0 technical specification.

(2) 80 MHz RISC MCU and 80MIPS Kalimba DSP.

(3) With integrated balun radio frequency module, the transmitting power of the radio frequency module is 10 dBm, and the receiving sensitivity is −90 dBm.

(4) 16 Mb internal Flash memory, which can support external expansion to 64 Mb SPI flash memory.

(5) Dual-channel ADC stereo audio decoder can support up to 6 microphone inputs.

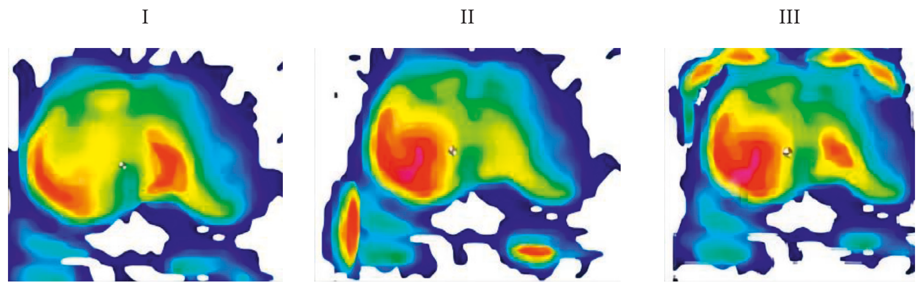

Figure 1: Hot zone map of three seat cushions.

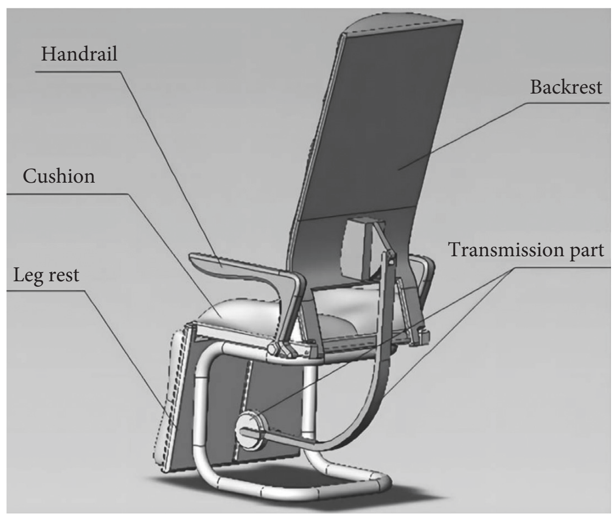

Figure 2: Learning 3D modeling of intelligent seat in intelligent classroom.

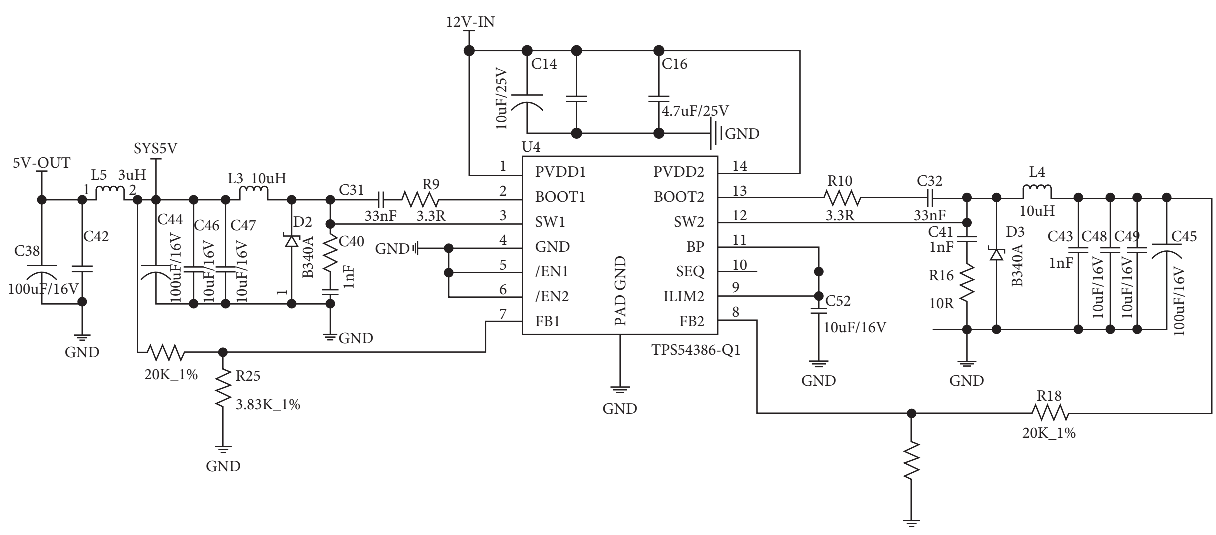

Figure 3: Circuit diagram of TPS54386 buck conversion.

(6) The audio interface supports I2S, PCM, and SPDIF.
(7) Support CSR's latest CVC noise reduction technology.

According to the above characteristics, it can fully meet the functional requirements of intelligent classroom learning intelligent seat control system. The circuit schematic diagram of Bluetooth module BT86 based on CSR8670 is shown in Figure 4.

3.3.2. Voice-Adjusted Seat Height Design. This paper proposes the design of intelligent seat height adjustment by voice based on the previous design to meet the needs of smart seats for various sitting positions, heights, and weights. The design of the voice-adjusted seat height in this section is based on STM32C8T6 single chip microcomputer, as well as the motor drive module, power supply module, and voice recognition module, which integrates the path planning algorithm and performs voice-controlled lifting.

(1) Top Management System. The STM32F103 series based on Cortex-M3 core should be used as the main control chip, with the highest working frequency of 72 MHz, including 32–512 kB Flash memory and 6–64 kB SRAM memory. There are 11 timers inside, with 3 12 bit ADCs, 2 IIC interfaces, and 5 USART interfaces and CAN interfaces. In addition, the chip is powered by a low voltage of 1.7~3.6 V. The schematic diagram of the minimum system core is shown in Figure 5.

(2) Lifting System. The lifting is completed by adopting a putter motor with a rising speed of 7 mm/s, which is in line with the time difference from voice recognition to processing and issuing instructions by the voice module. The lifting is driven by DC, which transfers the horizontal rotation to the vertical lifting. By changing the positive and negative poles of the motor to ascend and descend, there is a travel limit switch at both ends of the push rod, and the telescopic rod will automatically lock when it reaches the bottom or reaches the top, thus avoiding the idling burning of the motor.

(3) Voice Control Adjusts Seat Height. LD3320 speech recognition module is used in speech control, and it has the function of double password control recognition: password mode + I/O control mode, which increases the recognition accuracy. The voice feature information we extracted is the input voice spectrum data. After setting the primary password, the next secondary password can be used for control operation. Furthermore, LD3320 supports speaker-independent speech recognition technology and does not need recording training. Speak specific speech recognition instructions (which have been entered in advance) through MIC microphone, carry out signal processing and judgment, and transmit the obtained results to STC slave control system for processing.

This module has a 5V TTL serial port and 16 I/O ports, which can communicate with external single-chip microcomputer, exchange information, and can also control relay and other equipment. Therefore, the voice recognition module is directly connected with the relay to control the lifting of the push rod motor.

(4) Adaptive Weight Regulation. The original purpose of the weight adjustment mechanism was to accommodate students of various weights in seats. When students of various weights sit in the seats, the upper and lower floors of the seats drop to varying degrees. Different students' weights can be quite different. Chinese students' weight can range from 45 to 100 kilograms. As a portion of a student's weight should be supported by their arms and legs, which do not act on the seat suspension system, 75 percent of them, according to experience, are supported by the suspension system. The seat's estimated dead weight is 10 kg. As a result, the possible variation range of the effective mass acting on the seat suspension system can be estimated to be 45–85 kg. Because each student's weight varies, the equivalent spring-loaded mass will vary as well. The compression amount of the vertical spring is different, and the length of the vertical spring is different when the seat suspension is in equilibrium. To make the seat suspension suitable for students of various weights, the lower end point of the vertical spring should change with the weight of the students, ensuring that the upper end point of the vertical spring is always in the same position when the seat suspension is balanced.

3.3.3. Folding Design of Seat. The automatic folding seat with infrared sensor includes backrest, cushion, chain wheel, chain, limit switch, and control structure. The passive infrared sensor installed on the head of the seat senses whether someone exists, which has the following three functions [23]:

(1) When someone approaches the seat, the seat will control the motor to rotate and slowly open the seat.
(2) When a person stands temporarily and has not left the seat, the seat will not fold automatically.
(3) When a person leaves, the seat will be folded slowly without perceiving the existence of the person.

The structural design of the folding seat is shown in Figure 6 below.

The control structure comprises a controller, a brake, and a motor, wherein the controller is electrically connected with the brake and the motor, respectively. The motor is connected with the brake shaft through a coupling. The hardware of infrared foldable seat includes the following: core processor STC15w408AS, single chip microcomputer, active infrared sensor, passive infrared sensor, and motor. The hardware design block diagram is shown in Figure 7 below.

Select STC15w408AS single chip microcomputer, which integrates high-precision RC oscillation circuit and high-reliability reset circuit internally, so that the direct external crystal oscillator and reset circuit can be omitted, and the chip can work directly after being powered on, can output multichannel PWM to control the rotation of the motor, and sense whether someone approaches by reading the level change of the passive infrared sensor. By reading the level change of the active infrared sensor, we can sense whether someone has the tendency to sit down to speed up the rotation of the motor and open the seat.

Active infrared sensor has strong adaptability to ambient light. It has a pair of infrared transmitting and receiving tubes, which emit infrared rays with a certain frequency. When there are no obstacles in the transmitting and

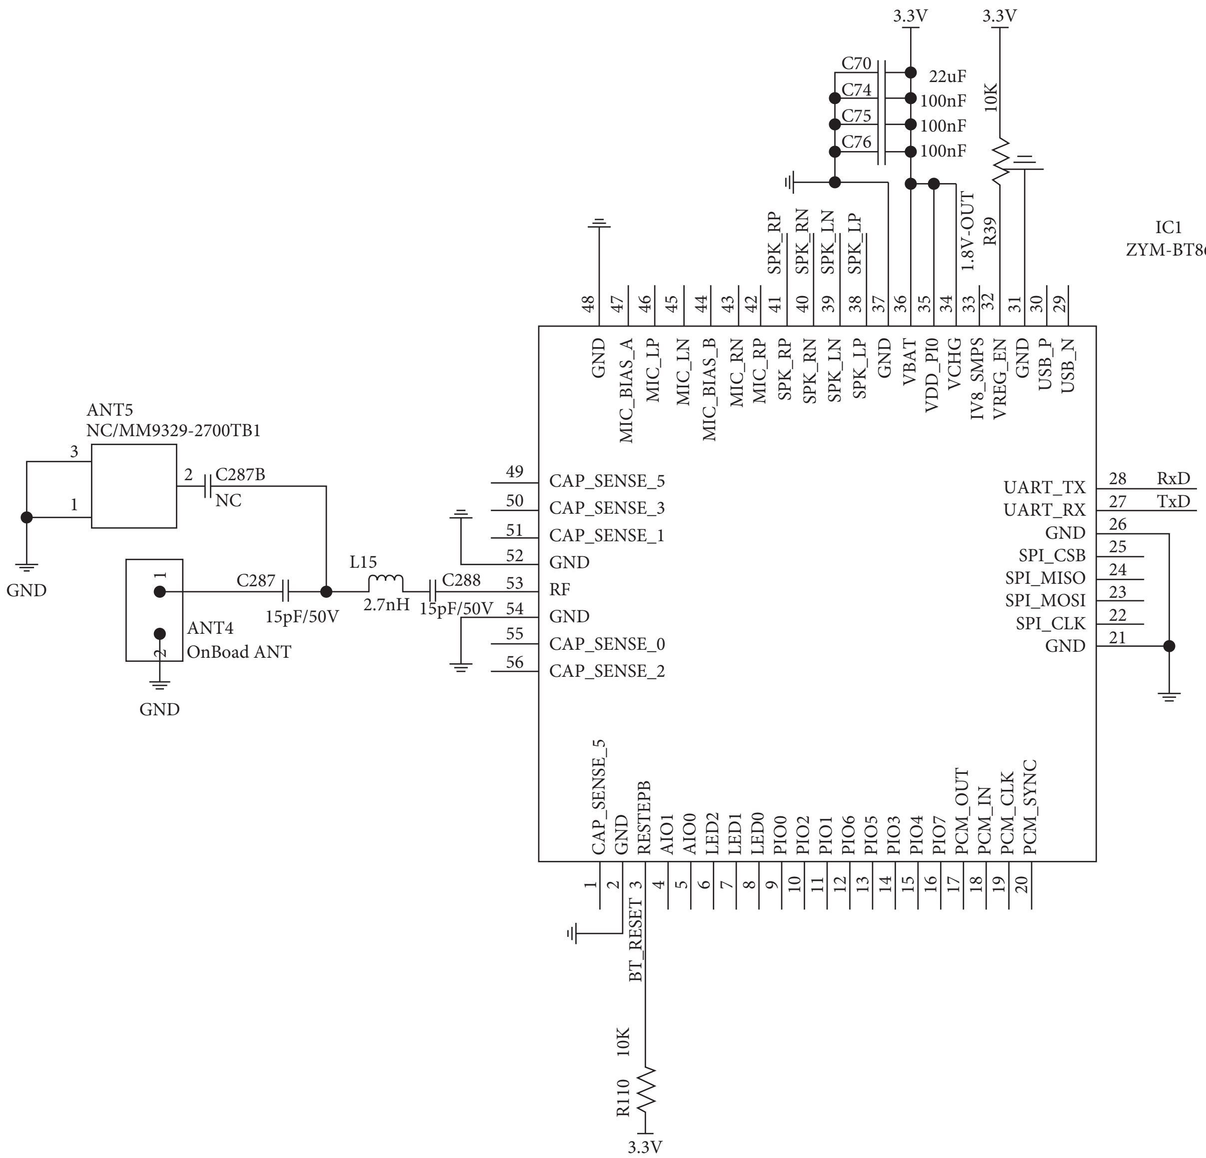

Figure 4: Circuit diagram of BT86 module.

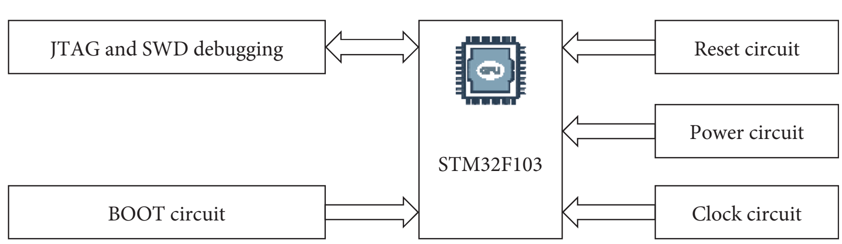

Figure 5: Structure diagram of STM32 core circuit.

receiving tubes, the receiving tube receives the infrared rays emitted by the transmitting tubes, and the green indicator lights up. At the same time, the signal output interface outputs a digital signal and a low-level signal, and the sensitivity can be adjusted by a potentiometer knob.

The sensing module adopts a binary probe, the window of which is rectangular, and the binary is located at both ends in the longer direction. When the human body walks from left to right or from right to left, there is a difference in the time and distance when the infrared spectrum reaches the binary. The larger the difference, the more sensitive the sensing. When the human body walks from the front to the probe, from top to bottom, or from bottom to top, the binary cannot detect the change of infrared spectrum distance, and

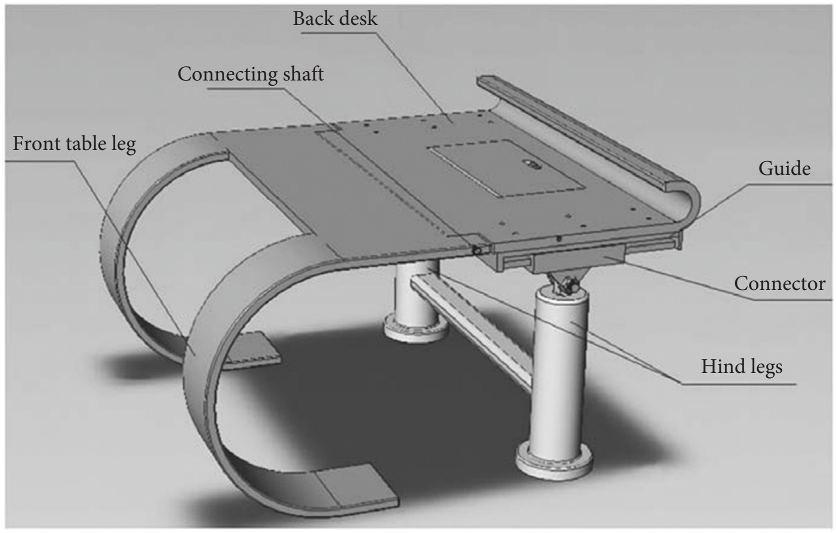

Figure 6: Structural design drawing of folding seat.

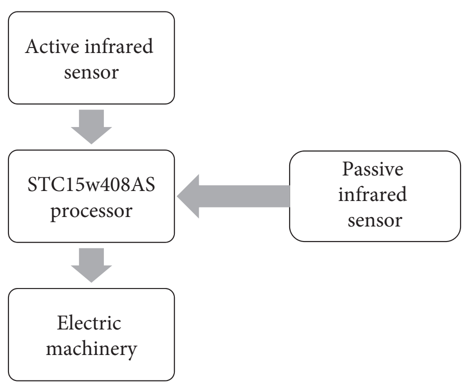

Figure 7: Hardware design block diagram.

there is no difference. Hence, the sensing is insensitive or not working.

The procedure of infrared automatic folding seat is shown in Figure 8.

(1) Start running the program, initialize all parameters and functions, and judge whether the seat is folded.
(2) The program senses whether someone exists by receiving the level change of the passive infrared sensor installed on the head of the seat. When someone approaches the seat, the level changes from high level to low level, and the MCU outputs PWM to control the motor to rotate and slowly open the seat.
(3) The program judges whether people have a tendency to sit down by receiving the level change of the active infrared sensor, and if so, the MCU outputs PWM to control the motor to rotate and quickly deploy the seat.
(4) When both the passive infrared sensor and the active infrared sensor are at high level, no user exists, and the seat is automatically folded.

4. Experimental Analysis

The medium seat is used as the research object for seat deduction in this paper. In this chapter, a comparison experiment is conducted between study seats in a university smart classroom and seats in a regular classroom to determine the effectiveness of the smart seat prototype designed in this paper in maintaining students' healthy sitting posture. Following the shape verification deduction of seat design, the design scheme of learning seat in the smart classroom of university is chosen to make physical products, and the prototype is made based on the short-time static test results. This chapter mainly verifies the two prototypes and assesses the subjective scale of the students. The effectiveness and rationality of the intelligent seat designed in this paper to maintain students' healthy sitting posture are confirmed through these two prototypes, and the effectiveness of the seat shape design and whether it meets the original purpose of designing the seat is confirmed through the pressure distribution experiment.

Experimentation: the subjects' body sizes were measured using a weight scale and a body size measuring ruler before the experiment began. Then, in a table, record the measured

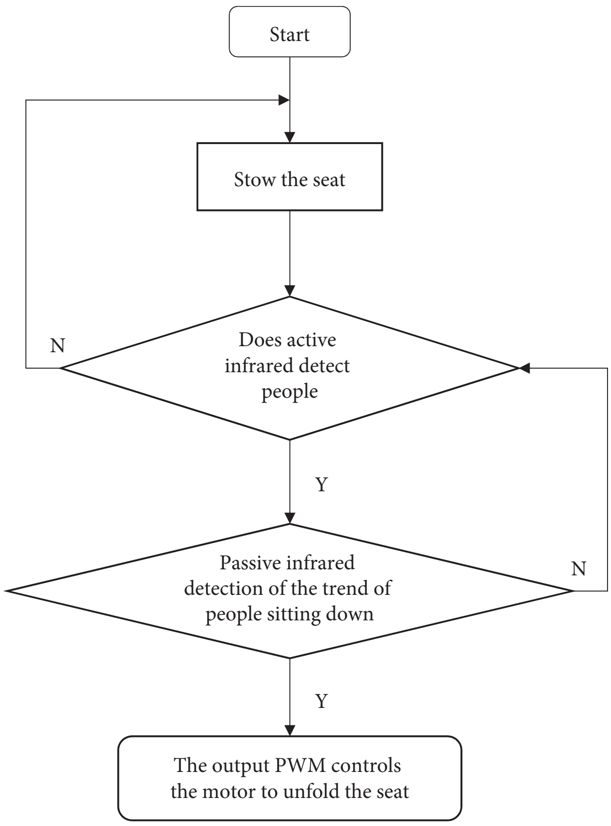

Figure 8: Flow chart.

data. Students' classroom environment is simulated in the laboratory to make the experiment more scientific and reasonable. The students will sit in the standard sitting position while a computer plays the video of the teacher's lecture. The subject is asked about his or her subjective body feeling of seat comfort after the pressure distribution is measured. Complete the subject evaluation scale on a subjective scale.

After the experiment is completed, the experimental data are sorted and made into a data sample database, and then a set of data is randomly selected for comparative analysis according to the experimental comparison items. To observe the displacement of the subjects when using the seat for a long time more intuitively, a set of data is obtained through experiments, which is the plane displacement coordinate data of the pressure center points of the subjects' backs and buttocks, and the data are sorted out, as shown in Figures 9 and 10.

Figure 9 shows the fluctuation diagram of the pressure distribution center point of the common seat back, and Figure 10 shows the fluctuation diagram of the pressure distribution center point of the common seat surface. The broken line Row in the diagram represents the lateral displacement, and the broken line Col represents the longitudinal displacement.

When the subjects started the experiment, their sitting position and position shifted, and with the passage of time, the range of displacement became larger, especially the movement of the backrest was more obvious, which

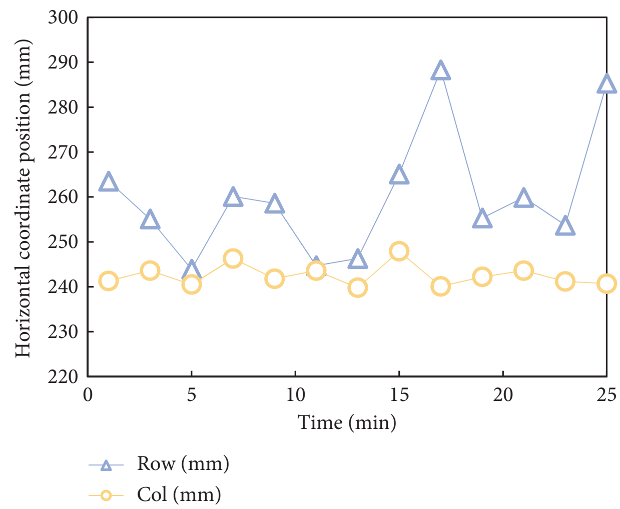

Figure 9: Line chart of the fluctuation of the central point position of common backrest pressure distribution.

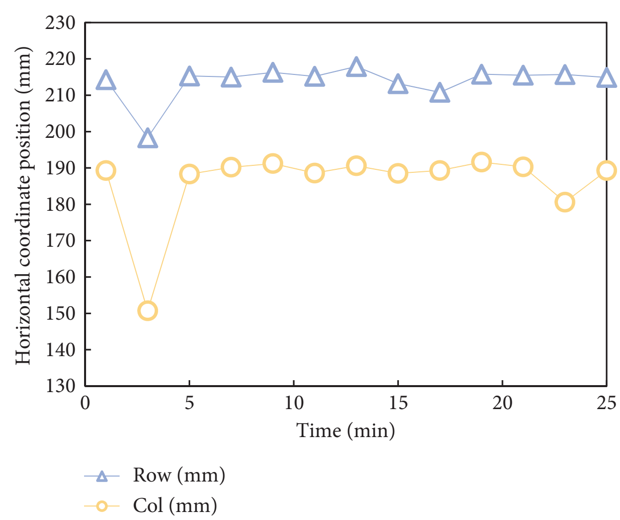

Figure 10: Line chart of the fluctuation of the central point position of pressure distribution on common chair surface.

indicated that the ordinary seats had poor binding force on the subjects' sitting position and could not maintain their healthy sitting position.

Then, the pressure distribution of the intelligent seat designed in this paper is tested. To observe the displacement of the subjects when using the seat for a long time more intuitively, a set of data is obtained through experiments, which is the plane displacement coordinate data of the pressure center points of the subjects' backs and buttocks, and the data are sorted out, as shown in Figures 11 and 12.

It can be seen from the fluctuation of the pressure distribution center position in the above Figure 12 that the body displacement of the subjects is slight during the whole 25-minute test. These phenomena indicate that the intelligent seat designed in this paper can play a certain role in maintaining a healthy sitting posture and can maintain well

the healthy sitting posture of the subjects. After the experiment, the subjective evaluation forms filled in by five students were sorted and analyzed. The statistical results are shown in Table 1.

From the comfort point of view, the comfort of ordinary seats is the worst. The intelligent seats designed in this paper feel better overall comfort. The shape design of the intelligent seat designed in this paper not only restricts the sitting behavior of students but also supports the back and waist to ensure a certain degree of comfort. Experiments show that the smart seat designed in this paper has reasonable comfort and can be used for a long time.

5. Conclusion

The research on the design of study seats in smart classrooms should be based on the construction and development status of smart classrooms, which can be considered from the perspectives of interactivity, functionality, and comfort and rely on Bluetooth, virtual desktop technology, VR, AR, and other information technologies to realize the automatic arrangement of seats, data transmission, classroom feedback, and efficient management, so that students can better integrate into the classroom and ensure teaching quality. Through the mechanical analysis of the chair, the intelligent student chair is designed with infrared folding structure, so that the backrest and cushion can move according to the rest needs of students at the same time. The antioverturning base ensures that the seat will not tilt backward and fall over when the students rest. The self-locking seat wheel can move freely when the seat is not stressed by a simple braking mechanism, and the seat wheel cannot move after the student sits down. In addition, the design of voice-adjusted seat height meets the needs of different sitting positions and different heights and weights. Compared with the seats in ordinary classrooms, the intelligent seats designed in this paper basically achieve the function of maintaining a healthy sitting posture, have a certain restraining effect on students' sitting posture, and provide a more reasonable pressure distribution. The shape design of the intelligent seat designed in this paper not only constrains the students' sitting behavior but also supports the back and waist, ensuring a certain degree of comfort. In the bionic modeling design, the size of the seat and the man-machine data are not sufficient. Hence, it is necessary to improve the data analysis of students' sitting posture. With the development of automation technology, all kinds of products serving human beings tend to be intelligent. Therefore, it is also the general trend to realize the intelligentization of learning seats.

Based on the concept of "smart tourism," this paper designs and implements a tourism management information system based on PSO-optimized NN. The foreground tourism web page of the system adopts DIV + CSS mode for page planning and layout, PHP as the client script language, and SQL server as the database to store and analyze user information. At the same time, the system adds personalized components to the user's search ranking results, so that the routes and scenic spots presented in front of users in the result interface are more in line with users' consumption habits. In order to verify the performance of the model and algorithm constructed in this paper, several experiments were carried out in this paper. Experimental results show that the prediction accuracy of this algorithm is 94.67% and the recall rate is 96.11%. This algorithm can overcome the disadvantages of traditional algorithms and provide some effective suggestions for tourism management. At the same time, this paper applies the concept of "smart tourism" to specific tourism informatization, which can promote the transformation and upgrading of tourism industry structure and further enhance the overall development level of tourism industry.

1. Introduction

Tourism informatization contributes significantly to the growth of tourism and is increasingly becoming a key competitive advantage in global resource allocation [1]. The three major industries in the world are tourism, automobiles, and oil, and tourism is also known as the "smokeless industry." The tourism industry has grown rapidly in tandem with the improvement of people's living standards, but it has also brought many problems. Travel agencies currently deal with a large amount of data, with low efficiency and significant errors. With the advancement of the economy and the improvement of people's living standards, many people are turning to holiday tourism to relieve stress and relax [2]. As a result, people's demand for tourism will continue to rise. It is critical to develop a tourism management information system that meets application requirements and has comprehensive functions in order to better adapt to the current market situation. Wisdom tourism is a higher-level and more comprehensive guiding strategy for tourism informatization development, as well as a more profound embodiment of the value of tourism informatization development. With the rapid advancement of computer technology, database management systems are becoming increasingly sophisticated [3]. People are gradually paying attention to modern enterprise management as a result of the establishment of scientific management systems and the popularisation of modern computer management mode, particularly due to the rapid development of computer technology and modern communication technology [4]. The use of computer-assisted management emerged and grew quickly. The importance of carrying out informatization construction in the tourism industry is both theoretical and practical.

People's office efficiency and cost savings can be greatly improved with a tourism management system. However, tourism development is currently slow, and there is no effective management strategy in place. Enterprises with poor information management are less efficient. It is not smooth due to a lack of informatization, a single management mode, and limited communication channels in the tourism administrative department. The tourism industry's development is hampered by these issues. Simultaneously, how to quickly and accurately find high-quality information from the vast amount of Internet data; how to thoroughly analyze customers' consumption habits and formulate user strategies is an important field of Internet technology research [5]. As an information processing system that mimics biological neurons, the ANN (Artificial Neural Network) offers non-linear approximation, parallel processing, self-learning, self-organization, and fault tolerance. As a result, it has some advantages in terms of practical application. The most widely used NN (Neural network) model is the Bpnn (Back propagation neural network) [6]. To adjust the weight, BPNN typically uses the gradient descent method. However, it has some flaws, such as the ability to fall into local minima, slow convergence speed, and easy oscillation [7]. This paper introduces PSO (Particle Swarm Optimization), which is used to train the weights and thresholds of NN in order to address these flaws. This paper builds a tourism management information system based on PSO-optimized NN based on the concept of "smart tourism." The following are some of its innovations:

(i) This paper mainly researches and develops the system according to the idea of software engineering design, and uses a variety of cutting-edge technologies to complete the establishment of tourism management information system. Aiming at the time-consuming problem faced by users in choosing tourist routes, this paper puts forward a brand-new price comparison decision method. It can help users easily get all kinds of travel route information of various travel websites. In addition, the security and reliability of this system are effectively verified by testing.

(ii) BPNN generally adopts gradient descent method to adjust weights. In this paper, an improved PSO-optimized NN algorithm is proposed, aiming at its inherent defects of falling into local minima, slow convergence and easy oscillation. Compared with the traditional NN algorithm, the results show that the performance of PSO-optimized NN algorithm is better.

This paper will be divided into five sections based on the content of the paper and the needs of the article structure, with the following contents for each section: the introduction is the first section. This section provides an overview of the paper's research background, significance, and innovation. The work in the second section is related. This section describes the current state of research on the research topic both at home and abroad, as well as the research work and ideas presented in this paper. There are two parts to the third section. Section 3.1 examines the tourism management information system and the NN algorithm in general. Section 3.2 A tourism management information system is built and implemented using a PSO-optimized NN algorithm. Many experiments are carried out in the fourth section to investigate the performance of the proposed system and the improved algorithm. Summary and prospects are covered in the fifth section. This chapter summarises the paper's research findings. Finally, the paper's shortcomings are discussed, as well as future research directions.

2. Related Work

With the fierce competition of more and more tourism industries, how to improve the service quality and management of tourism is becoming more and more important. At the same time, with the rapid development of mobile Internet, cloud computing, AI and other technologies, the integration of tourism industry and IT industry is getting closer and closer. among them, ANN has been well applied in many fields. At present, many scholars have combined NN with tourism and made some achievements.

In order to improve the prediction accuracy of popular tourist attractions, Du et al. proposed a prediction model of popular tourist attractions based on genetic algorithm optimization [8]. Zhou et al. used use cases for travel service recommendation [9]. This model organizes the user's historical data into case forms and stores them; when the user has a demand, the system will search through the case by the method of similarity calculation to find the case that is close to the user's needs; The case is adjusted according to local needs and a recommended solution is generated. Liu et al. introduced the radial basis function NN with strong non-linear modeling ability to describe the non-linear change characteristics of popular tourist attractions, and optimized the parameters of the radial basis function NN to establish the optimal prediction model of tourist attractions [10]. Bai and Han made dynamic prediction of tourist attractions based on grey system and NN [11]. Lv uses the improved genetic algorithm to optimize the structure and initial weight of the BPNN in the research of improving the genetic algorithm to optimize the BPNN for prediction [12]. In the PSO optimization NN prediction model, Zhao et al. used PSO to optimize the weight parameters of the BP network [13]. This method improves the problem that the BP network is easy to fall into the local minimum value, and improves the convergence speed. The system proposed by Sundriyal et al. uses demographic information to recommend tourist attractions, and classifies users by using Bayesian methods and support vector machines; and assumes that users in the same class have similar interests and preferences, recommending similar Other attractions of interest to users to solve the cold start problem [14]. It has a certain effect. Du achieves a balance between the global search and local search of particles through the linear decrease of the inertia weight and acceleration factor of the PSO, and improves the optimization performance [15]. Behjaty and Monfared proposed a PSO-optimized NN ensemble tourism prediction model based on support vector machines [16]. Zhang designed a tourism demand forecasting system based on

BPNN. The system can dynamically predict tourism demand and has good prediction accuracy [17].

This paper discusses the mode of "smart tourism" and builds a tourism management information system based on PSO optimized NN based on an in-depth review of relevant literature. To begin, an improved PSO optimization algorithm is used to optimize the weight parameter combination of the BPNN model repeatedly. The algorithm is then used to precisely optimize the obtained network parameters. Finally, for prediction, the most accurate optimal parameter combination is used. Customer receipt management module, customer information management module, management module, customer group, tourism resource management module, and functional module have all been completed through design and practise. Finally, the experimental simulation demonstrates that the improved method presented in this paper improves the accuracy of prediction results while requiring few parameters and being simple and effective.

3. Methodology

3.1. Tourism Management Information System and NN Algorithm. The brain is the most complex, perfect and effective information processing system known in the universe. The number of nerve cells in the brain is huge, and these nerve cells are also called neurons. It is hundreds of millions of such neurons that make up our human brain through complex connections. Neurons are the only cells in human body that can sense stimulation and conduct shock, and are also the basic units of nervous system in morphology, structure, function and nutrition. Inspired by the bionics research of ANN [18–20], the operation mode of brain neurons was simulated. NN has the characteristics of massive parallelism, learning autonomy, high nonlinearity and self-organization, and is widely used in many fields. ANN is a complex network composed of a large number of simple components connected to each other. It has a high degree of nonlinearity, and is a system that can perform complex logical operations and realize non-linear relationships. ANN can process information, and its core idea is to adjust the connection relationship between internal nodes according to the different complexity of the system. It has all the characteristics of non-linear dynamic system, such as irreversibility, various types of attractors, chaos and so on. BPNN is the most commonly used NN model at present. Because of its good adaptability and strong non-linear mapping ability, BPNN has been widely used, but it also has some shortcomings. For example: ① the random initialization assignment of BP network connection weight and threshold before network model training makes the network easy to fall into local extreme points and affects the accuracy of prediction. ② For the determination of BPNN structure, there is no exact formula for the number of hidden layer nodes. Improper selection is prone to over fitting or insufficient learning ability, which affects the generalization ability of the network. BPNN model generally has input layer, hidden layer and output layer. The neurons in adjacent layers are fully connected, and there is no connection between neurons in each layer. The structure of NN is shown in Figure 1.

BPNN is a multilayer feedforward NN with two processes: forward transmission of input signals and error back propagation. Various neurons in a feedforward network accept the previous layer's input and output to the next layer without receiving feedback. There are two types of nodes: input cells and calculation cells. There can be any number of inputs, but only one output per computing unit. The basic idea behind the BPNN algorithm is to first initialise the weight and threshold of NN, and then calculate the corresponding output value using the transfer function between NN layers; finally, calculate the error between the output value and the expected output value, and then reverse the weight and threshold of NN. NN is trained by performing forward and reverse error corrections repeatedly. The operation is terminated when the error value reaches the set standard. The neuron state of each layer only affects the neuron state of the next layer in the BPNN model. To approach any rational function with any accuracy, the network structure usually only requires a single hidden layer. The number of neural nodes in the input and output layers of the network is determined by the dimension of the input and output vectors of training samples. The characteristics of neurons, the form of neuron interconnection, and learning rules are the three factors that determine NN's overall performance. We must improve the BPNN model's inherent flaws in order to better apply it. PSO stands for swarm intelligence optimization. The algorithm is simple to use and is used in a variety of optimization problems. This paper will build a tourism management information system using a PSO optimized NN algorithm.

The development of information and Internet technology has completely changed people's life, and the intellectualization of tourism management has also become a trend. At present, the websites of travel agencies all over the country are in their own array in terms of function, information service and business operation, and the phenomenon of "information island" is serious [21]. The tourism management information system is convenient, which can manage, store and share resources through the network and various types of tourism resources. It greatly saves the labor cost, reduces the work difficulty and improves the intelligent level of the tourism industry. Continuously improve the level of tourism informatization management, optimize the allocation of resources, and realize the industrial chain of enterprises; It can promote the development of enterprises, expand employment and realize the positive role of tourism economic development. Therefore, developing a tourism management information system that can not only store but also update and query data is critical. The requirements for building various formats of informatization in smart tourism are extensive. The creation of a smart travel agency, for example, necessitates the network realization of various functions such as data collection and resource procurement, product planning and release, product sales, tourist service, order management, team management, statistical settlement, and so on. However, in the current reality, only a few tourism businesses use the network to carry out the aforementioned functions. The tourist route can be inquired by inputting tourist places; Travel agency management route; Recommended by popular

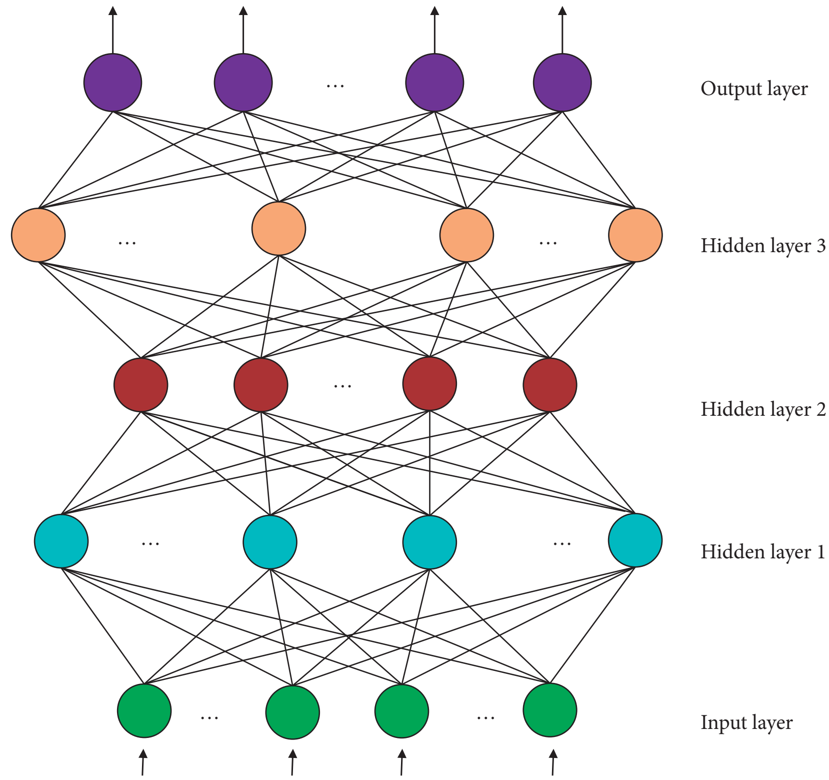

FIGURE 1: NN structure.

scenic spots; Scenic spot reservation; Order processing, and so on are the main functions of a tourism management information system that can satisfy the application. It should also have a user-friendly interface and provide appropriate operation tips. Decision-making is central to management, and prediction [22, 23] is the foundation of decision-making. In tourism development and planning research, we should employ appropriate forecasting methods and models to determine the tourism economy's development law, as well as predict and speculate on tourism's future development trend, direction, and possibility, in order to better serve tourism planning, project decision-making, and management. Before developing an application system, we must understand the design and actual requirements of the system, assess the technology and principle's feasibility, and plan for development. The system should be simple to use once it has been launched, and most ordinary users with Internet experience should be able to use it without difficulty. At the same time, system administrators must have a thorough understanding of computers. General computer-related professionals can become competent after reading the instruction book. The paper then provides an overview of the system's overall design and implementation functions, as well as the system's overall test and trial operation, using an example design.

3.2. Construction of Tourism Management Information System Based on PSO-Optimized NN. This system combines NN and PSO to create a tourism management information system. It is concerned with network applications. The function, or purpose, of a network management system should be the first step in its development [24]. The functional requirements are usually to clearly express a network management theme, to accommodate various types of content, and to adapt to various resolutions. Second, the design structure should be obvious. Because there are so many databases in this system, the databases must be designed ahead of time. It is the foundation of the data tourism management information system, the core content of the smart tourism city construction, and it provides crucial data support for the application service system construction. A data dictionary is made up of data items, data storage, data flow, data structure, and data processing, with data items being the smallest unit of the data dictionary. Data items make up the data structure. Data structure and data items are used to describe the data dictionary. A solution system for industry-wide data perception is proposed in this planning scheme, which is integrated into tourism intelligence data based on industry-wide data. Many weight adjustment methods for BPNN algorithms based on gradient descent exist, but they all have drawbacks, such as slow convergence, long training times, and global convergence. PSO's optimization process is independent of gradient information, and it does not require that the function be differentiable or that the derivative be excessive. PSO is used as the NN training method in this paper to reduce NN training time and improve search efficiency. The flow chart of optimizing PSO NN algorithm is shown in Figure 2.

A perfect system should have good stability, reliability, security and scalability, and can run efficiently. Therefore,

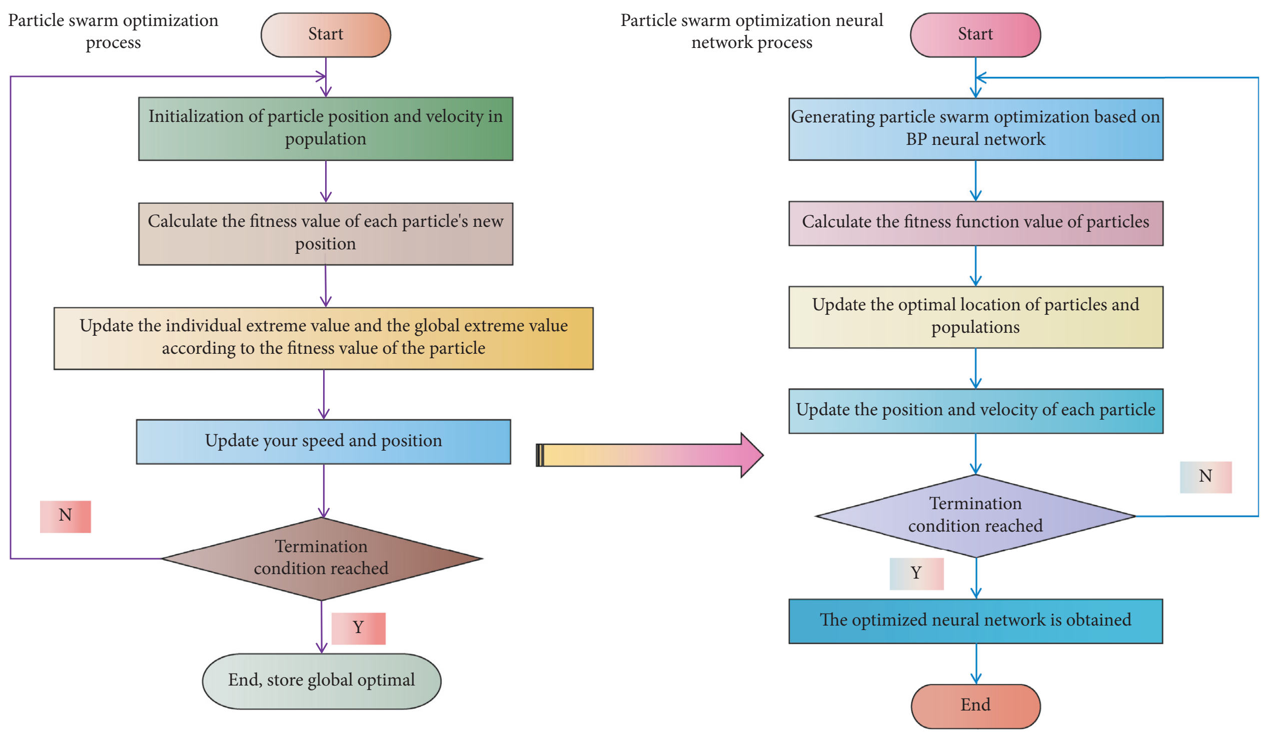

Figure 2: PSO optimization NN algorithm flow.

this system meets the following performance requirements: ① correctness. ② Reliability. ③ Easy practicality. ④ Maintainability. ⑤ Reusability. ⑥ Understandability. ⑦ Safety. ⑧ Effectiveness. The system's basic information data for users primarily consists of gender, age, occupation, city, and historical comment items, while the comment data primarily consists of the user's comment text information on previous tourism service items and the corresponding scores. The system covers all end users based on the characteristics of the online travel network. The system also allows for real-time online operation, and the front page of timeliness and variability consistently sets high standards. The establishment of tourism data security standards ensures the security of data circulated in the tourism industry. Data transmission security standards, data storage security standards, and data exchange security standards are all included in the construction. Traditional linear modeling methods cannot accurately describe influencing factors and tourist attractions because they have a strong non-linear relationship. In order to fit the non-linear relationship between influencing factors and tourist attractions, this paper uses PSO to optimize NN. This paper uses a three-layer NN with only one hidden layer for the topological structure of NN in order to balance the algorithm's simulation and prediction accuracy, and because the more hidden layers, the more over-fitting of practical problems will occur. The number of nodes in the input layer represents the dimension of the original data, while the number of prediction indexes represents the number of nodes in the output layer. The activation function of a neuron and a network is what determines the network's function. Its primary function is to control the activation of input to output and to perform functional conversion on input and output in order to transform an infinite domain input into a limited range output. S-type function is used in this paper. The output formula of NN is

$$Y(X_n) = \sum_{i=1}^{I} W_i \Phi(X_n, t_i). \tag{1}$$

In the formula, W_i represents the weight between the nodes of the hidden layer and the output layer; t_i represents the center of the NN function; Φ represents the NN function, which is defined as follows:

$$\Phi(x) = \exp\left(\frac{\|x - c_i\|^2}{\delta_i^2}\right), \tag{2}$$

where δ_i represents the radius of the radial basis, and c_i represents the center of the response function. For the three-layer BPNN used in this paper, the optimization dimension is

$$D = m \times n + n \times k + n + k. \tag{3}$$

Set the threshold vector from the input layer to the hidden layer as

$$A_1 = [a_{11}, a_{12}, a_{13}, \ldots, a_{1n}]^T. \tag{4}$$

Set the threshold vector from hidden layer to output layer as

$$A_2 = [a_{21}, a_{22}, a_{23}, \ldots, a_{2k}]^T. \tag{5}$$

Set the encoding on each particle dimension in the algorithm to

$$x = [IW_{11}, \ldots, IW_{mn}LV_{11}, \ldots, LV_{nk}a_{11}, \ldots, a_{1n}a_{21}, \ldots, a_{2k}]. \tag{6}$$

The adjustment of weights and thresholds in BPNN is based on the mean square of errors. The fitness function optimized by PSO is used as the back-propagation function of the BP network error, and the equivalence relationship between the mean square value of the error and the fitness function of PSO is established. The objective function expression is

$$f_i = \frac{1}{N}\sum_{k=1}^{n}[y(k) - y_m(k)]^2. \tag{7}$$

In the formula, N represents the total number of training samples, f_i represents the square error sum of the objective function; $y(k)$ and $y_m(k)$ represent the target output value and actual output value of the objective function, respectively.

The related parameters are coded based on the setting of the NN structure, and the optimization dimension is represented by the weights and thresholds of the NN connection. Using cyclic iteration, the number of hidden layers is determined, and the optimal number and weight of NN hidden layers are found. The optimal position of the current particle and PSO is updated based on the fitness function value. Then, to generate a new group of PSO, update each particle's position and velocity. The individuals in the improved PSO optimization algorithm are coded into the weights and thresholds of the three-layer feedforward NN structure. Set the variable value intervals in the improved PSO optimization algorithm, then randomly initialise PSO's position and speed within the initialization range. The performance of particle local search and global search will decrease if the inertia factor of PSO is linearly adjusted, according to the basic PSO. The non-linear method is used to overcome the limitations of the linear decreasing method. At this time, the inertia factor expression is

$$w(k) = w_{\min} + (w_{\max} - w_{\min})\exp\left(-\frac{25k}{T_{\max}}\right). \tag{8}$$

For the problem of network evaluation, the widely used evaluation indicators include MSE (Mean squared error), RMSE (Root mean square error), MAE (Mean absolute error) and MAPE (Mean absolute percentage error). The specific expressions of these four indicators are given here:

$$\begin{aligned}
\text{MSE} &= \frac{1}{n}\sum_{k=1}^{n}\left(y_k - \hat{y}_k\right)^2,\\
\text{RMSE} &= \sqrt{\frac{1}{n}\sum_{k=1}^{n}\left(\left|y_k - \hat{y}_k\right|\right)^2},\\
\text{MAE} &= \frac{1}{n}\sum_{k=1}^{n}\left|y_k - \hat{y}_k\right|,\\
\text{MAPE} &= \frac{1}{N}\sum_{k=1}^{n}\left|\frac{y_k - \hat{y}_k}{y_k}\right|.
\end{aligned} \tag{9}$$

Table 1: Settings of simulation test environment parameters.

Serial number	Test parameters	Set up
1	Hidden layer	One
2	CPU	4 nuclear
3	RAM	64 GN
4	Hard disc	1T
5	Display card	512G
6	Operating system	Windows

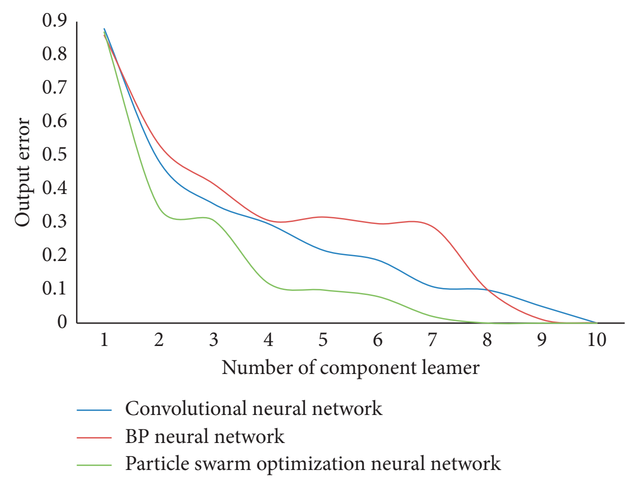

Figure 3: Training results of different networks.

Among them, y_k is the actual value, and $\hat{y}_k$ is the output value.

Using the system's HTML page, manage and maintain the online travel network. The customer and logical interface are displayed using the presentation layer. The presentation layer represents users, and the presentation layer also represents the link between users and the system. The presentation layer realises the client's request, and the data is transmitted, primarily in the business layer, with the results displayed. The goal of the data exchange interface design is to create a system that is open, extensible, adaptable, efficient, and stable. The data exchange interface has its own hierarchical authority management mechanism, and it also manages the security authentication of data acquisition and storage for other data exchange application systems, as well as effectively encrypting the data during transmission. The goal of this paper is to promote online tourism, and the principle of serving users is used to design a tourism management system that meets the actual needs of tourism management. Furthermore, the goal of a simple and clear interface, stable functionality, low implementation cost, and meeting a variety of service tourism demands has been met. Provide assistance to tourism businesses in making decisions.

4. Result Analysis and Discussion

This system is developed in B/S mode, and the interface of presentation layer is realized through WEB browser, mainly for the realization of text, Flash, pictures and other functions. Through the client browser HTML form, URL and Flash request realization, the data is given to the

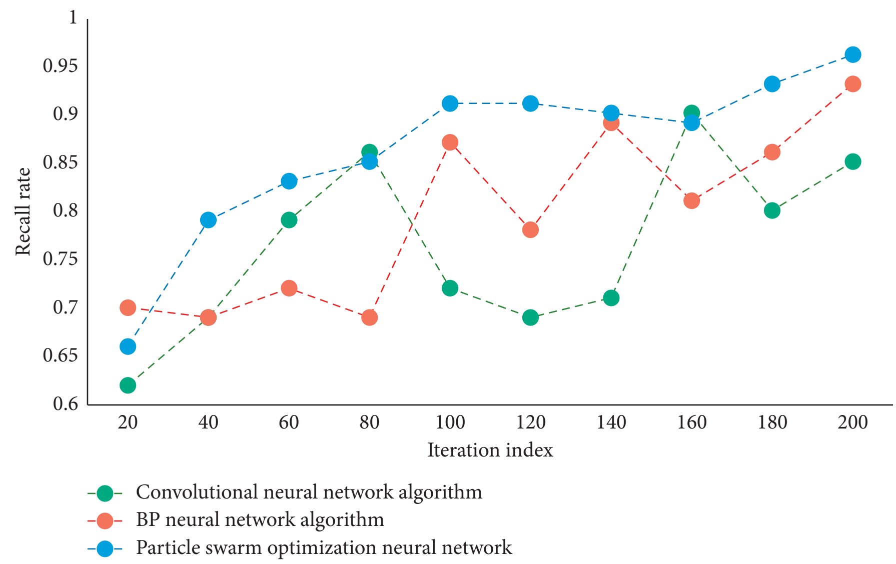

Figure 4: Comparison of recall rates of different algorithms.

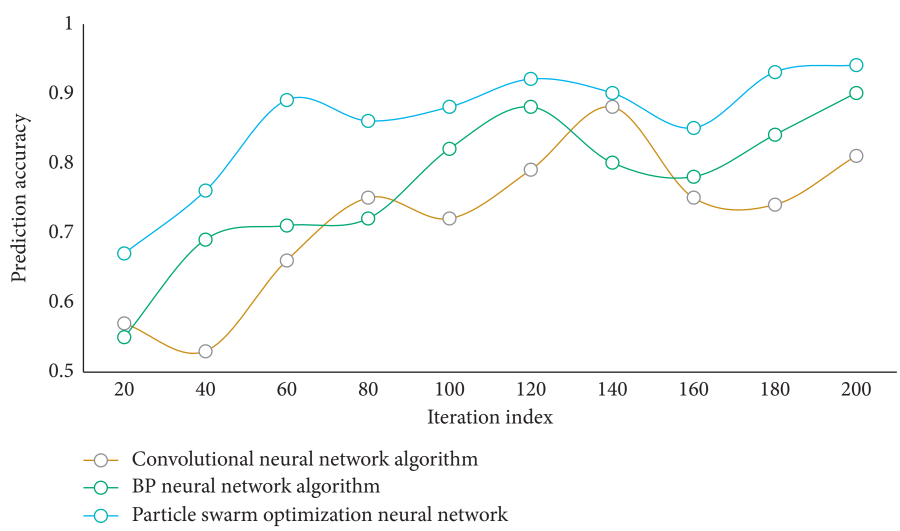

Figure 5: Comparison of prediction accuracy of different algorithms.

programming model, and the system provides J2EE realization to develop and realize the system. In order to verify the practical application effect of the system, simulation experiments are carried out in this chapter. Table 1 shows the parameter settings of simulation test environment.

Tansig function is used as the conversion function between the input layer and the hidden layer, and Purelin is used as the conversion function between the hidden layer and the output layer. The maximum training step is 1000, and the number of particles in the parasitic group and host group in the improved PSO is set to 50. The network is trained and the results are shown in Figure 3.

It can be seen that the convergence speed of this network is faster. In this paper, PSO is combined with NN, and the weight and threshold of NN are determined by using improved PSO instead of BPNN based on gradient descent. Therefore, the optimal parameter combination is obtained for NN to forecast the tourist volume in tourist areas. Three different models are used to predict the test set, and the prediction results are compared and the performance is analyzed. Test the recall results of different algorithms at the same time. The comparison results of recall rates of different algorithms are shown in Figure 4. The prediction accuracy results of different models are shown in Figure 5.

Table 2: Test index values of different methods.

Algorithm	MSE	RMSE	MAE	MAPE
Convolution algorithm	0.154	0.499	0.803	0.614
BPNN algorithm	0.108	0.279	0.627	0.512
Traditional ANN algorithm	0.094	0.301	0.614	0.487
Improved PSO algorithm	0.057	0.213	0.551	0.369

According to the data analysis in Figure 4, the recall rate of this algorithm is the highest, and it is better than the

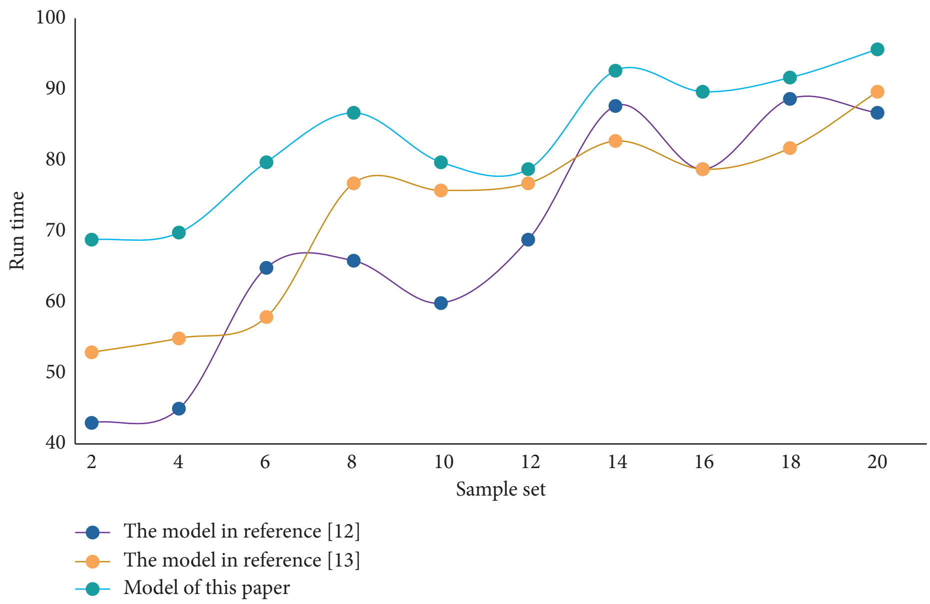

Figure 6: Running time results of different systems.

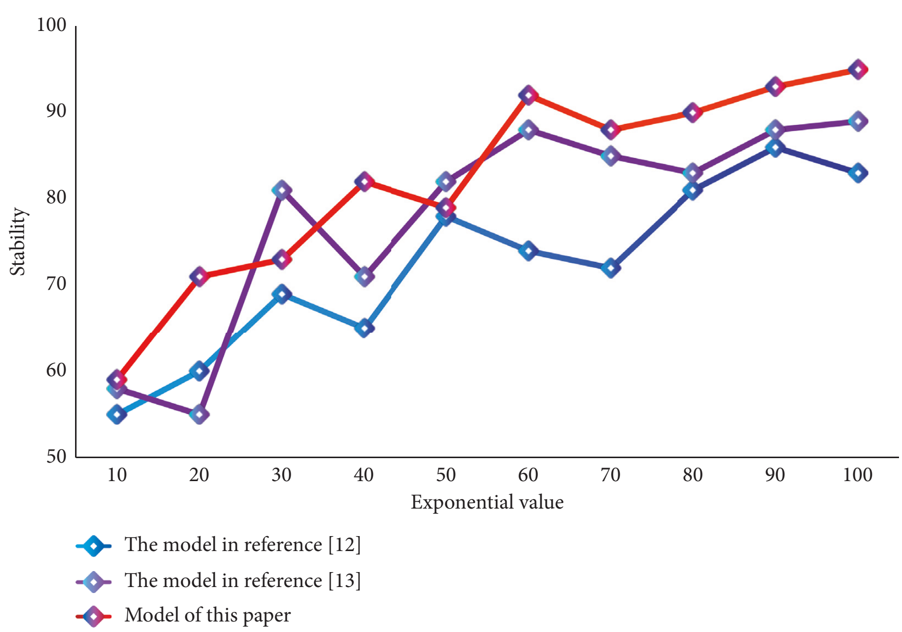

Figure 7: Stability test of different systems.

comparison algorithm. According to the data analysis in Figure 5, the prediction accuracy of this algorithm is at a high level, up to 94.67%. It shows that the model in this paper can be well applied to forecast the number of tourists in tourist areas. This further verifies the feasibility and effectiveness of this method. Table 2 shows the test index values of different methods.

It can be seen from the data results in the table that the fitting accuracy of BPNN algorithm is much higher than that of cluster analysis algorithm; However, the accuracy of improved ANN is better than that of BPNN algorithm and traditional ANN. Comparing the performance of different systems, the running time results of different systems are shown in Figure 6.

Considering the migration of different database management systems, SQLSERVER database replication is adopted. Through the data layer, it mainly operates the query, database storage, transaction processing and update of the system; Realize the return of database data results through the data layer. Test the stability of different systems as shown in Figure 7.

According to the data analysis in the figure, the stability of this system is higher than that of the other two comparison systems. It has the highest stability. Moreover, the response time of the system in this paper is short, which can achieve high efficiency. This data verifies that the system in this paper has certain superior performance. It can be applied to tourism information management. In this chapter, to verify the performance of the tourism management information system based on PSO-optimized NN proposed and designed in this paper, a simulation experiment is carried out. The simulation results show that the prediction accuracy of this algorithm is 94.67% and the recall rate is 96.11%. The performance of this system can meet the practical application requirements and provide some effective suggestions for tourism management decision-making.

5. Conclusions

The development of the tourism industry has been accelerated by the rapid development of computer technology, and the traditional tourism industry has changed dramatically. As a result, a tourism management information system with high availability, expandability, and ease of maintenance is required. This paper completes the construction and application of a tourism management information system using a PSO-optimized NN algorithm. The improved PSO is used to optimize BPNN in this paper, and the PSO's optimization performance is improved by nonlinearly decreasing the inertia factor. Simultaneously, the system provides end-to-end service, including system setup, management personnel analysis of tourism resource management, and statistical category reports. This can provide a great deal of convenience for visitors and have a significant positive impact on tourism benefits. Several experiments were conducted in order to verify the performance of the model and algorithm developed in this paper. The prediction accuracy of this algorithm is 94.67 percent, and the recall rate is 96.11 percent, according to experimental results. This system uses the Scrapy framework to crawl travel website route information, allowing it to efficiently and accurately capture travel route information; providing a user registration interface, clustering users based on user information, and storing user clicks in different categories on different lines; and rearranging route information to make search results more personalized and accurate. The system's performance is adequate for the application's needs. At the same time, this paper applies the concept of "smart tourism" to specific tourism informatization, which can help the tourism industry transform and upgrade its structure, as well as improve its overall development level. This research has made some achievements, but due to the time problem and the limitation of knowledge level, there are still many deficiencies in this system. In the future, distributed crawling and distributed storage should be considered to improve the system performance. At the same time, a more humanized interface should be designed.

With the generation of images, videos, and other data, how to identify the gait of the action in the video has gradually become the focus of research. Aiming at the problems of complex and changeable movements, strong coherence, and serious occlusion in dance video images, this paper proposes a dynamic recognition model of gait contour of dance movements based on GAN (generative adversarial networks). GAN method is used to convert the gait diagrams in any state into a group of gait diagrams in normal state with multiple angles, which are arranged in turn. In order to retain as much original feature information as possible, multiple loss strategy is adopted to optimize the network, increase the distance between classes, and reduce the distance within classes. Experimental results show that the average recognition rates of this model at 50°, 90°, and 120°are 93.24, 98.24, and 97.93, respectively, which shows that the recognition accuracy of dance movement recognition method is high. And this method can effectively improve the dynamic recognition of gait contour of dance movements.

1. Introduction

The posture and movement of a person walking is referred to as gait. The majority of today's gait research focuses on human gait movement. Gait is the only noninvasive method that can be employed, unlike fingerprints, face, and iris. Gait recognition, when compared to other long-distance biometric recognition technologies, has the benefits of long-distance recognition, noncontact, difficult concealment, and so on and has a lot of potential and application possibilities. Few universities or institutions have studied dance movements among the many studies on human body movement recognition, mainly because dance is a way of expressing emotions to the public through body movements, and dance movements in this category also include many dance movements with their own characteristics [1]. As a result, dance movement research is still in the stage of dance movement analysis. Most of the time, the gathered dance movements are gesture analyzed and then adapted to animated character performances utilizing animation processing software.

In order to solve the problem that the training gait cannot meet the training requirements of dance action steps, domestic and foreign scholars have successively carried out research on the generation method of personalized training gait. Qin et al. established the motion trajectory generation models of hip, knee, and ankle joints with multilayer perceptron, respectively [2]; Rida et al. established an ellipse model, which divided the human body into seven parts according to the proportional relation of the center of mass of the ellipse, and modeled each part [3]. Deng et al. proposed the method of deep gait and used the pretraining model VGG-16 to obtain the feature representation of gait map [4]. Li et al. proposed to learn the similarity between gait diagrams directly through the depth CNN (convolutional neural network) and extract the features of gait diagrams through CNN for matching recognition [5]. Zhao et al. extracted the information of human motion shape by Canny edge detection to represent the information of motion edge and then achieved the purpose of human motion recognition by matching similar edges [6]. Hnatiuc et al. changed the traditional separate training and combined attitude estimation and action recognition in order and put forward a framework for combining attitude estimation and action recognition [7]. Luo et al. reconstruct the 3D structure of human beings to generate views and 3D models that can be generated in any 2D by projection, but they usually need to fully control and cooperate in multiple camera environments [8]. However, there are still some shortcomings in the personalized gait generation experiment in the above research: the research object is limited to single or local joints, lacking comprehensive consideration of joint coupling relationship and overall coordination of motion. It is difficult to accurately describe the walking characteristics of human body only by the difference of gait parameters.

The input for recognizing human dance movements must be a series of motions, yet dance movements are similar to other sorts of movements. The activities in the video contain a lot of redundant information, and while the directions of the actions may alter, they can all be considered the same action based on the sequence of events. Traditional dynamic recognition methods based on the approach have a low identification rate, are unable to distinguish joint changes in precise dance motions, and have a poor recognition effect. In light of this shortcoming, this research investigates a GAN-based dynamic recognition and analysis method for dance movement gait contour (generative adversarial networks). The global coordination of the generated gait and whether it fits the standards of naturalness, adaptability, and stability are investigated using the gait stability criterion, which is based on the notion of human balanced perception. We intend to develop a tailored gait generation approach that can accurately represent distinct human gait features and give theoretical support for personalized training as a result of this research.

1.1. Innovation of This Paper

(1) In order to extract effective gait features for cross-view gait recognition, this paper proposes a cross-view gait feature extraction method based on GAN, which only needs to train a model to transform the gait template into any view. Retain the original identity information to the greatest extent, thus improving the accuracy of gait recognition.

(2) In this paper, GAN is used to transform the gait map, and a GAN recognition model is proposed to make full use of the feature information of the gait map, thus improving the accuracy of gait recognition.

1.2. Organizational Structure of This Article. The first chapter introduces the research background and significance, and then introduces the main work of this paper. The second chapter mainly introduces the related technologies of gait contour dynamic recognition of dance movements. The third chapter puts forward the specific methods and implementation of this research. The fourth chapter verifies the superiority and feasibility of this research model. The fifth chapter is the summary and prospect of the full text.

2. Related Work

2.1. Overview of GAN Research. With the innovation of information technology and the constant replacement of computing power of hardware devices, artificial intelligence [9–11] is developing vigorously in the information society, and the field of machine learning represented by generative model continues to attract researchers' attention.

The performance of GAN model proposed by Vma and others in generating image data surprised researchers. At present, its research in computer vision, medicine, natural language processing, and other fields has been active. It shows that there are few summary papers on the structure and performance of GAN at present, and other research work mainly focuses on the performance verification of different types of GAN architectures. Because the benchmark data set cannot reflect the diversity well, the comprehensive discussion of GAN in these works is limited. Paulo et al. proposed a GAN framework based on FC layer modeling, which only showed high performance in a few groups of data distribution. The deep convolution GAN model proposed by Switonski et al. can smooth the training process of generator and discriminator and contribute to improving the stability. Creswell et al. proposed a framework based on GAN, called Fu-sionGAN, which generates a fused image by controlling two input images [12]. Experiments show that the fusion method can change the shape and features of the input image and generate a new image while retaining the main content of the input image. Wang et al. summarized the image super-resolution technology based on deep learning and divided it into three types: supervised, unsupervised and specific application fields, and provided systematic super-resolution theory and practical methods [13]. Lei et al. proposed a framework that can be used to decipher passwords, so that GAN can be applied to decipher passwords [14]. In addition to the above areas, GAN has been successfully applied in other directions, such as domain adaptation, sequence generation, semi-supervised learning, semantic segmentation, attack resistance, machine translation, automatic driving, and so on.

2.2. Research Status of Gait Recognition. In recent years, gait recognition has attracted more and more attention in video surveillance and computer vision fields such as crime prevention and forensic identification, and its development will greatly promote the development of application, society, and computer vision. Therefore, gait recognition will become more and more important in the future. Unfortunately, gait recognition is still a challenging task because it has many potential sources of change, such as angle change, transportation, and clothes change.

Mosser et al. put forward the application of single linear projection, called view invariant discriminant projection, whose single property enables cross-view gait recognition without knowing the query gait view [15]. Lu et al. used the stacked progressive automatic encoder to convert the angle and converted the arbitrary angle of gait features into a single side view angle [16]. Yao et al. used 2D stick map obtained by connecting nine body points extracted from gait to simulate human movement [17]. Cai and others simulated human legs and used them to analyze human walking and running [18]. The research of Gadaleta et al. also simulates human legs, in which the legs are represented by many thick lines connected at one point [19]. Connie et al. put forward a method to predict 3D pose from 2D pose matching database, which predicts 3D pose according to the mutual constraint relationship of every joint in human body [20].

Gait is periodic, coordinated, and balanced, and the analysis in one cycle of gait can reduce the calculation amount of gait recognition and improve the operation efficiency. Gait periodicity can be analyzed according to the changes of the features of the graphic areas in each frame of binary images, such as area, centroid, and external rectangle. Risi et al. analyzed the periodicity of gait sequence according to the width signal of the binding frame of human body area and proposed a cycle calculation method under the condition of large lateral angle and lateral angle deviation [21]. Zhao et al. used PSO (particle swarm optimization) algorithm to optimize the pattern recognition method of SVM (support vector machine) [22], and the experimental results showed that the recognition rate of PSO-SVM classifier was higher than that of nonparameter optimized SVM classifier for lower limb analysis of five normal walking gait. Mannini et al. used k-nearest neighbor method to classify and recognize gait [23]. DTW (dynamic time warping) is to regularize the motion feature templates with different time lengths according to a certain time warping curve, so as to make the feature templates have the same length and then match them. This method has the advantage of solving the similarity measurement and matching problems of dynamic patterns.

3. Methodology

3.1. Gait Image Preprocessing. Gait recognition mainly analyzes and processes moving image sequences containing people, which usually includes four stages: target segmentation, feature extraction, feature processing, recognition, and classification. It should be noted that gait itself and compared with other biometric technologies also have many shortcomings, which are mainly influenced by emotion, object use, and gait angle. At present, most gait recognition algorithms use cameras to acquire gait data and use two-dimensional methods for gait recognition. In order to improve the recognition effect, the application of multicamera gait recognition algorithm and 3D method can be studied. By using multiple cameras, the problem of feature extraction caused by occlusion can be improved, and 3D modeling of human motion can extract the gait features [18] of human body more accurately and realize more complex feature matching. Multicameras and 3D methods are also the trend of human body recognition. If a motion sequence does not have a separate background picture, we must get the backdrop of motion sequence images [20] in order to collect some local photographs as background images in preparation. It should be noted that the light intensity has a significant impact on the background map selection, and the data of the background map vary substantially depending on the light intensity. Multiple backdrop photos should be picked and collected for optional use to eliminate this influence.

The volume contour area also appears in its own contour area, so there will be repetition in the calculation. Because of the noise in these small areas, the edge tracking algorithm cannot work smoothly, so we must use image connectivity algorithm to remove these small areas and get pure object images. There are many marked points to be extracted in the image sequence and other background noises. In order to extract the target points from multivalued digital images, binarization must be performed.

That is, by setting a threshold T [11], the image data are divided into pixel groups larger than T and pixel groups smaller than T with different values, respectively, so as to extract the feature points we care about, as shown in formula 1:

$$I_B(u,v)=\begin{cases}255, & I_P(u,v)>T,\\ 0, & I_P(u,v)<T,\end{cases} \tag{1}$$

where $I(u,v)$ represents the pixel value of a certain point in the image.

After binarization, the image sequence has only two areas: bright and dark, in which the marked points are bright. By programming and calling the function library, we can get the coordinates (u,v) of the center of each marked point in the forward process. In the sagittal plane of human body, the distance between waist and hip joint is measured as D_{mm}, and the number of pixels between these two points is obtained as d in the image plane, and the corresponding proportional relationship between the two coordinate planes is obtained as follows:

$$s=\frac{D}{d}. \tag{2}$$

Therefore, the coordinates of the image plane are converted to the coordinates x, y of the sagittal plane of the human body, and the change curve of the displacement of the subject's arch in x, y direction is obtained, as shown in Figure 1:

In this paper, the gait energy map is used as the gait template [16], and the gait energy map can be obtained by averaging the gait contour maps in the gait sequence, which can effectively retain the feature information during walking. As shown in Figure 2, the brightest pixel in the gait energy map represents the highest frequency of the position in the whole gait sequence.

The degree of coordination of human joint movement directly affects the stability of gait when walking, so the author's previous results are used to analyze the stability of the generated gait [18], thus reflecting its overall coordination. With the passage of time, the coordinates of the soles of the feet in two directions are extracted, and then the trajectory of the soles of the feet in two directions is fitted by the least square curve fitting method. The trajectory described by polynomial is to calculate the first derivative to get the gait speed curve of normal walking.

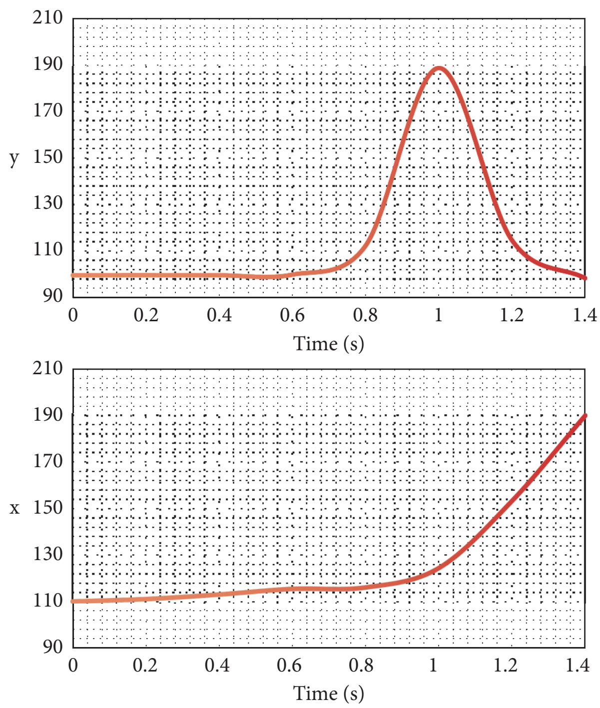

Figure 1: Change diagram of arch x, y displacement.

3.2. Dynamic Recognition of Gait Contour of Dance

3.2.1. Gait Feature Extraction Based on GAN. Human posture characteristics are derived from human posture information, which can be obtained in two methods. The first is to use attitude estimation on the test set to retrieve the position of human joints and calculate the joint angle; the second is to utilize the coordinates of each joint of the human body received when the motion capture equipment gathers the dance video. Most dance moves involve two arms and two legs, although there is no definite correlation between arms, arms and legs, and legs. The full-body region was chosen because various activities, such as those performed by the actor from bottom to top as a whole, turning about, strolling around, and so on, should be judged and identified by the motion information of the actor's entire body. By partitioning the human body area by the human body position, the impact of garment occlusion on motion recognition can be decreased. The background information with little or no change in the image can also be filtered according to the optical flow value in the process of optical flow feature extraction, so the areas where the information is finally retrieved are the upper body, lower body, and the entire actor's body. As a result, some features of the source gait map may not be effectively reflected in the gait map generated after the conversion due to angle conversion. As the angle difference grows, more feature information in the source gait map is masked, and the amount of feature information in the source gait map that can be expressed by the converted gait map decreases, resulting in a lower recognition rate.

In the experiment, the camera is stationary, and people walk in front of the camera without being blocked by objects. Therefore, contour extraction is essentially to eliminate the background from the sequence images to obtain the contour of the moving target. Its implementation steps are as follows:

(1) Because the scene is approximately still in the whole video sequence, the background corresponds to low-frequency information. Therefore, the average value of pixels in sequential images can be used to estimate the static background.

(2) Background difference method is used to detect moving targets in sequence images, and binary segmentation of images is performed under a set threshold.

(3) The contour information of the moving person in the sequence image is further extracted by the inner boundary tracking algorithm.

In order to eliminate the inconvenience of feature extraction caused by motion change, the centroid points of human body contour are calculated, respectively, and used as the coordinate origin of the image.

Let (x_c, y_c) be the centroid coordinate, N_b be the total number of boundary pixels, and (x_i, y_i) be the pixels on the boundary, then

$$\begin{cases} x_c = \dfrac{1}{N_b} \displaystyle\sum_{i=1}^{N_b} x_i, \\ y_c = \dfrac{1}{N_b} \displaystyle\sum_{i=1}^{N_b} y_i. \end{cases} \tag{3}$$

In order to eliminate the influence of image scale and signal length on the training and recognition process, the minimum-maximum normalization method and equally spaced resampling method are used to reduce the amplitude and length of the signal, respectively. The prediction of 3D pose mainly depends on the identification and planning of each person's crossing angle. It is difficult for us to predict 3D posture, which requires a lot of work and research. The 2D pose is drawn on the image plane. When the view changes, the 2D pose will change greatly, so it will not resist the change of viewpoint. The solution proposed in this paper is to estimate 3D pose from 2D pose.

After getting the 3D pose, we still need to do normalization, and there are 14 3D joint points. The length unit is the distance from the neck to the center of the hip, the position of the hip is in the center of the left and right hips, and the neck is at the origin of the plane coordinate system. So the joints of the body are normalized as follows:

$$J_i' = \frac{J_i - J_{\text{neck}}}{H_{nh}}, \tag{4}$$

where $J_i \in R^2$ is the position i of body joints, J_i' is the position of J_i after normalization, J_{neck} is the position of neck, and H_{nh} is the distance between neck and hip.

The postures from three different individuals after normalization are shown in Figure 3, from which we can find

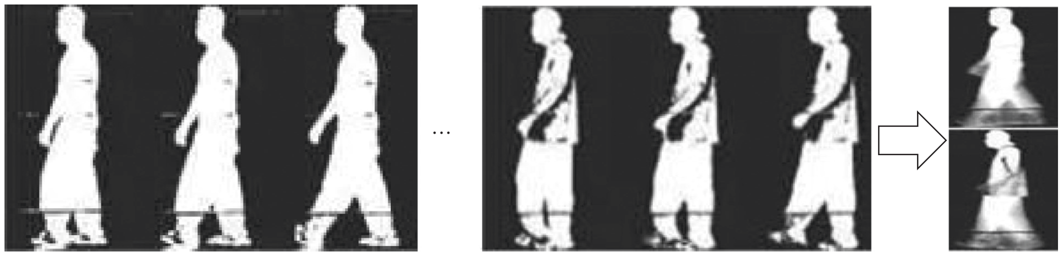

Figure 2: Synthesis of gait energy diagram.

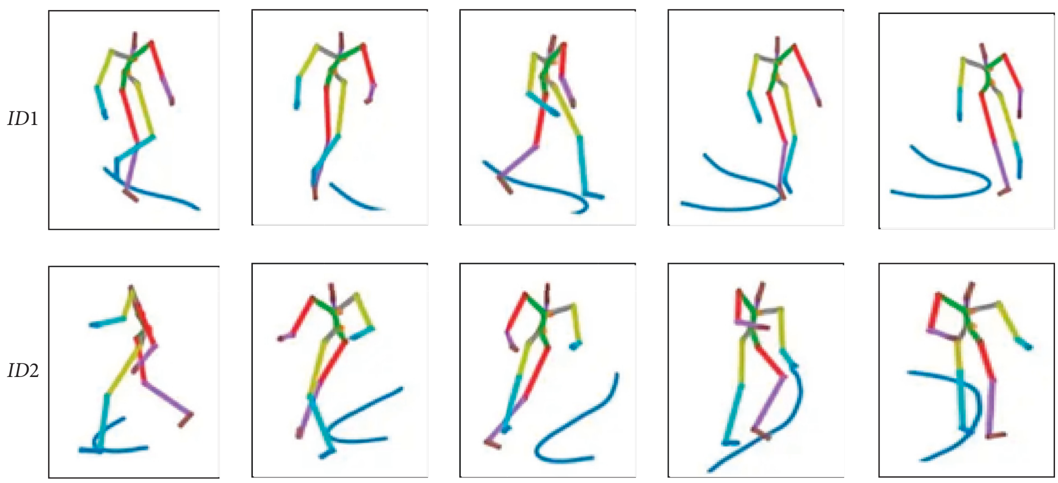

Figure 3: Example figure of posture after returning to one.

the differences of leg movement patterns among three different individuals.

Figure 4 shows the flow chart of the whole algorithm.

First, all the gait video sequences of test set, training set, and verification set are uniformly processed into the same gait template. Then, z^p is converted from perspective a to perspective b through a perspective converter V and the feature implicit representation $z^g = V(z^p, a, b)$ after perspective conversion is obtained.

Finally, it is determined that the identity of p^a is in the verification set of perspective b, and the calculation formula of nearest neighbor classifier is as follows:

$$x = \arg\min \left\| \tilde{z}^g - z_i^g \right\|_2, i \in \{1, 2, \cdots, n\}. \quad (5)$$

Here, $\| \cdot \|_2$ stands for L_2 norm.

3.2.2. Motion Gait Contour Tracking. An important clue to determine the intrinsic movement of pedestrians is the change of human body contour with time. In order to eliminate the information redundancy and reduce the computational complexity, we convert the two-dimensional contour shape changes into one-dimensional distance signals to approximate the spatiotemporal change pattern of gait movement.

The target movements of the dance gait contour extracted during the dance process are divided into heel strike stage, load-bearing reaction stage, middle support stage, end support stage, start stage, prestart stage, swing

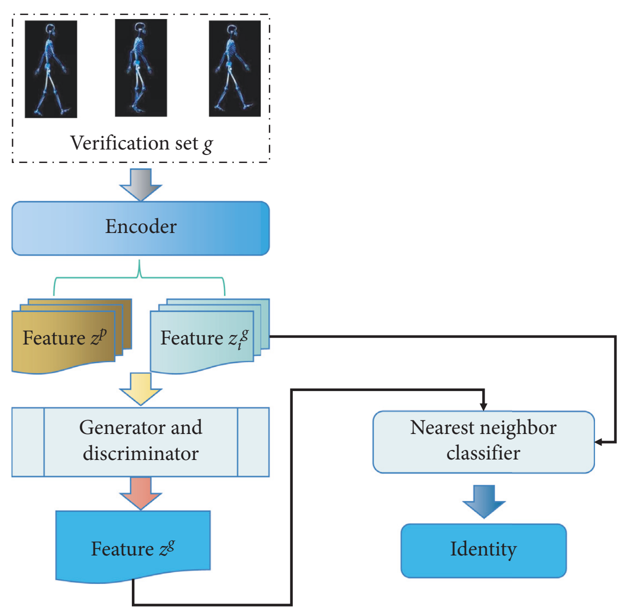

Figure 4: Algorithm flow chart.

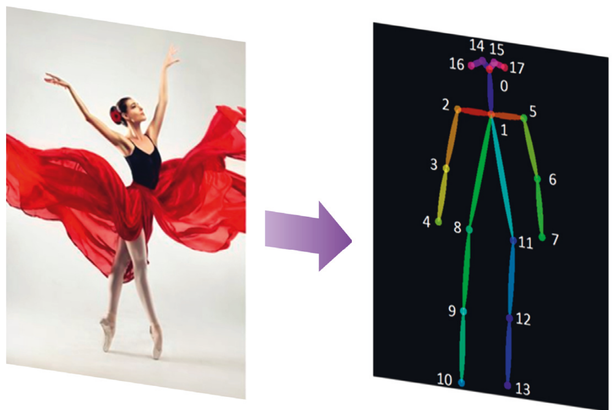
stage, initial swing stage, middle swing stage, and finally swing stage, when the heel touches the ground again and waits for 9 time periods [7]. In the actual dance process, these nine time periods will appear repeatedly with each point in Figure 5, showing certain regularity and periodicity.

Taking the top edge point as the reference starting point, the contour boundary is expanded counterclockwise to



Sample dancer image

Outline of the dancer's gait

Figure 5: Divide the gait contour points of dancers based on.

become a one-dimensional signal composed of the distance from the boundary pixel point to the centroid.

$$d_i = \sqrt{(x_i - x_c)^2 + (y_i - y_c)^2}. \tag{6}$$

In order to eliminate the influence of image size and signal duration on the training and recognition process, we normalize the signal amplitude and duration, respectively. When normalizing the amplitude, we divide each distance signal by the maximum value of the distance, so that its value is between 0 and 1. For length normalization, we use equally spaced sampling to make the number of edge points within a certain range, such as 400.

3.2.3. Dynamic Contour Recognition. The input of the authenticity discriminator network is an image, which can come from the sample generated in the target domain or the image in the source domain. The goal of this discriminant model is to learn a classifier to separate the two types of samples as much as possible. Through the contradiction training between the generated model and the generated model, the generated model can generate samples with source domain attributes as much as possible.

That is, the authenticity discriminator acts on the generation network to generate realistic images, where I^i is the source image and $\widehat{I}^i$ is the sample image generated by the generator. Here, the discriminator generates a probability to indicate whether the image is true or not, and its loss function L_D^R is expressed in the form of cross entropy as follows:

$$\begin{aligned} &L_D^R(I) = -t \cdot \log\left[D_R(I)\right] + (t-1)\cdot \log\left[1 - D_R(I)\right], \\ &s\cdot t\cdot \quad t = \begin{cases} 1 & \text{if } I \in \left\{I^i\right\}, \\ 0 & \text{if } I \in \left\{\widehat{I}^i\right\}. \end{cases} \end{aligned} \tag{7}$$

Because of the uncertainty of the target, an extra loss function is needed at the top of the generator to restrict the generated target image, and an independent network named domain discriminator is connected at the top of the converter. The discriminator takes the source image and the target image as inputs and is trained to generate the scalar probability of input-to-correlation.

Gait is a space-time movement, so we expect to use STC (spatiotemporal correlation) to capture its spatial structure characteristics and time translation characteristics.

For any two gait sequences, after the above processing, they are converted into distance signal sequences $I_1(t), I_2(t)$; The feature space $[\ell_1, \cdots, \ell_k]$ is constructed, and their projection trajectories $P_1(t), P_2(t)$ in the feature space are as follows:

$$\begin{aligned} P_1(t) &= [\ell_1, \cdots, \ell_k]^T I_1(t), \\ P_2(t) &= [\ell_1, \cdots, \ell_k]^T I_2(t). \end{aligned} \tag{8}$$

Then the similarity measure between them can be defined as

$$d^2 - \min_{ab} \sum_{i=1}^{T} \left\| P_1(t) - P_2'(at+b) \right\|^2. \tag{9}$$

Among them, $P_2'(at+b)$ is the vector trajectory that is dynamically normalized according to time expansion and shift, and the selection of parameter a, b depends on the change of velocity and phase between different sequences, respectively.

For the training of generators and discriminators, we adopt the common confrontation loss, and the formula is as follows:

$$\min{}_G \max{}_D L_{\text{adv}} = E\left[\log D\left(\widehat{y}^b\right)\right] + E\left[\log\left(1 - D\left(G\left(V\left(E\left(p^a\right)a, b\right)c\right)\right)\right)\right]. \tag{10}$$

Among them, E, V, G, D represents encoder, angle converter, generator, and discriminator, respectively, p^a is the original input gait energy map from a angle of view, c represents the unique thermal coding of walking state, and $\widehat{y}^b$ is the real gait energy map.

Universal templates representing various categories can be used as template patterns to directly match with test actions for identification. Assume that x, y represents a certain frame of the test sample and the general template, respectively, which supports the similarity calculation $s(x, y)$:

$$h_p'(x, y) = \begin{cases} 1 & \text{if } x_p \in y_p, \\ 0 & \text{otherwise.} \end{cases} \tag{11}$$

In its calculation process, if the x, y of the two frames does not match, then $s(x, y)$ is no longer assigned to zero, but a negative value, $h(x, y) - 5$, is given as a punishment, thus enhancing the differentiation between different actions.

In the process of recognition, each frame of input action should be divided into five parts in turn, and each part should be mapped to the trained cluster. If the key frame is the key frame, we will search the results of each part in its corresponding key table in turn. The real-time action recognition process is shown in Figure 6.

The accumulated scores of these results can be used as the basis for identification, and the end point of the input

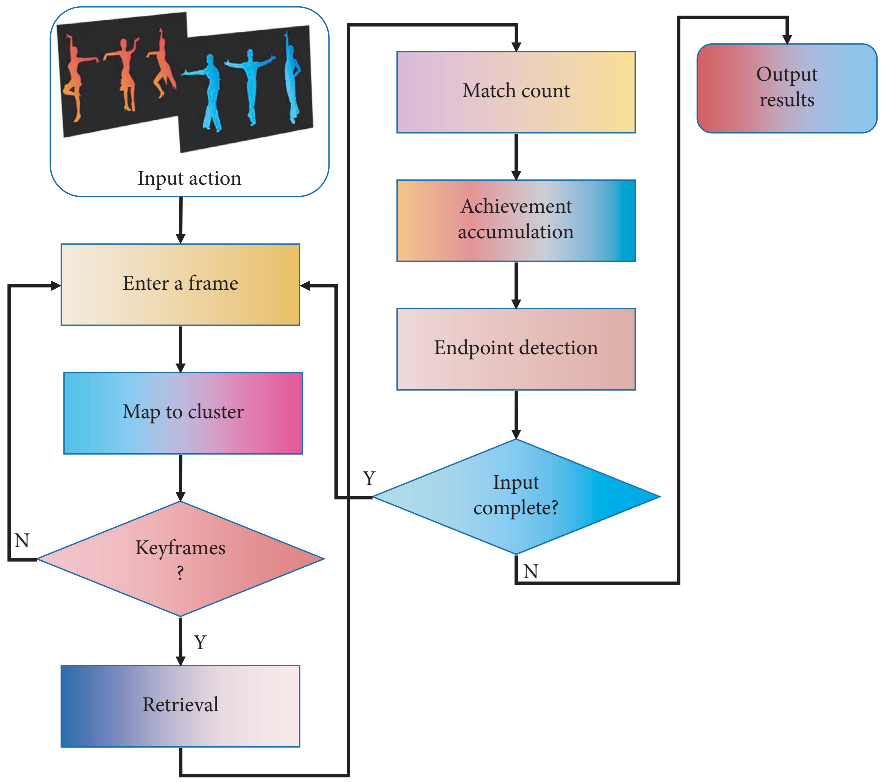


Figure 6: Real-time action recognition process.

action pattern and whether it is a legal action can also be judged by matching.

4. Experiment and Results

4.1. Experimental Data Set and Its Settings. In order to better verify the accuracy of the dance action recognition method designed in this paper, the most commonly used PASCAL VOC 2011-val (Data_P) and Stanford 40 actions (Data_S) data sets [14, 15] and the dance image to be executed (Data_D) are used. After the data collection is completed, use ipi Mocap Studio software to preprocess and correct each frame of the captured contour data. It is defined that the right heel leaves the ground as the gait cycle and the right heel touches the ground as the gait cycle. The gait contour data of 70 dancers were collected.

The generator in this model is an end-to-end unified network, which can be divided into two parts, an encoder and a decoder. The encoder part consists of four convolution layers, which extract features from the source image into a new spatial expression z. The extracted features z are sent to the decoder, so as to construct the correlation generation target through four decoding layers. We use the generated gait energy map as gait feature. In the testing stage, we trained many models to generate gait energy maps for the test data set and used the nearest neighbor algorithm to calculate the feature recognition rate. The detailed information of encoder and decoder structure is shown in Table 1 and Table 2. The discriminator structure uses four convolution layers.

4.2. Experimental Result. After the experiment on the Data_P data set, we selected three methods (ref [17], ref [19], ref [20]) to achieve better recognition results without cross-viewing and compared the average rank-1 accuracy on the same data set. The average rank-1 accuracy in three walking states and all cases is shown in Figure 7.

From Figure 7, it can be seen that the method proposed in this paper has no great advantages over the other three methods in the “running” and “walking” state, but the recognition accuracy is improved in the “jumping” state, which proves that the method proposed in this paper has better adaptability to the interference factor of clothing. In order to verify that actions are divided according to human body structure and consider their advantages, respectively, we have also implemented a case of treating human body actions as a whole in Data_S and Data_D data sets. When the action data are treated as a whole, we choose $\theta = 45$ as the quantization error of K-means clustering, and the two action data sets after clustering generate an average of 210 and 150 clusters, respectively, in three groups of experiments. Table 3 compares the recognition results of this method and the method based on whole-body segmentation under two whole-body segmentation schemes.

It can be seen that the classification performance of our method on these two data sets is better than the general body-based pattern, especially on the Data_D data set. This is because the Data_D data set covers basic daily actions, such as running and jumping, which may lead to more changes in the class. Therefore, when these actions are calculated and recognized as a whole, the recognition accuracy will be

Table 2: Settings of decoder in generator.

Layers	Number of convolution kernels	Convolution kernel size	Step length	Batch processing	Activation function
F-Conv.1	779	5 × 5 × 384	1/4	Y	L-ReLU
F-Conv.2	364	5 × 5 × 193	1/4	Y	L-ReLU
F-Conv.3	188	5 × 5 × 99	1/4	Y	L-ReLU
F-Conv.4	98	5 × 5 × 3	1/4	N	Tanh

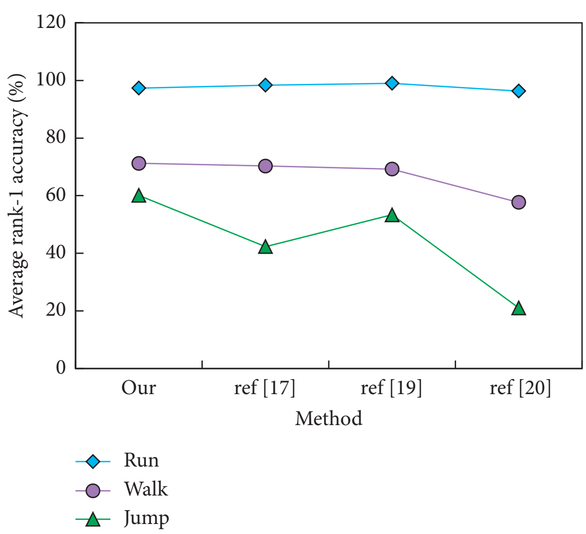

Figure 7: Walking state.

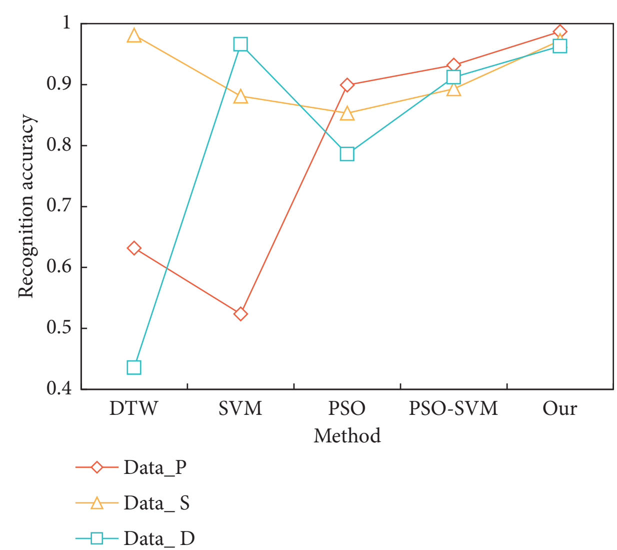

Figure 8: Comparison of the results of several recognition methods in the recognition of segmented actions.

Table 3: Recognition result under two scheme.

Data set	Plan	Recognition accuracy
Data_ S	Method base on whole-body segmentation	0.869
	Methods of this paper	0.941
Data_ D	Method base on whole-body segmentation	0.712
	Methods of this paper	0.924

seriously affected, and our limb-based segmentation method can avoid this shortcoming.

In order to further prove the effectiveness of our method, we also compare it with other commonly used motion recognition methods (DTW, SVM, and PSO). The recognition results of the above methods on the data set are shown in Figure 8.

On the Data_ S data set, the result demonstrates that DTW has the highest recognition accuracy. On these three data sets, the classification performance of SVM and PSO is not as good as this technique. PSO-accuracy SVM's on these three data sets is extremely near to the best score, demonstrating the method's stability and efficacy once again. Figure 9 shows the experimental results of this strategy on the Data_ D data set. In the experiment depicted in Figure 9, the registration set consists of four normal walking sequences from each sample, while the verification set consists of the latest two normal walking sequences.

The experimental recognition rate of Data_ *D* data set is shown in Figure 10. The experimental results in Figure 10 are used to evaluate the single angle of view.

The results show that the method proposed in this paper has obvious advantages for gait recognition with view changes. This means that the GAN model can generate better features and is robust to the change of viewing angle.

In order to better verify the performance of the model, several methods with better recognition effect (SVM, PSO, and PSO-SVM) were selected for comparison, and the experimental results are shown in Figure 11.

Compared with other methods, the model in this paper achieves better results from every angle, and the recognition rate is better than other methods. Under all test set angles,

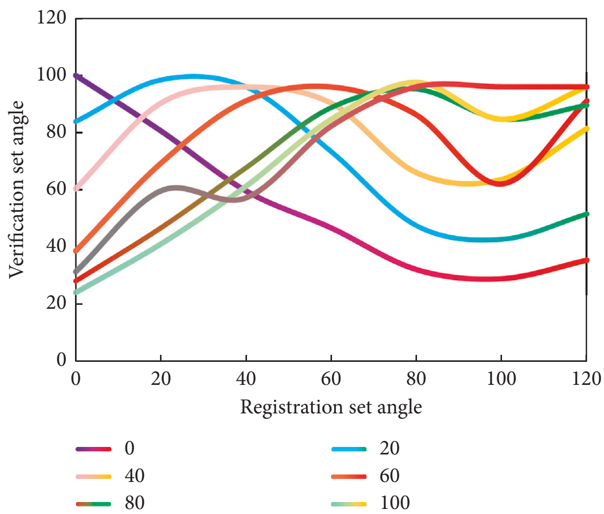

Figure 9: The training set includes three walking conditions.

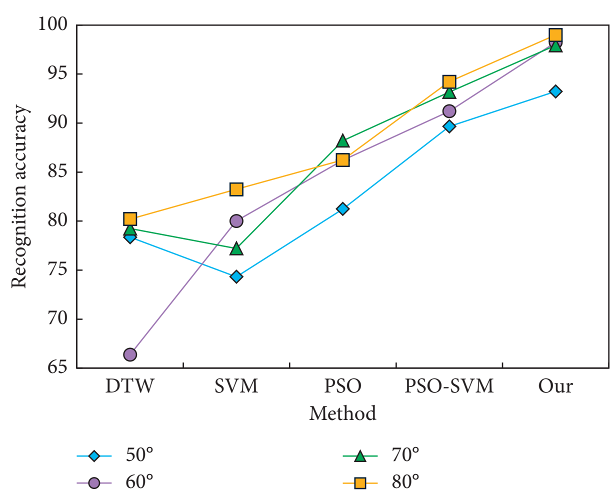

Figure 10: Recognition rate from four perspectives on Data_ D data set.

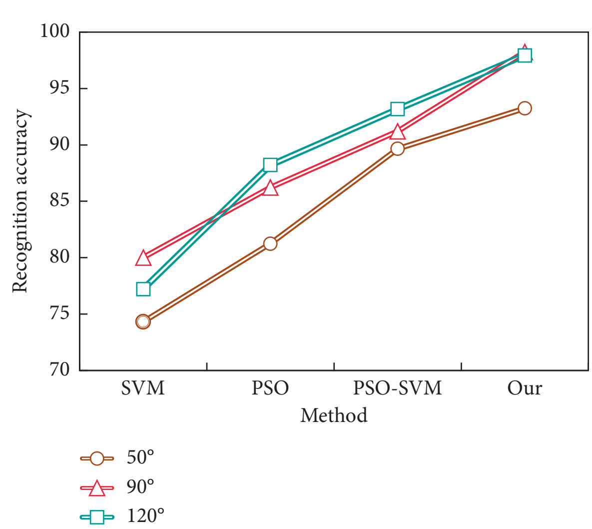

Figure 11: Recognition rate under different test set angles.

compared with the three methods in Figure 11, the best average recognition rate is obtained. The average recognition rates of the model in this paper are 93.24, 98.24, and 97.93 at 50°, 90°, and 120°, respectively, which shows that the model in this paper has good stability, can effectively deal with various test set angles, and maintains a high recognition rate.

5. Conclusions

Gait recognition, as a biometrics research center, has a wide range of applications in intelligent monitoring, human-computer interaction, security, and other fields, each with its own set of benefits. Computer vision technology can be used by experts in a variety of settings, such as competition refereeing, beginner dancer teaching, and dancer motion correction, to recognize motion in dance video images. In this research, we propose using GAN to dynamically recognize the gait contour of dancing motions. The average identification rates of this model at 50°, 90°, and 120°, respectively, are 93.24, 98.24, and 97.93, indicating that the recognition accuracy of the dance movement recognition approach is good. Simultaneously, a comparison of this strategy to other existing ways demonstrates that it is both successful and practicable. Although GAN is good at extracting contour data, dynamic features are crucial for gait identification. This paper suggests studying between frames, and I believe there is a bright future ahead.

Teachers in traditional English education devote a great deal of time and effort to developing excellent English teaching courseware and other teaching materials. However, because the network's powerful sharing capability was not fully utilized, poor resource sharing hampered the school's overall teaching efficiency. The goal of this paper is to investigate how to use a ubiquitous learning resource sharing platform and a neural network to analyze the method of English major education resource sharing. Because the BP neural network algorithm has better classification and prediction functions, it was proposed because it can classify and predict information in the sharing of teaching resources for English majors. This allows for seamless sharing of teaching materials. According to the findings of this study, there were 562.13 million people learning English in China in 2015, accounting for 37% of the population. By 2018, 945.61 million people were learning English, accounting for 85 percent of the population. Almost every student is learning English, demonstrating the language's importance. As a result, the importance of English instruction is clear, and the sharing of teaching resources should be prioritized.

1. Introduction

Colleges and universities are educational institutions and departments with the most resources. The level of sharing of teaching resources for English majors in China is largely determined by the sharing of teaching resources for English majors. However, there are numerous issues with China's current resource construction and sharing that are impeding the growth of co-construction and sharing of teaching resources for English majors in China. As a result, the theoretical and practical implications of how to solve these problems and realize the co-construction and sharing of digital teaching resources among colleges and universities are significant. The resource sharing class provides rich resources, including video resources, but also these resources cannot be copied. Basic resources are provided for free, and teachers in different schools should be based on the actual situation of the school. They need to refer to relevant practices to construct courses suitable for their students and truly teach students in accordance with their aptitude.

The ubiquitous learning environment is a comprehensive learning environment produced from the physical, social, information, technological environment, and other aspects. In particular, various educational institutions, seminars, communities, and families are organically linked through networked devices. In addition, in a common learning environment, many scattered smart devices such as computers, mobile phones, and PDAs are used. Anyone can access the right source of information from any device at any time.

The innovation of this paper is that (1) it introduces related theoretical knowledge of English teaching resource sharing and neural networks, and proposes a neural network-based BP neural network (BPNN) algorithm. It examines the role of the BPNN algorithm in teaching resource sharing. (2) The effects of the BPNN algorithm and the other two algorithms on classification and prediction are compared and analyzed in this paper. The BPNN algorithm's classification and prediction effect are higher than the other two algorithms, as demonstrated by the experiment. This allows for data analysis in teaching resource sharing, resulting in increased efficiency.

2. Related Work

Rich and attractive teaching resources are the core link to make English professional education efficient. The sharing of teaching resources for English majors has begun to attract attention. Therefore, Yuan found that the intelligent network teaching system provides learners with rich teaching resources and an efficient learning environment. However, online teaching resources are widely distributed and difficult to concentrate. Resource sharing has become a key problem to be solved urgently in the network environment. Based on this, he studied link prediction methods in online education and builds a model suitable for online education. He used neural network sorting algorithm to realize online learning knowledge prediction [1]. Guichon proposed a method for creating multimodal corpora. This corpus can be shared to analyze simultaneous online teaching interactions. He described an analysis of the steps involved in creating a multimodal and shareable corpus [2]. Yan discovered that the university video management system has evolved into one of the most important video communication platforms. He created a microgrid-based teaching video resource management system to improve the storage and sharing of teaching video resource systems in colleges and universities. He realized video network storage and improved network sharing efficiency by constructing micro-technology network storage [3]. Tucker et al. found that one of the main difficulties in achieving effective online teaching was the difficulty of accessing the vast teaching resources of teachers. He also discovered the speech and language repository as a central repository for sharing, managing, and developing resources for science teaching [4]. The main purpose of Liu R's analysis of the fusion of network media and secondary English was to better play the function of secondary English. He discovered that using resource integration technology to manage distributed teaching resources helped colleges and universities improve their level of informatization [5]. Bai and Li designed a platform for statistical analysis of educational data and studied the storage of educational multidimensional data models in order to meet the rapid growth of educational data and improve operational efficiency and scientific decision-making. He then used educational big data to test query efficiency and storage space, demonstrating the utility of the Hadoop-based educational big data platform [6].

With the rapid advancement of education in recent years, teaching resources have expanded as well. Modern education is no longer limited to textbooks and individual teachers. Many developed countries encourage the sharing of educational resources, and many universities and primary and secondary schools in China are doing so as well. China's English professional education began late, but it has a brief history. Many aspects must be standardized and improved. As a result, traditional teaching resources are limited to teachers, and they are unable to meet the information-based teaching needs of modern society. Teacher resources can be shared to make teaching more efficient and the classroom more colorful.

3. Sharing of Teaching Resources for English Majors Based on Neural Network

3.1. Ubiquitous Learning Resource Sharing Platform Based on Web2.0 Environment. The importance of English is growing due to the informatization of social life and the globalization of the economy. English has become the most widely used language in all aspects of human life as one of the most important information carriers. English is now considered a necessary skill. If a student can learn a foreign language, he can open the door to a new world of learning and ultimately achieve the goal of multiple learning and value. With the progress of globalization, English is very important especially for those who want to communicate with foreigners. On the other hand, English is a necessary factor for understanding the outside world. In today's world, most of the communication of cultural confidence is achieved through the linguistic form of English, especially through high information [7]. The number and percentage of English learners in recent years are shown in Table 1.

The number of people learning English is increasing, as shown in Table 1. The term "ubiquitous learning network" refers to a technology that allows users to freely access and exchange information over broadband and wireless networks at any time, from any location, using any tool. The Internet, digital TV networks, satellite networks, wireless networks, and 3G mobile communication networks are all part of it. The communication network is the backbone of the entire learning environment and is in charge of basic data transmission [8]. Intelligent terminals are linked together to allow for the transmission and sharing of information and resources, and they help to create a ubiquitous learning environment. Figure 1 depicts the creation of the ubiquitous learning network.

As shown in Figure 1, ubiquitous learning is also referred to as seamless learning, pervasive learning, and ubiquitous learning, among other terms. It refers to all forms of communication and learning at all times. It is a way for anyone, anywhere, at any time, to get any information they require. In human learning, the important part of ubiquitous computing technology is to provide learners with a ubiquitous learning environment. The most obvious feature of a universal learning environment is the universality and conditionality of learning [9].

For example, a teacher may use a computer in the classroom to look for additional teaching materials, assign homework to students using a mobile phone, or better organize his teaching schedule. A learner in the park can use his phone to get information from his friends and classmates, such as learning tasks [10].

In recent years, China's scientific and information technology has developed faster and faster. Among them,

Table 1: Number and percentage of English learners from 2015 to 2018.

years	Number of people (thousands)	Percentage (%)	Effective percentage (%)
2015	56,213	37	37
2016	63,890	49	49
2017	67,583	52	52
2018	94,561	85	85

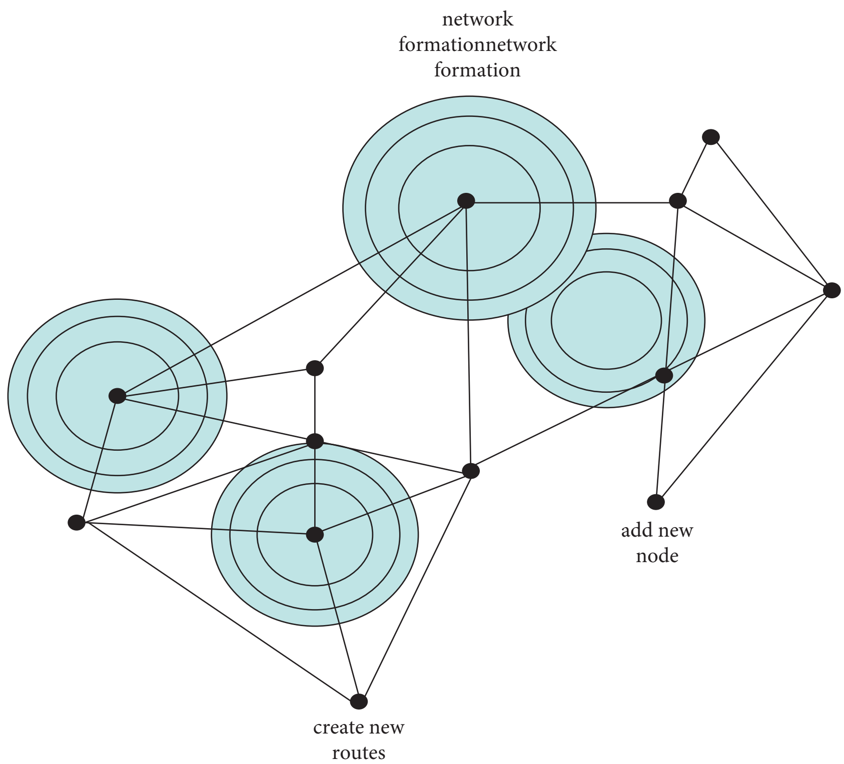

Figure 1: Ubiquitous learning network construction.

Web2.0 and other related information technologies are used more and more widely, and the information resources are also more and more abundant. This also makes the information-based teaching constantly improved in recent years. From the point of view of system design and technology, Web2.0 has the characteristics of adaptability for user interaction, main participatory architecture, open architecture for other systems, multiple nonlinear mechanisms, and sociality [11]. The Web2.0 teaching resource sharing platform is shown in Figure 2.

Traditional network resource construction has some flaws, as shown in Figure 2. Meeting user needs, such as user participation, creating or adding content, forming a community, and so on, is insufficient. And some Web2.0 application commonalities can just about satisfy it. It facilitates communication between those who have resources and those who require them, and it makes network resources social and open [12]. The free sharing and integration of information resources is the source of Web2.0. To achieve this goal on the web, a mechanism and technology must be in place to support resource exchange and matching, and these mechanisms and technologies are sufficient to meet the needs of Web2.0 sites.

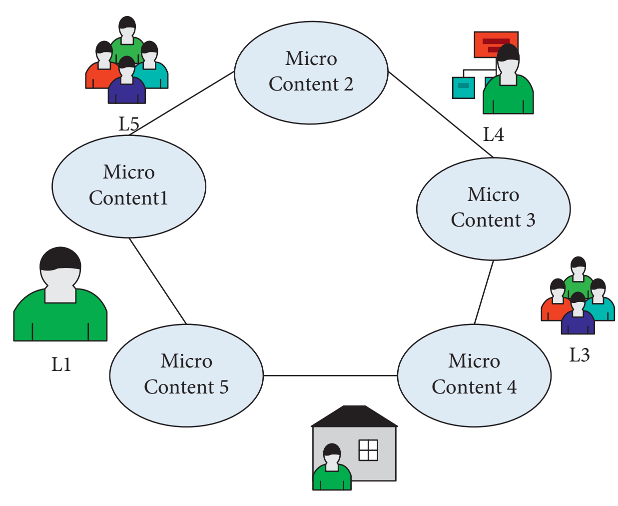

Figure 2: Web2.0 teaching resource sharing platform.

3.1.1. *Open API.* API generally refers to an application programming interface. The main purpose of the API is to provide applications and developers with the ability to access

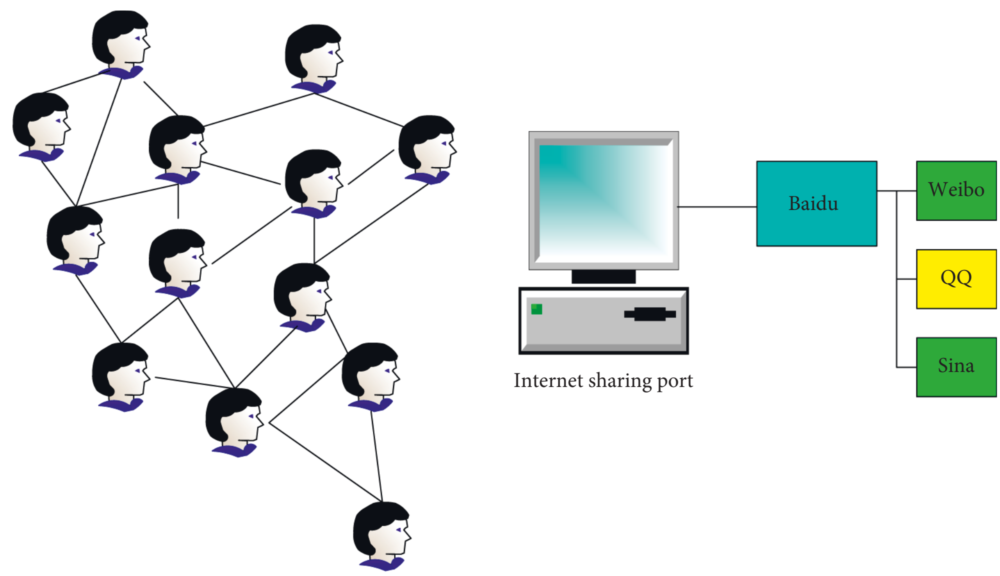

Figure 3: Internet sharing API.

a set of routines without having to access the source code or understand the details of the inner workings. Software that provides the functionality defined by an API is called an implementation of that API. The application of Web2.0 is becoming more and more popular, and this open architecture gradually emerges in the application process. From API to open API in other various websites and social software programmable web, the system pays more and more attention to the interaction and integration with other systems. Whether it is open and can form good writing with other systems becomes the key to whether web information resources can attract and be reused by users [13]. The Internet sharing API is shown in Figure 3.

As shown in Figure 3, the opening of all APIs makes the sharing, acquisition, and service of a large number of network information resources simple and easy, reducing the threshold of user experience. Simultaneously, these open platforms also bring greater value to users, developers, and small and medium-sized websites [14].

3.1.2. RSS. RSS is a data exchange method and distribution protocol for individuals to share content among other websites and is an XML form for distributing and aggregating web content. RSS builds a technical platform for the rapid dissemination of information, making everyone a potential information provider. RSS is widely used in major websites and blogs. To realize the sharing and recompilation of information resources, its significance lies in the realization of machine readability of information content, synchronization, and integration of content between systems [15].

3.2. Problems Faced by the Sharing of Teaching Resources for English Majors. The main resource builder should make detailed plans for the construction of course resources to ensure shared use of teaching resources for English majors. Participating in resource development should result in useful teaching materials [16]. A special English teaching resource library can be established to meet the needs of different teachers and students when it comes to this subject's teaching resources. Accessing the teaching resource library, as shown in Figure 4, allows college teachers and students to find and use the teaching resources they require.

As shown in Figure 4, prosperous English teaching resources have brought benefits to people. Not only colleges and universities themselves have made huge profits, but more importantly, college users can enjoy more and richer resources. It also provides an effective development method for the development of lifelong education and distance education in China [17]. But after years of resource construction, the consequences of blindness and disorder have become more and more obvious. It is mainly reflected in the following aspects:

(1) Scattered resources, lack of normative and systematic

Many universities are now developing their own resources, and university students have access to some digital resources as well. However, the majority of these resources are dispersed, and many of those created by universities lack a unified classification standard and plan. The amount of resource data grows as the number of resources built increases, and the interface problem becomes more apparent. The sharing of digital educational resources has been greatly hampered, and the resource utilization rate has been significantly reduced, due to the lack of various resource technology platforms and tools to provide users with services.

(2) The phenomenon of "information island" is serious, and repeated construction leads to a lot of waste

Because the interconnected functions and advantages are not fully utilized, and the human, material, and financial resources invested in the process of resource construction, universities are rarely willing to provide free resources to others. This will greatly

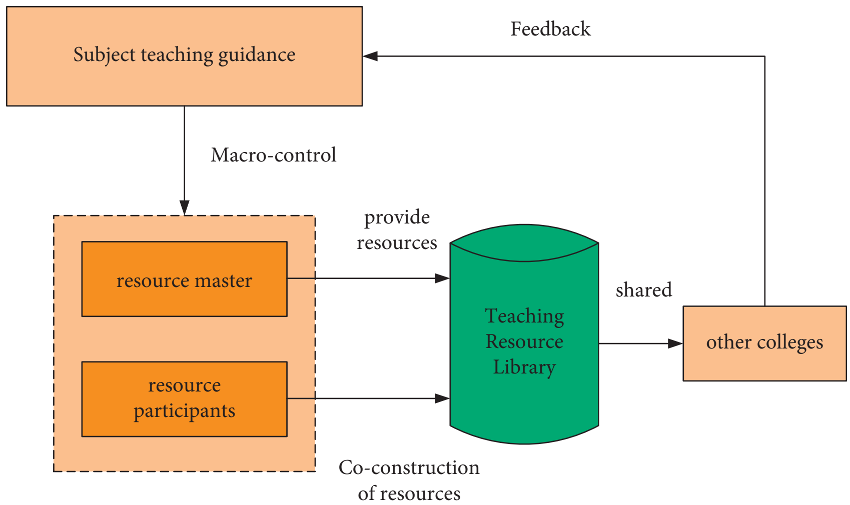

FIGURE 4: Shared structure diagram of subject teaching resource library.

limit resource sharing. Despite significant progress in the development of educational resources, there are still numerous issues. Co-construction resources are scarce, sharing coverage is limited, construction duplication is common, resource quality is poor, and resource inhomogeneity caused by platforms and data forms is on the rise. People should use BP neural networks [18] to better understand educational resource information classification [19, 20] and prediction [21], as well as to share educational resources more effectively [22].

3.3. The Classification Function of BP Neural Network. Large-scale parallel processing, decentralized storage and processing, self-organization, self-adaptation and self-learning ability, nonlinear approximation characteristics, and so on are all advantages of neural networks as one of the classic methods for dealing with classification and prediction problems. It is appropriate for dealing with inaccurate data, but there are a few things to consider. Retraining the network takes a long time when the trained learning system needs to learn new knowledge from new samples. On the premise of preserving the majority of previously learned knowledge, incremental learning can partially adjust network parameters to adapt to new knowledge.

The BP neural network is a multi-layer feedforward network with error backpropagation training (referred to as error backpropagation). It uses the BP algorithm, which is based on the gradient descent method. The complex network structure and repeated learning process of BP neural network make it not affected by random or unknown factors, and it has outstanding fitting ability to complex chaotic systems. The fitting ability of the BPNN is shown in Figure 5.

Figure 5 shows that the neural network has strong self-adaptive learning and parallel processing capabilities, but it is difficult to properly represent the input-output relationship obtained. One of the most widely used and successful artificial neural networks is the BP neural network model. It can be used in a variety of fields, including image and sound,

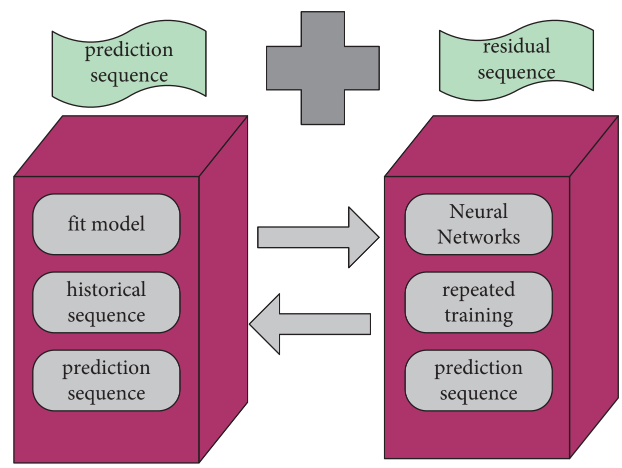

FIGURE 5: Fitting ability of BP neural network.

due to its powerful nonlinear mapping capability. When the BPNN is applied to time series data, a large amount of data preprocessing is not required, allowing the previous time to be effectively reduced. As shown in Figure 6, the sequence classification algorithm is designed to improve classification performance while extracting features.

The number of nodes in the output layer, as shown in Figure 6, is set according to the needs of the actual problem. The number of nodes in the hidden layer determines the neural network's complexity. In general, the more nodes in the network's hidden layer, the more difficult the problem is to solve. A neural network is known to have n input layer nodes, m hidden layer nodes, and one output layer node. It can update the weights of each connection chain using formula (1) to describe the neural network's training process:

$$\mathrm{net}_j = \sum_{i=0}^{n} v_{ij} a_i, \quad j = 1, 2, \ldots, m. \tag{1}$$

net_j represents the excitation value of the first node, a_i represents the output value of any node in the hidden layer, and v_{ij} represents the excitation function of the hidden layer node. It generally uses the sigmoid function, such as formula

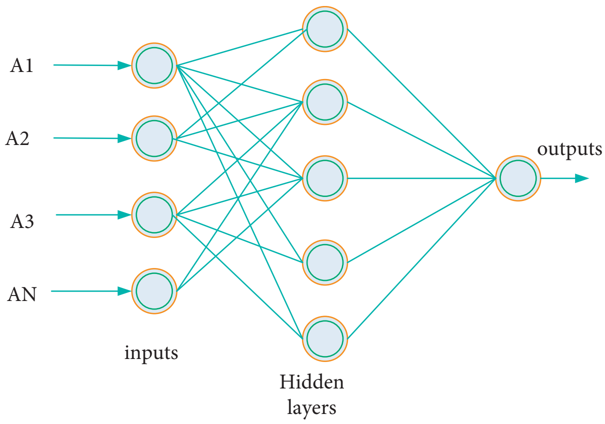

FIGURE 6: BP neural network structure diagram.

$$f_H(a) = \frac{1}{1+\exp(-a)}. \quad (2)$$

The output value of the output layer node is shown in formula

$$O = f_0\left(\sum_{j=0}^{m} w_{jk} b_i\right). \quad (3)$$

f_0 is the excitation function.

Compared with a single classifier or predictor, ensemble learning can achieve better performance and generalization ability. The main methods of ensemble learning include bagging, boosting, AdaBoost (adaptive boosting), and other algorithms. Bagging algorithm constructs different training sets by sampling samples with replacement, thereby generating different learners. It finally gets the final result by voting.

The principle of AdaBoost algorithm is to adjust the sample weight and weak classifier weight. It selects the weak classifiers with the smallest weight coefficients from the trained weak classifiers and combines them into a final strong classifier. The AdaBoost algorithm assigns different weights to different sub-models under the same training set. The algorithm first assigns the same initial weight to each input sample. In each round of iteration, it adds new base classifiers until a preset small enough accuracy is reached or all base classifiers are used for training to determine the final classifier.

AdaBoost. HM algorithm is an improved algorithm of AdaBoost algorithm. AdaBoost algorithm calculates the error of the classifier on the initial weight distribution by calculating the classification error rate of the base classifier. The AdaBoost. HM algorithm calculates the error of the classifier on the initial weight distribution by calculating the classification accuracy of the base classifier. Its calculation formula is

$$u(a_z) = h^{y_z}(a_z) - \max_y h^y(a_z). \quad (4)$$

Among them, $z = 1, \ldots, Z$ is the total number of input data, and h^y represents the class label data consisting of multiple 0 s and 1 s. The formula for calculating the weight of the base classifier in the final classifier is also different. The formula for the AdaBoost algorithm to calculate this weight is formula

$$\gamma = \frac{1}{2}\text{in}\left(\frac{1-r}{r}\right). \quad (5)$$

The formula for the AdaBoost.HM algorithm to calculate this weight is

$$\gamma = \frac{1}{2}\text{In}\left(\frac{1+r}{1-r}\right). \quad (6)$$

r is the error of the base classifier.

In this paper, improvements are made to the AdaBoost.HM algorithm. The classifier coefficients calculated by the formula are often not optimal. Therefore, people add a coefficient to the formula for calculating the weight coefficient of the base classifier in the final classifier and use the particle swarm optimization (PSO) algorithm to optimize the coefficient. People use the result of the base classifier as a kind of weight. It uses the direct output of the base classifier to compute the final classifier instead of converting it to class label data. It selects a classifier with the lowest current error rate as the first base classifier. It calculates the accuracy of this classifier as formula

$$u_l(a_z) = \begin{cases} 1, & b_z = f_l^z, \\ -1, & b_z \neq f_l^z. \end{cases} \quad (7)$$

f_l^z represents the actual output class of the lth base classifier relative to input a_z. The error of this base classifier on the d_l-distribution is formula

$$r_l = \sum_{z=1}^{Z} d_l(z) u_l(a_z). \quad (8)$$

The weight of the base classifier in the final classifier is calculated as formula

$$r_l = p\text{In}\left(\frac{1+r_l}{1-r_l}\right), \quad p \in [0,1]. \quad (9)$$

It updates the weight distribution of training samples as formula

$$d_{l+1}(z) = \frac{d_l(z)\exp(-\gamma_l u_l(a_z))}{\sum_{z=1}^{z} d_l(z)\exp(-\gamma_l u_l(a_z))}. \quad (10)$$

It combines each base classifier according to the weight of the base classifier to obtain the final classifier as formula

$$H(A) = \arg\max_o \sum_{l=1}^{M} \gamma_l H_l^o(A). \quad (11)$$

$H_l^o(A)$ represents the direct output of the lth base classifier.

3.4. Naive Bayes Algorithm. The Bayesian method is based on the Bayesian principle and classifies the sample dataset using probability and statistics knowledge. The Bayesian classification algorithm has a very low false-positive rate due to its solid mathematical foundation. The principle of the

Naive Bayes algorithm is simple. It assumes that the various characteristic attributes of the sample have independent effects on the classification of the sample. It can more accurately estimate the necessary parameters when the amount of data is small. In addition, the classification model is characterized by simple installation, fast classification speed, and high accuracy.

The training process of the Naive Bayes classifier is to estimate the class prior probability $P(c)$ based on the training set D.

$$P(c) = \frac{|D_C|}{|D|}. \tag{12}$$

It estimates the conditional probability that the ith feature in the training sample appears in class c as formula

$$P(a_i|c) = \frac{D_{c,a_i}}{D_c}. \tag{13}$$

Although the Naive Bayes classifier is simple and efficient, when the labeled data are small, the number of samples much larger than the training will cause the problem of over-adaptation, which will lead to insufficient classification effect.

3.5. Prediction Model of Teaching Resource Sharing Based on BP Neural Network. Using neural network as the base classifier or predictor of ensemble learning can improve the generalization ability of the network and the effect of classification or prediction.

Prediction usually works through classification or valuation. That is, predictions are usually modeled by classification or estimation, and the models are applied to predictions of unknown variables. The target of prediction is to predict the unknown variables in the future, which often takes time to verify. The process of modeling and training using neural network is as follows:

Since the impact factor units are inconsistent, people first normalize the data to the [−1, 1] interval. Its formula is

$$a_k = \frac{a_k - a_{\min}}{a_{\max} - a_{\min}}. \tag{14}$$

The output of the BP rule in the BP wavelet neural network is the wavelet function. The network not only has the self-learning and self-adaptive ability of BP neural network, but also has the characteristics of wavelet function. In this section, the wavelet function used is expressed as formula

$$\varphi_{il}(a_i) = -\zeta_{il}\exp\left(\frac{-\zeta_{il}^2}{2}\right). \tag{15}$$

ζ_{il} is the translation factor and scaling factor of the wavelet function.

The first layer is the input layer, and the ith output can be expressed as formula

$$f_1(a_i) = a_i, \quad i = 1, \ldots, n. \tag{16}$$

The second layer is the pooling layer. Each node of this layer is used to calculate the membership function of the BP subset corresponding to input variable a_i. In this section, the Gaussian BP function is used to input the neural network, and the output of the neuron node of this layer can be expressed as formula

$$\mu_{il} = \exp\left(-\frac{(a_i - m_{il})^2}{2\sigma_{il}^2}\right), \quad (i = 1, \ldots, n). \tag{17}$$

The third layer is the regular aggregation layer. It uses the multiplication operator to calculate the membership of each rule. The output expression of this layer is formula

$$\mu_l = \prod_{i=1}^{n} \mu_{il}. \tag{18}$$

The fourth layer is the normalization layer, whose main function is to normalize the membership degree of each BP rule to formula

$$v_l = \frac{\mu_l}{\sum_{l=1}^{L}\mu_l}. \tag{19}$$

Here are $0 < v_l \le 1$ and $\sum_{l=1}^{L}\mu_l = 1$.

This paper uses a learning rate based on the idea of variable universe for parameter learning. This paper uses the classification accuracy of the network with the training sample set to construct the scaling factor. It can adaptively adjust the size of the learning rate according to the training effect of the network. Its expression is as formula

$$\eta(k) = \left(\frac{100 - \text{accuracy\_train}(k-1)}{\text{acc\_const}}\right)^T \eta(k-1). \tag{20}$$

Among them, k is the number of iterations, and $100 - \text{accuracy\_train}(k-1)$ is the percentage value of the classification accuracy of the training set samples predicted by the network after the last iteration.

When the values of acc_const and T are determined, it is not difficult to see from the expression of the scaling factor that at the beginning of the iteration or when the number of iterations is small, the value of the model classification accuracy $100 - \text{accuracy\_train}(k-1)$ is very small, and the value of T is greater than 1. The learning rate for the k-th iteration is increased relative to the previous iteration. This can improve the global search ability of the model and speed up the network convergence speed.

Before dealing with the time series forecasting problem, it first divides the time series data into training set and test set. It converts the predicted input and output data into a matrix representation. It is assumed that the first s sequence values are used to predict the sequence value at the next moment, and the formula is

$$\begin{bmatrix} a_1 & \cdots & a_s \\ a_t & \cdots & a_{t+s-1} \\ a_T & \cdots & a_{T+s-1} \end{bmatrix} \longrightarrow \begin{bmatrix} a_{s+1} \\ a_{t+s} \\ a_{t+s} \end{bmatrix}. \tag{21}$$

Table 2: Experimental data.

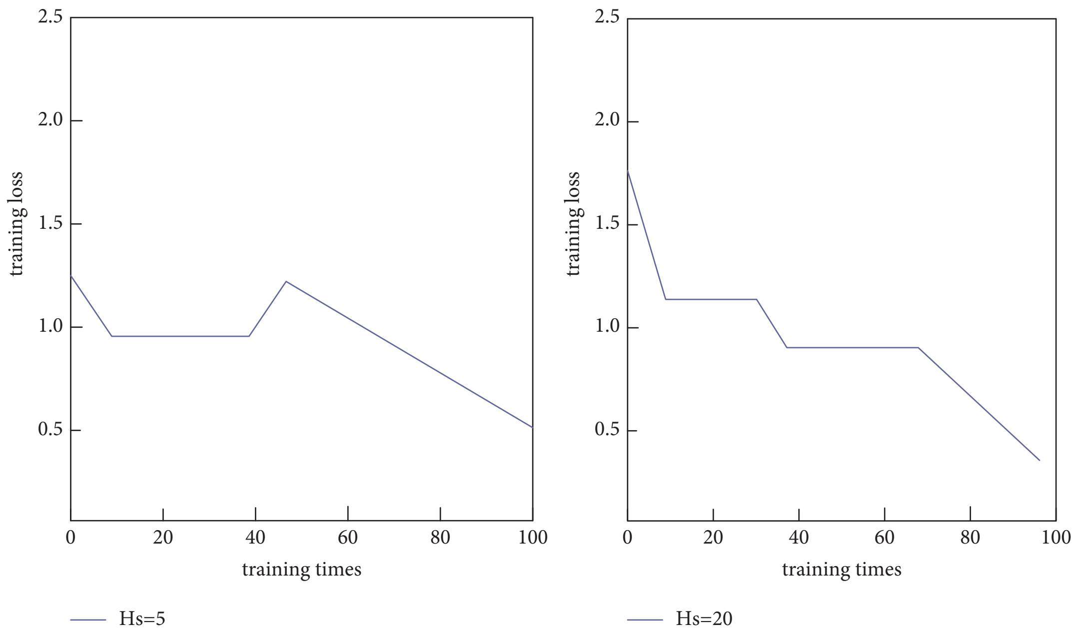

Figure 7: Training loss of BP neural network on Beef dataset.

Matrix A represents the input to the model, a_{s+1} represents the output of the model, and T is the number of rows in matrix A. The arithmetic mean of the results of the two base predictors is directly taken as the integrated prediction result; that is, each base predictor is given a weight of size N_f and then weighted and summed. The integration result is as formula

$$b_{\text{ensemble}} = \frac{\sum_{l=1}^{N_f} b_i}{N_f}. \tag{22}$$

b_{ensemble} is the result after ensemble, b_i is the result based on the lth predictor, and N_f is the number of base models participating in the ensemble.

4. Experiment and Analysis of Classification and Prediction of BP Neural Network

4.1. Classification Function Experiment of BP Neural Network. In the experiments, 9 sets of time series data were selected from various data sources in the UCR time series classification software house. The specific information of the experimental data selected from the UCR time series classification software house is shown in Table 2.

As shown in Table 2, the BPNN constructed in this paper has a three-layer structure. The amount of nodes in the input layer is the data length of the time series data, and the number of nodes in the output layer is the number of data categories.

The setting of neural network training time usually needs to be manually adjusted according to the experimental results. If there is insufficient labeled data, the training loss of the neural network may converge faster due to fewer training samples. The training loss of the neural network in the datasets Beef and Gun-Point is shown in Figure 7.

As shown in Figures 7 and 8, the neural network's training time setting must usually be manually adjusted based on the experimental results. A neural network is a distributed parallel information processing algorithmic mathematical model that mimics the behavioral characteristics of animal neural networks. Due to fewer training samples, the neural network's training loss may converge faster if there are insufficient labeled data.

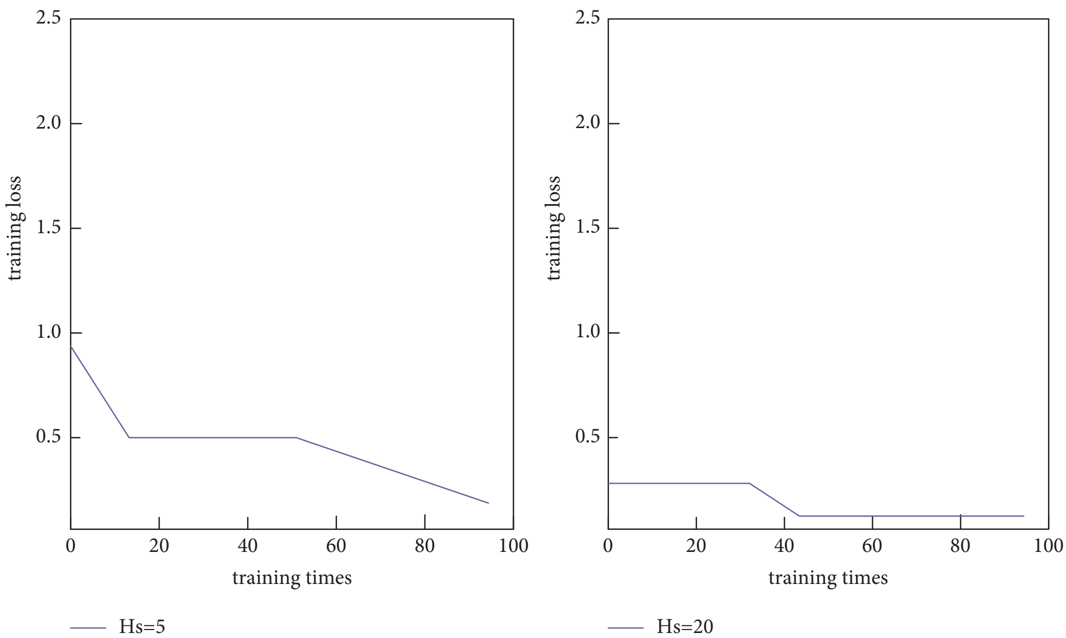

Figure 8: Training loss of BP neural network on Gun-Point dataset.

Table 3: Classification accuracy of different methods on different datasets.

Data name	Naive Bayes	Support vector machine classification algorithm	BP classification algorithm
Beef	0.89	0.750	0.932
Gun-Point	0.654	0.473	0.790
Trace	0.703	0.648	0.743
ItalyPowerDemand	0.926	0.732	0.964
Lightning-7	0.583	0.549	0.674
OSU Leaf	0.269	0.216	0.315
Wafer	0.894	0.809	0.932
WordSynonyms	0.237	0.251	0.367
Yoga	0.518	0.437	0.522

For the above 9 datasets, the proposed BP classification algorithm is compared to the conventional SVM classification algorithm and the simple Bayes algorithm in this paper, as well as the classification effect of the classifier using only a limited number of labels. The accuracy of classification is used to assess the strengths and weaknesses of various algorithms. The best classification results of various parameter settings are BPNN classification algorithm, support vector machine classification algorithm, and Naive Bayes algorithm. Table 3 illustrates this.

Table 3 shows the following: the highest accuracy is 0.964 for the BP neural network classification algorithm, while the highest accuracy is 0.809 and 0.926 for the support vector machine classification algorithm and the Naive Bayes algorithm, respectively. The BPNN classification algorithm outperforms the support vector machine and Naive Bayes classification algorithms. The best classification effect is achieved by the BP algorithm proposed in this paper. The BP algorithm and the Naive Bayes algorithm proposed in this chapter are used as benchmark classifiers in this experiment. It expands the label set with the AdaBoost algorithm and compares the classification effects by building a temporal classification model. Figure 9 depicts the experimental results.

As shown in Figure 9, in the Beef dataset and Gun-Point dataset, if the BP algorithm proposed in this paper is used as the benchmark classifier, the simple Bayes algorithm has matching rate, recurrence rate, and metric values. If the BP algorithm proposed in this paper is used as a benchmark classifier, unlabeled data can be labeled more accurately. The AdaBoost algorithm can take into account unlabeled data and make better use of unlabeled data information for improvement.

4.2. Prediction Experiment and Analysis of BP Neural Network. This part compares the accuracy of the prediction model through experiments and evaluates the performance of English major teaching resource sharing prediction based on BP neural network. In the following comparative experiments, it selects the BPNN prediction model and the Naive Bayesian model as the experimental comparison object and selects the error index of the prediction sequence as the model evaluation standard.

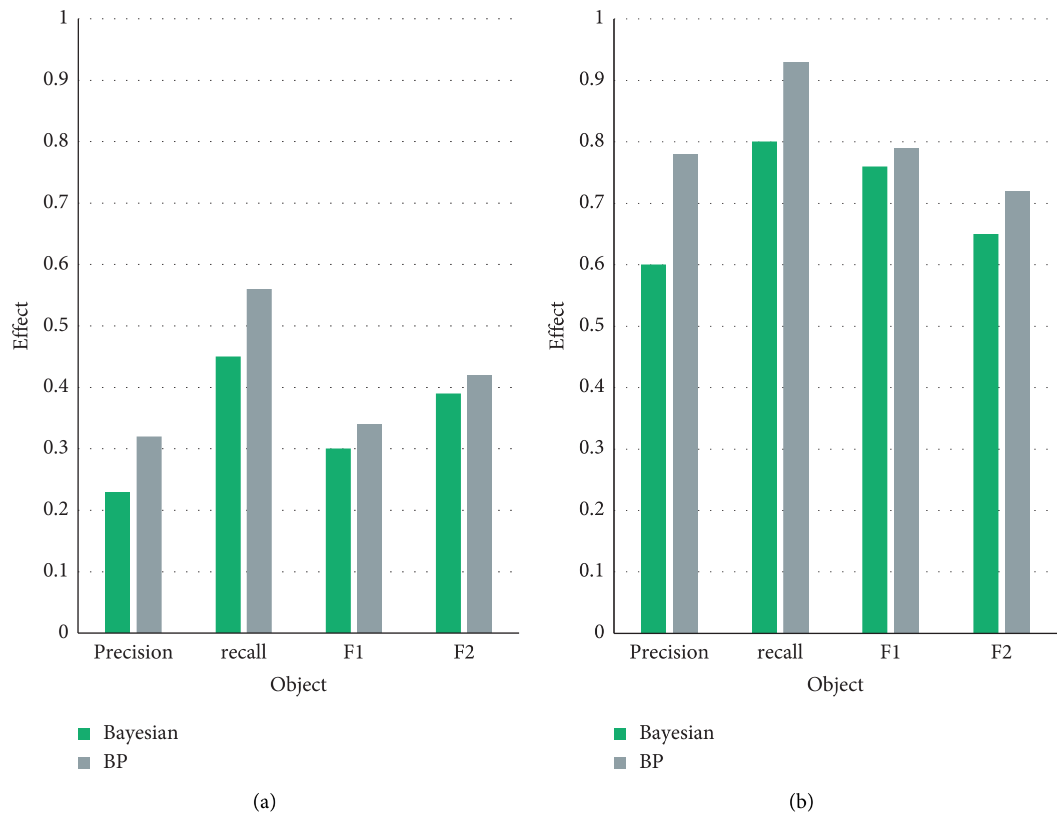

FIGURE 9: Comparison of the classification effects of the two algorithms on different datasets. (a) Comparison of classification effect of Beef dataset. (b) Comparison of classification effect of Gun-Point dataset.

In order to better explain the experimental results, on the one hand, it shows the error rate of the prediction results, and on the other hand, it visually shows the fitting effect and prediction results of each prediction model to the experimental data. In general, it evaluates the performance of forecasting models according to the following three generally applicable error measures: mean absolute error (MAE), mean percentage error (MAPE), and root mean square error (RMSE).

$$\begin{aligned} \mathrm{MAE} &= \frac{\sum_{i=1}^{n}\left|b_t - b_l\right|}{n}, \\ \mathrm{MAPE} &= \frac{\sum_{t=1}^{n}\left|b_t - b_l\right|}{n \times \left|b_t\right|} \times 100\%, \\ \mathrm{RMSE} &= \sqrt{\frac{\sum_{t=1}^{n}\left(b_t - b_l\right)^2}{n}}. \end{aligned} \tag{23}$$

Among them, b_t is the actual value of the time series at time t, and b_l is the predicted value of the time series at time t.

This experiment is to compare the Naive Bayesian model and the BP neural network prediction model. The datasets are the data of teaching resources of English majors in College A and the data of teaching resources of English majors in College B.

In this experiment, under the setting of the same neural network structure, the fitting effect of the two models on historical data and the prediction results for a period of time in the future are, respectively, shown. It also compares the model's performance on datasets with significantly different lengths and features, as shown in Figure 10.

As shown in Figure 10, the BPNN has a very good fitting effect on historical data and can basically reproduce the real data. The fitting effect of the Naive Bayesian model on historical data is slightly worse than that of the BP neural network. It cannot accurately recover the short-term numerical fluctuations in historical data, but it can still grasp the trend of time series movement. The prediction results of the Naive Bayes model and the BP neural network on the data are shown in Table 4.

As shown in Table 4, the prediction error of the Naive Bayesian model is between 0.69 and 0.75, and the error of the BP neural network is between 0.21 and 0.43. The Naive Bayesian model has a bigger gap than the BPNN in the prediction results of time series data. With the increase of the prediction step, the Naive Bayes model will be limited to the periodicity of local fluctuations, and there will be periodic

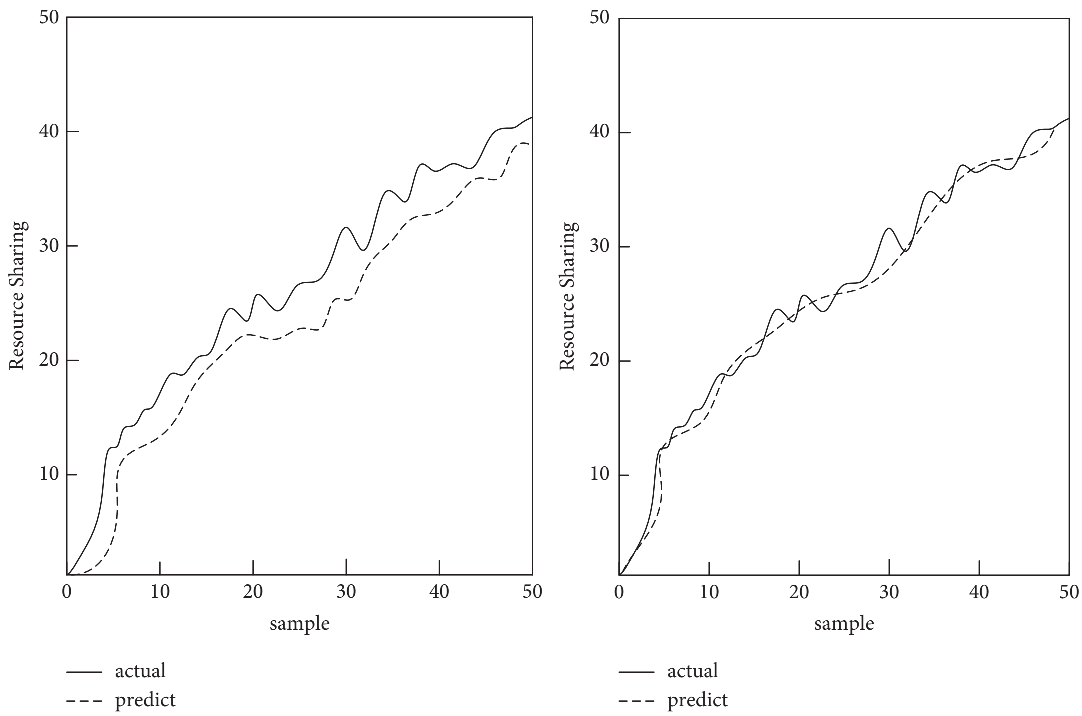

Figure 10: Fitting diagram of Naive Bayes model and BP neural network prediction.

Table 4: Prediction results of the two algorithms.

Error	Naive Bayes model	BP neural network
MAE	0.75	0.43
MAPE	0.70	0.36
RMSE	0.69	0.21

repeated numerical fluctuations. The BPNN model can basically predict the change of the shock trend in time.

5. Conclusions

The contradiction between the shortcomings and unbalanced development of the educational needs of colleges and universities has made all sectors of society focus more and more on this. This also makes the sharing of higher education resources an important requirement to promote the rapid development of China's higher education. Teachers rely on computers for education as a result of the advancement of modern computer technology, and the distribution of many software and assignments is dependent on networks and computers. This can improve resource sharing efficiency, expand educational resource content, and maximize the use of educational content. In recent years, the English major has grown in popularity, and major colleges and universities have increasingly focused on teaching English majors. This paper focuses on how to use teaching resource sharing responsibly and deliver effective instruction. The ubiquitous learning resource sharing platform is described in detail in this paper, and it is discovered that the platform has numerous advantages. It not only enables teachers to share resources at any time and from any location, but it is also very efficient. This paper briefly discusses the challenges of sharing teaching resources for English majors before highlighting the neural network's function. The neural network is used primarily for classification and prediction in this paper. The classification and prediction effects of the BP neural network are higher than those of the Bayesian classification algorithm, according to a series of experiments. There are still some errors in the data due to the experiment's technical and environmental factors. The author will continue to learn from his mistakes and strive to improve his work in the future.

In recent years, the research work of artificial intelligence technology has progressed rapidly, and various classic Few-Shot learning models have achieved unprecedented success in many artificial intelligence application fields. These include face recognition, object classification detection and tracking, speech recognition, and natural language processing, which greatly facilitate our lives. This paper aims to identify dance fitness movements based on contour image spatial frequency domain features and Few-Shot learning technology. This paper proposes a Few-Shot learning method based on contrastive average loss for Few-Shot learning. This method makes the learned model more representative by improving the loss function and performing a normalization process, and it proposes a feature extraction algorithm that combines improved LBP and HOG for action recognition technology. The experimental results show that the recognition accuracy of the algorithm in this paper is 93.10%, 90.30%, and 92.70% for walking, opening hands, and running, respectively. This illustrates the effectiveness of the fusion feature algorithm.

1. Introduction

In the early days, research based on images and videos was an important part of human action recognition methods. With the continuous development of computer technology, intelligent machines and equipment have gradually attracted widespread attention from human beings. These methods mainly take the RGB information collected by the camera equipment as the research object and use the features such as texture and color information in the two-dimensional image to perform action recognition. However, the changes of lighting conditions, background interference, and occlusion and self-occlusion problems cannot be solved well, which has become the bottleneck of this type of research method. In order to enable deep learning models to overcome the problem of relying on large-scale data and obtain the ability to quickly learn new categories of things similar to humans, Few-Shot learning came into being.

The general action recognition method works by extracting features from the original input and then training a classifier using those features. Robust feature representations must be obtained to ensure the accuracy of the final algorithm, which necessitates a significant amount of computational and testing effort. Massive labeled data are usually difficult to obtain in real-world applications. On the one hand, some industries find it difficult to collect image data for a variety of reasons, including privacy and security; on the other hand, even if image data are collected, labelling it is often costly. These disadvantages severely limit the application of image classification models. As a result, for dance fitness action recognition, it is necessary to investigate the spatial frequency domain features of contour images as well as Few-Shot learning technology.

On the basis of predecessors, this paper has the following two innovations for human body recognition research: (1) a contrastive average loss-based Few-Shot learning method is proposed. Few-Shot learning is a commonly used method in human action recognition research, but the traditional Few-Shot learning method will be hampered by the action's noise and background processing. This problem can be solved using the Few-Shot learning method based on contrastive average loss proposed in this paper. (2) The three movements of running, walking, and opening hands are used to research dance fitness movement recognition. Because these three movements are the most common in dance and fitness, and because other movements are based on their extensions, research on these three movements can better represent the entire movement.

2. Related Work

There are numerous studies on human action recognition that are related. To compensate for the flaws of traditional algorithms, Tarn C et al. used the Few-Shot learning method to fit data online. Their proposed method was tested on ten datasets using different collision energy settings and instruments such as Velos, QE, Lumos, and Sciex. Their findings show that Few-Shot learning can improve prediction accuracy while using virtually no computational resources [1]. Research performed by Szcs and Németh aims to aid medical workers' work by analyzing pathological X-ray recordings with only a few images. They propose the Deep Neural Network-based Dual View Matching Network (DVMN), an improved method that addresses the problem of Few-Shot learning and different views of pathological records in images. Its main contribution is the use of convolutional neural networks in image representation for feature extraction and multiview processing [2]. Li et al. proposed Joint Distance Maps, a simple and effective method for encoding the spatiotemporal information of skeleton sequences into color texture images, based on the good performance of deep learning (JDMs). They also used convolutional neural networks to extract distinguishing features from JDMs for recognizing human action and interaction. The proposed method has been validated by state-of-the-art results in single-view and cross-view settings on the large RGB + D dataset and the small UTD-MHAD dataset [3]. SkeletonNet, a deep learning framework for skeleton-based 3D action recognition, was investigated by Ke et al. They begin by extracting features based on body parts from each frame of the skeleton sequence. When compared to the original coordinates of the skeletal joints, the proposed features are translation, rotation, and scale invariant [4]. Wang et al. analyzed human activity recognition from videos using multimedia and convolutional neural network features. They feed frame-level CNN sequence features to a long short-term memory (LSTM) model for video activity recognition, treating video as a sequence of frames [5]. To process video data, Ullah et al. proposed an action recognition method using convolutional neural networks and deep bidirectional LSTM-LSTM networks. First, every six frames of video are analyzed for deep features, which helps to reduce redundancy and complexity. Then, using a DB-LSTM network, order information between frame features is learned, with multiple layers stacked together in the forward and reverse passes to increase the depth of the network. By analyzing features within specific time intervals, the method can learn long-term sequences and process lengthy videos. On three benchmark datasets, UCF-101, YouTube 11 Actions, and HMDB51 [6], their experimental results show that the proposed method achieves significant improvement in action recognition compared to existing action recognition methods.

Many studies on human actions are based on machine learning methods, and the extraction of video information is emphasized, as evidenced by a review of related research. These kinds of processing methods are quite complicated.

3. Few-Shot Learning Based on Contrastive Average Loss

3.1. Introduction to Few-Shot Learning. In recent years, Few-Shot learning is a subfield of machine learning [7, 8]. The definition of machine learning is that a computer program learns from experience (experiences, E) to solve a certain task (task, T) and perform a certain performance measure (performance, P). Performance P on task T improves with experience E. While Few-Shot learning is a class of machine learning problems (specified by E, T, and P), where E contains little supervision information for the target T. Specific to the image classification [9, 10] task based on Few-Shot learning, T is the image classification task, E is a small number of labeled pictures and prior knowledge used for the classification task, and the performance measure P is the accuracy rate. According to the definition of machine learning, the classification task should be to improve the experience E based on the measured accuracy, while the few labeled images are fixed. Therefore, only the part corresponding to the prior knowledge can be improved. Specifically, the prior knowledge may be some original images of other categories or a pretrained model. Figure 1 is an example of rooster single-sample recognition. The model only needs to judge which birds on the right are roosters based on the rooster image on the left.

Therefore, the training method of Few-Shot learning is different from the training method of conventional deep learning models [11–13]. Specific to the image classification problem, the training process usually contains two datasets, namely the support dataset and the query dataset. Formally, the training set learned by Few-Shot contains multiple samples of different classes. The model is required to learn how to distinguish the c classes from the Few-Shot with the number of training sets *ck*. Such a task is called a c-way k-shot classification task. The value of k is usually 1 or 5. When k is 1, this Few-Shot learning is called one-shot learning, as shown in Figure 2:

The core problem of Few-Shot learning is insufficient sample size. In order to "learn" from a small number of samples to a deep learning model that can be generalized, the current main solutions can be divided into three categories: Few-Shot learning methods based on data augmentation, metric learning, and meta-learning. As stated in Chapter 1, the current research status at home and abroad, the probability-based generative model in the nondeep learning stage is the mainstream of the Few-Shot classification task; and the current mainstream is the deep learning-based discriminative model. So far, there are three main methods for using discriminative models to solve the Few-Shot classification

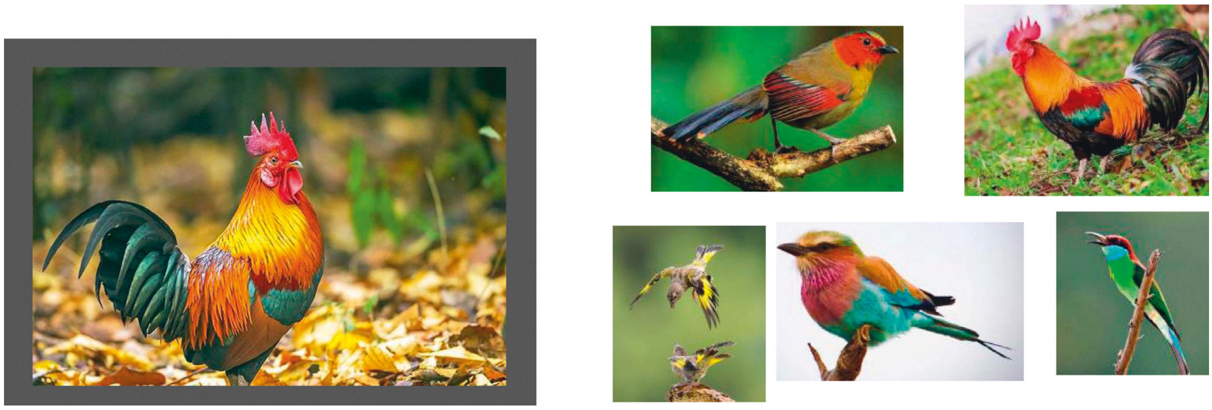

Figure 1: Example of rooster single-sample image classification.

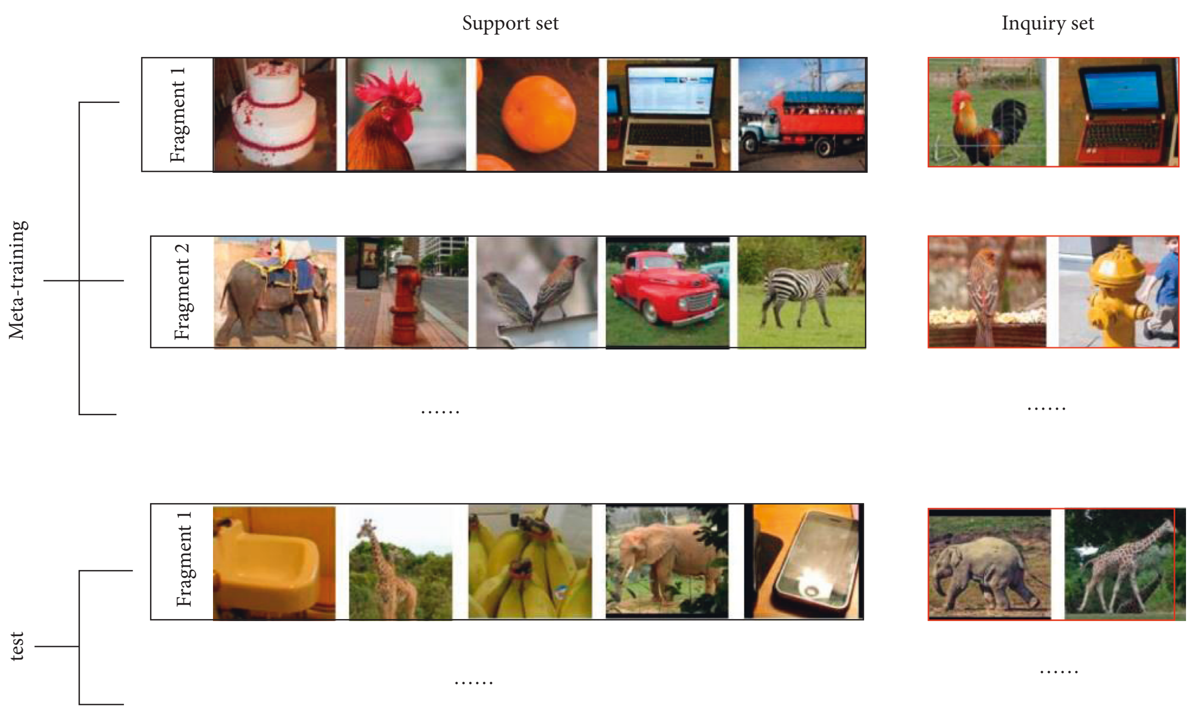

Figure 2: Schematic diagram of segment training mechanism for c-way k-shot image classification, where $c = 5$ and $k = 1$.

problem: data augmentation, metric learning, and meta-learning. They solve the problem of Few-Shot image classification from three aspects: directly expanding the diversity of label samples, using prior knowledge (training set data) to learn better feature models, and optimizing hyper-parameters to make the model learn quickly. The following three methods are briefly introduced.

3.1.1. Few-Shot Learning Based on Data Augmentation. The data augmentation method based on Few-Shot learning is a method to enhance data and improve data diversity through prior knowledge. There are two types of data augmentation methods, one is a generative model that generates new samples through transformation; the other is a transduction model that uses the model to label unlabeled samples and then further trains the model. The specific working method is shown in Table 1. The converter inputs the unlabeled image u and the reference sample image x, and its label y and outputs the synthesized image x and label y, which are used to enhance the training dataset of Few-Shot.

Table 1: Few-Shot image classification method based on data augmentation.

Type	Input (u, x, y)	Converter t	Output (x, y)
Generating model	Original (u_i, x_i, y_i)	Transformation model based on training set learning	$(t(u_i), y_i)$
Transduction model	Unmarked picture	Classifier based on training set learning	(x_i, y_i)

Image processing [14, 15], zoom-in and zoom-out, random cropping, adding noise, mirror flipping, and other

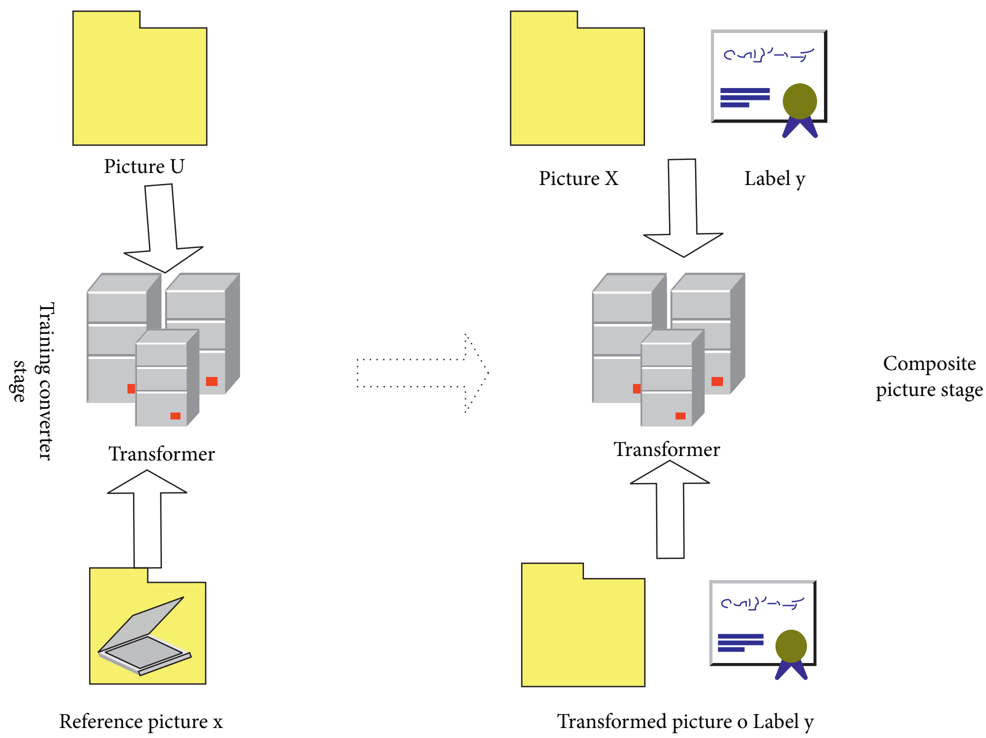

FIGURE 3: Schematic diagram of data synthesis method based on generative model.

basic data augmentation methods based on generative models are among the most basic. These manual transformers can create new images that have the same tags as the old ones. The amount of data generated above for Few-Shot learning is far insufficient to improve the model's generalization ability. Many new methods have been developed as a result of the development of deep learning, the majority of which are based on autoencoders (AE) or adversarial generative networks (GAN) [16]. DAGAN learns on the training set using a generator that combines U-Net and ResNet, as well as a discriminator that uses DenseNet. This trained GAN model is then used to generate new sample images for Few-Shot image classification on the test set [17, 18].

It can be seen that the difference between this type of data expansion method and other Few-Shot learning methods is that there are two more steps before training image classification, as shown in Figure 3, which are training converters (generators), and then synthesizing new data.

3.1.2. Metric-Based Few-Shot Learning. Metric learning refers to extracting features from samples and embedding them into a feature space with a small dimension, and then using the distance between two features to measure the similarity of two samples. Commonly used distances in feature space include Euclidean Metric and Cosine similarity [19, 20].

(1) Siamese Network. Siamese network is the first to introduce metric learning into Few-Shot learning. As shown in Figure 4, the network structure consists of two convolutional neural networks (CNNs), which input a pair of samples (x_i, y_i). At the same time, the two CNNs share the convolution kernel weight, then output two feature vectors through the fully connected layer, and finally output the similarity score $p(x_i, y_i)$ of the two samples according to the distance between the two vectors. The distance metric function of the two features is directly a weighted 1 function, and the loss function of the network structure is shown in the following equation:

$$\nabla = \sum_{q} y_{ij} \log p(x_i, y_i) + (1 - y_{ij}) \log (1 - p(x_i, y_i)). \tag{1}$$

Among them, $y_{ij} = 1$ when x_i and x_j belong to the same category. After the model is trained, the parameters of the Siamese network are fixed and tested on the Few-Shot task, and then, the nearest neighbor classifier (NearestNeighborClassifier) is used for classification.

(2) Matching Network. Unlike Siamese networks, which share parameters for training and test sets, matching networks are the first to design a piecemeal training mechanism. The matching network adds a support set attention model. Specifically, in the training process, the convolutional neural network is used to extract features for the support set and the query set, and then, the attention weight corresponding to each support set is calculated according to the sample features of the query set, and then calculate the possible labels of the query set samples according to the attention weights, and finally use the cosine similarity to measure the matching degree of the support set samples and the query set

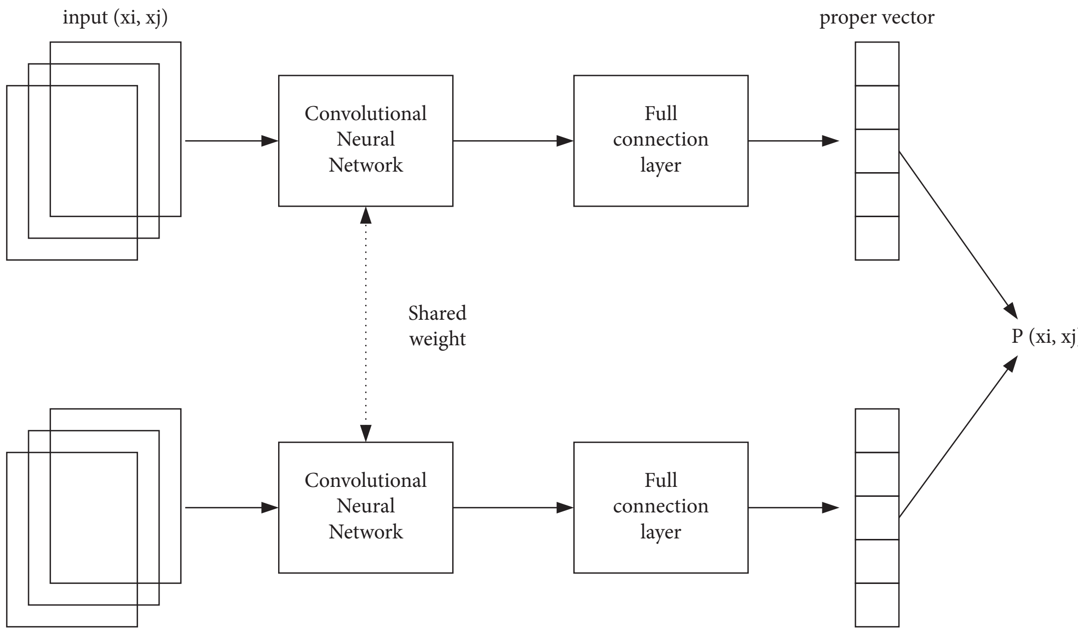

FIGURE 4: Siamese network structure diagram.

samples. The calculation formula of attention is shown in the following equation:

$$\alpha(x, x_i)\frac{\exp[c(f(x), g(x_i))]}{\sum_{i=1}^{k}\exp[c(f(x), g(x_i))]}, \tag{2}$$

where x represents the query set sample, x_i represents the i-th support set sample, $c(,)$ represents the cosine distance, and $f()$ and $g()$ represent the feature extraction function of the query set and support set, respectively.

(3) Prototype Network. Since the matching network studies the single-sample problem, the number of each sample learned by Few-Shot is less than 20. In order to solve the problem of solving the similarity of feature space in the case of multiple samples of each type, the prototype network has designed the concept of prototype. First, the support set samples are embedded in the feature space, and then, the center of each class of the support set is designed as a prototype. The prototype calculation formula is shown in the following equation:

$$C_k = \frac{1}{S_k(x_i, y_i)}\sum_{(x_i, y_i)\in S_k} f_\varphi(x_i). \tag{3}$$

Among them, $f_\varphi(x_i)$ represents the feature extraction function, and S_k represents the support set containing k samples for each class.

Then, the similarity is calculated by calculating the Euclidean distance $d(,)$ between the query set and the prototype. In the test, the normalized exponential function is used to calculate the distance between the test sample and the prototype of the support set. The specific formula is shown in the following equation.

$$p_\varphi(y = k|x) = \frac{\exp\left[-d\left(f_\varphi(x_i), c_k\right)\right]}{\sum_k \exp\left[-d\left(f_\varphi(x_i), c_k\right)\right]}. \tag{4}$$

Prototype networks do not suffer from class imbalance since there is only one prototype per class. Also since the prototype can only capture the mean of the support set, naturally its variance information will be lost. The features extracted from the support set are updated by extracting the features from the query set of the task as environmental features, so that each task has its own different feature output, so as to solve the problem that the variance information will be lost.

(4) Relationship Network. As shown in Figure 5, the relational network model mainly includes two modules: an embedded module and a relational module. The former is the feature extraction module that every metric learning must have; and the relational module is the metric module, which directly connects the sample features of the query set and the support set, and then input into a convolutional neural network and directly classify and score through the fully connected layer. The classification scoring formula is shown in the following equation:

$$r_{i,j} = g_\phi\left[C\left(f_\phi(x_i), f_\phi(x_j)\right)\right], \quad i = 1, 2, \ldots, C. \tag{5}$$

Among them, x_i and x_j represent the support set and query set samples, respectively; $f_\varphi(x_i)$ represents the embedding function; $c(,)$ represents the concatenation of the embedded feature maps; and $g_\phi(x_i)$ represents the relation function.

3.1.3. Few-Shot Learning Based on Meta-Learning. Metric learning, hyper-parameter optimization-based meta-learning, and model-based meta-learning are some of the meta-learning-based methods for Few-Shot image classification. Metric learning, and thus its widespread use, has become a separate branch among them. Model-based meta-learning

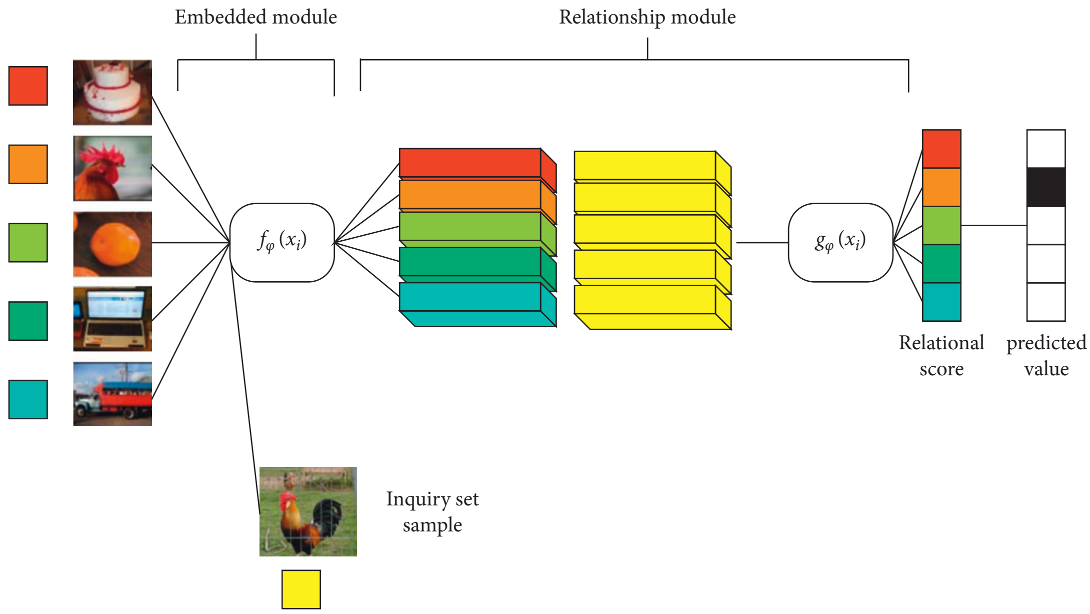

FIGURE 5: Schematic diagram of the relationship network structure.

methods are frequently combined with metric learning and hyperparameter optimization meta-learning. As a result, the following sections focus on hyperparameter optimization-based meta-learning methods.

The core idea of MAML (Model-Agnostic Meta-Learning) model is to set initialization parameters suitable for fast learning for basic learning model parameters through cross-task training strategy. In this way, the base learning model can generalize well to new tasks using only a few samples of the support set. Specifically, the parameter update formula for the basic learner of task T is shown in the following equation:

$$\theta_b^T = \theta_b - \alpha \nabla_{\theta_b} L\left(D^T, \theta_b\right), \tag{6}$$

where α is the learning rate, $L(D^T, \theta_b)$ is the loss function of task T on the support set, and θ_b is the initialization parameter of the basic learner.

In the meta-learning stage, MAML optimizes the meta-learner model by balancing the loss corresponding to parameter θ_b^T of the basic learning model on multiple tasks. The specific formula is shown in the following equation:

$$\theta_m = \theta_m - \beta \nabla_{\theta_m} L\left(D^T, \theta_b^T\right). \tag{7}$$

It is worth noting that the meta-learning model and the basic learning model in MAML in Table 2 are the same model, that is, parameter $\theta_m = \theta_b$. In fact, there are many MAML-based variant models. The MAML-based variant models and their improvement points in recent years are shown in Table 2.

TABLE 2: Improved model based on MAML framework.

way	Improvement point
MAML	
BMAML	A parameter-free reasoning model based on MAML is designed to solve the uncertainty problem of MAML model.
MT-net	Simplify the parameter space of MAML meta-learning model into a subspace composed of each layer of activation space, thus reducing the difficulty of fast learning.
TAML	Unbiased task unknowable experience is added to the initial model to solve the problem of poor performance of MAML framework in meta-training.
LEO	Combining MAML with metric learning, the model can quickly learn hyperparameters in low-latitude embedded space.

3.2. Few-Shot Learning Based on Contrastive Average Loss. In metric learning, a prototype network is a representative algorithm framework. It uses the feature embedding module to process the data and represent it as a prototype for a specific category. The metric module is a parameter-free module that compares query set samples to all prototypes and chooses the prototype category with the shortest distance as its own category. When the algorithm creates category prototypes, however, it only takes into account the relationship between samples and similar prototypes, which can cause issues in more complex situations.

This paper proposes a new loss function based on the prototype network. In comparison with the average loss (CDM), the loss function compares the difference between the sample and different prototypes at the same time, reducing the difference between Few-Shot and the same type of prototype while increasing the differences between samples and different types of samples. This will improve the feature embedding function's ability to represent features, making the learned prototypes more representative. Prototypes of various categories are more differentiated, which improves the model's generalization ability. The method is tested on a benchmark dataset for image classification, and the results show that it can effectively improve the model's performance.

The loss function proposed in this paper will consider the relationship between samples and prototypes of different categories at the same time. Through the adjustment of hyperparameters, it can flexibly convert between the overall category and some categories. Experiments show that this method can improve the performance of the model on the dataset. Note the training dataset $D = \left\{ (x_i, y_i)_{i=1}^{N} \right\}$. For a support set sample, the number of categories is k, and the prototype of a category is denoted as C_k. The class prototype to which sample x_i belongs is C_i, and the distance between sample x_i and class prototype C_j is denoted by d. The measurement method of distance can be selected by yourself. The distance contrast is recorded as l, and the optimization goal is to minimize it, as shown in the following equation:

$$l = d^2 (x_i, c_i) - \frac{1}{m} \sum_{j \neq i} d^2 (x_i, c_i). \tag{8}$$

In the formula, m is an adjustable hyperparameter. Its function is to adjust the number of comparisons between a single sample and different types of prototypes, and its maximum value is $k - 1$. In machine learning, gradient descent is a commonly used optimization algorithm. According to the amount of data used to update the parameters each time, it is divided into batch gradient descent, mini-batch gradient descent, and stochastic gradient descent (SGD). After the model training is completed, given a query set sample, the corresponding prediction is as shown in the following equation:

$$y_q = \arg\ \min_k d\left(f_\theta \left(x_q, c_k \right) \right). \tag{9}$$

That is, the sample will be marked as the class of the closest prototype to it. The distance metric part of this loss function consists of two parts. Considering that the proportion of the difference between the two may have a certain impact on the results, parameters can be added before the two parts to control, such as the following formula:

$$l = \alpha \times d^2 (x_i, c_i) - (1 - \alpha) \frac{1}{m} \sum_{j \neq i} d^2 (x_i, c_i). \tag{10}$$

The value range of α is between 0 and 1. By adjusting the value, the numerical proportion of different parts in the loss can be adjusted. However, after experiments, the effect of α is very limited, and the addition or not has little effect on the experimental results. And α is a hyperparameter, and the adjustment of the parameters must be considered after adding it. Taking it into consideration, it is more secure to remove it; that is, the part of the lost contrast remains unchanged.

4. Contour Image Spatial Frequency Domain Feature Extraction Algorithm

4.1. HOG Feature Extraction Algorithm. The essence of HOG is to rely on the statistics of gradients in the image. This gradient information is usually at the edge of the image, and the directional density distribution at the edge can better reflect the information and shape of the local target in the image. The primary basis of HOG is to segment the image and divide it into connected regions called cell units; next, we need to collect the edge or gradient direction histogram of each pixel in the segmented cell unit above, and finally combine them to obtain the feature descriptor we need. These combined directional gradient histograms need to be diffused from the local area, and the contrast normalization operation is performed in a larger area in the image. This larger area is called a block, which is an interval. The main operation steps are to first calculate the density of the histogram of each direction in the whole area, and then normalize the whole cell unit according to the calculated density, so as to reduce the influence of light and shadow on the detection result.

The concept of directional gradient histogram (HOG) was proposed earlier, and it has many advantages compared with other algorithms. First, it is not very sensitive to the effects of optical and geometric distortions in the image, because all its operations are performed in local grid cells. The second point is that under the condition that the local optical normalization is relatively high, the sampling in the spatial domain is relatively coarse, and the sampling in the direction is relatively fine, and some relatively small movements of the human body can be allowed. Usually, these relatively small actions are ignored and have little effect on the final result. Through the above content, we can find that the directional gradient histogram will have a wide range of applications in human body recognition in images.

4.1.1. Calculate the Image Gradient. The gradients of the horizontal and vertical coordinates in the image are calculated, respectively, to obtain the value of the gradient direction of each pixel in the image. Through this derivation method, we can reduce the sensitivity to light and obtain information such as human contours and textures in the image.

The gradient component of the pixel point (x, y) is shown in following equations:

$$G_x (x, y) = H(x + 1, y) - H(x - 1, y), \tag{11}$$

$$G_y (x, y) = H(x, y + 1) - H(x, y - 1). \tag{12}$$

The gradient magnitude and direction of the (x, y) point are as shown in following equations:

$$G(x, y) = \sqrt{G_x (x, y)^2 + G_y (x, y)^2}, \tag{13}$$

$$\alpha(x, y) = \tan^{-1}\left(\frac{G_y (x, y)}{G_x (x, y)} \right). \tag{14}$$

In the directional gradient histogram, the following methods are often used: in the first step, the gradient operator is used to perform convolution calculation to obtain

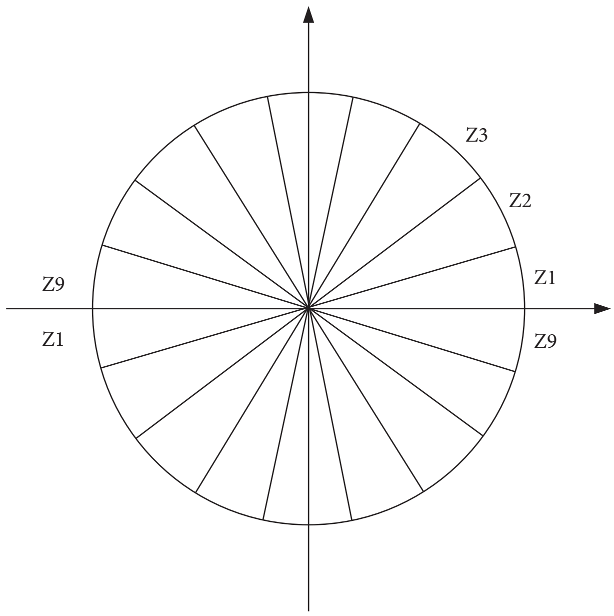

Figure 6: Schematic diagram of gradient direction segmentation.

the gradient component in the horizontal direction; the second step is to use the gradient operator to perform convolution calculation to obtain the gradient component in the vertical direction; and finally, formula (13) and (14) are used to calculate the gradient direction and size at the pixel position.

4.1.2. Construct the Gradient Direction Histogram for Each Unit. This step is mainly to provide a code to the local area, but without destroying the weak sensitivity to human targets while encoding. First, the processed image is divided into several units called cells. Here, we assume that a cell contains 36 pixels, that is, 6×6, and the gradient information of these 36 pixels is counted through the histogram. A cell has a gradient direction of 360 degrees, and we divide it into 9 parts, as shown in Figure 6.

4.2. Classifier. Now add the following explanation: SVM is an effective method to solve the problem of Few-Shot pattern recognition. Finding the generalized optimal classification hyperplane is in high-dimensional space. In order to realize the recognition of multiple categories, it is necessary to make corresponding improvements to the SVM.

At present, many researchers have extended SVM and proposed many excellent algorithms to solve multiclass classification problems. For example, using multiple two-class classifiers and other methods in action recognition, the commonly used kernel functions of SVM include linear kernel and histogram. In this paper, the two factors of SVM classification accuracy and computational complexity are comprehensively considered, and through experimental comparison, the histogram cross-kernel is used as the kernel function of the classifier. Its expression is as in the following equation:

$$K\left(X_i, X_j\right) = \sum_{n=1}^{m} \min\left(a_n, b_n\right). \tag{15}$$

Among them, X_i, X_j is two arbitrary eigenvectors, a_n, b_n is the eigenvalue of the nth dimension, and m is the dimension of the eigenvector. Compared with the other two kernel functions, the histogram cross-kernel has the characteristics of low computational complexity and good classification effect. Then, we input the previously obtained feature vector based on the histogram cross-kernel SVM to obtain the final classifier. After obtaining the test set features, we use the classifier just obtained to make corresponding predictions on the results, and finally achieve action recognition.

4.3. Improved LBP Algorithm. When the improved LBP encodes, firstly, the difference between the gray value of the pixel at the center position and the gray value of its adjacent pixels is taken separately, and then, the difference is added and the average value is obtained to obtain the threshold M, as shown in the following equation:

$$M = \frac{1}{p} \sum_{i=0}^{p-1} \left|g_i - g_c\right|. \tag{16}$$

Then, we use the gray value of the neighboring pixels and the gray value of the center pixel to perform a subtraction operation in a certain order (clockwise or counterclockwise) to get the absolute value, and then add it compare with the threshold M. If the value is greater than M, it is coded as 1; otherwise, it is coded as 0. Its coding formula is shown in the following equation:

$$S\left(g_p - g_c\right) = \begin{cases} 1, & \left|g_p - g_c\right| > M, \\ 0, & \left|g_p - g_c\right| \leq M. \end{cases} \tag{17}$$

Finally, we convert the encoding. Since the computer encoding system uses binary data, we convert it into decimal data that are easy to calculate, as shown in the following equation:

$$\mathrm{LBP}_{P.R}^{*} = \sum_{i=1}^{p-1} S\left(g_p - g_c\right) 2^{p}. \tag{18}$$

4.4. Feature Fusion. Multifeature fusion can retain the effective identification information of various features and can also remove the redundant and invalid parts of various features to a certain extent. Many current feature fusion methods directly merge two sets of feature vectors into a new feature vector in a serial manner. In order to solve this problem, this paper compresses the two features extracted at the beginning and performs weighted fusion, so as to achieve effective fusion of feature vectors, and at the same time appropriately reduce the dimension of feature vectors.

At present, there have been many related researches on multifeature fusion, including the fusion of HOG features and SIFT features, the fusion of HOG features and ordinary LBP features, and the fusion of SIFT features and LBP features. The SIFT feature is a scale-invariant feature transform. SIFT features remain invariant to rotation, scale scaling, brightness changes, etc., and maintain a certain degree of stability for viewing angle changes, affine transformations, occlusions, and noise, and are relatively stable local features. However, it detects too few feature points for blurred images and images with smooth edges, resulting in a low recognition accuracy. In the follow-up experiments, the proposed algorithm is also compared with these existing fusion methods.

Due to the above shortcomings of a single feature, this paper proposes a method based on the fusion of HOG features and improved LBP features. Feature fusion first needs to extract a large amount of feature information and then compares the information. Although this can enhance real-time performance, it will lead to missing information and inaccurate results. However, if we adopt serial fusion, although the recognition accuracy can be improved, it will lead to an increase in the amount of data and reduce the detection efficiency. Select a video from Weizmann and YouTube, respectively, and then extract the video frame image, and perform grayscale and normalization processing on the image. It is mainly to standardize Gamma and color space and also to reduce the influence of lighting and other factors on the detection results. Therefore, this paper adopts the method of weighted fusion of HOG features and improved LBP features. The algorithm flowchart is shown in Figure 7.

(1) In an image, the exposure of the local surface layer accounts for a large proportion of the texture intensity. By normalizing the image, we can greatly reduce the lighting and the effect of shadows on the local part of the image. Typically, we first convert the image to grayscale. The Gamma compression formula is shown in equation (19), and Gamma is represented by 1. In this experiment, the value of 1 is taken as 0.5.

$$I(x, y) = I(x, y)^{\gamma}. \tag{19}$$

(2) Normalize the scale of the two feature sets obtained.

(3) Use a weighted method to perform feature fusion to obtain the final feature set, as shown in equation (20). Among them, $\alpha, \beta \geq 0$ is the weight, which satisfies $\alpha + \beta = 1$.

$$T(l) = \alpha L(I) + \beta H(I). \tag{20}$$

(4) Use the SVM classifier to identify in which the SVM kernel function adopts the histogram cross-kernel.

5. Recognition and Analysis of Dance Fitness Movements

Dance fitness movements are complex, especially under high-speed movement, various movements are difficult to capture and cannot achieve good results. In this paper, three common movements in dance fitness are selected for identification and analysis. The three movements are walking, opening hands, and running. The feature extraction structure of a single frame is shown in Figure 8.

As shown in Figure 8, in different actions, the contours extracted from the two feature maps are relatively clear, but some details are still blurred. Therefore, the action recognition for dance fitness still needs to be optimized.

For the Omniglot dataset, the training epoch = 100, the learning rate is 0.001, and the dynamic adjustment strategy is adopted, and the learning rate is adjusted to one-half of the original every 20 rounds. The value of episode is set to 100 in one epoch, and the number of categories in each episode is set to 60. By adjusting the number of samples for each category in the support set to 1 and 5, and the number of categories to 5 and 20, the corresponding n-way k-shot training is completed. For the miniImageNet dataset, due to the large amount of data, the total number of training rounds is set to 200, that is, epoch = 200, and the learning rate is 0.001. The dynamic adjustment strategy of the learning rate is the same as above, and the value of episode in each epoch is also 100. When the image is input, it will be scaled to a size of $84 * 84$. In order to speed up the convergence, the RGB channels of the image will be normalized. During SeProtNet training, the value of γ is set to 16.

The training process under the 5-way 5-shot setting is shown in Figure 9. When the number of iterations is 161,000, the image classification model based on Transformer Few-

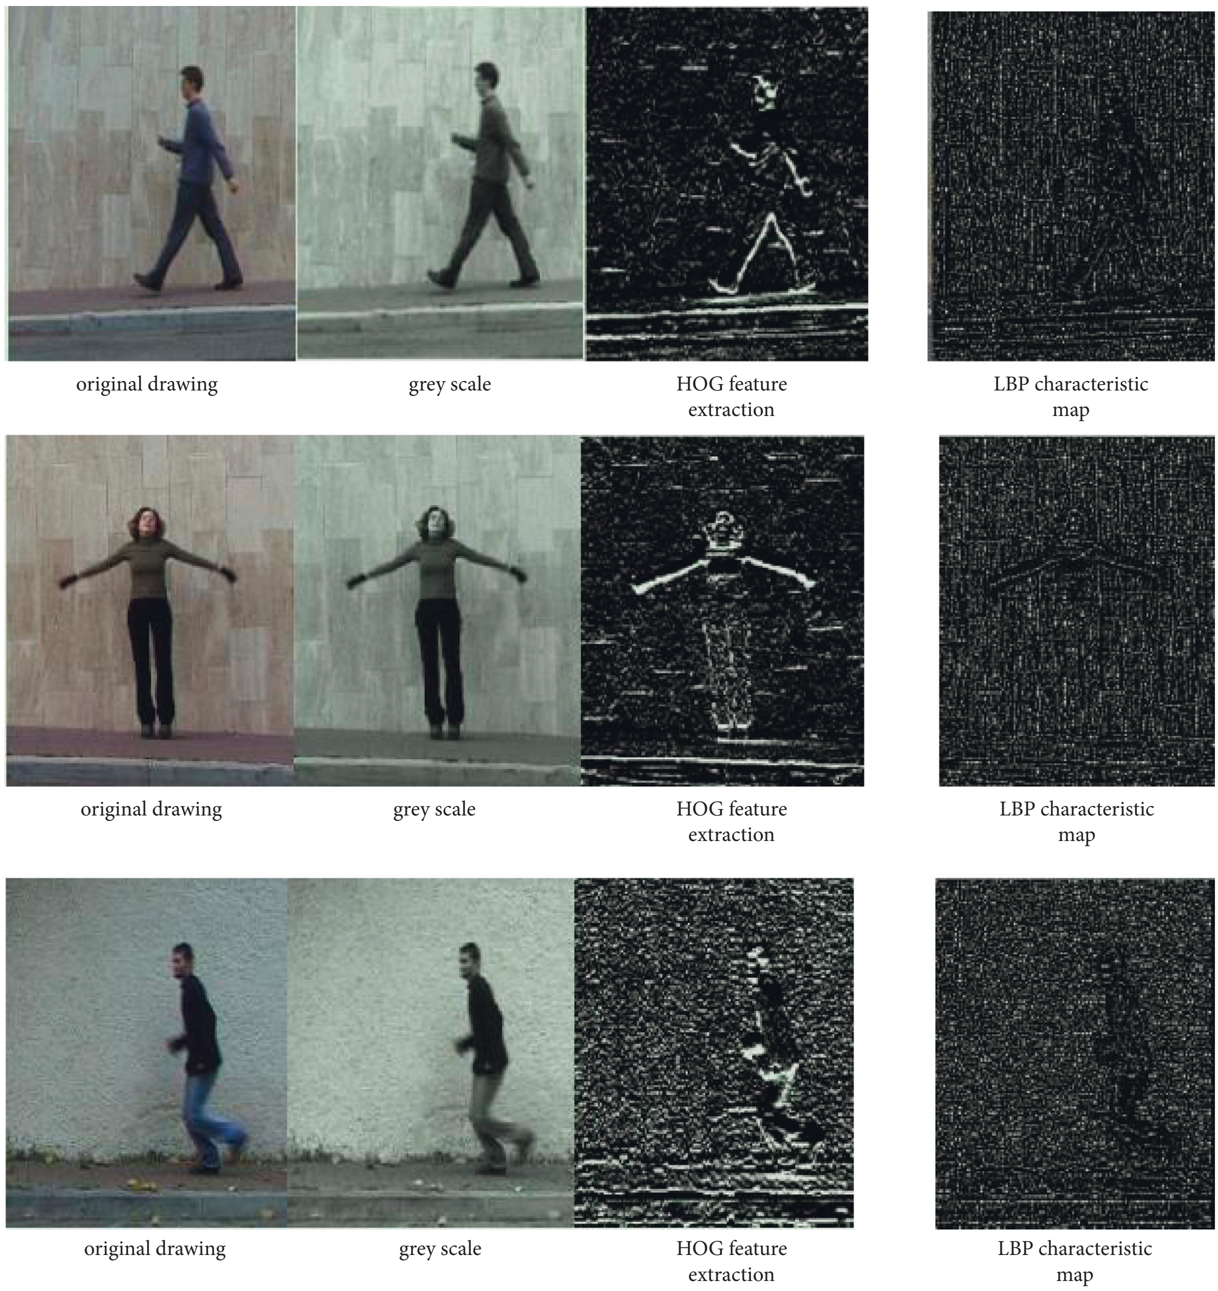

Figure 8: HOG and LBP feature maps under different actions.

Shot learning achieves the highest accuracy rate of 85.28% on the validation set. It can be seen from Figure 9 that the image classification model based on Transformer Few-Shot learning in the case of 5-shot, when the accuracy rate and loss basically converge, the fluctuation range is much smaller than the 1-shot setting.

As shown in Table 3, in the testing phase, the trained model performance is measured by randomly building 600 segment tasks. The accuracy of the Transformer Few-Shot-based learning model is better than the other methods in both settings, with 66.75% accuracy under 1-shot setting and 82.05% under 5-shot setting. Among them, the prototype network, that is, the model without Transformer and group regularization, is the basic network of this model. Compared with the prototype network, the accuracy of this model has been greatly improved, with an increase of 6.43% under the 1-shot setting and 4.03% under the 5-shot setting.

As shown in Figure 10, the three actions of walking, opening hands, and running are analyzed under the dataset. The accuracy of different algorithms is different, but the recognition efficiency of the feature extraction algorithm that combines HOG and improved LBP algorithm has always been high. The recognition accuracy rates of walking, opening hands, and running are 93.10%, 90.30%, and 92.70%, respectively. This illustrates the effectiveness of the fusion feature algorithm.

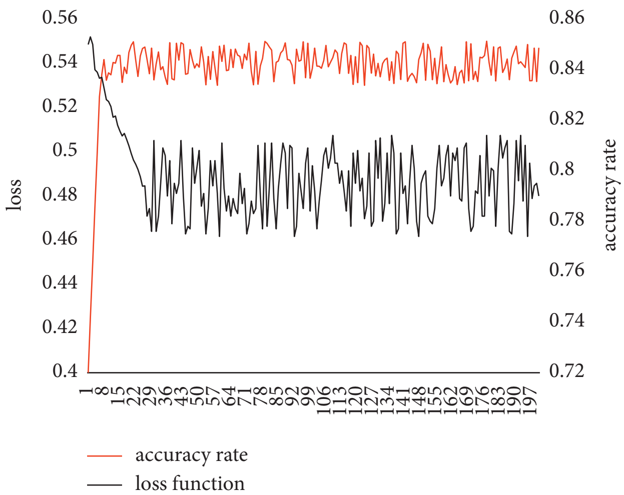

Figure 9: Iterative curve of accuracy loss in 5-way 5-shot.

Table 3: Few-Shot classification results based on different methods.

way	1-Shot (%)	5-Shot (%)
HOG	60.37	78.02
LBP	62.08	78.63
Improved LBP	62.64	80.51
HOG + LBP	64.60	79.51
HOG + Improved LBP	66.87	82.44

6. Conclusions

Few-Shot and data imbalance are frequently symbiotic in practical applications. Data augmentation, knowledge transfer between similar categories, data synthesis, structured knowledge graph, domain adaptive learning, and model solvability are all strategies that can help Few-Shot learn better. At the moment, Few-research Shot's is primarily focused on image data modeling and processing. Many fields of supervised learning, such as video object detection and semantic segmentation, have an urgent need for Few-Shot learning, and other directions are also worth exploring. Furthermore, in the future, directions such as natural language processing and recommendation systems will be important application scenarios for Few-Shot learning.

The smart bracelet has become a hot-selling commodity, according to a daily consumption survey. Based on people's interest and concern for their health, the smart bracelet, as a design and application for achieving healthy weight loss monitoring, is quickly becoming a popular new favorite. This bracelet detects fat using the near-infrared diffuse reflection principle, with the goal of assisting people in controlling and maintaining a healthy weight. A large amount of data has been accumulated in all walks of life due to the development of the Internet network and data storage technology. As a result, the emergence of machine learning plays a critical role in the data analysis of human sports health monitoring of smart bracelets. Based on machine learning, this paper investigates the data analysis of human sports health monitoring smart bracelets. When the population index reaches 50 in the analysis of health monitoring data, the average accuracy of data mining is 86.8 percent, the average accuracy of the association rule algorithm is 85.9 percent, the average accuracy of the collaborative filtering algorithm is 84.3 percent, and the average accuracy of the machine learning algorithm is 90.1 percent in this paper. Among the four algorithms, the method presented in this paper is clearly the most effective, stable, and accurate. The system's stability and accuracy have been greatly improved by the addition of GPS-assisted and hand-up misjudgment algorithms. Because the smart bracelet is inexpensive, easy to wear, and consistent with consumer psychology, it is becoming increasingly popular to use it to monitor the human body's sports health.

1. Introduction

With the increasingly fierce social competition, young people's work pressure is gradually increasing, and they have little time to pay attention to the travel activities and vital signs of the elderly and children, such as obesity caused by less exercise, falling alarm of the elderly, exercise monitoring and calorie consumption, and measurement of heart rate and exercise [1, 2]. The smart bracelet has become a hot-selling commodity, according to a daily consumption survey. Based on people's current interest and focus on health, the smart bracelet, as a design and application for achieving healthy weight loss monitoring, is quickly becoming a popular new favorite. This bracelet detects fat using the near-infrared diffuse reflection principle, with the goal of assisting people in controlling and maintaining a healthy weight [3]. Currently, scientific researchers in the field of sports health use the traditional acceleration motion sensor worn at the waist to monitor physical activity, obtain effective data for analysis and processing, provide a scientific foundation for mass sports fitness, and increase the scientificity of mass sports fitness. However, the bracelet must use its own algorithm to calculate the acceleration vector length changes in three directions of wrist movement during human movement. However, because the wrist's movement direction cannot be determined, calculating the number of steps of the bracelet in software requires high accuracy. Because the traditional acceleration motion sensor is small and convenient and does not require subject review, it can effectively reduce recall bias and accurately provide information about energy consumption, frequency, intensity, and duration of physical activities through the validity tests of various methods, and it has been widely accepted and applied in scientific research.

With the development of the Internet network and data storage technology, a large amount of data has been accumulated in all walks of life. The application of health monitoring data mainly refers to the use of Internet technology and big data technology [4, 5] for data mining and analysis, the analysis and integration of health information and data at all levels, and the improvement of health services, to make the operation of various medical industries at all levels more efficient and make the services of various medical industries at all levels better under the background of China's informatization. Machine learning [6–8] can not only be applied to the preprocessing stage of monitoring data but also, more importantly, it is necessary to establish a learning model and actively learn the information contained in the data to evaluate the safety of the structural state and reflect the health state in time. In the face of a large amount of information generated all the time, the traditional manual method is simply unable to make efficient and rapid judgment [9, 10]. Machine learning first appeared in the last century. Learning in machine learning actually wants to express learning from data. It consists of three parts: unsupervised learning, semisupervised learning, and supervised learning. Machine learning uses computers to simulate human learning activities. Today, machine learning is the main way to deal with big data. As a multidisciplinary field, machine learning is widely used [11].

The use of machine learning in the analysis of human exercise health monitoring data from a smart bracelet is reflected not only in the preprocessing of raw data and the efficient operation of the learning model but also in the "iterative optimization" of the machine learning model. The most significant difference between machine learning and traditional manual quantitative and qualitative analysis is that the algorithm has the property of "iterative optimization," which means that the learning model established by machine learning can be optimized step by step. The more data samples there are, the more effective the information the learning model has, and the model's accuracy and precision can be continuously improved [12, 13]. To accurately and efficiently synthesize existing motion capture data into a new motion sequence, three basic problems must be solved: how to establish a mathematical model of human motion, how to reduce the dimension of the motion data, and how to quickly and accurately synthesize a new motion sequence [14]. Because these three fundamental problems are so closely related, the applicable dimensionality reduction method and synthesis algorithm are determined by the specific mathematical model. Simultaneously, the specific synthesis algorithm and dimensionality reduction method require the assistance of specific mathematical models. The accelerometer principle is also used by the smart bracelet to monitor physical activity. By connecting with the corresponding mobile phone application software, the public can intuitively obtain physical activity index data such as energy consumption and daily steps, thus effectively monitoring the realization of long-term or short-term physical activity goals. In addition, because the smart bracelet is affordable, easy to wear, and in line with the public's consumption psychology, it is becoming more and more popular to apply the smart bracelet to monitor the level of human sports health [3]. The innovations of this paper are as follows:

(1) Based on machine learning, this paper builds an intelligent Bracelet human motion health monitoring data model. The machine learning process entails training the model on a large number of task-related data sets; iterating the training model continuously to obtain a reasonable model fitting the data set; applying the training adjusted model to the real scene. The selection of input parameters, output parameters, and learning algorithm is part of the process of developing a predictive GRF learning model.

(2) A data collection system for intelligent Bracelet human movement health monitoring is built. Although researchers are dedicated to testing the validity of sports intelligent Bracelet monitoring physical activities, the intelligent Bracelet human sports health monitoring data system is still in its early stages. This paper analyzes and summarizes existing research results and research progress by combing the relevant literature on the validity of sports intelligent Bracelet evaluation steps, energy consumption, distance, and physical activity intensity, in order to serve as a reference for future research.

The following sections comprise the overall structure of this paper: The first chapter discusses the history and significance of human movement in intelligent bracelets before moving on to the main work of this paper. The second chapter focuses primarily on the related work of intelligent Bracelet human movement both at home and abroad. The algorithm and model of machine learning are introduced in the third chapter. The fourth chapter describes the implementation of human motion health monitoring data from an intelligent bracelet, as well as the experimental part's analysis. The fifth chapter is a synopsis of the entire document.

2. Related Work

2.1. Research Status at Home and Abroad. Ciocca Gianmarco proposed that the health monitoring system of human movement of the intelligent bracelet is indeed much more efficient than the traditional manual method, but it also brings many challenges while providing real-time data: How to transform the noisy original data into processable and effective information, and how to further improve the computing power of the algorithm model to process the increasing real-time monitoring data [15]. Tang et al. proposed that while adding some new functions, the design and development of an intelligent bracelet will take the advantages and disadvantages of the 37-degree bracelet as a reference. On the basis of avoiding similar disadvantages, some design improvements have been added to the bracelet developed this time [16]. Garofolini a et al. proposed that human motion recognition technology based on acceleration sensors has been a hot research topic in the field of human motion recognition and health monitoring data analysis for a long time. It aims to use various information or data processing technologies to establish a behavior perception platform for the purpose of finding the representation, modeling, and prediction methods of health monitoring data movement [17]. GFA B et al. proposed that the core of the health monitoring system of human movement of the intelligent bracelet is a set of systems that analyzes the output response state based on structural information, historical records, and real-time data collected by sensors to evaluate the use and safety [18]. Vaz *d* v et al. proposed that in recent years, artificial intelligence technology is in the stage of rapid development, and the big data analysis industry is booming. Borrowing artificial intelligence technology is not only the trend of human motion recognition but also the inevitable result of the development of the motion recognition field [19]. Aerenhouts Dirkdirk proposed that there are two kinds of posture recognition technologies: wearable and nonwearable. As the name implies, wearable technology refers to the human body posture recognition technology, such as image recognition, in which the posture recognition device is not in direct contact with the human body. Compared with nonwearable, wearable human posture recognition technology has the advantages of unlimited space and has a better development space in research and application [20]. Julie M et al. proposed that for common physical activities, using the acceleration and gyroscope in smartphones to recognize human motion can achieve good accuracy. It has great potential to develop timely action classification and recognition and feedback programs with intelligent mobile terminals [21]. Higueras-Fresnillo S et al. proposed a PHM system based on Bayesian estimation theory and general particle swarm filtering framework, which integrated the modules of human motion data processing, eigenvalue extraction, fault diagnosis, and failure prognosis of the smart bracelet. Purdue University's Intelligent Process System Laboratory has put forward different solutions based on knowledge discovery, neural networks, and statistical analysis in the field of risk identification of complex systems [22]. Yanci Javier proposed to use the smart bracelet to recognize human motion, which is basically the processing of the information of human motion captured by sensors in the bracelet. Considering that the research object of this subject is people, which have wide differences and the quality of smart bracelets worn is also different, the acceleration sensor equipped with each smart bracelet is used as the human motion data acquisition module based on human motion recognition of smart bracelets [23]. Monajati Alireza Larumbe proposed that the basic human motion recognition method of a smart bracelet is the threshold detection method. That is, by judging whether the sensor value exceeds the set value, several kinds of actions can be distinguished. For example, several ongoing basketball playing actions can be identified by the data interval and vibration amplitude collected by the acceleration sensor [24].

2.2. Research Status of Human Motion Health Monitoring Data of Intelligent Bracelet Based on Machine Learning. This paper uses machine learning to analyze the human movement health monitoring data of an intelligent Bracelet. In comparison to previous studies, this method has the functions of step counting, positioning, and vital sign monitoring. It can calculate the number of steps a person walks using the pedometer function and the movement distance using the GPS positioning function to calculate the number of calories consumed, making it easy for people to understand their own and family members' movements. A heart rate sensor is a sensor that detects the rate of the heart. Accurate motion analysis can be achieved by collaborating with other sensors. Typically, three methods are used: photoelectric transmission measurement, test ECG signal measurement, and vibration measurement. When the heart is bleeding, the blood absorbs light of a specific wavelength. This characteristic of blood is used by the photoelectric transmission measurement method to determine heart rate. In light of this phenomenon, this paper performs hardware circuit design and software debugging, relying on the intelligent bracelet as the medium, so that the bracelet can not only realize indoor high-precision positioning but also upload the carrier's vital signs information to the positioning server, so that family members can accurately understand the internal position and physical condition in time. Furthermore, people may feel uneasy in the continuous monitoring environment for an extended period of time. This uneasy state will impair a person's activity performance and lead to inaccurate behavior detection. Furthermore, the video acquisition results will contain information about the life of the monitoring object, and improper use will result in the disclosure of users' personal information. Researchers have increasingly introduced various methods in machine learning into the research of human motion health monitoring of intelligent bracelets due to the high-dimensional characteristics and great temporal and spatial correlation of human motion data, which has made great progress in the research of human motion health monitoring of intelligent bracelets.

3. Algorithm and Model of Machine Learning

Simulated learning is another name for machine learning. In layman's terms, this means that computers are learning how to think like humans. It stimulates the human learning process in order to achieve learning. Computers are used to simulate human learning activities in machine learning. Following the computer learning process, it will acquire data information and new knowledge in order to continuously improve its performance. Machine learning is defined as "a process in which a model learns and explores the existing connections and potential information among data based on the existing information set, in order to continuously optimize its own performance." When compared to traditional computing methods, the most distinguishing feature of machine learning is its "self-learning and self-adaptation." It has achieved great success in many fields such as finance and biology by fully drawing on the working mechanism of the human brain "neurons are connected hierarchically and information is updated iteratively." The decision tree algorithm is a popular machine learning algorithm that is used not only for classification but also for regression. This algorithm serves as the foundation for many other advanced algorithms. Machine learning is classified into two types: supervised learning and unsupervised learning, depending on whether the training samples are labeled manually in advance. Supervised learning is a learning method that uses labeled data as the training data set, learns the rules for dividing objects from the training data set's characteristics, applies this rule to predict classification results on the test data set, and outputs the labeled results. Unsupervised learning is a learning method that is used to deal with data that has not been labeled or classified. Its goal is to discover potential relationships and statistical laws between data in order to determine the characteristics of the sample data. A decision tree is an inverted tree structure composed of a root node, an inner node, a leaf node, and an edge. The root node is the highest node, the leaf node provides the judgment conclusion, and the internal node is a relative concept. The purpose of building a decision tree is to perform classification or regression. The purpose of this paper is to investigate classification or the relationship between target variable categories and attributes. We can predict the category of the test data set once the relationship is built. At the moment, more research is needed on the high integration of "data collection, data preprocessing, data analysis, model evaluation, information visualization, and early warning mechanism." Figure 1 depicts the basic structure of a common structural health monitoring system, which is made up of five major components: "online test, real-time analysis, damage identification, condition assessment, and maintenance decision."

The main information about each meal in the file has two parts. One is the position and rotation information of the root joint. The second is the rotation information of each joint. Therefore, each frame of human motion can be expressed as follows:

$$f_i = \left(p_i, r_i^1, r_i^2, \ldots r_i^n\right), \tag{1}$$

where f_i represents the data of the i, p_i represents the position and rotation information of the root joint in the frame, $r_i^1, r_i^2, \ldots r_i^n$ represents the rotation angle $r \in R^3$ of each joint, and n is the number of joints defined in the ASF file.

Therefore, a motion sequence defined by the $ASF - AMC$ capture data file can be expressed as follows:

$$\text{motion} = \left(f_1^T, f_2^T, \ldots f_m^T\right), \tag{2}$$

where f_i^T is the transpose of i frame data f_i, and m is the number of rounds of the motion sequence.

Mathematicians have proved that the connection of a rotation sequence is equivalent to a single rotation. Therefore, any angular displacement can be expressed as a single rotation of an object around a certain axis. That is, a corner of the axis is used to describe (n, θ) s orientation, n represents the unit vector of the axis, and θ represents the angle of rotation around the axis. This method is seldom used in implementation, usually replaced by Euler angle or quaternion.

$$\begin{aligned} q &= \left[\cos\frac{\theta}{2}, n\sin\frac{\theta}{2}\right], \\ q &= \left[\cos\frac{\theta}{2}, \left(n_x\sin\frac{\theta}{2}\right) n_y\sin\frac{\theta}{2} n_x\sin\frac{\theta}{2}\right]. \end{aligned} \tag{3}$$

Therefore, if the quaternion $p = [0, (x, y, z)]$ is used to represent a standard point in the three-dimensional space, and the corner of the rotating axis is (n, θ), let the quaternion $q = [\cos\theta/2, n\sin\theta/2]$, and the formula can show that the point p rotates by θ degrees around the n axis.

$$p' = qpq^{-1}. \tag{4}$$

According to the connectivity of rotation, if the point p rotates through quaternions a , b , according to the associative law of quaternions, it can be expressed as follows:

$$\begin{aligned} p' &= b\left(apa^{-1}\right)b^{-1} \\ &= (ba)p\left(a^{-1}b^{-1}\right). \end{aligned} \tag{5}$$

Therefore, the rotation of a certain point in three-dimensional space can be expressed by the connection of multiple quaternions.

Let two similar motion sequences T, R, whose sequence lengths are t, r, respectively. Normally, $t \neq r$ can be known from the following formula:

$$\begin{aligned} T &= \left[T_1 T_2 \ldots T_t\right], \\ R &= \left[R_i R_2 \ldots R_r\right]. \end{aligned} \tag{6}$$

Among them, the dimension of $T_i, R_j (i \in [1, t], j \in [1, r])$ is P . The purpose of $DT\ W$ algorithm is to find an optimal synchronization path by pattern matching the two motion sequences, so that the two motion sequences have the same length and retain the most complete data information, that is, to find the sequence F^* in a grid

$$F^* = \{c(1), c(2), \ldots, c(k), \ldots, c(K)\}, \max(t, r), \tag{7}$$

where $c(k)$ can be expressed as follows:

$$c(k) = [i(k), j(k)]. \tag{8}$$

$c(k)$ means that when the k frame is matched, comparing the $i(k)$ frame of sequence T with the $j(k)$ frame of sequence R , $c(k)$ can be regarded as a point in $t \times r$ grid. With the increase of k , it moves in $t \times r$ grid, and the curve formed by its moving track is the matching path. Therefore, F^* is also called time bending function.

Since the generated shortest matching path must be equal to the length of motion sequence T , $k = t$ and $k = i$ can be obtained

$$F^* = \{c(1), c(2), \ldots c(i), \ldots, c(t)\}. \tag{9}$$

Obtain the shortest matching path F^* , an asymmetric algorithm called $DT\ W$. Including all frames of the standard reference sequence T , and some posts in the sequence R to be aligned are compressed or stretched due to different local

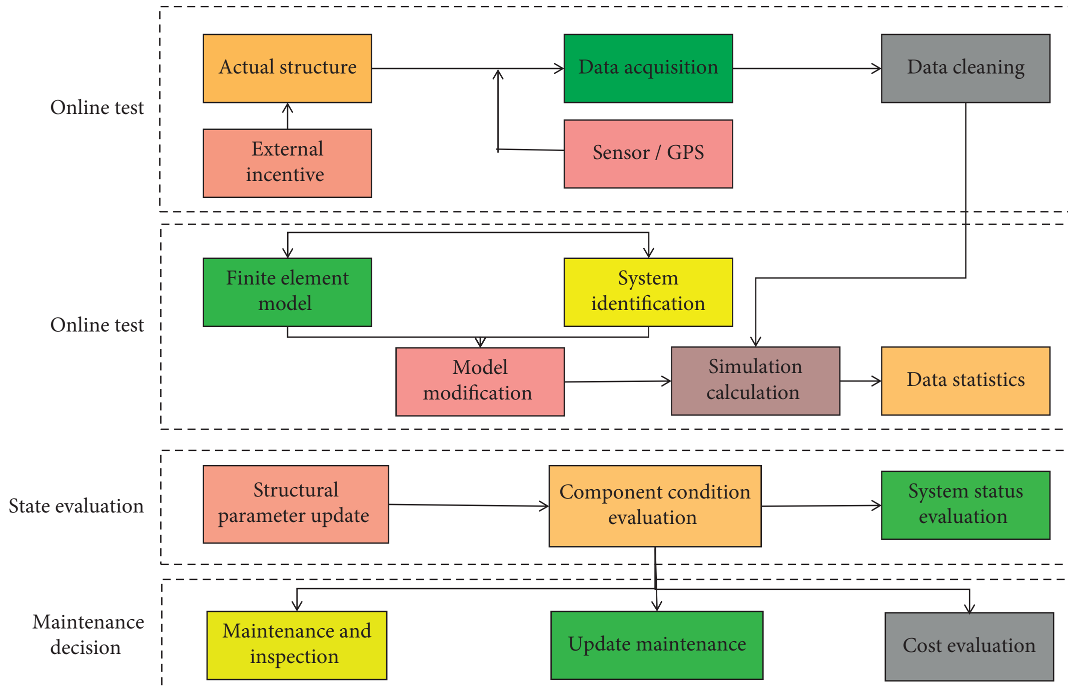

Figure 1: Machine learning health monitoring model.

features from the standard reference sequence. After this processing, the motion data before and after alignment are different, resulting in the following effects.

In the algorithm of machine learning, the artificial neural network is a mathematical model which can imitate brain neurons to a certain extent. In the algorithm of machine learning, artificial neural network processes data in this way, and the application of an artificial neural network is also very much. The process of machine learning includes using a large number of task-related data sets to train models. Through the error of the model on the data set, the model is repeatedly trained, and a model that fits the data set reasonably is obtained. Apply the trained and adjusted model to the real scene. A process of building a predictive GRF learning model includes the selection of input parameters, output parameters, and learning algorithm. Decision tree algorithm has the general characteristics of machine learning algorithms, which build models based on specific data, so it is different from traditional statistical models. It does not need prior assumptions, and it does not need data to obey any probability distribution. This is actually a very good feature because the actual data is generally difficult to meet the settings of those boxes. The core idea of deep learning is that unsupervised learning from bottom to top trains the data layer by layer and extracts the statistical characteristics nonlinearly, constantly updates and establishes the mapping relationship in the calculation, establishes the initialized network, and iteratively updates and optimizes the network parameters by using supervised learning from top to bottom, thus achieving the expected effect. Different from the shallow network structure, the multihidden layer structure of deep learning can break through the parity problem of the shallow structure, can complete the approximation of complex functions, realize the accurate processing of complex problems, and has good generalization ability. The smart bracelet system designed in this paper consists of two parts: smart bracelet and ultrawideband positioning system. The smart bracelet can be divided into six modules according to its functions, and the relationship between the components of the modules and the sensors is shown in Figure 2.

The power management module, which consists of a charging chip and a voltage stabilizing chip, is one of the six modules of the smart bracelet: A microcontroller can control data acquisition and processing; There is a mobile node and low-power Bluetooth communication module; Gyroscopes are used to realize the motion state module of step counting and motion state analysis. TFT-LCD display screen is used in the display module. A sign sensor module includes a heart rate and blood pressure sensor, a blood oxygen sensor, and a temperature sensor. The sensor's data can be transmitted to the mobile app via low-power Bluetooth, and it can also be viewed on the display screen. Second, the mobile node in the UWB positioning system can communicate with the basic positioning wireless network to master the accurate location of the bracelet carrier in real time. Traditional signal processing and kinematics methods have lost their advantages in these technologies due to the rise of machine learning methods because traditional methods cannot well model some complex characteristics of the above motion data, whereas appropriate machine learning methods can not only model them but also effectively use these characteristics to complete specific tasks. Although the tasks of motion restoration and motion denoising differ slightly, the former is dedicated to regaining the lost joint position during the capture process, while the latter is dedicated to combating noise, but their methods are similar. As a result, they are not

deliberately distinguished when introducing the current state of motion restoration research.

4. Realization of Monitoring Data of Human Exercise Health with Intelligent Bracelet

4.1. Design of Intelligent Bracelet Human Exercise Health Monitoring Data System. The monitoring data of human exercise health of intelligent bracelets is the key technology and the most difficult link in the process of exercise data reuse. The analysis of human exercise health monitoring data system under machine learning has high dimensions, a large amount of information, and a complex structure, all of which bring challenges to exercise synthesis. The synthesized motion data will eventually be used for viewing, and the human eye is very good at finding out the incongruities in the motion, which puts forward higher requirements for motion synthesis. Usually, there are many physical quantities in the data of human motion recognition, and different physical quantities have different measurement methods, so they cannot be directly compared with each other. Therefore, it is necessary to normalize the feature vectors so that different feature vectors are in an equal and comparable position. In this paper, the normalization function map minmax in Matlab is used to normalize the characteristic data. After normalization, the restriction of units between different eigenvalues is eliminated, and the differences between different individuals are also reduced, and they are converted into pure values to facilitate feature extraction and comparative analysis. In the data system of human exercise health monitoring with an intelligent bracelet based on machine learning, users can switch measurement functions and observe data through touch screen, so three interfaces are designed according to bracelet functions. One is a clock interface to display real-time time. The main menu interface allows users to independently select the functions to be measured. The other is the display interface to display the measured data in real time. The structure of the sports bracelet includes a system processor module, sensor module, GPS module, and OLED display module. MK60DN512ZVLQ10 chip is adopted as the processor, which is a 32-bit processor with ARM-CORTEX-M4 as the core introduced by NXP. Whether it is used for scientific research or mass fitness, it is very important to evaluate its validity.

At present, under the intelligent Bracelet human sports health monitoring data system, although researchers are committed to testing the validity of sports intelligent Bracelet monitoring physical activities, it is still in its infancy. This paper analyzes and summarizes the existing research results and research progress by combing the relevant literature on the validity of sports intelligent Bracelet evaluation steps, energy consumption, distance, and physical activity intensity, so as to provide reference for further research. The sensor module includes an acceleration sensor mpu6050, which includes a multichannel ad, which can convert the obtained analog data into digital signals and transmit them to the processor through IIC. Through processing, it can obtain the human motion state, realize the step measurement function and control the OLED on and off function. The pulse heart rate sensor pulse sensor outputs analog signals, which are processed by ad to detect human heart rate data in real time. The GPS module sends data to the processor in the form of serial port to obtain position coordinate information. Therefore, motion synthesis has always been a very hot research topic. With the deepening of research, some excellent motion synthesis algorithms have emerged. Among them, the data-driven motion synthesis method can maintain the temporal and spatial characteristics of motion data, so it has been widely studied and applied. According to its different implementation methods, it can be divided into four categories: motion mixing, motion synthesis based on graph search and motion transition, parametric motion synthesis, and motion synthesis based on deep learning. Then machine learning is used to analyze the acceleration data of the smart bracelet to realize the attitude recognition on the mobile device. Finally, the comparative analysis of human motion based on various methods verifies that the analysis system of human motion health monitoring data system of intelligent bracelet based on machine learning is more accurate than traditional recognition methods such as support vector machine, more convenient and more practical than computer-based analysis platform.

4.2. Experimental Results and Analysis. The type of SVM selected in this study is C-SVC. When studying the effect of the RBF kernel, the loss function C of C-SVC and the gamma function G of the RBF kernel have a major impact on the recognition accuracy. The labeled test set is brought into the classifier for verification, and the classification accuracy rate is 94.4652%. The results expressed in are shown in Table 1. The training time is 45.702 seconds, and the testing time is 0.0242 seconds.

As the gamma function does not need to be set for the linear kernel, this study only needs to set the loss function C of C-SVC when testing with linear kernel and bring the labeled test set into the classifier for verification, and the classification accuracy rate is 93.0495%. The results are shown in Table 2. The training time is 60.885 seconds, and the testing time is 0.023 seconds.

From Tables 1 and 2, it can be seen that both RBF kernel SVM algorithm and linear kernel algorithm can achieve more than 90% recognition rate for the problems studied in this paper, and the recognition accuracy of RBF kernel SVM classification algorithm is slightly higher than that of linear kernel SVM algorithm, and the memory occupation and training time of the former are better than those of the latter. It can be seen that the RBF kernel is more suitable for the human motion recognition algorithm studied in this paper.

In this experiment, the human movement health monitoring data of intelligent bracelets are analyzed, and the data mining algorithm, association rule algorithm, collaborative filtering algorithm, and machine learning algorithm are used to compare the steps of left and right hands wearing bracelet randomly and test walking and running, respectively. The experimental results are shown in Figures 3–5.

Figures 3–5 show that when the population index reaches 50 in the analysis of health monitoring data, the average accuracy of data mining is 86.8 percent, the average accuracy of the association rule algorithm is 85.9 percent, the average accuracy of the collaborative filtering algorithm is 84.3 percent, and the average accuracy of the machine learning algorithm is 90.1 percent. Among the four high-accuracy algorithms, this method is clearly the most effective and stable. The addition of GPS assistance and a hand raising misjudgment algorithm improves the system's stability and accuracy significantly. The monitoring data of human exercise health of smart bracelets are analyzed in this experiment, and the curves of time consumption increasing with the sequence length of the data mining algorithm, association rule algorithm, collaborative filtering algorithm, and machine learning algorithm are used in this paper, respectively. The experimental results are shown in Figures 6 and 7.

As can be seen from Figures 6–7, the time consumption curve of the machine learning algorithm in this paper is the highest among the four algorithms, and the linear complexity of the algorithm is verified from an experimental point of view. The time consumption curves of the data mining algorithm, association rule algorithm, and collaborative filtering algorithm indicate that they have quadratic complexity, and the linear complexity is another advantage of the algorithm in this chapter. Because accelerometer data and gyroscope data are three-dimensional data, and there are many sampled data, the extracted feature dimensions are too large, which is not conducive to the subsequent classification and recognition. At the same time, more redundant features will also reduce the classification accuracy so that the most effective features can be selected to achieve the effect of dimension reduction and improve the classification accuracy.

Table 1: Forecast details of RBF core test set.

	Walk	Go upstairs	Sit-up	Run	Go downstairs	Wipe	%
Walk	102	6	1	2	1	4	85.82

5. Conclusions

In this paper, a set of human motion recognition systems is developed using the intelligent bracelet's built-in acceleration sensor. In this paper, machine learning is used as a human motion recognition algorithm, and for the first time, this method is realized by an intelligent bracelet on a mobile terminal. This method is then contrasted with the data mining algorithm, the association rule algorithm, and the collaborative filtering algorithm. When the population index reaches 50 in the analysis of health monitoring data, the average accuracy of data mining is 86.8 percent, the average accuracy of the association rule algorithm is 85.9 percent, the average accuracy of the collaborative filtering algorithm is 84.3 percent, and the average accuracy of the machine learning algorithm in this paper is 90.1 percent. This method is clearly the most effective and stable of the four high-accuracy algorithms. The addition of GPS assistance and a hand raising misjudgment algorithm greatly improves the system's stability and accuracy. With the rapid advancement of science and technology in recent years, we believe that the development of smart bracelets will be extremely beneficial. The combination of smart bracelets with sports, medical treatment, and mobile payment will make our lives more convenient and fast in the future. Current machine learning models, on the other hand, are based on smaller data sets. Data sharing can provide larger data sets for developing a comprehensive learning model for a broader range of people. Simultaneously, the current learning model is primarily used for walking, running, and a few special movements. Its wide range of applications in various human movements warrants further investigation.

This paper uses image segmentation technology to examine the biomechanical parameters of martial arts routine athletes' whirlwind legs and backflips, two difficult jumping sports. The successful completion of the whirlwind leg, a typical martial arts jumping difficulty, during the buffer period of the take-off stage, the left knee angle flexion, the drop of the body's center of gravity, and the drop of the horizontal speed of the center of gravity are all significantly correlated, so it is only necessary to grasp airborne altitude and speed from landing. The 720-degree cyclone foot has a flying height of 0.470.11 m, which is 4 cm higher than the 540-degree cyclone foot (0.430.11 m). The antigravity of the last foot is greater than about 1.3 kgf/kg of the left foot during the run-up stage, which allows for a higher rotational angular velocity and completion of the 720-degree difficulty of the whirlwind foot. As a result, it is crucial to pay attention to how you step with your right foot. In the backflip, the coordination of the two legs and the upper body is crucial. The right foot's effective braking can help to increase the body's rising angle. The trunk inclination angle in the flying stage is between 110° and 120°, the knee angle is between 60° and 70°, and the angle between the two legs is between 35° and 35°. When lifting off the ground and landing, the tibialis anterior muscle discharge is greater than the gastrocnemius muscle discharge, which helps to maintain the balance between the fulcrums. As a result, it is necessary to let the non-supporting leg fall first in order to achieve the goal of a smooth landing.

1. Introduction

With the advancement of the athletes' competitive level, competitive martial arts is gradually evolving in the direction of "high, difficult, beautiful, new, stable, and refined." The movement difficulty in competitive martial arts routine competition is increasing, and the movement between the movements is becoming more difficult. Athletes must complete difficult movements delicately, steadily, and with high quality in order to achieve excellent competition results, especially as the trend of changing connections becomes more complex. These difficult movements include not only the fast rotation of the trunk around the sagittal and coronal equiaxes during the jumping process, but also the stable balance of the connection after the difficult jumping movements have been completed [1]. The difficulty of the movements from fast movement to sudden stillness and stable support, as well as the high-difficulty and graceful posture shown by the jumping movements, adds color to the viewing of competitive martial arts routines. On the other hand, as sports science and technology advance, and training quality improves, the gap between athletes' physical fitness and competitive level narrows [2]. The success of any action has a significant impact on the evaluation of the quality of the athlete's entire set of actions and the final score, especially when the level and strength are similar. In competitive martial arts routine competitions, the error rate of athletes' jumping movements is quite high, and athletes of any level have certain deficiencies in the completion time and quality of their balance movements. Therefore, the mastery and stable performance of jumping movements are also the decisive criteria for judging the level of athletes' competitive level.

In order to make the technical practice of the athlete's balance movement more scientific and effective, this paper has a preliminary understanding of the balance movement by visiting relevant experts, watching on-site, or watching martial arts competitions and other aspects. According to factors such as the frequency of occurrence, difficulty level, and share of balance movements in martial arts competitions in recent years, two movements of backflip and whirlwind leg were selected for analysis. Using image segmentation technology to analyze the biomechanics method reveals its movement law. It provides a reference for improving the rationality and optimization of the balance movements of martial arts routine athletes, so as to solve the technical difficulties of balance movement practice encountered in daily training, so as to achieve the purpose of improving the athletes' competitive level and refining and perfecting technical movements.

Analysis systems based on modern digital image processing technology [3, 4] are becoming increasingly important in the process of analyzing martial arts routines. Because of its intuitive and rapid characteristics, it can effectively overcome the drawbacks of traditional martial arts teaching, assist learners in quickly mastering the fundamentals of martial arts movements, and attract an increasing amount of attention from martial arts enthusiasts. The research on identification, detection, and analysis technology in the jumping process has a lot of potential due to the unique movement mode of martial arts routines. A set of Wushu routine movement analyzer systems is developed in this paper using image recognition technology [5–7] on the basis of video acquisition and video processing. Through the front-end camera and the capture card, the system collects and records the martial arts routine motion video into the specified file, adds a variety of line drawing analysis tools to the video playback and comparison process, and uses graphics and lines to aid in the action video analysis. This paper investigates a set of image recognition algorithms that use the background difference method to grayscale captured image sequences, extract edges, median filtering, and binarization, based on the premise that basic video acquisition and analysis functions can meet the needs of martial arts teaching. The movement trajectory of the jumping process is finally obtained after processing; using the frame-to-frame difference method to compare the change trend of the two frames before and after, the analyzer system can assist martial arts practitioners in correcting swinging and jumping movements, and cooperate with the later developed man-machine interface and simple file management module, which makes the analysis of high-difficulty jumping movements in martial arts more convenient. The system meets the requirements for analyzing and using high-difficulty jumping movements in martial arts after a large number of field experiments.

The innovation of this paper: this paper analyzes the actual needs of martial arts routine athletes training and the particularity of martial arts high-difficult jumping movements. Image recognition technology can intelligently identify the details of martial arts athletes' jumping movements and gradually analyze the biomechanical parameters of each environment.

The structure of the article: first, we introduce some international researches on the analysis of the physical force of sports movements based on image recognition technology; the biomechanical parameters of the whirlwind leg and backflip in the jumping action are analyzed; finally is a summary of the full text.

2. Related Work

In today's social production and life, the application value produced by the combination of video processing technology and image recognition technology is more and more concerned by the majority of scientific researchers, and the fields involved are also very wide. Human motion detection and tracking system is mainly used to deal with image sequences including moving human body. Motion detection extracts foreground motion regions from the background from an image sequence. Motion detection is the basis for the classification and tracking of moving objects, as well as the analysis and understanding of moving human movements. The processing results at this stage directly affect the effect of subsequent processing. With the continuous progress of the development of sports science and technology, the technical research on jumping movements also tends to use electronic and digital scientific instruments for analysis and research [8]. Tripodi et al. [9] mainly focused on the study of its "backward jumping" action, using close-range dynamic stereo photogrammetry as the research method, and using the Aijie motion image analysis system to analyze technical movements, respectively. The speed change, the center of gravity displacement change, and the torso displacement change have been comprehensively studied. The analysis results show that the strength of the legs is the key factor affecting the stability of the back jump. The small muscle group of the right supporting leg of the martial arts routine athletes is weak, and strength training should be strengthened [9]. Li and Zhang [10] also used this method to study the jumping movements of "sidekicking and holding the feet upright" of martial arts routine athletes. The technical indicators such as the swinging leg, the opposite side arm of the swinging leg, the speed of the center of gravity, and the displacement of the center of gravity are selected as parameters, and the swing speed of the swinging leg and the opposite side arm of the swinging leg in the X-axis direction is changed. The maximum swing speed of the swing leg is slightly greater than the swing of the opposite arm of the swing leg, but when it swings over the central axis of the body, the swing speed of the arm is faster than the speed of the leg. At the same time, reach the best jumping state to complete the action. In addition, it can be seen from the comparison curve of the center of gravity speed and displacement that martial arts routine athletes change evenly in the center of gravity speed during the entire movement process, which lays the foundation for their stable jumping support [10]. Through a series of data analysis, Mastalerz et al. [11] concluded that, in the practice of martial arts jumping movements based on muscle strength, attention should be paid to strengthening the coordinated development of upper and lower limb muscle strength and the flexibility of the legs [11]. In the study by Tagaev et al. [12], the kinematics comparative analysis of the sidekicks and the upright jumps of the martial arts routine athlete and Zhang Yanan, the two champions, was found in the comparison. Sex is closely related to the swing speed of the right arm and the swing sequence of the two [12]. Strengthening the rapid arm swing exercises to form a rapid cooperation between the arms and the legs can greatly enhance the stability of the jumping action. In the study of other martial arts jumping movements, Lewis et al. [13] conducted a technical analysis of the sea-exploring jumping and lying-fishing jumping movements in swordsmanship routines to clarify the principle of maintaining the stability of jumping movements. Find the difficult points of the jumping action. It calculates and draws the coordinates of the center of gravity of each link of the body and the coordinates of the total center of gravity of the body with reference to the Japanese body model of Hideji Matsui to evaluate the stability of the jumping action. At the same time, it also pointed out the main muscle groups involved in the movement of the sea-exploring jumping movement and studied the stability regulation of the flexion and extension muscle groups of the body on the sea-exploring jumping [13]. In Atalay et al.'s [14] article on the muscle EMG analysis of Sanda's sidekick action, the EMG test was performed on seven muscles including the rectus femoris, medial vastus, biceps femoris, and semitendinosus, which are mainly involved in the movement of the contralateral kick action. Analysis and research show that the time sequence and sequence of muscle force exerted by excellent Sanda athletes in the sidekick action are relatively close and evenly concentrated, while the time and sequence of muscle force exerted by ordinary athletes when they complete the same action are uneven, uniform, and scattered. The importance of strengthening muscle coordination exercises during training was emphasized [14]. The attacking leg of the whipping technique was studied simultaneously by three-dimensional kinematics analysis and surface electromyography measurement to explore the movement speed of each link of the attacking leg, the contraction mode of the main muscle groups, and the order of force at the attacking moment [15]. The study found that when the knee angle of the attacking leg presents about 140° in the preparation moment of the whip leg attack, it is beneficial to move quickly on the ring and maintain the angle of each joint to achieve better results. Through the analysis of the electromyography tester, it was found that, in the stage of knee flexion and leg raising, sartorius, tensor fascia lata, biceps femoris, and gastrocnemius participated in the muscle contraction, and the rectus femoris EMG contributed the most, and the tensor fascia lata muscle contributed the most. It is the smallest, but it is mainly done by the tensor fascia lata in the stage of widening the knee [15].

With the combination of martial arts and computer technology, more and more martial arts-related equipment has introduced information technology. However, professional golf swing analysis systems are still relatively rare in the world, and the difficulty of jumping martial arts routines using image recognition technology is even rarer, and some martial arts routine sports coaching software that simply uses video processing and analysis technology is available in some countries. The particularity of Wushu sports determines the special requirements for equipment of Wushu sports teaching analysis system. The existing teaching system has shortcomings such as low software intelligence, poor image quality, single video angle, etc., and there is currently no professional golf course. The swing analysis system cannot well complete the Wushu sports teaching task. Therefore, the analysis of the jumping difficulty of Wushu routine athletes based on image recognition in this paper is very meaningful for the research in this field.

3. Image Segmentation-Based Feature Extraction Method for Jumping Action

This paper proposes a method to calculate the period based on the geometric shape of the signal. Before extracting the signal, the original signal should be median-filtered to make the period clearer. It is worth pointing out that, due to the median filtering, horizontal lines may appear in the signal. Since the minimum point of the signal is required to extract the period, when a horizontal line appears, there may be several consecutive identical minimum points, which will interfere with determining the distance between each minimum point, so the horizontal line in the signal should also be removed. The lowest point of each cycle appears in cycles, and the cycle in which the lowest point appears can be regarded as the cycle of the signal [16]. The steps to determine the cycle of the signal are shown in Figure 1.

Motion regions are extracted by thresholding pixel-based temporal differences between adjacent images in successive image sequences [17]. The early temporal difference method is to use the difference of two adjacent images to obtain the motion area, as shown in

$$D_k(x, y) = \left|f_k(x, y) - f_{k-1}(x, y)\right|, \tag{1}$$

where $f_k(x, y)$ is the gray value at the midpoint (x, y) in the k-th frame and $f_{k-1}(x, y)$ is the grayscale value at the midpoint (x, y) in the $k-1$-th frame. The D_k binarization of the difference result is shown in

$$R_x(x, y) = \begin{cases} 1, & D_k(x, y) > T, \\ 0, & D_k(x, y) \leq T. \end{cases} \tag{2}$$

Pixels with values of 1 and 0 correspond to the foreground (moving object area) and background (non-moving area), respectively [18]. The differenced D also includes the change of the scene between two consecutive frames. This change is composed of many factors, including the movement of the target, lighting, shadow, noise, etc. It can be considered that the change of the moving target is obvious. Set a threshold T; when the difference of a certain pixel value in the difference is greater than the given threshold T, the pixel is considered as a foreground pixel; otherwise, it is considered as a background pixel. The interframe difference method is the simplest method to detect changes between adjacent frame images. It directly compares the difference in gray value of corresponding pixels in two or three

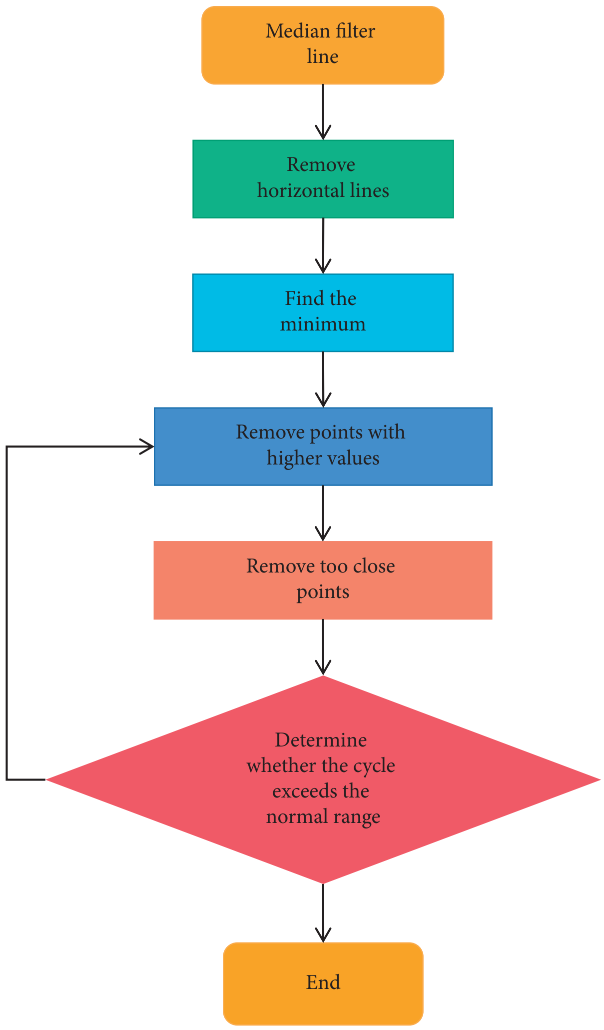

Figure 1: Flowchart of the cycle algorithm.

consecutive frames of images in a video sequence and then sets a threshold to extract motion regions in sequence images [19, 20]. The main advantages of the interframe difference method for target detection are that the algorithm is simple to implement, the programming complexity is low, and it is easy to realize real-time monitoring. Based on the adjacent frame difference method, since the time interval between adjacent frames is generally short, the method is generally less sensitive to changes in scene light. The most basic interframe difference method can detect changes in the scene and extract the target, but in practical applications, the result of the interframe difference method is not very accurate, and it is difficult to obtain an accurate description of the target area [21].

The background subtraction method is a motion detection method that uses the difference between the current image and the background image to extract the motion area, and it is also a widely used method at present [22], which can generally provide complete data of the target. The principle of the background difference method is to use the current image and the background model to differentiate and then threshold to obtain the moving object. In practical application, it is difficult to get the background directly from the monitored area because of the movement of objects or the change of environment, such as the moving target becoming a part of the background, the local background becoming a moving target, etc. Therefore, it is very necessary to acquire, reconstruct, and update the background [23].

The background difference method assumes that the background is stationary, so the background does not change with the number of frames. First, the difference D_k between the current f_k and the background b_k is obtained by using

$$D_k(x, y) = \left|f_k(x, y) - b_k(x, y)\right|. \tag{3}$$

Then, the difference is also binarized according to formula (2). Whether the threshold T is selected accurately or not directly affects the quality of the binary dipper. If the threshold T is selected too high, the area determined as a moving target in the binary value will be fragmented; on the contrary, if the threshold T is selected too low, a lot of noise will be introduced. The most common method for selecting the threshold T is to use the grayscale histogram with double peaks or multiple peaks and select the grayscale value at the bottom of the valley between the two peaks as the threshold value. The background subtraction method is simple to calculate and fast, and the obtained result directly gives the position, size, shape, etc. of the target, so that a complete and accurate description of the moving target area can be obtained [24].

4. Case Study of Jumping Action

4.1. Analysis of Biomechanical Parameters of Cyclone Foot Movement. Approach, take-off, air, and landing make up the 720-degree cyclone foot. When starting, the right foot is buckled in, and the right leg is bent and squatted and quickly pushes the ground, while the left leg swings to the left and the body is twisted counterclockwise; when taking off, the right foot is buckled in, and the right leg is bent and squatted and quickly pushes the ground. After the right leg completes the straight swing and the body's center of gravity is near the highest point, the left hand taps the right sole, the two legs are completed in the air, the limbs are kept vertical, and the arms are close to the body. After rotating in the air for nearly two weeks, spread the limbs and slow down the rotation speed, touch the ground with both feet, take the horse step or drop the vertical fork, and finish the landing action. The subjects for this study were seven martial arts routine athletes. The average vertical distance between the right swing leg and the lowest shoulder point was 0.180.16 m after the subjects completed the strike in the air. The results are shown in Figure 2.

During the flying stage, the subjects completed the 720-degree cyclone foot with an average flying height of 0.47 ± 0.11 m, which was 4 cm higher than the 540-degree $(0.43 \pm 0.11\ \text{m})$ cyclone foot. This is a comparison of the overall samples that completed the C-level and B-level jumping difficulty movements of the cyclone feet. The paired t-test was used to find that the same athletes completed the

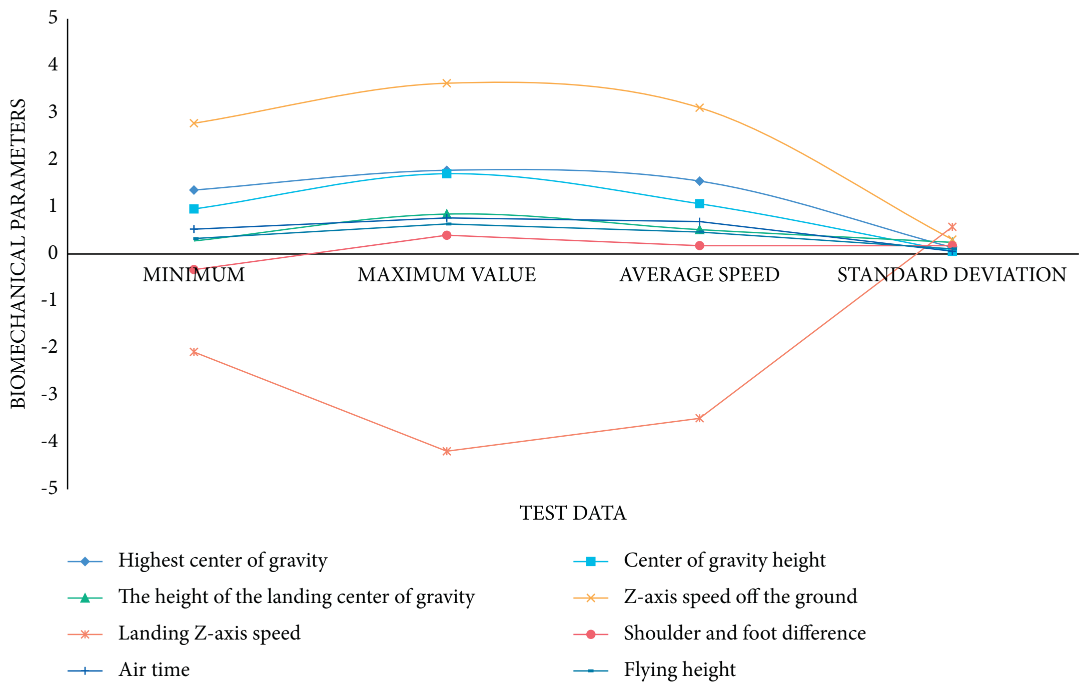

Figure 2: Kinematic parameters of the cyclone foot at 720°.

C-level and *B*-level jumping difficulty movements of the cyclone feet, respectively, and the flying heights of the two were not significant. It can be considered that the same athlete has no difference in the height of the air when completing the *B*-level and *C*-level jumping difficulty movements of the whirlwind foot, and the main reason is that the rotation speed in the air is increased. The comparison of kinematic parameters of cyclone feet with different difficulties is shown in Figure 3.

The average maximum ground reaction force of the left foot in the final step of the approach stage is 2.151.03 kgf/kg body weight, while the average maximum ground reaction force of the right foot in the final step is 3.500.76 kgf/kg body weight, which is significantly greater than the starting braking. The action of the left foot indicates that the last step's ground reaction force should be high in order to help raise the air's height. The turning moment around the body's longitudinal axis is large, allowing for a higher rotational angular velocity and completing the whirlwind foot's 720-degree difficulty. As a result, it is important to pay attention to how you walk with your right foot.

The EMG signal strength of the vastus medialis muscle is the strongest in the take-off and landing stages; the EMG signal of the vastus lateralis muscle is stronger in the take-off and landing stages; the EMG signal of the rectus femoris in the take-off stage is average, and there is a discharge signal in the flight stage, which is consistent with the discharge time of the adductor magnus. It shows that this stage is the clicking action when flying, and there is also an EMG signal when landing; the gastrocnemius discharge time is the earliest, because the right leg has a certain angle with the ground when taking off, and the triceps of the calf keeps the ankle joint through isometric contraction. At a certain joint angle,

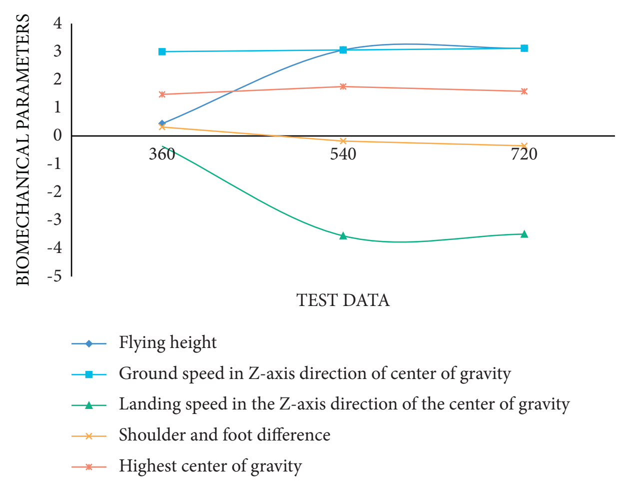

Figure 3: Comparison of kinematic parameters of cyclone feet with different difficulties (mean value).

the ground reaction force is transmitted through the calf to the thigh. In training, attention should be paid to the exercises of calf strength, especially the isometric strength exercises to strengthen the calf.

Athletes who use one foot to perform a 720-degree take-off with a whirlwind foot should obtain a certain degree of rotation as much as possible before leaving the ground; that is, the human body has already rotated part of the body before it is in the air, so as to improve the height of the air and complete the degree of rotation. The training methods for the *B* and *C*-level jumping difficulty of the whirlwind foot include the click of the legs together, the legs together, and the landing technique. In the flying stage, when the center of gravity of the human body rises close to the highest point, the click must be completed, and the time from take-off to the completion of the click should be as short as possible, so as to achieve the corresponding degree of leg rotation in the flying stage as soon as possible. Athletes choose horse stance in the dynamic and static connection of Changquan and Nanquan. Although individual athletes avoid landing with both feet, foot movement, or jumping in sequence, they focus on one leg in order to stabilize the movement. In the action quality score, points are deducted if the squatting legs are not level and the distance between the feet is too small. Therefore, the 720-degree stance of the whirlwind foot must strengthen the awareness of movement norms and training requirements. Figures 4 and 5 show the kinematic parameter diagrams of the athlete's front extension.

It can be seen from Figure 4 that the left knee angle of the seven athletes is $(119.74 \pm 20.83)^{\circ}$ at the lowest point of the center of gravity of the body. At this time, the left leg is firmly supported by the inside of the foot and actively stretches, and the knee angle begins to increase. When the right foot hits the ground, the angle is $(139.26 \pm 14.17)^{\circ}$, when the left foot is off the ground, the knee angle is $(164.93 \pm 4.19)^{\circ}$, the kicking range is $(45.19 \pm 21.48)^{\circ}$, and the vertical velocity of the center of gravity is (1.91 ± 0.35) m/s. After inspection, the left knee extension during the front extension period is significantly positively correlated with the vertical speed of the center of gravity when the left foot leaves the ground, indicating that the greater the left knee extension during the front extension period, the higher the vertical speed of the center of gravity when the left foot leaves the ground. In addition, the active stretch action of the left leg can quickly push the hip and body weight forward, which is of great significance for obtaining a larger impulse during take-off and quickly stepping on the right leg to the take-off point. The horizontal distance of the body's center of gravity moving forward and the horizontal speed of the center of gravity were (0.18 ± 0.08) m and (2.21 ± 0.81) m/s, respectively, during the forward stretch. After testing, the horizontal distance of the body's center of gravity moving forward during the forward stretch is significantly correlated with the horizontal speed of the center of gravity when the left foot is off the ground, indicating that the more fully the left leg is stretched during the forward stretch, the greater the horizontal distance of the body's center of gravity forward, and the more it is beneficial to obtain a larger horizontal velocity of the center of gravity when the left foot is off the ground. 1, 2, 5, and 6 give full play to the left leg's positive role during the forward stretch period, allowing the right leg to quickly transition to the stretch action and the early swing of the left leg after stepping on the take-off point. The main reason for the disparity among athletes is that the left leg is not actively stretched, which is extremely detrimental to improving center of gravity speed and maintaining good body posture when taking off. Figure 6 depicts the swing speed of the two arms during the front kicking and extension period.

It can be seen from Figure 6 that the swing of the left and right arms shows different changing laws during the front kicking and extension period. From the lowest point of the center of gravity to the moment when the right foot hits the ground, the swing speeds of the left and right arms continue to increase. When the right foot hits the ground, the swing speeds of the left and right arms are (8.64 ± 1.47) and (9.33 ± 1.73) m/s, respectively. Based on the previous analysis, it can be seen that, from the moment of the lowest point of the center of gravity to the moment when the right foot hits the ground, the athlete pushes the center of gravity forward through the active stretch of the left leg and the accelerated swing of the two arms, creating a favorable situation for the right leg to move towards the take-off point actively and quickly. condition. 1, 2, 5, and 6 have more sufficient kicking and stretching actions, and the swing speed of the left and right arms is higher than that of other athletes, which indicates that the athletes such as Zhou can make full use of the swing of the arms to take-off better than other athletes. After the right foot touched the ground, the swing speed of the left arm continued to increase. When the left foot was off the ground, the swing speed reached the maximum (10.21 ± 2.24) m/s, while the swing speed of the right arm showed a decreasing trend. After kicking off the ground, the swing speed of the right arm drops to (7.01 ± 1.51) m/s. After inspection, when the left foot leaves the ground, the swing speed of the left arm has a significant positive correlation with the horizontal speed of the center of

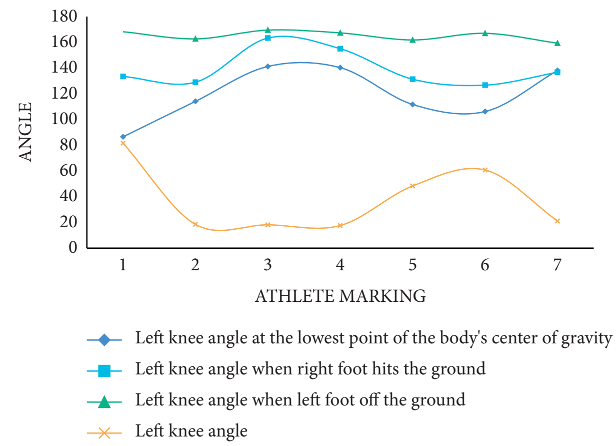

Figure 4: Kinematic parameters of the athlete's front extension.

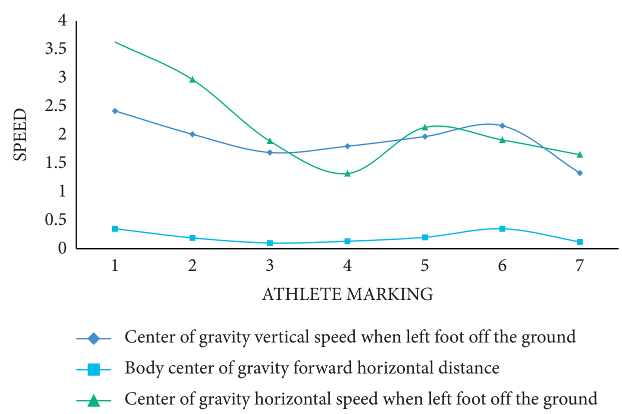

Figure 5: Kinematic parameters of the athlete's front extension.

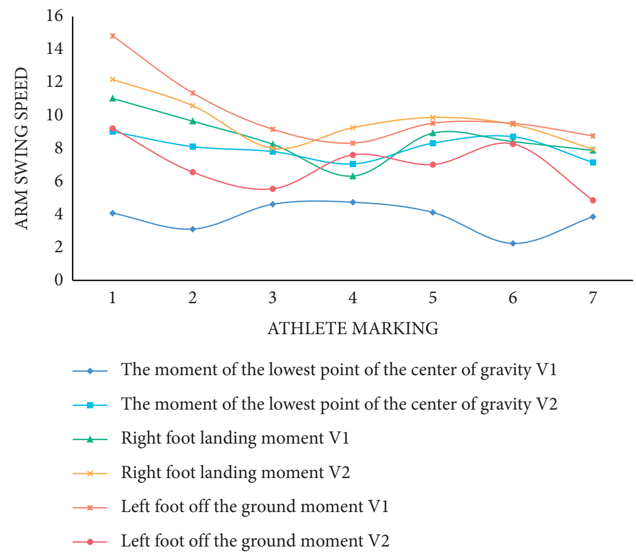

Figure 6: The variation characteristics of the swing speed of the athlete's arms during the forward extension period.

gravity at this moment. It shows that the greater the swing speed of the left arm, the greater the horizontal speed of the center of gravity when the left foot leaves the ground. It can be seen that, from the moment when the right foot hits the ground to the time when the left foot leaves the ground, the horizontal speed of the center of gravity of the body is maximized by the rapid swing of the left arm, and the body balance is maintained by reducing the swing speed of the right arm.

4.2. Analysis of Biomechanical Parameters of Backflip. The backflip consists of four steps: run-up, take-off, flying, and landing. In the run-up stage, try to keep the balance of the body and run in a straight line; in the take-off stage, the right heel brakes on the ground, the upper body is leaned back, and the left leg is raised and the left leg swings up. Raise your legs and swing your knees to your chest, and tuck your legs in the air; in the landing stage, after your body has completed a 360-degree backward rotation in the air, land both feet on the ground at the same time, landing in a single butterfly step. In this paper, 6 martial arts athletes are selected for action analysis, and key information is proposed based on image segmentation technology. The torso anteversion is the angle between the torso and the supporting leg. The inclination angle of the non-supporting leg is the angle between the non-supporting leg and the horizontal position as shown in Figure 7.

The angle of the ankle joint of the supporting leg is controlled at about 90° when the backflip is stable, which means that, in the leaning-over balance, the body's center of gravity is moving forward. In the upright position, there is no discernible difference; however, the center of gravity is projected onto the support legs, making balance easier to control. The backflip's torso inclination angle is between 110° and 120°. Because the action requirements of each link differ, one requires raising the chest while the

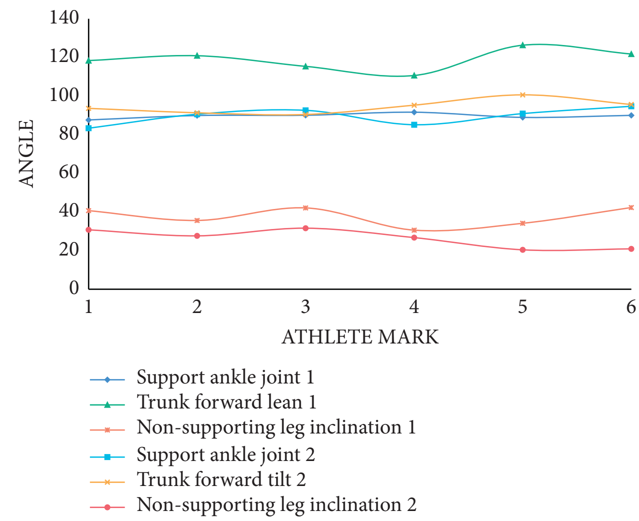

Figure 7: The angle of each link of the backflip.

other requires leaning forward. As a result, the trunk's forward inclination angle becomes the primary basis for the two groups' balance. The inclination of the non-supporting leg of the backflip, on the other hand, is found to be the same as the inclination of the supporting leg using statistical technical parameters of image segmentation. When the fulcrum stays the same, the forward probe of the torso causes the center of gravity to move forward, resulting in a change in the gravitational distance and an increase in the gravitational arm. The non-supporting leg compensates for the change in gravitational distance due to the forward movement of the center of gravity and ensures that the total external moment is zero in order to maintain the balance position with the torso in the air. The non-supporting leg's horizontal angle decreases, increasing the moment arm between the non-supporting leg and gravity and achieving the goal of maintaining balance and stability. As a result, the backflip's non-support leg angle is slightly reduced, as shown in Figure 8.

In the process of observing the support leg movement of the backflip action, the support leg of the backflip action is all the pelvis flexed at the hip joint and is in a forward tilted position. The support leg is always in the upright phase. The support leg is always in the upright phase. In both balanced stabilization movements, the torso and non-supporting legs are rotated counterclockwise to a horizontal position about the hip joint. In this state, the rectus femoris muscle contracts concentrically, the biceps femoris muscle contracts eccentrically, and the moment arm of the rectus femoris muscle is shorter than the moment arm of the biceps femoris muscle, and the movement balance is maintained under the condition of equal muscle force distance, so the discharge of the rectus femoris is greater than that of the biceps femoris. The calf is flexed at the ankle joint, the tibialis anterior muscle performs eccentric contraction, the gastrocnemius muscle contracts concentrically, and the muscle arm of the tibialis anterior muscle is much smaller than that of the

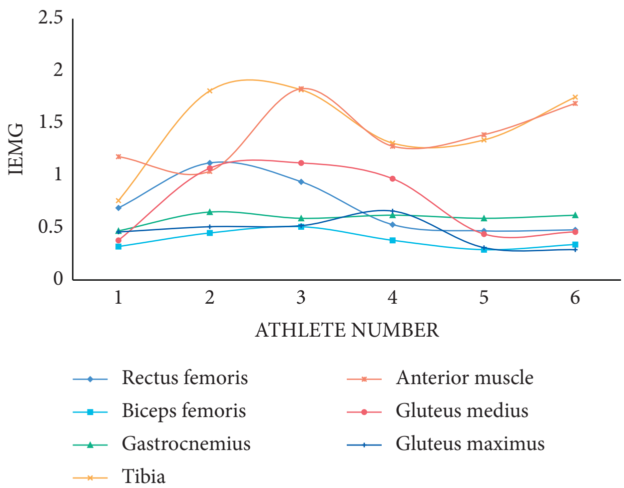

FIGURE 8: Muscle IEMG of backflip test of martial arts athletes.

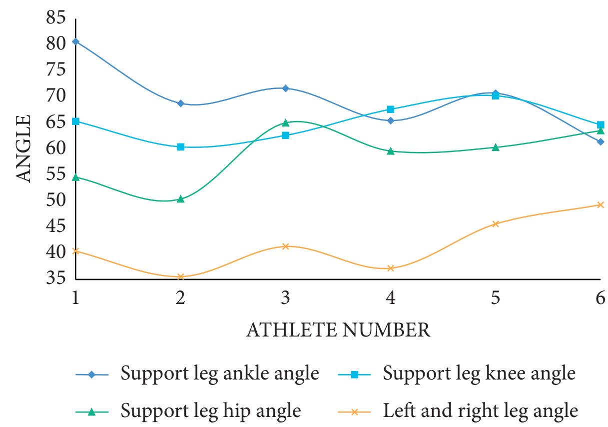

FIGURE 9: Body part angle of backflip.

gastrocnemius muscle, so the discharge of the tibialis anterior muscle is more than that of the gastrocnemius muscle. The gluteus maximus and gluteus medius do eccentric contraction in the hip flexion movement in the bending part, and the muscle arm of the gluteus medius is smaller than that of the gluteus maximus, so the discharge of the gluteus medius is more than that of the gluteus maximus. Figure 9 shows the angle of the body part of the backflip buckle leg link.

It can be seen from the figure that the ankle joint angle of the support leg becomes smaller in the stable stage of the backflip than in the upright stage, because the bending of the support leg causes the body's center of gravity to drop and move forward. At this time, the angle of the ankle joint decreases with the forward movement of the center of gravity, which increases the projected area of the center of gravity on the support surface, which is beneficial to control the stability of the center of gravity. Buckling balance requires the support leg and thigh to be kept as level as possible. According to the principle of parallel lines, the range of the knee angle is controlled between 60 and 70° to compensate for the increased moment arm due to hip flexion and squatting, so that the action can be balanced between the fulcrums. The trunk leans forward from the hip joint, so that the head is close to the vertical line of the center of gravity, which increases the balance and stability and makes the movement more graceful and stretched. The angle between the two legs is between 35 and 50°, which is to balance the component forces on the left and right sides of the action, so that the combined external force is zero, so as to achieve the purpose of landing smoothly. The swing speed and swing sequence of the non-supporting leg and the heterolateral arm have a great relationship with the stability of the movement. The swing of the opposite side arm should be prior to the swing of the non-supporting leg, which is conducive to improving the side swing speed, shortening the time to complete the action, and enhancing the stability of the balance while improving the quality of the action.

5. Conclusions

The results of image segmentation technology's biomechanical analysis of all martial arts high-difficulty jumping movements show that, whether the whirlwind foot jumps with one foot or two, the two feet should form a certain angle with the approaching route, which is conducive to the rotation in the air and the sound of the strike. The movement should be performed while the center of gravity is rising. The faster the run-up speed, the better in the warm-up phase. When the right foot touches the ground during the forward stretch phase of take-off, the sole of the foot is buckled inward, and the right foot pushes and stretches in a timely manner, with almost no concessional work. The range of leg extension is greater, and the key technology is the "orange pendulum combination" of the two legs and upper limbs. When the martial arts routine athletes slam their legs together in the vacant stage, the body's center of gravity rises, approaching the highest point of the body's center of gravity. The key to achieving a stable stance on the ground is to stretch the limbs as soon as possible after completing the rotation in the powder, in order to increase the human body's rotational inertia. When taking off, the backflip should increase the amplitude and speed of the upper body slanting downwards, and the possibility of adjusting the position of the left foot when the left foot is pushing the ground should be minimized. It is crucial to get the body and the running route to form a certain angle, and the backflip's running braking technology and group body technology are crucial. In terms of image processing technology, although motion detection-related algorithms can extract the motion trajectory of the jumping action process, it is still very difficult to recognize the hands and feet of the system. It is necessary to consider the operation time of the system and ensure the accuracy of the detected target. In future research, you can try to add some advanced algorithms of image matching and perform template matching for hands and feet.

Music and dance videos have been popular among researchers in recent years. Music is one of the most important forms of human communication; it carries a wealth of emotional information, and it is studied using computer tools. In the feature engineering process, most present machine learning approaches suffer from information loss or insufficient extracted features despite the relevance of computer interface and multimedia technologies in sound and music matching tasks. Multifeature fusion is widely utilized in education, aerospace, intelligent transportation, biomedicine, and other fields, and it plays a critical part in how humans get information. In this research, we offer an effective simulation method for matching dance technique movements with music based on multifeature fusion. The initial step is to use music beat extraction theory to segment the synchronized dance movements and music data, then locate mutation points in the music, and dynamically update the pheromones based on the merits of the dance motions. The audio feature sequence is obtained by extracting audio features from the dancing video's accompanying music. Then, we combine the two sequences to create an entropy value sequence based on audio variations. By comparing the consistency of several approaches for optimizing dance movement simulation trials, the optimized simulation method described in this research has an average consistency of 87%, indicating a high consistency. As a result, even though the background and the subject are readily confused, the algorithm in this research can keep a consistent recognition rate for more complicated dance background music, and the approach in this study can still guarantee a certain accuracy rate.

1. Introduction

The most common form is that the dance form evolves in response to the music [1]. Music theme information is communicated through a variety of dance expressions. Dance action matching technology in music arrangement [2] is the process of determining the shape of dance works based on the music style. Effective dance video clip retrieval can assist dance teachers in organizing dance and supporting dance teaching activities [3]. The emotional expression of dancers' works is intimately linked to musical comparison [4]. The dance team's variable or scattered arrangement and creation are similarly difficult to distinguish from the music's production and design [5]. Music is one of the most essential forms of auditory data in multimedia. Computers have carefully studied music as a strong analytical tool in today's digital music era, which has become an unavoidable trend.

In the field of computer vision research [6–8], optimization simulation is currently a highly difficult problem. Its purpose is to analyze dance video data utilizing image processing [9, 10], classification [11], and recognition technology to distinguish motions. With tens of thousands of new songs released each year and the rapid emergence of millions of digital songs that were previously unclassified, existing matching approaches are unable to keep up with the changing times. Because real-world human behavior is based on three-dimensional space, three-dimensional information is critical for music matching optimization simulation. However, extracting 3D information about the human body from RGB dancing photos is difficult. To gather 3D information about the human body, some traditional methods use a depth camera or a laser scanner. The development of matching optimization simulation has been considerably aided by research into human behavior recognition technologies based on artificial intelligence [12] and computer vision. It takes a series of keyframes from a dancing video sequence, generalizes the original video content from high-level semantic information to low-level visual features, and retrieves the original video content using the keyframes as the index, which has a direct impact on video quantity and quality. Final search results in efficiency and accuracy [13].

By annotating the written description of each video frame and matching query keywords with annotations, the multifeature fusion completes the video search [14]. This method begins by incorporating picture band decomposition theory, extracting low-frequency grass-roots information and high-frequency detail information from the dance, and then mapping the corrected grass-roots image. It incorporates multiple functions such as speech, motion, face recognition, and others in a new way, collects diverse human body movements using RGB and infrared cameras, analyzes and recognizes them, and enables intelligent human-computer interaction [15]. It has been discovered that the multifeature fusion of dance and music matching optimization simulation approach may not only aid dance experts assess dance videos but can also be used for teaching, cultural heritage protection, and excavation. The following are the study's unique features: (1) because too many repetitive dance moves in dance motions reduce the retrieval rate, this research provides a method for extracting crucial frames from music and dance videos. (2) In order to improve the classification effect of multimodal features, a multifeature fusion-based optimization simulation method for matching dance and music is proposed, with the goal of transforming low-level audio features into a bag-of-words model that is unified to the lyric text regardless of time or frequency domain. (3) In this study, a multifeature fusion strategy is utilized to learn the implied links between higher-order features recovered by the feature encoding network, allowing for early detection of information interactions between distinct features.

The research framework of this study consists of five major parts, which are organized as follows:

The first part of this study introduces the background and significance of the research and then describes the main work of this study. The second part introduces the work related to the optimal simulation of dance movement and music matching, and multifeature fusion. The third part of the study introduces the design methods of music and dance movement feature extraction and multifeature fusion dance-music matching simulation, so that the readers of this study can have a more comprehensive understanding of the multifeature fusion-based dance-music matching simulation method. The fourth part is the core of the thesis, which completes the description of the multifeature fusion-based optimization simulation analysis from two aspects: optimization simulation and multifeature fusion of dance and music. The last part of the study is the summary of the whole work.

2. Related Work

2.1. Optimization Simulation of Match between Dance and Music. Music is a kind of artistic expression that is more powerful than images but less so than words. Dance, on this premise, transforms the rich information of dance images buried in music into rich three-dimensional and multidimensional visual images, presenting the meaning of dance to its fullest extent. The significance of music emotion analysis can be seen in the following ways: the study ideas of the music emotion model can be applied to artificial intelligence in emotion recognition, and this research can also be applied to other domains of pattern recognition. Domestication technology and intelligent human-computer interaction have advanced rapidly. The analysis of these music and dance videos is performed using matching optimization simulation, and organically related music and dance action segments are obtained, which not only reduces the work intensity of dance professionals but also facilitates the retrieval of music and dance video data and dance arrangement automation.

Zhou and Zhang developed an application software to improve the content-based matching function on the Internet and make the matching or optimization of music and dance more intelligent [16]. Hong et al. proposed an optimization method based on genetic theory to match the technical movements of dance and music. This method first determines the music style, obtains the basic style characteristics of music and dance, and then analyzes the correlation between the basic characteristics of music and dance to remove the repeated feature pairs [17]. Sun and Ruan used the depth and bone information obtained by the camera for dance action recognition [18]. The recognition accuracy is improved by using the information obtained from the offline data set, including RGB information and available depth and bone information. Ng et al. proposed an optimization method based on machine learning to match dance technical movements and music in music arrangement [19]. First, combined with machine learning theory, this method constructs the mapping relationship between dance action and music based on historical sample data set and obtains the evaluation function of the harmonious relationship between dance action and music. Wang et al. proposed a method to quickly and accurately predict the 3D position of dance movements in a single depth image without using time information [20].

2.2. Research on Multifeature Fusion. In the human perception of music, a music category refers to a group of songs that usually feel the same interpretation. Music genres provide important emotional descriptions and are used to classify music. In recent years, many domestic and foreign scientific research institutes and relevant scholars are committed to the research of dance movement recognition, which has made great contributions to the development of movement recognition research. However, how to classify dance movements and music in the music genre classification system is an arduous task.

Zhang and Zhao proposed an optimization method for matching dance technique movements to music based on greedy theory [21]. The method now adapts a given dance movement and that movement to the beat of the music, and then performs music-dance movement matching based on this. According to Pandeya and Lee motion recognition based on static RGB image features, in videos dealing with complex backgrounds, static features are susceptible to factors such as background, illumination, and human motion, making feature extraction difficult [22]. Huang et al. focused on dynamic scene understanding, target tracking, and motion recognition through multifeature fusion and successfully applied it to applications such as real-time surveillance, teleconferencing, and intelligent robot navigation [23]. López-Ortega proposed an optimal matching method for multifeature fusion images based on correction and balancing techniques in dance [24]. The method first maps the luminance of each pixel in the dance correction and balance technique image to the luminance range that can be output by the display device according to a one-to-one correspondence. Roy et al. developed an intelligent video surveillance system based on multifeature fusion that overcomes the interference of scene illumination changes and can automatically detect music in the video with the function of automatically matching the dance [25].

The dance competition is not only a competition for dancers' skills but also a competition for general arts other than dance, such as music creation, theme script, and stage art. As an important part of dance, dance music is unparalleled in dance works.

3. Optimization Simulation Method of Dance and Music Matching Based on Multifeature Fusion

3.1. Feature Extraction of Music and Dance Movements. The variability of dance movements and too many overlapping movements leads to major problems in extracting movement features [26]. The movements of music and dance videos are complex, changeable, and repetitive, which makes it difficult to analyze and identify dance movements [27]. The artistic form of music is stronger than abstraction and weaker than an image, but its rigid organizational logic, artistic structure, and rich symbolic meaning strengthen people's thoughts and connect and synthesize metaphors into moving sounds [28]. On this basis, a genetic algorithm is used to train the corresponding relationship of different music and dance movements, and its accuracy is taken as the fitness function to obtain the optimal music and dance movement matching. People are greatly inspired by the research in the field of art and music psychology. The analysis model of music emotion perception is shown in Figure 1.

First, in the process of dance action matching and optimization in music arrangement, the synchronized dance action and music data are segmented through music beat extraction theory to obtain multiple short action music fragment combinations. After calculating the entropy value of each image in the image sequence, the entropy value corresponding to the current frame is compared with the previous frame. If it is greater than the threshold, it is considered as a keyframe. The following formula is often used to calculate the entropy between samples. The smaller the entropy, the greater the similarity between samples. For an n dimensional space, the Minkowski distance between point X and point Y can be expressed as follows:

$$dis(X,Y) = \sqrt[p]{\sum_{i=1}^{n} |x_i - y_i|^p}, i = 1, 2, ..., n, \tag{1}$$

where x_i is the i dimensional characteristic data of point X and y_i is the$i$ dimensional characteristic data of point Y.

Using the keyframe sequence as input, the RGB image information of the keyframes is input to the spatial convolutional neural network to extract the video shape information and the optical flow information of the keyframes and adjacent frames, which is used to extract the temporal convolutional network motion information of the video frames. Therefore, in this study, each joint point of the image is assigned a motion contribution weight, and the joint contribution weight formula of the feature vector can be expressed as follows:

$$\mathrm{dis}\left(x^{(m)}, x^{(n)}\right) = \sqrt{\sum_{i=1}^{N} \omega_i \left(x_{ix}^{(m)} - x_{ix}^{(n)}\right)^2 + \left(x_{iy}^{(m)} - x_{iy}^{(n)}\right)^2}. \tag{2}$$

Before the comparison, in order to select more representative features and reduce the computational complexity, the CHI feature selection method based on the difference mentioned above is used to select features for both audio words and text words. Generally, the feature extraction process is shown in Figure 2.

Second, the transition point of music is detected, the beat prediction position obtained in each stage is aligned, the correlation coefficient between dance action and music part is calculated, and the dance action matching optimization objective function is obtained. The dance action is represented by the dispersion of different coordinate positions in the whole video. The more active the action is, the higher the dispersion degree is. The dispersion degree of dance action i is measured by the variance of coordinates:

$$\sigma_i^2 = \frac{\sum_{f=0}^{n} \left(x_i^{(f)} - x_i\right)^2 + \left(y_i^{(f)} - y_i\right)^2}{n}. \tag{3}$$

Here, $x_i^{(f)}, x_i$ are the abscissa and ordinate positions of joint point i in frame f, x_i, y_i are the average abscissa and ordinate positions in the whole video sequence, and n is the video frames.

Then, the motion contribution weight of joint point i can be expressed as follows:

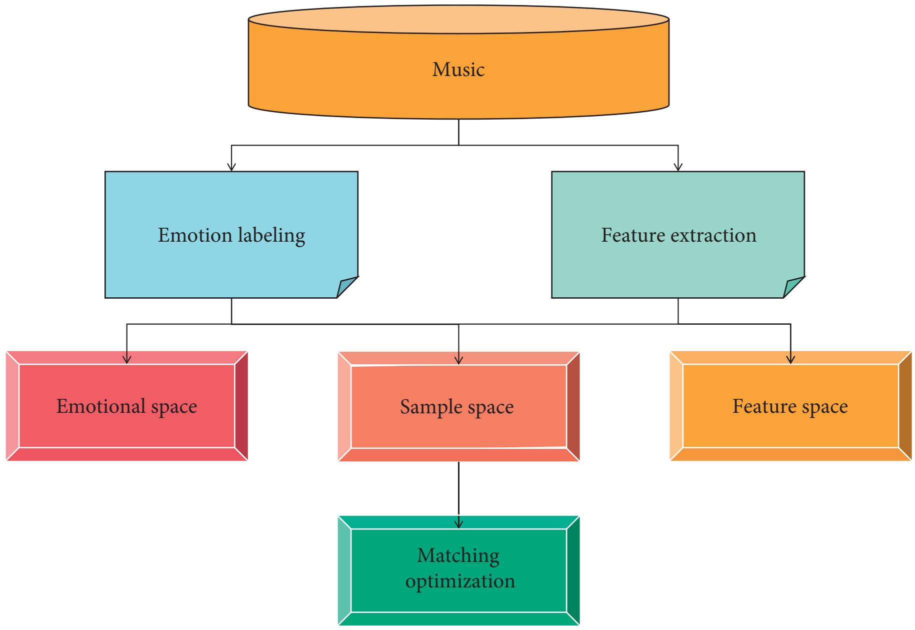

Figure 1: Analysis model of music emotion recognition.

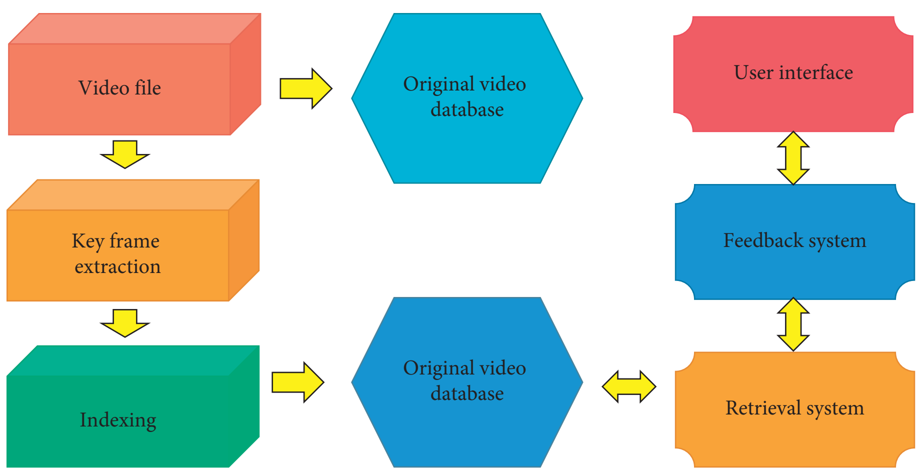

Figure 2: Feature extraction process diagram.

$$\omega_i = \frac{\sigma_i^2}{\sum_{k=0}^{n} \sigma_k^2}. \quad (4)$$

The duration of the dance video, the number of frames in the image, and the frame rate of the video are all known during these audio and dance movements, and interval operations are performed using standard deviations, corresponding to audio and audio values computed once per second. Entropy value sequences and functions are combined [29]. The contrast and visual quality of the image are increased by mapping pixels concentrated in several grayscales to other grayscales and distributing them uniformly by dividing the color gamut point by point by the chromaticity priority of the standard layer image [30].

Finally, to achieve dance action matching in music arrangement, all music and dance action parts of the music arrangement are adaptively adjusted to pheromone fluctuation factors according to pheromone concentration, and pheromones are dynamically updated according to the optimal solution of dance action matching. The order of entropy values is calculated after feature fusion. In comparison, the difference in entropy values between two adjacent frames is not utilized as a benchmark for determining keyframes, but instead, it is determined by comparing this value with the threshold using the following formula:

$$\mathrm{V} = \frac{\left| H_{\text{current}} - H_{\text{key}} \right|}{H_{\text{key}}}. \quad (5)$$

Here, $H_{current}$ is the entropy value of current frame and H_{key} is the entropy of the current keyframe.

For the skeleton 3D coordinate data in each frame of the video sequence, k frame is randomly selected as the sample center, and then the 30 3D coordinate data in k extracted at last are unchanged or less than a certain threshold through iteration in turn by using the above algorithm.

3.2. Specific Design of Multifeature Fusion Dance and Music Matching Optimization Simulation. In the first mock exam of video, there are many modes in its content, such as appearance, optical flow, and depth. These modes complement each other, convey important information, and integrate these modes, which can effectively solve the problem of insufficient expression of single modal video information. The distance between the keyframe sequence KF and the original video sequence set F can be expressed by the maximum semi Hausdorff, which is defined as follows:

$$D = (F, KF) = \max\{D(F_i, KF)|i = 1, 2, \ldots, N\}. \tag{6}$$

Music in a narrow sense refers to the basic elements of music sound, including pitch, length, intensity, and timbre. These basic elements combine to form the "formal elements" of common music. After extracting low-level features from audio's auditory and visual features, we use feature coding network to study the low-level features to obtain high-level features. Emotion recognition presents a hierarchical feature, as shown in Figure 3.

Because music genres are often distributed in local and repeated audio clips, if the music is divided into segments that are too short, it will be difficult to reflect the relationship between local characteristics. The specific design method of multifeature fusion music recognition method is shown below.

First, the optical flow information in the video is extracted by the denseflow software, and the video is divided into frames. Recall (R) is used to measure the missing detection of extracted keyframes and can be expressed as follows:

$$R = \frac{N_c}{N_c + N_m} \times 100\%. \tag{7}$$

Here, N_c is the number of keyframes correctly extracted from the extracted results and N_m is the number of missed keyframes.

The open pose posture estimation tool is used to extract the coordinate information of human joints in the image and normalize it. First, the collected music data are divided, and the movement segments are connected and constructed in the dance movement database, so as to obtain the basic features of historical music and dance movements, extract some feature pairs by correlation analysis, and calculate the gender coefficient by the correlation between music and dance features. In order to avoid the situation that the weight tends to be long text, which is not conducive to short text, this study normalizes the weight of the calculated feature words, and the formula is as follows:

$$W(t, d) = \frac{1 + \log_2 tf(t, d) \times \log_2 (N/n_l)}{\sqrt{-\sum_{t\epsilon d}[(1 + \log_2 tf(t, d) \times \log_2 (N/n_l))]}}. \tag{8}$$

Here, $W(t, d)$ is the weight, $tf(t, d)$ is the frequency, N is the total number of all videos in the training set, and n_t is the number of documents, in which the feature word t appears.

In the actual work process, if the length of the lens and the complexity of the video content under the lens are not considered, if the lens is too long, it is difficult to summarize the content of the lens with only a few music clips. Therefore, relevant features are extracted from the original data according to the needs and analyzed and processed in combination with the differences of various feature information. The difference here is defined as follows:

$$\Delta\ dis(w) = \frac{abs\left(chi_i - chi_j\right)}{\sqrt{\max\left(chi_i, chi_j\right)}}. \tag{9}$$

Second, we constructed temporal and spatial convolutional network models based on the Res Net152 structure, respectively, and then fine-tuned the dual-stream network model by migration learning to obtain high-level semantic features, image functions, and optical stream functions of RGB. In this system, audio features and lyric features are fused at the feature level, and the fusion is done in a linked manner. That is, the features of the two modes are directly linked to form a new feature vector. Unlike semi-infinite linear programming, it exploits the smoothing property of the objective function and uses gradient descent to update the kernel function weights. The kernel function weights are given by the following equation:

$$D_m = \begin{cases} 1, \left(\text{if} dm = 1, \text{and} \dfrac{\partial J}{\partial d_m} - \dfrac{\partial J}{\partial d_\mu} > 0\right), \\[2ex] -\dfrac{\partial J}{\partial d_m} + \dfrac{\partial J}{\partial d_\mu}\ (if dm\ > 1, \text{and}\, m \neq \mu), \\[2ex] \displaystyle\sum_{i=1} \dfrac{\partial J}{\partial d_v} - \dfrac{\partial J}{\partial d_\mu}\ (if m = \mu)\,. \end{cases} \tag{10}$$

Here, D_m is the direction of gradient descent.

To keep the input sample size sufficient and increase the number of input samples, the original audio stream is separated into continuous segments. The trajectories created by SIFT matching between video frames are one type, while the trajectories obtained by optical flow tracking sampling points are the other. The sampling sites are sampled near each sift point. Finally, we construct a spatiotemporal graph convolutional neural network model based on the graph convolutional neural network structure to capture the spatial information of the joint points in the time series. Then, based on the extracted audio sentiment features, these features are used to obtain a pixel-value representation of the lyrics based on the codebook. The new pixel value is considered as a background pixel when the nearest Gaussian distribution belongs to any of the above B Gaussian distributions; otherwise, it is a foreground pixel. Then, a sector template with a circular angle of 70° is rotated and slid in a circular area to obtain the vector formed by the sum of the Harr responses in each sliding window, and the direction corresponding to the maximum of the sum of the sums is chosen as the reference direction of the feature.

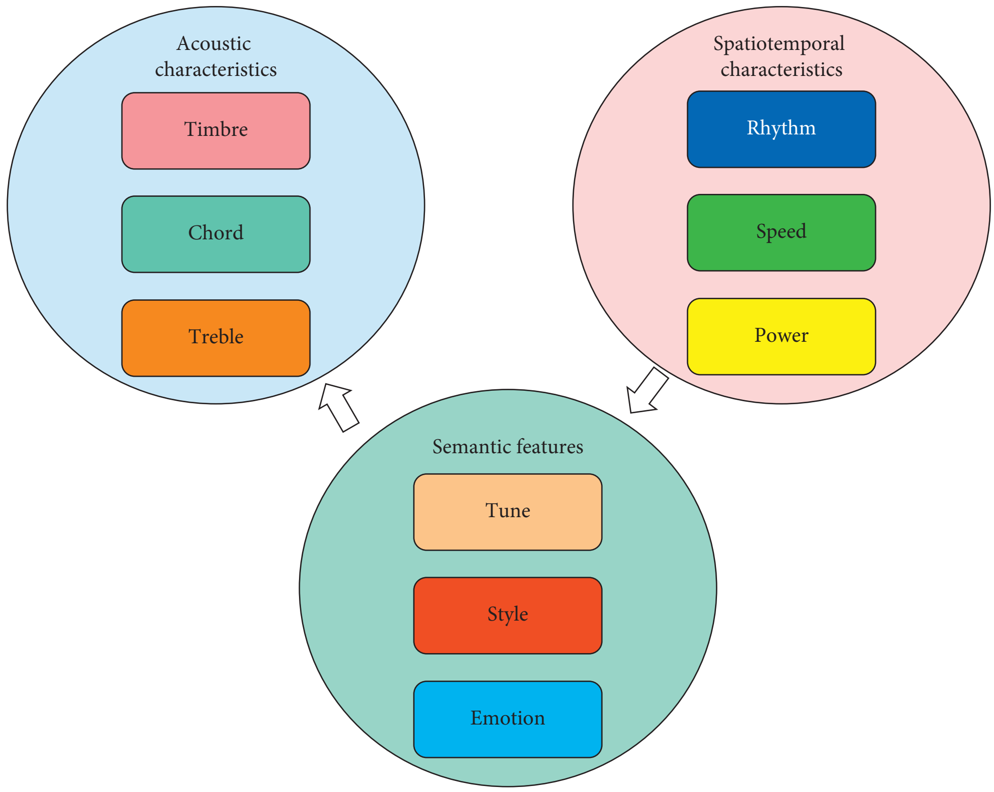

Figure 3: Hierarchical characteristics of music emotional cognition.

4. Simulation Analysis of Matching Optimization Based on Multifeature Fusion

4.1. Optimization Analysis. When we appreciate dance (especially the artistic dance carefully created by choreographers), music and its melody, harmony, rhythm, mode, and texture are indispensable components of dance works. In the process of music and dance movement matching optimization, based on the objective function of dance movement matching optimization, combined with the optimization simulation theory, the objective function is optimized. The concentration adaptively adjusts the pheromone volatilization factor, dynamically updates the pheromone according to the advantages and disadvantages of the optimal dance action matching scheme, and completes the dance action matching optimization in music choreography. Since the features extracted here are exactly the same as those in the single-mode music emotion recognition based on audio, the main factor to judge whether the two clips are similar is the feature factor, which is the feature value video obtained by matching the information. It is the principal component to measure whether two things are consistent with one result. Therefore, the characteristic factors should occupy a high weight. The accuracy of video clips in the two dance data sets under different weights is shown in Figure 4.

First, we create a sliding window containing many pixels in the window and use the median of all these pixels as the new value for the center of the window. Viewing a band in this window, the harmonic content remains fairly constant, while the shock structure is shown as a peak. Low-level music features usually use statistical function variables to summarize the variance or central tendency in the music. Among them, the boundary direction histogram is a boundary-based shape analysis method that is independent of the size and location of the image object, simple to compute, and can better describe the shape of the object boundary. In this section, the Mel spectrogram of the dataset is used as an input to select the appropriate size of music segments and the number of heads in the feature encoding network, and the results are shown in Figure 5.

Second, it sorts the gray values of all pixels in the window. After sorting, the median of the array is taken as the new value of the gray value of the central pixel of the window. According to the comparison results between the ratio of the nearest distance and the next nearest distance and the threshold, a pair of matching points is accepted, then one-way matching is completed, whether to obtain a group of candidate matching pairs is judged, and the same method of using the matching points of the next frame is used to inverse match with the previous frame to obtain a pair of inverse matching feature points. Because it is difficult to describe and measure an image frame accurately and comprehensively by relying on only one image feature, it is necessary to integrate several different image features to measure the similarity in order to describe the original image content more comprehensively and accurately. This study compares the different λ values that affect the experiment. The results show that the best test accuracy can be obtained when the value of λ is set to 0.05. The influence of self-

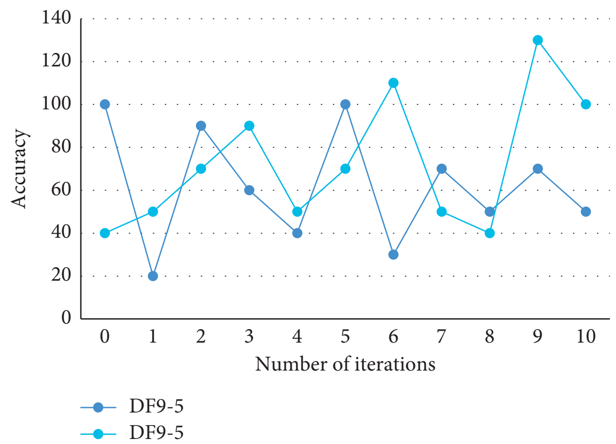

Figure 4: Accuracy of video clips in two dance datasets under different weights.

attention mechanism and net VLAD on a feature coding network is shown in Figure 6.

Finally, the directional gradient histogram feature used to describe the dance movement information is extracted from the image. Features are described as the boundary direction histogram, and texture features are described as wavelet transform containing various image features.

This is because the method in this study first incorporates music beat extraction theory to segment the synchronized dance movement and music data to obtain multiple short movement-music fragment combinations and calculate the correlation between the dance movement-music fragments. It is used to obtain the optimal objective function for dance movement matching, which improves the degree of dance movement-music matching in the music choreography performed by the method of this study.

4.2. Multifeature Fusion Analysis of Dance and Music. The smallest unit of any fully structured music is a part. The phrases and parts in a part are the internal building blocks of the structural unit. Similarly, the features of dance images provide other information for motion recognition, and image features provide appearance information closely related to the human movement in the image in the process of motion recognition. The comprehensive effectiveness of this method needs to be verified by simulation. The experimental data are from the dance action capture database provided by Carnegie Mellon University Laboratory, and the length of each music segment is about 5 seconds. Using the methods of this study and references [17] and [19], the optimization experiment of dance action matching in music choreography is carried out, and the matching degrees (%) of the three methods are compared. Figure 7 shows the comparison results of dance movements in music arrangement.

The results show that the average matching degree between the optimized simulation methods in this study is 87%, and the matching degree is very high. This is mainly because the method in this study first detects the transition point of a music segment, aligns the beat prediction position obtained in each stage, and adaptively adjusts the pheromone fluctuation factor according to the pheromone concentration of all music dance motion segments. The music arrangement uses the method of this study to match the dance movements well.

The calculation procedure is to use the k vectors clustered out in each video sequence about the sample centers of 3D joint node positions, the clustering centers of the joints in each vector, and the coordinates of the corresponding 3D joints in each frame of the video sequence to calculate the Euclidean distance, respectively. The appearance information of objects in an image can be well described by the direction of gradients or edges, and the method generates descriptors by calculating the statistical information of local image gradient directions. Two images can be generated by using a median filter to filter in the horizontal and vertical directions of the magnitude spectrogram of the descriptor. If the median filter is applied at the frequency, the shock events are enhanced and the harmonic components are suppressed. The best combination of features is input to the meta-CNN and the training process is visualized on the model GTZAN and Extended Ballroom datasets. The results are shown in Figure 8.

Second, in the training process, the feature pyramid network (FPN) extracts features and returns to the key points of human skeleton, and the simple key points will be basically completed in the FPN stage. The detailed network structure of FPN is listed in Table 1.

Multicore learning can be understood as having great interpretability when learning the weighted convex combination of several cores, and the weight coefficient is crucial for extracting features from different modes. It is possible that such a probability value is zero. To avoid the occurrence of zero probability, it is a common practice to apply various data smoothing procedures. A pixel with a significant difference value in two orthogonal directions is particularly unique and ideal for tracking, even if it is on an edge. As a result, the RGB picture data recovered from the keyframe, as well as the stacked optical flow generated by the keyframe and its surrounding 10 frames, are fed into the spatial and temporal convolution networks for testing. The results are listed in Table 2.

Finally, the strong and weak edges and details of each layer are separated by limiting the number of strong edges, then the layered mapping function is constructed for each layer, and point-by-point mapping is performed for each layer by enhancing the details of each layer and the contrast of the weak edges and keeping the strong edges, thus realizing the remapping process for each layer. The video frame with the largest C value is calculated, the index of the frame with that C value is obtained, and finally, the keyframes are sorted by index value, and if the number of indexes is the same, the keyframes are determined based on the sum of the calculated distance between the nodes in the frame and the nodes corresponding to the clustering center, and the one with the smallest sum is the keyframe. Thus, the edge features of each image of a video frame are accumulated in a single image, and finally, the directional gradient histogram features are extracted from the image of the accumulated edge features.

Number of keyframes	10	20	30
Accuracy (%)	44.8	52.9	89.8
Average consumption time (s)	3.6	4.2	2.1

5. Conclusions

Unique or expressive rhythms, such as strength, weight, and melody, are primarily used to define the integration of music and dance. Music sentiment analysis, such as music sentiment expression models, music review feature identification, emotional music classification, and emotional music search, is a hot trend in artificial intelligence. Music and dance matching is crucial in music discovery and can be used to manage and tag music content on websites and device music engines. On the basis of multifeature fusion, a strategy is given for optimizing dance technology movement and music matching simulation. By obtaining optimal performance on a dataset, multifeature fusion illustrates a good application case. The multifeature fusion-based dance and music matching optimization simulation approach, which includes feature extraction of music and dance movements, is described in this work. The dance music multifeature fusion and multifeature fusion-based matching optimization simulations are thoroughly examined. This aggressive and comprehensive matching approach is more universal and scalable, and it can give a platform for additional distinct songs and dances besides chime music and dance. In this way, the same cultural isomorphism, emotional isomorphism, affective isomorphism, and imagery synthesis of music and dance matching can both express the music's sensual characteristics and reach the audience's mind. Music expresses emotion, while music ultimately reproduces the form of space through dance, ultimately creating an audience through audio-visual fusion.

One of the most effective approaches to improve resource usage efficiency and degree of resource collecting is to integrate resources. Many studies on the integration of information resources are also available. The search engines are the most well-known. At the same time, this article intends to optimize the integration of British and American literature information resources by employing distributed cloud computing, based on the needs of British and American literature. This research develops a model for the dispersed nature of cloud computing. It optimizes the method by fitting the mathematical model of transmission cost and latency. This article analyzes the weaknesses of the current British and American literature information resource integration and optimizes them for the integration of British and American literature resources. The Random algorithm has the longest delay, according to the results of this paper's experiments (maximum user weighted distance). The algorithms NPA-PDP and BWF have longer delays than the algorithm Opt. The percentage decline varies between 0.17 percent and 1.11 percent for different algorithms. It demonstrates that the algorithm presented in this work can be used to integrate and maximize information resources from English and American literature.

1. Introduction

In the past ten years, cloud computing has experienced rapid development and has been widely used. Many commercial cloud computing service providers (cloud service providers, CSPs) began to provide a variety of public cloud computing services. More enterprises and organizations have also built their own private cloud infrastructure or built hybrid cloud facilities. Achieving efficient utilization and management of cloud computing resource pool resources can not only reduce service costs, but also improve service quality and competitiveness. The current problem is how to allocate resources to meet the service quality requirements of diversified businesses, reduce costs, and increase profits. Therefore, resource allocation is one of the most basic and core issues in cloud computing service deployment.

At the same time, the research on British and American literature is becoming more and more enthusiastic, and the demand for British and American literature resources is increasing. Whether it is a literary worker or the general public, the thirst for literary knowledge is getting higher and higher. However, the resources of British and American literature are widely distributed in archives, websites, and libraries around the world, which makes it difficult and costly to obtain. In addition, the language of British and American literature includes Old English, confused language, and other mixed languages, which are not easy to read. Therefore, combined with the characteristics of distributed cloud computing, it is necessary to integrate and optimize the global British and American literature resources.

The main innovations of this paper are as follows: it optimizes the delay and cost of migrating distributed big data of British and American literature to the cloud. Firstly, the selection target of data center during data migration is analyzed. It proposes an approximate algorithm for fair data placement and optimal data placement. It simultaneously extends the traditional k-supplier problem, the capacity-unlimited facility location problem, and the k-middle point problem. Aiming at the two goals of minimizing data placement for transmission cost and minimizing data placement for total cost, a nearest data center priority heuristic algorithm is proposed. The proposed algorithm can effectively reduce latency, save costs, and solve the problem that some data centers are unavailable due to regulatory restrictions or user preferences during data migration.

2. Related Work

In order to maximize the profits of CSPs and optimize the user experience, in recent years, it has become a trend to use multiple cloud networks to provide services in a unified manner. In the multi-cloud structure, cloud broker service has been recommended as a basic cloud service and has attracted extensive attention from industry and academia. Tsai and Lo proposed an efficient distributed mobile cloud computing service authentication scheme. His scheme reduces the authentication processing time required for communication and computation between cloud service providers and traditional trusted third-party services. Formal security proofs and performance analysis show that the scheme is both secure and efficient [1]. Hirai et al. modeled the task scheduling server as a single-server queue, where the server consists of many workers. When a task enters the server, the task is split into subtasks. Each subtask is served by its own worker and an alternate different worker [2]. Xiong et al. believed that, with the rapid development of mobile services, mobile cloud computing (MCC) has received great attention from researchers in academia and industry. He will design an enhanced and provably secure authentication scheme for distributed MCC services [3]. Kakade et al. eliminated the need for an uninterruptible power supply (UPS) in the data center by connecting direct current voltage from a backup power source directly to the motherboards of multiple servers in the data center. The alternating current power received from the electric utility service is converted to a lower voltage by on-site transformers and then supplied to one or more power distribution units on-site [4]. Liao et al. proposed an active data prefetching scheme on the storage server of the distributed file system for cloud computing. Experiments demonstrate that their proposed active prefetching technique can benefit distributed file systems in cloud environments to achieve better I/O performance [5]. Deng et al. proposed a distributed intrusion detection based on hybrid gene expression programming and cloud computing (DID-HGEP Cloud) for the massive and high-dimensional intrusion data behavior in cyber-physical power systems. Through comparative experiments, it is shown that the algorithm they proposed has obvious advantages in false attack rate, DAR, average time consumption, etc. Furthermore, the proposed algorithm has excellent parallel performance [6]. Alhazmi et al. believed that cloud computing provides on-demand IT services through large distributed data centers on high-speed networks. Virtualization is a key cloud computing technology. It allows service providers to offer computing services in a cloud environment without platform compatibility differences. He formulated the virtual network configuration in a geographically distributed cloud computing data center supporting SDN as a mixed integer linear programming (MILP) problem. The formulation of the proposed Optimal Virtual Network Provisioning (OVNP) model is studied by simulation. The experimental results verify the effectiveness of his proposed method [7]. However, through the summary of related research, it can be found that although the current research on distributed cloud computing is very in-depth, there is no research on resource integration for British and American literature. This is detrimental to the development of the resource integration of English and American literature in China.

3. Distributed Cloud Computing

Cloud computing has become the preferred platform for big data analysis [8, 9]. Especially when data is generated from multiple geographically distributed locations, local users need to use local data frequently, and sometimes all local data need further joint analysis. Therefore, it is more appropriate to use a cloud platform. For example, for a multinational sales company with many subsidiaries around the world, subsidiaries in each country need to analyze data generated by local users in a timely manner for business purposes. At the same time, all data should be aggregated and analyzed to report to headquarters or support cross-border transactions. For example, US demographic data is stored by state. Huge remote sensing data are stored in data centers across regions. Although these data are managed regionally, they may also require collaborative analysis for a common goal [10, 11]. Generally speaking, large-scale cloud computing is networked in a distributed manner. It has multiple geographically distributed data centers (Amazon has at least 11 DC1s across 4 continents; Google has at least 13 DC2s across 4 continents). Each DC configures computing and storage resources on a pay-as-you-go basis. This kind of infrastructure can provide nearby services and is especially suitable for data processing distributed across regions.

In order to process big data in cloud computing, the prerequisite is to migrate and store the data on a suitable data center (DC) [12]. Moving hardware directly is an optional way to move large-scale data. The Amazon Import/Export service, for example, recommends using removable storage devices to transport data, and sometimes it is even possible to move entire machines. But this is only suitable for infrequent, or one-time, bulk data movement. This method has a large delay and cannot meet the growing demand for real-time analysis of data. It also contradicts the idea of automated management and requires more labor participation. Transferring data over the Internet is very expensive and impractical due to the large delays. For example, it takes roughly 13 days to transmit 1 TB of data through a 10 MB internetwork. It is generally recommended to transfer real-time data over a high-speed dedicated connection (such as AWS Direct Connect1), which can speed up the transfer. But even relying on high-speed dedicated connections, transferring data across continents is difficult. For example, AWS

Direct Connect does not provide cross-continental service, and international private lines are too expensive. This limits the movement of all large-scale data across the globe to the same DC [13, 14]. Also, using a DC to store data results in more frequent local data analysis delays. Especially in some regions, data security laws require that some data must be stored locally (e.g., some countries in the European Union). All in all, it is necessary for users to follow some rules to choose a suitable storage location for their data. As Amazon suggests, being closer to the user can reduce latency in data usage, meet specific legal and regulatory requirements, or reduce costs, etc.

Figure 1 simulates the distribution of DCs and users (for simplicity, users are used to represent subsidiaries or data owners).

There are a total of 10 DCs and 9 users in Figure 1, spanning 4 continents. Different users can use different DC services or prefer different DCs. For example, users 4, 5 in Europe can only be scheduled to DC5, 6 in Europe. Users in Asia only prefer DCs in Asia Pacific.

Cross-DC data analysis is now possible with various MapReduce-based frameworks, such as G-Hadoop and G-MR [15, 16]. A lower-cost cross-data center big data processing method is also proposed in this research. Using numerous DCs instead of just one can meet the needs of comprehensive data analysis while also ensuring faster local data analysis and cheaper expenses.

Considering the underlying incomplete graph,

$$G = (U, V, E). \tag{1}$$

Among them, the side length

$$e_{ij} \in E, \quad (i \in U, j \in V). \tag{2}$$

It satisfies trigonometric inequalities, as well as positive integers $k\,(k \le |U|, k \le |V|)$. This chapter aims to find a DC subset D ($|D| \le k$) from the available DC set V to store the data of all users in U according to different goals. For any $i \in U$ and $j \in V$, if user i's data can be moved to DC j (at least not restricted by regulations or excluded by users), there is an edge between them. This problem assumes that all i are adjacent to at least one j; otherwise the problem has no solution. Also it assumes that

$$|E| = m. \tag{3}$$

Among them,

$$m \le |U| * |V|. \tag{4}$$

Each user is assigned a weight w_i, which represents the activation level of current or foreseeable future data generation, or the importance of local users. w_i increases with the amount of data or the importance of the user. The activation level rather than the data volume is used because it can tolerate the dynamic changes in the data while providing a modest approximation to the data volume. The activation level can be based on the amount of data uploaded per day. For example, for a typical company uploading 200 GB per day [17], 10 GB can be used as the threshold for determining the activation level. If a subsidiary generates less than 10 GB of data per day, a weight of 1 can be assigned. For subsidiaries between 20 and 30 GB, a weight of 3 is assigned. By analogy, for user i with activation level w_i, a fee $w_i e_{ij}$ will be charged to move data to DC j.

Each DC has a different price for compute and storage resources. For more economical storage and processing of data, lower prices are of course preferred. Given DC j, assume that the price of one VM instance processing data per hour is a_j. On average, such instances are able to analyze b_j GB of data per hour. Then, the price for processing 10 GB of data is

$$p_j' = \frac{10 * a_j}{b_j}. \tag{5}$$

If the storage cost for 10 GB of data is p_j'', then the total cost on the DC side for a user with activation level 1 is

$$p_j = p_j' + p_j''. \tag{6}$$

For user i with activation level p_j', if it wants to store and process data at DC j, it needs to pay $w_i p_j$.

Because of the high scalability of cloud computing, this chapter assumes that the DC has no computing and storage capacity constraints. For data integrity, a user's data is only stored in one DC. The target data center selection problem can be summarized as follows: it selects at most k target DCs and assigns each user to a target DC such that it satisfies the following objectives.

Fair data placement (FDP): the maximum distance between the user and the assigned DC is minimized so that each local user can access data with minimal delay:

$$\min D \subseteq V, |D| \le k^{\max}; i \in U, j \in D\left(e_{ij}\right). \tag{7}$$

Preferred data placement (PDP): the maximum weighted distance between the user and the assigned DC is minimized, allowing local users with more data to access data with minimal delay:

$$\min D \subseteq V, |D| \le k^{\max}; i \in U, j \in D\left(w_i e_{ij}\right). \tag{8}$$

If needed, it also uses

$$w(i, j) = w_i e_{ij}, \tag{9}$$

to represent the weighted distance.

Transmission cost minimization data placement (TCMDP): transmission cost is defined as the minimization of the sum of the weighted distances between all users and the DC to which they are assigned:

$$\min D \subseteq V, |D| \le k\left(\sum_{i \in U} j \in D\left(w_i e_{ij}\right)\right). \tag{10}$$

Total cost minimization (cost minimization data placement, CMDP): the total cost is defined as the minimization of the sum of the costs for all users:

$$\min D \subseteq V, |D| \le k\left(\sum_{i \in U} j \in D\left(c_{ij}\right)\right). \tag{11}$$

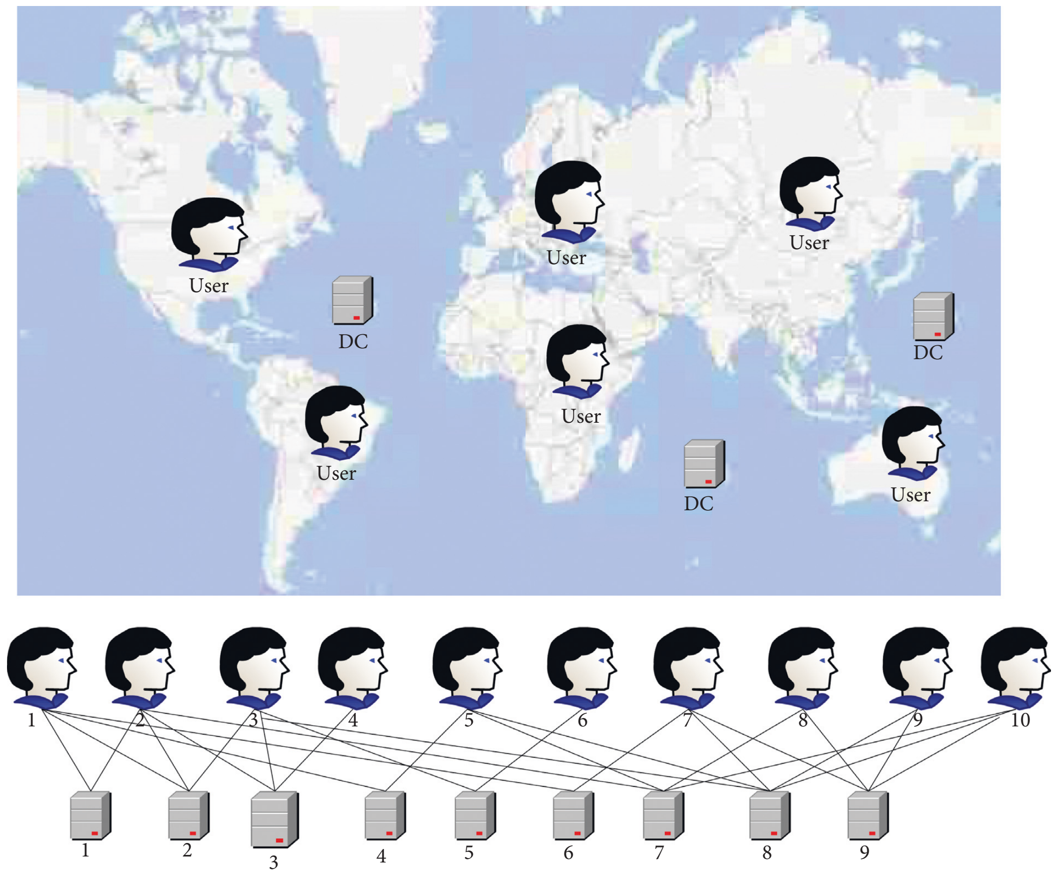

Figure 1: Data centers and users distributed across geographies.

It needs to note that goal 1 is a special case of goal 2 when $w_i = 1$. Goal 3 is a special case of Goal 4 when $p_j = 0$, and subsequent discussions will focus on goals 2 and 4. The corresponding results can be directly applied to objectives 1 and 3, respectively.

Suppose x_{ij} is a Boolean variable that indicates whether user i is assigned to DCj. It is 1 if i is assigned to j, and 0 otherwise. y_j is also a Boolean variable that indicates whether DCj is used. It is 1 if used, and 0 otherwise.

The PDP problem wants to minimize the largest weighted distance z, where

$$w_i e_{ij} x_{ij} \leq z \; \forall i \in U, j \in V. \tag{12}$$

PDP can be formalized as the following 0–1 mixed integer program:

$$\begin{aligned} &\min z \\ &\text{s.t} \end{aligned}, \tag{13}$$

$$\sum_{j \in V} x_{ij} = 1, \quad \forall i \in U, \tag{14}$$

$$y_j \geq x_{ij} \; \forall i \in U, j \in V, \tag{15}$$

$$x_{ij} \in \{0,1\}, y_j \in \{0,1\}, \tag{16}$$

$$x_{ij} = 0 \text{ for some } i \in U, j \in V. \tag{17}$$

Constraint (13) guarantees that every user must be assigned to at least 1 DC. Constraint (14) guarantees that this DC must be used. And the number of selected DCs cannot exceed k (Constraint (15)). Moreover, not all DCs can be used by every user (Constraint (16)); that is, the underlying bipartite graph is incomplete.

CMDP can be formalized as the following 0–1 integer linear program:

$$\begin{aligned} &\min \sum_{i \in U, j \in V} \left(w_i e_{ij} + w_i p_j\right) x_{ij} \\ &s.t \;\; (13), (14), (15), (16), (17) \end{aligned}. \tag{18}$$

In the objective function, both e_{ij} and p_j are in normalized form. The first half $\sum_{i \in U, j \in V} w_i e_{ij} x_{ij}$ is the transmission cost. The second half, $\sum_{i \in U, j \in V} w_i e_{ij} x_{ij}$, is the cost of storing and processing data in the data center.

PDP is an extension to the k-vendor problem, while CMDP is a common extension to the UFL and k-middle point problem. Because of the k-vendor problem, both UFL and k-middle point problems are NP-insoluble [18, 19]. So both PDP and CMDP are NP-insoluble. This section presents an approximation algorithm for PDP and a heuristic algorithm for CMDP. For the convenience of reading, the special summary abbreviation table is shown in Table 1.

4. Strategies and Methods for Integrating Information Resources of British and American Literature

4.1. Engine Search Aspects. The search engine is mainly composed of four parts, namely, the information collector (robot or spider or crawler), the analysis indexer (indexer), the searcher (searcher) and the query interface. The composition and structure of the current mainstream search engines generally include miners for data mining and user information mining [20]. Its connection mechanism is shown in Figure 2:

The availability of engine search is poor, and it is difficult to cope with the challenge of information islanding. The countermeasures include improving the ranking of mainstream engine search and improving the daily management system of engine search by improving the intelligent search engine. One of the major reasons why users cannot find the information they need is that they are not familiar with literature classifications; that is, users may not understand the classification information of English and American literature websites. Or the literary works recommended by the website are too professional, so that users cannot find the information they need when searching in plain language.

A better solution is to filter the correspondence between the vernacular words and the official words according to semantic analysis and probability statistics by collecting the search keywords of users on British and American literature websites. And according to the corresponding relationship, a lexicon of common people is generated. After receiving the vernacular words input by the user, the intelligent search engine system will query the Baiqiao style thesaurus, obtain official words matching the vernacular words input by the user, and search the website according to the obtained official words. Intelligent guidance, keyword association, and other technologies used in business engines such as Baidu are widely used to intelligently correct and sort retrieval results, so as to facilitate user retrieval. At the same time, box calculation can also be used to optimize the user's search results. The difference between this approach and the traditional approach is that, in the traditional search, users need to filter the search results. This kind of search system displays application services on the search result page by formulating association rules and engine search application containers.

When users use the search system to retrieve the information they need, they often do not search the system through the engine on the homepage of the English and American literature website but directly retrieve the required information in the mainstream search engine. Therefore, the search for British and American literature can improve the ranking of website information resources by purchasing services on mainstream engines such as Baidu. It can learn from the relatively mature engine search optimization guidelines in the United States and the United Kingdom and strive to enhance the visibility of information resources.

In the engine search of English and American literature websites, the latest search is empty, the information resource structure is single, and the update is not timely, which will cause the poor search function of the engine. Therefore, this article recommends that an experienced and first-class technical information management professional team be responsible for the maintenance of the search system, and to update and maintain the system in time. At the same time, English and American literature websites can consider using information integration and real-time monitoring procedures for user experience to achieve automatic integration and manual integration, daily integration and emergency integration, individual integration, and coordinated integration. In this way, a complete management chain such as real-time information monitoring, crisis early warning, and emergency response can be realized, and the search ranking of information resources on Chinese English and American literature websites can be improved.

In the face of the impact of emerging information technologies such as big data and the threat of information islanding, the website management department should put the needs of citizens first. This is also the core of the new

Table 1: Algorithm abbreviation correspondence table.

Name	Abbreviate
Fair data placement	FDP
Preferential data placement	PDP
Transmission cost minimization data placement	TCMDP
Cost minimization data placement	CMDP

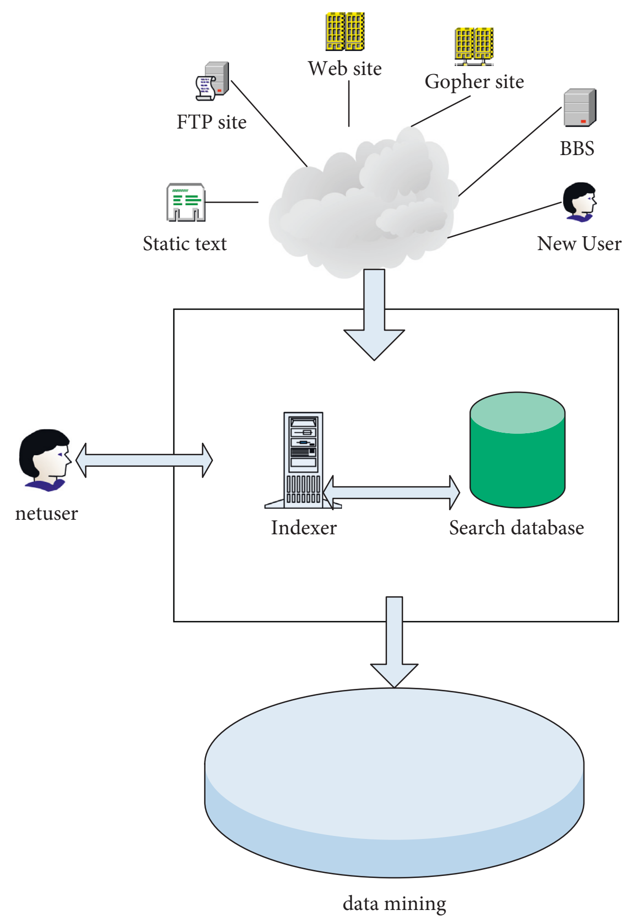

Figure 2: Search engine basic structure process.

public service theory; that is, the engine search design of the website should be more humanized and intelligent. The website content should show more hotspots that are closely related to civic life. The management department should take citizen satisfaction as the basis for evaluating website performance. Open data should be more concerned with fulfilling citizens' needs for specific data. On this basis, website management can consider strengthening the top-level design to improve the information resource management system. Website management should continue to improve the intensive construction of infrastructure, avoid duplication of construction, and improve the efficiency of equipment use.

4.2. Content Integration of British and American Literature. Internet search and information disclosure are the core and private content of Chinese British and American literature websites. It examines website content integration from the perspective of web search. It conducts an online survey on the online search services of English and American literature websites across the country. The current network search services are summarized as follows: (1) based on the account of the English and American literature website at the same level, the Internet search service of Bukou is integrated. The main feature of this model is that the service interface is unified and easy to integrate. However, this form of integration only guides users to the websites of various ministries, districts, and counties through address links for online search service requirements and does not actually integrate service resources on a unified platform. (2) Relying on brick-and-mortar bookstores, the online center at the same level is integrated. The advantage of this mode is to provide users with a unified login entry, and to realize the combination of the front-end service and the back-end service system; that is, the English and American literature website already has a service system. However, there are problems such as inconsistency in the handling process and service content between the newly built service integration platform and the already built service integration platform.

From the angle of information disclosure of English and American literature websites, the integration of website content is investigated. By analyzing the search, download, and reading usage of British and American literature websites, it finds that the biggest shortcoming is that although the number of British and American literature websites has been increasing actively, the number of applications for disclosure has not decreased accordingly but has continued to increase. In the software evaluation, the websites of districts and counties within the range of 600 were also tested. It found that about 90% of the websites were blocked and the updates were not timely enough. More than 80% of the websites have the phenomenon that the page cannot be opened or the function cannot be used. 90% of websites have fake links, dark links, and unusable links. The operation, maintenance, and management of grassroots websites need to be improved.

4.3. Open Data Integration of British and American Literature. The evaluation report on the construction of English and American literature websites of the State Information Center believes that, in the construction of open data, the situation of information islanding is serious. In a research evaluation of the practice of open data on British and American literature websites across the country, it was found that, as of May 2019, 86.25% of the data were updated annually or not at all. Only 13.75% of the data are updated monthly or daily.

From the problems of open data platforms, it can be seen that the number of data applications provided by open data platforms in various places is poor. Although some platforms have opened data application channels, the existing "applications" on the platform are not downloadable and useable data applications, but only the results of functional tests. Although some platforms provide downloadable and useable data applications, most of them do not use the data of this site or only use basic data such as geographic location in a shallow level. Or even if the data of this site is used, it does not explain which data is used. Some platforms offer "data apps" that do not live up to their name. In fact, it is the business processing system of local literature, and it is the source of open data, not the practical application after data opening, which greatly dampens the enthusiasm and creativity of users.

First of all, many British and American literature websites lack the awareness of change and do not realize the impact of big data and other information technologies on Chinese British and American literature websites. The main problem is that information technology such as big data is only understood as a common technical means. It did not realize that big data would improve the integration efficiency of information resources of English and American literature websites and promote the reform of literature administration. Many developers are not clear about the trend of e-government reform such as open data and even have resistance. Developers' awareness of technological innovation needs to be enhanced. Secondly, it is difficult for the laws and regulations of China's informatization standards to keep up with the pace of technological change. The laws and regulations of electronic technology informatization and big data construction are relatively lagging behind. The information integration of Chinese English and American literature websites requires the personnel in charge of British and American literature websites to strengthen the top-level design, enhance the efficiency of Chinese big data to promote the information integration of British and American literature websites, and improve the pertinence of problems. Finally, the talent construction of Chinese English and American literature websites cannot meet the impact of big data and other information technologies. The phenomenon of insufficient innovative talents and professional and technical talents, low level of internationalization of talents, and serious loss always exists. The key reason lies in the disconnection between China's e-government personnel training system and selection system. This requires China's public service department to reform its management system, select the right talent in an unorthodox way, and break down the identity barrier. Only in this way can it form an open, inclusive, and orderly pattern of talent selection.

5. British and American Literature Information Resource Integration System

Aiming at the problems existing in English and American literature websites and search platforms, this paper focuses on three aspects: engine search optimization, content integration optimization, and public information integration optimization. Combined with the low cost and high efficiency of distributed cloud computing, combined with the problems of wide distribution of English and American literature websites and many kinds of languages, it optimizes the experiment and cost of the website.

5.1. Optimization of Engine Search. To evaluate the impact of DC size on the BWF algorithm, it is assumed that users 1~9 can be served by different numbers of candidate DCs. It adds one DC at a time to DCs 1~10 in order from 11 to 14. The performance of each algorithm is shown in Figure 3.

As shown in Figure 4, the time delay (maximum user weighted distance) of the Random algorithm is the largest. The delays of the algorithms NPA-PDP and BWF are larger than those of the algorithm Opt. First, the algorithms NPA-PDP and BWF both choose DC2, 6, 9. When the number of DCs increases from 10 to 13, the delays of the algorithms NPA-PDP and BWF and the assignment relationship from users to DCs are the same. This is because none of the 3 DCs added subsequently are better than the preceding DCs, so none of the 3 DCs are chosen. When DC14 (Beijing) is added, the delays of algorithms NPA-PDP and BWF both increase. The reason is that user 8 (Xian) has the largest user weight, so the algorithm selects it as the user representative for the Asia-Pacific region. Because user 8 is closest to DC14 (Oakland), the algorithm abandons DC9 and chooses DC14 instead. Users originally assigned to DC9 are reassigned to DC14. This causes the delay to rise as the weighted distance between Beijing and Oakland.

The Opt. algorithm has the smallest delay. Although the number of DCs has increased, the delay has remained the same. Although the delay solved by the BWF algorithm is slightly larger than that solved by the Opt. algorithm, the average is about 5%. Experiments show that the Opt. algorithm can only optimize the main objective function value but cannot optimize the delay of other clusters. For example, the algorithms NPA-PDP and BWF both choose DC2, 6, and 9. Algorithm Opt. chooses 2, 5, 7. Among the three algorithms, the users served by DC2 are the same, namely, users 1, 2, and 3. NPA-PDP and BWF assign users 4, 5 to DC6. And Opt. assigns them to DC5. Users 6, 7, 8, and 9 are assigned to DC9 by algorithms NPA-PDP and BWF, and assigned to DC7 by algorithm Opt. The delays for each user are compared in Table 2. Obviously, the total delay of the Opt. algorithm is larger than that of the other two algorithms. This is because the Opt. algorithm cannot consider all clusters.

The experiment also increased the number of users from 9 to 19. It joins two users at a time in numerical order. The delay results are shown in Figure 5.

When users 18, 19 join, the delay changes because their minimum weighted distance is greater than the current delay. This also reveals that even if the number of users increases, it is not necessary to use more DC. Only when more distant users join is it possible to cause greater delays and thus require more DCs. Although the Opt. algorithm finds the optimal solution, the experiment again observes that the total delay of the Opt. algorithm is larger than that of the BWF algorithm. Although limited by the randomness of user location selection, a purely increasing delay curve cannot be drawn, but the simulation results still reveal a trend: the delay will not decrease as users join.

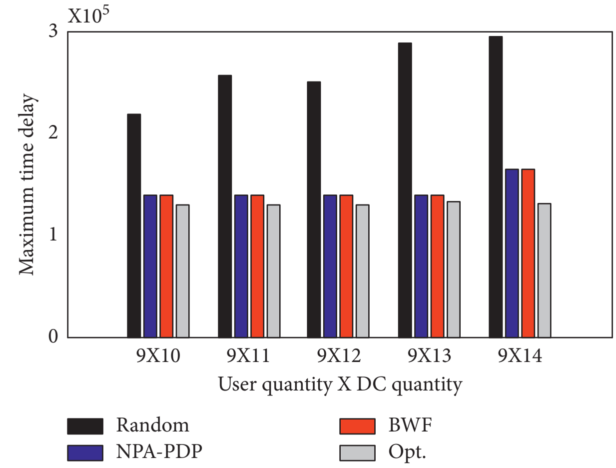

Figure 3: Comparison of the maximum delay obtained by the algorithm when the number of DCs increases.

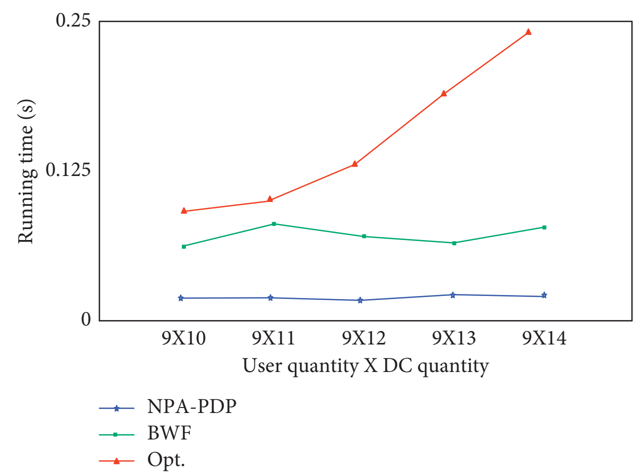

Figure 4: Comparison of algorithm running time when the number of DCs increases.

Table 2: Opt. algorithms cannot optimize every cluster.

User	BWF	Opt.
User 4	6679	25189
User 5	5137	23172
User 6	17893	9496
User 7	18542	54108
User 8	38263	88790
User 9	141337	134541

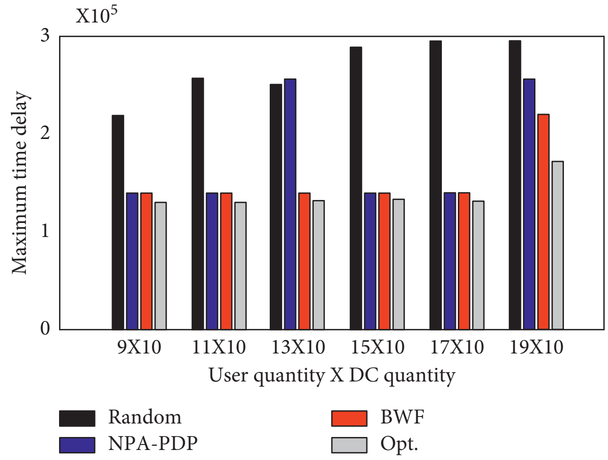

Figure 5: Comparison of the maximum delay obtained by the algorithm when the number of users increases.

It is worth noting that when users 12 and 13 join in, the delay of NPA-PDP algorithm increases sharply. This is because the NPA-PDP algorithm simply deletes a DC without considering the user's grouping attributes. This also reflects the instability of NPA-PDP algorithm.

In terms of running time, Random algorithm and NPA-PDP algorithm are faster than the other two algorithms. All in all, the Opt. algorithm requires more time than the BWF algorithm. With the addition of DCs and users, the time consumption of the Opt. algorithm increases rapidly. The time consumed by the BWF algorithm is much slower, so it is more suitable for large-scale applications.

5.2. Content Integration and Optimization. In order to make full use of the various dimensions of PM resources, this section introduces the "similarity" boxing mechanism. Figure 6 reveals the effectiveness of this mechanism. Simulation experiments are carried out for three scenarios, and the three sets of experiments include 450, 900, and 1500 VMs, respectively. In each set of experiments, the residual resources of each dimension of PM used were compared in the order of network bandwidth (N), CPU (C), memory (M), and hard disk storage (D). It can be seen from Figure 6 that the algorithm achieves a balanced use of resources in each dimension.

In order to save resource costs without compromising quality of service requirements, this section formalizes the problem as a stochastic multi-objective nonlinear programming. It targets a common situation (that is, VMs can be independent or related, and PMs can be heterogeneous and networked in a tree topology), while optimizing server and network bandwidth, which account for most of the data center cost. VM partitioning, statistical multiplexing, and "similarity" methods are used to implement a new offline algorithm and a new online algorithm. The effectiveness of the algorithm is verified through extensive simulation experiments. Experiments show that the algorithm proposed in this section is more effective. Not only do they drastically reduce PM and network-related resource costs, but they also guarantee a suitable quality of service.

5.3. Integration and Optimization of Public Information. The number of PM in each DC follows a U(3050) distribution. And the type of PM is uniformly chosen from four options. PM's configuration is based on the IBM SystemxM5 and Systemx3300M4 server types. The resource configuration requirements of the VMs in this chapter are based on the setup of four types of VMs from Amazon EC2's m3-series (for consistency with PM, GB is used to replace GiB). The M3-series is the most representative and is designed for general use. The number of logical cores per PM is equal to or at most twice the number of physical cores, according to VMWare8. The number of logical cores in a PM cannot exceed the number of vCPUs in a VM. Assume that vCPUs and physical cores have a one-to-one connection; the details are provided in Table 3.

Table 4 reflects resource pricing as well. Experiments strive to use Amazon as much as possible to expose data in order to maintain prices consistent. Because of the complex interaction between PM setup and VM resource requirements, only the medium type resource pricing is shown here. The prices of the remaining categories are expected to have the same multiplier relationship; for example, the price of xLargeVM with 4 vCPUs is four times that of the medium type. The pricing for storage is from Amazon S3. It may be computed that transferring 1 GB of data costs $0.0243 using the Amazon Import/Export service pricing.

TLGGA convergence is seen in Figure 7 when there are four DCs (DC1DC4). The value of the objective function decreases rapidly and the curve is highly steep in the first 200 iterations (including crossover, mutation, and local optimization of all populations), according to simulation experiments. The curve begins to flatten down over the next 800 cycles. The goal function value declined extremely slowly after roughly 1,000 times, despite the fact that the method took longer. In less than two seconds, a good solution can be found.

There is a similar convergence pattern for different numbers of DCS. The cost values for 1,000 and 10,000 iterations are shown in Figure 8. It demonstrates that multiple repetitions do not result in a proportional reduction in the goal value. The decrease in percentage was merely 0.17 percent to 1.11 percent.

The use of Reducer deployment in Hadoop for big data processing across data centers is examined in this study. It first formalizes the challenge as a two-tier plan to keep expenses down and follow typical Hadoop localization principles. Layer 2 planning can take into account the co-selection of a DC and a server at the same time. The new architecture is then used to offer a novel cross-data center large data processing technique based on key distribution. The Reducer can be deployed to the DC with the greatest data to process and the lowest cost of other resources with this approach. Finally, the system is implemented using a two-layer grouping genetic algorithm (TLGGA). The approach employs a local optimization strategy and a customized starting population creation mechanism. TLGGA's efficiency is demonstrated through simulation results. It outperforms both the baseline Hadoop method and the most recent G-MR algorithm.

6. Conclusion

This paper focuses on the global British and American literature websites and studies the resource allocation algorithm in distributed cloud computing. Firstly, based on the sequence of cloud computing service deployment, it adopts the top-down engineering theory method to divide cloud computing deployment into three stages: cloud network selection, data center selection, and server selection. Then, based on the specific business, it systematically studies the resource allocation methods in cloud computing according to the different goals and resources required by the business in each stage. Resource allocation based on distributed cloud computing still has many problems to be solved. The next step will focus on the research of distributed cloud computing algorithm.

This paper proposes a new algorithm composition network from the perspective of machine learning, based on an in-depth study of related literature. At the same time, this paper examines the characteristics of music and develops a model for recognising musical emotions. Using the model's information entropy of pitch and intensity to extract the main melody track, note features are extracted from bar features. Finally, the cosine of the vector included angle is used to judge the similarity between feature vectors of several adjacent sections, allowing the music to be divided into several independent segments. The emotional model of music is used to analyze each segment's emotion. By quantifying music features, this paper classifies and quantifies music emotion based on the mapping relationship between music features and emotion. Music emotion can be accurately identified by the model. The model's emotion recognition accuracy is up to 93.78 percent, and the algorithm's recall rate is up to 96.3 percent, according to simulation results. The recognition method used in this paper has a higher recognition ability than other methods, and the emotion recognition result is more reliable. This paper can not only meet the composer's auxiliary creative needs, but it can also help intelligent music services.

1. Introduction

With the development of economy and society, people put forward higher requirements for spiritual life. In today's society, people's entertainment life is richer and more diverse, and music is a special social ideology, which can not only cultivate sentiment and regulate emotions, but also develop thinking and glow emotions, and it has a strong appeal [1]. Music is becoming increasingly important in human life as a spiritual food. Simultaneously, digitalization, as the core of information technology, has aided the rapid development of a variety of emerging technologies; digitalization of audio has become the digital trend's intermediate force. As a result, the marriage of computer and music has become a research hotspot [2]. "Computer music" is a new technology that combines music art and computer technology. It is an important component of multimedia technology. Music has a higher scientific and technological content, as well as its own distinct and colourful artistic expression. The use of algorithms to create musical works is known as computer composition. One method of composing music is to use an algorithm set [3]. More researchers have devoted themselves to the research field of algorithmic composition because concrete music and random music differ greatly from the theoretical system and creative thinking of traditional composition techniques. Probability model, rule system model, genetic algorithm model, and NN (neural network) model are the most commonly used algorithm composing methods today. The motivation of composition and the development of motivation are precisely the application of these thoughts as the guidance of technological innovation in the universal law of music creation. The composition algorithm is both a simple mathematical operation and an expression of the artistry that exists in human thought. Computer automatic composition will greatly improve music creativity as machine learning advances, while also assisting composers in generating new creative ideas. However, as the amount of music produced grows, it is becoming increasingly important to classify and manage it.

The application of algorithms to solve specific problems is at the heart of algorithmic composition on a theoretical level, and the knowledge contained therein comes from musicology, mathematics, computer science, and other disciplines. These levels encompass not only specific technical methods of theoretical techniques and mathematical operations, but also a deeper expression of human thought. Music comes from life and reflects the creators' emotions [4]. Music is a psychological process that includes a variety of human emotional factors that are produced when people interact with music. Because of its heavy workload, difficult description, and impersonality, the early text annotation method has some limitations. Furthermore, as digital music production technology advances and the number of different types of music styles grows, text-based music retrieval becomes obsolete, and people begin to investigate new classification retrieval methods to aid in the retrieval of target music from massive data. The advantages of digital music over traditional music are primarily in the areas of production, storage, dissemination, and retrieval. Users' demand for music emotion can be met by emotion-based retrieval. In addition, a real-time soundtrack for multimedia video should be created based on the emotion conveyed by the video content. Music emotion recognition is a pattern recognition task, and the mapping of data from high-dimensional music feature space to low-dimensional emotion space must be done correctly. However, most musical emotion studies are limited to categorising an entire piece of music into one emotional category. Music's emotion, on the other hand, is not static. This paper uses a machine learning algorithm to create a model of music composition and emotion recognition. The following are some of its innovations:

(1) There is basically no complete set of music data expression rules in algorithmic composition system. Based on the in-depth study of related literature, this paper proposes a new algorithm composition network from the perspective of machine learning algorithm [5–7]. It restrains the style and quality of generated music by using music theory rules to construct a reasonable Reward function. At the same time, the general machine learning methods created by deep learning network in the field of algorithm are summarized, so as to generate music with polyphonic structure. It can meet the composer's auxiliary creative needs and provide more support for intelligent music services.

(2) In this paper, the average pitch, average sound intensity, speed, and other characteristics are analyzed, and the classification model of emotion feature vector input is constructed. It can select an appropriate formula according to the applied scene; at the same time, several adjustable parameters are set to adjust the similarity. This paper classifies and quantifies music emotion according to the mapping relationship between music characteristics and emotion by quantifying music characteristics. The model can accurately identify the emotion of music.

2. Related Work

Computer-aided music creation and algorithm-based music creation have a long history since computers and digital systems were widely used. At present, researchers have put forward various methods for computer composition, among which the influential ones are hidden Markov chain, rule-based system, music grammar, genetic algorithm, NN technology, etc.

Zheng and Lu used LSTM (long short term memory network) to process blues music of twelve bars and realized the generation of chords and melody in blues music [8]. The hidden layer of the model uses four LSTM modules, the input is the current note, and the output is the predicted note at the next moment. Jenke et al. mainly introduced the related research on algorithmic composition using recursive NN. For the possible gradient vanishing problem, the LSTM algorithm that avoids the gradient vanishing problem is used [9]. Zhang et al. applied generative adversarial networks to algorithmic composition and created the MidNet popular melody generation system [10]. In this network structure, the CNN (convolutional neural network) used by both the generator and the discriminator is trained by converting the midi format data set into a piano roll and inputting it into the network. Then the generator inputs random noise and generates music melody, and then the discriminator will make a true or false judgment on the generated melody. Majumder et al. mainly used the sampling of audio data and mainly designed and innovated the structure of NN [11, 12]. However, this method has certain limitations on the accuracy of preprocessing of music data. Hong et al. adopted a trained LSTM to predict the next note in a monophonic melody and used reinforcement learning to enhance it [13].

With the continuous development of various disciplines, scholars have done a lot of work in the research of music emotion. People gradually recognise people's response mechanism to emotion, establish a unified emotional standard, and establish an open and correct corpus. The unified algorithm evaluation system has continuously promoted the development of emotion recognition technology.

Jiang et al. used the SVM (support vector machine) classification algorithm to extract the spectral features of music and perform sentiment classification [14]. Mattei et al. studied a variety of acoustic features, including low-level features and features such as melody, pitch, and high-level genre, style, etc.; these features were then reduced to a D-dimensional space and associated with semantic features. Finally, automatic recognition of music emotion was done using k-nearest neighbor algorithm [15]. Kaya and Salah explored the effectiveness of random forest classification algorithm in music emotion recognition [16]. Compared with the SVM classification algorithm, this method has greater advantages in generalization and robustness against noise and is very suitable for audio classification tasks. Nordström and Laukka used a continuous emotional mental model and used regression modeling to predict the emotional value of music, using two fuzzy classifiers to measure the emotional intensity to identify the emotional content of music [17]. Yun et al. completed music emotion classification by extracting the pitch, width, and brightness features of music frequency domain [18]. Wang et al. used the SVM method to identify the emotional type of music by extracting the spectral features of music and training these features [19].

The related literature of algorithmic composition and emotion recognition is thoroughly examined in this paper, and a composition and emotion recognition model based on a machine learning algorithm is proposed. According to the information entropy of pitch and intensity, this paper extracts the main melody track. Second, take note features and extract bar features. Finally, the cosine of the vector included angle is used to judge the similarity between feature vectors of several adjacent sections, allowing the music to be divided into multiple segments. The speed, melody direction, intensity, tempo, rhythm change, major third degree, minor third degree, and timbre of each segment are extracted using digital music feature extraction technology, and the emotion of each segment is analyzed using a music emotion model. This paper employs a two-layer filtering mechanism in order to improve retrieval speed. To begin, dissimilar music is quickly filtered out based on time length and category vector. The user is then presented with the most similar music, which is calculated using the exact similarity calculation formula. The study found that the model's retrieval speed is faster, its accuracy is higher, and all indexes are high.

3. Methodology

3.1. Algorithm and Emotion Recognition. The regular vibration of the vocal body produces music, which is a type of sound art. The composer's inspiration and music creation rules, which primarily include the melody, interval, harmony, chord, mode, and form of music [20], are used to create music. Music's allure stems from the unpredictable nature of creative motivation, and the new auditory experience it provides can often elicit emotional resonance. Music can convey emotions and regulate the mood of listeners as an important part of human life. It is an important aspect of emotional music, and the relationship between computer music, music, and emotion has sparked a lot of research. The various elements of music work together and have a constantly changing expressive force. Melody is the foundation of music, while other elements are the branches and leaves. The image of music will change to varying degrees as each element changes. Melody is a musical sound movement that is organised and harmonious according to certain rules. It is the most common way for musical works to express their feelings. Melody is the heart of music, the foundation of its creation, and the expression of music's image and thought. The pitch relationship between two tones is indicated by the interval. It measures the auditory distance between sounds in degrees, which is a normalised representation method. A sound combination in which multiple tones are arranged according to certain rules is referred to as harmony. The vertical combination of three or more pitches is known as a chord. When it comes to overlapping, it can be done in a third-degree or non-third-degree relationship. The absolute height of a sound is expressed by its phonetic name, which is the expression of its pitch frequency. Every song has a tonic, whose tuning height is represented by key signature and whose height is the key of the scale. Form is a musical structure that combines people's cognition of certain music works in a specific cultural context, and it is a summary of the theoretical laws of music. The smallest unit of sound behaviour in music is the note. A note is a sound that has a specific time length and frequency. In addition, the intensity and timbre of notes should be taken into account when describing them. We can derive the basic characteristics of notes from this: pitch, dynamics, duration, and timbre. Digital music is a new genre of music created with computer technology, stored in digital format, and distributed via digital media technologies like the Internet. Digital music, in comparison to traditional music, has taken on new characteristics as a result of the rapid advancement of digital technology.

The algorithm is a logical and systematic instruction for solving a problem that represents the description of a specific problem and the strategy for solving it. Through normative data input, an excellent algorithm can produce effective and standardized output results in a specified amount of time. Musical elements, writing logic, algorithm, structural model or rule system, and a series of composing techniques formed by matching algorithm thinking with the smallest decision-making model in composition thinking are all examples of algorithm concepts. Computer music differs from traditional music in terms of how it deals with sound, as well as the principles of sound creation and organisation. The creator's perspective and the computer's automatic learning of big data are two common approaches to computer composition. From the perspective of the creator, it is necessary to condense a large number of music-making rules into a single routine. This method produces high-quality music, but it takes a lot of manpower to establish rules and routines in the early stages. Big data [21, 22] automatic learning composition allows computers to learn the laws in music data and then compose music using calculators. Using a computer to learn from big data music can save time and money, and the music generated is more diverse. The way music is processed, manufactured, and organised differs significantly from traditional music. The irrelevance between playing method and timbre breaks through the quantitative limit of timbre [23]. Digital music has various sound effects, and its sound is produced by a point oscillator. However, at this time, the computer is unable to create music that reflects subjective emotion and thought. It is even more difficult to meet people's requirements for pleasant music by simply using a computer to compose music using an algorithm. And, like words, music has emotional connotations. The process of establishing music characteristics and music database is shown in Figure 1.

Music emotion is an essential feature of music, and more research on music information behaviour shows that emotion is an important standard used by people when retrieving music. In fact, there is no such thing as pure musical emotion, and emotion is only meaningful when it is associated with people. When it comes to the same emotion, everyone has different reactions. As a result, if you want to share your musical emotional experience with others, you

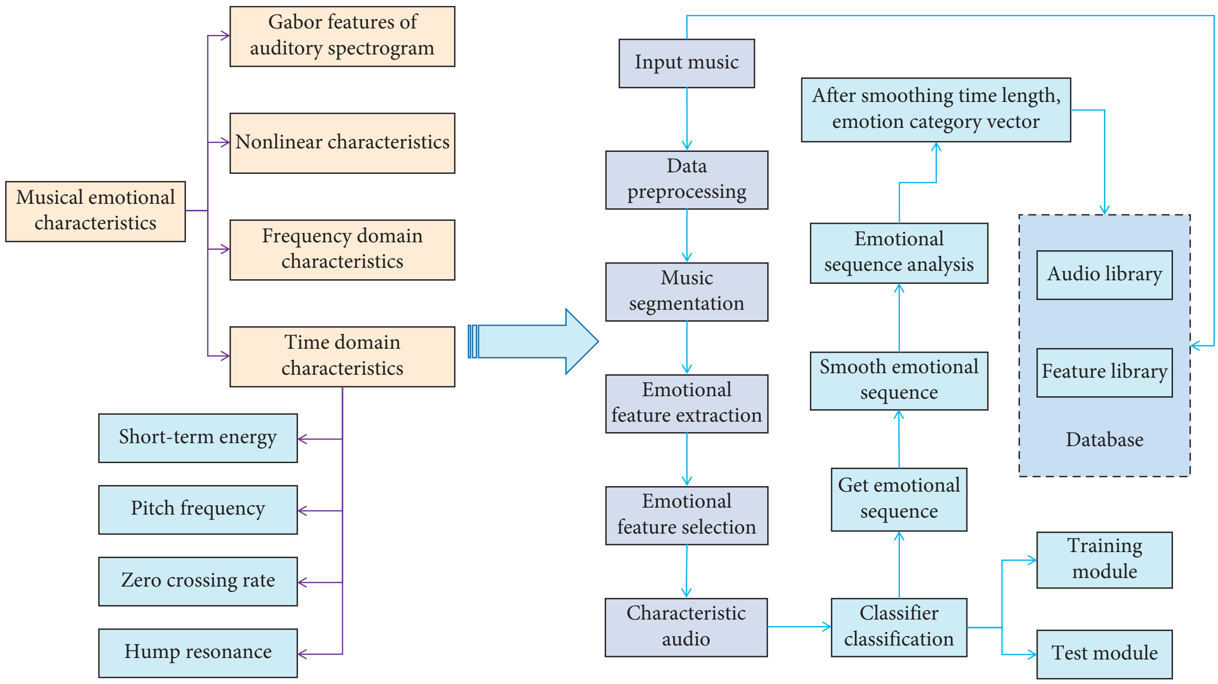

Figure 1: Emotional characteristics of music and the establishment process of music database.

must express music using a specific rule and symbol, and the same rules and symbols represent the same emotional expression in different types of music. Music emotion recognition, which is one of the important research directions in digital music, is at the heart of emotion-based music retrieval. Computers are unable to perceive the emotions contained in music. As a result, we should summarize the related elements of music into mathematical models and conduct quantitative analysis of them, so that the computer can recognise the emotional connotation of music based on its musical characteristic parameters and rules. Everyone's emotional response to music is a series of brain reactions following the acquisition of characteristic information from the music, with the results reflected in expression and psychological feelings. We must first understand the classification and expression of emotion types in order to study the relationship between music and emotion. Individual needs and desires mediate emotion, which is a psychological state. Emotion is difficult to quantify because it is complex and subjective, and different people have different levels of understanding of it. People have deepened their understanding of emotional types by constantly exploring the changing rules of emotions. At different points in time, a complete piece of music may have emotional changes. Music can be divided into two types of rhythms: fast and slow. Gentle rhythm refers to a slow-changing rhythm. The abrupt rhythm, on the other hand, is a rapidly changing rhythm. Music with a smooth rhythm can evoke a sense of calm, whereas music with an abrupt rhythm can evoke a strong sense of emotion.

3.2. Algorithm Composition and Emotion Recognition Model Construction Based on Machine Learning. Based on the deep learning theory [24], aiming at the problems existing in the current algorithmic composition system, this chapter puts forward a new NN structure of music creation from the perspectives of machine learning and music theory creation and constructs a music emotion recognition model. Different music formats have different structural characteristics and extraction methods [3, 25]. This section determines the format of music, making preparations for the extraction of emotional features of music. Generally, music files include three categories: sound files, MIDI files, and module files. MIDI file is a binary file that records the sequence of MIDI instructions. Its basic structure consists of header file and data description. In this paper, MIDI files are selected as experimental objects. The reasons are as follows: ① accurate sampling; ② easy feature extraction; ③ occupying less space; ④ high utilization rate. To begin, obtain the corresponding music score data and music data in MIDI format; after obtaining the music data, it is necessary to create a music data set in accordance with the standard; then, data normalisation, note extraction from music in MIDI format, and other preprocessing operations must be performed on the data input into the network. Multiple audio channels are usually used in MIDI music production because the music is more stereo and beautiful. The main melody is first identified from the MIDI format files in this paper. Input a classical music database in MIDI format, set initial notes to randomly generate music, collect the generated music, and construct a music generation sample database, marked as 0; mark the training data set as 1. Simultaneously, a binary classification model is built to pretrain the CNN network. The music sequence is generated by the LSTM network by setting the initial notes. LSTM, Dropout, Dense, Softmax, and other network layers are commonly used in this paper. After creating the appropriate music generation network, the network must be trained using the appropriate deep learning framework. The specific training scheme is to iteratively optimize it using cyclic operations until a satisfactory result is obtained or the specified number of iterations is reached. Figure 2 depicts the algorithm's emotion recognition flow.

This model is based on the chess game concept. The generated model is optimized by the Reward function, so that the generated music and the training sample have as much confusion as possible, and the recognition output probability of the classification network CNN is closer to 1; that is, the difference between the generated sample and the training sample cannot be distinguished, and music with similar style and theme to the training sample cannot be distinguished. The music feature analysis model is divided into two sections: one for extracting the main melody and another for extracting the musical emotional features from the main melody and constructing the musical emotional feature vector. The process of NN training is essentially the updating of weights. To update the weight between each neuron, the samples propagate forward through NN to get the output of the output layer and then backward to minimise the difference between the output of the output layer and the sample label. In this paper, a music evaluation function, Reward, is proposed, which can monitor and adjust the generated music in real time, make up for the deficiency of using LSTMNN alone for algorithm composition, make it closer to the composer's creative thinking, and meet the needs of the audience. In most music, the pitch of the main melody is generally higher than that of the accompaniment melody, and the basic contour algorithm is applicable to most music. However, for a small number of music with higher accompaniment melody, we cannot just use the pitch feature as the criterion to judge the main melody, so the basic contour algorithm has limited effect. To solve this problem, this paper proposes an improved contour algorithm based on track features to extract the main melody.

In order to improve the effectiveness of Reward function introduced in this paper, the reference value 1 is subtracted when calculating the probability, as shown in the following formula:

$$p_{(\mathrm{CNN})} = \begin{cases} 0, & \mathrm{fort} < T, \\ D_{\varphi}\left(a_{1:T}\right) - 0.5, & \mathrm{fort} = T. \end{cases} \quad (1)$$

If a piece of music has the interval difference between the adjacent notes in the a group greater than the octave, the remaining b group is less than or equal to the octave. It can be expressed by the following formula:

$$g_1(x) = \frac{a * 0 + b * 1}{a + b}. \quad (2)$$

In order to make the generated music more aesthetic, the following standards are set here:

$$\begin{aligned} I_b &\in \{0, 2, 3, 4, 5\}, \\ I_{bb} &\in \{0, 2, 3, 4, 5, 7\}, \\ I_{\longrightarrow p} &\in \{6, 7, 9, 10, 12\}, \\ N_{i=1} &\in \{1, 2\}. \end{aligned} \quad (3)$$

Among them, I_b, I_{bb}, and $I_{\longrightarrow p}$, respectively, represent the interval sample values corresponding to the measures within the measure, between the measures, and to the climax. $N_{i=1}$ is the number of minor second intervals in a piece, and the minor second can highlight the tension of the interval. If there are more than four consecutive notes at the same pitch and duration in a piece, this parameter will be recorded as 0; otherwise it will be 1.

$$g_3(x) = \begin{cases} 1, & \dfrac{1}{n-1}\left|\sum_{i=1}^{n-1} \mathrm{interval}_i \leq 4\right|, \\ 0, & \mathrm{else}. \end{cases} \quad (4)$$

The normalisation strategy in this system adopts the Min-Max scaling method, as follows:

$$X_{\mathrm{normal}} = \frac{X - X_{\min}}{X_{\max} - X_{\min}}, \quad (5)$$

where X_{normal} represents the normalised value of the digitized note data. X represents the digitized note data, $X_{\min}$ represents the digitized minimum value of note data, and $X_{\max}$ represents the digitized maximum value of note data.

The algorithm's quality evaluation mechanism plays an important role in improving the quality of music generation in the next step. This paper evaluates the quality of music from both subjective and objective perspectives in order to test the generating effect of algorithmic composition. The learning rate indicates how quickly weights are updated during the training process. The larger the amplitude of updating weights each time, and the faster the initial convergence speed, the higher the learning rate. However, an excessively high learning rate may cause the network to cross the minimum point, making convergence difficult. With the right learning rate, the objective function can converge to the local minimum in a reasonable amount of time. Music emotion recognition is the process of associating music with specific emotions based on the characteristics of the music and given reasoning rules. Emotion recognition is a mathematical mapping process that converts the features of dimensional music into dimensional emotion space. The main melody's relevant features are extracted from the melody of the alternative tracks in this paper to determine the likelihood of each track channel containing the main melody. The higher the score is, the more likely the main melody will be included. Six features of the alternative track melody are extracted based on the musical theory characteristics of the main melody when the related features of the main melody are extracted. These six characteristics are sound source balance, main volume, pronunciation area, loudness area, average pitch, and average sound intensity. Music is a kind of time series. In this paper, LSTM network is used to generate music series. LSTM has a special function of sequential memory. On the basis of ordinary multilayer NN, the structure adds the horizontal connection among the units in the hidden layer. Through a weight matrix, the

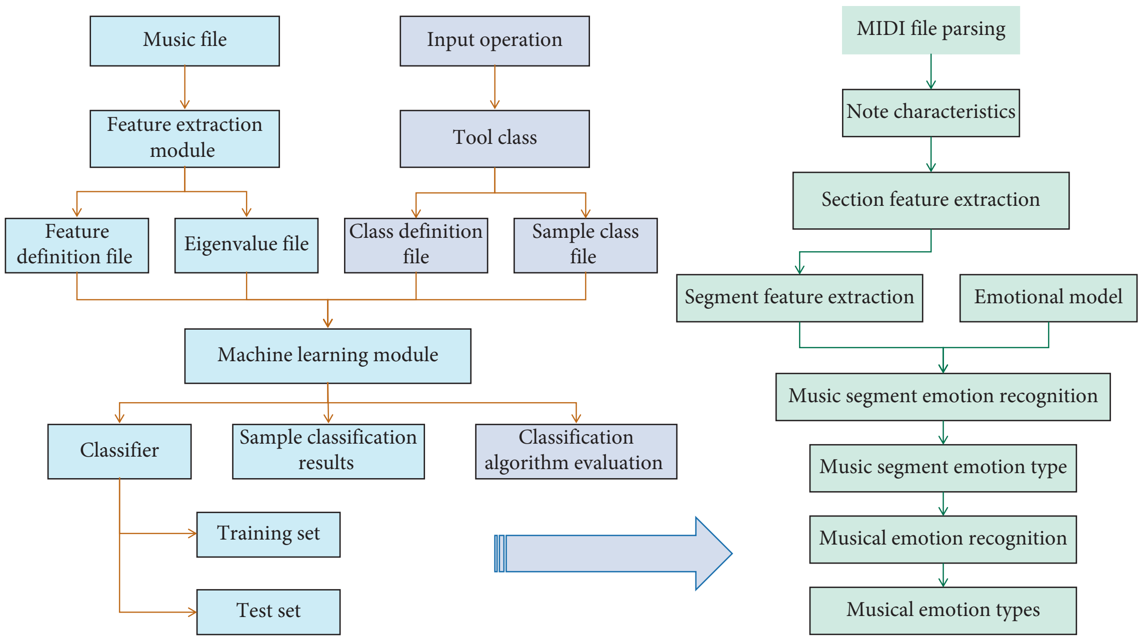

Figure 2: The algorithm emotion recognition flow in this paper.

previous information can be connected to the current task; that is, the next sequence action can be predicted by the previous generated sequence. After the data set is made, the data preprocessing of the data set will be carried out. Its purpose is to make the note data input to NN have a unified standardization standard, thus effectively reducing the number of event types in huge data and effectively improving the generalization ability of the system. It contains many core musical data expressions.

In this paper, we use information entropy to evaluate the amount of information in each track of MIDI file. The formula of entropy is as follows:

$$H(p(x)) = -\sum p(x)\log_2^{p(x)}, \tag{6}$$

where $p(x)$ is the probability density function. The input s_j of each intermediate layer unit is calculated by using the input sample $X = (x_1, x_2, x_3 \ldots, x_n)$, the connection weight W_{ij}, and the threshold θ_j, and then the output b_j of the intermediate layer unit is calculated.

$$\begin{aligned} s_j &= \sum_{i=1}^{n} w_{ij}x_i - \theta_j, \quad j = 1, 2, 3, \ldots, p, \\ b_j &= f(s_j) = \frac{1}{1 - e^{-s_j}}, \quad j = 1, 2, 3, \ldots, p. \end{aligned} \tag{7}$$

Global error of the calculated network:

$$E = \frac{1}{2}\sum_{i=1}^{q}(y_i - c_i)^2. \tag{8}$$

The changing intensity of rhythm can be expressed by the length and intensity of notes in a passage, and the formula is as follows:

$$\text{Rhy} = \sum_{i=1}^{n-1}\left|\frac{I_{i+1} - I_i}{D_i}\right|. \tag{9}$$

The main melody track typically has a large number of notes, and the number of notes in the main melody track should not be less than half of the average number of notes in each track. As a result, before determining the main melody track, tracks with less than half the average number of notes should be eliminated. Musical emotion cannot be expressed solely through the basic information contained in musical notes, and musical emotion analysis must take into account the organisational structure and changing rules of musical notes. As a result, we divide music features into two levels: high-level features and note features, based on the composition form of music features and the audience's hierarchical cognitive process of music features. Following the division of the music into segments with distinct emotions, the forms and methods of music expression are investigated, and some features that have a significant impact on music emotions are chosen to represent music. For each segment, feature extraction is performed, and the extracted features are used to create the segment's feature vector. In this paper, the introduction of attention mechanism will assign different attention sizes to each part of the frame, reflecting the influence degree of each original information on the current information. This number is also the attention size assigned to each word by attention mechanism when learning the current information. When new information is introduced, the training efficiency will be improved.

4. Result Analysis and Discussion

This section conducts an experimental comparison of various models in order to verify the performance of the algorithm composition and emotion recognition model based on machine learning proposed in this paper. The network model in this paper is created using Matlab. To begin, create two large loops. After that, the data blocks are then input into the set network model, and the output results are obtained after weight calculation. To ensure the experiment's objectivity, the same training set is used for all algorithms, and the number of network layer units is set to 512 with 200 iterations. Tansig and Logsig are the excitation functions for the network's hidden layer and output layer, respectively. Each note sequence corresponds to a one-hot vector and is 192 characters long. Table 1 shows the parameter values set by the network in the training process.

The loss value specifies how the difference between the prediction result and the actual label should be calculated. Because note prediction is a multiclassification problem, the categorical cross-entropy function is chosen because of its high performance. The distance between the predicted value and the real value can be minimised by minimising the cross-entropy, achieving the ultimate goal of training. This chapter examines the impact of network parameters on experimental results by looking at the number of iterations. The influence of the number of iterations on the loss value is shown in Figure 3.

The findings show that the longer iteration times are, the more weight parameters are learned and adjusted, which can improve the model's accuracy to some extent. And as the number of iterations increases, the loss function decreases more slowly. When learning and training a NN, the numerical distribution changes dramatically as the number of layers increases, accompanied by error accumulation. The resulting layer-by-layer superposition will drastically alter the high-level input distribution. As a result, the normalisation strategy can be used to process the data distribution to the [0, 1] interval in order to reduce the impact of distribution change. The training set is processed using feature analysis, the emotional feature quantity is used as the model's input, and the classification result is used as the model's output. The error results of different music algorithms are shown in Figure 4.

It can be seen that the error of the music algorithm generated in this paper is the smallest, and its performance is better. In this network, the more units in the hidden layer, the stronger the network's ability to learn abstract data features. The dimension of hidden layer has an important influence on the experimental results, but the more layers there are, the larger the calculation amount of NN will be. Comparison of algorithm recall results is shown in Figure 5.

According to the data analysis in Figure 5, the recall rate of this algorithm is higher than that of the other two algorithms. This algorithm has certain reliability. This chapter verifies the quality of music generation through professional evaluation. 100 music professionals from a university were invited to comprehensively grade 30 samples generated by each model. The results are shown in Table 2.

As can be seen from Table 2, the music generation algorithm in this paper has more advantages in results. This proves the effectiveness of the model in music generation, and it can be seen that the network model constructed in this paper has stronger practical value. In this paper, the emotional classification of music is realized by fusing the time domain features, frequency domain features, auditory spectrogram features, and nonlinear Hurst parameters of music. Through experiments, the accuracy of emotion classification of different algorithms is shown in Figure 6.

It is clear that this model has a higher retrieval accuracy. The results confirm the model proposed in this paper's validity and correctness. In this paper, choose an appropriate training set as the network's input and constantly revise the network's connection weights and thresholds to

make it converge. Finally, the emotion recognition model is used to identify the emotion of the music in the test set, and the algorithm's accuracy is evaluated. The emotion recognition accuracy of different algorithms is shown in Figure 7.

When compared to the results of three different algorithms for accurately recognising emotion samples, the algorithm in this paper has a better effect, with higher generalization, stability, recognition rate, and practical value. Several experiments are carried out in this chapter to verify the performance of the algorithm and model proposed in this paper. The model's emotion recognition accuracy is up to 93.78 percent, and the algorithm recall rate is up to 96.3 percent, according to the experimental analysis. The model's retrieval speed is quick, and its accuracy is excellent. Many results show that the recognition method used in this paper is superior to other recognition methods in terms of recognition ability, and the emotion recognition results are reliable.

5. Conclusions

Research on an efficient music generation algorithm and emotion recognition model has become a research hotspot as artificial intelligence technology matures. The construction of an emotion recognition model of composition is a multidisciplinary research topic. This paper builds an algorithm composition and emotion recognition model based on an in-depth study of machine learning. This paper examines the workflow of a music emotion recognition system and summarizes the contents of digital music emotion recognition and music features. The features are used to represent music, and then algorithms are used to analyze the features to determine the emotional categories of music. The model's emotion recognition accuracy is up to 93.78 percent, and the algorithm recall rate is up to 96.3 percent, according to the experimental analysis. The segmented emotion recognition method proposed in this paper can better show the movement of music than the whole music emotion recognition method. It has a strong ability to recognise emotions. The experimental results show that this recognition method has superior recognition ability, fast retrieval speed, and certain reliability when compared to other recognition methods. The method proposed in this paper is feasible and effective, and it produced the expected outcomes. On the level of computer-aided music creation, artificial intelligence music is expected to help creators fill the thinking gap in creation in the future, and users will be able to choose the most appropriate candidate sequence to increase creator inspiration. You can also recreate entirely new music in the style of specific musicians and composers. This study, however, has some flaws due to the influence of our knowledge level and time constraints. We can continue to research the emotional model in order to more scientifically represent the emotional categories of music in future work.

Academic Editor: Xin Ning

Decentralization, stability, security, and immutability are all features of blockchain technology. Blockchain, as the underlying technology of Bitcoin's digital monetary system, is currently sweeping the globe. Blockchain is a revolutionary decentralized database technology that employs encryption, a timestamp chain data structure, a distributed consensus mechanism, and other technologies to achieve decentralization, tamper resistance, easy tracking, and programmable smart contracts. In the face of rising financial technology, we must maintain inclusive, technological, and invasive regulatory principles that not only foster financial innovation, but also conduct dynamic supervision to avoid systemic financial hazards. The consensus algorithm is one of the main blockchain technologies that has a direct impact on the system's functioning. As a result, in this paper, we propose a blockchain-based development and supervision method for financial technology, as well as an application of this technology to commercial settlement, which can significantly reduce data complexity, time consumption, and the structural chain phenomenon in existing transaction settlement. We bring the idea of pow competition into DPoS, construct a consensus algorithm with an upgrade mechanism, and call it delegated proof of work, based on an in-depth investigation of the working principle of pow (proof of work) (dDPoS). The blocking efficiency of the dDPoS consensus method is around one block every 10 seconds, which is significantly higher than the blocking efficiency of the POW and POS consensus algorithms. As a result, it offers a potential answer to traditional centralized institutions' concerns of high brokerage costs and insecure central storage, as well as a wide range of application possibilities.

1. Introduction

Financial English "Fin Tech" is an abbreviation for "Financial Technology," which refers to the integration of finance and IT, as well as the use of various scientific and technological techniques to improve efficiency and successfully cut operating costs in the traditional financial industry [1]. Financial liberalization and globalization, on the other hand, make the entire financial system more vulnerable. Financial supervision has become a focal point of concern, particularly during the 1990s, as a result of massive, devastating, and recurring financial crises [2]. The price of Bitcoin has witnessed two strong surges and falls in recent years, owing to the progressive popularization of the notion of Bitcoin and the influence of investor mood and government supervision, which has sparked broad discussion and interest [3]. Although technology is transforming China's financial industry, it is also posing new challenges to legal concepts, norms, and regulatory structures [4]. The financial legal system is experiencing new issues as a result of decentralization, as represented by blockchain, and legal supervision reform, as represented by supervision technology [5].

The legislation of financial supervision and the financial industry is complementary. The financial industry's growth encourages financial supervision law innovation, and the financial supervision legislation ensures the financial industry's healthy growth [6]. On the other hand, if the legal structure of financial supervision cannot keep up with the financial industry's expansion, the financial business outside of supervision may provide unanticipated hazards [7]. Blockchain has a strong basis of trust as a sharing technology

[8]. However, the blockchain technology development cycle is short, and the technology's evaluation is mixed [9]. The existing calculating methods may lead to a complex conversion procedure and low efficiency of long-term encryption and decryption process [10], yet all nodes in the blockchain network maintain the same block sequence and attain agreement according to the accepted norms [11]. In this research, we present the dDPoS algorithm and compare the experience with existing methods to verify the performance of the proposed method. This study examines the development and oversight of blockchain technology in financial settlements, as well as the associated concepts of blockchain technology, and explains, summarizes, and summaries them.

People began to recognize the usefulness of blockchain technology as the basic underlying technology when the price of bitcoin fluctuated dramatically [12]. Although blockchain is undeniably appealing to the banking industry, most banks are still in the early stages of adopting it, and many financial businesses are currently proving the concept and developing their own blockchain strategies or are only now becoming aware of it [13]. Furthermore, financial technology has altered the manner in which the financial industry operates, rather than the nature of the industry [14, 15]. Financial regulatory authorities in industrialized nations have been exploring how to monitor complex financial institutions, which has become the most significant responsibility, in order to achieve financial stability and avert financial crises. We should be aware of new hazards as a result of financial technology, not just the changes in the financial business. The efficient and complete evaluation of consensus algorithm is realized in this paper's financial technology development and supervision method based on blockchain, in order to discuss its working principle on private blockchain platform and how it affects the overall performance of blockchain, as well as the efficient and complete consensus algorithm, complete analysis and comparison of performance characteristics of various consensus algorithms, and a complete evaluation of consensus algorithms.

(1) This study analyzes and describes the technological model, advantages and disadvantages of blockchain technology in as much detail as possible, based on a complete analysis of the existing academic literature, various research reports, and white papers in the industry.

(2) The selected nodes can be the initial permanent nodes with resources and the right to vote in the DPoS process, and the PoW is used to "screen" the node sets with a specific computational capacity to vote in the election.

(3) The use of blockchain technology in financial technology development and supervision can improve the loan quality and procedure in the financial industry, as well as ensuring loan business efficiency and endorsement transparency.

This paper's research framework is divided into five sections, which are as follows:

The first section of this paper introduces the research background and significance before moving on to the paper's primary work. The second section introduces the work on financial technology development and oversight, as well as blockchain and related algorithms. The third section analyzes the combination of financial efficiency and supervision, as well as structural optimization methodologies, to provide readers with a better knowledge of visual composition and semantic expression. The fourth section is the meat of the study, and it covers two areas of blockchain technology: blockchain core technology and consensus algorithm analysis. The final section of the paper is a recap of the entire study's work.

2. Related Work

2.1. Financial Technology Development and Supervision. Financial technology refers to financial innovations that create new business models, applications, processes, or products through technology. These innovations can have a significant impact on financial markets, financial institutions, or financial service delivery methods. Although deregulation and self-regulation can maintain market competitiveness, it is difficult to cope with the actual financial crisis, and international arbitrage has increased due to deregulation. In the face of the crisis, it has become an important topic for Chinese and foreign legal circles to have some thoughts, opinions, and constructive opinions, and how to improve the current financial supervision mode.

Zachariadis and others believe that regulatory adjustment is necessary because there are external influences that lead to serious information asymmetry, natural monopoly, and market failure in the financial market [16]. Kabra et al. analyzed the mechanism and application of blockchain consensus algorithm in the field of financial supervision, chose Java Spring framework as the implementation framework of the platform, and adopted Dockers technology to realize multi-node private chain deployment [17]. Cretarola and others systematically studied the supervision mode of world commercial banks and its relationship with financial development. However, the effectiveness of various financial supervision theories has not been systematically verified in the existing literature [18]. Egelund Muller and others believe that the public interest theory lacks empirical support, and the reason why many industries are regulated is not because of the higher degree of monopoly or easier to trigger monopoly [19]. The public interest theory of financial supervision proposed by Yu et al. is based on three assumptions: sufficient government information, contribution to the overall welfare of society, and sufficient credit. It allows individuals to supervise powerful financial institutions [20].

The financial supervision law needs to determine the future financial supervision reform plan from the perspective of national historical development. In terms of respecting and understanding China's actual situation, this paper attempts to explore a practical legal system of financial supervision, so as to create a platform for others and themselves to continue their research in the future.

2.2. Blockchain and Its Related Algorithms. In order to meet the needs of social development, the blockchain is constantly changing, and the core technology of blockchain-consensus algorithm also needs to be innovated. For example, Ping An Yizhang chain solution, Wanxiang blockchain laboratory baas platform, Zhonghui interbank joint loan clearing project, ant financial service social welfare project, etc. all show that domestic financial technology enterprises attach importance to blockchain technology application research and consensus algorithm. Many scholars at home and abroad have done a lot of in-depth research on financial supervision and investigated in detail the impact of various specific financial supervision measures on financial development.

Sun et al. proposed a technical model for the first time. Aiming at the problem of repeated payment of existing third-party electronic payment, this paper attempts to establish a decentralized point-to-point direct transaction e-cash system based on P2P network technology and uses cryptography, timestamp, and consensus mechanism to ensure that the data is easy to trace but not easy to tamper [21]. Zhu and Zhou analyzed the security and performance of different consensus mechanisms and network parameters in public by introducing a new quantitative framework [22]. The framework can objectively analyze the trade-off between the performance and security of public blockchain under the conditions of network propagation, block size, block generation interval, information propagation mechanism, and network malicious attack. Nathan and Jacobs proposed a private blockchain evaluation framework [23]. At present, the design of BLOCKBENCH is carried out through three most mature blockchain platforms that can support smart contract functions: Hyperledger Fabric, ETHEREUM, and PARITY. Cong and He put forward the model of Ethereum and developed a programming script language with complete Turing and more complex intelligent contracts for the first time based on technology [24]. delegated Byzantine fault tolerance (DBFT) is an improved Byzantine fault tolerance algorithm initiated by domestic small ant team, which has been applied to its original ant shares (NEO) project [25].

Therefore, through a unified input-output interface, the underlying code of performance simulation evaluation of consensus algorithm is integrated into the platform visualization management module, which is convenient for blockchain practitioners to start performance simulation by inputting certain specific parameters.

3. Combination of Financial Efficiency and Supervision and Structural Optimization Method

3.1. Combination Method of Financial Efficiency and Financial Supervision. In the current credit economy, financial resources are fresh resources required to maintain social and economic progress [26]. The Pareto optimality criterion is extended and applied to resource allocation [27]. The Pareto optimal allocation of financial resources is then the so-called financial efficiency. As a result, advancements in financial technology not only raise the risk of consumer information disclosure and fraud, but also make customer personal information protection and remedy more difficult. These are regulatory concerns that need to be addressed as financial technology develops. Data layer, network layer, consensus layer, incentive layer, contract layer, and application layer are the six levels that the blockchain system separates its infrastructure into, from low to high, according to distinct functions. The blockchain infrastructure model is shown in Figure 1.

Firstly, according to the Pareto condition of optimal distribution of commodities among consumers, when there are two or more consumers and two or more commodities, when the marginal substitution rate between two commodities is the same for any one consumer, and when it is equal to the ratio of product price, the distribution of commodities will reach Pareto optimal. Financial regulators are responsible for supervision. Select the appropriate key generation function according to the different encryption methods of each part, which must meet the conditions under the following formula:

$$K_{2i} = f_i\left(U_i R_i, H_i(CF)\right). \tag{1}$$

The blockchain is distributed and stored at each node of the network in the form of encryption. All transaction records of each node of the whole network are stored on the chain, so the blockchain can be regarded as an account book recording all bitcoin transactions [28]. The cost of regulators' hard work will be significantly higher than the cost of laziness, while the benefits of hard supervision and laziness are not obvious. Therefore, the net benefits of regulators' hard work will be significantly lower than the net benefits of laziness, that is,

$$\left(R_2 - C_2\right) > \left(R_i - C_i\right), \left(R_2^*, C_2^*\right) > \left(R_1^*, C_1^*\right). \tag{2}$$

Blockchain technology has a natural trust advantage, because it cannot be tampered with, is easy to trace, and is very suitable for scenarios where some information is opaque, credit risk is high, and losses may be high [29]. Set up various financial supervision departments corresponding to different types of financial institutions and delimit the jurisdiction of each financial supervision department, and the supervision departments of one type of financial institutions shall not supervise other types of financial institutions beyond their authority. At this time, there is also a refined Bayesian Nash equilibrium, where regulators choose to be lazy, and the public choose to pay low remuneration when

$$p = \frac{\left(R_p^* - C_p^*\right) - \left(R_p^* - C_p^*\right)}{\left(R_\mathrm{q} - C_q\right)}. \tag{3}$$

Secondly, according to the Pareto condition of the optimal allocation of producer input factors, the input

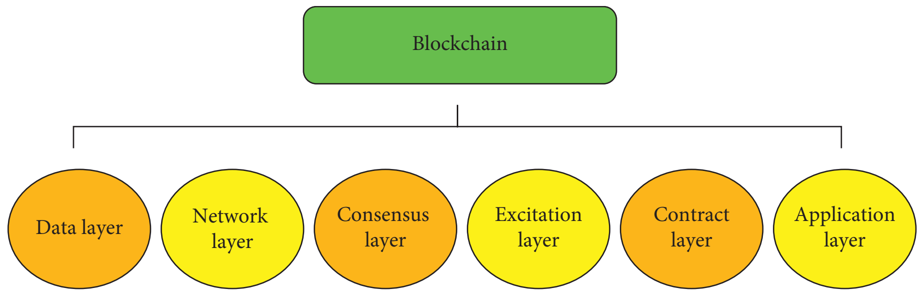

Figure 1: Blockchain infrastructure model.

combination of the optimal allocation of producer input factors is an input combination that meets the equal marginal rate of technology substitution of any two inputs and is equal to the ratio of input factor prices. Through multiple transaction intermediaries, the transaction efficiency is greatly reduced, the transaction cost is increased, and the moral hazard is high. The application of blockchain technology can realize point-to-point direct transactions with high trust of all trading parties, so as to improve efficiency and reduce costs. Use performance indicators to express the expected objectives of the system:

$$J = f_{t0}^{tf} L[x(t), u(t), t] \mathrm{d}t. \tag{4}$$

Then, combined with the encryption algorithm, the transaction results are made public (that is, the prototype of blockchain), and a decentralized property authentication system is established. Due to the specialized operation of the supervised subjects, the supervision level is highly specialized, which greatly guarantees the stability and security of the financial system in a certain period of time. The method of selecting the optimal process and strategy can be solved by establishing Hamiltonian function:

$$H(x, u, \lambda, t) = L(x, u, t) + \lambda(t) f(x, u, t). \tag{5}$$

Finally, for financial resources, if the supply and demand of financial resources are to be roughly balanced, that is, to meet the distribution of financial resources among financiers and financial commodities among investors, the marginal financing conversion rate of financiers must be equal to the marginal commodity substitution rate of investors. If the business scope of financial institutions is clearly and strictly divided, and the responsibility of financial supervision is relatively clear, the separate supervision system of institutional supervision is feasible. Since financial institutions only need to accept the supervision of one regulatory department, they can avoid the cross supervision and overlapping supervision of regulatory departments, reduce the cost of regulators, and indirectly reduce the cost of consumers. Any authorized person can see the records of the whole data chain at any node, so that the audit department and regulatory department will celebrate warmly.

3.2. Optimization Method of Financial Supervision Structure. Vulnerability is the fundamental motivation of financial supervision and the core and springboard of long-term historical development of financial supervision [30]. With the increasingly blurred division of business among heterogeneous financial institutions, institutional supervision is likely to lead to gaps in financial supervision and potential risks, especially the subsidiaries controlled by financial groups can carry out banking, securities, and insurance business separately. Therefore, it is necessary to realize the stability of monetary function and financial function, including the stability of financial market function and the stability of financial enterprises. The optimal control problem is defined by mathematical language; that is, the state equation of the given continuous-time economic system is

$$x^{\circ}(t) = f[x(t), u(t), t]. \tag{6}$$

That is, under the background of computer-driven trading, the trading frequency and trading volume are rising rapidly. Therefore, the structure of financial supervision needs to be optimized. On the basis of giving full play to the role of basic services, the party applying funds, the party providing funds, and other participants in the supply chain are constructed together, as shown in Figure 2.

First, handle the relationship between financial supervision and financial supervision structure adjustment. Under the condition of modern financial economy, the investment of financial resources comes from savers' savings in a broad sense, including the financial assets investment behavior of individuals and enterprises. When implementing the institutional supervision mode, even if the main supervision system is adopted for the business approval and supervision of a certain type of financial institutions, and several financial supervision institutions are responsible for coordination, the supervision objectives are diverse, not a single one. The real economic system, in addition to its constantly changing environment, will also change its internal structure, thus affecting the performance of the economic system. The general equation of adaptive control is

$$\mathrm{A}\left(Z^{-1}\right) Y(t) = Z^{-d} B\left(Z^{-1}\right) u(t) + C\left(Z^{-1}\right) W(t). \tag{7}$$

Before extracting the main features of distributed big data from the database, set the evaluation criteria of distributed data features, and apply them when evaluating the importance of features to determine the ability to distinguish feature classes. When publishing data on the blockchain, everyone can access it and issue transactions waiting to be

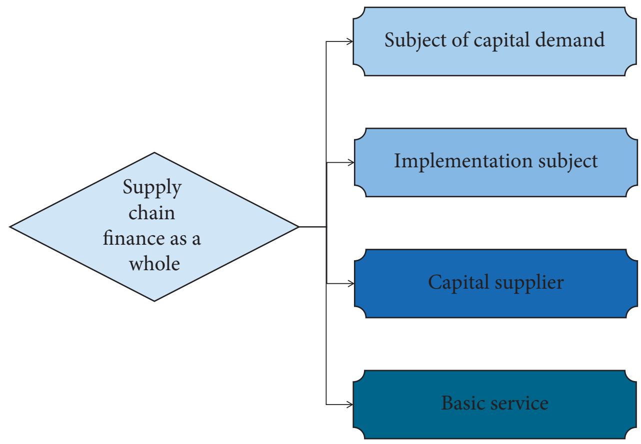

Figure 2: Overall financial application structure model of supply chain.

written into the blockchain. Suppose that $S = S(i)$ represents the surplus of consumers or investors of financial products, and $\Pi = \pi(i)$ represents the profit of financial enterprises. They are all functions of financial market price. Then, the political production function is as follows:

$$M = M(S, \pi). \tag{8}$$

Secondly, the compatibility between regulatory structure and regulatory objectives: the setting of regulatory structure should ensure the smooth realization of regulatory objectives and reduce the interference of structure to regulatory objectives. This condition shows that the marginal substitution rate between any two commodities is equal to the marginal product conversion rate of producers between these two commodities. Therefore, a possible boundary of political production can be deduced:

$$S = S(i(\Pi)) = S\left[\pi^{-1}(\Pi)\right]. \tag{9}$$

Since one of the purposes of blockchain is to reduce excessive human interference, it emphasizes automation. Through the setting of mathematical algorithms and the formulation of some rules, transactions should be automated. We should not only maximize the number of votes, but also make the marginal substitution rate of politics equal to the marginal substitution rate of mutual transfer between enterprise profits and consumer surpluses, so as to achieve a balance. Therefore, the interest rate of financial supervision is solved as follows:

$$\max_i M(S(i), (i)). \tag{10}$$

Less than 51% of the nodes in the system can intervene and verify the transaction; otherwise, a single node cannot play any role in data tampering, and at the same time, the nodes of the whole network will be alert to it, and it will be automatically rejected by the system. The financial supervision structure model is shown in Figure 3.

Finally, the financial supervision system must be based on market law and cannot substitute subjective administrative intent for the market mechanism. Its goal should be to support financial innovation, financial efficiency, and financial stability. Anyone may find the information they need thanks to binary value (hash value) query entries, which make the system's data information more transparent. The use of blockchain in bitcoin is to use the blockchain to validate blocks containing transaction data in order to achieve the goal of irreversible and undisputed transaction confirmation. Each regulatory authority's jurisdiction is determined by the kind of regulated financial institutions such as commercial banks, securities firms, and insurance firms. The regulatory structure optimization is based on cryptographic algorithm technology, which ensures the unique direction of account address and has some application potential in the areas of authentication and company identity certificate.

4. Blockchain and Consensus Algorithm Analysis

4.1. Analysis of Blockchain Core Technology. When the blockchain was first proposed, it was designed to solve the problem of safe transaction between the two parties in the unknown network environment without a third-party certification authority, that is, to create a payment mechanism through communication channels without a trusted party. Therefore, only by using blockchain to supervise financial institutions can the government overcome the negative impact of market failure, improve the governance level of financial institutions, improve the efficiency of financial operation, and maintain the stability of the financial system.

Firstly, distributed ledger refers to the accounting technology of data sharing, data replication, and data synchronization among nodes in computer network. Pow, namely, workload proof, is a consensus mechanism, which first appeared in bitcoin. An input value of any length can be calculated into a binary value of a specified length. For example, the SHA-256 algorithm applied in the blockchain system can calculate the fixed length output with the growth of 256 bits for transactions or other data of any length, and the output binary value is hash value (also known as hash value). Learn from the data processing mechanism of separate storage of cold and hot data and separate storage of

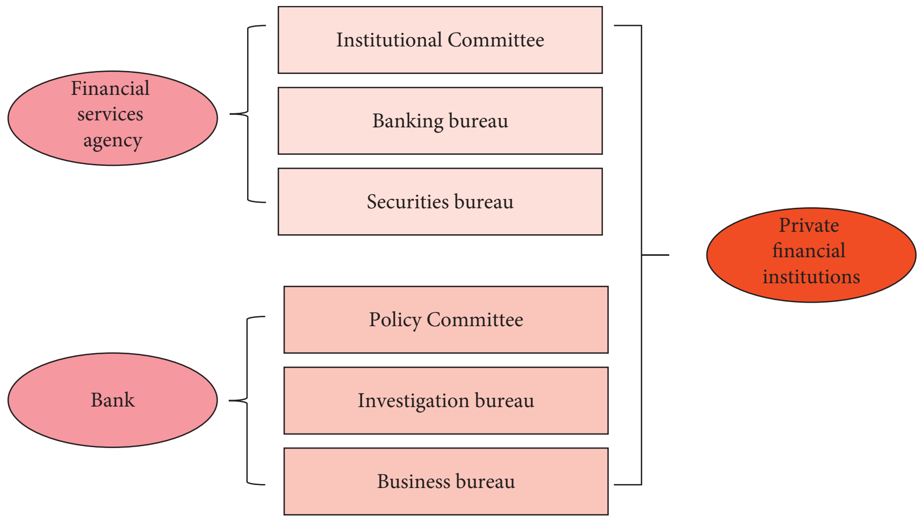

Figure 3: Financial supervision structure model.

cold and hot data in traditional financial data processing methods to realize the effective storage of a large number of node data. When a node reaches the target value, it will broadcast the block to other nodes, and all other nodes must confirm the correctness of the hash value with each other. The specific transaction information is stored in blocks, and the data structure of blocks is shown in Table 1.

Secondly, in the blockchain system, all transaction data is publicly visible, but the personal identity information of the nodes is encrypted, and only after the information owner authorizes the nodes to access the information, which is to protect the security of transaction data and the privacy of personal identity information. The data structure of the header is shown in Table 2.

Blockchain system is a point-to-point network composed of a large number of nodes. There is no centralized hardware or management organization. The whole system depends on the cooperation of all nodes in the network, and all nodes have the same business mode, rights, and obligations. POW collects all pending transactions on the network after creating the last block. Then, the transaction data received within a certain period of time forms a Merkle tree data structure through hash operation at each distributed node, encapsulates the nodes that have obtained the consensus mechanism, connects the current longest main chain, and creates the nearest main chain. The Merkle root of these transactions is then calculated and filled with block serial number, 256-bit hash of the previous block, current target hash, random number, and other information. In order to release data uniformly and avoid problems between the two armies, some specific data processing links can only be processed in serial mode, not in parallel.

Finally, the consensus mechanism is a method to prove the correctness and legitimacy of a block by reaching consensus among all the nodes participating in the consensus in the blockchain network environment. Since there is only one "Merkel root" at the end of processing a large amount of transaction data, it is not necessary to encapsulate all the underlying data in the block header, which greatly improves the operation efficiency and scalability of the blockchain. The consensus mechanism depends on the ability of the kernel, using CPU and memory resources to isolate the operating system's view of applications through a separate namespace.

4.2. Consensus Algorithm Analysis. POW competes for the computing power of each node and then competes for the power of generating blocks, which greatly consumes computer resources and power resources. The submodule will regularly poll the status of the sent transaction request until all the unconfirmed transactions in the local sequence are confirmed and removed from the sequence, and all the transaction requests sent by the client are completed. The network environment composed of consensus nodes is called consensus network. In the dDPoS algorithm, the consensus network changes with the change of consensus nodes. In addition, the consensus efficiency of pow is too slow. It takes 10 minutes to generate a block. Among them, the web module provides basic web-oriented integration features. The web servlet module package contains the spring MVC implementation of web applications. The number of consensus nodes elected by DPoS consensus algorithm is 100, which has the advantages of reducing the number of consensus nodes, improving consensus speed, and reducing energy consumption in the consensus process. This indicator represents the transaction response time of the blockchain and can directly reflect the performance of the consistency algorithm. The number of blocks generated by the three consensus algorithms pow, POS, and dDPoS in 0–100 minutes and under nodes with different sizes of 500–5500 is shown in a broken line diagram, as shown in Figures 4 and 5.

Firstly, select the consensus node module: functionalize all nodes in the blockchain system, and different types of nodes undertake different tasks, which are mainly divided into consensus nodes and transaction nodes. During the change of transaction request rate from 20 times per second to 200 times per second, the average

Table 1: Block data structure.

Field	Describe	Size (byte)
Block size	The size of all information after this field	1–10
Block head	The general name of all the information constituting the block header	92
Number of transactions	The number of transaction information stored in the block	1–20

Table 2: Data structure of block header.

Field	Resource consumption	Size (byte)
Pervious block hash	Enormous	20
Merkle tree root	Big	87
Timestamp	Small	20–30

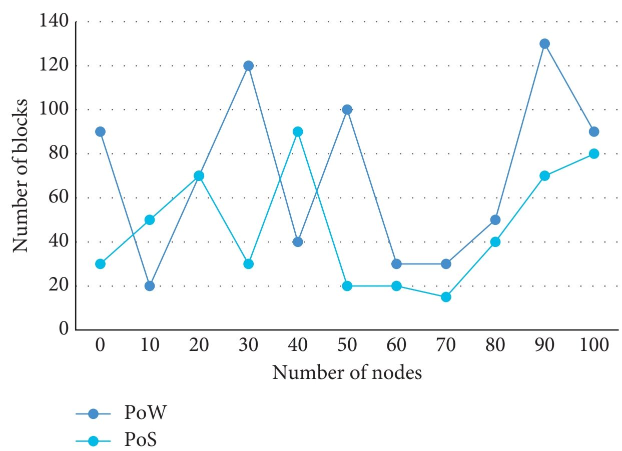

Figure 4: Comparison diagram of block broken lines generated by PoW and PoS within 100 minutes.

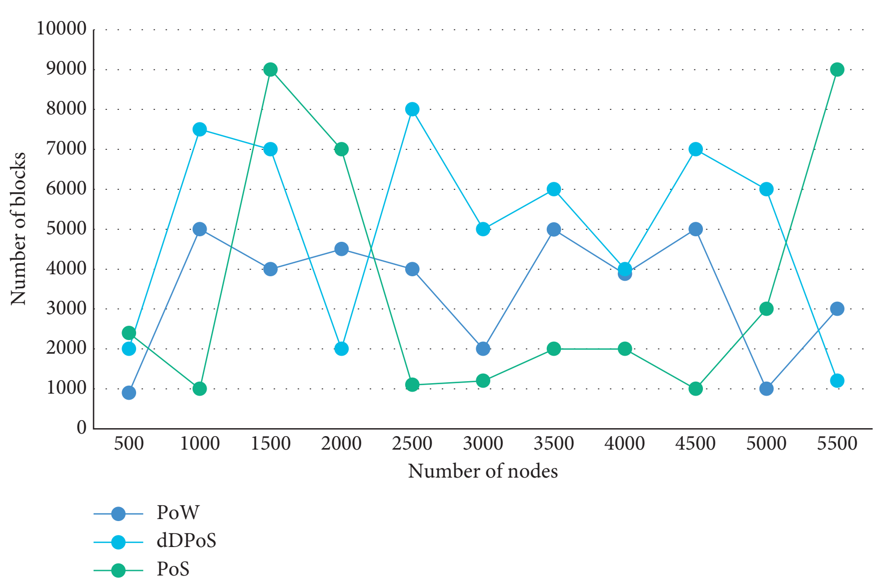

Figure 5: Comparison diagram of block broken lines generated by PoW, PoS, and dDPoS under 5000 nodes.

delay of PoW first increased and then decreased, while the delay of DPoS fluctuated around 5 seconds, during which the peak delay of PoW reached 50 times that of DPoS. The logarithmic graph of average delay of PoW and DPoS consensus algorithms at different transaction request rates is shown in Figure 6.

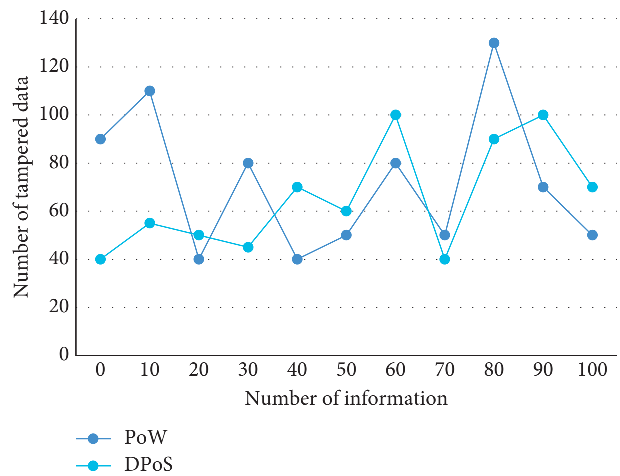

Figure 6: Comparison line chart of average delay of consensus algorithm under different transaction requests.

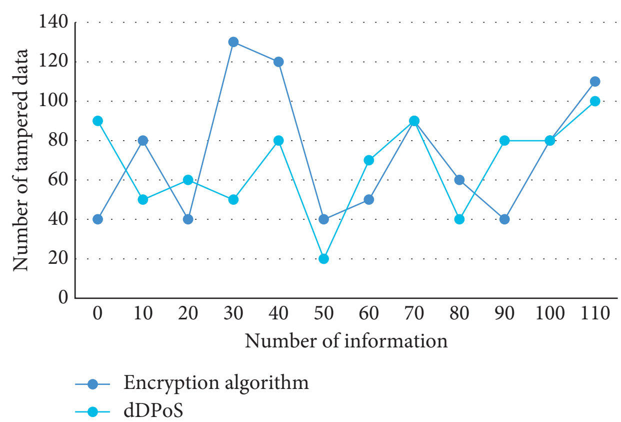

Figure 7: Comparison of antiattack performance between encryption algorithm and dDPoS algorithm.

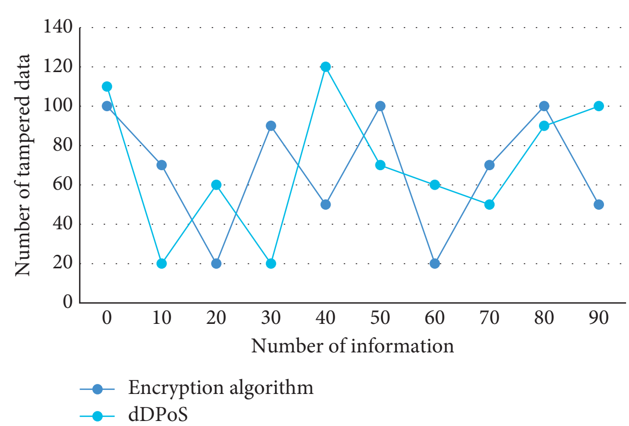

Figure 8: Comparison of protocol security in distributed network.

The blocking efficiency of the dDPoS consensus algorithm is about one block every 10 seconds, which is much higher than that of the pow consensus algorithm. Data entry permission can set multiple users in a unified account and provide users with different work permissions according to their different work needs, so as to meet the use scenarios under the control of multiple users. All data are extracted from the financial database of decentralized supply chain and mapped into a multidimensional space. This is because some interest groups may not make public support or opposition after cost-benefit comparison. On the one hand, the demand for financial supervision system depends on the comparison between the number of beneficiary groups n and the number of damaged groups $(N - n)$; on the other hand, it depends on the degree of support f expressed by beneficiary groups and the degree of opposition h expressed by damaged groups. The security and integrity of information and data in the decentralized supply chain financial network can be better protected. Figure 7 shows the antiattack performance comparison of encryption algorithm and dDPoS algorithm.

Secondly, remove the malicious node module: when the malicious node appears, dDPoS algorithm enters the malicious node removal mode and introduces the upgrade mechanism to complete the upgrade conversion between the malicious node and the candidate node. During data processing, ECDG, PCI, and R DTP protocols were tested, and the final test results are shown in Figure 8.

Filter much transaction information of blockchain finance through artificial intelligence, big data, and cloud computing technology, and write algorithms and models that can automatically calculate and analyze these data to capture, identify, and analyze abnormal behaviors of regulatory objects. One of the problems to be solved in the initial design of blockchain system is the problem of repeated payment in electronic transactions; that is, a sum of money cannot appear in two transactions. It is a method of filtering data features using split equation and a feature extraction method for calculating the score corresponding to size features. In particular, it should be noted that some damaged groups may evade regulation, which mainly depends on the comparison between the net income of publicly opposing the success of regulation and the net income of evading regulation.

5. Conclusions

The rapid advancement of financial technology may provide significant benefits to regulators. Blockchain technology, as opposed to the old centralized approach, uses cryptography, distributed consensus, and economic incentives to achieve the benefits of decentralization, nontampering, data traceability, and programmable smart contracts. We can create a blockchain-based evidence retention and collection system based on this characteristic of blockchain technology. Financial supervision not only necessitates a genuine increase in the enthusiasm for nongovernmental financial industry oversight, but also actively improves the independence of financial supervision organizations. The goal of effective supervision is to reduce the expense of supervision while increasing the contribution to social welfare.

This study proposes a strategy for integrating financial efficiency and oversight, as well as a method for structural optimization, based on blockchain. In addition, the blockchain's underlying technology and consistency algorithm are thoroughly examined. This paper effectively integrates relevant theories and knowledge of financial supervision and financial efficiency, with the goal of improving financial efficiency. It attempts to reveal the mechanism of financial supervision on financial efficiency and discusses the impact of financial supervision on improving financial efficiency. It can not only assist blockchain practitioners understand the characteristics of consistency algorithm and make acceptable decisions, but it can also improve the performance simulation efficiency of consistency algorithm and promote further research into consistency algorithm. It can help related businesses develop and process information more quickly, allowing for the effective and practical application of blockchain technology. It can also help solve problems with the original model, allowing the new model to be implemented and popularized more quickly, contributing to the development of a good trade settlement environment in China. This can help financial organizations fix their financial transaction data, prevent tampering and data loss, and preserve the integrity of their financial data.

Commercial banks are facing unprecedented credit risk challenges as the financial market becomes more volatile. Based on this, this study proposes and builds a credit risk assessment model for commercial banks based on GANN from the standpoint of commercial banks. In order to provide commercial banks with an effective and dependable credit risk assessment method, the indicators in this study are classified using cluster analysis, and then various representative indicators are chosen using a factor model, which takes into account the comprehensiveness of the information and reduces the complexity of the subsequent empirical analysis. On this basis, the network structure, learning parameters, and learning algorithm of commercial banks' credit risk assessment models are determined. Furthermore, advancements in data preprocessing and genetic operation have been made. According to simulation results, the highest accuracy rate of this method is 94.17 percent, which is higher than the BPNN algorithm 89.46 percent and the immune algorithm 90.14 percent. The optimization algorithm presented in this study improves the convergence speed and search efficiency of traditional algorithms, and the final experimental results show that the scheme is feasible and effective and can be used for commercial bank credit risk assessment.

1. Introduction

Commercial banks, as the financial institution with the most influence, the greatest number, and the broadest coverage in the financial market, play a variety of roles, including financing monetary capital, guiding capital flow, and regulating the balance of social supply and demand [1]. It holds a unique and crucial position in the entire financial system, as well as the national economy. At the moment, the rate of economic globalization is gradually accelerating, and financial market volatility is increasing by the day. Commercial banks face increasing financial risks as the "general hub" and "regulator" of a country's economic development [2]. Commercial banks' credit risk refers to the risk of economic losses caused by the customer's failure to perform the obligations in the agreed contract, that is, the possibility of the borrower defaulting due to the borrower's failure to repay the bank loan on time and in full for a variety of reasons [3]. Commercial banks' credit activities are divided into two categories: obtaining funds and using funds. If the risk of capital utilization is not effectively managed, the bank will face difficulties in obtaining funds, making it impossible for the bank to continue operations. Credit risk management is the most critical and difficult aspect of commercial banks' financial risk management. Effectively preventing and reducing credit risk has become the primary function of commercial bank operations and management. Simultaneously, in the context of interest rate marketization, commercial banks' pricing of loan interest rates is essentially the pricing of credit risk. As a result, credit risk is the most significant risk that commercial banks face. The ability to effectively control credit risk has become critical to commercial banks' profitability. Accurate and scientific credit risk evaluation is critical for providing a better basis for loan pricing. At present, most commercial banks, especially urban commercial banks with a short establishment time, mainly rely on manual work to complete credit risk assessment, which is unable to assess all enterprises with loan needs, and the assessment results are difficult to update in time. The development of ANN (artificial neural network) [4–6] and GAs (genetic algorithms) provides a new direction for credit risk analysis and evaluation of commercial banks.

ANN is a parallel distributed mode processing system developed by applying mathematical methods based on the research results of neuropsychology and cognitive science. It has high parallel computing ability, self-study ability, and fault tolerance. The basic constituent elements of ANN are neurons, which are connected together in the form of nodes through some mode, and nodes can communicate with each other. The output information will be transmitted to other nodes through the connection right, which can inhibit or excite the information being transmitted, just like a real neuron. ANN can carry out complex logic operations and deal with nonlinear problems and abstract, simplify, and simulate biological NN (neural network). ANN is not strict about the distribution of data, and it is not necessary to describe the functional relationship between independent variables and dependent variables in detail. These characteristics make it a hotspot of credit risk analysis methods. Although NN has been widely used, it also has its own shortcomings, which are mainly reflected in the uncertainty of the training process. The emergence of GA makes the training of NN have a new look. Using GA instead of NN algorithm to search the connection weight of NN can solve the problem of NN falling into the local minimum. Therefore, this study constructs a credit risk assessment model for commercial banks based on GANN (genetic algorithm neural network). The specific innovations are as follows:

(1) Aiming at the shortcomings of BPNN (back-propagation neural network), such as easy to fall into the local minimum and slow convergence speed, this study introduces GA to design a practical GA coding scheme. In addition, reasonable fitness function, crossover operator, and mutation operator are used in genetic operation to optimize BPNN.

(2) This study establishes a credit risk evaluation index system based on industry classification, with quantitative indicators as the main factor and qualitative indicators as the auxiliary factor. And the improved technology and method of credit index data pre-processing are given. On the basis of discussing the related theories of credit risk assessment of commercial banks, this study focuses on the in-depth study of credit risk assessment methods and makes empirical analysis by using the constructed model and evaluation index system to verify the rationality and feasibility of the evaluation system constructed in this study.

The study is organized as follows: Section 1 introduces the background and significance of the topic selection and puts forward the research innovation and structural arrangement of this study. Section 2 describes the related works and analyzes the research status of NN and commercial bank credit risk at home and abroad and gives the research content and work of this study. Section 3 summarizes the relevant theoretical basis, constructs the bank credit risk assessment model based on GANN, and introduces its software implementation method in detail. Section 4 makes an empirical analysis of the index system and the improved GANN model, verifies the scientificity and rationality of the evaluation system, and shows that the algorithm model constructed in this study has certain practical value. Section 5 summarizes the conclusions and limitations of the full-text research and puts forward the future research direction.

2. Related Works

With the advancement of global economic integration, financial security has become a global concern. How to achieve financial security and how to ensure commercial banks' credit risk management are also common issues discussed by countries all over the world. Many aspects of ANN make it a popular credit risk analysis method. In recent years, with the advancement of information technology, an artificial intelligence method [7–9] with machine learning [10] capability has been introduced into credit risk assessment. The main goal of this stage is to develop a quantitative credit risk assessment model.

Cole and others studied the credit risk assessment of commercial banks by using genetic programming method and tested the model empirically by using the actual data of commercial banks in China. The test results show that this model is superior to a traditional statistical model, NN model, and decision tree model in prediction accuracy, practical value, and robustness. Masoudik et al. analyzed the microscopic and easily quantified non-systematic risks in the financial risks of commercial banks. On the basis of identifying types and root causes, referring to international practices and international financial regulations, and combining with the reality of Chinese commercial banks, this study systematically designs the non-systematic risk monitoring and early warning index system and corresponding early warning signals of commercial banks [11]. Eckert et al. and others can make efficient and timely judgments by introducing domain knowledge and using specific artificial intelligence methods such as GA, NN, and decision tree and provide effective decision support for decision makers [12]. The research of Yu et al. and others showed that under the same data environment, the accuracy of credit risk assessment by NN is higher than other assessment methods [13]. Huang et al. compared the early warning model based on ANN with the early warning model based on probability and reduced the rate of occurrence errors by reconstructing the data set. The results show that the NN model is superior to the probabilistic model in discrimination accuracy [14]. Soui et al. and others discussed and compared the application of the expert system in the field of credit risk analysis from the perspective of knowledge acquisition [15]. Labriola used a fixed-length code to represent the risk identification criteria and solved the credit risk assessment problem by using GA [16]. Plosser and Santos and others thought that when using GA to solve practical problems, operators need to have a deep knowledge of algorithms and a comprehensive understanding and good judgment of the problem itself, and the limitations of genetic coding itself hinder the application of GA to a certain extent [17]. Zhang et al. and others used NN to predict the failure of a company, and the results showed that NN-like prediction had better prediction ability than discriminant analysis [18]. Zhang et al. and others suggested that GA should be used to screen the input indicators and combine them with ANN to work together. They used this method to analyze the data of bankrupt enterprises 3 years before the bankruptcy, and the results showed that the discrimination accuracy of ANN network model was much better than that of comparison model [19]. Wang et al. and others used a rough set and NN method to predict credit risk, and the rough set was used to screen financial variables, thus improving the explanatory ability of the NN method, and the prediction accuracy was correspondingly improved [20]. Based on the research of previous relevant literature and GANN, this study puts forward and constructs the credit risk evaluation model for commercial banks. Aiming at the shortcomings of BPNN, such as easy to fall into the local minimum and slow convergence speed, GA is introduced to design a practical GA coding scheme. A credit risk assessment index system classified by industry, dominated by quantitative indicators, and supplemented by qualitative indicators has been established. It also gives the improved technology and method of credit index data preprocessing. In genetic operation, more reasonable fitness function, crossover operator, and mutation operator are used to optimize BPNN. Experiments verify that the evaluation system constructed in this study has certain accuracy and feasibility.

3. Methodology

3.1. GANN. The three elements of ANN are (1) synapse or connection weight: the connection degree between different neurons is given by the connection weight, negative value indicates inhibition and positive value indicates excitation; (2) summation unit or adder: similar to linear combiner, it obtains the weighted sum of input information; and (3) activation function or transfer function: nonlinear mapping, which can distribute the output value within a certain range, such as [0, 1] or [−1, 1]. As a powerful tool to study complexity, the ANN method has shown its unique advantages in pattern recognition and classification, automatic control, financial distress prediction, etc. It can deal with a series of ratio type information input, and then find its law from a large number of complex data of unknown mode through continuous learning and produce corresponding output, so as to generate a mode that successfully reflects the corresponding relationship between input and output variables. According to the information flow and network topology, the ANN model can be divided into feedforward network and feedback network. Each layer of neurons in feedforward NN receives input information from the previous layer and transmits it to the next layer. There is only one direction and there is no feedback of information. It is the most common and easy to program network structure. A feedforward network includes two basic forms: single-layer feedforward network and multilayer feedforward NN [21]. A single-layer feedforward network consists of an input layer and an output layer. There is no hidden layer in the middle. It can only solve the classification problem of linear separability. A multilayer feedforward NN is composed of an input layer, several hidden layers, and an output layer. It can be used to solve nonlinear classification problems. A single-layer feedforward network is the simplest layered network, whereas a multilayer feedforward network is the most widely used network structure in NN. In the feedback NN, the output information of some neurons is fed back to the upper layer or the same layer, and the information flow is interleaved in the forward and reverse directions.

The role of ANN in credit risk analysis is carried out through the classification function of ANN [22]. That is to say, firstly, a group of factors that affect the classification is found, which are used as the input of ANN, and then an ANN credit risk analysis model is formed through training with or without tutors. For the new sample input, this model can produce the discrimination of credit risk. The NN model includes two processes: training and testing. Firstly, the neurons are trained with training set data, so that different input vectors can get corresponding output values. By repeatedly adjusting and modifying the parameters and thresholds until the error is within the specified range, the training process of NN is completed. The test process is to input a group of data of non-training indicators into the model generated in the training process to test the accuracy of model classification. The ANN method overcomes the complexity of traditional analysis process, especially the establishment of model function and brings great convenience to modeling and analysis. BPNN is a kind of multilayer feedforward NN. BPNN is considered to be the most suitable approximate relationship for analog input and output. It is one of the most widely used ANNs with mature algorithm. BPNN is a multilayer feedforward NN according to the backward propagation of errors, and its learning process consists of forward propagation of signals and backward propagation of errors. Although BPNN has been widely used, it also has its own shortcomings, which are mainly manifested in the uncertainty of the training process.

GA is a relatively new and effective optimization technology. GA is the most well-known evolutionary algorithm at the moment, and it is widely used in machine learning, engineering technology, data mining, computer science, pattern recognition, image processing, social science, and other fields. GA is a global random search algorithm that solves complex problems by simulating the genetic and long-term evolution processes of biology. GA is a group optimization algorithm with the ability to perform global searches due to its multipoint search, allowing the search results to avoid converging to the local optimal solution. As a result, the global optimal solution is obtained, and the accuracy of network evaluation is improved. Some criteria can be used to determine the termination condition of GA, and the algorithm's running process can be terminated when it is determined that the population has matured and there is no evolutionary trend. There are two commonly used criteria:

(1) reaching the preset number of iterations and (2) the difference of average fitness of successive N generations of individuals is less than a certain minimum threshold. The evolutionary nature of GA makes it possible to search for excellent structure in parallel, thus reducing the possibility of falling into local optimum, and this method is also sensitive to the change of credit index. The emergence of GA makes the training of NN have a brand-new look. Using GA instead of BP algorithm to search the connection weight of NN is expected to solve the problem that BPNN falls into the local minimum.

3.2. Credit Risk of Commercial Banks. Credit risk can be defined in two ways: broadly and narrowly. Generalized credit risk refers to the uncertainty or volatility of the future impact of various uncertain factors on commercial banks, such that actual income deviates from expected income, suffers losses, or gains additional income. Narrow credit risk perception means that in the credit business, if the debtor or borrower fails to perform the contract and repay the loan principal and interest, the creditor or bank will incur financial losses because it will not receive the expected benefits. Commercial banks are credit-based industries with high debt and risk, with the profit point of settlement business and money management lending. Commercial banks' operating characteristics, as well as their important position and key role in maintaining national economic stability, have resulted in the characteristics of concealment and diffusion of bank operating risks. Credit risk arises from the asymmetry of information between the two parties to the transaction. This phenomenon occurs before the two parties sign the contract, which is referred to as asymmetric information beforehand, and it is easy to produce adverse selection. Customer credit risk has a direct impact on the quality of bank credit assets, and it can even lead to bank bankruptcy.

Credit risk management process is the concrete implementation of credit risk management policy, the refinement and embodiment of credit risk management, and the main content of credit risk management. Credit management reflects the core competitiveness of commercial banks, and directly or indirectly affects the quality of bank assets, asset growth, income level, and financing strategy. The main goal of credit management is to evaluate the credit risk so as to effectively supervise and control the risk. In the transaction activities in the financial market, for commercial banks, there are intricate credit and interest relationships with borrowers, and the interrelated borrower enterprises form a credit chain. Once an enterprise in the credit chain defaults and fails to repay its accounts payable on schedule, it will cause a series of enterprises in the credit chain to default. Credit risk and credit risk for commercial banks, their subjects are the same, and all of them are due to the change of the debtor's credit status, which leads to the emergence of the value risk of bank credit assets. The difference lies in the range of financial assets they cover. The general framework of the commercial bank credit risk assessment model is shown in Figure 1.

Commercial banks develop relevant policies in order to create an efficient risk management organizational structure and to identify, analyze, evaluate, and respond to credit risks. Credit risk is an unavoidable risk in the day-to-day operations of commercial banks because banks themselves are in high-risk industries, and the asset market is volatile. The goal of improving credit risk management is to reduce the likelihood of such losses occurring. Credit risk assessment refers to the qualitative analysis and quantitative calculation of credit risk influencing factors using appropriate technical means, as well as the assessment and calculation of the borrower's default probability, in order to provide a decision-making basis for commercial banks' credit activities. The overall framework of the credit risk management system primarily consists of the organizational structure, management process, internal control, and credit risk management information reporting and disclosure. After nearly a century of evolution, the basic methods of commercial bank credit risk evaluation have progressed from simple to complex, including proportional analysis, statistical analysis, and artificial intelligence analysis. The methods used in the proportional analysis and statistical analysis stages, for example, can also be referred to as traditional credit risk assessment methods. Despite the fact that the traditional credit risk assessment method has significant limitations, it serves as a valuable reference for modern credit risk assessment.

3.3. Construction of Bank Credit Risk Evaluation Model Based on GANN. In this section, GA is used to optimize BPNN, which is easy to fall into the local minimum and slow in convergence. Before modeling, the data should be standardized to eliminate the influence of different dimensions and improve the accuracy of the model. The basic idea of the optimization algorithm in this study is: firstly, GA is used to globally optimize the weights and thresholds of NN, and then BPNN is used to accurately solve the problem, so as to realize complementary advantages and better solve the problem. Because the system is always developing and changing, the selected learning samples should not only reflect the characteristics of the system when it develops steadily, but also reflect the characteristics of the system when it suddenly changes, and at the same time, take into account all stages of the system development. According to the differences of financial indicators of different enterprises, this study divides the samples into different sets according to the comparability and similarity of financial characteristics of enterprises, and each such set is called a model. The division of patterns is related to the financial characteristics of enterprises and is limited by the number of valid samples under this pattern. If the number of pattern samples meets the requirements of building an evaluation model, the pattern is called an effective pattern; otherwise, it is called an invalid pattern. When establishing the index system, this study selects 18 financial and nonfinancial secondary indicators reflecting the status of loan enterprises. According to whether these indicators have significant differences

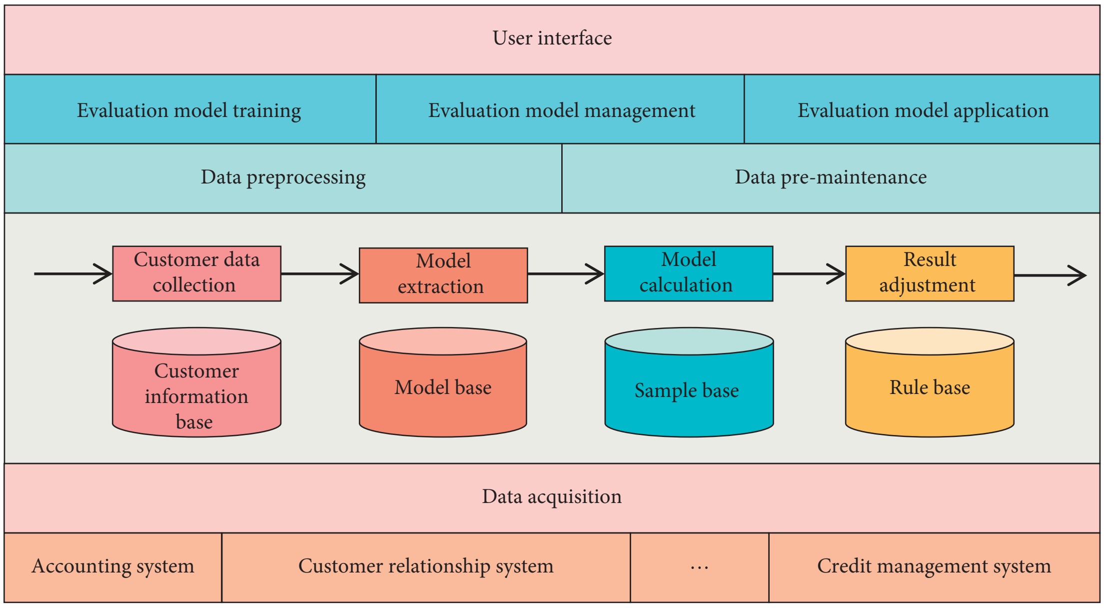

FIGURE 1: Overall structure of the credit risk assessment model for commercial banks.

between normal loans and loss loans, it is determined whether the indicators can be used as input index vectors. This study constructs the index system and follows the following basic principles: scientificity, comprehensiveness, pertinence, and applicability. Considering the availability of data, it constructs a credit risk evaluation index system suitable for commercial banks. The flow of genetic algorithm optimization is shown in Figure 2.

The article chooses three-layer BPNN structure. The input layer contains 19 input units, the hidden layer has 10 nodes, and the output layer contains 4 output units. Since the input initial values and initial weights have a great relationship with whether the learning can reach the local minimum and converge, it is necessary to preprocess the input initial values, that is, normalize them. For the continuous data in qualitative indicators, the feature discretization technology can be used for reduction. The advantage of this technology is that it simplifies the data description, not only greatly reduces the complexity of data mining calculation, but also makes the relationship between data and the final data mining results easier to understand. Data discretization is the process of merging attribute values. By scientifically merging attribute values, the number of attribute values is reduced, thus reducing the complexity of the problem. It is beneficial to improve the classification performance of rule sets obtained in the process of knowledge learning. Generally, when determining the number of neurons in the hidden layer, it is usually necessary to satisfy the following two formulas:

$$\begin{aligned} m &= \sqrt{x+y} + R(10), \\ 2^m &> y, \end{aligned} \tag{1}$$

where m is the number of neurons in the hidden layer, x is the number of neurons in the output layer, and y is the number of neurons in the input layer. $R(10)$ represents any integer between 1 and 10. Assuming that the set $X = \{U_2, U_3, U_4, U_5\}$ and the conditional attribute set $C = \{A_1, A_2\}$, the roughness calculation process of the set X is as follows:

$$\begin{aligned} R^{-}(X) &= \{x \in U | R(x) \subseteq X\} = \{U_2, U_3, U_4, U_5, U_7\}, \\ R_{-}(X) &= \{x \in U | R(x) \cap X \neq 0\} = \{U_2, U_4, U_5\} \neq \varnothing. \end{aligned} \tag{2}$$

Therefore:

$$\rho(X) = 1 - \frac{|POS_C(X)|}{|R^{-}(X)|} = 0.6. \tag{3}$$

If $X = \{U_2, U_3\}$, it is not definable because:

$$\begin{aligned} R^{-}(X) &= \{x \in U | R(x) \subseteq X\} = \{U_2, U_3, U_5, U_7\}, \\ R_{-}(X) &= \{x \in U | R(x) \cap X \neq \varnothing\} \neq \varnothing. \end{aligned} \tag{4}$$

Because there are redundant attributes and noise data in training data, it will affect the efficiency and convergence speed of GA. Therefore, attribute reduction of raw data is needed to improve the algorithm efficiency. This study uses the attribute reduction algorithm based on attribute importance. This method can accurately reduce redundant attributes and maintain the original correlation between data, which provides a strong guarantee for the performance and accuracy of GA. The output layer of this study adopts a neuron, and the output value is close to indicate that the enterprise is classified as a high-risk category, and the closer the output value is, it indicates that the enterprise belongs to a low-risk category. Suppose that in the qth iteration, the output error p of the $e_p(q)$th node at the output end:

$$\begin{aligned} e_p(q) &= t_p(q) - y_p(q), \\ p &= 1, 2, \ldots, k, \end{aligned} \tag{5}$$

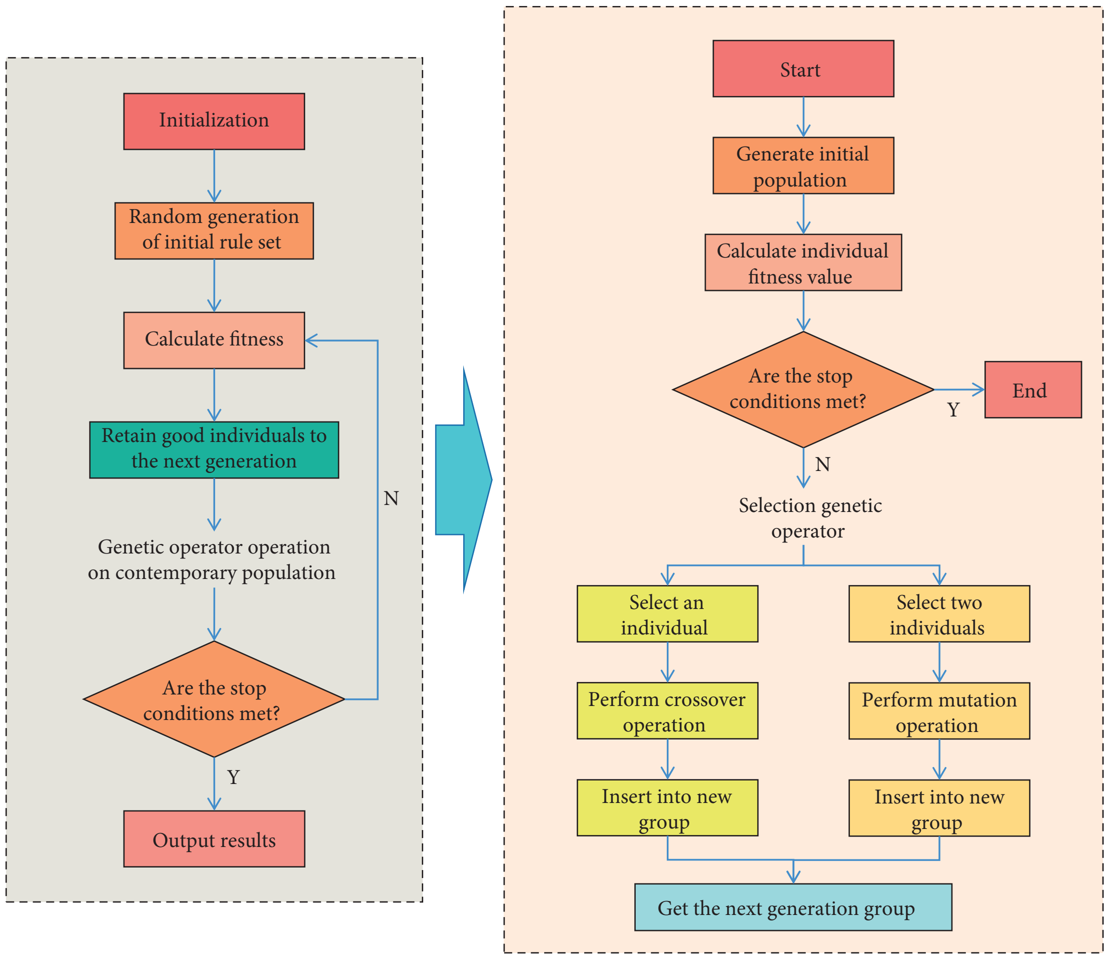

Figure 2: Genetic algorithm optimization process.

where $t_p(q)$ is the target output value, $y_p(q)$ is the actual output value, and the mean square error signal is:

$$\begin{aligned}\xi_p(q) &= \frac{1}{M}\sum_{s=1}^{M}\left(\frac{1}{k}\sum_{l=1}^{k} e_p(q)^2\right)\\ &= \frac{1}{M}\sum_{s=1}^{M}\left(\frac{1}{k}\sum_{l=1}^{k}\left(t_p(q)-y_p(q)\right)^2\right).\end{aligned} \tag{6}$$

The above formula can be expressed as a vector:

$$\xi_p(q) = \frac{1}{M}\sum_{s=1}^{M}\left(\frac{1}{k}\sum_{l=1}^{k}(T(q)-Y(q))^2\right). \tag{7}$$

The gradient of $\xi(q)$ with respect to $v(q)$ is:

$$\begin{aligned}\nabla(\xi(q)) &= \frac{\partial\xi(q)}{\partial v(q)}\\ &= \frac{\partial\xi(q)}{\partial Y(q)}\cdot\frac{\partial Y(q)}{\partial v(q)}\\ &= -E(q)g(U(q))\left[g\left(W(q)^T\right)X + B_1(q)^T\right]^T.\end{aligned} \tag{8}$$

The initial parameters are set as follows: initial threshold θ, initial weight W, and momentum term α. The values of Z_j and y_k are calculated according to the following formulas:

$$\begin{aligned}z_j &= f\left(\sum_{i=1}^{n} w_{jk}x_i - \theta_j\right),\\ y_k &= f\left(\sum_{j=1}^{l} w_{jk}z_j - \theta_k\right),\end{aligned} \tag{9}$$

where n is the number of samples, θ_i is the threshold between the hidden layer and the input layer, θ_k is the threshold between the output layer and the hidden layer, and l is the number of neurons in the hidden layer. The error between the layers is found according to the following formula:

$$\begin{aligned}\delta_{jk}^{\phi} &= \left(t_l^{\phi}-y_l^{\phi}\right)y_l^{\phi}\left(1-y_l^{\phi}\right),\\ \delta_{ij}^{\phi} &= z_j^{\phi}\left(1-z_j^{\phi}\right)\sum_{k=0}^{m}\delta_{jk}^{\phi}w_{jk},\end{aligned} \tag{10}$$

where m is the number of neurons in the output layer.

When using GANN model for credit risk assessment and analysis, we should first set the corresponding parameters of NN to ensure the effective operation of the assessment model. Then the credit risk evaluation index value and target value of the evaluation sample are inputted, and the network to make the output value close to the target value is trained. In this study, in the process of optimizing BPNN by GA, the main functions and parameters of GA are: determining 800 generations of genetic algebra. Using real coding method, the fitness function is selected according to the error. The larger the error, the smaller the fitness. The selection is based on the fitness scale method. Single point crossing, the crossing rate is 1. Uniform variation, the variation rate is 0.08. The fitness function will directly affect the efficiency of solving problems with GA. A good evaluation function should better reflect the background knowledge of solving the problem, which is more conducive to guiding GA to search for a better solution space. In this study, every training data are matched with every rule of the solution. If any rule matches the training data, it is considered as a correct classification of the solution. The fitness of each individual can be defined as the square of the ratio of the number of times it correctly classifies training data to all training data. Learning rate is the magnitude of weight adjustment after each step of training. The greater the learning rate, the greater the magnitude of weight adjustment and the faster the error curve converges. The gradient descent method used in NN operation may cause the error plane to fall into the local minimum, and the additional momentum model constructed in this study can effectively solve this problem.

4. Result Analysis and Discussion

In the simulation experiment, the number of nodes in the input layer is determined by the number of sample indexes. Different number of hidden layer nodes will form different NN models, which need constant and repeated debugging to obtain appropriate network parameters, thus forming an effective credit risk assessment network model. In this study, the company that has been specially treated is called ST company, and the company that has not been specially treated is called non-ST company. It means that the company's credit risk is relatively poor, which means that the company has fallen into debt repayment or has a high possibility of credit risk. Non-ST company means that the company operates normally and the possibility of default is very small. It is used to represent the sample with good credit. ST is used to represent the default sample, and the output value in the model is represented by 1. The output value of non-ST company in the model is represented by 0. The number of output layer nodes is 1. With 0.5 as the critical point, when the output value is less than 0.5 and close to 0, it belongs to ST enterprise. When the output value is greater than 0.5 and close to 1, it is a non-ST enterprise.

This study selects 350 listed companies as test samples, including 56 ST companies and 294 non-ST companies. After the data of 350 companies in the test sample are standardized, the value of credit risk evaluation index can be used as the input mode. The 350 companies selected in this study cover the electronics industry, chemical industry, paper industry, wine industry, chemical fiber industry, science and technology industry, pharmaceutical industry, automobile manufacturing, and other industries, which are quite representative. The specific settings are shown in Table 1.

Table 1: Performance comparison of different algorithms.

Industry	ST company	Non-ST company
Electronic industry	39	8
Chemical industry	51	4
Paper industry	28	7
Brewing industry	17	10
Chemical fiber industry	45	6
Technology industry	42	4
Pharmaceutical industry	26	5
Automobile manufacturing industry	34	9
Other industries	12	3
Total	294	56

This study uses MATLAB tools to build GANN, and then uses VisualC++, which can develop applications with good interactive functions, compatibility, and expansibility, to write user interface programs. In the standardized test sample input, the network model is used to simulate the operation, without setting the target expectation value, and the output value of the model is compared with the sum to check the accuracy of the simulation. The function of gradient descent backpropagation algorithm with adaptive adjustment of learning rate and momentum factor is a combined optimization algorithm of gradient descent method and adaptive adjustment of learning rate method. In this study, the training function chooses traingdx algorithm. Figure 3 shows the training of different models.

It can be seen from the Figure 3 that the traditional NN algorithm evaluation model took 912 steps to achieve the accuracy requirement, the BPNN algorithm evaluation model took 742 steps to achieve the accuracy goal, and the improved BP algorithm evaluation model only took 523 steps to achieve the accuracy goal.

In order to further illustrate the accuracy and reliability of the model constructed above, we also need to verify it with test samples. The training errors of traditional NN algorithm, BPNN algorithm, and GANN algorithm on data set A are shown in Figure 4. The mean absolute error of traditional NN algorithm, BPNN algorithm, and GANN algorithm on data set B is shown in Figure 5.

It can be seen from Figures 4 and 5 that the MAE values of GANN algorithm on different data sets are all at a low level. Compared with the contrast algorithm, the error is smaller, which shows that this algorithm has certain accuracy. In this study, the initial weight, learned weight, training data set, test data set, application data set, and other data are established into files to facilitate program call. The performance comparison of immune algorithm, traditional NN algorithm, BPNN algorithm, and GANN is shown in Table 2.

From the data in the table, it can be seen that BPNN with GA optimized weights has greater advantages in time and accuracy than other three different models. It can be

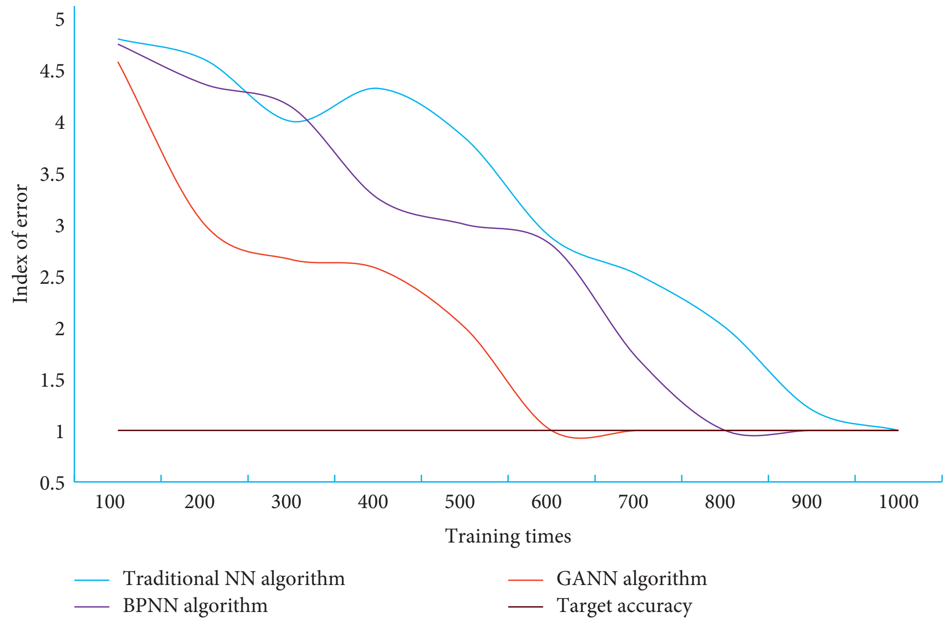

Figure 3: Training of different models.

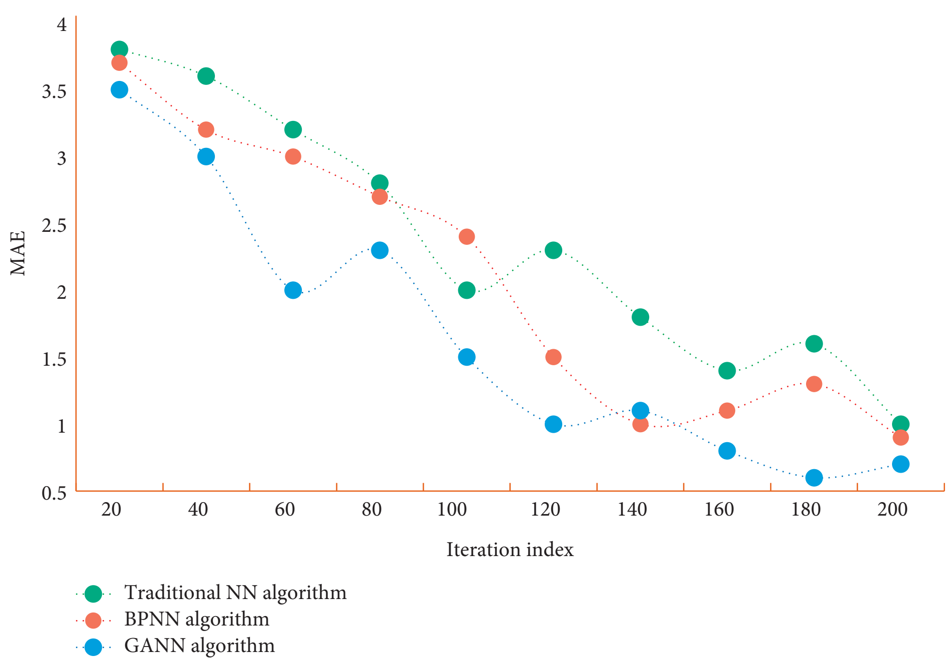

Figure 4: MAE of different algorithms on data set A.

seen that GANN has strong advantages in evaluating the credit risk of commercial banks. In order to ensure the reliability and credibility of the obtained results, this study draws the accuracy performance of different algorithms on different data sets into data graphs, as shown in Figures 6 and 7.

It can be seen that the accuracy of this method is always at a high level, whether on data set A or B. The highest accuracy rate of this method is 94.17%, which is higher than that of BPNN algorithm 89.46% and immune algorithm 90.14%. The accuracy of GANN in this study is better than the other two algorithms, and this result shows the accuracy

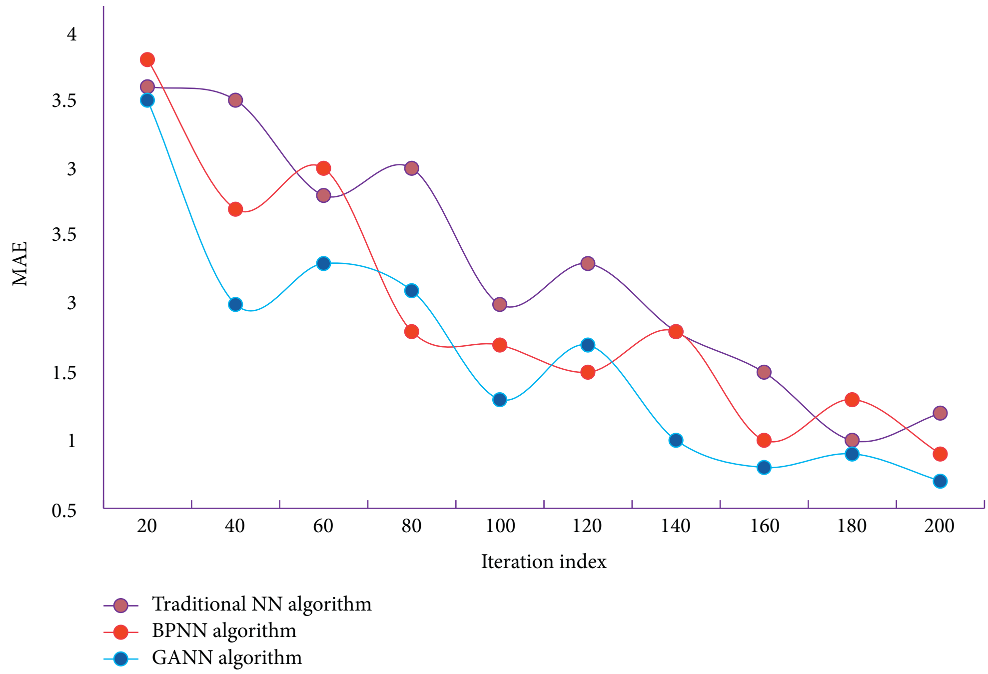

Figure 5: MAE of different algorithms on data set B.

Table 2: Performance comparison of different algorithms.

Algorithm	Accuracy (%)	Training time
Immune algorithm	90.14	7.412
Traditional NN algorithm	86.73	8.293
BPNN algorithm	89.46	7.014
GANN algorithm	94.17	6.154

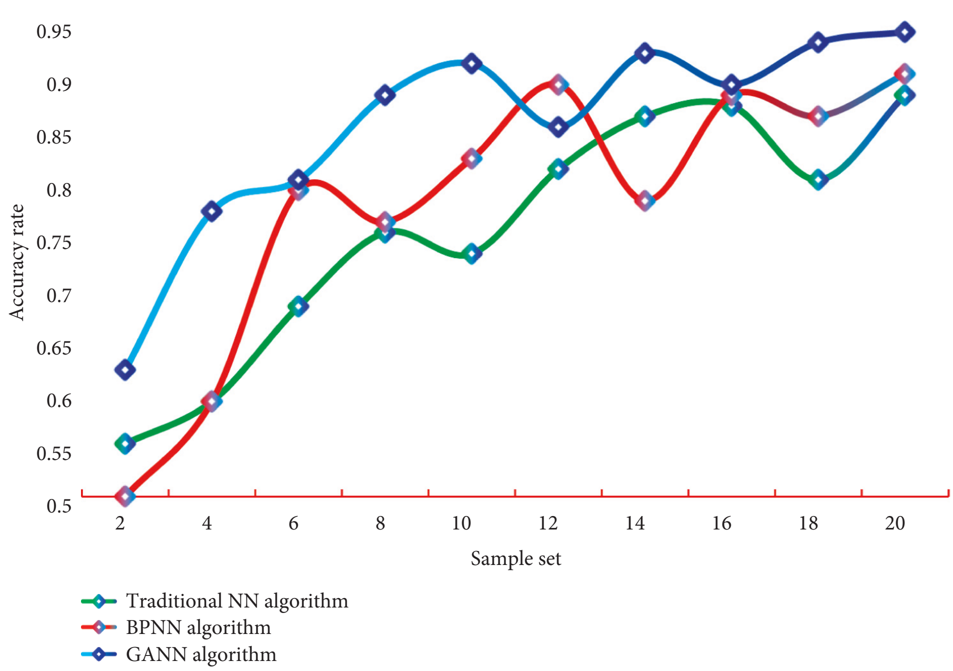

Figure 6: Accuracy performance of different algorithms on data set A.

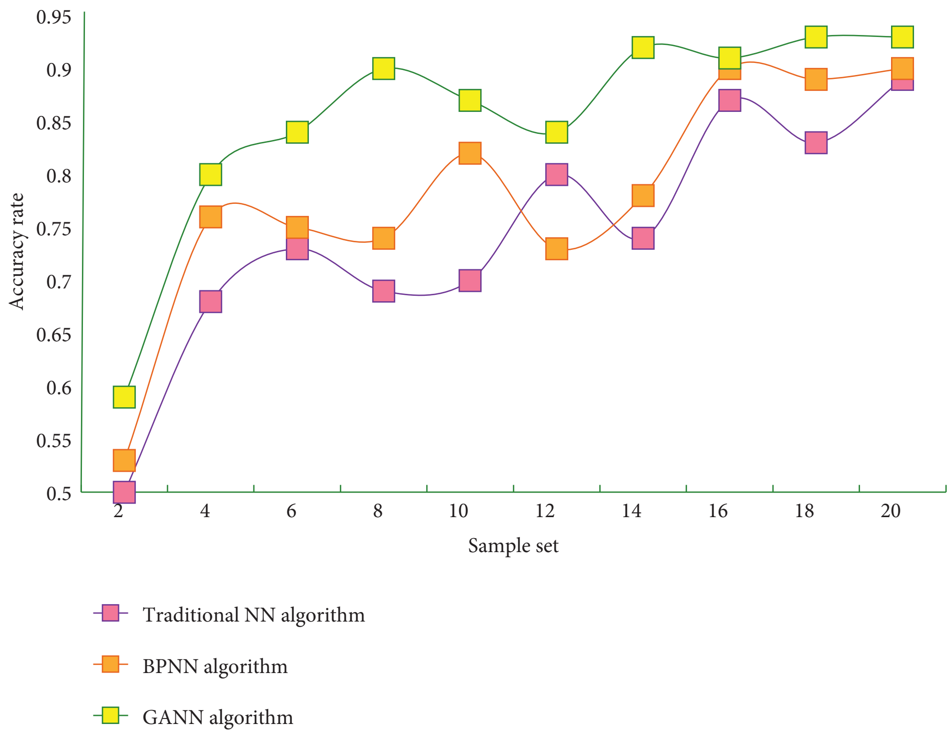

FIGURE 7: Accuracy performance of different algorithms on data set B.

and reliability of the optimization algorithm in this study. It can be seen that the model constructed in this study has certain practicability and practical significance.

5. Conclusions

Commercial banks play an important role in the implementation of financial policies and social investments. Credit risk identification, evaluation, monitoring, reporting, and control are the main components of commercial banks' credit management. The assessment of credit risk is the cornerstone of all of them. This study builds a credit risk assessment model for commercial banks using GANN based on credit risk research. In this model, GA is used to create a practical GA coding scheme that addresses the shortcomings of BPNN, such as its tendency to fall into the local minima and slow convergence speed. In addition, a credit risk evaluation index system is established, which is classified by industry and is primarily based on quantitative indicators, with qualitative indicators supplemented. In addition, improved credit index data preprocessing technology and methods are presented. According to simulation results, this method has a higher accuracy rate of 94.17 percent than the BPNN algorithm (89.46 percent) and the immune algorithm (90.14 percent). Traditional algorithms' convergence speed and search efficiency are improved by the optimization algorithm presented in this study. It has some practical value and significance, and it provides a method for commercial banks to assess credit risk that is both effective and reliable. However, due to time and level constraints, some parts of this study continue to have flaws: the improvement in the fitness function and the correlation analysis of credit risk assessment indicators are insufficient. The following step in this study will optimize the improvement in the fitness function and investigate the correlation of credit risk assessment indicators in depth.

Retracted: Design of Teaching Quality Analysis and Management System for PE Courses Based on Data-Mining Algorithm

Computational Intelligence and Neuroscience

Received 26 September 2023; Accepted 26 September 2023; Published 27 September 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Advances in network technology have led to extensive information technology construction work in all walks of life; universities, as a key component of national development, cannot be overlooked in this regard. In today's universities, the Web-based integrated academic management information system is widely used, promoting higher education management system innovation and improving the management level of education departments and teaching management. The traditional management mode is incapable of locating "knowledge" in the mountains of student transcripts, and the original management mode must be improved. In business, finance, insurance, marketing, and other fields, digital exploration technology is widely used. This article describes the design approach for a data mining-based analysis and management system for PE course teaching quality, as well as the application of information technology and data mining technology in PE by combining actual PE teaching in schools, with the goal of realizing a data mining-based PE performance management system to serve PE teaching in schools and improve PE teaching quality. The results show that the time required to find frequent itemsets using a traditional algorithm running on a single machine, as well as the time required to scan the database several times for frequent itemset search in a distributed cluster of 20 computing nodes, is significantly longer than that required by the data mining algorithm. As a result, the proposed sports performance management system is functional, simple, and scalable, with each functional module operating independently and cooperatively, reflecting the concept of "high cohesion and low coupling."

1. Introduction

Along with the expansion of college operations, the number of students is increasing year by year, and the teaching of physical education, which is an important part of school education, has sparked a wave of pedagogical reform [1]. Classroom teaching is the primary means of achieving educational goals in schools, and its effectiveness has a direct impact on the learning quality of students [2]. Colleges use improving higher education quality and cultivating special talents as the purpose of school operation in order to respond to the national call and achieve the state's higher education development goals [3]. The original grade data analysis method, on the other hand, is unable to thoroughly analyse and capture information useful for teaching and learning from large amounts of grade data, resulting in inefficient use of teaching information resources. This has resulted in grade management based primarily on simple statistical analysis, such as processing student identity. Data mining [4, 5] is a vital information processing technique [6, 7] that has been widely adopted in a variety of industries around the world, generating significant economic and social value.

The service that universities provide to students as a "service-oriented enterprise" is "education." We can only "produce" a high-quality product—graduates—and establish a brand name in the education market by continuously and effectively improving education quality [8]. Knowledge and rules in the knowledge base are created by experts or programmers using external input in traditional decision support systems [9]. Data mining is an automatic process of acquiring knowledge from within a system with the goal of discovering undiscovered knowledge in a large amount of data [10]. Online query and analysis can be used to process information that is clearly understood by decision-makers [11]. It is beneficial to motivate teachers, improve teaching quality, and strengthen faculty construction and scientific management by establishing a good teaching quality evaluation mechanism [12].

Many schools now conduct physical activity and achievement tests for their students [13]. The majority of these post-test scores, however, are only saved as data or files in school computers, and these students are unaware of their physical condition despite having completed the relevant physical fitness tests [14]. Analysing and processing these massive amounts of data using traditional data analysis and data query validation methods are not only computationally intensive but also completely reliant on pre-assumed and estimated data relationships. In data, there is a growing demand for tacit knowledge [15]. The use of parallel computing and data-mining arithmetic can help to solve this problem to a large extent, because parallel computing can provide the computational power required to process large amounts of data, and clusters can scale up the computational power as the data grows. In response to the problems and current state of PE in universities, relevant information is compiled, and modern data mining techniques are fully employed to automate the processing and analysis of large amounts of sports data in order to assist students. Professors and consultants analyse statistical data. In this paper, technology for digital exploration is introduced into the performance analysis of the university teaching system, with the goal of identifying factors affecting students' performance and specifically improving teaching quality. The innovative points of this paper are as follows:

(1) Using data mining techniques to uncover possible hidden relevant factors that affect teachers' teaching level, provide specific indications for improving teaching level, and apply them to teaching practice.

(2) Research and analysis of existing student data information using association rule extraction technology, and statistical analysis of some factors affecting teaching quality in schools using scientific methods, so as to evaluate teaching quality and student learning quality.

(3) The purpose of the analysis and management system of PE curriculum with quality according to data mining algorithm is to enhance the productivity and accuracy of PE teachers in schools, free them from tedious and boring work, and then improve their management-level teaching quality.

The first part of this paper introduces the background and significance of the study, and then introduces the main work of this paper. The second part introduces the work related to the teaching quality analysis and management system of PE courses, data-mining arithmetic. In the third part, the system functional module design and the logical system design of the physical education database are explained so that the readers of this thesis can have a more comprehensive understanding of the design idea of the physical education curriculum teaching quality analysis and administration system based on the data mining algorithm. The fourth part is the core of the thesis, which describes the usage of data mining algorithm in the quality control system of physical education from two aspects: data point set compression and discard analysis and large-scale data set clustering process analysis. The last part of the thesis is the summary of the full work.

2. Related Work

2.1. Quality Analysis and Management System of PE Course Teaching. To enhance the cultural qualification of all the people, China's higher education has made rapid progress, with major breakthroughs in system reform, successive expansion of various colleges and universities, and leapfrog development in the scale of college operation. However, it is impossible to implement the national education policy, let alone to implement quality education, if the physical health training of young people is neglected. Therefore, classroom teaching quality monitoring has great significance as an essential component of the university's education quality supervision mechanism, and the study and improvement of the teacher classroom teaching quality evaluation system is one of the hot spots and priorities of the current higher education evaluation of quality management.

From the perspective of effectiveness, Cao defined teaching quality evaluation as the evaluation process, which is essentially the process of determining the extent to which curricula and learning programmes actually achieve educational goals [16]. Cui and Yoon proposed a decision tree data extraction method that combines this algorithm with the SLIQ algorithm and applies it to a database of student grades to analyse various data and build a decision tree model through analysis [17]. Parmezan et al. proposed a teacher teaching quality assessment questionnaire that includes nine dimensions such as teaching quality, value of learning, enthusiasm for teaching, teaching organization and clarity, group interaction, interpersonal harmony, breadth of knowledge, examinations and test scores, homework, and other reading materials [18]. Zhang et al. conducted an in-depth study on mining techniques and proposed the ID3 algorithm to manage the university faculty-related data was extracted and analysed to discover correlations between various course environments with a view to providing data university decision reference [19]. Yin discussed the application of distortion-resistant algorithms in mining association rules. This algorithmic technique significantly reduces the number of database scans by a factor of even less than two. The algorithm with the shortest scanning time is the use of sampling to collect relevant data [20].

Teaching quality analysis is an important tool for evaluating teaching and learning. Data-mining arithmetic is used to analyse data generated from examination processes and teaching sessions at multiple levels and perspectives. Utilizing the analysis results to assist teaching decisions is an inevitable requirement for assuring teaching excellence and enhancing the quality as well as the overall competence of students and teachers.

2.2. Data-Mining Arithmetic. Given the current rapid development of higher education, self-monitoring of school teaching quality has become an important guarantee for scientific administration, and the development and implementation of teaching quality evaluation systems has become an important tool for implementing teaching control. Currently, digital exploration technology is widely used in telecommunications, commerce, banking, and enterprise production and marketing, but it has a limited use in education. As a result, this research focuses on the performance analysis characteristics of PE courses and integrates them with practical work to propose a data mining-based algorithm for identifying the keys that have the greatest impact on students and enhancing their learning experience. Dan and Li classify the original data set for large-scale data sets, analyse the OS virtual memory implementation mechanism, and improve the original FP-GROWTH algorithm in terms of spatial and temporal locality to make it a mining algorithm with perceptual input and output [21]. Gong and Lin proposed a multivariate strategy, which combines previous mining and discovery techniques and applies them to the qualification database to help universities make better decisions. To assist teachers in making teaching decisions, the results of each subject are computed, as well as a performance analysis report and related analysis table [22]. The hardware and software infrastructures for distributed association rule mining algorithms were investigated by Atta-ur-Rahman and DaSh. They looked at distributed data mining algorithms, parallel mining algorithms, and distributed parallel databases [23]. Li et al. discussed the Apriori association rule algorithm and the well-known decision tree ID3 algorithm, as well as their application scope [24]. Huang used a similar algorithm, Random-kmeans [25], to sample the original data set statistically and pool the smaller data set after sampling. The relationships and trends that are hidden in large amounts of data are beyond the ability of even the experts who manage these data to discover, and this information is potentially and critically important for decision-making, which is what data mining aims to solve.

3. Design Ideas of Teaching Quality Analysis and Management System of PE Courses Based on Data-Mining Arithmetic

3.1. System Functional Module Design. An important task of the generic system design phase is to determine how the system will accomplish the intended functionality using a more abstract and generic approach [26]. Thus, the overall design phase has three main subphases, starting with the test type management module, followed by the test project management module, and finally the result management module. Data mining is the complete process of extracting previously unknown, valid, and useful information from a database through data mining tools and using this information for decision-making or knowledge enrichment. The system functional module diagram is shown in Figure 1.

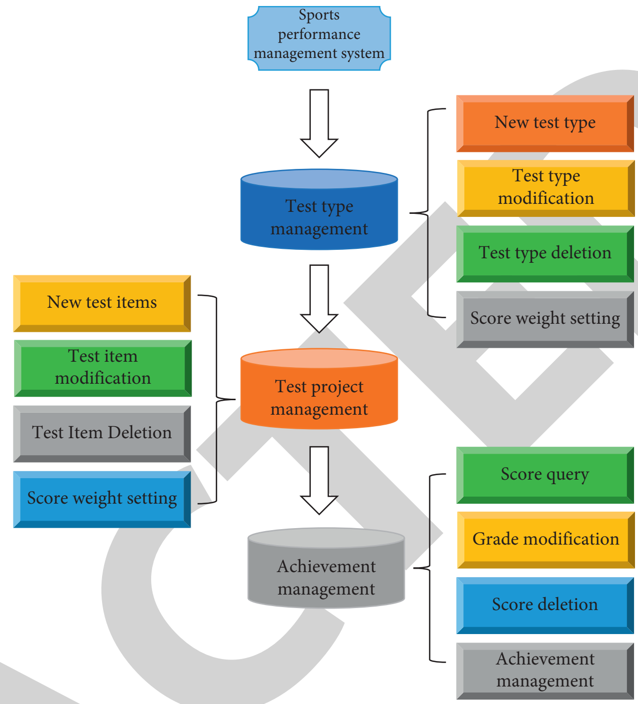

Figure 1: System function module.

First, the test type management module completes data preprocessing [27] and management of sports event types, including adding, modifying, deleting, and configuring the weights of event types. Data preprocessing is mainly done by cleaning, integrating, selecting, transforming, and conceptually layering data attributes to form tuples from the data training set. The information entropy of sample classification is as follows:

$$I(x_1, x_2, \ldots, x_n) = -\sum_{i=1}^{n} p_i \log_2 p_i. \tag{1}$$

The construction of the teaching quality evaluation system includes two aspects: the determination of indicators and the determination of weights. Indicators are specific, measurable operational and behavioural goals of a particular aspect; that is, they do not reflect the complete goal, but only one aspect of the goal. Simultaneous comparative analysis of factor data of different dimensions requires their standardization. The value of i factor j in all samples is as follows:

$$Z_{i,j} = \frac{X_{i,j} - \mu_j}{\sigma_j}, \tag{2}$$

where μ_j is the mean value of the i th factor and σ_j is the standard deviation of the j th factor.

The business problems to be mined are identified by a detailed understanding of the raw data to be extracted and the business problems to be applied in practice before starting data mining. In data mining, determining the purpose of mining is crucial. Mining produces unpredictable results, but the problem to be mined must be predictable, and mining blindness must be minimized. It is necessary to determine whether the test type contains test elements. It is impossible to remove something that already exists. Otherwise, the deletion procedure is carried out. Figure 2 depicts the programme flow for performing this function.

Secondly, the evidence project management module completes the operations of adding, modifying, deleting, and setting weights of sports evidence items. Due to the large amount of data, among these data, the required data suitable for this data mining are selected to establish a data mining library [28]. It generally includes data selection, selection of relevant data, noise, data purification and elimination, inference of missing data, conversion of discrete-valued data to continuous-valued data, grouping, and classification of data values. Each itemset needs to carry a decision attribute d, and when performing a join to produce a candidate $k+1$ itemset, two frequent k itemsets that can undergo the join operation must satisfy

$$(l_a, l_h) \in \{(l_1, l_2)|\text{diff}\,(l_1, l_2) = 1, d_1 = d_2\}. \tag{3}$$

As a result, the test management module enables the administration and maintenance of classroom quality assessment programmes, as well as the adjustment of the number of test questions or test content as needed. An independent internal hierarchy to describe the functions or characteristics of the system is created based on the requirements of the questions, and a judgement matrix of higher-level elements is created by comparing the relative importance of factors or objectives, criteria, and plans. To get a sequence of relative importance of relevant elements to higher level elements, a recursive hierarchy is built. Confidence thresholds must be set in order to extract rules from a set of frequent items and calculate the confidence level of the bar rule when extracting sports databases using the active search mining algorithm.

$$\text{Confidence} = \frac{\text{support}}{|\text{matched}|}. \tag{4}$$

Finally, the score management module completes the operations of adding, modifying, deleting, querying, exporting, and grading system conversion of students' sports test scores. The incomplete, noisy, and random data are sorted out, and the unwanted data are cleaned. Suppose S is the set of s data specimens, and the expected amount of information required to classify a given sample assuming that the class label attribute has a distinct value

$$I(s_1, s_2, \ldots s_m) = -\sum_{i=1}^{m} \log^{2}\frac{s_i}{s}. \tag{5}$$

Then, according to the data mining objectives and data characteristics, appropriate analysis models are selected for the data-mining arithmetic and the data are transformed. The module can classify courses. Different assessment items can be set for each course type. For courses that do not require assessment, you can also set up multiteacher classes to allow for more specific assessment of students. Relevant factors are broken down into levels based on their attributes

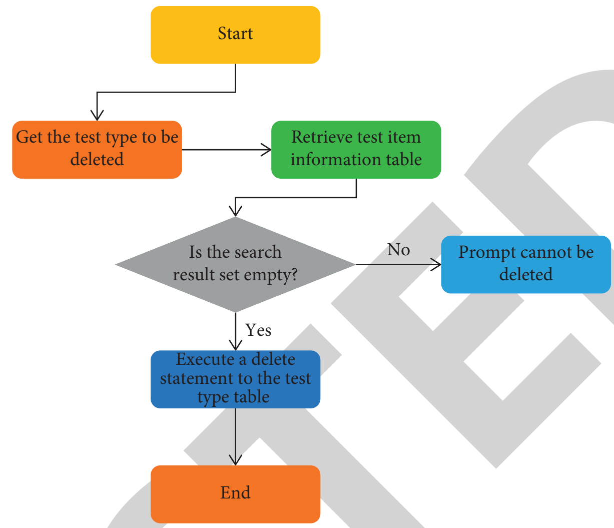

Figure 2: Process of test type deletion programme.

from top to bottom, with each factor at the same level being subordinate to, or having an influence on, the higher level factor, while dominating the lower level or being influenced by the lower level factor. Then, using a prototype system, developers brainstorm with users to iteratively modify and expand the prototype until the final system is formed.

3.2. PE Database Logic Design. The database logical design determines the overall performance of the database and its applications, tuning location [29]. If the database logic is poorly designed, all tuning methods will have limited effect on improving the database performance. The flow of data mining is shown in Figure 3.

First, the conceptual structure is transformed into the corresponding data model, such as relational model, network model, and hierarchical model. The data are cleaned, synthesized and filtered from data sources, and then entered into the database for data mining, pattern evaluation, and knowledge representation. According to the level of abstraction of datum in the proposed rule, association rules can be classified into single-level correlations and multiple-level correlations. KL scatter, also known as relative entropy, is used in the field of statistics to calculate the degree of agreement of two probability distributions, and in the area of machine knowledge to measure the closeness of two functions, and is calculated as follows:

$$KL(pq) = \sum p(x)\log\frac{p(x)}{q(x)}. \tag{6}$$

Single-level association rules do not consider the hierarchical nature of the actual data attributes, but simply describe the attributes of the data [30]. Metadata is the core of the data warehouse and is used to store data models, define data structures, transformation planning, data warehouse structure, and control information. The management part includes data security, archiving, backup, maintenance, and recovery. The index interval $[a, b]$ of the soft constraint is given based on empirical data and detects whether there exists

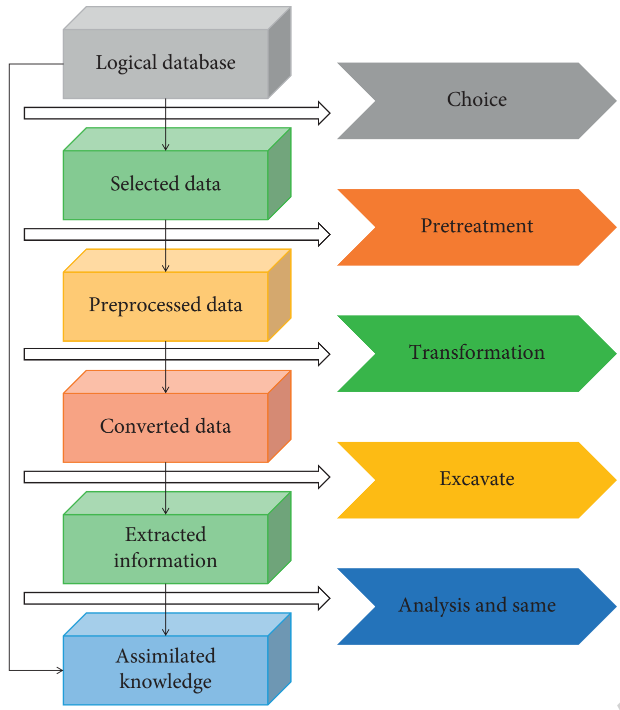

FIGURE 3: Process of data mining.

a solution within the initial solution set T that meets the requirements of the soft constraint. If it exists, it is marked as a feasible solution; otherwise, the parameter range of the constrained indicator interval is adjusted until a feasible solution exists; assuming that B is a diagonal matrix, the above formula can be transformed into the following form.

$$e(y,z) = \left[\sum_{j=1}^{p} b_{ij}\left|y_j - z_j\right|^s\right]^{(1/2)}, \tag{7}$$

where b_{ij} represents the i, j data attribute in the database.

In this step, data will be extracted and integrated from the operational environment, semantic ambiguities will be resolved, dirty data will be removed, etc. The process of summing data and calculating data averages are both statistical methods, and the results of these calculations are represented by certain graphs, such as histograms and pie charts. The absolute value function of the factor coefficients in the regression equation is added to the model as a penalty term to make some regression coefficients smaller. By regression, the coefficients of factors whose absolute values are not sufficient to explain the dependent variable can be changed directly to 0. The expression of the LASSO method can be written as follows:

$$\overline{\beta} = \arg\min\left\{\|Y - X\beta\|^2 + \lambda\sum_{j=1}^{p}\left|\beta_j\right|\right\}. \tag{8}$$

Next, these data models are converted into data models that can be supported by the corresponding database management system. First, all frequent itemsets in the data set are found, and the itemsets that satisfy the minimum support threshold are called frequent itemsets, and then, association rules are generated from these frequent itemsets, mainly by extracting frequent itemsets from all the generated high confidence levels. As a large amount of detailed and descriptive data is stored in the data warehouse, the data set is relatively large and requires a large number of join operations between relational tables to respond to the user's analysis request, increasing the response time user. But the data are stored only once, saving space compared to MOLAP, and analysis can get more detailed data; that is, the granularity of analysis can be relatively fine. So, the branching of attributes is carried out cyclically, and the information gain is the entropy compression expected after knowing the value of the attributes, which is given by the formula:

$$\text{Gain}(A) = I(s_1, s_2, \ldots s_m) - E(A). \tag{9}$$

The database is logically divided into several disconnected blocks, each of which is considered individually and for which all frequency sets are generated. The generated frequency sets are then combined to generate all possible frequency sets, and finally, the support of these element sets is calculated. It is possible to distinguish the similarity of tedious repetitive data in the database, and feature vectors can describe the relevant data with high similarity in the database. The variation parameters of the different features of the data attributes can be calculated using the following formula:

$$e(y,z) = \left[\sum_{j=1}^{p}\left|y_j - z_j\right|^s\right]^{(1/s)}. \tag{10}$$

Finally, the association rules are verified and the transformed model is optimized. If the extracted rules meet the evaluation mechanism's requirements, the knowledge is sent to the evaluation system and stored in the knowledge base. The knowledge is also stored in the knowledge base if the extracted rules do not meet the evaluation system's requirements. The indexing strategy, data storage location, and storage allocation operation are all determined. Data modelling is needed after determining the data warehouse information to be searched to determine the process of extracting, cleaning, and transforming data from data sources to data warehouse, analysing and dividing dimensions, and determining the physical data storage structure. The primary goal of grade data processing in the academic affairs system is to unify and disambiguate data types. Data decomposition reads data from segmented blocks into memory for processing and then merges all processing results, overcoming the memory bottleneck and improving data set extraction efficiency.

4. Analysis of Data-Mining Arithmetic in PE Teaching Quality Analysis and Management System

4.1. Data Point Set Compression and Discard Analysis. When the data-mining arithmetic performs in-memory clustering, the data point set is clustered in general and the resulting clusters are marked as the main clusters, and then, the data set in the main clusters is discarded and compressed for deletion. The main memory space reads the data to be clustered again and continues clustering until all clustering work is completed. By setting the maximum available size of the programme, it is shown that this data-mining arithmetic can extract association rules for large data sets in a small memory space. A comparison of the system CPU and GC activity is shown in Figure 4.

First, the discarding process is completed in two steps, which are called primary discarding and secondary discarding. The IP of the data node is obtained from the configuration file, so each node must be a static IP address. The specific configuration table of IP of this system is shown in Table 1.

The main idea of these two discard processes is to move the points that do not change the cluster attributes out of the main storage and store them in the discarded data set. The points in the marker set are not involved in this process and always guide the mining process. Information entropy, called entropy in information theory, is used to measure the average value of the transmitted information. Here, since the process of generating frequent itemsets from candidate itemsets must pass through the database, the most critical part of this process is how to generate the minimum number of candidate itemsets correctly. Therefore, for processing, users classify the data according to their needs and then extract the different parts, thus increasing the extraction speed. The statistical experiment time also does not include the time to write the discovered itemsets to disk in order to accurately count the running time of each algorithm. The support levels are set to 5 and 10, and each algorithm is executed 5 times at each support level, and the average of the statistical record execution time is shown in Figure 5.

Secondly, the main idea of the compression process is to replace high-density regions during the pooling process to clean up the main storage space. It divides the recommendation process into two parts: offline and online. The offline part constructs a cluster using the similarity between users and uses the average rating value of the users in the group as the centre of the group. The set of data points within this region has the same category affiliation and the categories change as a whole. The breast cancer data set was preprocessed, and files of different sizes were obtained by backup. Each file size is approximately 150 million and contains 2 million transaction records. Three D_1 to D_3 data sets were defined, and their specific configurations are described in Table 2.

While the traditional algorithm for finding frequent itemsets using a single machine running a distributed cluster of 20 compute nodes requires multiple scans of the database, the data-mining arithmetic can complete the task of finding frequent itemsets with little time consumption. It only needs to scan the transactional database twice, and does not generate a large number of temporary intermediate key-value pairs, and takes advantage of parallelization very efficiently.

Thus, it can be considered as a whole and can keep its grouping information and have sufficient statistical information. According to the rules defined by the data definition component, the data from the data source are extracted into the data warehouse, cleansing, and transformation; integration work is done; the data are loaded into the data warehouse; the data warehouse data are periodically cleansed; inconsistencies between data are eliminated data storage and source databases; and invalid data are eliminated. A basic principle is that when a transaction does not contain a large set of length k, it should not contain a large set of length $k + 1$. The information transferred at the source consists of a limited number of mutually exclusive joint

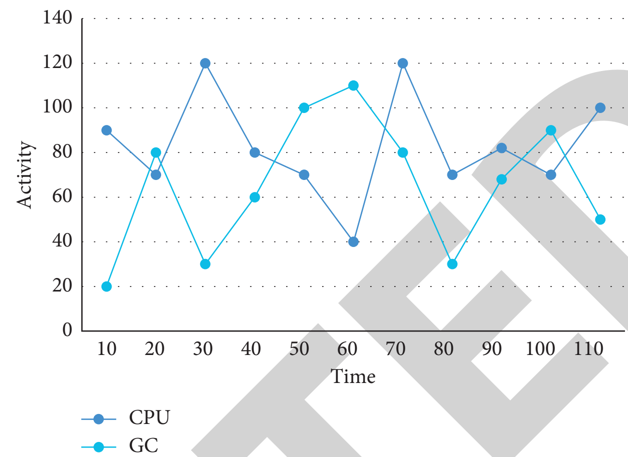

Figure 4: Comparison of CPU and GC activities.

Table 1: IP-specific configuration table.

Machine name	Masker	Slave 1	Slave 2	Slave 3
IP address	192.168.5.23	192.168.5.34	192.168.5.25	192.168.5.31
Attribute	Name node	Data node	Data node	Data node

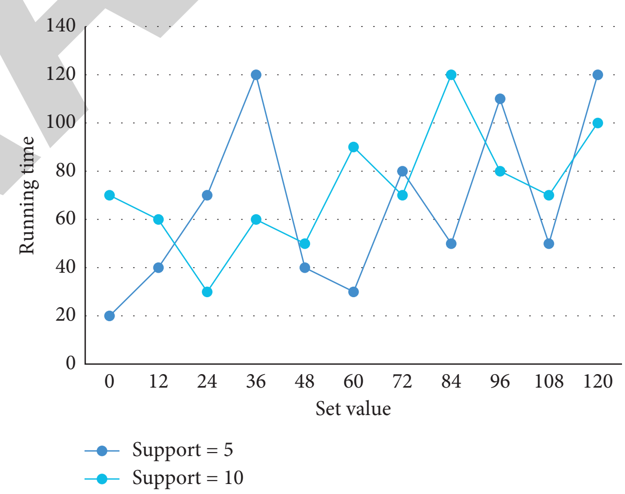

Figure 5: Running time of the system with different durations.

Table 2: Data set size based on mining association rules.

Data set	D_1	D_2	D_3
Average number of items	35	41	49
Number of data files	5	10	12
Transaction record number	6000	13000	13000

complete events, all of which occur with a certain probability. The effect of the size of the data set on the clustering algorithm is tested by varying the size of the data set and fixing the size of the storage space. The results are shown in Figure 6.

Finally, when semisupervised clustering is performed for the data points, labels, SS, and OUTS in the main memory, the data points contained in them are not involved in the compression and discard, thus allowing the set to guide the mining in the main memory all the time. If the description is a model of linking relationships between pages, the logical description can be in the form of a matrix. When mining with aggregate data not only does the mining time increase accordingly, the useful rules are drowned in a sea of rules that are not of interest to the user, but there may be rules that cannot be mined due to the "dilution" of the overall data. Each element of the matrix indicates whether the node represented by the matrix row label to the node represented by the matrix column label is related, which is the hyperlink between the pages in the domain. If the consistency index test passes, the consistency design of the judgement matrix is reasonable, and the corresponding weights reflected by the feature vector are also relatively reasonable.

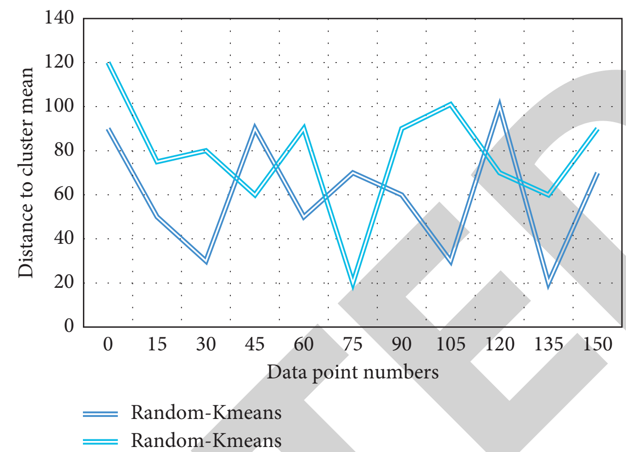

Figure 6: Quality scene of each cluster when the real data set is increasing.

4.2. Analysis of Clustering Process of Large-Scale Data Sets.

For a certain scale of transaction database, which contains a particularly large number of candidate itemsets, a transaction can also contain many candidate itemsets, so the number of candidate itemsets will be the main factor limiting the performance of the algorithm. Therefore, it is necessary to choose a large-scale data set clustering process to abstractly describe the various network linkage relationships in reality. At the same time, it is necessary to find a suitable data structure in a high-level language to store the mathematical model in a structured way in the computer, which is easy to analyse and process in the high-level language. To compare the performance of DISK-MINE, DRBFP-MINE, and data mining test algorithms on large-scale data sets, experiments were conducted using a combination of records generated from 2000 different items, and the comparison results are shown in Figure 7.

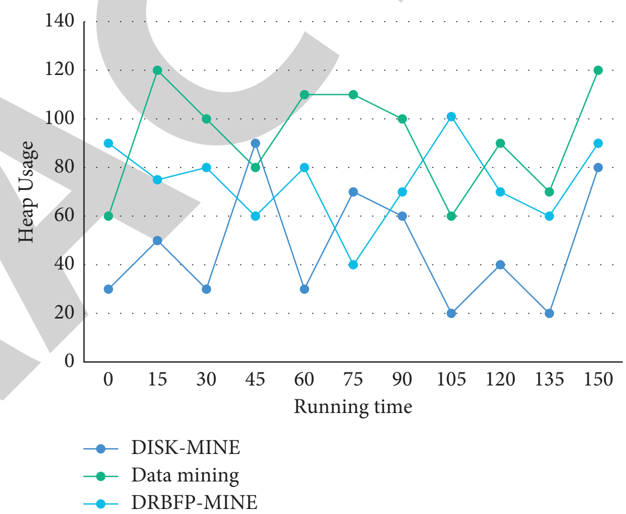

Figure 7: Performance comparison and analysis of large-scale data set algorithms.

First, data points from the data set are sequentially read (or otherwise read) into a finite memory called a pipeline until the pipeline's space is filled. The distance between data points is calculated, the data's neighbourhood is determined, the sample's centroid is determined based on the density of the neighbourhood, and the data's global centroid is determined for sampled data. Based on the sample centroids' data, the criterion for selecting the attribute is the information entropy. The information entropy value is calculated based on the data, and then, the sizes of each information entropy are compared, with the largest information entropy being chosen as the selection criterion. The element's information entropy is calculated, and it serves as the decision tree's root node. While all variants of the one-level correlation rule ignore the fact that practical data are multilevel, the multilevel character of the data has been adequately taken into account in the multilevel correlation rule.

The data points in the pipeline are then subjected to semisupervised clustering on finite primary storage until convergence. The entropy value of the system is minimized after using this property to divide the example set into subsets, and the average path from the nonleaf nodes to each descendant leaf node is expected to be the shortest, resulting in a small decision tree. The proposed data to be handled will be related to multiple dimensions using multidimensional correlation rules. In addition, the set of points removed from the main storage goes through a triad after each stage of the discard and compression process, preserving the data point information and grouping information. Density validation and sampling centroids can be done in order, but this takes a long time with large sample sizes and long sampling times, and the sample validation centroids are useless. As a result, it is necessary to consider various influencing factors and compensate each factor appropriately, integrate factors with similar influence, and consider the distribution width and representativeness of factors appropriately during the actual evaluation operation. The comparative analysis of clustering

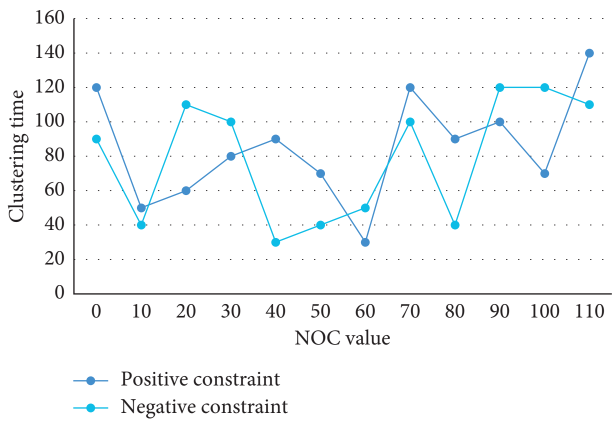

Figure 8: Comparison of clustering time between positive constraints and negative constraints.

time with positive and negative constraints is shown in Figure 8 to study the influence of the amount of information of equivalent partial constraints on the quality of clustering results and clustering efficiency.

Finally, the data points in the pipeline are compressed and discarded. The data point sets that satisfy the compression conditions are replaced and the corresponding data points are removed from the main memory. The higher the entropy of a training sample set in terms of target classification, the messier and messier it is; the lower the entropy of a training sample set in terms of target classification, the clearer and more ordered it is. The correctness of the algorithm is guaranteed by all possible frequencies established at least in the given block. The online part first calculates the similarity between the target user and the centre of the cluster, then divides the target user into the most similar clusters, and finally finds the nearest neighbours of the target user in the cluster, and then performs item recommendation. In this process, the data points in the algorithm design set can change the attributes of the clusters and also allow new clusters that were not originally in the original set to appear, avoiding wrong labels in the initial set and making the algorithm somewhat fault-tolerant.

5. Conclusions

PE to serve the daily physical education in school is an integral step in today's information age. Student evaluation is the system that makes up the most of the teaching quality monitoring system at universities and plays the most important role. The common practise is to use information technology and network technology to assess and predict teaching quality. The ability to apply complex statistical methods and calculations to these data and the rapid access to big data by data mining provide exciting reasons for the rapid development of data mining. Data mining techniques in teaching management, particularly in teaching quality evaluation systems, will provide some data support for university administrators, allowing them to improve teaching quality and make more effective decisions. Using computers to evaluate teaching quality can simplify and improve management. In this paper, we propose a data-mining arithmetic-based design of a teaching quality analysis and management system for PE courses, with the goal of standardizing the workflow related to sports performance management, achieving scientific management and information management, transforming the traditional complex teachers' workplace, and increasing work efficiency through the application of the target system. The system can mine the correlations between PE course grades, analyse these relationships scientifically, provide good decisions for educators and teachers and teacher management, better guide teaching work, and make students' teaching quality assessment data a truly important resource.

Relying on the advantages of its input factors, the resource-based economy has achieved rapid development. However, with the global emphasis on scientific development, various contradictions have sharply reduced the competitiveness of the resource-based economy. In the process of a new round of changes in the world economic pattern and the adjustment of China's development strategy, most resource-based economies have begun to implement transformation actively or passively. Resource-based economy was mostly established and developed in the period of planned economy, which made great contributions to national construction and accomplished brilliant achievements in regional economic and social development. However, the development of natural resources always goes through stages of development, growth, maturity, and decline. Therefore, resource-based cities also have problems of rise, prosperity, and decline. From the perspective of adaptive space division, this paper analyzes and studies the teaching of the coordinated development of resource-based economy in the transformation of the resource-based economy and environment economy and puts forward the panel data model, logistic curve, and other algorithm models. After optimization, the collaborative development model is designed. Based on the analysis of the model, it is found that the error analysis of the model has improved by 77.3% and the average growth rate of transformation benefits is generally 56.8%.

1. Introduction

As the source of basic energy and important raw materials in my country, resource-based economy has made outstanding contributions to the development of the national economy [1]. The question of how to avoid repeating the mistakes; develop high-efficiency industries based on resource advantages; scientifically demonstrate, optimize, and adjust economic development from the source of decision making; and protect economic ecology and environment while developing the economy has become a key problem that needs to be solved in the development of the emerging resource-based economy [2]. Resource-based economy is mostly established in the desolate backcountry, which is mostly old, small, and poor areas [3]. My country is a rare resource-rich country in the world, with a wide variety of resources, among which coal, iron, oil, and other resources are exploited on a relatively large scale, which plays an important role in the formation and development of their corresponding resource-based economy [4]. Since the establishment of New China, due to the large-scale demand for energy and raw materials in national economic construction, the construction of the resource development base has received great attention [5]. The rise and development of the resource-based economy has provided a large number of employment opportunities for these areas and accelerated the process of economization [6]. The high concentration and large-scale development of resource-based industries have greatly changed the economic development mode and lifestyle of their surrounding areas and promoted the development of regional economy [7].

The transformation of resource-based economy is a worldwide issue. This type of economy rises or develops due to the exploitation of natural resources and also stagnates or even declines due to the reduction and depletion of natural resources [8]. The operability of sustainable development is based on regional sustainability. Resource-based economy plays an important role in China's national economic and social development [9]. The nonrenewable nature of natural resources makes the development of resource-based economy face more difficulties than other economies [10]. My country is now in an important period of economic development and transformation. It is necessary to guide the direction of economic development with the concept of green and ecological projects and to build an ecologically civilized society as the goal of economic development. Only when the economic development model is successfully transformed can we build an ecological civilization. This strategic goal has become a reality [11]. In general, the environmental scheduling problem is to optimize the economic minimization of resource scheduling as a single objective by analyzing and using the constraint model of power scheduling. However, these methods cannot effectively solve the nonconvex Pareto optimal problem. At present, the multiobjective optimization algorithm that simultaneously processes two or more objectives in parallel has been applied to the multiobjective environmental and economic scheduling problem [12]. The core of building a conservation-minded society is to conserve resources, that is, in all aspects of production, circulation, consumption, and other fields, through the adoption of comprehensive measures such as technology and management, strict conservation, continuous improvement of resource utilization efficiency, and reduction of resource consumption and environmental costs as much as possible. A development model that meets people's growing material and cultural needs was needed [13]. Environment-friendly society is a social form of harmonious coexistence between man and nature. The relevant research mainly adopts the research means of economic geography, and the application of management theory and economic analysis methods is very few. The research method is relatively single, so it is urgent to strengthen the normative theoretical research [14]. In addition, the resource-based economy relies too much on the resource-based industries and forms a tie relationship with the resource-based industries.

This paper will examine the special problems and special laws in the sustainable development of resource-based economy, as well as the theory and method of sustainable development of the resource-based economy and the main methods of implementation, based on the basic theory of sustainable development and the actual development of resource-based economy. From the standpoint of sustainable development, it will present theoretical foundations and operational decision-making suggestions for my country's resource-based economy [15]. However, in the transformation of resource-based economy based on adaptive space division, the previous research did not perform a good optimization analysis on the coordinated development of resource-based economy and environment. However, in the transformation of the resource-based economy, it is critical to solve or improve the problem or process of coordinated development of resource-based economy, environment, and economy. As a result, the following innovations are proposed in this paper:

(1) This paper puts forward a new mode of industrial development of resource-based economy: intensive-green-chain network development mode. Based on the analysis of the coordinated development of resources, environment, and economy in resource-based economy transformation, this paper studies the connotation and characteristics of transformation based on the theory of sustainable development, analyzes the feasibility of transformation and the theoretical conditions of sustainable development, and designs a dynamic development model on this basis.

(2) This paper makes a multiobjective analysis on the coordinated development of resources, environment, and economy in the resource-based economy transformation in the adaptive space division because the adaptive space division solves the problem of different subspaces in the multiobjective optimization problem. In the experimental analysis, it can be divided into a large number of subspaces, and several important theories such as the panel data model algorithm are proposed in the algorithm to obtain the comparison of these algorithms in detection.

2. Related Work

In order to improve the level of intensive and friendly use of the construction land in the Chang Zhu Tan area and realize the sustainable use of land resources, Feng et al. [16] first analyzed the relationship between "two oriented" social construction and intensive and friendly use of construction land, explained the connotation of saving and friendly use of construction land, and then constructed the evaluation index system of intensive and friendly use of construction land. The factor analysis method is used to dynamically analyze the evolution trend of intensive and friendly utilization of construction land in the Chang Zhu Tan area [16]. Stevenson et al. [17] proposed a multiobjective particle swarm optimization algorithm based on bi-local optimization and combined it with the constraint processing method with the best feasible solution to solve the multiobjective EED problem [17]. Halder et al. [18] and others believe that efforts should be made to form a scientific form of economic development mode, social development mode, rational economic structure, and spatial pattern of resources and environment that do not waste resources and rather improve environmental quality. On the basis, the waste of resources and environmental damage are completely reduced [18]. The study by Morais et al. [19] shows that improving the quality of social development is the objective requirement of social development under the background of the new normal. Only by improving the quality of economic development can we promote the smooth transformation and optimization of social and economic structure, the improvement of development quality, and the improvement of ecological civilization construction performance [19]. Song et al. [20] and others think that after entering the post-industrialization, the status of natural resources as the main factor of production has been shaken, and the dependence of resource-based economy on resources and the constraints of resources on economy have become the bottlenecks of this economic growth. Due to the restriction of the life cycle of natural resources development and the gradual shrinking of the traditional product market, the resource-based economy began to decline, even faced with extinction, and the resource-based economy gradually changed from "core economy" to "marginal economy" [20]. Wang et al. [21] proposed that in multitarget tracking systems, the number of targets is usually unknown and constantly changing, and each target is in constant motion. The MTT algorithm plays a vital role in the multitarget tracking system. Through the target information obtained from sensors, such as position information, target attributes, and target strength, it can achieve stable positioning and tracking of multiple targets [21]. The research results of Chen and Guo [22] show that if economic growth continues at the expense of environment and quality, it will be difficult for resources and environment to bear its weight. After experiencing the rapid growth and re-industrialization since this century, China's economy has also reached an important juncture of transformation and upgrading [22]. Yu et al. [23] and others think that "the practical goal of building socialist ecological civilization is to build a sustainable modern economic model that is coordinated between ecology and economy, which is mainly manifested in developing circular economy, building an eco-safe economy and society, and realizing the development of ecological green civilization" [23]. The research of Chatterjee and Dutta [24] explained that the economy is an inevitable product of the development of human society and economy. The process of industrialization and economization in our country is accelerating, and a large number of rural surplus labor are transferred to the economy, which makes the economy quickly gather a large number of people. The rapid expansion of the economic scale and the rapid expansion of the population have brought problems such as water and soil resources' shortage and ecological damage [24]. Babamiri and Marofi [25] analyzed the country as a whole. The results show that the problems of forest land loss and sustainable forest management are related to the number of state-owned public stops and the differences between developed and developing countries. This gap is also an important factor affecting the sustainable development of state-owned forests [25]. Vondolia et al. [26] think that under the multitarget system, due to the problems of missed detection, clutter measurement, the emergence and extinction of targets, the simultaneous matching of motion models for multiple targets, and the unknown correspondence between multiple targets and measurements, all these will have a great impact on the performance of multitarget estimation [26]. The research of Pang et al. [27] and others shows that the leading industries of resource-based economy are developed on the basis of local advantageous resources. This resource-oriented development model is in the early stage of industrialization and economization, and the resource market supply has its practical significance under the condition of shortage [27]. Marin G, Marino M, and Pellegrin C believe that the two oriented development of industry refers to taking technological innovation and management innovation as the means and for the purpose of improving economic, social, and ecological environmental benefits, promoting the development of the industrial system in the direction of low resource consumption and less environmental pollution, so as to optimize the industrial structure, enhance the sustainable development capacity of the industry, and make it meet the requirements of the construction of two oriented society; we further constructed the evaluation index system of the development level of two oriented industry and conducted an empirical analysis [28].

On the basis of the above related research, the positive role of adaptive spatial division of labor in the coordinated development of resources, environment, and economy in the transformation of resource-based economy is determined, and a new strategy for coordinated development of resources, environment, and economy is constructed. Based on the spatial adaptive division of the resource-based economy in transition, in-depth analysis and research were conducted on the coordinated development of resources, environment, and economy, with a view to making more effective use of resources, exploring the hidden value behind resource data, and identifying potential problems affecting the coordinated development of resources, environment, and economy in the transformation of a resource-based economy.

3. Methodology

3.1. Research and Analysis of Related Theories

3.1.1. Adaptive Spatial Partitioning. The adaptive multiobjective evolutionary algorithm based on the division of solution space solves the multiobjective optimization problem. First, the solution space of the multiobjective optimization problem is divided into a large number of subspaces. In the process of algorithm evolution, each subspace retains a nondominated solution set to ensure the diversity of the population. From this, we can know the general continuous multiobjective optimization model:

$$\text{Minimize}\, F(x) = \left(f_1(x), f_2(x), \ldots, f_m(x)\right). \tag{1}$$

$x = (x_1, x_2, \ldots, x_n) \in R^n$. represents a decision vector, Ω is the decision space, and $F\colon \Omega \longrightarrow R^m$ is an objective space composed of m objective functions $f_1, f_2, \ldots, f_m$. For adaptive space partitioning, all the original frames are basically closed, and all the objective functions are continuous functions of their decision vectors. The completion time and cost of workflow are two conflicting optimization objectives, which we call multiobjective optimization problems. According to the value characteristics of variables, multiobjective optimization problems can be roughly divided into continuous multiobjective optimization problems and discrete multiobjective optimization problems. The multidimensional search space is divided into multiple grids. The particles in the grid adjust their speed and position by sharing the empirical information of "guiding" particles.

3.1.2. Resource-Based Economy and Resource-Environment-Coordinated Economy. Generally speaking, a resource-based economy is a kind of specialized functional economy, which refers to the economy that rises with the development of resources, or the economy that thrives again due to the development of resources in its development process. As a special type of economy, an economy built or developed basically relying on resource development, its leading industries are extractive industries and primary processing industries built around resource development. The industrial development mode of "high consumption, high investment, and high pollution" of the resource-based economy has many disadvantages. While developing the economy, it leads to the excessive consumption of natural resources and the destruction of ecological environment. It is an unsustainable production and consumption mode. The mechanism behind the course of resources is actually very simple, that is, under severe pressure, resource-poor economies have to abandon the traditional growth mode, adopt technological innovation and institutional innovation, and embark on a new economic development route. The sustainable development theory, system theory, and self-organization theory have provided us with good inspiration for understanding and managing economic problems and provided us with basic ideas, directions, and guiding principles for the study of the resource-based economy. Figure 1 shows the basic connotation of sustainable development.

Sustainable development is a comprehensive concept involving economy, society, culture, technology, and natural environment. It refers to the development that not only meets the needs of contemporary people but also does not endanger the ability of future generations to meet their own needs. The coordinated operation of the regional system will be affected by multiple factors, which can be divided into two categories: beneficial factors and limiting factors, collectively referred to as nuclear factors and factors. The relationship between these two factors is different, and the development situation is also different. When the leading factors play a dominant role, the development process is reflected in the competition of human activities for the leading factors, and a large number of people have invested in obtaining sufficient material and environment. Due to the stimulation of competition, this stage of development has grown rapidly; the leading factor is gradually consumed, and the emergence of a series of limiting factors hinders the regional development. This generally refers to the economic structure and a form of coordinated development of resources and environment. In order to realize the coordinated development of environmental resources and economy, it is necessary to understand the value measurement of environmental resources. Only by clarifying the value of environmental resources can we better protect environmental resources and realize coordinated development in practice. According to the adaptive spatial division theory, the value of environmental resources lies in its usefulness, scarcity, and conditions of development and utilization.

3.2. Research and General Mechanism Analysis of Economic Development in Transition. The transformation of the resource-based economy is a long-term and complex systematic project. It takes the industrial transformation of the resource-based economy as the starting point and leads and thus triggers social, economic, environmental, and other multifaceted and multilevel changes. Therefore, the transformation of the resource-based economy should be based on the transformation of the industrial structure, change the mode of economic development, and then carry out a comprehensive transformation of the system. In terms of structure, the basic structure of the regional resource environment economic system should be a complex system composed of a resource subsystem, environment subsystem, and economic subsystem. The coupling of the regional resource environment economy system is formed by three levels of system coupling development. First, the internal coupling and coordinated development of a single subsystem. Second, the coupling and coordinated development between the two subsystems. Third, the coupling and coordinated development among the three subsystems. Figure 2 shows the structure of the resource-based economy.

As shown in Figure 2, a resource-based economy consists of a resource subsystem, an economic subsystem, an environmental subsystem, a social subsystem, and several other factors. Each subsystem is interconnected, influenced, and restricted by human activities, resulting in a crisscross network structure. Furthermore, people are the main body and core of a resource-based economy. People are at the heart of any economic transformation or theory of sustainable development and they are the most important factor in achieving it. As a result, people control the production and distribution of all resources in the network structure depicted in Figure 2. The multiobjective evolutionary algorithm is simple, effective, and has a high degree of generality, making it appealing for solving multiobjective optimization problems. Multiobjective evolutionary algorithms, such as NSGA-II, MOEA/D, MOPSO, and others, are widely used in many fields, including data mining, cloud computing resource management and task scheduling, engineering project scheduling optimization, and Earth observation satellite task planning. This is an evaluation index that is used to determine whether Pareto's optimal solution is reasonable and reliable under self-use space division. Therefore, the objective function is generally introduced to achieve the requirement constraint of space division:

$$\min\left[\sum_{i=1}^{N_G} F_i\left(P_{Gi}\right), \sum_{i=1}^{N_G} E_i\left(P_{Gi}\right)\right]. \tag{2}$$

Among them: $F_i(P_{Gi})$ is the resource consumption function, $E_i(P_{Gi})$ is the pollution amount function $i = 1, 2, \ldots, N_G, N_G$ are the total number of all resources in the space. The Pareto optimal solution of a continuous multiobjective optimization problem is a piecewise continuous dimensional manifold in the objective space. In the process of evolving $m-1$, if the population lacks diversity, the algorithm may ignore some key search areas

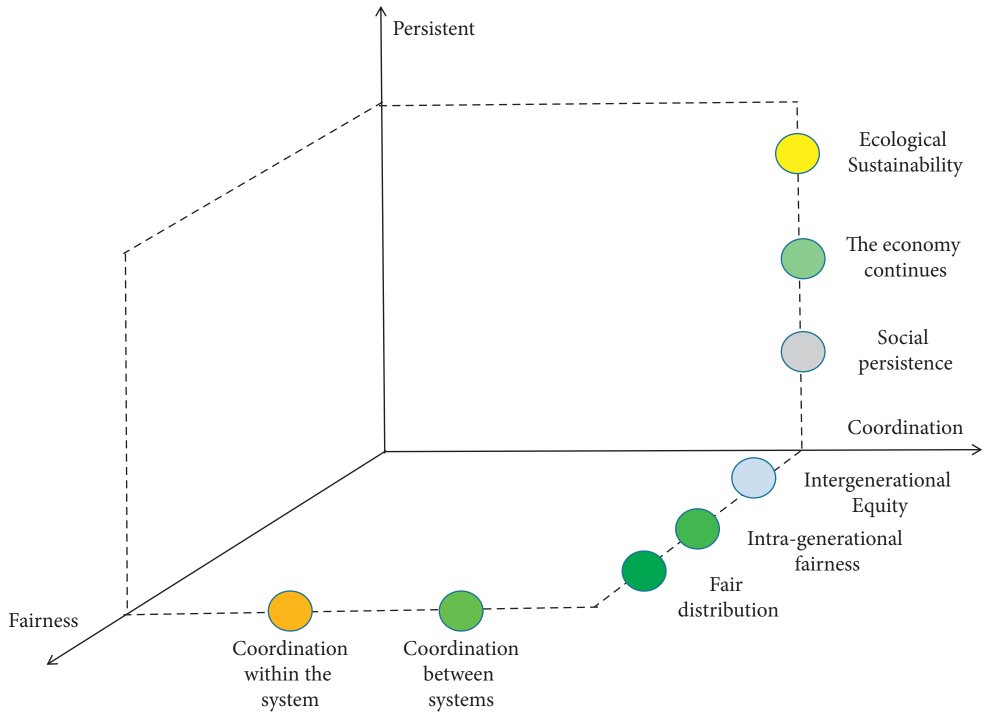

Figure 1: Basic connotation of sustainable development.

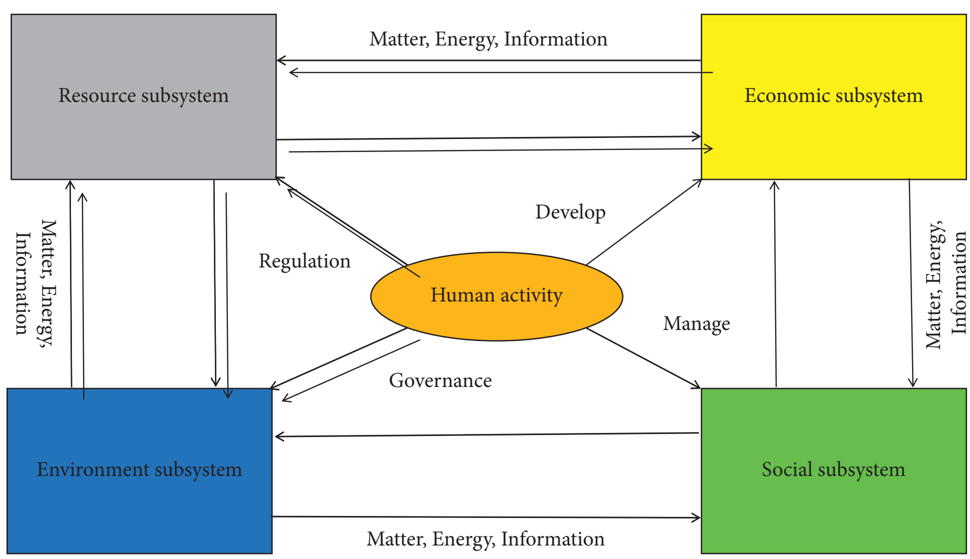

Figure 2: Resource-based economy structure diagram.

and weaken its search ability, making the convergence ability of the algorithm weak or even unable to converge to the real *PF*. Therefore, the general mechanism of resource-based economic transformation can be proposed as shown in Figure 3.

The resource-based economy needs to evolve harmoniously under the action of internal and external forces in order to achieve a successful transformation. Figure 3 lists several key elements of internal and external forces of the resource-based economy. First of all, we should know that scientific and technological strength and innovation are extremely helpful to the promotion of the economy. Different from the mechanism by which capital and labor promote economic growth, a technological progress has an accelerating effect, a delaying effect, a magnifying effect, or a leading effect on economic growth. The infrastructure affects the industrial scale and industrial structure of the economy by affecting the rate of return of economic industries and shaping the ability of the economy to attract talents, technology, capital, resources, and other elements. The construction and improvement of the infrastructure can provide transportation, communication, energy, and power facilities for the optimization of economic and industrial structure and economic development.

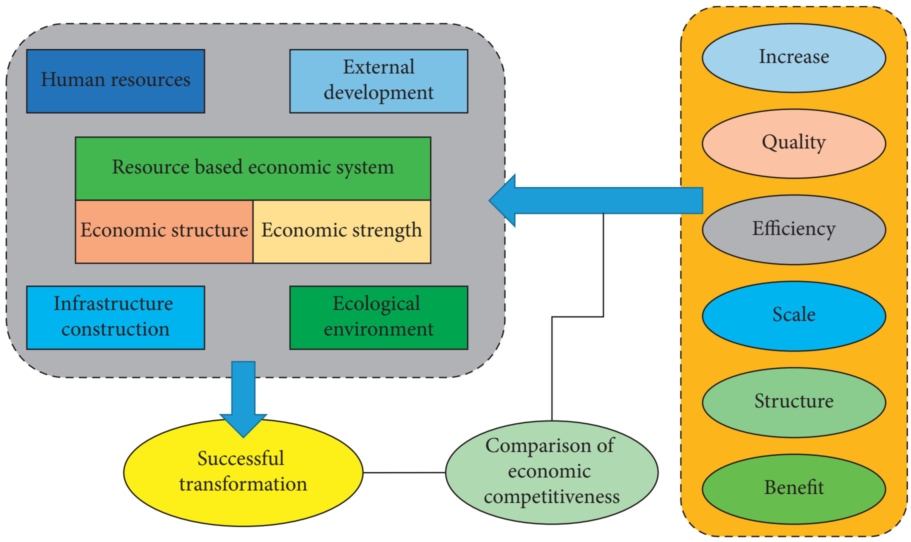

FIGURE 3: Schematic diagram of the general mechanism of resource-based economic transformation.

3.3. Dynamic Model Design for Coordinated Development. Because collecting transition economy samples is difficult, an algorithm model that can expand data processing in the same period must be introduced. As a result, this paper proposes the panel data model for designing and processing the algorithm portion of the model in order to meet the model's design requirements. The panel data model can effectively weaken the mutual influence and differences between various economies, as well as be described in very specific terms in dynamic changes. The model's design accuracy can be improved when multicollinearity weakens. As a result, the following is the fundamental model proposed in this paper:

$$\mathrm{TRA}_{it} = c + \alpha_2 \mathrm{MAR}_{i,t} + \alpha_4 \mathrm{URB}_{it} + \alpha_5 \mathrm{EDU}_{i,t} + \alpha_6 \mathrm{INF}_{i,t} + \varepsilon_{it}, \tag{3}$$

where i, t represents the i region and t year, respectively, and ε represents the random interference term. The meaning of each variable and coefficient standard are as follows. TRA in the model represents the transformation degree of the resource-based economy. In this paper, the vector angle is used to calculate the industrial structure transformation coefficient, which makes the model quite operable. It not only takes into account the change degree of the same industrial proportion in different years but also reflects the average change degree of the ratio of different industries, which is difficult to achieve by the general coefficient standard. Its specific expression is as follows:

$$\theta = \arccos\left[\frac{\sum_{i=1}^{n} s_i(t_1) s_i(t_2)}{\sqrt{\sum_{i=1}^{n} s_i(t_1)^2 \sum_{i=1}^{n} s_i(t_2)^2}}\right]. \tag{4}$$

In the formula, n is the number of industrial sectors, $s_i(t_1)$ refers to the share of the added value of i industrial sector in t years in the GDP of t years, and θ is the angle between $s(t)$ and $s(t-1)$ vectors, which generally becomes the transformation coefficient of the industrial structure. Generally, TEC is expressed as the level of technological progress, and the measurement formula is as follows:

$$\mathrm{TEP} = G - \alpha k - \beta l. \tag{5}$$

In the formula (5), G represents the average annual growth rate of GDP, $k \cdot l$ represents the average annual growth rate of capital and labor input, respectively, and $\alpha \cdot \beta$ is the elasticity coefficient of capital and labor, respectively. Generally, in economics, the two values are 0.56 and 0.44. If you need to calculate the value of k, you need to calculate the capital stock K. Its basic formula is as follows:

$$K_t = K_{t-1}(1 - \delta_t) + I_t, \tag{6}$$

where $K_t \cdot K_{t-1}$ represents the capital stock in the t year and the $t-1$ year, I_t represents the material capital investment in the t year, and δ_t represents the depreciation rate in the t year. Among the many economic factors, the two main factors, labor and capital, should be emphasized. This paper adopts the transformation of the Douglas function:

$$Y = A_t K^{\alpha} L^{\beta}. \tag{7}$$

By deriving and simplifying both sides of the equation at the same time, we obtain the following:

$$Y = a + \alpha K + \beta L. \tag{8}$$

The specific meaning of formula (8)$\mathrm{d}Y/\mathrm{d}t/Y = Y, \mathrm{d}A_t/\mathrm{d}t/At = a, \mathrm{d}k/\mathrm{d}t/K = K, \mathrm{d}L/\mathrm{d}t = L$ is that the growth rate of

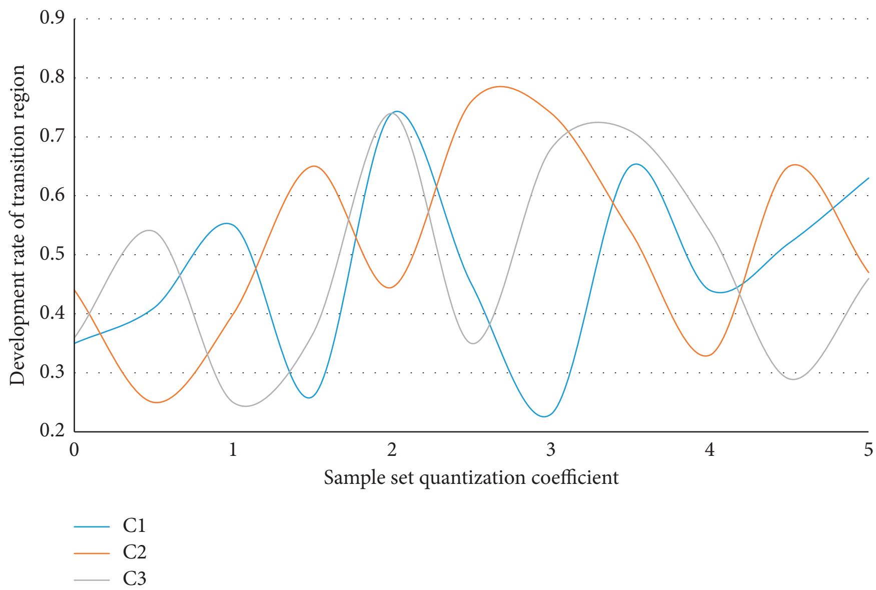

Figure 4: Analysis of the development speed of transitional regions.

economic benefits is determined by technological progress a, labor input L, and capital K. After observation, it can be found that the economic benefits of transformation are proportional to technological progress. After knowing formula (8), the contribution rate can be calculated as follows:

$$E_A = \frac{a}{y} \times 100\%, \tag{9}$$

where E_A represents the ratio between the annual technological innovation speed and the economic benefit growth speed in transition. The logistic curve is also checked for the transformation of the resource-based economy. Therefore, if $X(t)$ represents the transformation process of the resource-based economy, the development speed of the model is $\mathrm{d}X/\mathrm{d}t$. Due to the restriction of resource set and environmental capacity, the resource-based economy generally shows a nonexponential growth, which is generally in the form of the following curve:

$$\frac{\mathrm{d}X}{\mathrm{d}t} = \pi X\left(1 - \frac{X}{X_m}\right). \tag{10}$$

Among them, π is the growth rate required for development and X_m is the saturated capacity of the development factor. Generally speaking, if the threshold value of the capacity is found, the entire economic system will collapse directly. Therefore, X_m is a key element of transformation and represents reasonable development. The importance of, so continue to discuss X_m, which can be obtained after scoring it as follows:

$$X = \frac{X_m}{1 + Ce^{-m}}, \tag{11}$$

where C is a constant $C = X_m - X_0/X_0 > 0$ and when $t \longrightarrow \infty$, X converges to the threshold X_m. When the derivative is 0, we know that,

$$\begin{aligned} X_1, X_2 &= X_m, \\ X_3 &= \frac{X_m}{2}. \end{aligned} \tag{12}$$

It can be found that X_1, X_2 is an extreme situation. When $X = 0$, it indicates that the factor base of resource economic development is 0 and $X = X_m$ indicates that the development has reached the threshold of the economic system. Through the above algorithm design and improvement, the dynamic change trend of main parameters under the transformed economic model can be obtained, which will be helpful for analysis and decision making.

4. Result Analysis and Discussion

The foundation for the coordinated development of resource-based and resource-environmental economies is the establishment of a scientific, feasible, and practical model system. The coordinated development model of resources, environment, and economy proposed in this paper will examine and address a number of key parameters, including the transition region's development speed, the transition logistics' change rate, the model estimation error rate, the benefit rate of coordinated development, and coordinated development efficiency. Let C1, C2, and C3 be the analysis and comparison data charts of three sample sets of the resource-based economy transformation resource environment economic system in terms of transformation region development speed, transformation logistic change rate, and model estimation error rate as shown in Figures 4–6.

The abovementioned three indicators are in a stage of greater volatility between 1 and 3 in the above graph due to interference items in the transformation. Of course, this is also foreseeable, and the economic transformation may necessitate a variety of policy adjustments. Market

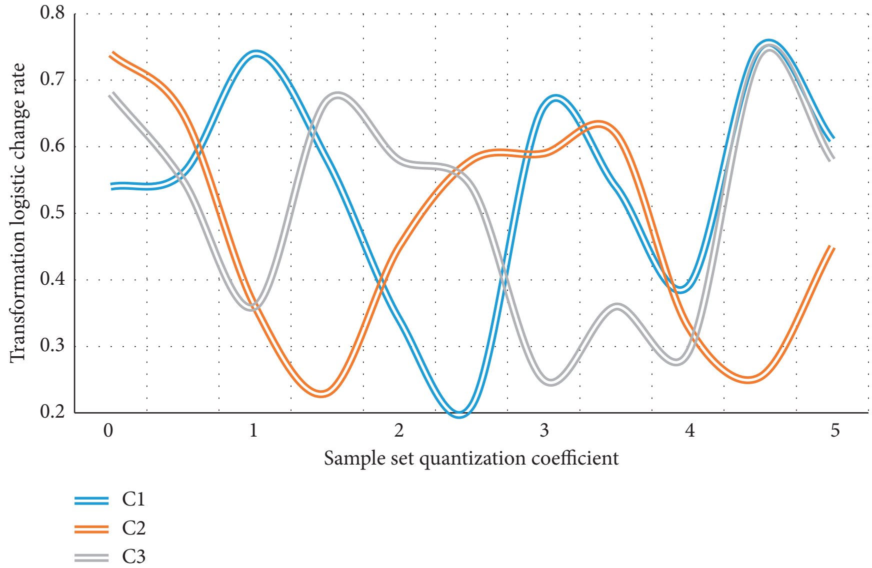

Figure 5: Analysis of the transformation rate of the logistic change.

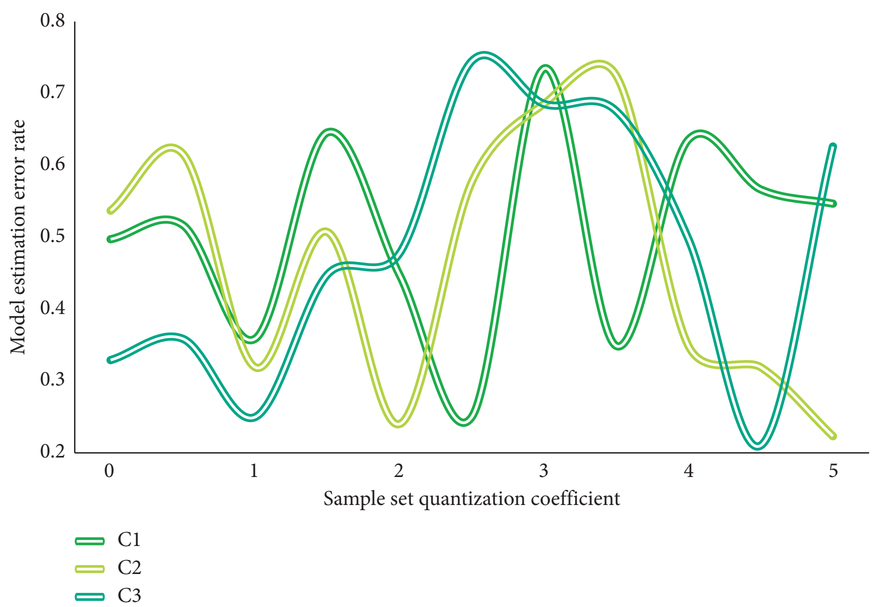

Figure 6: Analysis diagram of the model estimation error rate.

fluctuations, for example, can stymie the transformation process. As a result, while the transformation is risky in practice, the overall trend in the transformation area is upward, implying that despite the presence of interference items, the economic situation is improving. The system will benefit as a whole if it begins to transit from a resource-based economy to a resource-environmental economy with co-ordinated development. In terms of the logistic change rate, it is discovered that three different sample sets in the entire change process, especially in the 0-1 and 4-5 stages, have the same trend change tendency, proving that the model designed in this paper is universal, and the control of change rate reaches 87.4 percent, greatly improving the model's capture and mastery of unfavorable factors in the transition process. The model's error is analyzed intuitively in the experiment. In the three sample sets, it can be found that the overall error analysis state of sample set C2 is good. It is found that due to the existence of evaluation models for different risks in sample set C2, this also makes the model designed in this paper more accurate after comparing the other two sample sets and having better control over the risk, with a 77.3% improvement in error analysis. Assuming that $X1$ and $X2$ are two different sample sets of coordinated development benefit rate and coordinated development efficiency, Figures 7 and 8 are the analysis diagrams of the two.

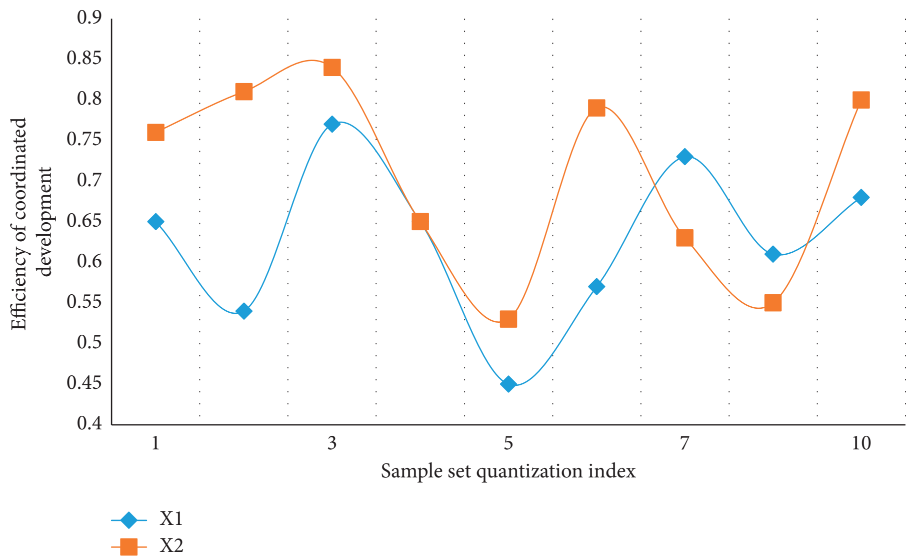

Figure 7: Analysis of the benefit rate of coordinated development.

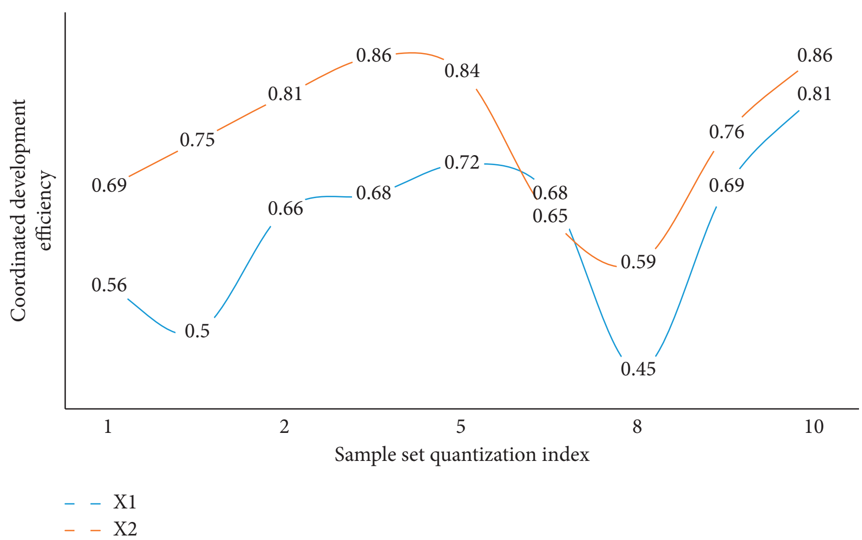

Figure 8: Analysis of coordinated development efficiency.

From Figures 7 and 8, it can be concluded that the benefit rate of coordinated development is basically kept at a high level, which reflects that the model designed in this paper has a very good promoting effect, and it promotes its rapid growth in the coordinated development of resources, environment and economy in the transformation of the resource-based economy. Although the benefits fluctuate in the 3–5 stages, they quickly return to the high-speed growth level, and the average growth rate of the transformation benefits generally reaches 56.8%. The efficiency of coordinated development is an important reference index. For the region after adaptive spatial division, under the constraints of the model, it basically promotes the development efficiency of the economic system after coordinated transformation. It is worth noting that the stability is basically maintained on the entire quantization axis, which is generally difficult to achieve in practice, but because the panel data model is embedded in the model designed in this paper, the stability of the model is greatly enhanced.

5. Conclusions

This paper conducts a systematic, selective, and focused exploratory research and analysis on the sustainable development of a resource-based economy, based on systematically summarizing related research results at home and abroad, with the goal of constructing a theoretical research framework and platform for the coordinated development of resources, environment, and economy in resource-based economy transformation. The goal of resource-based economy industrial development model innovation is to achieve sustainable development, long-term competitiveness, a reasonable economic structure, a healthy ecological environment, and social harmony and stability.

We must follow the principles of sustainable development, intensification, environmental protection, and efficiency to achieve this. To achieve a coordinated transformation from disorder to order, the resource-based economy requires a combination of internal and external factors. Three levels of analysis are used to examine the resource-environment-economic subsystem. To begin with, the resource-environment-economy subsystem's basic status is examined from four perspectives: natural environment, resources, economy, and environmental conditions. In terms of adaptive space division, the collaborative model is designed based on important theoretical algorithms such as the panel data model. The error analysis is improved by 77.3% and the average growth rate of transformation benefits is 56.8%.

Traditional financial accounting has gradually evolved into management accounting in order to adapt to changing times and developments. To avoid being obliterated by the times, accountants must gradually improve their professional and comprehensive abilities in order to create greater value for businesses in the AI (Artificial Intelligence) era. This article presents an AI-based financial management optimization design and proposes an AI-based accounts receivable management optimization framework based on the existing information system. A typical financial distress early-warning model is built using the BPNN (BP Neural Network) model, and the training samples of listed companies' financial data are processed iteratively using the neural network algorithm to realize the visual modeling of the object-oriented neural network and learn the training samples. Finally, the network's ability to provide early warning is put to the test. The results show that BPNN's prediction accuracy is significantly higher than that of other types, especially after years of data, with prediction results exceeding 90%. The results show that the BPNN-based financial early-warning method is feasible.

1. Introduction

Accounting is the statistical analysis of an enterprise's financial data using professional recording methods in accordance with the accounting financial system's basic principles and the use of financial data to reflect a company's financial transactions and business information at a given point in time. Accounting is a management information system that employs systematic methods to analyze, evaluate, and manage the financial and economic data generated by an enterprise's business activities and assists management in providing supporting data for management decisions and operations. With the advancement of economic levels, generating more value in order to achieve sustainable development has become a problem that every business will face. The gradual implementation of AI (Artificial Intelligence) technology [1, 2] has a significant impact on social development and accounting work, with some traditional financial personnel potentially losing their jobs. In light of this, financial accounting must keep up with the times and strive to transform into management accounting in order to adapt to the transformation and development of the times. AI has accelerated the transformation and promotion of accounting work in the field of accounting. Financial robots can independently identify financial data, making large amounts of data processing simple and quick. At the same time, it imposes more stringent requirements on businesses.

In recent years, some issues in the company's economic activities, financial management, and high-risk fields have been exposed, whether through external audit or internal special inspection. It is necessary to research and develop perfect financial audit system functions and establish a unified financial audit management method and mode, in order to find and solve problems as soon as possible. To achieve centralized financial system management, Eckles et al. proposed that each member unit's financial business be concentrated in the financial sharing service center or rely on the financial organization [3]. Powell et al. emphasized that if an enterprise wants to improve its competitiveness, it must fully exploit its own advantages and devote its limited resources to its core business [4]. Kobrak stated that shared service is the first step in financial transformation, and financial shared service is an excellent practice of shared service, and he created a detailed and feasible optimization design for the organizational framework, process, financial information system, operation management, specific implementation, and other aspects of financial shared service [5]. Rau pioneered data warehouse technology in the banking industry as the primary tool for centralized data management [6]. Liu improved the BP neural network (BP neural network) and used it to predict financial distress, with good results [7]. Kirk et al. found that the data had an ideal effect of 89.16% using a nonlinear combination model of fuzzy neural networks [8].

Data in financial accounting can be automatically identified under AI conditions, accounting information can be efficiently recorded and reflected, and data can be analyzed with the help of a network and processing programme, which is more timely than traditional financial accounting. In the AI era, the accounting department should not only do a good job accounting monetary funds but also record relevant data resources based on the data of other companies in order to exert greater labour value and make greater contributions to the company. Although financial exchanges' accounts receivable business has been continuously optimized in line with the trend in recent years, issues such as too many manual operations, long working hours, low invoicing efficiency, and uncontrollable errors have not been adequately addressed. Despite its powerful functions in data calculation, reasoning, and pattern recognition, the intelligent prediction model lacks stability. This article discusses the specific steps in the transformation process by analyzing the differences between management accounting and traditional financial accounting.

1.1. Contribution of the Subject

(1) Based on the existing information system, this article designs an optimization framework of accounts receivable management based on AI, describes the application of BPNN in accounts receivable risk management in detail, analyzes the optimization contents, and puts forward concrete implementation suggestions from three aspects of financial team transformation.

(2) Using a neural network model and combinatorial thinking method, this article constructs the financial distress notification model of listed companies in China. The neural network method can reveal the nonlinear relationship contained in data samples, and a large number of processing units form a nonlinear adaptive dynamic system, which has good adaptability, self-organization, strong learning, relevance, fault tolerance, and capacity, and can flexibly and conveniently model complex unknown coefficients with various reasons.

1.2. Organizational Structure of the Article. The first chapter introduces the research background and significance and then introduces the main work of this article. The second chapter mainly introduces the related technologies of financial management. The third chapter puts forward the specific methods and implementation of this research. The fourth chapter verifies the superiority and feasibility of this research model. The fifth chapter is the summary of the full text.

2. Related Work

2.1. Financial Management Research. To construct the enterprise financial management and decision-making system, the technical route based on theory is to first establish a data warehouse and take the original data collection of the data warehouse as the main task. At present, the original data of the data warehouse established by the survey object come from relevant text information such as enterprise financial information platform.

Basic financial work is an important foundation to improve the level of financial management, covering accounting, system construction, process design, accounting supervision, performance evaluation, and other aspects of management. Dale pointed out that companies with scattered organizational structure or less hierarchical structure can gain management advantages by sharing human resources and technical resources [9]. Byrne defines the essence of a shared service center as an independent organizational entity and emphasizes that the objects of shared services should be molecular companies and business departments within the enterprise [10]. James believed that shared services can integrate all the resources of the company, reduce operating costs, and provide high-quality and professional services for different regions and internal partners, so as to realize enterprise value [11]. Luca and Meschieri believed that in the case of organizational failure, enterprises can gather many basic businesses in a semi-market organizational entity [12]. Tinoco et al. explained the mode of financial sharing service mainly from three aspects: entry management, outflow management, and comprehensive control [13].

2.2. Research on Early Warning of Financial Distress. At present, China has not yet established a complete financial early-warning system, and only some financial forecast information is disclosed in the financial statements, which is only a simple extension of the historical and present financial trends. The artificial neural network is a parallel distributed pattern processing system developed from the research results of neuropsychology and cognitive science by applying mathematical methods.

Huang et al. used multivariate discriminant analysis to discuss the prediction of financial distress of enterprises [14]. Gudmunson et al. put forward that the early-warning system is mainly composed of three subsystems: evaluation, warning, and response, in which evaluation is the evaluation and prediction of the existing alarm situation [15]; warning is to transform the forecast of the previous step into information and communicate with each department. Besancenot and Vranceanu used multivariate discriminant analysis to study the early warning of the financial crisis and adopted 22 financial ratios to establish the famous 5-variable Z-Score model through mathematical statistics screening. According to the discriminant score, the financial crisis of the research object was discriminated with a certain critical value [16]. The results of Olafsson's research show that factors such as enterprise size, financial structure, operating performance, and liquidity are highly correlated with the probability of financial distress [17]. Li et al. synthesized the academic definition of financial distress and divided it into four situations: failure, insolvency, default, and bankruptcy [18].

The financial early-warning system is an organizational operation system for analysis, early warning, monitoring, and implementation, which is established to prevent business errors. It adopts the information management method, selects appropriate early-warning indicators according to various financial analysis data, makes a comprehensive and systematic analysis of the company's related financial indicators, and timely informs the company's management about the risks of the company's financial operation system and other stakeholders, so as to take early action to prevent losses.

3. Methodology

3.1. Optimization of Financial Management Process Based on AI. In the process of transition from traditional accounting to management accounting, it is necessary to start with accountants' own quality, combine the advanced ideas of management accounting with the actual situation, and make good use of AI to cultivate a set of management accounting that can meet the needs of the new era. Accounting can use AI financial system to fully understand the company's cost management information, understand the linkage of cost differences through data analysis, and finally realize effective cost control through problem rectification. In order to make greater contributions, accountants must constantly improve their professional ability, expand their knowledge, and enhance their comprehensive ability to adapt to the development and progress of the times.

In the aspect of accounts receivable management, the main risks faced by enterprises include margin risk and settlement risk, which involve both owner's credit management and accounts receivable risk management. The original documents are mainly composed of manual documents and electronic documents, and the business departments of subsidiaries sort out the original invoices generated by various businesses. Through bill image scanning technology [19, 20], the original bill is converted into image data and stored in the database. Regarding the risk management of accounts receivable, as the damage of overdue accounts receivable to the company is directly reflected in bad debt risk, which damages the company's operating profit, the company should evaluate the risk of accounts receivable in time and guide the business personnel to choose an appropriate payment management method according to the evaluation results.

Relying on information technology such as cloud computing, financial services scattered in various departments with high repeatability, high turnover rate, and high standardization will be integrated into a new business service platform so as to realize process reengineering and standardization and provide users with quality products. According to the analysis in Figure 1, this document adopts "basic finance, financial management and strategic finance." Furthermore, the first step of building the platform is completed in collaboration with various departments of the company.

Most employees and users have access to financial information, which primarily includes online payment and reimbursement. The settlement and financial accounting modules, as well as the treasury payment system and banking system, are all linked; the budget management module is linked to the financial department to ensure one-to-one budget item correspondence. It will promote the most profound change in enterprise financial management and provide comprehensive and effective decision support for management while ensuring the efficient operation of the enterprise financial communication platform. Platform business process strategy should be in line with platform strategy. Business process strategy is a shared platform strategy, and business process goal is a shared platform goal, which guides business process optimization and design. After the auditor confirms the original paper receipt, the system will automatically generate the electronic accounting receipt, print the paper version, and begin the electronic payment programme. If the audit fails, the data will be returned in the same manner, with an e-mail sent to remind the refund staff to make the necessary changes.

Accounts receivable have high liquidity and high risk, and their safety and quality will have a significant impact on the company's resources, excess losses, cash flow, etc. and have an important impact on improving the business level of enterprises. Because of its strong fault-tolerant ability, BPNN can ensure that the accuracy of its training results remains at a high level. Assume that the number of nodes in the input layer of BPNN is c, the number of nodes in the output layer is d, the number of nodes in the hidden layer is e, the weights between the hidden layer and the input layer are V_{iw}, and the weights between the hidden layer and the output layer are V_{jw}. Let the hidden layer function be f_1 and the output layer function be f_2.

Among them, the output of the hidden layer node is as follows:

$$Z_k = f_1\left(\sum_{i=0}^{n} V_{ik} X_i\right), \quad k = 1, 2, \ldots, q. \tag{1}$$

For P sample sizes, the overall error value is as follows:

$$E = \frac{1}{2} \sum_{P=1}^{P} \sum_{j=1}^{m} \left(t_j^p - y_j^p\right)^2. \tag{2}$$

Accounts receivable system is a part of the financial management system, which can work independently or cooperate with other subsystems to transmit relevant data and vouchers. The relationship between the credit system and other subsystems of listed companies' financial participation system mainly includes the following four aspects:

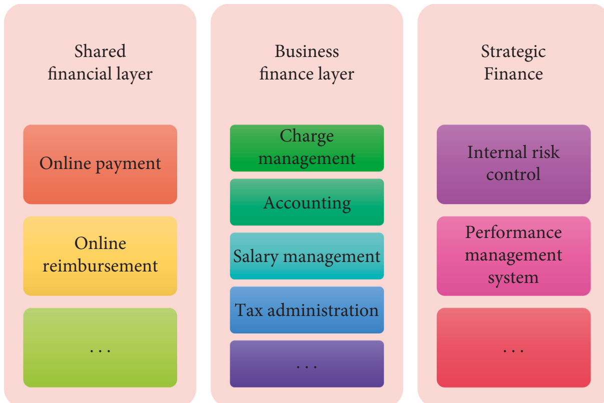

Figure 1: Organizational structure of enterprise financial sharing platform.

(1) The relationship between A/R management and sales management: A/R management and sales management share A/R balance information, and sales invoices issued by sales management will be fed back to the A/R system in a timely manner; (2) relationship between A/R management and A/P management: write-off of A/R and A/P is supported; (3) relationship between collection management and budget management: budget revenue and expenditure items can be entered in A/R management; (4) relationship between A/R management and fund management: the collection document can generate the fund system collection notice.

Based on the BPNN default risk prediction model, the automation of finance improves the efficiency of the clearing house and automates the processes with a high repetition rate but is prone to problems, such as invoicing, accounts receivable reconciliation, and collection cancellation, and theses processes have been optimized and improved. The optimization framework of accounts receivable management of listed companies is shown in Figure 2.

DT (decision tree) is an important classification technology [21, 22] in data mining. Its main function is to classify and process the data in the existing training set according to the attributes and class labels of the training dataset and to establish a model according to the algorithm and use it to classify new data. The core content of this algorithm is the process of constructing the DT model. Firstly, the data samples of the training set are analyzed, and then DT is constructed. The DT model is established to analyze the data and then predict and analyze the data.

An improved algorithm of DT algorithm is proposed: DT is actually an improved DT that combines a linear classifier and DT classifier. DT construction method is used to reduce the number of layers in the tree. This method is a measure of DT, which can better improve the efficiency of DT classification. The algorithm used is a supervised algorithm, in which the labeled classification training set is performed in advance.

Compared with the obvious Mahalanobis distance measurement method, all linear methods have the invariance of scale transformation. Let $y = Ax$, then, the vector be x_1, x_2, m_x, and the transformed distance between them be y_1, y_2, m_y. Mahalanobis distance is as follows:

$$\|x - m\|_M = (x - m)^T C^{-1} (x - m). \tag{3}$$

Under the Mahalanobis distance scale, this method provides the basis for distance judgment.

This algorithm introduces the concept of measurement method when calculating information drop gain, which can be used as a reference when selecting and classifying. The following Figure 3 shows the process of improving the algorithm.

(1) For a superset $C \in T$, C contains several categories of samples. They will wait until the next level to continue the classification.
(2) Choosing the best case for classification is the classification method adopted when no attribute set can be found.
(3) At the end of the process, all samples are classified or the sample classification cannot be continued.

3.2. Research on Financial Distress Prediction. The application and advancement of AI technology has gradually altered the traditional financial accounting function. Accounting work is no longer a single data record, and more financial accountants are needed to effectively organize and extract data. Accounting is an organization's internal accounting, and it focuses on providing information to help management make informed decisions. Financial accounting must be prepared according to strict accounting standards, and management is more flexible than financial accounting. AI can help businesses process financial data more quickly and efficiently and guide them through internal production processes. It can also serve as a reference for managers making predictive decisions. The transition from financial to management accounting is accelerated by AI.

When developing accounting functions, businesses are paying more attention to the integration of other departments and financial departments. As a result, when financial accounting becomes management accounting, the financial department's personnel must meet higher standards. We must start with the company's information construction when transitioning from financial accounting to management accounting. The old enterprise information system equipment should be replaced as soon as possible, and the entire system should be properly optimized to meet intelligence demand. With the advancement of information globalisation, the demand for the transition from financial accounting to management accounting is becoming more apparent, and the trend of enterprise and finance integration is becoming more apparent, which is more conducive to the innovation of the financial management mode of enterprises and increases market share. The unexpected occurrence of financial distress determines the uncertainty of financial distress management. Financial distress is influenced by a variety of factors, some of which can be understood and controlled and others of which are explosive and unexpected. With the advancement of economic globalisation, an increasing number of businesses rely solely on traditional management methods, leaving them unable to plan for rapidly

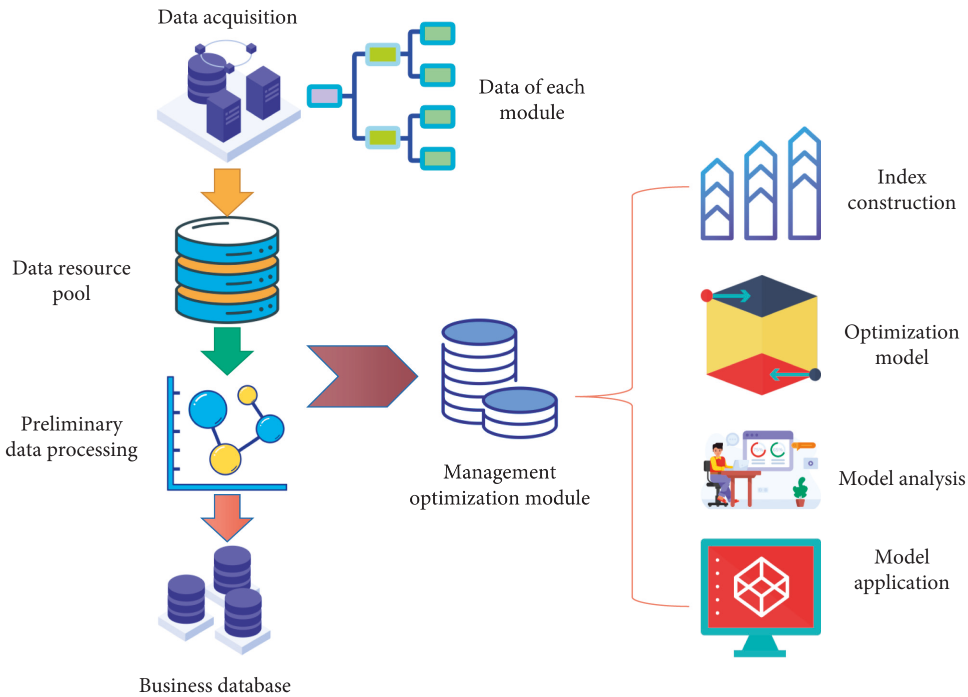

Figure 2: AI-based optimization framework for accounts receivable management of listed companies.

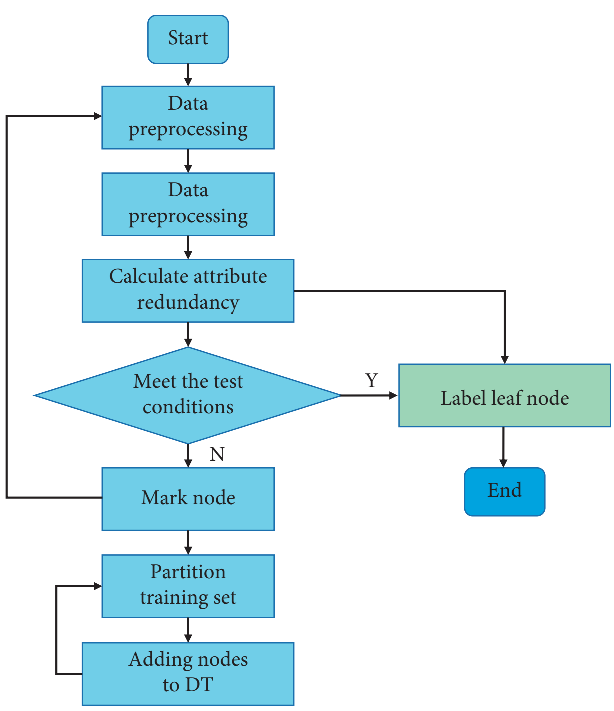

Figure 3: Improve algorithm flow.

changing activities and market dynamics, and deal with a variety of new problems. More importantly, business leaders are paying increasing attention to the prevention and management of financial difficulties and financial early warning.

Up to now, most of the samples used to test the prediction efficiency of the model have used paired samples, and there is no clear sample pairing rule. As the number of companies in financial distress is very small, the most diversified self-test models can always be found in a large number of nonfinancial distress companies, so the universality of the models is questionable. From the perspective of the neural network mapping relationship, the variable selection method based on the neural network not only avoids the practical difficulty of how to set the shape of function correctly in the modeling process but also expands the function types in regression modeling. Research that makes variable selection research more common and opens up an additional way for variable selection when the structure of the response function is unknown. Choosing forecast variables according to economic and financial theories can make up for this.

Theoretically, three-layer BPNN can approximate any function. In this article, we use a three-layer BPNN with only one hidden layer. The weight is adjusted according to the general gradient descent method: i represents the input layer, j represents the hidden layer, k represents the output layer, and l represents the learning step; w_{ij}, w_{jk} represents the weights of input to the hidden layer and hidden layer to output layer, respectively; $E(n)$ is the sum of error energies.

$$\begin{aligned}\Delta w_{ij}(n) &= -\frac{\partial E(n)}{\partial w_{ij}(n)},\\ \Delta w_{jk}(n) &= -\frac{\partial E(n)}{\partial w_{jk}(n)}.\end{aligned} \tag{4}$$

Here, we combine dynamic principal component analysis with BPNN to construct a BP prediction model, as shown in Figure 4.

Assuming that the ensemble is composed of N independent neural network classifiers, adopting the voting

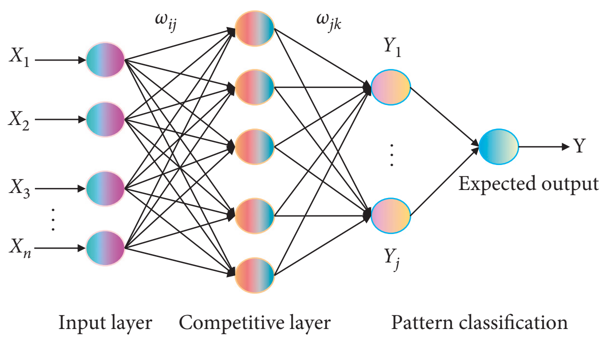

Figure 4: Schematic diagram of BPNN working principle.

method of an absolute majority, and assuming that each network gives the correct classification result with the probability of $1-p$, the errors among the networks are uncorrelated and the probability of errors in the ensemble neural network is P_{error}:

$$P_{\text{error}} = \sum_{k>N/2}^{N} \binom{N}{k} p^k (1-p)^{N-k}. \tag{5}$$

At $p<1/2$, P_{error} decreases monotonically with the increase of N. Therefore, if the prediction accuracy of each neural network is higher than 50%, and the errors among the networks are uncorrelated, the more the networks in neural network integration, the higher the integration accuracy. When N tends to infinity, the error rate of integration tends to zero.

Aiming at these shortcomings of the BPNN algorithm, this paper improves the original BPNN algorithm. The adaptive learning method and momentum summation method are used to modify the standard BPNN algorithm, which can effectively avoid the problem that the network falls into local minima. The artificial neural network can be mapped in any form, and financial early warning provides a new way of thinking.

The concrete improvement method of the BPNN algorithm is shown as follows.

In fact, the traditional BPNN algorithm is a simple high-speed descending static optimization algorithm. When correcting the weight $w(k+1)$, it is only corrected according to the negative gradient direction at time k, without considering the previous accumulated experience. Its weight correction function is written as follows:

$$w(k+1) = w(k) + \eta(k), \tag{6}$$

where the weight of $w(k)$ connection is the negative gradient of k moment:

$$D(k) = \frac{-\partial V}{\partial w(k)}, \tag{7}$$

where V is the square error between the actual output and the desired output of the network, and η is the learning rate.

A good learning rate at the beginning of training may not be suitable for later training. In order to solve this problem, it is natural to think of automatically adjusting the learning rate during the training process, so an improved algorithm of self-adaptive adjusting the learning rate appears, and its calculation formula is as follows:

$$\begin{aligned} w(k+1) &= w(k) + \eta(k)D(k), \\ \eta(k) &= 2^{\lambda}\eta(k-1). \end{aligned} \tag{8}$$

It can be seen that when the gradient direction of two successive iterations is the same, it means that the descent is too slow and the step size can be doubled; when the gradient directions of two successive iterations are opposite, it means that the descent time is too long, and the step size can be halved. Therefore, the network convergence can be accelerated by constantly adjusting the learning rate.

4. Experiment and Results

In order to analyze the progress of the company's financial budget implementation and the past years, it is necessary to extract the past years' budget data from the financial data warehouse and achieve the purpose by data aggregation and other calculation methods. The implementation of intelligent decision-making in financial budget management is divided into two steps:

(1) For analysis and application, firstly, intelligent decision-making based on the company's financial data warehouse and multidimensional analysis is established;

(2) Data mining is used to perform intelligent decision-making function.

The calculation of information gain depends on the attributes with more values, and the information gain depends on the number of attribute values, but in fact, this choice is meaningless in some cases. For example, the identification number is the identification attribute of a piece of data, and the identification attribute is the unique identification of the corresponding information. As the data value becomes larger and larger, the information gain corresponding to the port attribute is finally maximized.

In the process of DT construction, the key step is the splitting of nodes. Algorithm C4.5 uses information gain rate to measure the advantage of split nodes. In the formula of information entropy and information gain, the ratio of information gain is information gain and information entropy.

ID3, C4.5, and improved DT algorithms are run on different datasets, and the experimental data are obtained. The improved DT algorithm, ID3 algorithm, and C4.5 algorithm are compared, respectively, and the classification performance of the improved DT algorithm is compared. The error rate of the improved DT algorithm is significantly higher than that of the ID3 algorithm and C4.5 algorithm. The DT constructed by the improved algorithm is compared with the DT constructed by the traditional algorithm ID3 and C4.5, as shown in Figure 5.

The improved DT produces three layers of DT, according to the experimental results. Only one dataset is misclassified in each classification structure. When you examine the

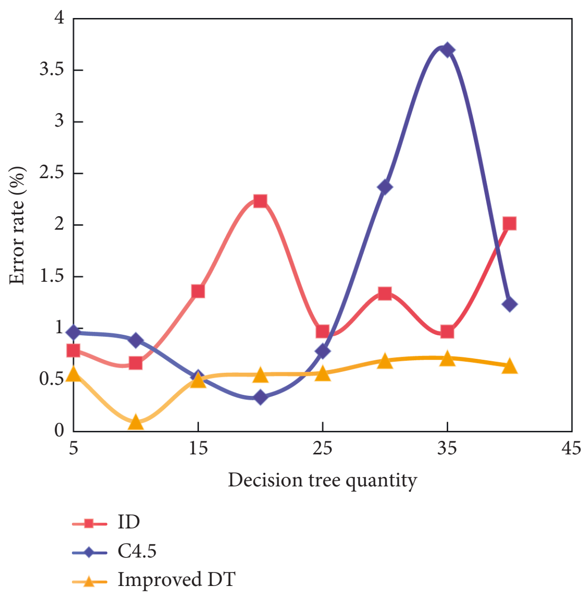

Figure 5: Comparison between DT constructed by the improved algorithm and traditional DT.

misclassified data, you will notice that each characteristic value is very similar to the misclassified class, not its own. The accuracy of the improved algorithm has improved. There is no guarantee that the final results will be the best, and the relationship between them is not linear. The tree hierarchy can be reduced effectively in order to improve the classification result.

The focus of accounts receivable analysis should be on the liquidity analysis of accounts receivable. Through trend analysis and structure analysis, we can find out the changing rules of accounts receivable, then pay attention to accounts receivable in abnormal situations, and analyze the economic essence that causes abnormal changes. The p value of the Bartlett spherical test is close to 0, which indicates that there is a linear correlation between indicators, which is suitable for factor analysis. When the factor reaches the fourth place, the cumulative variance contribution rate is 95.32%, indicating that almost all the information of the original variable is retained. At this time, the number of factors is only 2/3 of the original, thus achieving the purpose of simplifying the indicators. Therefore, this article selects three factors for analysis, and the total explanatory variance is shown in Table 1.

Firstly, according to the comprehensive score of the owner unit, this article classifies the accounts receivable risk of the owner unit in the model sample and then finds out the dividing points of each level. The cluster analysis results are shown in Table 2.

After obtaining the evaluation results, carry out a risk assessment and select the appropriate collection strategy. Overdue accounts collection is the joint responsibility of the subsidiary business department and the legal department, and the legal department takes the lead in cooperation with the business department. Through various channels, we can fully and truly understand the reasons why the owner cannot pay the project payment on time. And the legal department of the business department shall adopt appropriate nodes to collect according to the split result and collection policy.

Table 1: Total variance of interpretation.

Component part	Total	Variance percentage	Cumulative%
1	2.201	36.252	36.252
2	1.936	30.287	68.632
3	1.002	15.642	85.241
4	0.425	8.869	93.368
5	0.225	4.213	99.012

Table 2: Cluster analysis results.

Central point	Sample size
−12.363	3
72.541	20
−69.283	1
30.325	14
−28.736	5

In order to easily reflect the role of dynamic principal component analysis in financial forecasting, we conducted three groups of experiments on three models. The first model: the original data are directly predicted by BPNN without any processing (called BP_A). Model 2: Firstly, the data are standardized to eliminate the industry differences, then the original data are processed by static PCA, and a new variable combination (called BP_B) is obtained. The third model is the same: the industry differences are corrected; first, the original data are processed by dynamic principal component analysis, and then the prediction is made by BPNN (called BP_C). The empirical results of the BP model are shown in Figure 6.

It can be seen from the experimental results that there is no difference between BP_B and BP_C, so there is no difference between their results. Compared with the BP_A model, the prediction accuracy is not greatly improved, but the stability is improved. However, because the BP_C model increases the amount of information without increasing the network input and the complexity of the network structure, it not only improves the accuracy but also keeps the stability. When using three-year data, although the complexity of the BP_A model is reduced and the accuracy is improved, it is still not as accurate as when using one-year data. Compared with BP_A, BP_B itself greatly reduces the input dimension, and its accuracy is also in the BP_C model. The input dimension and network complexity do not increase, which shows that the data have little impact on the business.

Here, we combine the dynamic principal component analysis with two network models to obtain two prediction models. In these two models, we select the single bound function and its first, second, and third derivatives to form the mapping function of network nodes. For the output node, we choose a single limiting function. For empirical data, we still use the three groups used above. The detailed results of the three datasets are shown in Figure 7.

Judging from the prediction results, compared with other types, the prediction accuracy of BPNN has been

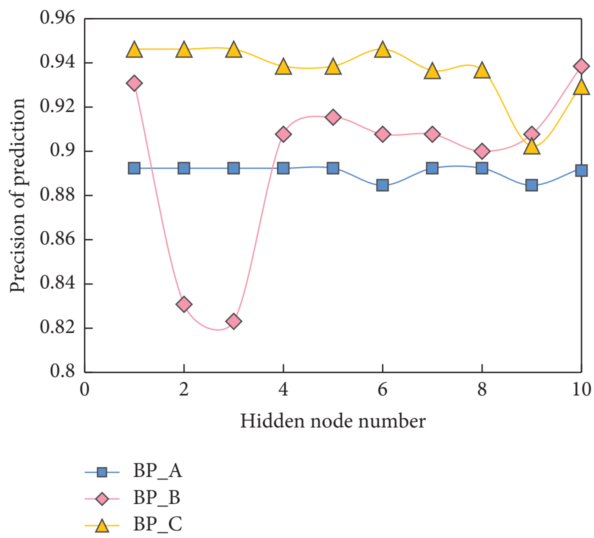

Figure 6: Empirical results of BP model.

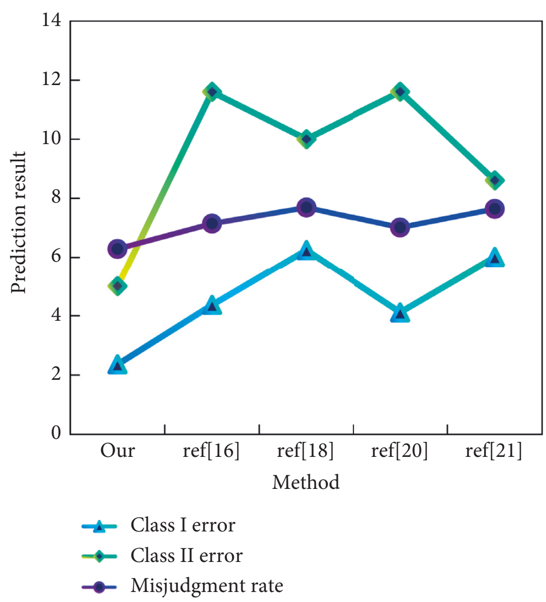

Figure 7: Detailed empirical results of three groups of data.

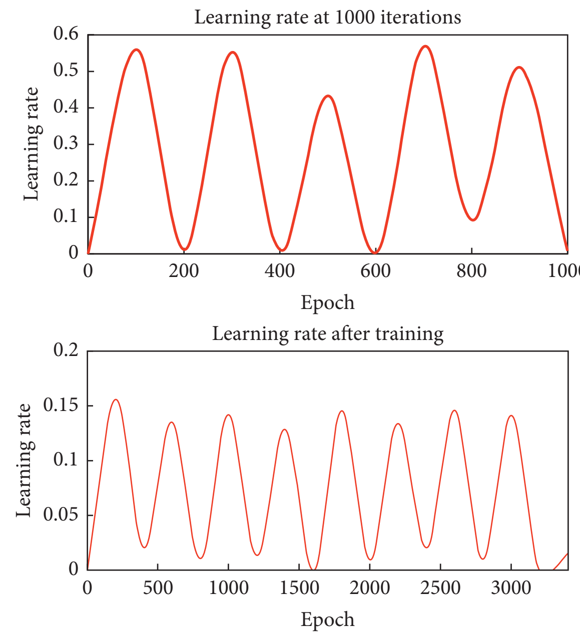

Figure 8: Learning rate curve after the training of financial distress early warning model.

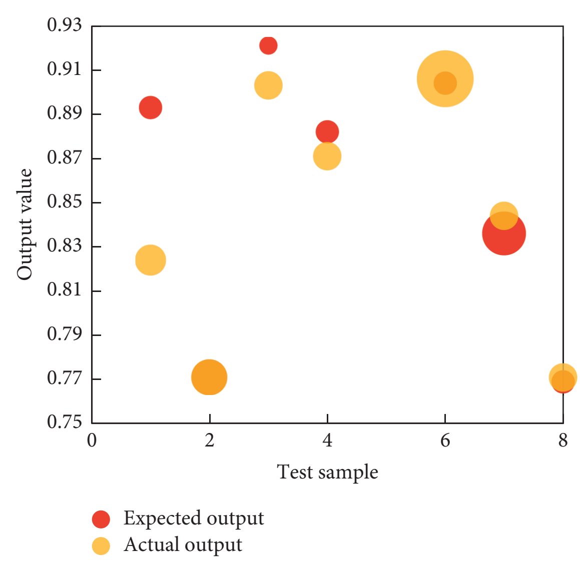

Figure 9: Judgment result of the neural model test.

significantly improved, especially after using data for many years; the prediction results have reached more than 90%, which is unmatched by other methods. Theoretically speaking, dynamic principal component analysis is used to select the variables of financial distress prediction, and an integrated network is used to predict the financial distress of listed companies, all of which have achieved ideal results. MATLAB is used to analyze and design the neural network system. First, a new M-File is created, and then a program is written in the editing bar. Because the input of this network model is a continuous variable, the premnmx function of MATLAB is used to normalize the training and unify the network output before processing. The learning rate curve of this network is shown in Figure 8.

Then the test sample is used for testing. See Figure 9 for the training and testing results.

The empirical research on the training, testing, and evaluation of the financial early-warning method model established in this article shows that the established neural network model has a good prediction effect and the actual results of the sample are close to the expected results, which are quite consistent, and its financial early-warning results are completely in line with its financial situation, which also shows that the application of BPNN in FinTech has a good prediction effect. On the other hand, the use of the BPNN algorithm and network topology configuration can be studied further, and a neural network and expert system combination can be used to see if the ability to predict financial difficulties can be improved. Naturally, this model has flaws, one of which is the number of nodes in the hidden layer. Constant training and sample testing are required to determine the number of nodes, and once convergence is achieved, the number of nodes meets the requirements. This procedure necessitates a significant amount of effort.

5. Conclusions

The shift from accounting to management accounting is a general trend that is unavoidable, given the new era's economic situation and the industry's long-term development. The role of enterprise accounting is changing, and the transition from financial to management accounting is speeding up, thanks to the advancement of modern information technology in the financial field. At the same time, management accounting is becoming more computerised. The government and other relevant departments must supervise the company internally. This document uses AI technology as the foundation for optimizing accounts receivable management in the integration mode and adopts a financial management optimization design based on AI to meet listed companies' accounts receivable management needs. The financial distress early-warning model of publicly traded companies is built using the BP neural network method. The empirical results show that, when compared to other types, BPNN has a significantly higher prediction accuracy. It has the potential to help operators take effective actions early in the financial crisis, improve their operating conditions, and avoid business failures.

Scientific analysis of students' incorrect actions in class, as well as timely and effective correction, is frequently an important link in the PE process. At the same time, it is an important symbol for assessing a teacher's teaching level and quality. In this paper, the analysis and correction model of sports wrong technical movements is built using DCNN to address shortcomings in the process of detecting wrong movements in PE and training. This article is based on CNN and has been enhanced by DL. The model learns both manual and DL features; the manual features use an improved dense trajectory, the DL features use CNN based on motion information, and the generalization ability of the kernel support vector machine is used to fuse the two. The simulation results show that the accuracy of the wrong action judgment of this method can reach 92.16 percent, which is 4.6 percent higher than the method of combining NN with region prediction and 5.7 percent higher than the method of detecting image matching score. This method can accurately describe the characteristics of human motion and identify incorrect movements, improve the ability of judging and correcting incorrect movements in sports training, and help athletes improve their sports level.

1. Introduction

With the continuous improvement of the technical level of sports, in the teaching process of sports technology, the demonstration of correct movements of sports has become a key research topic in the field of sports teaching [1]. Generally speaking, in the process of mastering motor skills, learners make mistakes, which can be prevented but cannot be absolutely avoided. Thus, correcting wrong actions has become an important task of PE (Physical education) and training [2]. In the actual PE teaching process, due to the obvious differences between students' cognition and understanding levels, some students have more wrong movements and are slow to master the correct movements of PE [3]. At the same time, in all kinds of sports, the technical specifications of movements are more complicated. Especially for some highly technical sports, it is necessary to carry out standardized training with correct movements to improve the level of sports training. In this state, how to effectively correct the wrong movements in sports has become the main problem to be solved urgently in this field. Due to the further development of research in related fields, computer image processing technology has been widely used in sports movement recognition. However, at present, there are various complex movements in sports training, and it is difficult to accurately judge the wrong movements by relying solely on traditional contour detection methods, which leads to the athletes' inability to get movements corrected in time.

With the continuous progress of computer science and technology, artificial intelligence technology [4, 5] has gradually matured. Once the concept of DL (Deep learning) [6, 7] was put forward, a large number of scholars devoted themselves to studying DL and made great progress and innovation. Nowadays, DL has been widely used in the process of human motion recognition and target detection. DL comes from the study of artificial NN (Neural network). In DL, it includes CNN (Convolutional neural network), cyclic NN, Boltzmann machine, etc., but now CNN is the most widely used one. Deep NN can automatically learn data features so as to discover sparse and distributed big data features. However, due to the poor hierarchy of the depth NN constructed in the current research and the failure to further process the action samples, the applicability of this method to the detection of wrong actions in PE teaching and training is poor. This technology can not be directly applied to capture human motion data. Scientific analysis of students' wrong actions in teaching, and timely and effective correction, is often an important link in the process of PE. It is also an important symbol to measure a teacher's teaching level and teaching quality. Based on the idea of improving the teaching quality, this paper improves the shortcomings of the current methods one by one, and builds a technical action analysis and correction model of sports errors based on DCNN (Deep convolution neural network). In order to quickly and accurately detect the wrong movements in PE and training and further improve the sports level of athletes. The innovations of this article are as follows:

(1) In view of the shortcomings in the process of detecting the wrong actions in PE and training, this paper is based on CNN and improves it through DL, adding a batch classification layer in the middle of the convolution layer and pool layer, and processing the wrong action samples in PE and training through batch normalization. Given the previous frame, the network can learn to predict the future moving frame and train the time encoder of human motion.

(2) In order to meet the needs of large-scale data sets and small-scale motion recognition at the same time, a human motion recognition algorithm based on multifeature fusion and motion information is designed. Through data enhancement, feature optimization, and transfer learning, the detection model in this paper is optimized to improve the detection accuracy and realize the real-time detection of the target. And through self-designed visual calibration objects, the uniqueness detection of multiperson identity can be realized. Experiments show that the algorithm can effectively identify large-scale data sets and small-scale actions.

The article is divided into five parts, which are arranged as follows: The first chapter is the introduction. This part summarizes the background and research significance of this paper and gives the organizational structure and innovation of this paper. The second chapter is related work. This chapter briefly describes the research status of motion recognition methods and target detection and analysis at home and abroad. And the research work and methods of this paper are introduced. The third chapter is divided into two parts. Section 3.1 outlines the concept of DL and related theoretical basis and introduces the related content of human motion detection based on DL. Section 3.2 puts forward and constructs the technical action analysis and correction model of sports errors based on DCNN. In chapter 4, the model proposed in this paper is simulated for many times, and the results are analyzed. The fifth chapter is the conclusion. This chapter summarizes the research work of this paper and looks forward to the future.

2. Related Work

Accurate recognition and analysis of human body posture can provide effective data support for sports training. By obtaining the relevant data of human movement and correcting the details of athletes' movements with the data of standard database, the athletes' sports level can be improved. Because of the far-reaching development significance, the detection and correction of wrong movements in sports have also become the focus of research in the industry, which has received extensive attention, and many detection methods have also appeared.

Miao et al. designed an action recognition method based on depth images. The algorithm projects the depth image in three projection planes, extracts features from the three projection images, and uses these features to train the extreme learning machine classifier. The algorithm is computationally efficient, but its performance is not ideal for small-amplitude action recognition [8]. Arrieta et al. proposed a temporal deep belief network that can complete online human action recognition [9]. Kluding et al. proposed a gesture feature extraction and recognition method based on acceleration trajectory images. The algorithm converts unknown gesture trajectory features into low-dimensional subfeature sequences by establishing an acceleration gesture trajectory map, which improves the accuracy and time efficiency of gesture recognition [10]. Ullah et al. model human motion information through asymmetric systematic bias [11]. The recognition algorithm proposed by Yao et al. achieves high recognition accuracy for small-amplitude movements, but the amount of features to be analyzed is large, which is difficult to apply to large-scale data sets [12]. Yassine et al. used two-dimensional wavelet packet technology and spatial clustering technology to analyze human behavior and actions and improved the accuracy of wrong action detection by analyzing PE training images. However, the features extracted by the two-dimensional wavelet packet technology are not comprehensive enough, so the subsequent detection results deviate greatly from the actual ones, while the spatial clustering technology is too extensive, ignoring the detailed features of the image edges, and the detection results are prone to errors [13]. Belczak et al. proposed a 3D modeling and detection method for wrong action images in sports without background information [14]. Department et al. proposed an image reconstruction method for wrong action images in sports based on feature moving frame differential scanning and adaptive compensation. In this method, infrared projection and edge contour feature extraction are performed on the wrong action images collected in sports, and the box filtering method is used for image filtering to improve the accuracy of image detection. This method is susceptible to disturbances, resulting in a high error rate for false action detection [15]. Mi et al. proposed a 3D modeling detection method for wrong actions in sports based on 3D contour feature decomposition [16]. The method proposed by Cai et al. uses edge contour reconstruction to repair the missing information of the image and uses the zero-cross point feature segmentation and corner detection method to perform adaptive positioning and detection of wrong actions in sports, image classification, and screening. This method improves the detection and recognition ability of wrong actions [17].

In this paper, the traditional methods of moving target detection and motion recognition are summarized, and their advantages and disadvantages are analyzed. Given the shortcomings in the current detection process of incorrect movements in PE teaching and training, a model for analyzing and correcting incorrect technical movements in PE is built using DL. The model learns both manual and DL features; the manual features use an improved dense trajectory, the DL features use CNN based on motion information, and the generalization ability of the kernel support vector machine is used to fuse the two. The detection model in this paper is optimized through data enhancement, feature optimization, and transfer learning to improve detection accuracy and achieve real-time detection of the target. Furthermore, the detection of multiperson identity uniqueness can be realized using self-designed visual calibration objects. This method can accurately describe the characteristics of human motion, identify incorrect movements in sports training, and improve the ability to judge and correct incorrect movements. It has theoretical and practical implications in the field of sports action recognition and correction.

3. Methodology

3.1. Human Motion Detection Based on DL. Artificial NN is an algorithm model inspired by nature and constructed by simulating human brain nerve activity. The basic unit of artificial NN is the neuron, which is also the most basic unit for processing all information. By simulating the process of the human neuron processing external stimuli, the neuron appears as a many-to-one nonlinear mapping unit. DL comes from the research of artificial NN [18]. There are four basic models of DL. Specifically: (1) Automatic encoder, sparse automatic encoder, and noise reduction automatic encoder with their variants. (2) Limiting Boltzmann machine. (3) Convolution Boltzmann machine. (4) Circulation NN. Action recognition is influenced by different lighting conditions, diverse perspectives, complex backgrounds, and great changes within a class. In this field, the improved dense trajectory method is the best method of traditional methods. It has good stability and the highest reliability, but the algorithm is very slow. The appearance of DL provides a new idea for action recognition and achieves good results.

DCNN is a multilayer backpropagation artificial NN designed for shape recognition in DL. Each layer of neurons is linked to the local visual field area where the front layer network intersects, but there are no connections between neurons in the same layer. DCNN is primarily a type of NN that employs DL to improve CNN by displaying changeable levels and backward propagation direction, allowing for error action detection [19]. Weight sharing and local connection are features of DCNN, which greatly reduce network complexity and improve algorithm performance. As a result, DCNN is the most popular NN [20]. The pooling layer is usually connected after the convolution layer. Then the convolution layer is alternated with the full connection layer. Convolution kernels of various sizes can be used to improve the overall generalization performance of the network during the convolution process. A classifier will be connected at the end of the network to classify the input data. The process of object detection based on deep learning is shown in Figure 1.

DCNN has certain advantages. It includes the following: (1) Minimize pretreatment. Most of the input data are raw data that have not been processed many times, and there is no accurate mathematical expression between input and output. Its feature extraction is trained within the network, which avoids the subjectivity and limitations of manual feature extraction. (2) DCNN is influenced by time delay NN and adopts the network structure of weight sharing, which reduces the computational complexity in the process of network training and makes it more suitable for time series data. DCNN weights are shared and the calculation during training is relatively simple, which can be widely used in the process of time series data analysis, and it can change the capacity of the wrong action detection model in PE and training through the depth and breadth of the network structure. The structure of the dual-flow network is that two NN mix features before the final decision. For the spatial information feature extraction network, only the intercepted video frames need to be grouped into network training to get the spatial features. For the time information feature, the optical flow information of several consecutive frames is usually selected as the input of the network and then added to the network for training. The intrinsic characteristics of the signal, the statistical characteristics of one part may be the same as those of other parts. Therefore, a small subimage can be randomly selected from the image for feature learning, and then the feature can be used as a filter to scan the whole image, and a different feature activation value can be extracted at each position of the whole image, thus realizing feature extraction of the image.

Intercepting video frames according to a set frame rate is the simplest way to deal with video for motion recognition. Processing video frames requires significantly less computation than directly processing video data. Pooling the feature map obtained from the convolution layer through the pooling layer yields the corresponding pooled feature map. A feature extractor is analogous to a convolution kernel. Different convolution kernels can be designed to extract features at different levels in the image, and all of the features processed by convolution kernels are then combined as the output of the convolution layer, so convolution kernel design is crucial. Convolution kernel size, number, and step size can all be customized. The convolution operation is carried out in the cube by combining several consecutive video frames into a video frame cube. The sequential convolution operation involves performing three consecutive video frames at the same time, and the time dimension of the convolution kernel is three, making it a three-dimensional convolution kernel. The video frame

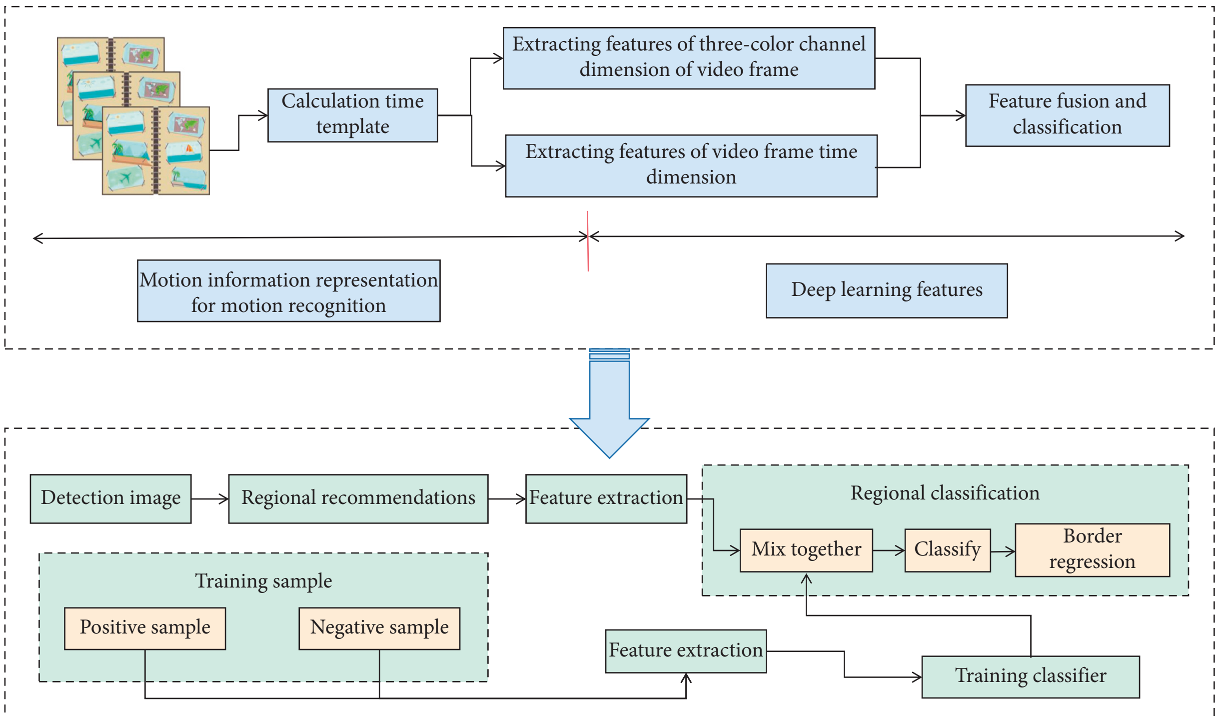

Figure 1: Target detection process based on deep learning.

cube's convolution kernel weights are shared. A variety of convolution kernels are used for convolution layer operation in order to better obtain the information in the video frame.

3.2. Analysis and Correction Model of Technical Action of Sports Errors. DCNN weight sharing has a network structure that is more similar to biological perception NN, and it can adjust model capacity by changing the depth and breadth of the network structure, which has strong statistical stationarity and pixel local correlation for natural images. Convolution and pooling are two important DCNN links. As a result, one of the key factors that determine the performance of a DCNN structure is the choice of convolution kernel size and sliding step size, pool kernel size, and sliding step size. The model's parameter training is also a critical factor in determining the network structure's performance. Because CNN requires a large number of training parameters, the model's complexity is high, which could lead to the trained model's error rate on the training set decreasing while the error rate on the verification set increases. The main reason is that in the training process, every input must be considered, and there are numerous parameters to consider. A small change in the input data has a big impact on the outcome, so keeping the parameters as small as possible is the problem that needs to be solved right now.

In this paper, the regularization method is frequently used in the full connection layer to prevent overfitting due to the small size of the data set used in the DCNN process. Because of the randomness of this method, the network structure corresponding to each transmitted data set will be inconsistent, but all network weights will be shared, greatly improving the stability of the wrong action detection model in PE and training and making it easier for neurons to adapt to one another. Every pixel in a video frame or image is made up of three primary colors. The amount of data read at one time during network training is large, which has a significant impact on the computer's computing speed. When training the model, end-to-end training can be done when the two pieces of information match, and the corresponding real frame can be chosen from a list of default frames with various aspect ratios, scales, and positions. The batch normalization algorithm is used in the batch normalization layer in this paper, which integrates the network layer input processing operation into the wrong action detection of PE and training. It processes the wrong action samples of PE and training through microbatch normalization. The flow of sports movement detection and analysis using this method is shown in Figure 2.

The size of convolution kernel has obvious influence on image processing. If the convolution kernel used is too small, the enhancement effect of the action information of interest to the image is not obvious, but it may increase the noise in the same frequency band and cover up some original details of the image. If the convolution kernel used is too large, the calculation amount of convolution will also increase, resulting in higher computational complexity. According to a large number of applications of DCNN structures in human motion recognition, this paper finds that the convolution kernel size is 3×3 convolution network structure. ResNet residual network is an improvement to solve the problem of deep network structure degradation. ResNet is based on the cross-layer connection structure of Highway Network. The number of layers of residual network is usually

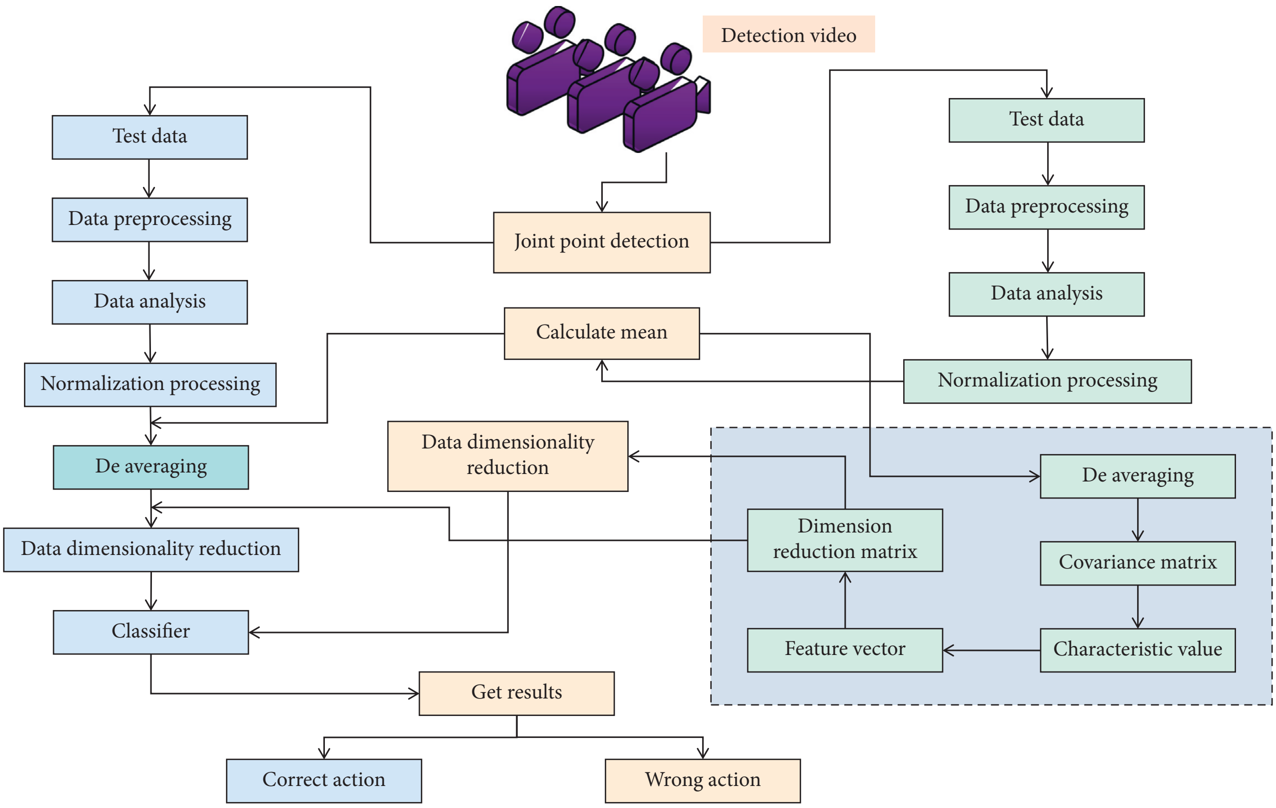

FIGURE 2: Sports action detection and analysis process.

very large, up to 100 layers, but this fast connection method makes the actual depth of the network not too deep. Experiments show that residual network can well solve the problem of deep network degradation. When the auxiliary features are used as input to pass through the last hidden layer of the proposed model and connected with the auxiliary output points, and the extracted features are closer to the output of the auxiliary features in the training stage of the proposed network model, the regularization of the model is completed. The convolution layer of DCNN applies the weight sharing method, and at the same time, it reduces the structural parameters and difficulty, prevents NN from overfitting in the early stage, makes it have better generalization ability, and ensures the stability of NN through pooling. Suppose the formula of the fully connected layer feature output $x^{(l)}$ of the l layer is as follows:

$$x^{(l)} = f\left(w^{(l)} x^{(l-1)} + b^{(l)}\right). \tag{1}$$

Among them, $w^{(l)}$ represents the weight parameter, and $b^{(l)}$ is the bias term. The Softmax regression classifier needs to iteratively update and learn, and the functions to be learned are as follows:

$$h_w(\overrightarrow{x}) = \frac{1}{\sum_{i=1}^{k} e^{\overrightarrow{w_i}\cdot\overrightarrow{x}+b_i}} \begin{bmatrix} \overrightarrow{w_1}\cdot\overrightarrow{x}+b_1 \\ \overrightarrow{w_2}\cdot\overrightarrow{x}+b_2 \\ \cdots \\ \overrightarrow{w_k}\cdot\overrightarrow{x}+b_k \end{bmatrix}. \tag{2}$$

Among them, k represents the number of categories to be classified, and b_i and $\overrightarrow{w_i}$ represent the offset vector and weight vector corresponding to the i th category. (3) represents the probability value that the sample $\overrightarrow{x}$ is the j class.

$$P(y=j\,|\,\overrightarrow{x}) = \frac{\overrightarrow{w_j}\cdot\overrightarrow{x}+b_j}{\sum_{i=1}^{k} e^{\overrightarrow{w_i}\cdot\overrightarrow{x}+b_i}}\ \sum_{j=1}^{k} P(y=j\,|\,\overrightarrow{x}) = 1. \tag{3}$$

After training and learning to get $\overrightarrow{w_i}$ and b_i, the objective loss function can be expressed as follows:

$$J(w,b) = -\frac{1}{m}\sum_{j=1}^{m}\sum_{l=1}^{k} 1\left\{y^{(j)} = l\right\}\log\frac{e^{\overrightarrow{w_l}\cdot\overrightarrow{x}+b_l}}{\sum_{i=1}^{k} e^{\overrightarrow{w_i}\cdot\overrightarrow{x}+b_i}}. \tag{4}$$

Among them, m represents the number of samples in the training set, k represents the number of classification categories, and $1\{\cdot\}$ is an indicative function. When $y^{(j)} = l$, the function value is 1. Otherwise, it is 0. Optimized by an autoencoder for high-dimensional input data $x \in R^N$:

$$\min_{f,g} \|x - f(g(x))\|. \tag{5}$$

Among them, the encoder $y = g(x)$ maps the input data to the low-dimensional space $y \in R^M, N > M$. Let $x \in R^N$ be the observations of time t. The optimization function of the time encoder is as follows:

$$\min_{f,g}\left\| X_{(t+1):\ (t+\Delta t)} - f\left(g\left(X_{(t-\Delta t+1):\ t}\right)\right)\right\|, \tag{6}$$

where the encoder $y = g(X_{(t-\Delta t+1):t})$ maps the input data to the low-dimensional space $y \in R^M$, $(N \times \Delta t)n!/r!(n-r)! > M$. The decoder $\widehat{X}_{(t+1):(t+\Delta t)} = f(y) \in R^{N\times\Delta t}$ is used to map back to the data space.

Neurons appear with a certain probability in each layer of the network structure, causing the training network to change every time, reducing the correlation between neurons and increasing the generalization and robustness of the entire network. The depth of NN affects the detection accuracy of incorrect movements in sports, and the features are related to representation ability. The NN depth will calculate all of the features of incorrect movements, and the deeper the final output, the better the feature extraction ability. The extreme learning machine is divided into two layers: the first calculates two feature cores, then fuses the two to form a fused feature core, and finally outputs the predicted scores of the three feature cores. All of the predicted scores are mapped to the final action classification by the second training classifier. This method's manual and DL features complement each other, and the video's human motion information is described from various perspectives. The independent batch normalization process replaces the joint normalization process of each dimension of data, and the formula is as follows:

$$\widehat{X}^{(k)} = \frac{x_i^{(k)} - E\left[x^{(k)}\right]}{\sqrt{\operatorname{var}\left[x^{(k)}\right]}}. \tag{7}$$

Among them, the k th dimension of the input sample is denoted by $x^{(k)}$, the expectation is denoted by $E[x^{(k)}]$, and the variance is denoted by $\operatorname{var}[x^{(k)}]$. Adding parameters $\lambda^{(k)}$ and $\beta^{(k)}$ to the k dimension of each input sample, the following formula is obtained:

$$y^{(k)} = \lambda^{(k)}\widehat{X}^{(k)} + \beta^{(k)}. \tag{8}$$

Among them, $\lambda^{(k)}$ and $\operatorname{var}[x^{(k)}]$ are equal and both are variances. The local binary fitting method is used to complete the information collection and the reconstruction of the feature database, and the regional pixel information can be obtained:

$$L = J(w,e) - \sum_{i=1}^{N} a_i\left\{w^T \varnothing(x_i) + b + e_i + y_i\right\}. \tag{9}$$

Among them, $J(w,e)$ refers to the repeated pixels of the motion position; x_i and y_i are the correct action and wrong action feature vectors of the i th Gaussian unit, respectively; a_i is the standard action configuration sequence; $\varnothing(x_i)$ is the contour feature distribution function. By estimating the probability of the motion feature obtained by dimensionality reduction in the Gaussian unit i, we can get the following:

$$r(i) = \frac{w_i p_i - v_i}{\sum_{i=1}^{k} w_i p_i(v_i)}. \tag{10}$$

Among them, p_i refers to the probability of being assigned to the i th Gaussian unit, and w_i is the mixing weight.

A low-dimensional mapping, that is, a fixed-length feature vector, is generated for each $n \times n$ sliding window position, and then these feature vectors are sent to two fully connected layers, respectively, one for border regression and the other for predicting the category of the sliding window target; that is, the transformation parameters of the border position are given. Because the gray-scale data and the original data are identical in video length, data set size, action types, etc., except for the single pixel data of the image, the gray-scale image is chosen to preliminarily determine the training parameters of the network structure. In the process of deepening the network depth, it is easy for the gradient to disappear, which leads to a decline in network performance. To solve this problem, the basic network used to extract features by DCNN is ResNet101, which can extract the subtle features of PE training sample data faster and better. At the same time, in the middle of the convolution layer and pooling layer, the normalized layer and residual block are added in batches through ResNet, which can speed up the network training and adjust the data transmission strategy to further optimize the network performance.

4. Result Analysis and Discussion

In DL, the more effective samples are produced, the better the robustness of the trained model will be. Therefore, this paper uses some data enhancement strategies at the beginning of the network and carries out some random operations for each input sample picture, including using the original input sample picture; Sampling the original picture at random; Cut the original picture randomly, etc. After the above operation, the sample sizes of all samples are normalized, and the samples are randomly flipped horizontally with a certain probability. In order to determine the batch size of network training, the network training is carried out at every 10 groups of samples based on the batch data from 10 to 100 under the condition of 10 iterations, 20 iterations, and 100 iterations, respectively. Among them, the parameter settings of DCNN are shown in Table 1.

In order to comprehensively evaluate the performance of this algorithm, experiments were carried out on video dataset A and video dataset B, respectively. Data set A has a low resolution and a large amount of data, which can test the recognition performance of this algorithm for large-scale data sets. The video data set B has a high resolution, including 35 actions, all of which are local actions of the human body, with a small range of actions. This data set can test the recognition effect of this algorithm for small-amplitude actions. During the experiment, the data set used in this paper is a nonpublic data set. All experimental data are divided into two groups on average, one for DCNN training and the other for experimental testing. The accuracy of action recognition of different methods on two data sets is shown in Figures 3 and 4.

In this paper, we sort the confidence of the default boxes of negative samples, then select some default boxes in the front as samples, and discard all other negative samples, so that the final ratio of positive and negative samples is about 1 : 3. Experiments show that this operation can accelerate the

convergence speed, and the training process is more stable, which is a very effective optimization strategy. In this paper, representative F1 indicators are plotted as data as shown in Figure 5.

In the process of recognition, the processing of different frames will also occupy different sizes of computing resources. In order to reduce the use of computing resources, before the network training, firstly, the key area of human motion is detected by the method of target detection, and this area is cut out, which is used as new data to join the network for training. The method in this paper, the method of combining NN with regional prediction and the method of image matching score are used to detect the wrong actions in the process of PE teaching and training, and the effects of the three methods in detecting the wrong actions in PE teaching and training are compared with the increasing number of experiments. The effects of three different methods on detecting the wrong actions in PE teaching and training on two data sets are shown in Figures 6 and 7.

From the data analysis in Figure 7, it can be seen that the method in this paper has a certain accuracy in judging wrong actions. Among them, the error judgment accuracy of this method is about 92%, the error judgment accuracy of the method combining NN with regional prediction is about 87%, and the error judgment accuracy of the image matching score method is about 86%. The problem of small target detection is addressed in this paper by adding another layer to the feature selection layer, selecting lower-level features, and retaining more lower-level detail features. The video data is preprocessed as network input and the network parameters are effectively trained. The extracted motion features are then convolutioned and

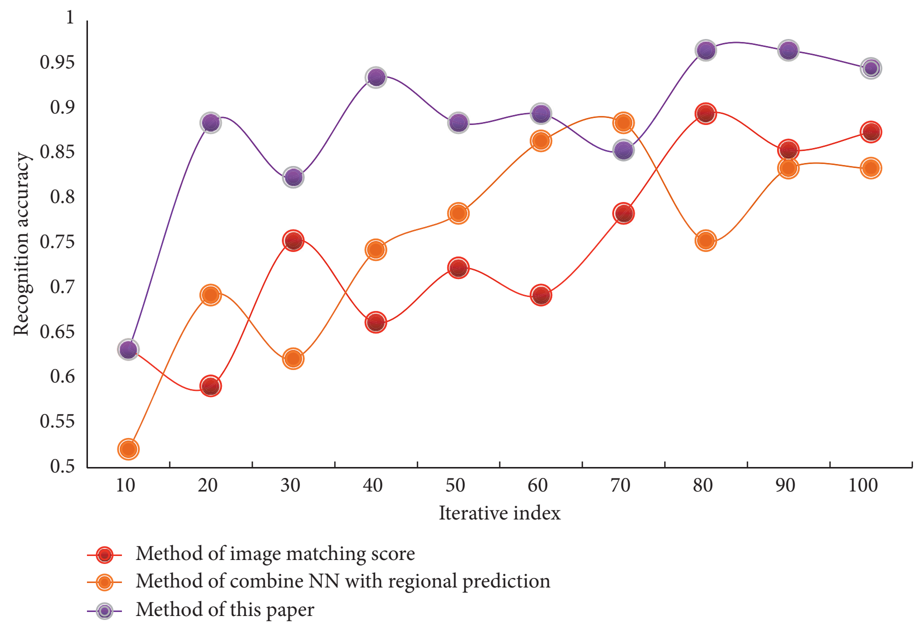

Figure 4: Action recognition accuracy of different algorithms—dataset B.

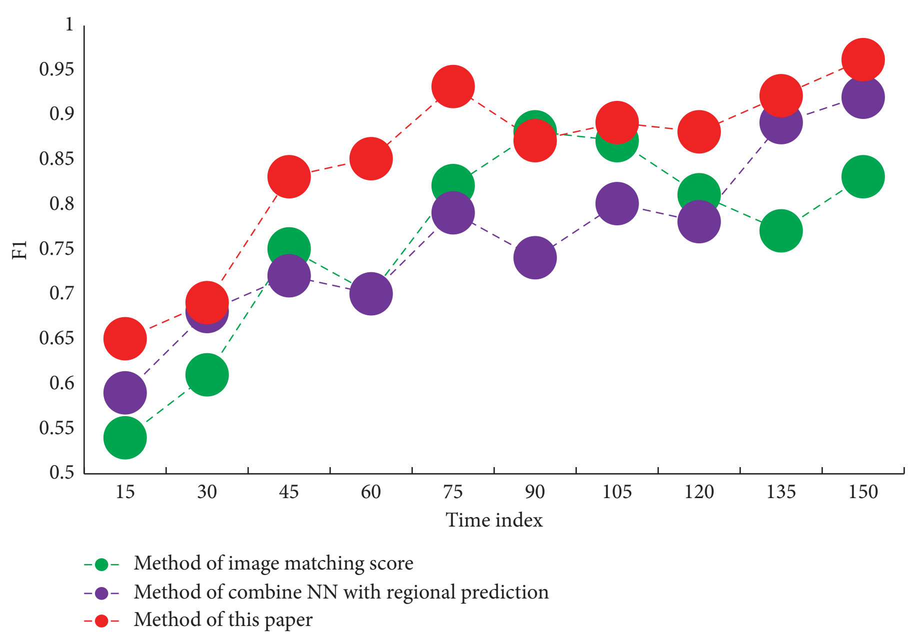

Figure 5: F1 value comparison.

pooled to add more time and space dimension information. Finally, it passed through the softmax classifier, which improved the accuracy of human motion recognition and better adapted to different changes in video data scenes, thanks to two layers of full connection. Six test indexes, namely accuracy, recall, sensitivity, complexity, specificity, and positive prediction rate were used for quantitative comparison in order to verify the effectiveness and robustness of this method in the detection of incorrect movements in sports training. The comparison results are shown in Table 2.

The data analysis in the table shows that among the three methods of detecting incorrect actions in PE teaching and training, the six parameters of this method are better than the method of combining NN with regional prediction and the method of image matching score. The model in this paper has fewer parameters, which reduces overfitting and reduces structural redundancy, resulting in a faster convergence speed and a shorter training period. It improves the accuracy of recognizing sports incorrect actions and reduces running time to some extent. This confirms the superior performance of the DCNN proposed in this paper.

5. Conclusions

It is natural for students to make mistakes when learning new movements in technology classes, and teachers should prevent and correct these errors. Preventing and correcting incorrect movements in technology teaching is a necessary condition for effectively exercising and avoiding sports injuries. However, due to the variety of complex movements in sports training, it is difficult to accurately judge the incorrect movements using traditional contour detection methods, resulting in athletes being unable to correct the movements in a timely manner. Traditional methods, on the other hand, are unable to accurately capture the incorrect movement characteristics of PE teaching and training, resulting in decreased detection accuracy. This paper proposes a DCNN-based detection model of incorrect actions in PE teaching and training based on this information. The model learns manual and DL features, with the manual features using an improved dense trajectory and the DL features using a CNN based on motion information, and the two features are fused using the generalization ability of a kernel support vector machine. Simulation experiments are conducted in this paper to demonstrate the efficacy of the method proposed in this paper for detecting incorrect actions in PE teaching and training. The results show that the accuracy of wrong action judgment can reach 92.16 percent, which is higher than the 4.6 percent accuracy of the method that combines NN and region prediction and the 5.7 percent accuracy of the method that detects image matching score. The accuracy and robustness of human motion feature analysis are improved because the network structure used in this paper can directly classify actions on features without fine-tuning. The findings show that this method can accurately detect athletes' incorrect movements during PE and training, control detection errors, and judge incorrect movements quickly and accurately. For the field of sports action recognition and correction, this study has some theoretical and practical relevance. Despite the fact that this paper yielded some research findings, it still has some flaws that need to be investigated and improved. We will continue to research how to improve timeliness and immediacy while also increasing recognition accuracy in future work. In PE teaching and training, provide strong technical support for detecting incorrect movements.

Landscape morphology is a significant area of landscape architecture research. One of the scientific and technological issues in recent landscape morphology research is the use of quantitative analysis technology driven by morphology indexes and computational models to describe, compare, and analyze form features. This article focuses on the form features of the polder landscape, based on existing theoretical and practical achievements in landscape morphology. First, we choose five landscape morphology indexes based on the morphological constituent units of the landscape (elongation, rectangular compactness, concavity, ellipse compactness, and fractal dimension). Then, using the self-organizing map (SOM), we create an identification model for clustering the types of constituent units. The experimental results show that the identification model can classify polder morphology and analyze the distribution of units using typical polders in the Yangtze River's south bank as study cases. This article presents a technical approach to polder landscape morphology classification as well as a reference and developable quantitative analysis method for landscape morphology research.

1. Introduction

Landscape morphology is an organic part of the landscape environment that condenses the landscape material space in a plane, which is one of the crucial representatives in distinguishing the landscape feature of different regions [1]. Digital identification and quantitative analysis of representative regional landscapes are of great significance for continuing and reshaping the features of regional landscape morphology [2]. With the support of landscape morphology and typo-morphology theories, developing quantitative analysis technologies suitable for identifying and analyzing polder landscape morphology has become one of the practical problems in the current landscape morphology research.

Contemporary studies on landscape morphology have gradually shown a trend of quantitative research, driven by emerging digital landscape research methods and technologies [3]. The analysis foundation for this type of study is to combine spatial information based on the morphological characteristics of the research object, and then obtain operable and comparable values and intervals. A crucial step is to keep optimizing the morphology index in order to achieve the mathematical translation of objective morphology. Exploring the morphological features of a research question requires building a quantitative analytical model that fits the research question. A landscape morphology analysis model created based on the machine learning model can transform traditional qualitative cognition into quantitative judgment [4]. Related research has been carried out in the fields of landscape classification [5], simulation prediction [6], landscape efficiency, and evaluation [7]. Exploring theoretical methods and technical means in the investigation of a typical zonal landscape morphological feature will effectively respond to the theoretical and practical needs of the refined development of landscape morphology. Meanwhile, it can provide a research basis and technical reference for quantitative research and digital development of landscape morphology [8].

2. Relevant Research

2.1. Polder Landscape Morphology. Polders are agricultural production environments formed by artificial water conservancy projects, mainly distributed in low-lying and water-rich river banks [9], estuary deltas, and coastal lowlands [10]. In the long-term production evolution process, the morphological features of the wetland polders are integrated with production methods, intertwining the landscape paddy fields, dry land, canals, ponds, and fields and ridges (Figure 1). One of the main difficulties in studying polder landscape is accurately describing and analyzing its morphological features.

In the study of interpretation, historical evolution, planning, and design of polder landscape, the unique landscape morphology of polder has the fundamental significance for regular summary and retrospective tracking. In terms of morphological interpretation and historical evolution, Steenbergen et al. analyzed and illustrated the development and distribution of polder morphology in the Netherlands, and then classified and analyzed the features of the polder from aspects of nature, water conservation, agriculture, and settlement [11]. Missiaen et al. summarized the landscape evolution of polders in northern Belgium [12]. Li et al. used remote sensing images to sort out the spatiotemporal distribution and development of polders in the Dongting Lake Plain in China [13]. In terms of planning and design, Velde and Wit summarized the methods of polder management and planning strategies of polder urban based on morphological research [14]. Nijhuis and Pouderoijen based on the GIS platform to visualize various polder data, introducing a digital orientation to the study and management of the polder landscape morphology [15]. The morphology of the polder also impacts the realization of its production, life, and ecological functions. Optimizing the polder morphology can improve flood management and the capacity for disasters in this area [16, 17]. The landscape morphology element is also a critical research indicator in evaluating the effectiveness of the polder transformation scheme [18] and the value of polder ecosystem services [19].

The polder form has gotten a lot of attention in landscape architecture research because of its distinguishing characteristics and crucial role in polder landscape research. Upgrading morphological classification from empirical cognition to quantitative judgment, as part of the digital landscape research trend, will aid in the promotion of polder landscape research.

2.2. Theory and Method of Landscape Morphology. American geographer C. O. Sauer first proposed landscape morphology in 1925 [20]. As an intuitive reflection of landscape environment on a two-dimensional plane, the specific syntagmatic relation and composition methods presented by landscape morphology are an essential carrier for exploring the feature of the landscape. As a branch of morphology research, landscape morphology research closely relates to the trend of morphology research. Since the 1950s, academic circles have paid increasing attention to the inheritance and protection of typical forms. Guided by the theory of morphology and graphical analysis, under the joint influence of Conzen [21] and Muratori-Caniggia [22] produced a morphological research method named typo-morphology, which provides a framework for the study of typical features of complex morphological systems. Specifically, it takes the basic constituent units of the research object's morphology as the entry point and selects geometric morphology indexes to describe the morphological features of the units. Then, identify the research object's morphological types and typical features by analyzing, comparing, and classifying the index value.

Current research continues to verify the applicability of morphology-type analysis to identify morphological features in the built environment and natural environment from multiple perspectives and scales. The perfection and development of digital landscape theory and technical methods also provide new research and practice tools for exploring the feature of morphological [23]. In research of urban morphology [24], settlement pattern [25], and landscape morphology [26] have accumulated a large number of indexes. Meanwhile, statistical and machine learning models are applied to morphology index analysis, expanding the visual analysis capabilities of multidimensional morphological data with large sample sizes. For example, Gil et al. used the K-means algorithm to analyze the typical urban block morphological dataset, realizing the objective classification of block morphology types [27]. SEM [28] and hierarchical clustering [29] also provide practical tools for a comprehensive analysis of morphological data. Machine learning methods such as back propagation neural network [30, 31] and convolutional neural network [32] can also achieve identification and classification of morphological unit types by learning morphological data [33]. On this basis, exploring data-driven landscape morphology research methods with the help of landscape morphology index and mathematical analysis model has positive significance for analyzing the feature of polder morphology.

2.3. Application of SOM in Landscape Architecture and Related Research. SOM is an unsupervised machine learning algorithm [34], which does not need to form an evaluation standard by learning samples with existing classification labels. It can perform competitive learning on the potential laws and fundamental attributes of the input samples after independently adjusting the connection weights of the network structure. Therefore, in the analysis without pre-classification criteria, often use SOM.

SOM is commonly combined with quantitative indexes and applied in element identification, comprehensive evaluation, and scheme optimization in landscape architecture and related disciplines research. It can be applied to SOM to hierarchical classification studies of building form [35], building space [36], and land use [37] in terms of

Polders in the Yangtze River in China | Seaside polders in Netherland | Coastal polders in Indonesia | Riverside polders in Bangladesh

Figure 1: Morphology features of the polders.

element recognition. When it comes to comprehensive evaluation, SOM is frequently used to analyze multifactor datasets and solve complex classification problems, such as a comprehensive analysis of tourist motivation and behavior in protected areas [38]. SOM can also be used to investigate relationships between research elements, such as correlations between river ecological indicators [39], pattern associations between different environmental conditions and physiological responses [40], and links between residents' lifestyles and their choice of residence within the city [41]. Using SOM to create a parametric building model can optimize the architectural design scheme [42].

In summary, SOM has substantial autonomy and a low degree of manual intervention. It can adapt to the high-dimensional data [43], which is highly suitable for polder landscape morphological identification's application scenario. In this sense, a polder landscape morphological identification model based on SOM will promote the refinement and intellectual development of polder landscape morphological identification and provide a quantitative analysis method for the research of landscape morphology.

3. Methods and Materials

3.1. Technology Roadmap. Under the guideline of landscape morphology and typo-morphology theory, we took polder landscape morphology as the research object, attempting to make a quantitative research process to analyze its landscape morphology feature based on the constituent units. The process combined landscape morphology index, SOM, and statistical methods to characterize the overall morphological features and internal differences of the polder units. This article conducted an empirical study on typical polders in the South of the Yangtze River, and the specific research steps are as follows (Figure 2):

(1) *Morphological Quantitative Translation*. Select suitable landscape morphology indexes, and convert the polder morphological constituent units into operable, analyzable, and comparable index values.

(2) *Morphological Data Processing*. Use factor analysis to integrate the multi-index into several common factors. Then, use common factors value for the subsequent cluster identification of the polder landscape morphology type.

(3) *Morphology-Type Clustering*. Use SOM to build a polder landscape morphological identification model. Then, realize the typo-morphology and distribution pattern analysis of the research area through self-learning and clustering of the common factors extracted by factor analysis.

(4) *Morphological Quantitative Analysis*. Use the ArcGIS platform to visualize the identification results. Then, establish a polder landscape morphological database, realizing the management, display, retrieval, and quantitative analysis of polder units [44].

3.2. Morphology Index Translation. Describing the polder morphology with the landscape morphology index is crucial for identification and classification of the polder morphology types. Based on the two-dimensional plane of the polder landscape constituent morphological unit [45], the morphology indexes selection according to the geometric features of the constituent units. Index selection principles combined scientificity, representativeness, comprehensiveness, and operability. The indexes abstractly translated the two-dimensional morphology of the polder units into the indexes value, providing primary data for subsequent morphology-type classification and feature analysis.

Long-term agricultural production and natural evolution have occurred in the polder landscapes studied in this article. Polder unit boundaries were originally almost regular geometric shapes. The polder units' boundary morphology tends to be tortuous as the water network expands and current scouring occurs, and some water network extends to the interior of the units. The morphology of polder unit boundaries then becomes diversification. A complex and diverse polder landscape morphology is formed by various constituent units. It is difficult to fully reflect the morphological features of the boundary morphology with a single landscape morphology index because the boundary morphology is complex and self-similar. As a result, an index system with comprehensive description dimensions and easy data acquisition is required to describe its morphological features.

We used an interdisciplinary perspective to summarize related index systems in typo-morphology, geoscience, computer vision, and pattern recognition. Then, selected landscape morphology indexes have been empirically effective for two-dimensional morphology measurements in related research. Extended degree, squareness, morphological concavity, and tortuosity were four angles to choose appropriate landscape morphology indexes in this article.

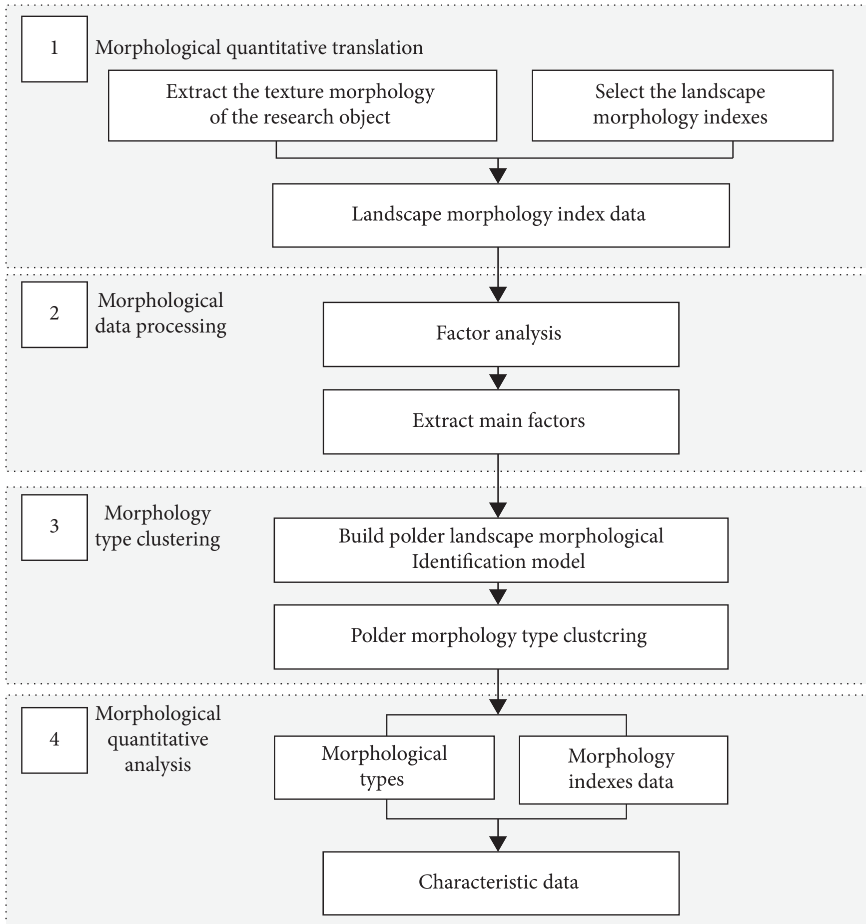

Figure 2: Technology roadmap.

Elongation (λ) is used to measure extended degree [46], rectangular compactness (S_1) is used to describe squareness [47], the concavity (V) is used to characterize morphological concaveness [48], and the ellipse compactness (S_2) and fractal dimension (D) jointly represent tortuosity [49] (Table 1). Then, we obtained the geometric attribute data to calculate the selected indexes value, such as area (A), perimeter (P), area of minimum bounding rectangle ($A_{\text{min\_ref}}$), area of the minimum convex hull ($A_{\text{min\_h}}$), long axis ($a_{\text{min\_ref}}$), and short axis ($b_{\text{min\_ref}}$). Landscape morphology indexes are linked and complementary to each other, which can jointly describe the boundary morphological features of the polder units.

3.2.1. Elongation (λ). Its geometric meaning is the ratio of the long axis to the short axis of the polder units. In the actual operation, use the ratio of the length of the long side ($a_{\text{min\_ref}}$) to the length of the short side ($b_{\text{min\_ref}}$) of the minimum bounding rectangle to reference it. We use this index to define the extended degree of the shape of the constituent units. The closer the ratio is to 1, the more likely the constituent units appear as equilateral shapes. The ratio is higher, the morphology of the constituent units is more likely to extend in a stripe shape:

$$\lambda = \frac{a_{\text{min\_ref}}}{b_{\text{min\_ref}}}, \tag{1}$$

where $a_{\text{min\_ref}}$ represents the length (m) of the long side of the minimum bounding rectangle of the constituent units and $b_{\text{min\_ref}}$ represents the length (m) of its short side.

3.2.2. Rectangular Compactness (S_1). Rectangular compactness (S_1) is the ratio of the polder morphological constituent unit area (A) to the minimum bounding rectangle area ($A_{\text{min\_ref}}$), and its numerical value ranges from 0 to 1. The closer the ratio is to 1, the more similar the constituent unit boundary to its minimum bounding rectangle. $S_1 = (A/A_{\text{min\_ref}})$, where S_1 represents the rectangular compactness, A represents the area of the polder units (m^2), and $A_{\text{min\_ref}}$ represents the area of the minimum bounding rectangle of the polder units (m^2).

3.2.3. Concavity (V). This article use concavity to define the degree of the concave shape of the polder morphological constituent units. A convex hull is the smallest convex polygon that can contain two-dimensional geometry. The concavity value ranges range from 0 to 1. The concavity is more similar to 1, and the boundary of the unit is less

Table 1: Summary table of morphology indexes and schematic diagram.

Name of morphology index	Elongation	Rectangular compactness	Concavity	Ellipse compactness	Fractal dimension
Formula of morphology indexes	$\lambda = a_{\min\_ref}/b_{\min\_ref}$	$S_1 = A/A_{\min\_ref}$	$V = ((A_{\min\_h} - A)/A_{\min\_h})$	$S_2 = (P/(1.5\lambda + 1.5 - \sqrt{\lambda}))\sqrt{\lambda/A\pi}$	$D = 2\ln(P)/\ln(A)$
Schematic diagram of morphology indexes					
concave. When $V = 0$, the shape of the polder unit is a convex polygon:

$$V = \frac{A_{\min\_h} - A}{A_{\min\_h}}, \quad (2)$$

where V represents the concavity, A represents the area of the polder units (m^2), and $A_{\min\_h}$ represents the minimum convex hull area of the polder units (m^2).

3.2.4. Ellipse Compactness (S_2). The ellipse compactness takes the ellipse with the same area (A) and the same elongation (λ) as the polder shape units as the reference figure. Calculating the ratio of the ellipse perimeter to the perimeter of the constituent units (P) can reflect the complexity of the constituent units. Due to the introduction of elongation, this index is more suitable for quantitative analysis of complex boundary patterns. The larger the value of S_2 is, the more tortuous the boundary is:

$$S_2 = \frac{P}{1.5\lambda + 1.5 - \sqrt{\lambda}}\sqrt{\frac{\lambda}{A\pi}}, \quad (3)$$

where S_2 represents the ellipse compactness, P represents the polder unit perimeter (m), A represents the polder unit area (m^2), and λ represents the elongation.

3.2.5. Fractal Dimension (D). The shape of the polder units tends to be complex and fragmented in the long-term evolution process, which shows a specific self-similar shape. Thus, we introduce the fractal geometry index to supplement the description of tortuosity. The fractal dimension (D) is the most important parameter for describing fractal geometry. Researchers often use it to study irregular shapes in natural and built environments. Since the polder morphology is a two-dimensional figure, the theoretical value of fractal dimension is 1-2. The fractal dimension is closer to 2, the shape of the polder unit is more complex.

$$D = \frac{2\ln(P)}{\ln(A)}, \quad (4)$$

where D represents fractal dimension, P represents the polder unit perimeter (m), and A represents the polder unit area (m^2).

3.3. Data Processing and Analysis Methods of Landscape Morphology. This article selects factor analysis to integrate the polder landscape morphology index value to avoid repeated information and explore the relationship between different indexes. Factor analysis is a standard multivariate dimensionality reduction statistical method in statistics. Analyzing the internal structural relationship of the original data correlation coefficient matrix converts multiple indicators with complex relationships into a few combinations of random variables, namely, the common factors, which can reproduce the mutual relationship between the original variables and the common factors [50]. The common factor value will be used as input data to identify the morphology type of polder units.

To identify the polder morphological features, selecting an appropriate machine learning model according to the research needs and data characteristics is necessary. We apply unsupervised machine learning for clustering analysis to identify the morphology types of polder units. SOM is a kind of unsupervised artificial neural network similar to the brain neural network. It consists of an input layer and a computational layer. When receiving external information input, different input samples activate various neurons. Through "autonomous learning," SOM can enable each neuron to form a specific response pattern, thus facilitating the grouping of input samples [51]. Therefore, SOM can directly use the input samples to complete the whole process from network training to sample clustering (Figure 3).

3.4. Research Object Extraction. We select the typical polders in China as the research object to explore the validity of the polder landscape morphological identification model. The research object is located in Gaochun District, Nanjing city, in the middle and lower reaches of the Yangtze River, with a total area of 3507 hectares (Figure 4). It belongs to the local typical agricultural production environment, with flat terrain and dense water network characteristics. The agricultural production there is closely related to the water network. The polder units formed under the limitation of natural river channels and artificial canals are the primary constituent units of the polder morphology in this area.

The data extraction for this research is based on the drawings surveyed in 2019. It combined the impact of Landsat 8 satellite remote sensing and field surveys for review and proofreading. We extracted the polder morphological constituent unit boundary as the basis for the study, took the water network and polder dykes as the boundary of the unit morphology, and retained the canals that extend into the polder units (Figure 5).

The study area extracted 381 polder unit samples; the sample size can meet the data requirements of SOM for

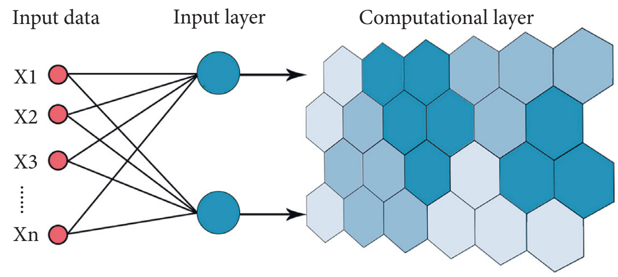

Figure 3: Structure of SOM.

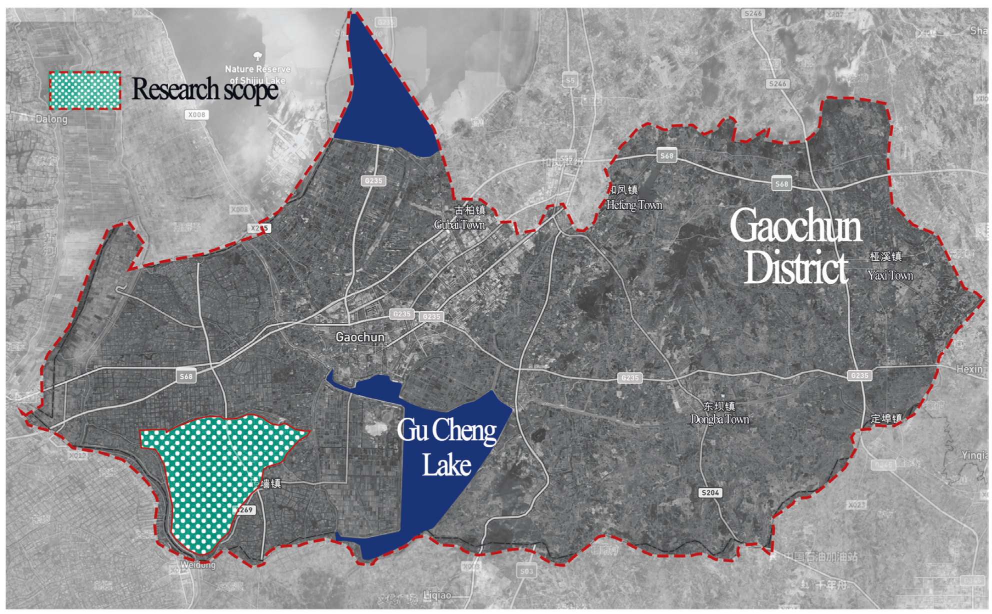

Figure 4: Location and scope of the research object.

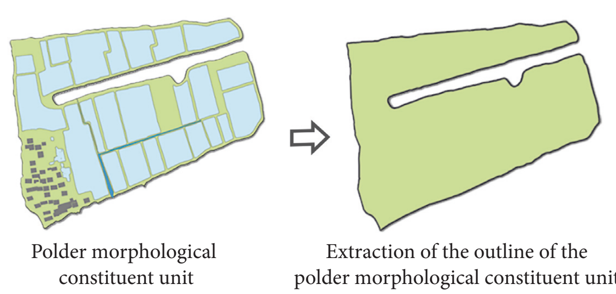

Figure 5: Schematic diagram of morphology extraction and optimization of the research object.

forming stable and reasonable classification results (≥100). Then, moderately smooth the boundary shape to avoid the measurement error. Store the data on the ArcGIS platform to generate the morphological unit's minimum bounding rectangle and convex hull. After that, extract the fundamental geometric values required for the polder landscape morphology index calculation. The final landscape morphology index statistics of each sample are shown in Table 2. The landscape morphology index statistics of each samples are shown in Table 2.

4. Quantitative Results of Polder Landscape Morphology

4.1. Data Processing Results. This article used SPSS (26.0) for factor analysis. First, standardize the morphology index data of the polder landscape and conduct moderate analysis by KMO and Bartlett's test. According to the test results, the KMO sampling adequacy is more significant than 0.5, and the significance level of the Bartlett test is less than 0.01, indicating that the tested data are suitable for factor analysis (Table 3).

Table 2: Descriptive statistics of landscape morphology indexes.

Landscape morphology index	Maximum	Minimum	Average value	Standard deviation
Elongation	11.10	1.00	2.42	1.65
Rectangular compactness	0.99	0.42	0.78	0.12
Concavity	0.67	0.00	0.10	0.12
Ellipse compactness	4.28	1.00	1.22	0.30
Fractal dimension	1.47	1.24	1.30	0.04

Note. Sample size $n = 381$.

Extract the first two factors with a characteristic root greater than 1 as the common factors, and the cumulative variance contribution rate is 80.79% (Table 4). It showed that the two common factors contain more than 80% of the original information of the landscape morphology indexes, which is enough to represent the main content of the variable information. The characteristic value of the first factor after rotation is 2.385, and the variance contribution rate is 47.706%. The characteristic value of the second factor after rotation is 1.654, and the variance contribution rate is 33.086%. These two common factors used linear combinations to replace the original landscape morphology indexes. The common factors jointly described the morphology of the polder unit for the following types of clustering (Table 5).

4.2. Clustering Analysis Based on SOM. The SOM model was driven by the two common factors to realize the polder landscape morphology-type clustering. The number of neurons in the input layer, computational layer, and total number of learning times are all important parameters to set when building a model. The input layer's number of neurons is determined by the data it receives. The requirement for morphological clustering is related to the number of neurons in the computational layer. We must determine the specific number combination, universality, and interpretability of the classification results based on the distribution characteristics of the input data. The neural network must reach a point of stability within the allotted learning time. This article used MATLAB R2019b to create a SOM model to achieve the clustering of the polder morphology types after several experiments to determine the parameters. Connect the results to the ArcGIS platform for visual display, and create a polder landscape morphological database to serve as the data and image foundation for polder morphology-type analysis. The specific clustering results are shown in Figure 6.

4.3. Morphology Clustering Results of Polder Landscape. From the SOM cluster results, the polder units' morphological features in the same clusters have consistency, and the features in different clusters have significant differences. A comprehensive analysis of the identification results of polder landscape morphology shows that the average value of the landscape morphology index of each category has a logical law, which indicates that SOM can autonomously make the clustering results of polder morphology types highly interpretable (Table 6).

Table 3: KMO and Bartlett's test.

KMO sampling adequacy		0.580
Bartlett's test	Approximate chi-square	894.835
	df	10
	Sig.	.000

(1) From an individual perspective, rectangular and polygonal units constitute the polder feature. From the landscape morphology index perspective, the morphological constituent units identified by SOM can classify into two categories: rectangular (Type A) and polygonal (Type B). The former has high squareness, low concavity, and low tortuosity, so this type of unit presents a relatively simple and square overall shape. The latter has low squareness, high concavity, and high tortuosity, so the morphological features are complex and tortuous. In the rectangular unit, due to the difference in elongation, the morphology type of the constituent units can further divide into low elongation rectangle (Type A1), medium elongation rectangle (Type A2), and high elongation rectangle (Type A3). In polygonal types, the concavity, ellipse compactness, and fractal dimension increase simultaneously as the rectangular compactness decreases. The morphology type of constituent units can divide into low complexity polygon (Type B1), medium complexity polygon (Type B2), and high complexity polygon (Type B3). In terms of the morphology of polder units, their boundary shapes tend to be complex, and the number and length of concave channels gradually increase.

(2) From an overall perspective, the distribution pattern of the polder units is closely linked to the morphological feature. Regarding the proportion and distribution of morphological units, the number of rectangular and polygonal units is basically the same: rectangular units accounted for 51.4% of the total polder morphological units, and polygonal units accounted for 48.6%. From the perspective of morphological distribution, the morphological composition of the polder shows the combination of different types of morphological units, which makes the polder in the studied area present a multicomplex morphological feature.

Table 4: Total variance explained.

Initial eigenvalues				Extraction sums of squared loading			Rotation sums of squared loading		
Component	Total	% of variance	Accumulative %	Total	% of variance	Accumulative %	Total	% of variance	Accumulative %
1	2.520	50.397	50.397	2.520	50.397	50.397	2.385	47.706	47.706
2	1.520	30.396	80.792	1.520	30.396	80.792	1.654	33.086	80.792

5. Analysis and Discussion

In this article, the identification of the polder landscape morphology based on the SOM identification model can effectively classify the types of polder landscape morphology in the research area. The results have application value for quantitative research and analysis on the morphology of the polder landscape. This technical route is suitable for in-depth development and horizontal expansion in the field of landscape morphology research.

(1) At the level of research effectiveness, the SOM identification model effectively classified the polder morphology in the studied area and obtained relatively stable six types of polder units, realizing the division of polder landscape morphology types in the individual perspective. We integrated and applied five landscape morphology indexes such as elongation and rectangular compactness, which can effectively translate the polder landscape morphology of the studied area. Thus, this technical system has

Table 6: The results of polder landscape morphology types and the average value of morphology indexes.

Type A—rectangular units	Type A1—low elongation rectangle 	$n = 119$ $\lambda = 1.68$ $S_1 = 0.87$ $V = 0.03$ $S_2 = 1.09$ $D = 1.28$	Type A2—medium elongation rectangle 	$n = 61$ $\lambda = 3.51$ $S_1 = 0.81$ $V = 0.07$ $S_2 = 1.08$ $D = 1.28$	Type A3—high elongation rectangle 	$n = 16$ $\lambda = 7.83$ $S_1 = 0.80$ $V = 0.12$ $S_2 = 1.04$ $D = 1.37$
Type B— polygonal units	Type B1—low complexity polygon 	$n = 123$ $\lambda = 1.59$ $S_1 = 0.72$ $V = 0.10$ $S_2 = 1.25$ $D = 1.28$	Type B2—medium complexity polygon 	$n = 41$ $\lambda = 2.48$ $S_1 = 0.65$ $V = 0.21$ $S_2 = 1.49$ $D = 1.33$	Type B3—high complexity polygon 	$n = 21$ $\lambda = 2.20$ $S_1 = 0.51$ $V = 0.47$ $S_2 = 1.95$ $D = 1.35$

specific reference significance and application value for the quantitative analysis of complex and wide-area landscape morphology such as polder.

(2) At the application level, we quantitatively translated and clustered the polder unites to achieve advanced research on polder landscape morphology. From an individual perspective, the technical system can quantitatively study the geometric properties of various polder units and the threshold of the morphology index. From an overall perspective, the technical system can present the units' composition features of the polder landscape morphology. Combined with morphology index value in different periods, it can play a role in tracking the morphological evolution of polders.

(3) At the level of research expansion, the technical route can further expand research and perfect. The landscape morphology indexes used in this article mainly focus on the two-dimensional plane. Follow-up research can further be developed by selecting landscape morphology indexes from other perspectives such as facade and space. It can also expand and enrich the research samples to improve the cognition of the polder landscape morphology type at different research levels and scales.

6. Conclusions and Prospects

This article took the quantitative analysis method of polder landscape morphology as the critical issue, constructed an index system to describe its morphological features, and formed an identification model based on SOM to classify its types. Taking the typical polders in the South of Yangtze River as the research object, we explored and verified machine learning classification, visualization, and quantitative analysis methods of the morphological features of the polder landscape. This article realized the research and development of automatic identification and quantitative judgment of polder landscape morphology, providing an analysis method and analysis technology that can be referred to and developed for landscape architecture morphology research.

Combining quantitative indexes and machine learning models is one of the quantitative research methods of landscape architecture. For landscape morphology research, the quantitative research process can not only enrich the theory and technical system, but also provide a data basis for analysis, comparison, summary, and traceability. Computer technology has brought a series of cutting-edge analysis methods such as machine learning to the development of landscape architecture. While promoting in-depth scientific research, the technology promotes the iterative development of professional theories, methods, and technologies. Thus, it is an inevitable choice for landscape architecture's informatization and intellectual development.

Academic Editor: Xin Ning

At present, China is facing problems such as the decline of fertility rate, gender imbalance, serious aging, and the reduction of youth and working population, which will have an adverse impact on the long-term development of social economy. Based on the literature review, combined with China's financial family data, combined with the innovative calculation model of the correlation between rural family fertility willingness and labor original equipment manufacturing (OEM) industrial development, through the empirical analysis of rural families, this paper investigates the relationship between fertility willingness and the development and endogeneity of labor OEM industry and finds that female labor participation has a significant negative impact on the number of children in rural families. Spouse labor participation has a negative effect on the number of children in rural families. The regression coefficient of women's willingness to have two children for career development is significant and negative ($c_1 = -0.181, P = -0.003 < 0.01$), and that of women's family status is significant and negative ($c_1 = -0.998, P = 0.031 < 0.01$). The relative opportunity cost of birth of individual operators is more concentrated in the range of 50%–80%. The results show that the development of labor OEM industry is significantly influenced by the fertility willingness of rural families. This paper concludes that differentiated policies and measures should be taken according to the type of industrial promotion.

1. Introduction

The introduction of the comprehensive three-child policy has greatly reformed the family planning policy that has been implemented for more than 30 years, which has attracted the attention of academia and the public. Some scholars worry that if the policy is liberalized, the pressure of fertility rate will still be great, and there will be another "population explosion." Some scholars have high hopes for the two-child policy, which will significantly increase the fertility rate. The aging population will aggravate the decline of labor supply [1]. The working-age population is gradually decreasing, and the population distribution is gradually disappearing, as a result of the aging society. In this case, increasing the labor force participation rate of the working-age population, including women, is a key strategy for reversing the demographic dividend decline [2]. Population aging and disparities are becoming global concerns. Population decline and rapid aging result from a fertility rate below the replacement level. According to the World Bank database, the proportion of people under the age of 14 in the total population fell to 25.94 percent in 2017, while the proportion of people aged 65 and up rose to 8.70 percent [3, 4], indicating that the world is becoming an aging society. In this case, increasing the participation rate of the age-appropriate population, including women, in economic activities is an important way to offset the current decline in the demographic dividend, while increasing the fertility rate is an important way to offset future economic growth declines.

As the main body of reproductive behavior, women bear the dual roles of work and family, which is not only an important part of the labor market, but also an indispensable human resource for China's economic development and is responsible for the future labor supply and human resources. Fatima and others believe that the fertility rate depends on the balance between the income effect and the substitution effect of reproductive demand [5]. Devaro and others found that young women can delay or give up childbearing by learning the skills of reducing unemployment risk and increasing income [6]. Long believes that demographic dividend promotes economic growth by stimulating investment expansion, because it reduces the burden of dependence on the productive population and can spend more time and energy on productive activities, thus increasing investment and promoting the expansion of economic reproduction [7]. The research results of Mao et al. show that there is no direct relationship between female labor participation and fertility rate, and it is found that female labor participation has a positive impact on fertility rate [8]. The existing literature pays more attention to the relationship between female labor force participation and fertility rate in developed countries, but less attention to developing countries, especially China. China's fertility rate has been lower than the population replacement rate for many years, so there is concern about this phenomenon. Labor force participation rate and number of births: we do not pay attention to the comprehensive influence of women's labor participation on childbearing age and number of births.

Child support, fertility willingness, support, and other factors all play a role in the decision-making process for family fertility in rural areas. This paper adds to the explanation for the discrepancy between them, which is primarily due to women's reproductive choices in the labor market. The goal of this paper is to use the model in conjunction with data on female employment and fertility in China to better understand the impact of rural families' desire for children on the development of China's original equipment manufacturing industry, as well as to theoretically support the practical importance of family economic theory. Exploring how to eliminate the negative impact of women's employment on fertility through policy measures is useful for providing a theoretical foundation and decision-making reference for the government's employment policy direction and focus in the context of the current human dividend's disappearance.

Possible innovations of this paper are as follows:

(1) A possible innovation of this paper is to link the influence of rural families' fertility willingness on the development of China's labor OEM industry with the demographic dividend, which is the growth source of the demographic dividend itself.

(2) According to the research object, this paper adopts a variety of research methods, using probit and logit analysis methods as explanatory variables of children's binary variables, and the number of children is an ordinal variable analyzed by OLS. For different research objects, adopt more scientific analysis methods.

2. Related Work

2.1. Study on the Relationship between Fertility Willingness and Fertility Behavior. Fertility desire is people's desire and pursuit for fertility, and it is also the individual's desire and requirement for fertility, which is reflected in the expectation of the quantity, time, gender, and quality of fertility. Because there is a strong correlation between fertility behavior and fertility willingness, the three-dimensional thinking of fertility behavior is applied, in which fertility willingness, number of children, and gender of willing children are the main components.

In a high fertility environment, unexpected births often occur, and the actual number of children born is larger than the expected number. They think that the level of fertility willingness is much higher than the actual fertility rate. Yakita believes that the deviation degree of fertility will and behavior is influenced by the life cycle of women [9]. Tian et al. found that the implementation of the "two-child policy" gradually converged the willingness and fertility, and the proportion of "willingness is the same as action" and "willingness is less than action" gradually increased [10]. Erten and Metzger believe that men at the middle level of gender role equality are in the transitional stage from the traditional concept of gender role to the modern concept of gender role, facing a higher level of family and workplace conflicts [11]. This also means that both the concept of gender role equality and the traditional concept of gender role are helpful in increasing the fertility rate. Codazzi and others found that increasing women's labor force participation and educational opportunities would reduce women's willingness to have children, and at the same time strengthen women's position in rural families and give them more choices [12]. Shen et al. believe that unwanted fertility rate, gender preference, children's substitution effect and female age have significant influence on fertility rate [13]. Fin and others believe that the fertility rate will affect the employment of rural women, and the number of children will affect the working hours and income of rural women [14]. Rong and others believe that a family-friendly policy that only considers women's fair social status from the family perspective will have a negative impact on women's social status and further reduce the fertility rate [15].

2.2. Research on Labor OEM Industry. OEM industry, as its name implies, is an agent processing industry, also known as outsourcing industry, which is composed of many companies engaged in OEM industry. Its main business is to share the processing and assembly defects in other enterprises' industrial chains, and the main types are processing with incoming materials, processing with imported materials and processing with incoming samples. Labor cost is the main component of production cost. If the level of labor cost or labor wage rises, the production cost of enterprises will also rise. Industrial transfer is a process in which the market continuously allocates resources. Maximizing the allocation of resources through industrial transfer can promote the industrial structure of a country or region, improve efficiency, and ultimately promote economic development.

Harrison and others studied many companies and multinational corporations on the basis of empirical analysis and thought that, in the highly industrialized open economy, labor-intensive industries were easier to transfer than before [16]. Through historical and theoretical analysis, it can be seen that the industrial overlap formed by international industrial trade and international industrial investment is the basic condition of international industrial transfer, and international industrial transfer requires that the technical composition of goods produced be similar and different. In terms of the composition of values, Han et al. established a two-step game analysis framework and concluded that if the game was repeated twice, the refined Nash equilibrium result of the subgame of urban cooperation between the former industries could be obtained [17]. Yan and others suggested that local government transfer should not only consider regional economic interests, but also update ideas and build industrial parks on the basis of cooperation to achieve win-win results [18]. Huang pointed out that enterprises may "escape" from the investment competition among local governments and emphatically analyzed the dynamic game process between local governments and enterprises and between local governments in the investment competition [19].

3. Methodology

3.1. Model Design. Analyzing the factors affecting fertility will help systematically understand the three child policy support needs of people of childbearing age. Through the analysis of the "three-child" policy and the wishes of children of childbearing age groups, it can be seen that the "three-child" policy is an important measure to solve the problems of China's population structure and population aging. The three-child policy is facing the dilemma of low fertility willingness, which is not conducive to the healthy development of China's society and economy [20].

I can divide the influencing factors into the following:

(1) The main economic factors are high economic pressure and high cost of raising three children.

(2) Social factors, including raising children to prevent old age, giving birth to elders, happy and complete family, unattended children, affecting the development of work and career, etc.

(3) Cultural factors, such as the hope of both children and children to satisfy parent-child feelings.

Due to the needs of China's actual national conditions, the family planning policy is China's basic national policy, and the influence of policy factors on fertility willingness of fertility families is also worth investigating. Therefore, this study divides the influencing factors of childbearing families into four dimensions: policy factors, economic factors, social factorsm and cultural factors. The theoretical framework of this paper is shown in Figure 1.

In order to observe the influence of rural families' fertility desire on the development of China's labor OEM industry, it is assumed that women decide both the employment situation and the childbearing time and that she has not changed her employment situation after giving birth to her first child, and she decides whether to work at the same time as giving birth to her child. Assume that the number of children and women employed in a given period is the result of this decision-making process.

The independent variable is the number of children in rural families, represented by Y_{th}, t is the time variable, and h is the family variable. The expectation of Y_{th} based on the exogenous feature z_{th} is represented by $E[Y_{\mathrm{th}}|Z_{\mathrm{th}}, \theta]$ and θ. According to the above model and iterative expectation law, the conditional expectation of Y_{th} can be obtained as follows:

$$E[Y_{th}|Z_{th}, \theta] = E_{I_{(Y_{th}>0)}, W_{th}}\left[E\left[Y_{th}|I_{(Y_{th}>0)}, W_{th}, Z_{th}; \theta\right] Z_{th}; \theta\right], \tag{1}$$

W_{th} represents the situation of women's employment ($W_{th} = 1$ means women's employment, 0 means other). $I_{(Y_{th}>0)}$ is the index function of children's existence.

Basically, the fact that the unobservable factors that determine women's employment status have nothing to do with whether they have children or not is not included in this model. Different from the case of univariate (probability and logarithm), the comparison between bivariate linear and multinomial logarithmic models is complicated, and there is no direct connection between the parameter estimates obtained from the two models. When children enter rural families, their conditional expectations are

$$E\left(Y_{\mathrm{th}}|W_{\mathrm{th}} = 1, I_{(Y_{\mathrm{th}}>0)} = 1; Z_{\mathrm{th}}, \beta_1\right) = 1 - \exp\left(Z_{\mathrm{th}}\beta_1\right). \tag{2}$$

For the existence of the second child, this setting always has an expected value greater than 1, which is limited by the existence of the child.

First, we examine the variables related to the number of children in rural families. The variable described in this paper is the fertility rate, which is a binary dummy variable with a value of 1 when a child is born. The model of logit, probit regression, is

$$\begin{aligned} Y_{th} = {} & \alpha_0 + \alpha_1 \mathrm{jobstatus}_h + \alpha_2 \mathrm{fjobstatus}_h + \alpha_3 \mathrm{fincome}_h \\ & + \alpha_4 \mathrm{wage}_h + \alpha_5 \mathrm{family}_h + \mu_h. \end{aligned} \tag{3}$$

The variables in the model are explained in Table 1:

There is a causal relationship between rural family fertility willingness and the development of Chinese labor OEM industry. The choice of female reproductive behavior mainly includes the choice of reproductive age and the choice of the number of children, which is also a process of mutual decision and influence. Based on this, this paper constructs the following simultaneous equations to evaluate the influence of women's labor participation behavior on the childbearing age and the number of children.

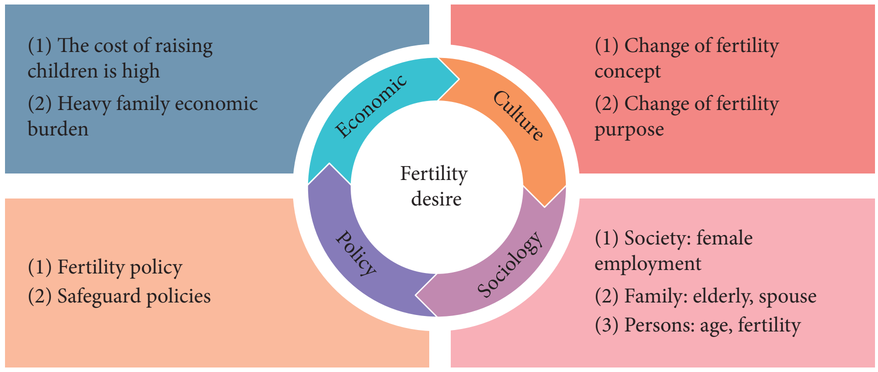

FIGURE 1: An analysis framework of influencing factors of childbearing family's fertility willingness.

$$\begin{aligned}\text{Number}_{\text{it}} &= \alpha_0 + \alpha_1 \text{Labor}_{\text{it}} + \alpha_2 \text{Age}_{\text{it}} + \alpha_3 X_{\text{it}} + \alpha_4 U_{\text{it}} + \alpha_5 P_{\text{it}} + \mu_{\text{it}},\\ \text{Age}_{\text{it}} &= \beta_0 + \beta_1 \text{Labor}_{\text{it}} + \beta_2 \text{Number}_{\text{it}} + \beta_3 Y_{\text{it}} + \beta_4 U_{\text{it}} + \mu_{\text{it}}.\end{aligned} \tag{4}$$

Among them:

$\text{Number}_{\text{it}}$, Age_{it}—Representing the number and age of women's childbearing respectively is the main index of reproductive behavior choice.

Labor_{it}—Variables reflecting women's labor participation, in this study, we will mainly consider whether women participate in labor and the nature of labor as variable indicators.

X_{it}—Personal characteristics affecting the number of births.

Y_{it}—Personal characteristics that affect the reproductive age.

U_{it}—Other controlled variables, mainly including the characteristics of family and community.

P_{it}—Virtual variable of family planning policy.

It can provide nonagricultural employment opportunities for surrounding women as a leader in economic development, and because of its proximity, it can also promote rural women's participation in nonagricultural work, which is beneficial to local rural women's participation in nonagricultural work. It is a problem that women should not consider when making reproductive decisions, just as it is a problem that women should not consider when making transportation facilities such as bus stops, development zones, and special economic zones. It only has to do with labor participation in decision-making and has nothing to do with reproductive choices.

We constructed a dynamic two-person and three-level game with complete information [21]. The competing government A and the company are located in the middle, and the company has three optional operations: requirement and default, A. The government adopts two selective measures to increase the preferential margin and maintain the status quo.

If the enterprise fails to ask government A to provide more preferential treatment, otherwise, it will move to Zhengzhou. Government A learns that government B has also implemented preferential policies for attracting investment. At this time, the economic aggregate of the enterprise is $(R + E_3)$, the economic aggregate of government A changes to $(G_1 - E_3)$, and the economic aggregate of government A does not change to G_2, with zero change.

In the third stage, the enterprise's strategies are migration, default, and requirements. At the time of migration, the economic aggregate of enterprises is $(R + E_2 - C)$, the economic aggregate of government A is $(G_1 - R)$, and that of government B is $(G_2 + R - E_2)$.

If the enterprise chooses the default at this time, the economic aggregate of the enterprise is $(R + E_1)$, the economic aggregate of government A is $(G_1 - E_1)$ at this time, and the economic aggregate of government B remains unchanged. This cycle continues until a certain local government withdraws from the game process. The whole game process is shown in Figure 2:

A^0 is defined as the game in which government A starts bidding. Because the whole game process is repeated indefinitely, A^0 does not affect the game analysis process at any stage. In this game, enterprises can freely choose whether to suspend negotiations with government A and turn to other regional governments.

Let π^0 be the upper bound of the payment that enterprises can get in this game equilibrium. We use A to represent the game that the enterprise has stopped the negotiation and turned to government B to renegotiate, and also let π represent the upper bound of the payment that the enterprise can get in equilibrium. We can clearly show the process of the stage game we intercepted with Figure 3 below.

In this model, we also need the following two constraints:

After bidding, the enterprise must wait for the counteroffer of government A, which is in the position of "insider," before deciding whether to suspend negotiations with it and start negotiations again with new "insider." The negotiation between an enterprise and a certain government must last at least T time periods.

Table 1: The variables in the model.

Variable	Explaining variables
Y_{th}	The number of children in rural families, h is the family variable
jobstatus	Female labor participation
fjobstatus_h	Employment of fathers in rural families
fincome_h	Per capita household income of the sample
wage_h	Binary explanatory variable
family_h	Other influencing factors in rural families that affect fertility rate
μ_h	The number of children in rural families is an orderly variable.

In game A^0, enterprises choose their own payment maximization, so there are

$$\pi^0 = \max\left(\sigma_1\left(1 - \sigma_2 + \sigma_2\pi^0, \pi\right)\right). \tag{5}$$

Because π is the supremum of the solution in game A equilibrium, so

$$\pi = \frac{\left(1 - \sigma_2\right)\left[1 - \left(\sigma_1\sigma_2\right)^{T+1/2}\right]}{1 - \sigma_1\sigma_2} + \sigma_1^{T-1/2}\sigma_2^{T+1/2}\pi^0. \tag{6}$$

According to (5), if $\pi^0 = \sigma_1\left(1 - \sigma_2 + \sigma_2\pi^0\right)$, there is

$$\pi^0 = \frac{\sigma_1\left(1 - \sigma_2\right)}{1 - \sigma_1\sigma_2}. \tag{7}$$

Substituting (7) into (6) results in

$$\pi = \frac{1 - \sigma_2}{1 - \sigma_1\sigma_2}. \tag{8}$$

If $\pi^0 = \pi$ is substituted into formula (6), the maximum payment of the enterprise is

$$\pi = \frac{\left(1 - \sigma_2\right)\left[1 - \left(\sigma_1\sigma_2\right)^{T+1/2}\right]}{\left[1 - \sigma_1\sigma_2\right]\left[1 - \sigma_2\left(\sigma_1\sigma_2\right)^{T-1/2}\right]}. \tag{9}$$

At this time, the payment of government A is $1 - \pi$.

Through the analysis in the last part, we compare the labor cost, land cost, and tax preference of the two places to illustrate the main differences of the expected profits of enterprises in the two places.

Random forest (RF) algorithm is an ensemble learning algorithm based on decision tree. Decision tree is a single learning method, called "Basic Learner," which combines multiple decision trees into a "Forest." By forming a strong learner in the integrated learning method, the predictive ability of the algorithm can be effectively improved. Create RF model:

$$y_n = f^*(\cdot) = \sum_{b=1}^{B} f^b \frac{\left(n, x, x_i, t_i, T, \lambda\right)}{B}. \tag{10}$$

Among them, x_i, t_i are the characteristic variable and the corresponding splitting critical value of each decision tree when splitting at the i-layer in RF algorithm according to the principle of "minimizing the sum of squares of residuals."

λ—The punishment intensity of complexity T obtained by cross-validation method;

n—Core characteristic variables;

x—Other characteristic variables;

B—Number of decision trees contained in RF.

After obtaining the results of parameters such as x_i, t_i, T, λ through algorithm training and verification, the relative opportunity cost of childbearing can be combined with the level of living burden to measure the degree that the opportunity cost of childbearing can be borne.

3.2. Data Source and Variable Description. The data used in this paper is the panel data of CFPS 2015–2021. In this study, the variables used in the equivalence scale method include income satisfaction, total family income, family size, and number of children. This paper chooses income satisfaction as the explanatory variable. We need to filter data and delete missing items and outliers of families with children under 20 years old. Because the answer of income satisfaction is set to 1 to 5, 1 means "unsatisfied," and 5 means "very satisfied," and the variable is discrete.

Compared with cross-sectional data, panel data has certain advantages: first, it can use the difference between groups to multiply the time trend, so as to eliminate the possible deviation caused by small samples; secondly, the endogenous problem can be overcome by using lag data. Table 2 reports the descriptive statistics of the main variables.

Among the basic elements of social support, this paper takes into account the respondents' maternity insurance status, peer reproductive pressure, and local infant community service facilities. Table 3 shows descriptive statistics of independent variables of basic state characteristics of social support.

From Table 1, we can see that most people still choose to enjoy maternity insurance, which may be because many people in this survey are in economically developed areas, and maternity protection in these provinces and cities is in place. According to Table 2, it is found that many respondents have fertility pressure. When processing the data, the author assigns the answers of "absolute influence," "greater influence," and "general" as 1. Infant service facilities have a great influence on fertility willingness, otherwise, 2. Infant service facilities have little influence on fertility willingness.

4. Experiment and Results

Increasing the female labor force participation rate can revitalize the current economy, but it will significantly reduce the female fertility rate, further affect the national

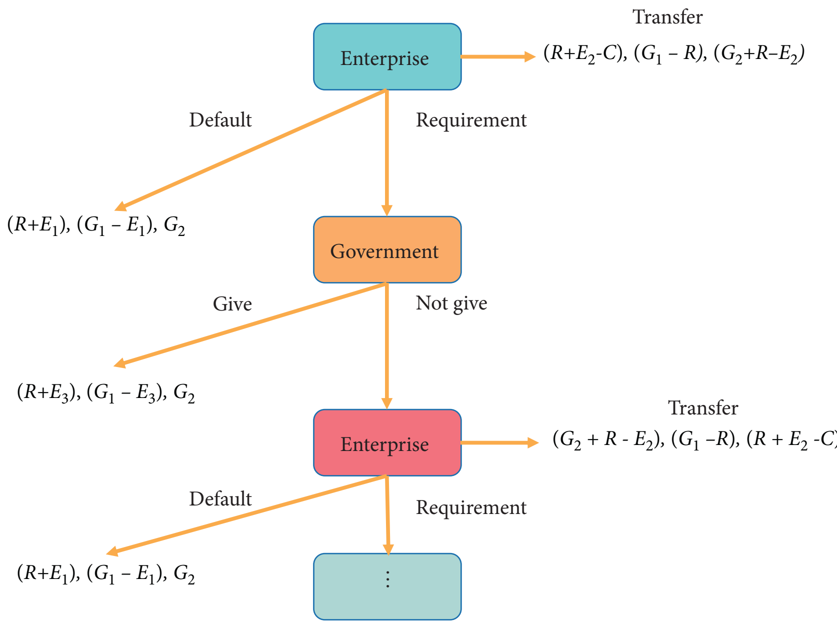

Figure 2: The second stage game process.

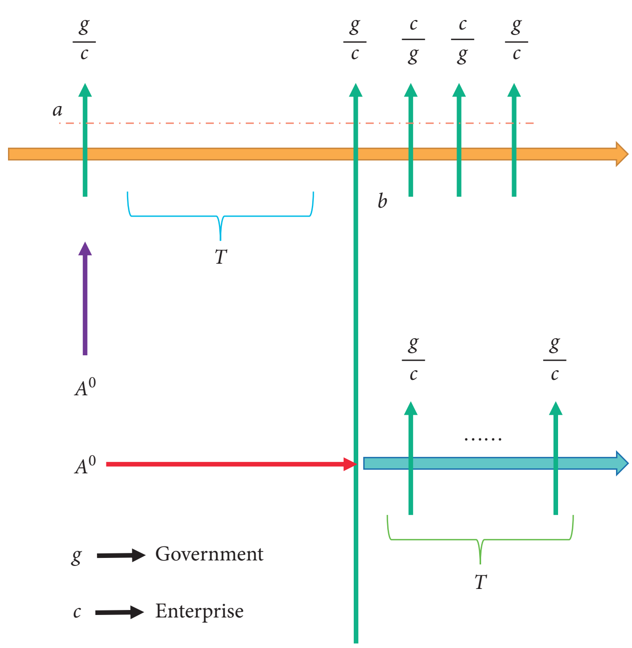

Figure 3: The process of intercepting stage game.

fertility rate, and affect the future labor supply and economic development. Therefore, it is the goal of all countries to maintain a high female labor force participation rate without affecting the fertility rate. Asian countries, especially some East Asian countries and Southeast Asian countries, should constantly improve policies to encourage women to bear children, such as parental leave and flexible working system.

The regression results in Figure 4 show that women's career development has a significant negative impact on the fertility willingness of the two children, and the rise of women's family status plays a part of the intermediary role.

The regression coefficient between women's career development and their willingness to have two children is significant and negative ($c_1 = -0.181, P = -0.003 < 0.01$), indicating that the better the career development, the lower the probability that women intend to have two children. The regression coefficient between women's family status and the willingness to have two children is significant and negative ($c_1 = -0.998, P = 0.031 < 0.01$), indicating that the higher the family status, the lower the probability that women intend to have two children. This means that the impact of a woman's professional advancement on her desire to have two children is at least

Table 2: Descriptive statistics of main variables.

Variable	Mean value	Standard deviation	Observation and measurement
Total fertility rate *T*	3.15	1.32	1136
Female labor participation rate *F*	44.1	20.01	1427
Proportion of urban population to total population *C*	50.31	25.68	1427

Peer fertility pressure *W*	1 = yes 2 = No	1	2	1.06	0.364
Influence of infant service facility on fertility willingness *E*	1 = greater impact 2 = minor impact	1	2	1.27	0.428

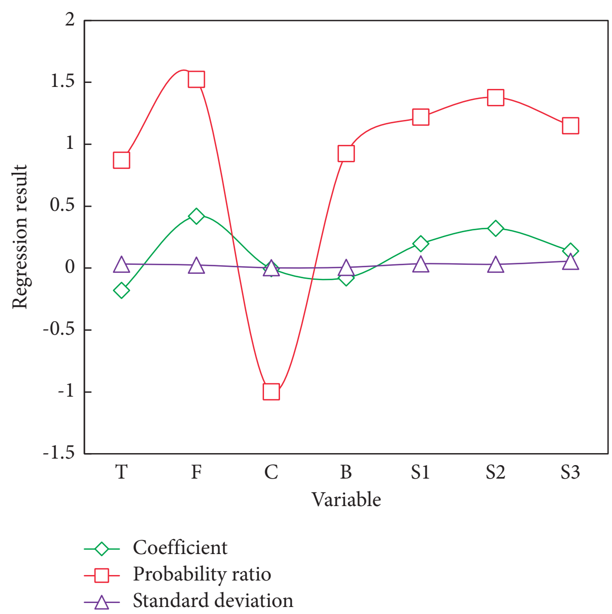

Figure 4: The influence of women's career development and family status on the fertility willingness of two children.

partially realized through the parameters of her family status. The improvement of women's family status is one of the negative effects of their career advancement on their willingness to have a second child. We made a comparison by age in Figure 5 to explain in detail the fertility wishes, current fertility behaviors, and future fertility plans of these women.

The following points can be observed from Figure 5:

(1) There are differences in women's fertility wishes of all ages, but the differences are not too great, fluctuating around 1.5.

(2) Compared with women in other age groups, the 20–24 age group has the lowest willing fertility rate.

(3) The gap between the maximum and minimum target fertility rate of women gradually narrows with the increase of age, which indicates that the younger the women, the greater the variability of family planning.

(4) With the increase of age and the distance between women's fertility ideal and future fertility plan, the possibility of realizing fertility ideal also increases. Women of different ages were born in different ages, and their fertility wishes, current fertility behaviors, and future fertility plans all reflect the differences among women of different ages.

From the calculation results of social support status factor model, it can be seen that the social support factors selected in this study have no significant influence on the

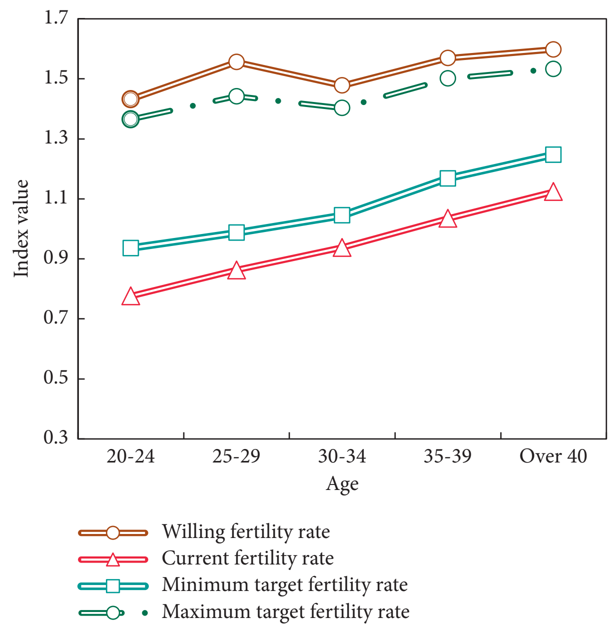

Figure 5: Women's will, current and target age-specific fertility rate in line with the two-child policy.

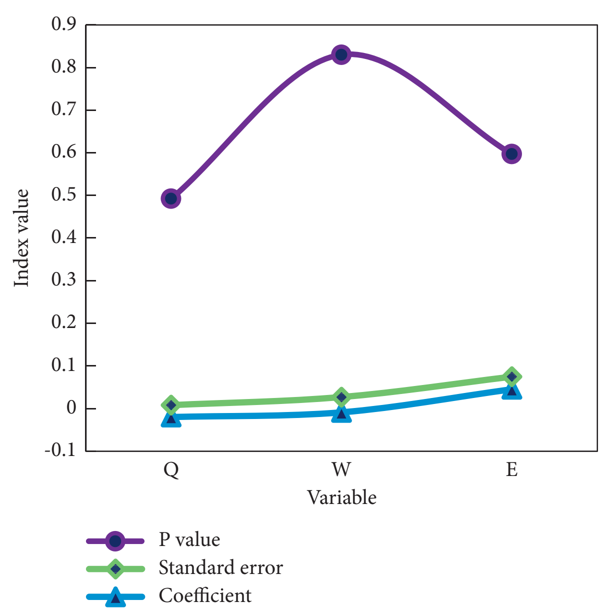

Figure 6: Social support condition factor model.

fertility desire of childbearing age families. The coefficient of maternity insurance coefficient is negative, and respondents without maternity insurance are more likely to have children, which may be because people without maternity insurance are often distributed in rural areas.

Age can have relatively traditional thinking. In addition, the above results can be obtained because the coverage rate and wages of maternity insurance are generally low, which can not be used as the guarantee of fertility (Figure 6).

Peer pressure factors have no significant influence on the willingness of families to bear children, and the absolute value of the coefficient is very small, which is 0.009, which may be the reason for sample selection. In addition, as shown above, it is found that the factors of infant service facilities in local communities have no significant influence on the family's fertility desire, which may be due to the imperfect infant service facilities in China. Many families of childbearing age with better economic conditions look for private kindergartens and other childcare facilities at their own expense, while families with poorer economic conditions often choose families. Therefore, for families of childbearing age, the factors of infant service facilities in local communities are very important, and the fertility will has no significant influence.

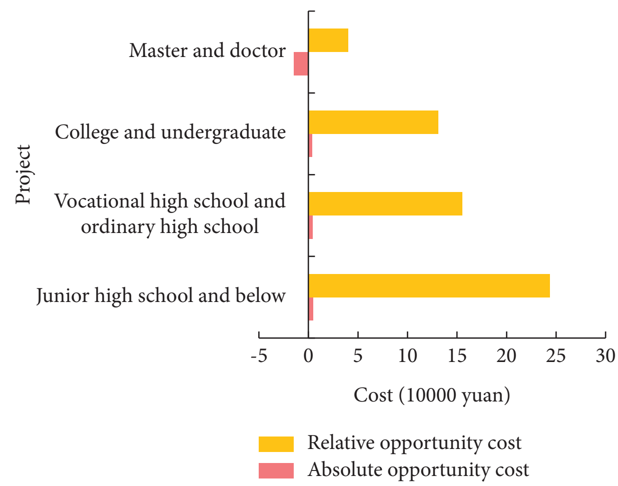

FIGURE 7: Differences in reproductive opportunity cost of women with different educational levels.

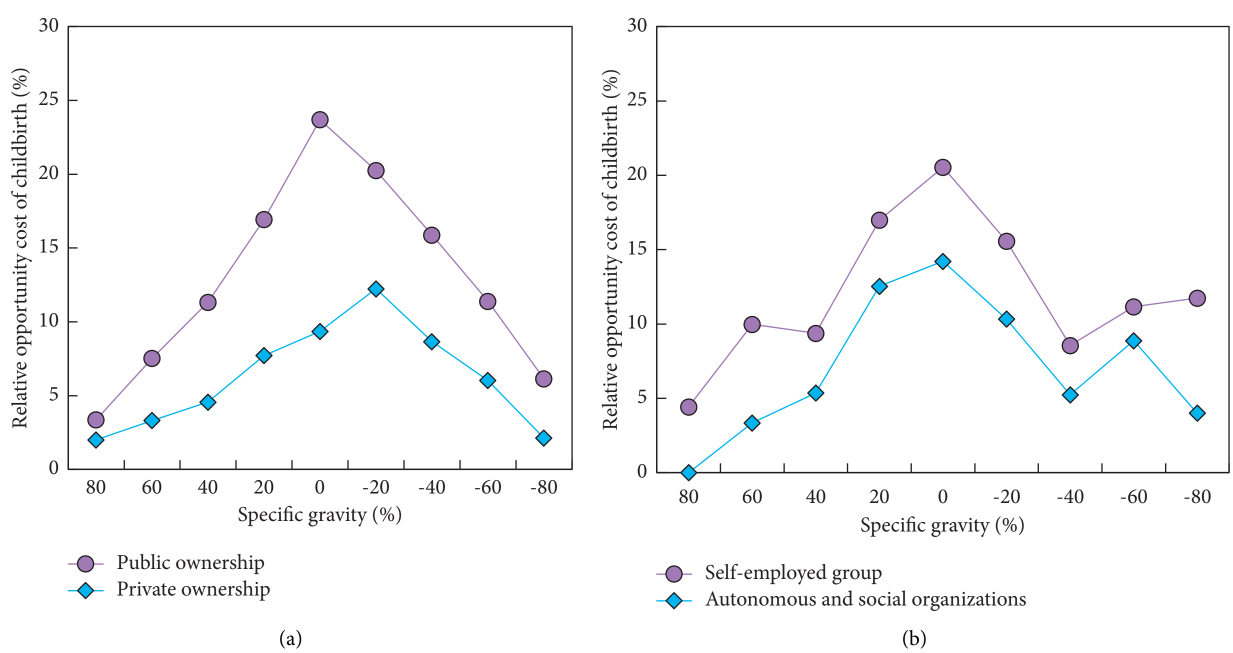

FIGURE 8: Comparison of reproductive opportunity cost of women in different employment units.

The difference of reproductive opportunity cost of women in different education levels and employment units also confirms the role of maternity insurance. As shown in Figure 7, on average, women with lower education level have higher absolute and relative opportunity cost of childbirth.

Women with master's and doctor's degrees have the lowest absolute and relative opportunity cost of childbirth, and this group of women is more likely to engage in high-paying jobs with high working threshold and high maternity insurance coverage. Because of the high opportunity cost of fertility rate, social security is not perfect.

Figure 8 shows the reproduction opportunity cost of employers according to the nature of legal entities. Figures 8(a) and 8(b) show that the relative opportunity cost of female fertility rate in public units is more obviously concentrated in the range of 0–10%, while that in private units is concentrated in the range of 10%–20%. The relative opportunity cost of female fertility rate of local governments and social organizations is concentrated in the range of 0~10%, which is distributed symmetrically around 0. However, the relative opportunity cost of female fertility rate of self-employed households is concentrated in the range of 50%~80%. Compared with other types of units, self-employed households cannot protect their own rights and interests because they do not buy maternity insurance.

According to the regression results, female labor participation has a significant negative impact on the fertility level of one and two children. In the regression process, the regression results obtained by probit and logit are consistent. In order to ensure the reliability of regression results, this paper uses OLS to test the robustness of probit regression results. The obtained test results are shown in Table 4, and

Table 4: Influence of labor supply on fertility level.

Variable	A family with one child	Families with a second child
T	−0.06***	−0.097***
F	0.121	0.041***
C	−0.002***	−0.066
B	−0.006	−0.001*
S1	0.017	−0.017
S2	−0.009	0.068
S3	−0.047	−0.087***
Q	−0.367***	−0.201
W	0.001*	−0.002***
E	−0.038	−0.047

Note: *, ** and *** are significant at the level of 10%, 5% and 1% respectively.

Table 5: Influence of labor supply on fertility level.

Variable	A family with one child	Families with a second child
Number of elderly people in rural families	2.318***	2.217***
Labor supply	−0.036	−0.863***
Average personal household income	−0.128	−0.221
Is there any wage income	−0.001	−0.003*
Total cash and deposits	−0.068**	−0.012***
Account status	−0.042	−0.076
Age	−0.033***	−0.038**
Gender	0.168	−0.156

the obtained results are remarkably consistent, and the regression results are stable.

Combined with the research direction of this paper and the availability of selected data, this paper chooses the number of elderly people in rural families as the tool variable of female labor supply model. The results are shown in Table 5.

The endogenous relationship between women's labor participation rate and fertility rate is solved using the instrumental variable method, and the rural elderly population is used as an instrumental variable in regression estimation. Female labor participation has a significant negative impact on one or two child fertility rates. The negative impact of women's labor on the two children is particularly significant in the empirical findings. An important reference is how to improve the three-child fertility rate in the context of China's three-child policy liberalization.

5. Conclusions

The research of this paper mainly focuses on the measurement of the correlation degree between rural families' fertility willingness and the development of China's labor OEM industry and investigates the main influencing factors of different children in rural families. The main findings are as follows:

(1) The regression analysis results considering the influence of female labor participation on fertility rate show that female labor participation has a significant negative effect on the number of children in rural families, and female labor participation will lead to the decrease of the number of children in rural families.

(2) The regression coefficient between women's career development and their willingness to have two children is significant and negative ($c_1 = -0.181, P = -0.003 < 0.01$), indicating that the better the career development, the lower the probability that women intend to have two children. The regression coefficient between women's family status and the willingness to have two children is significant and negative ($c_1 = -0.998, P = 0.031 < 0.01$), indicating that the higher the family status, the lower the probability that women intend to have two children.

(3) The relative opportunity cost of unit female fertility rate is more obviously concentrated in the range of 0–10%, while that of private ownership is concentrated in the range of 10%–20%. The relative opportunity cost of female fertility rate in local governments and social organizations is concentrated in the range of 0~10%, and distributed symmetrically around 0, but the relative opportunity cost of self-employed fertility rate is in the range of 50%–80%.

Diseases and pests are essential threat factors that affect agricultural production, food security supply, and ecological plant diversity. However, the accurate recognition of various diseases and pests is still challenging for existing advanced information and intelligence technologies. Disease and pest recognition is typically a fine-grained visual classification problem, which is easy to confuse the traditional coarse-grained methods due to the external similarity between different categories and the significant differences among each subsample of the same category. Toward this end, this paper proposes an effective graph-related high-order network with feature aggregation enhancement (GHA-Net) to handle the fine-grained image recognition of plant pests and diseases. In our approach, an improved CSP-stage backbone network is first formed to offer massive channel-shuffled features in multiple granularities. Secondly, relying on the multilevel attention mechanism, the feature aggregation enhancement module is designed to exploit distinguishable fine-grained features representing different discriminating parts. Meanwhile, the graphic convolution module is constructed to analyse the graph-correlated representation of part-specific interrelationships by regularizing semantic features into the high-order tensor space. With the collaborative learning of three modules, our approach can grasp the robust contextual details of diseases and pests for better fine-grained identification. Extensive experiments on several public fine-grained disease and pest datasets demonstrate that the proposed GHA-Net achieves better performances in accuracy and efficiency surpassing several other existing models and is more suitable for fine-grained identification applications in complex scenes.

1. Introduction

Agriculture is an industry that integrates technology, economy, politics, and national security, supporting the entire history of human evolution, and is increasingly multifunctional with social development and progress. Agriculture is an essential source of basic living materials for human society, which provides the primary products and material basic conditions for developing the global economy and feeding humanity [1, 2]. Plant pests and diseases affect the overall functioning of the plant, and it can lead to slowed growth, reduced fruit yield, leaf drop, and many other diseases. The sources of plant diseases are multifaceted. Sometimes, the diseases are spread from one crop to another caused by some fungus or other bacteria. Moreover, some viruses hidden in the seeds are transferred from one place to another place, resulting in outbreaks of diseases [3]. Due to the complex generation and transmission mechanism, pests and diseases have become one of the most challenging questions faced by global agricultural production. According to statistics, the annual loss of plant yields due to diseases and pests accounts for more than 50% [4]. Therefore, the accurate identification of disease and pest species is of great significance to controlling plant diseases and pests as well as improving crop yield.

Identifying diseases and pest maintenance in traditional agricultural production relies on some agronomy experts with professional knowledge and experience through their naked eyes [5, 6]. This approach is usually a time-consuming, uneconomical, and repeated job when invasive species appear or the production farmlands are changed, which affects the subsequent production operations. In recent years, modern agriculture is striving to make full use of innovative systems and methods to achieve intelligent production and management, including Internet of Things (IoT), automated robots, big data cloud computing, and artificial intelligence modelling [7–11]. With the development of information and intelligent technologies, the automatic and accurate identification methods handling various diseases and pests have become one of the important issues in the modern agricultural production process, which attracts many agricultural experts and enterprises to carry out related research [2, 12–14]. An efficient and reasonable solution is using some machine learning-based methods to identify the species of plant pests and diseases [15–17]. On basis of enough image data collected by visible sensors or devices, those methods firstly apply some classical statical learning or machine learning methods to identify the varieties of plant pest and diseases. Those classical methods mainly rely heavily on complex statical analysis and designed feature engineering to gain a modest performance, which occupy massive computing power and human resources to cover time-consuming model training process, leading to a lack of recognition ability in complex practical applications.

With the development of information technology and intelligent approaches, deep learning neural networks have made significant improvement in solving many intelligent applications, including image classification, object detection, and video tracking, which provide a promising candidate for a generalizable approach for complex environment practices. At present, several deep learning models, including convolutional neural network (CNN), recurrent neural network (RNN), and generative adversarial networks (GAN), have been introduced into the visual recognition of plant's disease and pest species [18–20]. With multilayer structure and massive majorization modules, deep learning methods could automatically learn the multidimensional feature expressions from a large amount of raw data and mine more potential rules at an abstract perspective, which obtained better accuracy and stronger robustness over traditional technologies in identifying different plant pest and disease types.

Although many studies provide credible references to demonstrate the superiority of deep learning approaches, accurately classifying plant diseases and pests is still challenging in a natural scene. The main problem is that the practical identification process of different diseases and pests is a typical fine-grained visual classification (FGVC) problem [21]. As a research hotspot of artificial intelligence in recent years, FGVC is mainly to identify image samples belonging to multiple sublevel classes via retrieving objects under a meta-level category, which is more complicated than simple coarse-grained identification of existing deep learning methods [22–25]. There are many fine-grained difficulties that need to be addressed in identifying plant diseases and pests. On the one hand, the same meta-level category contains vast sublevel samples with viewpoints, illumination, positions, growth periods, and environmental factors, which are easy to confuse the model, resulting in incorrect identification. On the other hand, there is a certain similarity among different meta-level categories. Different genera or subspecies of the same biological subject often have a highly similar overall appearance except for several critical local parts. Thus, deep learning models based on coarse-grained representation learning are generally lacking the effective and accurate ability to handle the identification puzzle for plant disease and pest.

To overcome the above problems, this study proposes a novel graph-related high-order architecture with feature aggregation enhancement to establish a fine-grained deep learning neural network (GHA-Net), aiming to promote the rapid identification of plant pests and diseases in complex natural applications. There are two main innovations in this proposed method. Firstly, a feature aggregation module is designed to improve the fine-grained feature perception capability of the cross stage partial network stage (CSP-stage) backbone network, which filters out multiscale discriminating features and pays more attention to local parts. Secondly, the graphic convolution module is constructed to analyse the graph-correlated representation of part-specific interrelationships by regularizing semantic features into the high-order tensor space. With collaborative learning and global optimization, our approach can achieve better fine-grained identification performance for massive plant diseases and pests in terms of accuracy and robustness, which is more suitable for practical recognition applications.

The rest of the paper is organized as follows: Section 2 introduces the related research of computer vision and machine learning techniques for plant pest and disease identification. Then, the details of the proposed algorithm and experimental datasets are explained in Section 3. Section 4 presents contrastive experimental results and performance evaluation. Finally, Section 5 concludes the whole work with future research prospects.

2. Related Work

Plants infected with diseases and pests usually exhibit visible marks or lesions on the leaves, stems, and fruits, which generally present unique visible patterns for intelligent diagnosis. Nowadays, lots of researchers apply machine learning and information processing techniques to identify different pest and disease species on controllable environmental conditions or public competition datasets. In this section, we review and summarize some relevant studies on machine learning technologies and coarse-grained deep learning methods for plant disease and pest classification, as well as some fine-grained recognition approaches, which is also a key issue of our work.

2.1. Machine Learning Technology for Plant Disease and Pest Identification. In order to guarantee the amount of training data for training complicated deep learning models, many studies have collected various public datasets of plant disease and pest categories. In the first stage of intelligent algorithm modelling, a sufficient amount of image data is necessary for feature extraction, including texture, shape, color, and motion-related attributes. Islam et al. [22] used a dataset of 300 potato leaves from the PlantVillage dataset [26] to design a classifier capable of identifying healthy leaves and leaves affected by late blight and early blight. Then, a multiclass support vector machine was used to classify leaf images based on ten colors and texture features. Qin et al. [27] proposed a solution to identify four leaf diseases affecting alfalfa grass by cropping the image to generate a subimage with one or more lesions. At the same time, the principal component analysis (PCA) method was used to reduce the dimension of *45* feature vectors, which offers the Naïve Bayes classifier to achieve good classification results. Similarly, Wu et al. [23] collected over *75,200* images covering *102* types of crop pests and framed more than 19,000 photos to handle visual classification and detection. Recently, some public competitions also provided public pest and disease datasets, such as AI Challenger 2018, which provided nearly 50,000 photos of plant leaves classified into 61 categories. Cassava Leaf Disease Classification competition provided a dataset of *21,367* labeled images of cassava, divided into four disease classes and health states [28]. These datasets often contain disease and pest infestations, providing a good foundation for intelligent algorithm modelling and optimization.

Meanwhile, several statistical learning and machine learning approaches have been widely introduced to the image identification of plant diseases and pests, including support vector machine (SVM), K-nearest neighbour (KNN), decision tree (DT), and artificial neural network (ANN). For example, Kumar et al. [29] designed an exponential spider-monkey algorithm to optimize an SVM-based classifier, which selects the high-dimensional essential features from the images of pests and diseases by eliminating unimportant features. Zhang et al. [30] proposed a hybrid clustering-based method for plant disease and pest identification. Through KNN clustering, the entire image is divided into several compact and approximately uniform superpixels, providing valuable clustering clues for guiding image segmentation, which effectively detects plant diseases and pests. Similarly, Khule et al [31] attempted to apply different machine learning methods for the classification of tomato diseases. Using image processing techniques combined with SVM, DT, and ANN algorithms, the proposed work achieves good identification performance with an accuracy of 93.75% for all leaf diseases. However, these traditional methods based on simple shallow structures need to rely heavily on manual feature design engineering to obtain satisfactory identification performance. Moreover, these methods lack good performance in the face of large-scale data and complex environment applications. Therefore, more and more researchers have begun to turn their attention to new technologies such as popular deep learning.

2.2. Coarse-Grained Deep Learning Recognition Approaches. Deep learning neural networks with multilayer structure and comprehensive optimization strategies have achieved better performance surpassing human recognition or traditional machine learning methods on different visual research aspects. At present, several deep learning-based convolutional neural networks (CNNs), such as AlexNet [26], VGG [32], ResNet [33], and GoogLeNet [34], have been applied in the image recognition of pest and disease species with considerable performance. For example, Mohanty et al. [35] employed the AlexNet and GoogLeNet models to identify various pest categories on the PlantVillage dataset, which obtained a better accuracy rate than other machine learning methods with shallow structures. Chen et al. [36] added a new batch normalization to the VGG network and replaced the fully connected layer with a global pooling layer, improving identification accuracy. Similarly, Yan et al. [37] replaced all fully connected layers of ResNet with global average pooling layers to identify apple leaf disease and pest categories. The experimental results show that the optimization algorithm improves the whole recognition rate of diseases and pests and dramatically shortens the training and recognition time of the model.

In order to improve the generalization of deep learning algorithms in practical applications, many researchers attempted to combine various machine learning strategies to optimize original CNN models with fixed network architecture. For example, Hu et al. [38] firstly introduced the SVM to design an improved conditional deep convolutional generative adversarial network (C-DCGAN) for local area segmentation. Taking lesion images as input, the proposed method could generate new training samples automatically to train the VGG16 model for identifying tea pests and diseases, which achieves better accuracy while relying on only a little image data. From similar thinking, Argüeso et al. [39] studied the identification problem of leaf diseases and pests to handle a small amount of data. Based on the Siamese network with a few-shot learning approach, the proposed method reduced dependence on data quantity while achieving relatively good recognition results.

Moreover, some studies have attempted to apply some knowledge distillation and structural lightweight methods to reduce recognition model parameters, in order to accommodate the real-time application requirements in natural practices. Take Liu et al. [40] for instance; MobileNet and Inception-V3 models with light-weighted structures are migrated simultaneously to construct the deep learning model for plant pest identification. Experimental results show that the optimal method can be transplanted to the Android system on mobile phones, effectively balancing the model's parameters and accuracy. Similarly, Zhang et al. [41] proposed a global pool dilated convolutional neural network (GPDCNN) for plant pest identification. The deep learning network replaces the global convolution of AlexNet with dilated convolution, aiming to reduce the computational complexity and parameter quantity, which are demonstrated to obtain enough recognition performance on cucumber leaf disease and insect images. Although existing coarse-grained methods have achieved some applications in the meta-level identification of plant pests and diseases, they lack the adequate perception for fine-grained features in the absence of particular designs or modules. It is still challenging to implement plant pest and disease recognition in natural settings meeting practical requirements.

2.3. Fine-Grained Visual Recognition Methods. Unlike coarse-grained image recognition, fine-grained visual recognition aims to correctly distinguish different sublevel samples within a sizeable meta-level class, which is a significant difficulty in pattern recognition. The critical link of fine-grained identification is discovering some powerful features or local regions, which could represent the potential rules for effectively distinguishing different subclasses with similar appearance and tolerating sample differences of the same class. Fine-grained identification methods are mainly divided into two categories depending on the local labeling approach. The first category is the strongly supervised learning method, which adds extra labels such as label boxes to the image, improving fine-grained identification ability. However, adding extra labels to massive images is a very labor-intensive and time-consuming process, which is not suitable for large-scale datasets. The second kind is the weak supervision method [9], which only relies on the attention method without extra labels to adaptively locate the discriminating part of the target. Such methods have attracted the attention of many researchers. For example, Cruz et al. [20] reduced the number of network layers by modifying convolution blocks as attention modules to contrast the proposed path aggregation network (PANet). This method obtains fine-grained positioning information on different receptive fields to enhance the multiscale features, which is conducive to detecting apple pests and diseases in complex scenes. Similarly, Hughes and Salathé [42] proposed a feature compensation model based on residual neural network (MDFC-ResNet), which grabs multidimensional local information from different granularities into fusing recognition results, achieving a better recognition performance than contrastive deep learning models.

In the above fine-grained methods, the discrimination parts of targets are often used independently. Considering that plant pests and diseases have obvious physiological spatial situations, learning the relationship between different discrimination characteristics can further enhance the discrimination ability. The relationship representation of different local parts can be regarded as a graph structure. Thus, graph neural network plays a vital role in applying non-Euclidean data to analyse the interpretable characteristics, which has excellent research significance in defining the intrinsic relevance of deep learning network nodes and parameters. Recently, deep learning-based graphic networks have developed several model variants, such as graph convolution neural network [43], gated graph neural network [44], graph attention network [45], and graph spatiotemporal network. In the aspect of fine-grained image recognition, Wang et al. [46] proposed the GCL model to exploit and utilize the semantic correlation between regional features fully, designed a cross graph to spread from the network to learn the correlation semantics between different regions, and then enhanced each region by cross-weighted aggregation of other regions. Zhao et al. [25] proposed an effective graph-based relationship discovery method to establish context understanding of high-order relationships. This method regularizes the high-dimensional feature library using high-order constraints of semantic awareness. It embeds the high-order tensor library into the low-dimensional space, which can grasp the context details of fine-grained objects.

In summary, due to the challenging fine-grained problems, traditional machine learning and coarse-grained deep learning methods are unsuitable for plant pest and disease recognition in practical applications. Inspired by graphic neural networks, this paper proposes a graph-related high-order approach via feature aggregation enhancement for fine-grained plant disease and pest identification, aiming to solve the existing identification problems of low accuracy and efficiency. For detailed method descriptions, refer to the following sections.

3. Materials and Methods

This section will introduce the details of the graph-based high-order model constructed for fine-grained plant disease and pest identification. Our proposed GHA-Net consists of three main parts: (1) improved backbone network based on the CSP-stage operations is subjected to extract rich coarse-grained feature maps; (2) feature aggregation enhancement module is proposed to learn more slight features of different parts; and (3) graph-related feature extractor is designed to explore intrinsic relationship among various local features and further mine hidden higher-order features of graph nodes and edges. The overall architecture is shown in Figure 1.

3.1. CSP-Based Backbone Network. According to actual application requirements, we apply some data enhancement operations, such as rotate, flip, random crop, Gaussian noise adding, and HSV changing, to enlarge existing image samples before model training. These preprocessing operations can ensure that the deep learning models have sufficient data volume to achieve good generalization and noise resistance to internal and external factor changes. Subsequently, all images are subjected to an improved CSP-based backbone network with the superiority of residual structure. After so many years of theoretical and application demonstrations, a basic knowledge has been recognized by everyone, that is, as the level of the deep neural network is deeper, the model can obtain more scales of receptive fields and rich features, leading to better identification performance. As network structures become more complex and deeper, there is a rapidly growing demand for more training data to fit the explosion of model parameters. However, too many model parameters will not only waste a lot of computing resources but also have little effect on improving model accuracy; due to this, the single path of information propagation in the complex network structure is easy to cause gradient vanishing or explosion.

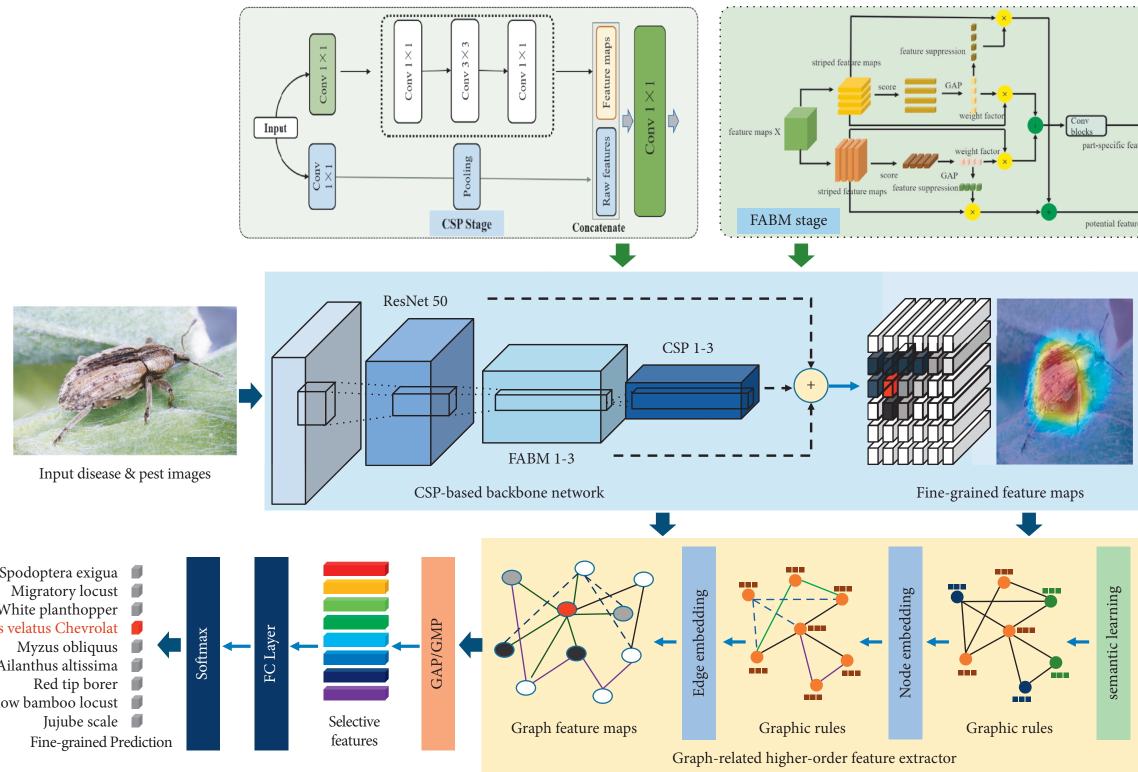

Figure 1: Schematic diagram of the proposed model structure.

Thus, the CSPNet50 [47], a new variant network of ResNet family, is selected as the backbone network in this paper. The backbone network consists of three CSP stages. Each stage adds several cross-channel branches on the primary residual block, so that a portion of features can directly skip all computational processes, which ensures network performance while reducing the number of parameters. As shown in Figure 2, the CSP-stage module firstly divides the input flow into two parallel parts, X1 and X2. The X2 branch is convolved as the feature of normal convolution to pass through the residual operation. Then, the primary branch X1 is connected to the spanning branch X2 by a 1×1 convolution layer. We replace the 1×1 convolution of the original model as a channel attention operation to realize the feature interaction, which further enhances the feature extraction ability of the proposed network. After passing through several ResNet layer structures, X1 is aggregated to enhance the learning capability as well as prevent excessive repetitive gradient information, which effectively reduces computational and resource costs. Each CSP-stage module could be combined with any CNN network structure, such as ResBlock or DenseBlock.

3.2. Feature Aggregation Enhancement Module. To further improve the backbone network's performance and to apply it to fine-grained image classification tasks, we also propose a novel feature aggregation enhancement module on basis of the attention mechanism, which makes the network more focused on the parts with discrimination information in the image. Usually, attention methods can be divided into two categories: strong attention methods and weak attention methods. The strong attention method relies on extra annotation boxes or other annotations, which requires much manual work. The weak attention method is more inclined to automatically add submodules to the network to locate the target position automatically. Our approach focuses on the weak attention method, which only uses the image-level label without adding additional annotations. However, the process of weak attention tends to pay attention to the most significant part, so other inconspicuous but distinguishable parts will be ignored. However, when the essential part is shielded or suppressed, the network will be forced to explore other potential parts. Inspired by Song and Yang [24], we designed a novel structure of weak-supervised attention named as the feature aggregation enhancement module (FABM), which includes an enhanced feature extraction module (EFEM) and feature fusion. In the FABM module, the EFEM module highlights the most prominent part of feature mapping in the current stage to obtain part-specific representations, suppress the representations, and force other potential features to be excavated in the next step. The unique fusion part fuses different elements learned in multiple stages and then obtains feature maps with numerous prominent features. The detailed illustration of FABM module is shown in Figure 3.

Consider feature maps $X \in R^{C \times W \times H}$ from a specific layer, where C, W, and H denote the number of channels, width, and height, respectively. In the next step, X is evenly split into k parts along the width and height dimensions, and the parts along the width and height are the same except for the division direction. Take the width division as an example:

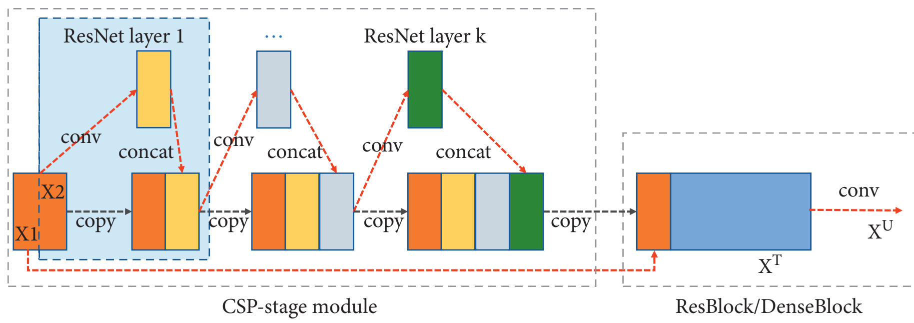

Figure 2: Illustrations of CSP-stage module.

each striped part is denoted as $X_i \in R^{C\times(W/k)\times H}$, $i \in [1,k]$. Then, we use a 1×1 convolution φ to explore the importance of each part:

$$A_{(i)} = \mathrm{Relu}\Big(\Phi\big(X_{(i)}\big)\Big) \in R^{1\times(W/k)\times C}. \tag{1}$$

The non-linear function Relu is applied to remove the negative activation. Φ is shared in different stripes, which plays the role of a grader. Then, we take the average of $A_{(i)}$ as an important factor b_0 of $X_{(i)}$, i.e.,

$$b_i' = \mathrm{GAP}\big(A_{(i)}\big) \in R, \tag{2}$$

where GMP denotes global maximum pooling. We use softmax to normalize $B\prime = (b_1',\ldots,b_k')^T$:

$$b_i = \frac{\exp\big(b_j'\big)}{\sum_{j=1}^{k}\exp\big(b_j'\big)}. \tag{3}$$

With the normalized importance factor $B\prime = (b_1',\ldots,b_k')^T$, the most significant part can be immediately determined. Then, the most significant part of the enhancement feature enhancement is obtained:

$$X_b = X + \alpha(B\otimes X), \tag{4}$$

where α is a hyperparameter, which controls the degree of enhancement, and $\otimes$ denotes the multiplication calculated by various elements. Then, a 1×1 convolution layer h is applied to X_b to get a specific partial representation X_p:

$$X_p = h(X_b). \tag{5}$$

By multiplying the parts with the most stripes, the suppression features X_s are obtained:

$$X_s = S\otimes X,$$
$$s_i = \begin{cases} 1-\beta, & \text{if } b_i = \mathrm{MAX}(B), \\ 1, & \text{otherwise,}\end{cases} \tag{6}$$

where $S = (s_1, s_2, \ldots, s_k)$ and β is a hyperparameter, which controls the degree of suppressing.

The data information carried by multilevel features is very high-dimensional. If each multilevel feature is calculated, it will lead to a large amount of calculation. Therefore, to reduce the amount of calculation, we fuse the multilevel feature information by means of feature addition, to obtain a feature vector with multiple discriminant information:

$$F = \theta\left(\sum_{i=1}^{3} X_i\right) \in \mathbb{R}^{W_1\times H_1\times C_1}, \tag{7}$$

where F denotes the feature obtained after fusion, X_i denotes the i-th extracted enhancement feature, and θ is 1×1 convolution.

After multistage fusion, the features obtained already aggregate multiple discriminant parts but ignore the relationship between different semantic channels. In order to increase the interaction between channels, we use the following methods to establish the relationship matrix between channels.

$$M = B\left(\frac{1}{WH}\sum_{i=1}^{WH} F^T\varphi(F_i)\right) \in R^{C_1\times C_2}, \tag{8}$$

where B denotes normalization, ϕ denotes convolution, and C_2 represents the number of channels after convolution.

3.3. Graph-Related Higher-Order Feature Extractor. From the FABM module, we can get the feature map with multiple discrimination parts, which can be extracted and processed by a downsampling operation. However, the feature map is still a matrix with high latitude. The high latitude matrix embedded into the low margin using the full connection layer will lead to training many learnable parameters. At the same time, by consulting relevant agricultural pest experts, we know that different pests and diseases have certain hidden information in space, and various pests and diseases have their spatial distribution and shape laws. Based on this, we think that the isolated use of discriminant features cannot learn this information. Inspired by Zhao et al. [25], we used a semantic learning module (SRL) which can further mine higher-order feature maps from raw images. Firstly, the module filters the massive information according to the previous network's feature map to obtain the critical discriminant features representing local parts. Then, we introduce the graph-related convolution network to learn the higher-order semantics between different discrimination parts. The nodes in the graph do not exist in isolation in graph data, so we can build a relationship between different sampling points through a graph convolution network. We construct a graphic dataset using sampling nodes as points and the correlation between points as an adjacency matrix.

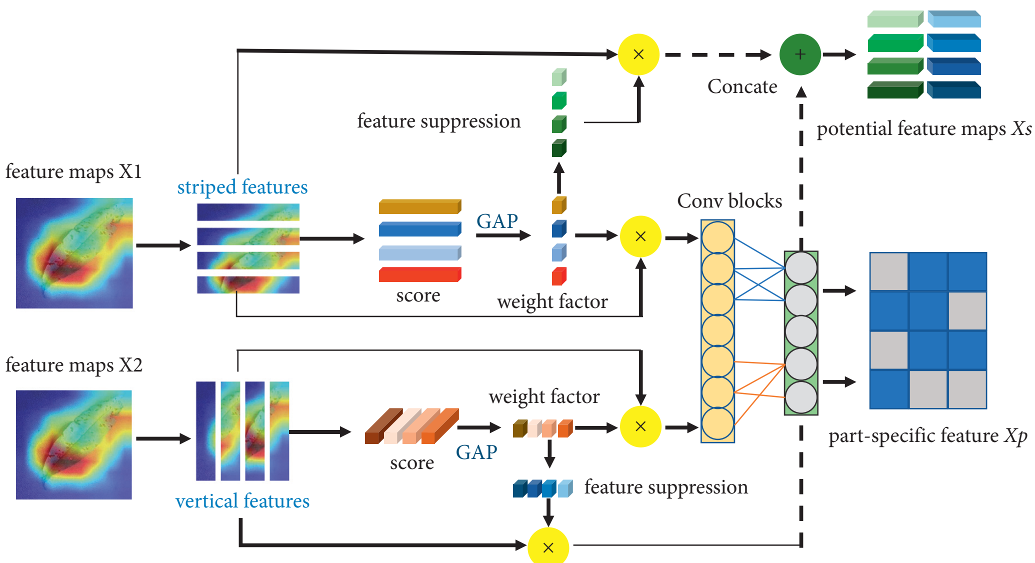

Figure 3: FABM attention module.

The higher-order features between parts are implicitly learned and discriminated by spreading on graph convolution network.

Inspired by Zhao et al. [25], we designed a sampler to sample the discrimination parts, which can extract the discrimination parts in the feature map. After obtaining the residual feature map, which aggregates the related features with the original input features, it is sent to the discrimination response layer. Specifically, we introduce a $1 \times 1 \times C_1$ convolution layer and a sigmoid function σ to learn discriminative probability maps $S \in \mathbb{R}^{N \times H \times W}$, which express the impact of discriminative regions on the final classification. C_1 is the number of channels in the feature map. Then, each selected patch will be assigned a corresponding discrimination probability value P_{ijk}. The formulation is as follows:

$$P_{ijk} = \left[t_x, t_y, t_k, s_{ijk}\right], \tag{9}$$

where $[t_x, t_y, t_k]$ represent the coordinates of each patch and s_{ijk} denotes the discrimination probability value of the i^{th} row, the j^{th} column, and the k^{th} channel.

After sampling discriminant feature, a discriminant feature library $\mathcal{K} \in \mathbb{R}^{C_1 \times C_2}$ can be constructed. Furthermore, the discriminant feature library $\mathcal{K} = \{f_1, f_2, \ldots, f_C\}$ can be described as a graph with C_2 nodes of C_1 channels as shown in Figure 4. These nodes share many information in essence, so we use graph convolution network to aggregate these features [43]. The relationship between pairs of adjacencies can be defined as

$$A_{i,j} = \frac{\tau(f_i)^T \cdot \tau(f_j)}{\left\|\tau(f_i)\right\|\left\|\tau(f_j)\right\|}, \tag{10}$$

where τ denotes the 1×1 convolution for dimension transformation, the last adjacency matrix is defined by self-circulation $\widetilde{A} = A + I$, and $\mathrm{I} \in \mathbb{R}^{C_1 \times C_2}$ is an identity matrix. Through this similarity aggregation, the update mode of each node is as follows:

$$H = \mathrm{ReLu}\left(D^{-\frac{1}{2}}\widetilde{A}D^{-\frac{1}{2}}KW^g\right), \tag{11}$$

where $W^g \in \mathbb{R}^{C_2 \times d_h}$ represent the learnable graph weights with a dimension d_h and $D = \sum_j \widetilde{A}_{i,j}$ is the diagonal matrix for normalization. K denotes the matrix of $\mathcal{K}$.

This operation can update the information of each node. At the same time, another purpose of graph embedding is to learn the context understanding of different discrimination parts. We use the following methods to form multiple groups to learn the relationship between contexts:

$$H = \mathrm{ReLu}\left(D^{-1/2}\widetilde{A}D^{-1/2}KW^e\right), \tag{12}$$

where $\mathrm{W}^e \in \mathbb{R}^{d_h \times C_r}$ represent the learnable graph weights. $G \in \mathbb{R}^{C_1 \times C_r}$ indicates the mapping function of each node from the original space to form a new graph node:

$$\begin{aligned} Z &= H^T \frac{e^{G_{i,j}}}{\sum_{j=1}^{C_r} \in R^{d_h \times C_r}}, \\ Z &= H^T \frac{e^{G_{i,j}}}{\sum_{j=1}^{C_r} \in R^{d_h \times C_r}}, \end{aligned} \tag{13}$$

where C_r represents the number of new embedded graph nodes. We design the softmax layer with the group dimension to accomplish the C_r by the calculation formula C_1/r.

This method can efficiently allocate a high-order feature library in low-dimensional manifold and map channel dimension and node dimension at the same time. Then, the remaining connections are grouped and characterized to construct the final embedding $\widetilde{Z} = Z + H$. Finally, these

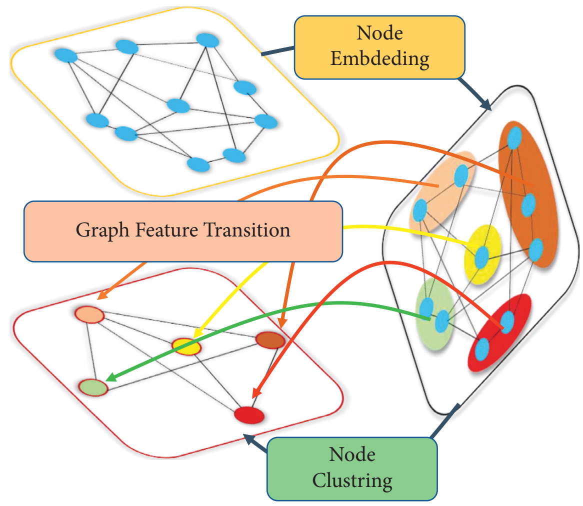

FIGURE 4: Schematic diagram of graph feature description.

embeddings can be finally predicted by applying a GMP or GAP and a classifier.

An obvious problem of infinite granularity classification is overfitting under challenging cases [25]. A preferable class clustering should be based on representative sample sets, while ignoring remote hard samples. This means that we use the centre of multiple samples of a specific class as the average feature to update the network parameters, so the loss function can be defined as follows:

$$L_{\text{loss}} = \frac{1}{NK} \sum_{n=1}^{N} \sum_{k=1}^{K} L_{CE}\left(\left(\frac{y_n}{y_n}\right)\right) y_n, \tag{14}$$

where y_n denotes the sample labels, N denotes the number of class, K denotes the samples in each class, and L_{CE} represents the cross-entropy function. The representative samples are applied to update the complex parameter features of the whole network, which help improve the model's identification performance with better generalization.

4. Experimental Results and Analysis

4.1. Experiment Setup. We use three datasets publicly available on the web for experiments: AI Challenger agricultural pest and disease dataset, Cassava leaf disease dataset (Cassava leaves), and IP102 dataset.

4.1.1. AI Challenger Agricultural Disease Dataset. This data contains 27 disease categories on 10 kinds of plant hosts, including apple, cherry, grape, citrus, peach, strawberry, tomato, pepper, corn, and potato. The entire dataset has a total of 47637 image samples. However, the data distribution is highly unbalanced, and the number of pictures in some categories is tiny. Therefore, we cleaned the dataset, eliminated the types with a few images in the dataset, and finally got 31,027 training sets and 4,739 test sets.

4.1.2. Cassava Leaves. This dataset consists of leaf images of cassava plants and contains 21397 cassava leaves. The disease types include cassava brown streak disease (CBSD), cassava mosaic disease (CMD), cassava bacterial blight (CBB), and cassava green mite (CGM). In this paper, the annotated image data are re-divided, including 17,115 images in the training set and 4,282 images in the test set.

4.1.3. IP102. This dataset has a total of 75,222 images, covering 102 different types of pests, including *corn borer*, *red spider mites, whitefly,* and *Spodoptera litura.* At the same time, the crops in the dataset images also contain a variety of crops, including rice, corn, grapes, citrus fruit trees, and mango trees. All images in the classification task are divided into the training set, validation set, and test set. The detection task uses 18,983 annotated images containing bounding boxes, including 15,178 photographs in the training set and 3,798 images in the test set. Since the dataset includes many image data crawled from the network, some of these image data contain some situations such as text occlusion and watermark. These factors will interfere with the training effect of the network, so we culled some parts and finally obtained the training.

In our experiments, the model we used uses ImageNet for pretraining. The images are processed before entering the network, including random cropping, random flipping, and brightness enhancement, to enhance the anti-interference ability of the model. In addition, all images are also normalized, and the image size is set to 448 × 448. In the network training process, the number of iterations is set to 150, and a checkpoint is set every 10 times. The optimizer is SGD, using momentum processing, the weight decay is set to 0.001, and the initial learning rate is set to 0.001. Our experiments are trained end-to-end on 4 NVIDIA P40 GPUs without adding additional part or bounding box annotations, only using image-level labels. In the network structure design, we use the CSPNet50 structure as the backbone network and use the three-stage FABM module in the network structure to extract the features of three different stages for aggregation enhancement.

4.2. Evaluation Indicators. In order to objectively evaluate the prediction results of different algorithms, four performance indicators of accuracy, precision, recall, and F1 score are selected to compare the prediction results of each model. ACC is the ratio of the number of correctly labeled items to the total number of observations. PRE is the number of true positives divided by the total number of items belonging to that category. Meanwhile, REC is defined as the number of true positives divided by the total number of items belonging to the category, also known as sensitivity. Through the above three indicators, the number of results in the confusion matrix can be converted into a ratio between 0 and 1, which can be calculated based on true positive (TP), true negative (TN), false positive (FP), and false negative (FN). In addition, another high-level indicator, F1 score, is adopted in this paper, which is the harmonic mean of ACC and REC with a better comprehensive evaluation of multiclass recognition problems. Here are the formula definitions for each indicator:

$$\begin{aligned} \mathrm{ACC} &= \frac{\mathrm{TP}+\mathrm{TN}}{\mathrm{TP}+\mathrm{TN}+\mathrm{FP}+\mathrm{FN}}, \\ \mathrm{PRE} &= \frac{\mathrm{TP}}{\mathrm{TP}+\mathrm{FP}}, \\ \mathrm{REC} &= \frac{\mathrm{TP}}{\mathrm{TP}+\mathrm{FN}}, \\ F_1 &= 2\times\frac{\mathrm{PRC}\times\mathrm{REC}}{\mathrm{PRE}+\mathrm{REC}}. \end{aligned} \tag{15}$$

The proposed model first selects several regions with the most robust feature performance according to the FABM module. Then, the SRL module tries to extract the discriminative features to construct the correlation between different discriminative parts. Finally, the designed GCN implicitly learns the high-order feature vector to achieve better fine-grained recognition performance. Therefore, to comprehensively evaluate the improvement effect of each module on the proposed method, this paper selects various indicators to analyze the experimental results of our model.

4.3. Comparative Results. To verify that the proposed method can identify crop pest species, we set up some experiments to compare the performance of deep stacking networks and other methods. In this section, some coarse-grained image recognition network methods are selected, including VGG [32], Inception [34], ResNet [33], DenseNet [48], CSPNet50 [49], and SeNet [50]; at the same time, several other fine-grained image recognition networks are selected for comparison, including LIR [51], WSAP [52], and FBSM [24]; these networks are trained separately on the three datasets using the same strategy.

The experimental results of AI Challenger are shown in Table 1. The experimental results of the model proposed in this paper are better than those of the commonly used coarse-grained recognition networks, indicating that our network can extract more features than coarse-grained networks. Our network considers learning the discriminative part features of multiple targets as much as possible and suppresses useless features. Therefore, our model is better than other models by comparing coarse-grained networks and some fine-grained methods. In AI Challenger, the best results have been achieved on the dataset, with an accuracy rate of 96.4%, a precision rate of 88.3, a recall rate of 86.7, and an F1 score of 0.87, all of which are optimal.

The experimental results on the Cassava dataset are shown in Table 2. Our experimental results are better than those of other models, except slightly lower than FBSM and LIR. We think this is because the Cassava dataset is more straightforward than the IP102 and AI Challenger. There is one plant category in the Cassava dataset, and the number of pests and diseases is also less. Specifically, the method proposed in this paper focuses more on locating the location of pests and diseases in complex backgrounds. In data with simpler backgrounds, the discriminant parts' enhanced parts receive significant gains. At the same time, since the SRL module learns, the spatial relationship depends on the complexity of the pests. The results show that LIR and FBSM benefit from simpler backgrounds on the Cassava dataset, while in complex environments, such as IP102 and AI Challenger, the method proposed in this paper is more dominant (Table 3).

In addition to this, we visually compare the F1 scores of ten models, as shown in Figure 5. It can be seen intuitively that compared with the coarse-grained method, the F1 score of our model is better than that of the coarse-grained method, indicating that our model has better recognition performance and is comparable to other fine-grained methods. In comparison, the F1 score of our model is also comparable to the rest of the fine-grained algorithms, indicating that our model is capable of fine-grained recognition.

As shown in Figure 6, we compared the loss trend of different models on the three datasets. We can see that the loss rate of the proposed model in the early catenary stage is lower than that of other models, since the FABM model and the high-order relation learning module added to the model structure are not pretrained. Hence, the convergence rate in the early stage is relatively slow, but after reaching a certain number of training times, the loss of our model also tends to converge.

To further illustrate the performance of our model, we plotted the confusion matrix of the accuracy rates of the three models, as shown in Figure 7. Our model has a high accuracy rate on each class on the Cassava dataset with the best effect. The worst is the third category, but the accuracy rate has also reached 95%, and the best impact is the 0th category.

To further judge the model's performance proposed in this paper, we visualized part of the model. We considered whether the model played a role through a visual operation. The visualization results are shown in Figure 8. We selected two different samples from each of the three datasets for a total of 6 image samples for visualization. The compared models are VGG19, ResNet50, and FSBM. The heat map shows that the features learned by VGG and ResNet50

	GHA-Net	57.1	46.7	45.3	0.48

contain a lot of background, which is unfavorable for the classification results. At the same time, our model focuses more on the discriminative parts of the target itself, indicating that our model can play the role of learning more discriminative features.

4.4. Ablation Analysis. To verify the effectiveness of our model, we conduct ablation experiments on each dataset. The results of our ablation experiments are shown in Table 4, including a feature enhancement module and a spatial higher-order relation learning module. In the absence of fine-grained classification of extra labels or local annotations, we perform feature extraction on the entire image through ResNet50, set it as the baseline network, and then improve the discrimination by eliciting features learned at different residual stages. Finally, the classification accuracy of the network is improved by further extracting and sampling the discriminative features and learning the spatial high-order semantic features between the discriminative parts through the graph. Xia Rong's experiments show that the FABM module can learn more features, and the model accuracy of the FABM module is improved by 1.5%, 5.5%, and 1.7% on the AI Challenger, Cassava, and IP102 datasets, respectively, compared to the baseline network accuracy.

Finally, we introduce the SRL module to learn the implicit relationship between features further, and the network progress is further improved. Ablation experiments prove that the proposed network can understand the discriminative regions, enhance the discriminatory feature values, and improve accuracy. Moreover, we also added a comparison of experimental results using ResNet50 as the backbone network. The experimental results show that after adding the FABM module and the SFL module to ResNet,

CSP + SFL	95.9	93.6	56.0
CSP + FABM + SFL	96.4	96.4	57.1

the experimental results are improved to varying degrees, which shows that our module can be used on other backbone networks, further illustrating the effectiveness of our model.

To further illustrate the effectiveness of our model, we visualize the different stages of the attention module FABM. As shown in Figure 9, our model has three FABM modules, which are denoted as FABM-1, FABM-2, and FABM-3. The aggregation of the three modules is characterized as FABM-Con, as shown in Figure 9. The non-stage FABM can focus on the features of different parts, and the fused FABM can locate multiple discriminative features of the target.

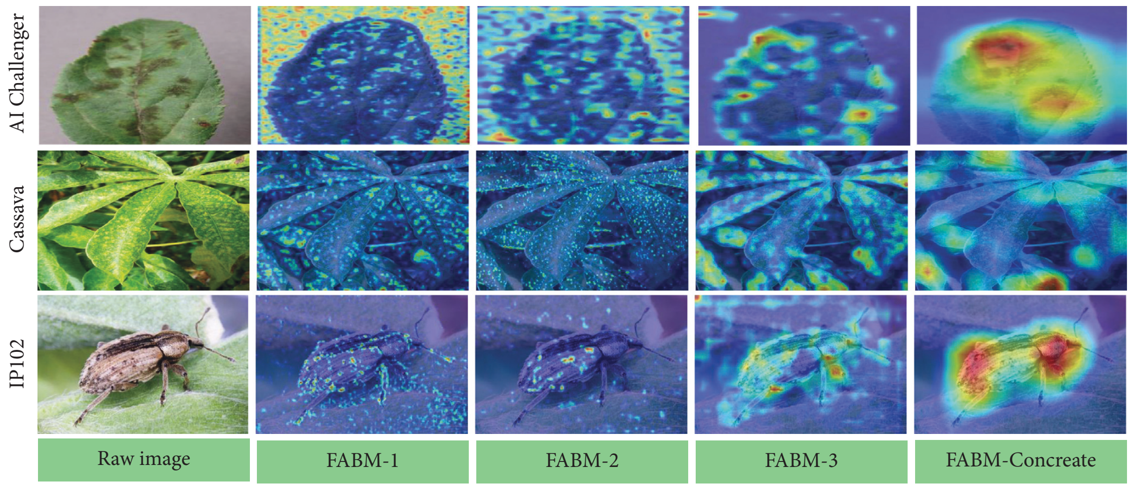

Figure 9: Heat map visualization of different FABM stages.

5. Conclusion

Aiming to solve the fine-grained identification problem of plant diseases and pests, this research proposes an effective graph-related high-order network with feature aggregation enhancement (GHA-Net) to promote the fine-grained recognition performance of deep learning technology. Based on the improved CSP-stage backbone network, the feature aggregation enhancement module is firstly designed to enhance multilevel attention for learning multiple discriminant features. Meanwhile, the graphic convolution module is constructed to analyse the graph-correlated representation of part-specific inter-relationships by regularizing semantic features into the high-order tensor space. Experiments on AI Challenger, Cassava, and IP102 datasets have demonstrated robust and accurate performance in terms of fine-grained plant disease and pest identification. Compared with other deep learning models, the proposed GHA-Net achieves the identification accuracy of 96.4%, 97.4%, and 57.1% on three public datasets, overperforming all compared methods with a minor error, which is verified more suitable for fine-grained identification applications in complex scenes.

The model structure will be optimized to improve the identification performance in further work. The related technologies will be investigated to expand the application scope of the proposed model in intelligent greenhouses and grain warehouses. Also, they can be applied to other fields such as temporal prediction, signal modelling, and control systems [53, 54].

With the increasing pressure on college students in terms of study, work, emotion, and life, the emotional changes of college students are becoming more and more obvious. For college student management workers, if they can accurately grasp the emotional state of each college student in all aspects of the whole process, it will be of great help to student management work. The traditional way to understand students' emotions at a certain stage is mostly through chats, questionnaires, and other methods. However, data collection in this way is time-consuming and labor-intensive, and the authenticity of the collected data cannot be guaranteed because students will lie out of impatience or unwillingness to reveal their true emotions. In order to explore an accurate and efficient emotion recognition method for college students, more objective physiological data are used for emotion recognition research. Since emotion is generated by the central nervous system of the human brain, EEG signals directly reflect the electrophysiological activity of the brain. Therefore, in the field of emotion recognition based on physiological signals, EEG signals are favored due to their ability to intuitively respond to emotions. Therefore, a deep neural network (DNN) is used to classify the collected emotional EEG data and obtain the emotional state of college students according to the classification results. Considering that different features can represent different information of the original data, in order to express the original EEG data information as comprehensively as possible, various features of the EEG are first extracted. Second, feature fusion is performed on multiple features using the autosklearn model integration technique. Third, the fused features are input to the DNN, resulting in the final classification result. The experimental results show that the method has certain advantages in public datasets, and the accuracy of emotion recognition exceeds 88%. This proves the used emotion recognition is feasible to be applied in real life.

1. Introduction

With the development of the times, the environment in which college students live is also constantly changing. The transformation of the identity of college students is accelerating, and they are faced with problems in study, work, interpersonal communication, and life. Most of the current college students were born after 1995. They have a strong sense of independence, have their own ideas, and are emotionally sensitive. In addition, in the current summer of the epidemic, students' learning and employment have been greatly affected. The epidemic not only affects the physical health of college students but also affects their emotions. On the one hand, when college students surf the Internet, they will be confronted with a variety of epidemic-related information, which will have a psychological impact. On the other hand, college students need to adapt to the comprehensive online teaching state and complete various learning tasks arranged by the school. College students will experience stressful emotions for an extended period of time under these conditions, and negative emotional states such as loneliness, anxiety, depression, and fear will emerge. If you do not pay attention and adjust in a timely manner, it may result in more serious consequences. As a result, whether it is college students or colleges and universities, they should pay close attention to the emotional state and mental health of college students while focusing on the epidemic and their studies.

For college student management workers, the traditional methods to understand students' emotions mainly include interviews, questionnaires, and oral presentations by class informants. The main problems in these methods are as follows: first, some students are worried that telling the truth will cause adverse effects and other reasons to falsely report information, resulting in inaccurate information collected. Second, some students are disgusted or impatient to fill in the questionnaire, so they fill in the content at will, resulting in inaccurate information collected. Third, some students' emotions are not exposed, so it is difficult to obtain accurate information through the observation of classmates and teachers. Therefore, in order to obtain accurate and effective emotional data, it is best to obtain it based on objective physiological data. Since the emotion recognition results based on physiological signals are more objective, various emotion recognition methods based on physiological signals emerge as the times require. These physiological signals are noninvasive in nature, easily obtained from the individual, and largely reflect the influence of emotion on the automatic nervous system. Electrocardiogram (ECG) [1], electromyography (EMG) [2], ElectroSkin (GSR) [3], respiration rate (RR) [4], and EEG [5] are all commonly used for emotion recognition. Physiological signals: in particular, EEG signals are most often used for emotion recognition [6, 7]. EEG signals have been widely used to study swallowing, analyze mental states, and assist in diagnosing neuropsychiatric diseases [8–10].

EEG-based emotion recognition research is mainly carried out from the following aspects. one is the research based on the recognition model, mainly based on machine learning algorithms and based on deep learning algorithms. Reference [11] applies Support Vector Machine (SVM) to binary classification tasks or to few classifications and achieves good results. In SVM, by calculating the distance between each support vector, a maximum interval space is optimized to realize the distinction of different categories [12]. Reference [13] annotates the feature information of the ECG signal according to the local features and overall features of the ECG signal, and SVM is used to identify the ECG. However, when the data scale becomes large, using SVM for classification will consume a lot of machine memory and computing time. Reference [14] classified four kinds of ECG signals through a decision tree ensemble algorithm, and the classification Fl-score exceeded 0.81. Reference [15] uses a one-dimensional convolutional neural network to perform feature extraction on ECG signals, and the accuracy rate reaches 86% in the ECG four-classification task. Reference [16] proposes to combine a convolutional neural network (CNN) with a recurrent neural network (RNN) to achieve a multiscale representation of ECG signals. However, due to the limited depth, the ECG signal feature extraction is incomplete, and the improvement of the classification effect is not obvious. Reference [17] extracted a set of ECG signal features to describe the morphological features of the entire ECG signal and improved the classification accuracy based on XGBoost. Reference [18] used DNN to classify 12 kinds of signals in single-lead ECG signal, and its classification performance accuracy was as high as 83.7%. The second is research based on different emotion expression models. There are mainly continuous emotional expression models that represent emotions, mainly two-dimensional [19], three-dimensional [20], 4-dimensional [21], and discrete emotional expression models [22–24]. The third is based on different EEG feature extraction. Methods of research include the power spectrum feature [25] and wavelet energy entropy feature [26].

At present, EEG-based emotion recognition is mainly carried out from the above three aspects. Multifeature extraction strategies are mostly combined with machine learning algorithms for research. Most of the research on deep learning algorithms focuses on improving the algorithm itself. Inspired by this, this study combines a multi-feature fusion strategy with a deep learning algorithm to further increase the emotional EEG′ recognition accuracy. Considering that different features can represent different information from the original data, in order to express the original EEG data information as comprehensively as possible, various features of the EEG are first extracted. Second, feature fusion is performed on multiple features using the autosklearn model integration technique. Third, the fused features are input to the DNN, resulting in the final classification result. The experimental results show that the method has certain advantages in public datasets, and the accuracy of emotion recognition exceeds 88%. This proves that the used emotion recognition method is feasible to be applied in real life.

2. Relevant Background Knowledge

2.1. Emotional Characteristics of College Students

(1) Anxiety and loss due to employment and higher education pressure: in addition to academic pressure, some senior students feel anxious when faced with the pressure of employment and further education. In order to protect the health of college students, the government requires college students not to return to school and colleges to reopen until the epidemic is effectively controlled. This means that many recent university graduates cannot improve their employability through internships. Due to the severe epidemic situation, many companies have not resumed work in time or have not resumed normal production and operations after the resumption of work, and corporate recruitment will inevitably be affected. Affected by this, college students who are applying for jobs generally show negative emotions such as anxiety and loss.

(2) Under the epidemic environment, online learning at home has led to burnout and anxiety. Affected by the epidemic, colleges and universities have delayed the start of school, and domestic colleges and universities have adopted online teaching methods to enable college students to study courses at home. The school arranges a week's class schedule according to

the students' course selection, and the teacher selects the appropriate online platform for teaching and assignments according to the needs of the course. Many college students are taking online classes for the first time. Coupled with the influence of factors such as irregular work and rest during the holidays, they have a lot of discomfort with online teaching, which in turn has an impact on their emotional state. Some students expressed their rejection of online classes and even thought of dropping out. Each teacher has different requirements and needs to use many software programs such as QQ, WeChat, and Tencent Conference. Due to problems such as network or software capacity, there are often problems such as freezes and flashbacks during class, which affect the status of the class. Teachers are worried about the effect of students studying at home, and they will assign more homework. Students feel that they are either taking online classes or rushing to do homework every day and feel exhausted.

(3) Sadness and anger caused by following all kinds of news: sudden emergencies will greatly stimulate the public's information exchange and dissemination behavior. With the help of Internet technology, the spread of epidemic-related information has become very fast. But for the recipient of the information, it can be difficult to discern which is credible and which is a rumour from the dizzying array of information. The prevention and control of the epidemic require the public to reduce going out. College students respond to the government's call to stay at home for a long time, and they can only obtain information through TV news, online media, and various social software. College students should be concerned about current affairs, but 24-hour reports on the epidemic, closed home isolation environment, etc. will make individuals pay too much attention to the epidemic. In addition, there are some negative news on the Internet that are exaggerated to attract attention. If you are too immersed in negative social information, you will have negative emotions that are not good for your physical and mental health.

2.2. Emotion Expression Model. The representation of discrete emotions is derived from basic emotion theory. The basic emotion theory divides emotion into basic emotion and secondary emotion. Basic emotion is determined by the human physiological autonomic nervous system. Assuming that there are various neural channels in the human body system, each basic emotion corresponds to its own functional channel and presents certain physiological feedback to the surrounding environment and situation. Such feedback may be physiological electrical signals, body movements, voice intonation, natural language expressions, and facial expressions. Secondary emotion is no longer restricted by basic emotion; it can reflect individualized emotion through the combination of different basic emotions or the fusion of cognition and inner needs. There are three typical evaluation criteria for discrete emotions, namely: Scherer affective state model [27], OCC affective model [28], and Roseman affective model [29].

Some scholars believe that emotional states do not exist in isolation but are distributed in multiple dimensional spaces. Therefore, any two affective states in a continuous affective space can be brought together by the continuity of dimensions. Emotions that are closer in space have a greater similarity. Conversely, the farther the distance in the space is, the smaller the similarity is, and the easier it is to distinguish. In addition, the continuous emotional space can also be measured by Euclidean distance, and the similarity of emotions can be quantified according to the distance, which makes it easier to analyze the emotional state. Typical continuous emotional expression models include Wundt emotional space [30], Schlosberg 3D cone emotional space [31], 3D emotional space for PAD [32], and Plutchik emotional wheel continuous space [33]. The relationship between the above two types of emotion expression models is not completely independent but an inclusive relationship. Continuous types of emotion models include discrete types of emotion expression models. Moreover, even within a certain type of emotion expression model, there is an inclusive relationship between several typical emotion expression models.

2.3. EEG Features. Before the EEG raw data are input to the classifier, it needs to perform preprocessing, feature extraction, and dimensionality reduction. Based on preprocessed EEG data such as denoising, multidomain feature extraction is required. Generally, effective features are extracted from the time domain, frequency domain, and spatial domain, respectively. A brief introduction to the features of each domain is shown in Table 1.

3. Emotion Recognition Models

3.1. Emotion Recognition Architecture. In order to maximize the use of feature data in various fields of EEG, the classification performance of the model can be improved as much as possible. This article extracts 8 features in the three domains of time domain, frequency domain, and spatial domain given in Section 2.3. The eight features are Hurst, sample entropy (SE), Hjorth complexity (HC), vector autoregression (VAR), wavelet entropy (WE), spectral entropy (SE), power spectral density (PSD), and complex network (CN). Although the increase of feature dimension can convey the features of EEG more comprehensively and objectively, the number of redundant and invalid features it contains also increases. While increasing the computational complexity, it also reduces the classification accuracy. Therefore, feature selection is very necessary. Feature selection is to filter out the most effective feature subsets from the original features. Model fusion aggregates the classification results of many models to improve single-model performance. Under the assumption that a single model produces uncorrelated errors, deep learning models based on multidomain features may allow incorrect models to be

Table 1: EEG features.

Domain	Feature
Time domain	Skewness, kurtosis, zero-crossing rate, instability index, Hurst's index Detrended fluctuation analysis, Pearson's fractal dimension, sample entropy, HFD, Hjorth activity, hjorth mobility, hjorth complexity Energy, RMS, vector autoregression (VAR)
Frequency domain	Power, wavelet entropy, spectral entropy, PSD, partial directed coherence (PDC) Band power (BP)
Spatial domain	Index of asymmetry, complex network (CN)

rejected in decision-making. Based on DNN, this article proposes a DNN model that combines multifeature input and applies it to the recognition of emotion EEG. Figure 1 illustrates the architecture of the used recognition method.

As shown in Figure 1, firstly, eight features are extracted from the input raw EEG data. Second, the importance of the features is sorted using a random forest (RF) algorithm, and the top 3 most important features are selected. Third, use the autosklearn model integration technology to perform feature fusion on the three features; fourth, input the fused features into the DNN to obtain the final classification result.

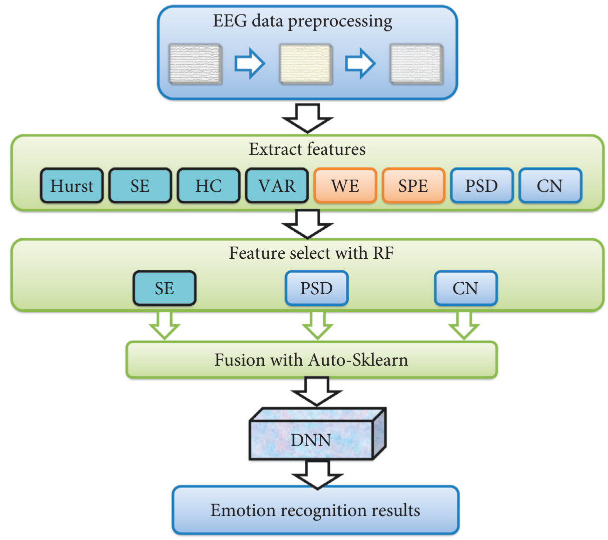

Figure 1: Emotion recognition architecture diagram.

3.2. Feature Selection Strategy. When filtering feature information based on RF, the importance value (IV) of all feature information can be calculated to sort the features according to their importance. Taking a decision tree *i* as the initial point, based on equation (1), the out-of-bag data error (OD_{error}) is obtained. After that, the value of the feature information H^j in the out-of-bag data is rearranged, keeping other eigenvalues unchanged. Then a new out-of-bag data set can be obtained, denoted as $OD_{error'}$. Similarly, use equation (1) to obtain a new out-of-bag data error (OD_{error}). The IV of the feature information F^j in the ith decision tree can be derived by subtracting the results of the two calculations.

$$\mathrm{OD}_{\mathrm{error}} = \frac{1}{n}\sum_{i=1}^{n}\left(x_f - x_c\right)^2, \tag{1}$$

where n represents the total amount of data, x_f represents the actual value of data, and x_c represents the classification value of data.

$$\mathrm{IV}\left(H^j\right) = \mathrm{OD}_{\mathrm{error}_i'} - \mathrm{OD}_{\mathrm{error}_i}. \tag{2}$$

According to the same principle, the corresponding IV is obtained for each decision tree in the random forest, and finally all the obtained IV are averaged to obtain the IV of the feature information H^j:

$$\mathrm{IV}\left(H^j\right) = \frac{1}{m}\sum_{i=1}^{m}\mathrm{IV}_i\left(H^j\right), \tag{3}$$

where m is the number of decision trees in random forests. It can be seen that if feature information is very important, its numerical value varies greatly among different samples. When the feature values in the out-of-bag dataset are reordered, the difference between different samples will be reduced so that OD_{error} will increase. Then according to (2) and (3), it can be concluded that the larger the IV of the feature information, the stronger its importance.

By calculating the IV of all feature information, combined with the reverse search method of the sequence, a set of optimal prediction feature information subsets can be obtained. Considering the high dimension of the track feature information, if the reverse search method of the sequence is used directly, the operation time will be too long, thus reducing the operability of the algorithm. Therefore, this article uses an improved sequence reverse search algorithm. Specifically, a rough selection stage is added before the reverse search method is applied to the feature information set. Specific steps are as follows:

Step 1. Train the random forest using the extracted eight kinds of feature data. After the training is completed, *IV* of all feature information can be obtained. At this time, the test set is used to evaluate the classification accuracy e_{all} of the random forest algorithm, and this value is set as the classification threshold.

Step 2. Sort the *IV* of all feature information in descending order. After the sorting is completed, the feature information corresponding to the first 15 *IV* is imported into the rough selection feature information set S_{pre}, which is initially an empty set, and this feature information is deleted from the initial feature set K at the same time.

Step 3. The RF is retrained based on S^i_{pre}, and the classification error e^i_{pre} of the test is obtained. The upper right corner mark i in the formula represents the number of feature information of the information set S_{pre}.

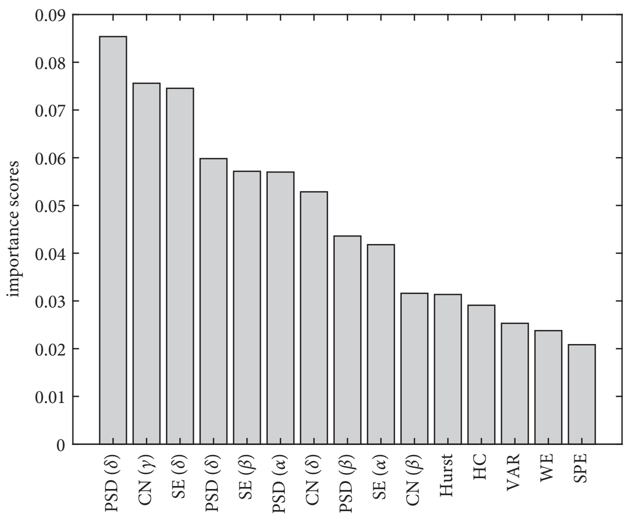

Figure 2: Feature sorting.

Step 4. Determine the size relationship of e_{pre}^{i}. If $e_{\text{pre}}^{i} \geq e_{\text{all}}^{i}$, then add 15 more feature information to the feature information set S_{pre}^{i} to form a new set S_{pre}^{i+15}. If $e_{\text{pre}}^{i+15} \leq e_{\text{pre}}^{i}$, do not add feature information to S_{pre}; otherwise, continue to select the top 15 feature information in K to add.

After the rough selection information set S_{pre} is determined, the reverse sequence search method is used for this set. The IV corresponding to all feature information in set S_{pre} are sorted from small to large, and then a feature information variable corresponding to the smallest IV is eliminated. The RF is trained again based on this set, and the classification results in the test set are saved.

After the above operations are completed, the feature information variable corresponding to the next IV is eliminated, and training, testing, and recording are repeated until the initial set S_{pre} becomes an empty set. Finally, considering the classification accuracy of each scheme comprehensively, determine the appropriate feature information set S_{best}.

4. Experimental Simulation and Discussion

4.1. Feature Selection Experiment. The PI value corresponding to each feature information is calculated based on RF and arranged in descending order. This selects features that play an important role in the classification decision-making process. The number of populations in RF is 500 by default. In order to better compare the importance of each feature, the calculated PI value is normalized to represent the importance of each feature. Figure 2 gives the top 15 features based on RF.

It can be seen from Figure 2 that the feature importance of each frequency band of the PSD ranks first, indicating that its importance is the greatest. It is speculated that the classification results of PSD in CNN may be good, so PSD is selected as one of the optimal feature subsets. After the PSD is the CN, and after the CN is the SE. Behind SE is Hurst. Considering that the more the features are, the longer the model training takes, and the classification results are not necessarily good. Therefore, this article finally selects the top 3 features, namely PSD, CN, and SE.

4.2. Model Evaluation Experiment. The dataset used in this article is the public DEAP dataset. The tenfold cross-validation strategy was adopted, and 70% of the EEG sample set was used as the training set to build the emotion recognition model. Use the established emotion recognition model to test the remaining 30% of the test samples to perform emotion recognition. The comparison models include SVM [34], CNN [35], DNN [36], RNN [37], LSTM [38], [39], and [40], and the parameter settings of each comparison model are consistent with those in the article. To make the model converge quickly, the Adam optimizer employs the adaptive learning rate method so this model employs the Adam

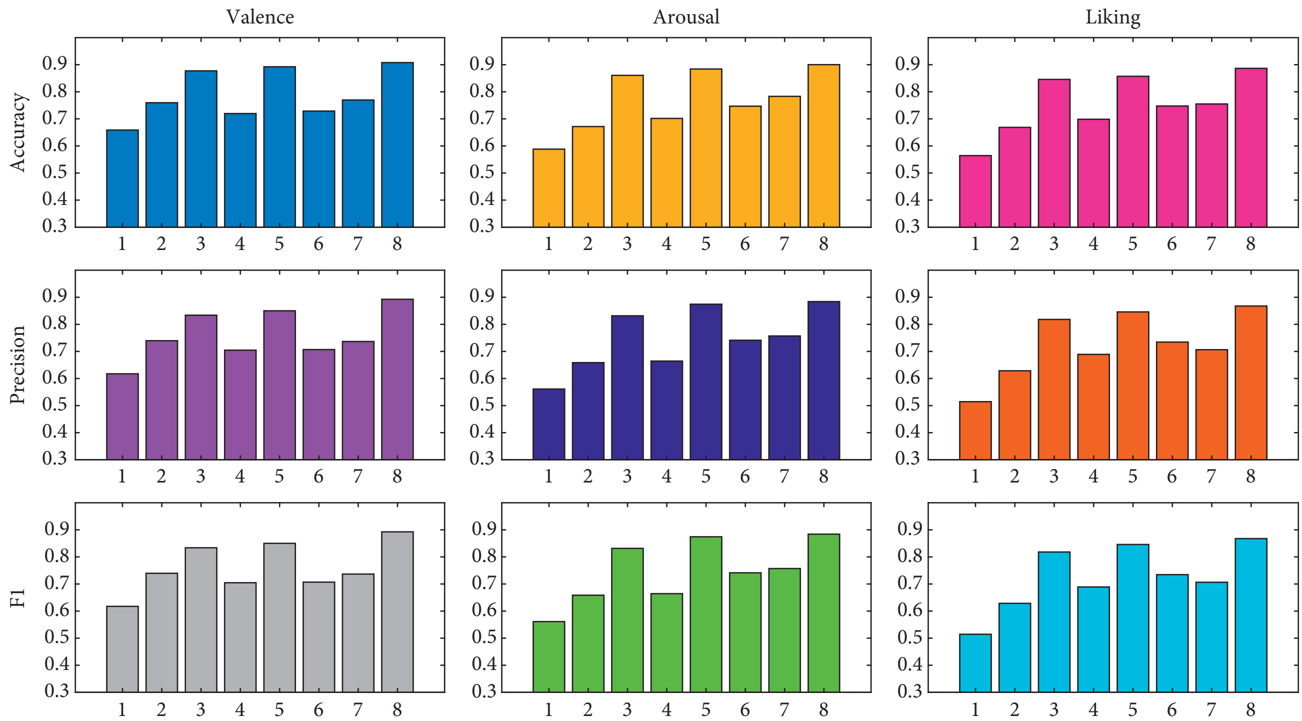

Figure 3: Comparison of experimental results.

optimizer, the initial learning rate is set to 0.001, the Dropout layer ratio is set to 0.2, and the batch size is set to 32. The epoch is 80, and for each epoch, a full training process is performed on all training sets. Table 2 depicts the experimental environment for this article. The accuracy rate, precision rate, and F1 score are the quantitative indicators used to assess the model's effectiveness. The three indicators' calculation formulas are as follows:

$$\begin{aligned} \text{Accuracy} &= \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}}, \\ \text{Precision} &= \frac{\text{TP}}{\text{TP} + \text{FP}}, \\ \text{Recall} &= \frac{\text{TP}}{\text{TP} + \text{FN}}, \\ F1 &= \frac{2 * \text{Precision} * \text{Recall}}{(\text{Precision} + \text{Recall})}. \end{aligned} \tag{4}$$

The experimental results of each algorithm on the DEAP dataset are shown in Table 3. Since the presentation method in the form of a table cannot visually show the small gap between the numbers, this article compares and displays the experimental data of each method on different indicators and different emotional dimensions in the form of legends, as shown in Figure 3.

The above simulation data illustrate that the overall recognition effect on the Valence dimension is the best, followed by Arousal, and the worst is Liking. Comparing the recognition results of each model, first of all, the machine learning representative algorithm SVM performs the worst, which shows that for EEG-based classification tasks, the deep learning algorithm has more advantages in terms of recognition accuracy. Second, comparing each deep learning model, the classification accuracy of each model is between 0.7 and 0.9. CNN, RNN, [39], and [40] are all below 0.8. The classification performance of LSTM is good. This is due to the fact that, despite being an RNN variant model that inherits most of the RNN model's characteristics, LSTM solves the vanishing gradient problem caused by the gradual reduction of the gradient backpropagation process, thereby improving model classification performance. The recognition accuracy of DNN has risen to more than 0.8. This demonstrates that increasing the number of network layers can improve the model's classification accuracy. Based on DNN, the model in this article has increased Accuracy, Precision, and $F1$ by 3.48%, 7.05%, and 9.07%, respectively, in the Valence dimension. In the Arousal dimension, Accuracy, Precision, and $F1$ increased by 4.6%, 6.31%, and 2.44%, respectively. In the Liking dimension, Accuracy, Precision, and $F1$ increased by 4.82%, 6.05%, and 2.1%, respectively. It can be seen that no matter which dimension it is, the recognition effect of the model in this paper is improved by more than 4 points compared with DNN. This fully demonstrates the effectiveness of this method in processing the input feature data.

This experiment records the classification accuracy and loss of the proposed method in the Valence dimension of the training set and the test set at different epochs. Figure 4 illustrates that when the training round reaches about 25 in the training set, the model gradually tends to be stable. At this time, the loss value is reduced to 0.082, and the accuracy rate reaches 0.9124. In the test set, when the number of training rounds reaches about 40, the model gradually

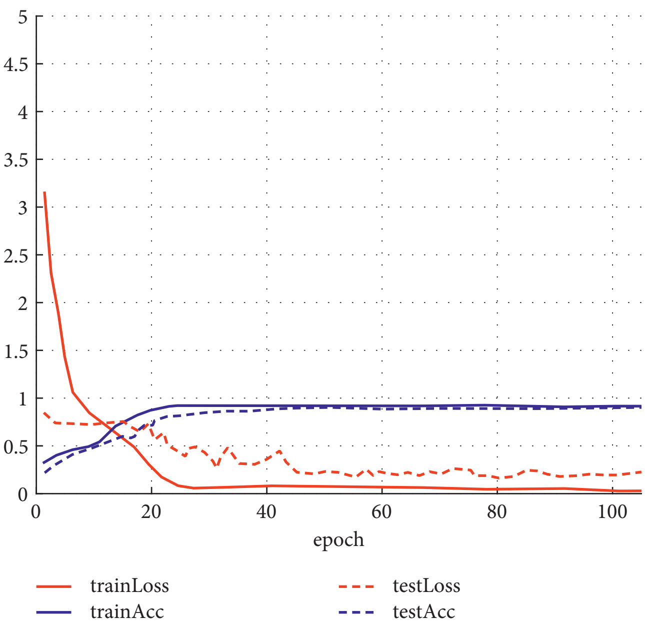

FIGURE 4: Loss and accuracy of training and test sets in Valence dimension.

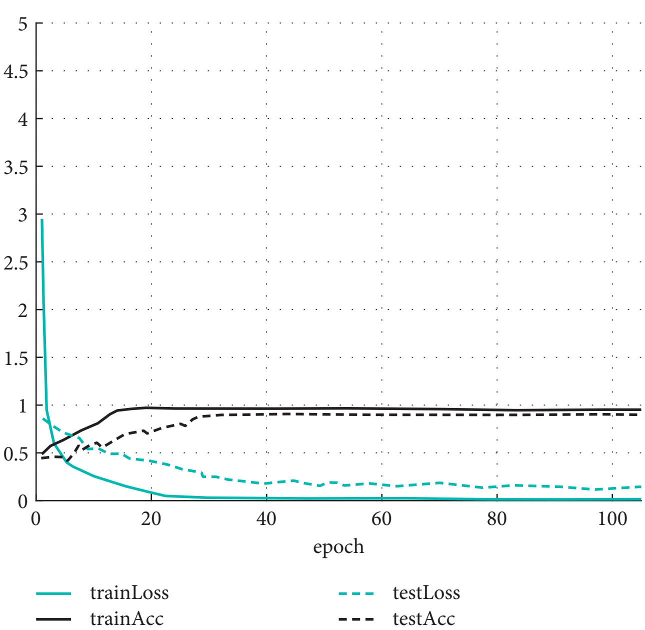

FIGURE 5: Loss and accuracy of training and test sets in the Arousal dimension.

stabilizes. At this time, the loss value is 0.2633, and the accuracy reaches 0.9078.

The experiment also records the classification accuracy and loss of the model in the training set and the test set in the Arousal dimension under different epochs. Figure 5 shows when the training round reaches about 20 in the training set, the model gradually tends to be stable. At this point, the loss value is 0.086, and the accuracy is 94.79%. In the test set, when the number of training rounds reaches about 30, the model gradually stabilizes. At this time, the loss value is 0.1703, and the accuracy reaches 90.21%.

Figures 4 and 5 show that the training set's classification accuracy and model convergence speed are greater than those of the test set. However, there is still overfitting, which has an impact on the final classification effect. Therefore, the improvement of the overfitting phenomenon will also be the content that needs further research in this article in the future. It can be expanded by increasing the amount of data, regular terms, or reducing the complexity of the model.

5. Conclusion

The identity and characteristics of college students are not the same as other students. They are relatively independent and have a certain rudimentary understanding of society and their own responsibilities. They are under increasing pressure in their studies, life, work, and other aspects as society and technology develop. College students' mental health is receiving increasing attention. The emergence of the epidemic in recent years has caused the global economy to suffer. Employment has dropped sharply, and college students' job-hunting and living pressures have intensified. Multiple internal and external pressures make the number of students with mental health problems increase year by year. If students with psychological problems can be identified as soon as possible and given timely and appropriate psychological counseling and help, many tragedies can be reduced. In order to detect students with mental health problems as early as possible, it is necessary to grasp the psychological state of each classmate as accurately as possible and be very clear about the emotional changes of students. Therefore, this article proposes an emotion recognition method based on EEG data. Considering that different features can represent different information from the original data, in order to express the original EEG data information as comprehensively as possible, various features of the EEG are first extracted. Second, use the autosklearn model integration technology to perform feature fusion on the screened features. Third, input the fused features into the DNN to get the final classification result. The experimental results demonstrate that the method in this article has a good effect on the emotion recognition of college students. The method shows certain advantages in public datasets, and the accuracy of emotion recognition exceeds 88%. The advantage of this method is that the recognition results based on physiological data are more accurate, and the recognition results are close to 90%, which can be applied in real life. However, there is still room for further improvement in this study, such as continuing to improve the recognition accuracy and how to easily collect EEG data in real life. The emotion recognition results of college students should not be limited to the application of mental health but can also be extended to classroom teaching. In the process of classroom teaching, if teachers can obtain real-time emotional changes in students, they can better promote the improvement of teaching methods. For example, when the teacher explains a certain knowledge point, some students are obviously anxious, indicating that these students do not understand the content of the teaching, then the teacher can change the teaching method at this time. When the teacher explained a certain knowledge point, the students' emotion recognition results were happy and positive, indicating that the students were very interested in this part of the content. Through the emotion recognition results, the students' learning situation can be sensed in real time in the classroom, and teachers can dynamically adjust their teaching methods and teaching progress according to the obtained results. On the other hand, although the EEG-based emotion recognition system is accurate, the data collection is inconvenient. Therefore, it is also important to develop a collection device that is convenient, fast, and low-cost and does not affect students' classroom learning.

The goal of this research was to provide a new approach for analyzing orthodontic teeth arrangement inside oral depending on the rotation matrix computation and resistance detection. The present method includes the following operations within a certain therapy period: first three-dimensional positions of the tooth were evaluated with a pierced laser beam and a three-dimensional system of surface-scanning. Second, the three-dimensional shape data was automatically registered at maxillary 1st molars, and methods of coordinate had been normalized. Third, a translation vector and rotation matrix had been evaluated from automatic registration of two position data of a particular tooth. Fourth, the limited spiral axes of teeth had been measured as the zero rotational dislocation locus; and impressions for a model of the dental cast had been taken at five different points: shortly before and after device was fitted, and ten days, one month, and two months after the treatment started. The results showed that existing analysis approach could more quickly classify a specific tooth's movement by spinning all over and translating along a finite helical axis. It can provide statistical visual three-dimensional data on complex tooth arrangement throughout orthodontic therapy.

1. Introduction

The orthodontic tooth arrangement is a complicated biological process characterized by the periodontal tissue's gradual reactions towards the biomechanical stimuli [1, 2]. The size, direction, and moment–force ratio of the force applied and physiological state of each patients' periodontal tissue substantially influence tooth arrangement [3–5]. Even though such studies only used a one or 2-D investigation, other morphometrical and theoretical studies about tooth arrangement have provided considerable information [6–9]. Moreover, all these investigations only explain the first tooth arrangement even before periodontium undergoes degenerative modification [10–13]. A statistical analysis utilizing the finite-element method produces a three-dimensional stress distribution throughout periodontal tissue and three-dimensional tooth dislocation under different loading conditions [13, 14].

The aim of this research had to create a new approach to evaluate the orthodontic teeth arrangement focusing on the calculation of rotation matrix, focusing on the precision of three-dimensional surface measurement and analysis of limited helical axis, for providing health-care professionals with accurate visual information [15, 16]. The main features of orthodontic treatment include jaw relation, tooth size, and tooth alignment [17, 18]. An oral cavity is examined, radiographs are evaluated, and dental casts are evaluated in order to collect the essential data for treatment decisions [19, 20]. However, from the perspective, there are limitations in correctly seeing the palate, lingual surface, and occlusal [21]. Furthermore, imprint treatments may be painful for the patient and need more chair duration [22, 23]. In addition to the logistical and financial challenges, the plaster casts require physical storage space. Furthermore, dental plaster casts visual examination does not allow physicians to check, measure, or monitor orthodontic tooth arrangement and the root region of surrounding bone [24, 25]. With each subsequent activation of the device, the application of orthodontic force via the appliance adjusts the teeth in progressive stages [26]. As shown in (Figure 1), symmetrical characteristics of the dentition are used in the reconstructed-based identical matrix point approach, a novel method of analyzing tooth arrangement [27].

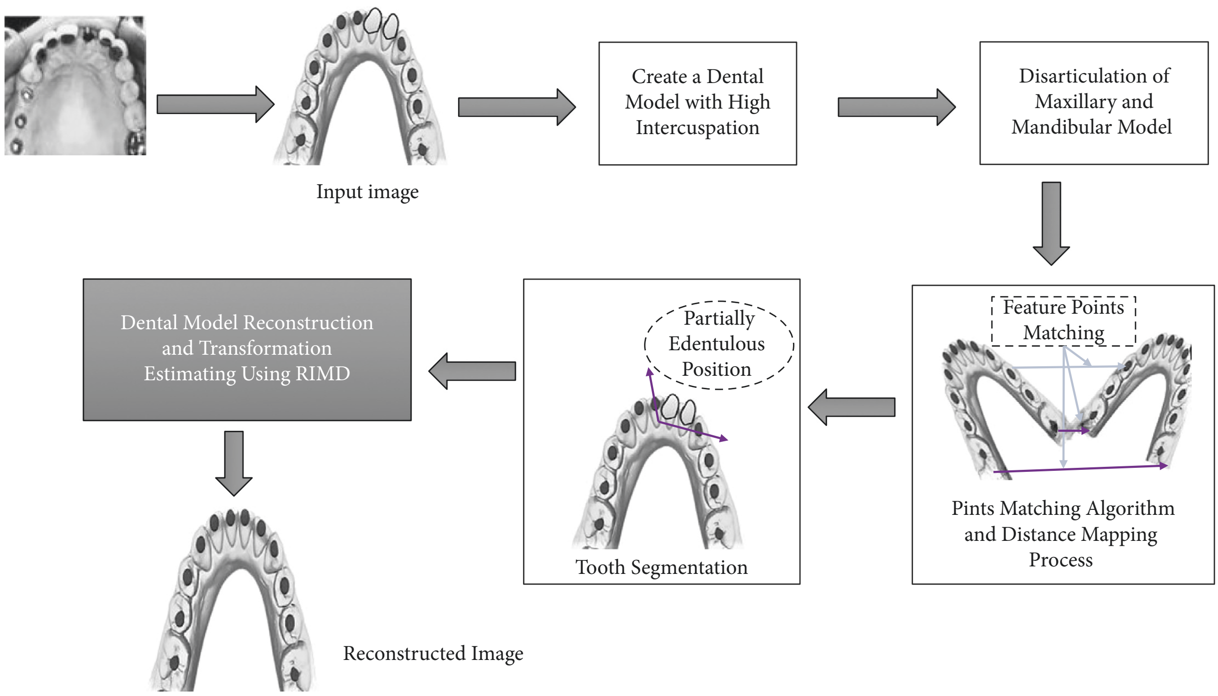

Figure 1: Overall design of reconstructed-based identical matrix point.

2. Literature Review

Saratti et al. [28] conducted a comprehensive literature search employing PubMed, a database of Cochrane Library, and Google Scholar. They provided up-to-date details on two issues. The first one was how natural tooth tissues combined to make architecture as strong, tough, and resistant to strain faults the tooth. The second was how 'bio-inspiration' was being implemented to develop and manufacture restorative dentistry while considering the limitations of existing dental methods. They expressed that bio-inspired principles had previously been effectively employed to improve the strength and toughness of artificially made materials in various engineering sectors. They highlighted that three-dimensional printing techniques also provide a novel and promising avenue for rebuilding dental tissues. Anil et al. [27] used a reconstructed-based identical matrix point (RIMP) approach to build a new way for re-establishing dental occlusion. They rebuilt the curvature of dental areas utilizing distance mapping to save calculation time. They also employed a technique of iterative point matching for precise re-establishment. They used a setup of dental experimental with high-quality digital camera pictures to examine satisfactory restoration and occlusion testing. Their suggested RIMP outperformed traditional approaches like GLCM, Fuzzy C Means, PCR, OGS, and OPOS in terms of the overall accuracy of 91.50 percent and an efficiency of 87.50 percent.

Schneider et al. [29] proposed optical coherence tomography, a revolutionary image-based approach that had significant potential in aiding regular tooth examination. They expressed that the cross-sectional pictures acquired were simple to comprehend and process. They observed that multiple uses of OCT in cariology had been studied, ranging from detecting various problems to restoration monitoring and reporting or the visualization of therapy processes. Their review based on chosen cases described the potential and limits of their approach in cariology and restorative dentistry, which were the most clinically essential domains of dentistry. Patil et al. [21] focused on polylactic acid, acrylonitrile styrene acrylate, polymethylmethacrylate, and limpet teeth (a mixture of chitin and goethite). They investigated the performance of novel materials using analytical and experimental approaches. However, they expressed that J-OCTA software had overcome experimentation-related difficulties such as costs and time. They concluded that compared to other simulation tools, this approach worked on the molecular dynamics principles to study the efficiency of the soft materials having more precision. They highlighted that the experimental techniques provide erroneous findings, while the analytical methods are confined to smaller materials because each particle has rotational and translational velocities.

Cho et al. [25] used atomistic simulations and sole fiber/microdroplet pull-out experiments in micro-scale to undertake a comparative study on the behavior of interfacial adhesion of short glass fiber and matrix of dental resin. They determined the interfacial shear strength at the molecule level by adding a factor of scale to the glass fiber. They compared the simulation findings to experimental findings of pull-out experiments. They expressed that both results confirmed the improved, reinforcing effects of modifying the surface with agents grafting of silane coupling on glass fibers. Furthermore, they investigated the mechanical characteristics and dynamic behavior of dental materials under transverse and longitudinal tension loadings that were using free volume variations. The results of their study provided optimum design recommendations for accurately predicting the mechanical properties of short fiber-reinforced dental composites using simulations, molecular dynamics, and testing. Lopez et al. [30] used a laboratory test that replicated the clinically apparent wear aspects to investigate wear processes inside a dental materials suite with a ceramic element and tooth enamel. They employed a tetrahedral ball-on-3-specimen analyzer with a revolving challenging opponent zirconia sphere to induce circular wear marks on the surface of dental composites using artificial saliva. They expressed that wear scars images allowed for the analysis of wear processes, while measurements of scar dimension quantify abrasive wear. They explained that Zirconia ceramics had the lowest rates, while lithium disilicate had the highest, having feldspathic ceramics and ceramic–polymer composites in the middle. They discussed that examination of fatigue scars showed surface residues, indicating a material removal process at the microstructural level. They accounted for mild and severe wear zones for utilizing microcracking and microplasticity models. They also used w ear models to assess the possible lifespan of various dental materials. They concluded that wear damage would produce significant material loss, resulting in early tooth or prosthesis failure.

Tahir et al. [31] suggested and tested a simulator of mechanical mastication that would simulate the force cycle of human rumination and record the requisite interactive loading via specially constructed force sensors. Their suggested method made the tooth-replacement surgery easier. They discussed that PKM completed a mastication cycle with six degrees of freedom, allowing any movement and rotation in the horizontal, vertical, and sagittal planes. Their proposed mechanism had a force transmission range of approximately 2000 N and would imitate the mastication cycle of humans. Their constructed load-sensing device would capture interactive forces ranging from 200 N to 2000 N using rapid reaction and high sensitivity to establish a simulator mechanical mastication using custom-made modules. Wei et al. [26] presented a learning-based strategy for quickly and automatically arranging teeth. They constructed the task of tooth arrangement as a unique structural 6-DOF pose estimation problem and resolved it by presenting a novel neural network structure to train from a vast number of clinical studies encoding successful orthodontic treatment instances. They claimed that extensive studies had confirmed their strategy, which yields promising descriptive and analytical results.

Zhang et al. [32] proposed a multi-manipulator tooth arrangement approach for full denture production. They suggested a revolutionary entire denture production method using a generator of dental arch and a multi-manipulator. They used an analytical technique to build the kinematics version of tooth arrangement of a multi-manipulator robot based on the concept of tooth arrangement for a complete denture. Their proposed multi-manipulator tooth-arrangement robot was used for preliminary tooth-arrangement tests. As per the jaw arch specifications, their multi-manipulator tooth-arrangement robot can autonomously design and produce a set of complete dentures for a patient. Their experimental findings confirmed the validity of the kinematics concept of the multi-manipulator tooth-arrangement robot and the viability of the whole denture manufacturing strategy implemented by the multi-manipulator tooth-arrangement robot. Cheng et al. [33] explained a newly created virtual, customized, and precise tooth arrangement mechanism based on comprehensive dental root and skull information. They made a feature-limited database of a three-dimensional tooth model. Second, they established anatomical points of reference, the reference lines and planes for tooth movement computational simulation. They thoroughly exploited the corresponding mathematical formalism of the tooth pattern and the concept of the stiff body's unique posture transformation. Their experimental findings suggested that the approach of virtual tooth arrangement would successfully arrange aberrant teeth and was suitably flexible. Their newly designed method was distinguished by its high-speed processing and quantitative measurement of each tooth's level of three-dimensional movement.

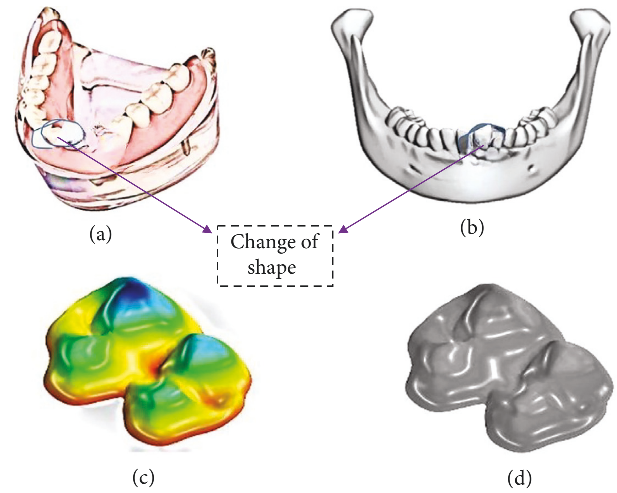

Figure 2: (a) Full mandibular model. (b) A component of mandibular model chosen. (c) The triangular mesh's foundation. (d) Cloud point as seen with the MATLAB-based toolbox.

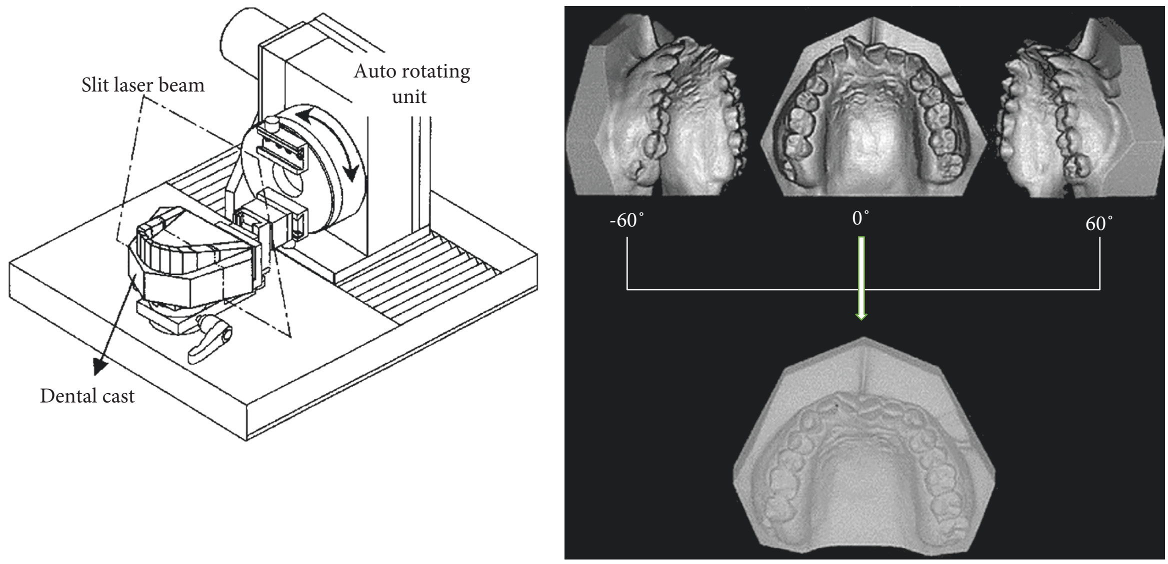
3. Methods

To put the existing procedure to the test, a male patient of 22 yr two months had been examined in the Dental Hospital. The hospital treated the patient's Angle Class III malocclusion with anterior teeth modest crowding with a tool of multi-bracket. Conventional hooks with edge of 0.460.64 mm standard slot size were used for the primary leveling and arrangement, together with 0.41 mm hardened Ni–Ti round wire as well as a rectangular wire of 0.41 mm to 0.410.56 mm. The paired maxillary initial molars related to a bar of transpalatal to improve anchoring as well as provide immovable reference features for superimposition. The models of d dental cast were generated at each step employing alginate impressions made by die stone. A model of complete mandibular is presented in Figure 2.



(a) (b)

Figure 3: (a) Three-dimensional strategy of surface scanning and a three-dimensional scanned shape of maxillary dental casts (b).

3.1. Printing Models of Dental Cast. Prints for models of the dental cast took 5 times: instantly before and after the appliance has been implanted (T0 and T1), ten days (T2), one month (T3), and two months with (T4) right after treatment started. To test the dental cast reproducibility, a model of proxy dental with the marks of hemisphere (reentrants; 3 mm in diameter) to the maximal incisor of right central and bilateral maximal first molars has been used as a template. A point of reference was placed inside the center point of every re-entrant. We created five alginate impressions, as well as die stone cast replicas. The points of reference distance were calculated 5 times on prototype as well as five duplicate models using a three-dimensional CNC of high-precision measurement machine. The average distance disparities between the duplicate models and prototype were calculated. The dental castings were calculated with a three-dimensional surface-scan machine equipped with the splitting laser beam known as VMS-150RD, UNISN, Japan. The system included a slicing laser projector, 2 CCD (charge-coupled device) cameras, a mounting unit with the auto-rotating feature, and one PC (Figure 3(a)). An X-axis resolution had been 0.01 mm, while the 0.1 mm resolution of the Y-axis.

A three-dimensional shape system of data-analysis composed of (Zx1, Intergraph) graphic workstations (Surfacer, Image ware) data-processing and -analyzing software and (Visual C++ 5.0, Microsoft), a newly constructed numerical and analytical program was utilized to demonstrate the limited helix axis.

Dental casts were scanned with three orientations to decrease blind areas by rotating the auto-rotational positioning unit of the computational tools. The post-processor combined the three data files into a single file (Figure 3(b)). It was used to test the measurement precision of the three-dimensional measuring equipment by measuring a calibration plane plate, and the best-fitted equation for plane was derived on all data inside about 73 seconds utilizing the least-squares approach. The most significant divergence between the projected plane and the actual data was used to assess the measurement accuracy. The placement of dental cast on auto-rotating modules remained random while scanning. A standard coordinate system must be built to predict tooth-arrangement three-dimensionally relying on the three-dimensional shape. Many fixed components known to every model had been chosen as superimposition points of reference. This study selected the maxillary 1st molars as registered components as they had been relatively stable after treatments. Registration conducted automatically (automatically, registration was built-in Surfacer software function). Figure 4 depicts the pre- and post-treatment normalized three-dimensional shape data for maxillary teeth.

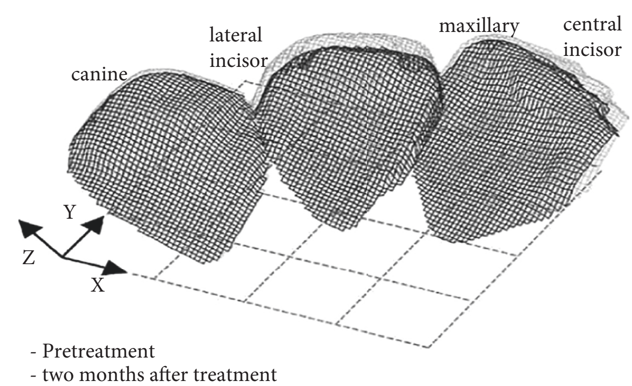


Figure 4: Before and after treatment view of a normalized three-dimensional anterior teeth. Black represents before treatment, and gray represents two months after the therapy.

3.2. Difference between Maxillary and Frontal Teeth Normalized Images. The difference between maxillary and

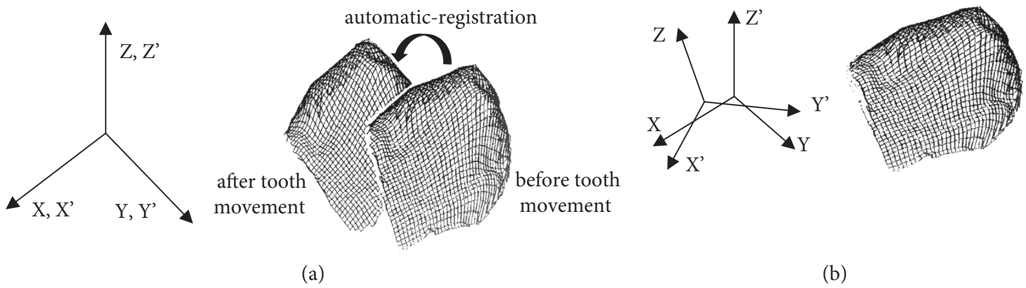

FIGURE 5: A coordinate system of automatic registration for assessing tooth arrangement is known as before-&-after registration. The coordinate systems ($x0$, $y0$, $z0$) and $P(x,y,z)$ adhere to tooth arrangement before-&-after.

frontal teeth normalized photos was defined as the tooth arrangement. A vector of translation and a matrix of rotation generated by adding the three-dimensional shapes before as well as after tooth arrangement could be utilized in (Figure 5) to represent the arrangement of a single tooth. Employing the least-squares technique to investigate the error of mean fitting for an automated registration of three-dimensional structures, a mean three-dimensional distance with every tooth point towards its closest neighboring point seen between points' sequences on the two registered forms was determined for every treatment point [34]. In the existing investigation, we employed a minimization strategy utilizing commercially using software to build a rotation matrix from autonomously recorded location data, and after, we also used the resulting matrix to predict the helical axis. After movement, every point of P (x^0, y^0, z^0) on the three-dimensional form was represented in the system of coordinate X, Y, and Z as a factor of six translations as well as rotation constants. So, Figure 3 depicts the three-dimensional dislocation of $P(x,y,z)$ with three-dimensional form prior to movement.

The formula is determined by

$$m = An + o, \tag{1}$$

where A depicts the 33-rotation matrix, m represents the arbitrary point position vector after the tooth arrangement, n shows the position vector of arbitrary point before arrangement, and o depicts translation vector. After that, tooth arrangement in three-dimensional space was identified as a p displacement vector with $(x' - x)$, $(y' - y)$, & $(z' - z)$ components. This motion includes both rotation and translation. Equation (2) is used to describe the (P) displacement vector.

$$p = (A - K)n + o. \tag{2}$$

K depicts the unit matrix that is also an initial coordinate's function. The 33 matrix A represents the all-around rotation axis that passes through the origin as well as parallel to a limited helical axis. Because the displaced vector p only runs parallel towards the limited helical axis and therefore is undisturbed by rotations for locations on this axis, this axis position has been given by

$$p = A^T p. \tag{3}$$

As a result, Equation (2) is multiplied by the AT and also applying the relationship within Equation (3).

$$(A - K)n + o = (A - K)n + A^T o. \tag{4}$$

Equation (4) becomes

$$\left(A + A^T - 2K\right)n + \left(K - A^T\right)o = 0. \tag{5}$$

Equation (5) becomes

$$\frac{d}{db} = \left\{\left((A - K)n + o^T (A - K)n + o\right)\right\} = 0. \tag{6}$$

This produces the locations n with the smallest displacements and resides on the limited helical axis. The relationship in Equation (6) holds at all positions along the helix axis. Though not distinct, the solution may be achieved by swapping the value for the component of Z.

When the b has been selected on a limited helix axis, as calculated by Equation (1), it is also on the same axis. A translation p with a limited helical axis equals to the distance between a and b. Following that, an arbitrary point d_0 was picked outside of a helix axis, and also its location after arrangement of tooth d_1 had been determined once again using Equation (1):

$$d_1 = Ad_0 + o. \tag{7}$$

Further, the d_0 and d_2 ($d_2 = d_1 - v$) orthogonal projection on helical axis calculated as

$$q' = q + \frac{(d - q).h}{h.h} h, \tag{8}$$

wherein q^0 is a point's position vector on the helical axis, q depicts any point's position vector on helix axis, d is either d_0 or the d_2, and the helical axis direction. Thus, this angle of rotation within space around a limited helical axis is just like angle among d_0, q^0, and d_2.

4. Results

Dental cast means the error was 0.07 mm from the incisor of right-center towards right 1st molar, 0.05 mm towards left 1st molar, and 0.04 mm for both the right and left 1st molars, showing that the die stone had slightly expanded during the setting process. Their standard deviations remained 0.04 mm or less. The three-dimensional measuring instrument has a

Table 1: Maximum errors also known as fitting error for the automated registration employing the method of least squares (mm).

Stages	Canine	Central incisor	Lateral incisor
T0–T1	0.05	0.05	0.05
T1–T2	0.04	0.04	0.04
T2–T3	0.03	0.02	0.02
T3–T4	0.02	0.03	0.03
Mean	0.04	0.05	0.05

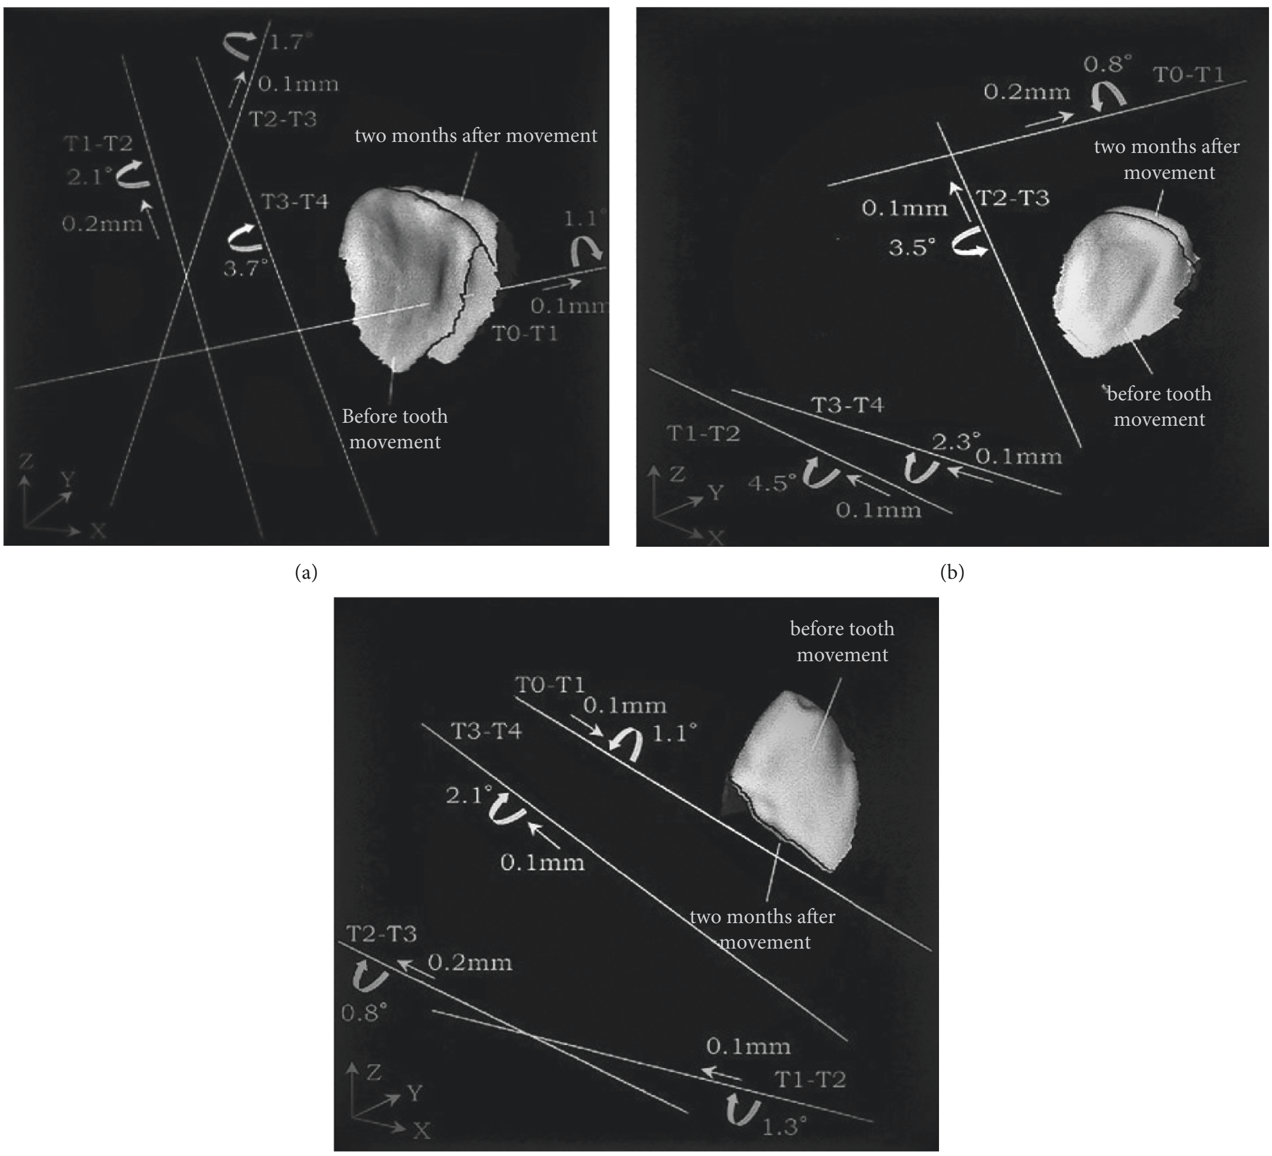

Figure 6: Graph depicting the three-dimensional displacement of the maxillary right centralized incisor, canine as well as lateral incisor during two months of therapy. The angle of rotation and amount of translation with a helical axis is++ used to indicate tooth movement. T0: shortly before device application; T1: instantly after device implementation; T2: Ten days of treatment; T3: one month of treatment; T4: Two months after therapy. The white bar represents the rotation axis; the curved arrow represents the rotation angle; and the little straight arrow represents the translation amount.

seven 0.05-mm measurement accuracy. The lateral incisor, centralized incisor, and canine had to mean fitting errors of 0.05, 0.05, and 0.04 mm, correspondingly (Table 1). The helix axis of the right central incisor would be within the crown and almost orthogonal to lingual surface of crown throughout T0 to T1 (Figure 6(a)). An angle of helical axis

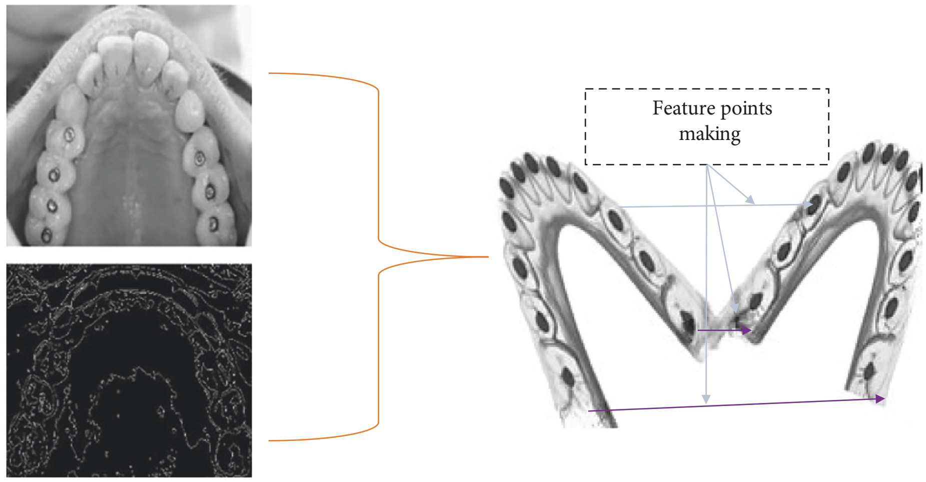

Figure 7: Proper articulation of dental prototypes.

rotation had been 1.11, and the lingual translation became 0.1 mm. In the first ten days of therapy, this helical axis migrated almost orthogonal to the occlusal plane (T1 to T2). Their occlusal translation approximated 0.2 millimeters and 2.11 degrees of the rotation angle. From ten days to one month after therapy (T2 to T3), the helix axis migrated labially and was almost parallel to tooth's long axis. The occlusal displacement gave 0.1 millimeters and 1.71° rotation angle. Their helical axis migrated palatially from one to two months after therapy (T3 to T4) and was approximately parallel to a helical axis through T1 to T2.

The translation was minimal, and the angle of rotation was 3.71. These data imply that immediately after the device was implanted, the center incisor translated considerably labially along with palatal tilt, then twisted histologically and pointed labially with the intrusion. The maxillary helical axis of the right lateral incisor was outside from crown and also was about 451 to the tooth's long axis from T0 to T1 (Figure 6(b)). The labio-occlusal translation measured value was 0.2 millimeters, and the rotation angle became 0.81°. From T1 to T2, a lateral incisor migrated significantly. At the root surface, the helix axis changed and nearly paralleled to the occlusal plane. Their distal translation approximated 0.1 millimeters, and the rotation angle was 4.51°. The helix axis of the tooth migrated towards the disto-palatal axis with a twist of 3.51 and an occlusal movement of 0.1 millimeters from T2–T3. T3–T4 saw a similar shift in the helical axis of T1–T2. The distal translation approximated 0.1 millimeters, and the angle of rotation became 2.31°. Its lateral incisor first inclined palatal, later labially by the intrusion, twisted mesio-labially, and ultimately slanted labially with invasion with these data. The helical axis of maxillary right canine was nearly parallel towards an occlusal plane during T0–T4, while direction of rotation and translation altered after T1 (Figure 6(c)). These actions included jiggling of labio-lingual.

5. Discussion

In this work, we used a screw axis, also known as a helical axis, to measure the three-dimensional motion of a solid body to investigate the arrangement of specific teeth compared to standard teeth [35, 36]. Woltring cross-validation method [37] illustrated that the angle of rotation and translation has become relatively well-focused. Still, the direction and position of the helix axis has been greatly sensitive to calculations errors of landmarks, particularly for the little rotations, the long distances towards the center of gravity mean of the monuments, and also small monument sizes of distribution. In the current work, we studied dental cast repeatability, the measurement precision of three-dimensional system of surface scanning, and a maximum superimposition error employing least-squares technique, and all errors would be within 0.05 millimeter range.

The number of orthodontic tooth arrangements differs across patients and therefore is determined by the force direction, moment–force ratio, force magnitude, and periodontal tissue quality [31]. The horizontal arrangement of a buccal cusp points of the maxillary premolars under a constant force of 0.5 N was calculated towards being 1.7 mm (ranging 0.5–3.4 mm) and 4.3 mm (range 2.7–7.1 mm), correspondingly, after 4 and 7 weeks. After four weeks, the tooth arrangement varied from 0.2 to 2.2 mm when a pressure of 1 to 1.5 N had been implemented towards the maxillary canine [38]. As a result, the current method's accuracy is enough to examine the orthodontic tooth arrangement. As shown in (Figure 7), when the feature points of camera photos are matched, the dental prototypes are appropriately articulated.

Translation (movement of the body), rotation (tipping motion), or a mixture of the two is caused by orthodontic force. The model of tooth arrangement is established by how the force's route of action correlates to the teeth's center of reluctance [27]. Traditionally, 1 or 2 two locations in the teeth were selected as points of reference [39], and the center of rotation position defined the final tooth arrangement [40]. When a horizontal force is given to the lingual surface, it induces simple rotation (tipping) along the root's bottom half. The present research clearly shows that the arrangement of orthodontic tooth is complex and varies greatly from past study data, specifically in severe crowding. The original tooth position and force applied to the teeth, and the

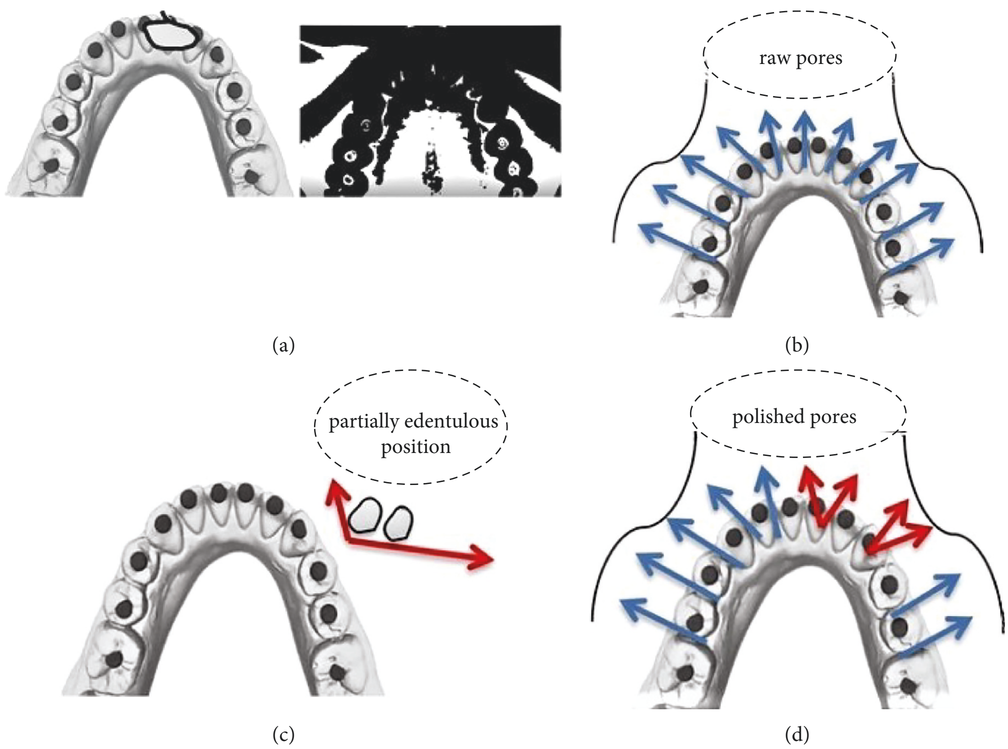

Figure 8: (a) Image selection for dental image classification. (b) Unprocessed image. (c) Edentulous area. (d) Extensive sequence.

contact conditions and movement behavior of surrounding teeth all influence orthodontic tooth arrangement. Surprisingly, the rotational axis position changed significantly throughout treatment stages, even though this was assumed that the rotational axis location would change gradually and consistently during tooth arrangement. Nevertheless, part of the axis variability might be attributable to measurement mistakes. A complete investigation of the accuracy of the axis parameters utilizing a new setup of the experiment would be required. The four stages of tooth arrangement and sequences are shown in Figure 8.

In this work, we created a new way to analyze orthodontic tooth arrangement that may provide orthodontists with accurate visual data on the tooth arrangement and may be a helpful strategy for developing an orthodontic technique. Moreover, three-dimensional data on teeth arrangement during therapy would enable orthodontic tooth-arrangement modeling, which might be included in treatment planning. The better architecture and the cheap treatment of orthodontic tooth arrangement would be an area of interest in future.

The relationship between urban public art and regional environment based on wireless network technology is studied. Combining domestic specific cases and referring to sociology, art, and design thinking, combing about the relationship between the city's public art and the regional environment, and further integration of its relationship components, at the same time, the planning study of Changning district, Shanghai, and the actual operation of the Shanghai Pudong International Airport, which incorporates the regional mesolevel background, are examples for case analysis. In reference cases and practical cases, they are deduced in sequence, starting from the environmental context of urban areas to the evolution model of public art. Moreover, the specific event background also constitutes a special opportunity period for the sudden growth of public art.

1. Introduction

There are two phases to the development of public art in contemporary China. The first is Hong Kong and Taiwan's earlier experience of absorbing the development of foreign public art and establishing independent institutions to promote the development of urban public art [1]. Furthermore, in recent years, major cities on the Mainland, such as Shenzhen, Beijing, and Shanghai, have actively conducted public art theoretical research and preliminary practical projects. Taiwan began researching and promoting public art such as fire and tea in the early 1990s, and in 1992, the "Regulations on Cultural and Arts Awards" were passed, defining the percentage of public art policies in Taiwan [2]. Every year since 1998, the competent authorities in charge of Taiwan's public art policy and implementation have compiled a "Yearbook of Public Art." Simultaneously, he paid close attention to public art cultural studies, actively organized social resources, and published a large number of related works during Taiwan's development of public art. Hong Kong's public art has followed Taiwan's lead, and it has grown rapidly in the first decade of this century. The Hong Kong Arts Centre serves as the implementing agency for Hong Kong's "Public Art," which was established in 2005 to promote the interaction of the arts, space, and the public. Its goal is to transform Hong Kong into a culturally vibrant metropolis. Interiorly, modern public art was enlightened in the late 1990s and has accelerated development in the last five years [3]. On the one hand, the advancement of public arts is linked to the advancement of the social environment, and on the other hand, it develops rapidly in the context of major historical events such as the Olympics and the World Expo [4].

2. State of the Art

The related topics of public art in China are based on the practical process of combining art with architecture and urban environment in the modernization after the reform and opening up. Whether it is the construction of murals or the development of urban sculptures, public art is involved in contemporary urban construction in various ways. In the face of vigorous development of practice, public art has lagged far behind in theory, breadth, and depth of research. Until the end of the 1980s, a group of well-known artists have conducted in-depth reflection on issues encountered in public art practice. The study of public art theory was first incorporated into the overall framework of contemporary social and cultural development [5]. Despite the fact that there are no monographs on regional environmental and public art relations studies in the publications related to public art, they provide a wealth of argumentation basis and can be roughly divided into four categories based on their contents: textbooks, thematic series, works, and doctoral student publications. Textbooks, whether they are monographs or other monographs, do not place a strong emphasis on problem exploration [6]. Its research aims to guide students in understanding the public consciousness in the social crowd through the concept and characteristics of public art and the design teaching of public art works so that students master a complete theoretical system and design method of public art design and then serve as a public art for students and the foundation of design ability and continuous research ability training [7]. As far as the research of this topic is concerned, these contents are the basic theory and case reference basis for the expansion of public art research. At the same time, from the compilation of a large number of public art related textbooks, it can be seen that public art is becoming a focus of training in domestic universities [8].

3. Methodology

3.1. Performance Analysis Algorithm Based on Key Chain Wireless Sensor Network Management Solution. It is possible that the above system will satisfy the security requirements of group key management in sensor networks [9–11], such as group key confidentiality, forward secrecy, and backward secrecy. We select k objects from n data objects to serve as the initial clustering centers and then group the other objects together based on how similar (or how far they are from these cluster centers) they are to these cluster centers (represented by the cluster center). Following that, the new cluster center value should be calculated (that is, the average of the objects in each cluster). This is repeated until the criteria function is no longer divergent. K objects $c_1, c_2, \ldots, c_K$ are randomly selected from the set of n objects $\{x_1, x_2, \ldots, x_n\}$ as the center of the initial K sets of clusters. Taking K objects $c_1, c_2, \ldots, c_K$ as the center, each object is divided into the most similar collection. The specific division principle is as follows: if $\|x_i - c_j\| < \|x_i - c_m\|, \quad m = 1, 2, \ldots, K; i = 1, 2, \ldots, n$ and $j \neq m$ divide x_i into the collection C_j. We calculate the average of the objects in each newly-collected object collection: $\overline{x_i} = 1/n_i \sum_{x \in C_i} x, i = 1, 2, \ldots, K$, where n_i is the number of objects in the collection C_i, so $C_i = \overline{x_i}, i = 1, 2, \ldots, K$. Calculation criterion function E is

$$E = \sum_{i=1}^{k} \sum_{x \in C_i} \left\| x - \overline{x_i} \right\|^2. \tag{1}$$

As a last resort, it is proceeded through step 2 until E does not appear to be changing any more. Because it is simple and rapid, the K-means algorithm [12] is a common solution for tackling the clustering problem. As a result, the approach is very scalable and efficient for processing big data sets, with a complexity of (n.k.t), where n is the total number of objects processed, k is the total number of clusters processed, and t is the total number of iterations processed. In the vast majority of circumstances, $k + n$ and $t + n$ are employed. The K-means method, on the other hand, has some shortcomings, including the following: because of the initial cluster center selection, it is possible that the K-means algorithm will converge to the local optimal solution before it is ready. When dealing with "noise" and outlier data, it is extremely sensitive, and even a small bit of it can have a significant impact on the average. The frequency distribution is defined as the distribution of the number of random events that occur in a certain number of trials (n trials in total). Variance is defined as the arithmetic mean of the square of dispersion. Specifically, the difference between each data in a group of data and the average of the group squared, summed, and divided by the number of data, represented by σ_X^2. Its definition formula is

$$\sigma_X^2 = \frac{\sum (X - \overline{X})^2}{N}. \tag{2}$$

Among them, $X - \overline{X}$ represents the dispersion (that is, the difference between each data and the average), $\sum (X - \overline{X})$ represents the sum of deviations, and N represents the total frequency. The standard deviation is the square root of the dispersion and the average square root. The square root of the variance, represented by σ_X. Its definition formula is

$$\sigma_X = \sqrt{\frac{\sum (X - \overline{X})^2}{N}}. \tag{3}$$

The standard deviation and variance are two fundamental markers of variation between two groups. It is important to square and make the variance a positive number since the dispersion of each data point and the average is positive and negative, but the unit of data is also squared; therefore, the variance must be made positive. It is necessary to reopen the square in order to make the unit of difference quantity consistent with the original data. The skewness and kurtosis coefficients are statistics that are used to describe the characteristics of a data distribution. This has resulted in the inability to recover the group session key that existed prior to its inclusion. A steady-state distribution model of the Markov chain [13] is first provided in order to examine the computational overhead of the sensor nodes in the scheme, as well as the communication overhead between the key server and the nodes. A wireless sensor network's channel instability, which occurs when a node gets the key distribution message, might result in the loss of group key distribution message packets or the failure of authentication. These two events are deemed to have the same probability of occurring and can be treated as separate random events in this scenario. Because of this, it is simple to describe the key buffer status of each sensor node using a one-dimensional Markov chain, as seen in Figure 1. The state of the node $\alpha = (\sum (X - \overline{X})^3/N)/\sigma_X^3$ represents the key buffer in the node, among other things.

When a key distribution message packet is lost or when a key update message event is successfully received [14], the node status is passed to the receiving node. If the frequency distribution is not normal, then the skewness coefficient and the kurtosis coefficient can be used to determine whether or not the distribution is normal. The following is the formula for determining the skewness coefficient when working with raw data:

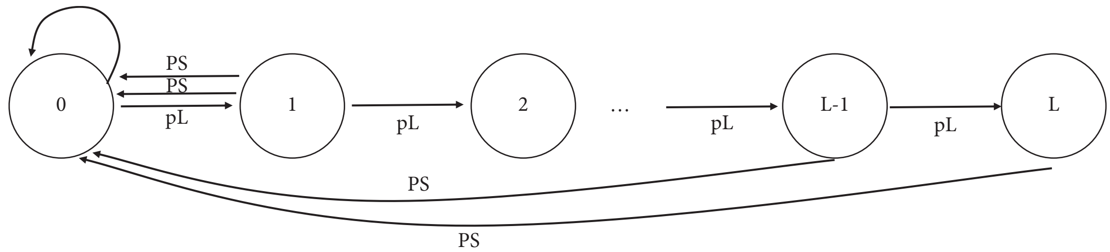

Figure 1: Diagram of sensor node state transitions.

$$\alpha = \frac{\sum (X - \overline{X})^3 / N}{\sigma_X^3}. \tag{4}$$

Among them, α denotes the skewness coefficient, X denotes the original data, $\overline{X}$ denotes the average number, N denotes the total frequency, and σ_X denotes the standard deviation when $\alpha = 0$, indicating that the frequency distribution is in a symmetrical shape, which is in accordance with the normal distribution. When $\alpha > 0$, the frequency distribution was positively skewed. When $\alpha < 0$, it shows that the frequency distribution is negatively skewed. When using the raw data to calculate the kurtosis coefficient, the formula is

$$\beta = \frac{\sum (X - \overline{X})^4 / N}{\sigma_X^4} - 3. \tag{5}$$

Among them, β represents the kurtosis coefficient, X represents the original data, $\overline{X}$ represents the average number, N represents the total frequency, σ_X represents the standard deviation, and the distribution has a normal peak. When $\beta > 0$, the distribution showed a high narrow peak, at which time the average frequency around the ratio was large. The distribution pattern is highly narrow. The relationship between the urban public art and the regional environment is first considered in its entirety, and it is related to the development of the city. Different periods of urban appeal and development have a great influence on the degree of public art. The specific integration into the urban system, with the driving force as the reference point, reflects the relationship between the urban public art and the environment. There are mainly several modes: the government-planned policy promotes the development of the regional cultural image. The method of shaping public art as an image is concentrated in the municipal squares, streets, and parks. Here, the public art represents the regional environmental aesthetics business card and the values of regional culture; the specific events are temporary breakout points. At the emergence of public art sprawl in specific areas, such core areas of public art are mainly associated with specific space backgrounds such as the Olympic Park and Expo landscape belt; there is also a combination of specific cultural site backgrounds, such as universities and monumental parks, with cultural self-building and social communication as the driving force, from the inside out public art divergent setting.

3.2. The Constitutive Relationship between Public Art and Regional Environment. John Ayer and Rigoberto Tols have been creating public art in the South Bronx of New York for 13 years. This community is the poorest area in New York City. Violence, drug abuse, and home destruction are commonplace here. Aahan and Tols used the method of living to overturn and convert the most common residents of the community into a single statue, and part of it was permanently hung on the walls of the neighborhood. Residents are honored to be able to reappear in the works of the artist and have a new experience and understanding of their own life. Maybe art does not change the living habits of these people. However, they have changed the narrow and closed concept of space here, which has transformed the residents here towards openness. Obviously, what Ai Heng and Tols pursued was not the "artistic" effect of the work but the "social" effect; the problem they were trying to solve was not the issue of beautifying the city and beautifying the environment, but rather a social issue that was due to race. The artist advocated both the affirmation of cultural diversity and the spirit of tolerance for different cultures through this creative activity, as well as demonstrating profound humanistic care for society's bottom population. The civil society places a premium on the exercise of public rights. On the people's petition, the "oblique arc" sculpture on the welfare square in front of the Manhattan Federal Office Building mentioned in Chapter 2 was demolished. Designer Serra, on the other hand, filed a lawsuit in court, claiming that this was a violation. The First Amendment Act guarantees the right to freedom of expression. The Court of Appeal, on the other hand, recognized Serra's right to freedom of expression in principle while also arguing that Serra had already relinquished his right to freedom of expression when he turned the work over to the General Services Administration. The term "slope arc" refers to property rather than expression. Some important issues in public art are addressed in the "oblique arc" debate, such as the artist's right to express, public choice, and artistic expression under the constraints of property rights. This kind of property rights and public rights awareness not only drew attention in the United States several decades ago, but it is now increasingly influencing the realization of public art in today's domestic situation. Although most people were familiar with Shanghai Pudong International Airport's "Day at the Airport" series of scene sculptures, some passengers

Table 1: Population characteristics of Changning district.

Classification	Population	Percentage of total population (%)	Compared to the previous census (%)	Ratio of the whole city (%)
65 and older	9.75 million	14.12	1.38	4
0–14 years old	4.80 million	6.95	4.24	1
All ethnic minorities	0.99 million	1.43	0.57	0.2
University level (college or above) population	25.73 million	37.26	18.04	1
Resident population	17.54 million	25.39	7.82	13

reported to the appropriate departments that one set of sculptures placed in chairs was occupying passengers. The rest, space, although the sculpture was not removed under the interpretation of coordination, it can be seen that the public is more sensitive to their own awareness of social rights, which also necessitates more careful consideration of space in the design and implementation process of public art. In China, the composition of human rights provides a more respected artistic experience for the general public. Citizens' spiritual needs are met first and foremost by contemporary urban public arts, which also promote the interaction of artistic needs. That is to say, artists use public works that are full of artistic appeal and cultural thinking to materialize social culture and public civilization in the form of public art. The public's cultural cognition is enhanced by people's cultural understanding, resulting in a socialized cultural artwork.

4. Result Analysis and Discussion

The relationship between public works of art and the environment is concerned, because the nature of the environment derived from the creation of public art is important, but this environment linkage does not need to be stereotyped as the inevitable requirements. The key is whether the installation of the work is to create a social significance for the public for the purpose of the aesthetic environment. As a result, this paper investigates and calculates using Shanghai as an example. Changning District has a permanent population of 690,600 people, 242,900 households, and an average household population of 2.49 people, according to the 2010 National Population Census results; daily residents are 334,600 men. There were 356,000 females, 21,400 more than males.

In addition to displaying basic population density data, these basic demographic data also provide some characteristics of the population environment in Changning District for the study of the project: the aging population tends to show a growing trend; the education level of the population is high; the population environment is diversified. The population has increased, the population of ethnic minorities has increased, and there is a relatively concentrated foreign population; the female population is high; the family size is small (Table 1). Therefore, focusing on the cultural life of the middle-aged and elderly people in the community as a background is a focus of public art; the protection of the local culture and the cultural context display will constitute a useful bridge between nonwoodland residents and communication; the scale of the family shows that the residents' attention to outdoor cultural life will be higher. As the East Hongqiao Business District has grown mature, its personnel education background should be higher than this average plan, which means that Hongqiao Business Centre as the energy of smart highlands will be more abundant; therefore, the artistic construction of this region also has a higher potential demand market. The promotion of public art as a means of promotion in high-quality population activity areas is also a choice to increase the satisfaction of residents in the area, and it is conducive to the formation of a virtuous cycle of comprehensive integration of talents. As is shown in Figure 2, Changning District is a comprehensive residential area with a wide range of areas and nature. From Xinli Residence to Garden House, from the grassroots community to the high-end villa area, the residential category and the nature of the residents are also distinct.

"Public art is the art of planning," says the artist. One of the ways in which it differs from conventional contemporary art and contemporary art in general is that it incorporates conscious methodological knowledge into the design process. This is the first topic to look at the interaction between public art and the surrounding environment in depth. The fundamental conclusion is concerned with the logical chain of this relationship, and the continuation is concerned with the public art methodology that is employed in urban planning. In this article, the program's overall performance is assessed and reviewed. When compared to existing schemes, the key advantage of the suggested system is that group members can choose their own personal secret information without the need for the group administrator to communicate it through a secure channel. Each member of the group is simply required to keep the identity of the persons he or she chooses a secret from the others. When it comes to storage overhead, communication overhead, and security, the performance of this project compares favorably to that of analogous solutions, as shown in Table 1; t is the maximum number of collaborators that can be accommodated by the system, m is the total number of sessions that can be accommodated by the group life cycle, and q is a prime number that matches the cryptographic key specifications. The fundamental mechanism of the layer μ UTESLA protocol is depicted in Figure 3.

Our group members can choose their own personal secret information, as seen in Figure 2, and as a result, each

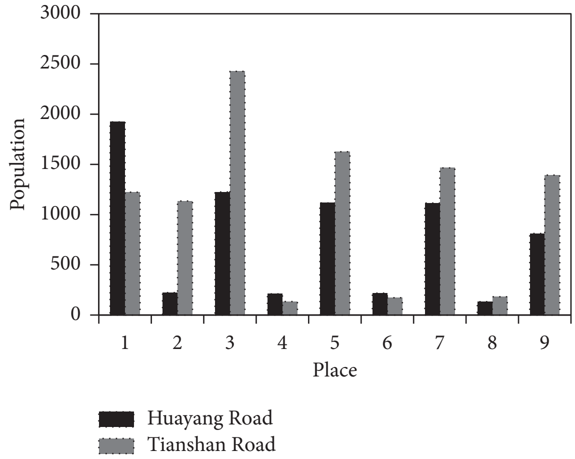

Figure 2: Comparison of population living in different streets in Changning District.

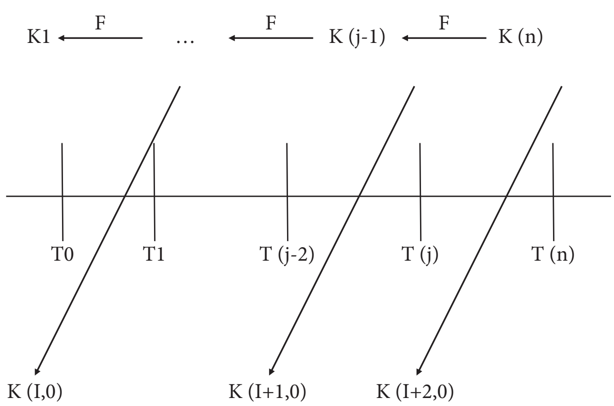

Figure 3: Layered μ TESLA protocol basic mechanism.

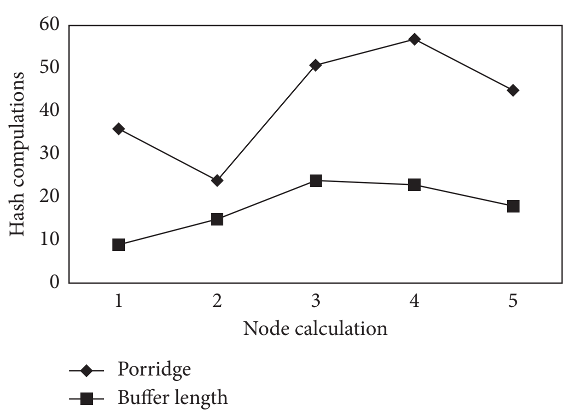

Figure 4: Schematic diagram of calculation cost results of sensor nodes.

group member only needs to keep a personal key of their choice throughout the self-healing key distribution process [15, 16]. It is necessary for scheme group members to maintain individual secret polynomial values that have been distributed by the group administrator, hence keeping the scheme's storage overhead to a minimum. After the parameter p_L changing to a different value, the graph of $E[N^H]$ as a function of the key buffer length l in Figure 4 can be seen in more detail. The average node update per key requires less computing overhead even when the channel packet loss rate is high (for example, $p_L = 0.5$), as illustrated in the diagram.

5. Conclusion

The results of public art reflected in different field backgrounds also have a symmetrical relationship with the environmental background. First of all, from the perspective of the city, the image language of the regional culture conveyed by the public art works depicts a certain aspect of the city image and is a label for the positioning of the city art; furthermore, from the specific regional environment, the public art often defines the vitality center of the region, infecting the public's sense of the environment with cultural cohesion; secondly, the positive energy that public art can transmit is also an important way of guiding social values. The exploration of the mode of public art also drives the corresponding discipline construction; essentially, the most important value of public art is the shaping of social cultural characters and the positive power of citizens' self-value recognition. The public experience is an important criterion for judging the value of public art in the environment. Public perception is a double-edged sword. On the one hand, public experience reflects the social value of public art. On the other hand, it is not enough for public perception. It may also hinder the realization of public art. Therefore, in the practice of public art and environment, we should pay attention to the value of the people's experience, but we should also do a good job of active cultural guidance.

Retracted: Influencing Factors and Improvement Path of Synergistic Value Creation Efficiency of Emerging Enterprises

Computational Intelligence and Neuroscience

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

The cooperation between emerging enterprises and different enterprises can stimulate innovation enthusiasm and realize synergistic value creation. At present, there is no regular pattern and rules for synergistic value creation among emerging enterprises, which cannot achieve effective synergistic value creation. Based on the complex network relationship and dynamic model of game evolution among multiple entities of value creation within emerging enterprises, the factors that affect the efficiency of synergistic value creation in the aspect of input, benefit assignment, and interaction mechanism of synergistic value creation are analyzed and then the path of the promotion of synergistic value creation among the entities of new enterprises is studied. The results show that the core enterprises play a leading role in the cooperation input among emerging enterprises, and if the balance of interests among cooperative enterprises is guaranteed, the revenue effect is the best, and the network cooperation density is the strongest. The game evolution shows that, in order to improve the efficiency of synergistic value creation, it is necessary to improve the expected coefficient and number of synergies between enterprises and establish a mechanism for equitable distribution of synergies by strengthening information exchange among enterprises in emerging industries, so as to build an atmosphere of synergies, the complementarity of assets and synergies.

1. Introduction

With the development of economy and society, the demand of the people and the market for different industries are constantly innovating, and different emerging industries are derived. Effective allocation of innovation resources and improvement of innovation efficiency can promote the development of relevant industries [1]. In the process of industrial development, the innovation ability of a single enterprise is limited, and the emergence of synergistic value creation effectively solves this problem. Synergistic value creation in emerging industries is an innovation behavior similar to an alliance, which is based on competition and cooperation between enterprises and mainly includes research and development cooperative innovation, product innovation, and market innovation [2]. Synergistic value creation of emerging industries has the advantage of saving technology transfer and technology exchange costs [3]. When technology spills over between and within industries, enterprises can form innovation alliances to tackle key problems and monopolize the technology within the alliances [4]. As a result, many emerging industries have a very strong motivation on synergistic value creation, and the main causes of competition between enterprises is now more emphasised on the customer knowledge economy, flexibility, rapid response, and the value chain of the internalization and unstructured. However, limited resources will inevitably lead to competition within and among synergistic value creation systems. Different subjects adopt corresponding strategies based on their own development interests, so the strategies of other relevant innovation subjects will also change accordingly [5].

The innovation of emerging industries needs the cooperation of various parties. There are important innovation resources within the industry such as scientific research institutions, governments, and universities. The flow and allocation of resources are the necessary conditions for innovation. Since the process of establishing industrial competitiveness is a process of competing for resources in essence, the innovation subjects must go through a process of evolutionary game. Innovation resources are mainly concentrated in enterprises, while heterogeneous resources such as talents and latest scientific research achievements are concentrated in universities and scientific research institutions. Therefore, in order to fundamentally improve the overall innovation capacity of the industry, effective flow and allocation of resources must be realized first. The emerging industries of China are still in the embryonic stage, so a series of help from the government and intermediary agencies is needed to achieve faster development. Of course, as the subject of innovation itself, strategic emerging industries should learn from each other and develop together. The innovations and contributions of this study are as follows:

(1) Based on the complex network relationship and dynamic model of game evolution among the multiagents of value creation within emerging enterprises, the influencing factors and upgrading path of synergistic value creation among the agents of emerging enterprises are studied.

(2) According to the analysis of historical data, the factors influencing the synergistic value creation of different types of enterprises from the aspects of initial investment, enterprise attributes, and profit distribution are analyzed.

(3) The trajectory of synergistic value creation among different enterprises is studied by means of game evolution and puts forward the path of synergistic value creation according to the changes of different variables, and it has certain practicality.

2. Related Work

In recent years, many experts have studied the theories and measures of synergistic value creation and value enhancement in enterprises. The present situation of synergistic value creation, synergistic method research, and complex network application is studied.

2.1. Collaborative Value Innovation of Enterprises. Frank and Piller believe that synergistic value creation can be defined as the active integration of different parties in the process of value creation within an organization, aiming to bring different parties together to create common valuable results [6]. Schreier proposed that enterprises have unique tangible and intangible resources, which can reduce the risk of failure and the cost of innovation when combined with the resources of service providers [7]. Stephan and Hankammer introduced customer groups and believed that synergistic value creation encourages customers (service consumers) to actively participate in the design and delivery of innovative customized services to meet customers' performance goals, thus greatly reducing the risk of service delivery failure [8]. Doren et al. studied Indian offshore service providers and found that Indian organizations can improve customer retention rate and attract new customers by promoting the acquisition and utilization of network resources through high-quality synergistic value creation with customers and maintaining innovation through close cooperation with customers [5].

2.2. Method and Framework of Enterprise Collaborative Development. Schweizer proposes a framework that facilitates the execution of successful collaborations. Schweizer proceeds to propose a ratio-driven approach and a value-adjustment mechanism, enhancing the probability of successes in pharmaceutical research collaborations [9]. Chesbrough considers open innovation requires collaboration among distributed but interdependent actors who rely on each other's capabilities for value creation and capture. Value in open innovation is driven not only by actors' value creation but also by their ability to capture value [10].

2.3. Complex Network Application. A complex network has a strong application background in the cooperative development of enterprises and government affairs. Arellano proposes a new algorithm to select the relevant nodes that maintain the cohesion of the network of the complex network. The result shows that the proposed approach outperforms degree, PageRank, and betweenness in most of the several real complex networks [11]. Meng proposes a Spearman coefficient reconstruction network (SCRN) method based on the Spearman correlation coefficient. In the SCRN method, we select entities in the real world as the nodes of the network and determine the connection weights of the network edges by calculating the Spearman correlation coefficients among nodes [12].

From the point of the current research status, different countries and enterprise development patterns vary, experts often seek emerging from the successful case enterprise synergy creation combining site and advantage, and it is not the professional model which combined with the actual enterprise development present situation, and it leads the study to one-sided. At the same time, synergistic value creation among emerging enterprises is usually carried out from enterprise types and product business, without analyzing the specific implementation process and influencing factors, resulting in an unclear promotion path of synergistic value creation and a lack of data analysis of evolutionary nature.

3. Analysis on the Influencing Factors of Synergistic Value Creation Efficiency of Emerging Enterprises

3.1. Construction and Evolution of the Complex Network Model. There are two types of emerging enterprises: one is the core enterprise that plays a leading role and the other is the general enterprise that has a certain research and development capability [13]. The connection mechanism of its network architecture is the synergistic relationship between enterprises. The partial schematic diagram of synergistic value creation network of emerging enterprises is shown in

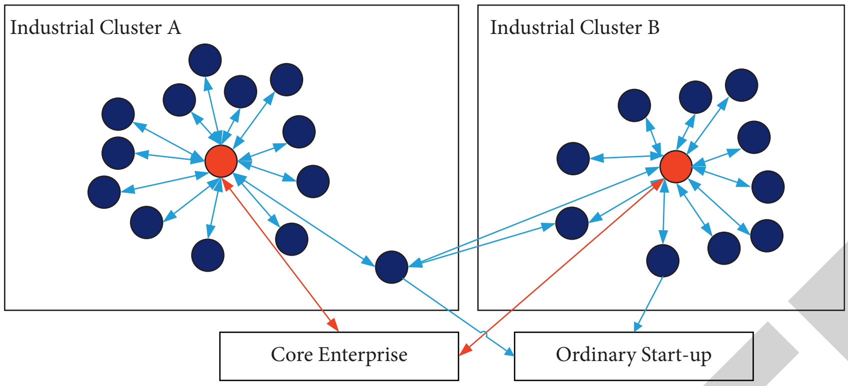

Figure 1: The partial schematic diagram of synergistic value creation network of emerging enterprises.

Figure 1. The blue line represents the coordination and cooperation between ordinary enterprises and core enterprises, while the red line represents the interaction and cooperation between core enterprises.

The evolution process of innovation network mainly includes initial network construction, node entry, and generation of edge and gradually evolves into the corresponding complex system through the continuous growth of network scale. Therefore, based on the initial network formed randomly, this study constructs the synergistic value creation network of emerging enterprises with three types of nodes, namely, $G(V, E)$. V is the set of all nodes in the network, and E is the set of all edges in the network. The evolution rules are as follows:

Step 1. Build the initial network. An initial network with m_0 nodes and edges is generated randomly.

Step 2. For each time step, a new node joins the network. First, set the parameter q, and $0 < q < 1$, then randomly generate the real numbers q', and $q' \in (0, 1)$. When $q < q' < 1$, the probability of this new node connecting to $m_1 (m_1 < m_0)$ node in the global network G is as follows:

$$\prod_i = \frac{k_i}{\sum_{j\in G} k_j}, \tag{1}$$

when $0 < q < q'$, randomly select M node from the current global network to form the LAN. In addition, the probability that the new node preferentially connects to $m_2 (m_2 < M)$ nodes in the LAN L is as follows:

$$\prod_i = \frac{k_i}{\sum_{j\in L} k_j}, \tag{2}$$

where k_i is the degree of any node in the network.

Step 3. Repeat the second step, and do not allow repeated edges and self-connection. Until the network node scale reaches N, the evolution ends.

In this study, the evolutionary mechanism of synergistic value creation of emerging enterprises is shown in Figure 2, which mainly includes synergistic value creation input, benefit assignment, and interaction mechanism.

In the synergistic value creation network of emerging enterprises, the interaction modes between different types of innovation subjects are diverse, which makes the innovation network present a nonlinear cooperative behavior evolution form. In fact, there are cooperative relations and competitive relations between innovation subjects in the network [14]. Cooperative relations are the premise of collaborative innovation activities between subjects, while competitive relations promote game behaviors between subjects. However, in the initial stage of innovation activities, because of the limited rationality of innovation individuals, their game decisions may not be optimal, and they need to constantly adjust and optimize their decisions by learning and imitating other individuals who are better than them, thus forming a dynamic evolutionary game process. From the individual point of view, the game decisions adopted by each innovation subject will affect the benefits obtained by other subjects, which makes the innovation subject with preference characteristics change their own strategies to maximize their own interests. From the overall point of view, innovation subjects are based on a certain learning and imitation mechanism, which makes excellent strategies gradually spread in the innovation network, thus promoting the evolution of the overall cooperative behavior of the network.

3.2. Game Evolution Model of Complex Network Evolution. The evolution of complex networks is influenced by input and benefit assignment. Production input is the basis of cooperation and can analyze the importance of the enterprise. Profit distribution describes the results of synergistic value creation, and the two factors describe the purpose and results of cooperation, respectively. Therefore, the above two factors are selected as evolutionary variables in this model.

3.2.1. Synergistic Value Creation Input Model Construction. In this study, cost and early income jointly determine the production input of game subjects in the cooperation process, and the production input of enterprises in each neighborhood is determined by the following formulas:

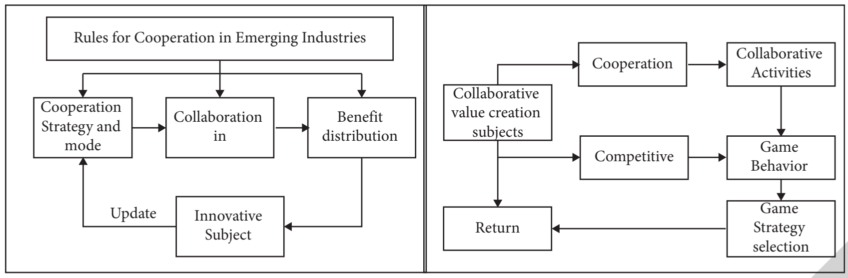

Figure 2: Evolutionary and dynamic mechanisms of synergistic value creation of emerging enterprises.

$$a_{x,y}(t_n) = (1 - w_1)\frac{e^{\alpha \cdot m_{x,y}(t_{n-1})}}{\sum_{i=0}^{k_x} e^{\alpha \cdot m_{x,y}(t_{n-1})}} + w_1 \frac{e^{\alpha \cdot k_x}}{\sum_{i=0}^{k_x} e^{\alpha \cdot k_i}}, \quad (3)$$

$$\sum_{y=0}^{k_x} a_{x,y}(t_n) = C, \quad (4)$$

where the benefit index is $e^{\alpha \cdot m_{x,y}(t_{n-1})} / \sum_{i=0}^{k_x} e^{\alpha \cdot m_{x,y}(t_{n-1})}$, which is the standardized ratio of the income of node x in the neighborhood y to the total income in the neighborhood y; the enterprise importance index is $e^{\alpha \cdot k_x} / \sum_{i=0}^{k_x} e^{\alpha \cdot k_i}$, which is the standardized ratio of the degree of the node x to the sum of the degrees of all nodes in the neighborhood y, reflecting the importance of the node x in the neighborhood. $t_n = 2, 3, \ldots, T$ represents the number of rounds of the game.

3.2.2. Benefit Assignment Model Construction. This study uses the utilization allocation model created by Chen [16]. In this study, the cost and innovation input jointly determine the benefit assignment of the game subjects in the cooperation process, and in order to simplify the model, the evaluation error of enterprise innovation input is ignored here. After the end of the t_nth round of game, the net income of the node x in the neighborhood y is determined by the following formula:

$$m_{x,y}(t_n) = \left[w_4 \frac{e^{\beta \cdot a_{x,y}(t_n)}}{\sum_{i=0}^{k_x} e^{\beta \cdot a_{x,y}(t_n)}} + w_3 \frac{e^{\beta \cdot b_{x,y}(t_n)}}{\sum_{i=0}^{k_x} e^{\beta \cdot b_{x,y}(t_n)}} + w_2 \frac{e^{\beta \cdot k_x}}{\sum_{i=0}^{k_x} e^{\beta \cdot k_i}} \right] \pi_y(t_n) - a_{x,y}(t_n) - b_{x,y}(t_n). \quad (5)$$

According to formula (5), the income distributed by node x in the neighborhood y is jointly determined by its production input index, cooperation input index, and degree index in the neighborhood. β is the regulation coefficient, w_2, w_3, and w_4 respectively represent the degree weight, cooperation input weight, and production input weight of the node x, and $w_2 + w_3 + w_4 = 1$.

After the end of the t_n round of game, the total income of node x in each $k_x + 1$ neighborhood is as follows:

$$M_x(t_n) = \sum_{y=0}^{k_x} m_{x,y}(t_n). \quad (6)$$

3.2.3. Innovation Model Construction. Innovation can reflect the vitality of new enterprises and the value of cooperation. This study evaluates the effect of enterprise cooperation by combining enterprise value cocreation with innovation ability. At present, it is generally accepted at home and abroad to judge the innovation ability of enterprises by measuring the international patent classification number. According to the previous research results of some scholars, innovation ability is often related to "the number of technological innovation projects," "product update speed," "the number of patents," and "customer satisfaction." In this study, the number of patents obtained by enterprises in the recent five years is selected as the standard to measure the innovation capability of enterprises.

3.2.4. Design of Policy Update Rules. At the end of each round of game, each node x randomly selects its neighbor nodes y and compares its total income $M_x(t_n)$ with $M_y(t_n)$ of its neighbor nodes. If $M_x(t_n) \leq M_y(t_n)$, the node will adjust the game strategy and follow the strategy of the node x in the neighborhood y according to a certain probability W. In this study, Fermi updating rule is used to determine the imitative probability.

The variable description is listed in Table 1.

Table 1: The variable description of the model.

Variable	Description
$e^{\alpha \cdot m_{x,y}(t_{n-1})} / \sum_{i=0}^{k_x} e^{\alpha \cdot m_{x,y}(t_{n-1})}$	Benefit index
$e^{\alpha \cdot k_x} / \sum_{i=0}^{k_x} e^{\alpha \cdot k_i}$	Enterprise importance index
y	Neighborhood
$M_x(t_n)$	Total income of x
α, β	Regulation coefficient
t_n	Number of evolution

3.3. Evolutionary Simulation and Analysis of Complex Network Evolutionary Game. The MATLAB simulation platform is used to simulate the evolutionary game model of

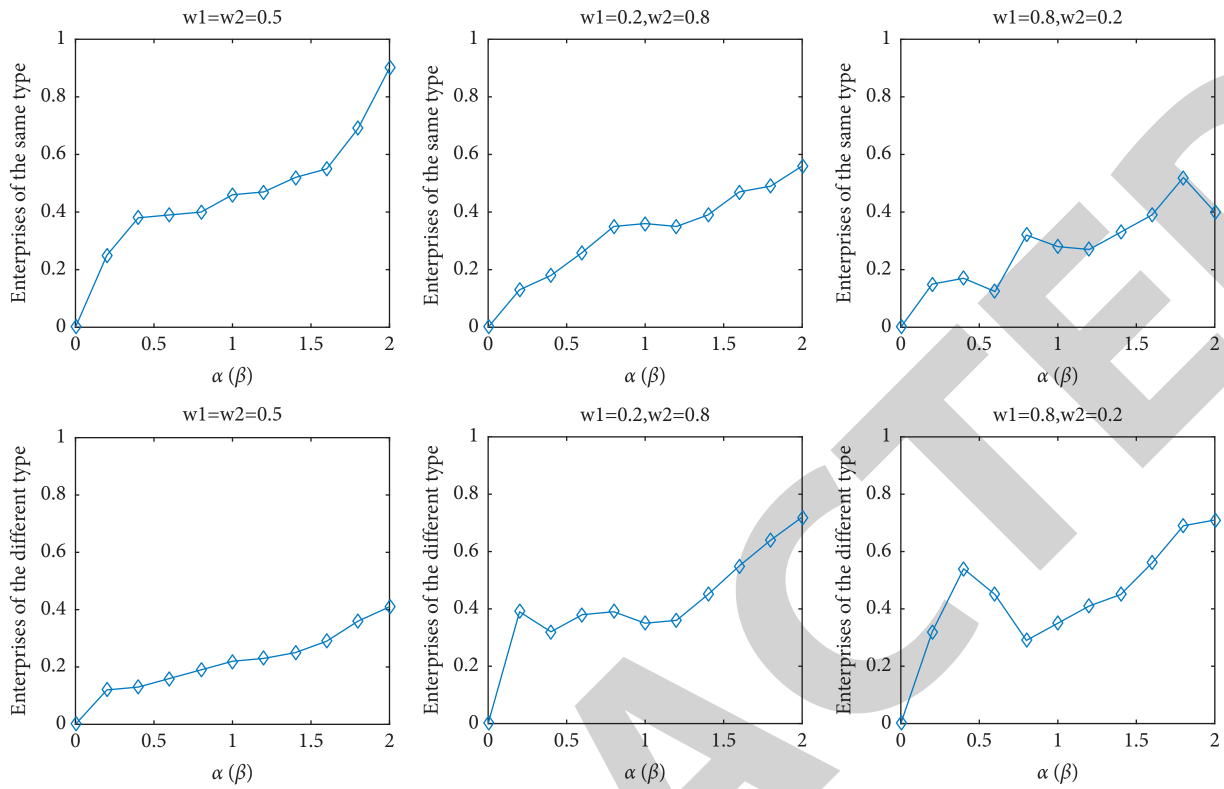

FIGURE 3: Influence of input on network density.

synergistic value creation network of emerging enterprises. The simulation algorithm and related parameters are set as follows.

Step 4. Set the initial parameters of the synergistic value creation network for emerging enterprises. $r = 2$, $\alpha = \beta = 0.5$, $w_1 = w_2$, $w_3 = w_4$, $B = C = 1$, noise factor $K = 0.1$, and total number of rounds of game $T = 400$.

Step 5. Determine the initial game state of the synergistic value creation network of emerging enterprises. In the beginning, the total production input that can be paid by each node is evenly distributed among its participating neighborhoods, and the initial cooperation rate of each node is 0.5, which is randomly distributed.

Step 6. The game players in the synergistic value creation network of emerging enterprises determine their innovation input according to the established rules and determine the benefits of all game players according to the benefit assignment rules.

Step 7. The strategy updating process of game subjects in the synergistic value creation network of emerging enterprises. The game subject updates the strategy according to the established strategy updating rules.

Step 8. Repeat Steps 6 and 7, and the simulation will be terminated when the set game iterations are reached. The simulation results of the innovation network achieving dynamic equilibrium are the average values of the last 50 rounds under each group of parameters, and several independent experiments are conducted respectively.

Two experimental scenarios are designed in this study, which is the comparison of network density between two cooperative enterprises with different input ratios and different income distribution ratios. The experimental results are shown in Figures 3 and 4.

The test results show that if the two companies are the same kind of enterprises, and the disparity of the property and asset size is small, then the network density rises, and as the disparity of enterprises gradually increases, the network density is reduced. The result suggests that synergistic value creation of the same kind of enterprises tends to be homogeneous. At the same time, if the two enterprises are of different types, such as the core enterprise and the general enterprise, and the disparity of enterprises is small, then the network density decreases, and as the disparity of enterprises gradually increases, the network density increases instead, and it shows that synergy value creation of the same kind of companies tends to be dependent.

By selecting the number of cooperative patents between enterprises of different orders of magnitude as a parameter variable, the network density of emerging enterprises is counted. The impact of innovation on network density is listed in Table 2. It can be seen from the results that with the increasing number of cooperative patents between enterprises, the degree of cooperation is closer and the easier it is to produce industrial clusters.

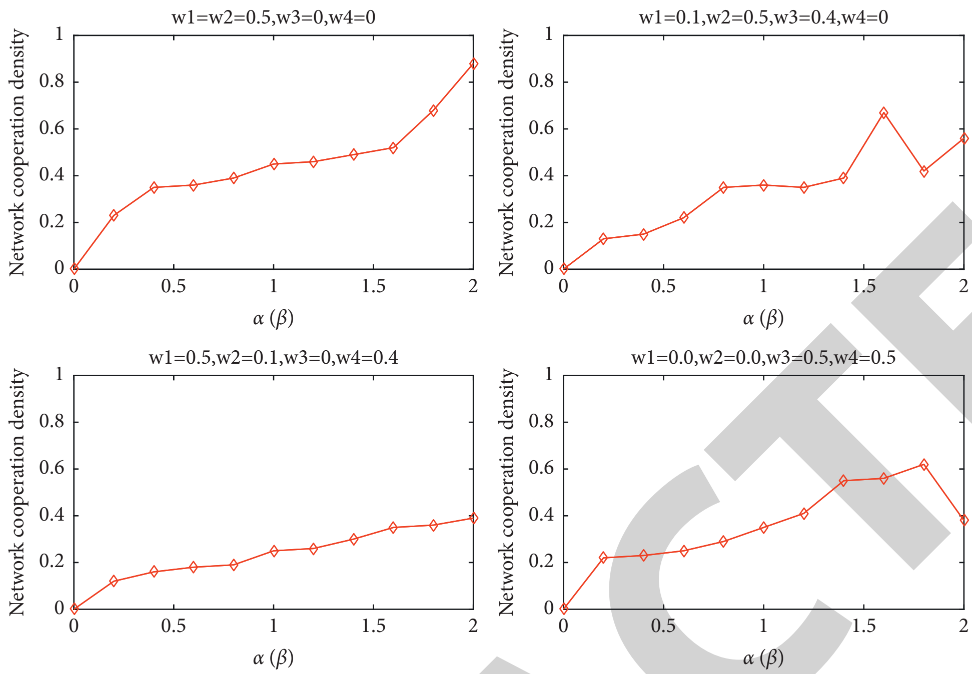

Figure 4: The effect of revenue distribution on network density.

Table 2: The impact of innovation on network density.

Cooperative patents	0	5	10	15
Network density	0.12	0.19	0.23	0.31
Cooperative patents	20	30	40	50+
Network density	0.42	0.56	0.67	0.82+

It can be seen from Figure 4 that when emerging enterprises cooperate with each other, the profit effect is the best and the network cooperation density is the strongest. The reason is that the high degree weight will make many ordinary enterprises choose not to cooperate, which leads to the serious loss of interests of core enterprises with high degree, while the damage degree of backbone enterprises is less than that of core enterprises. At the same time, with the increase of and coefficient, the network cooperation density between enterprises gradually increases.

3.4. Analysis on the Influencing Factors of Synergistic Value Creation Efficiency. Through the analysis of the evolutionary dynamics of the cooperative behavior of the cooperative value creation network of emerging enterprises, it can be seen that the benefits gained by the innovation subjects can be an important driving factor of whether they change the game strategy through a learning mechanism. However, as the innovation subject, benefits obtained through collaborative innovation actually only play a certain guiding role in the self-organization evolution of synergistic value creation of emerging enterprises [14]. As for the factors that affect the evolution of network cooperative behavior, it is necessary to investigate the root, which can be analyzed from external factors and internal factors, respectively.

According to the data analysis results, we build the synergistic value creation network operation mechanism of emerging enterprises and make the distribution of interests between innovation subjects consider the innovation investment and important degree. However, the different types of enterprises in the process of collaborative innovation input will exist a certain difference of importance, which makes the innovation main body produce an obvious income gap, leading to cooperation between the players to change. As for the equitable benefit assignment structure, it can promote the stable development of innovation activities in the collaborative innovation network, thus attracting a large number of subjects to participate in the collaborative innovation to share the benefits. However, the unfair profit distribution structure will lead the innovation subject with low income to produce negative cooperative behaviors and transfer them to other innovation subjects in the network, thus inhibiting the positive evolution of network cooperative behaviors. Over time, more and more innovation subjects will withdraw from cooperation. Therefore, whether the benefit assignment structure is reasonable or not will directly affect the development of synergistic relationship between participants, and thus it has an impact on the evolution of cooperative behavior of synergistic value creation network of emerging enterprises.

4. Evolutionary Game and Promotion Path of Synergistic Value Creation of Emerging Enterprises

4.1. Model Construction of Game Equilibrium. To build the model and simplify the calculation, the following game elements are considered:

(1) *Participants of the Game.* It is assumed that the proportion of the assets of the two enterprises X, Y

participating in innovation in the emerging industry in the total assets of the emerging industry is X_1, and the proportion W_1 of the input in synergistic value creation is directly proportional to the total assets. The total input (including the input of human resources, material resources, financial resources, technical resources, and other factors, which can be converted into currency) is I, where the share of enterprise X input is $X = X_1 W_1$, the proportion of enterprise input in the total assets is W_2, and the input share is $Y = Y_1 W_2$.

(2) *Behavior*. If enterprises trust each other and adopt synergistic value creation behaviors, then the enterprise synergistic income c is distributed according to the proportion of input, and the enterprise income is ac. The size of revenue c is positively correlated with the expected synergy coefficient $\eta\,(\eta > 1)$ of the two enterprises. If both enterprises A, B do not trust each other and both parties betray each other, then it is considered that there is no synergy and no income. In this case, the payment of both parties is 0. If company A cooperates with each other and B is selfish, it can be considered that the input of new industry companies is completely taken by the company B, which leads to no further cooperation.

Suppose that the probability of A cooperative behavior is p, the probability of selfish behavior is $1 - p$, the probability of enterprise B taking collaborative behavior is q, the generalization of selfish behavior is $1 - q$, and suppose that the collaboration between enterprises A, B is motivated by a positive feedback, expressed by θ $(\theta > 0)$. The more times of collaboration can cause the more tacit collaboration and make the rational increase. Synergy is cumulative, and every success of synergy will receive a positive incentive on the original basis.

(3) If the enterprises in the emerging industry trust each other and cooperate before the synergistic value creation for n times, each enterprise will continue to adopt the strategy of cooperation. However, once one enterprise in the emerging industry betrays in the n th stage, the enterprises in the emerging industry will not cooperate in the future.

According to the above assumptions, the payment matrix of the enterprises A and B in the nth synergistic value creation can be constructed, as listed in Table 3.

Table 3: The payoff matrix.

Enterprise A	Enterprise B		
	State (probability)	Synergy (q)	Betrayal ($1-q$)
	Synergy (q)	G_{1A}, G_{1B}	0, G_{2B}
	Betrayal ($1-q$)	G_{3A},0	0,0

4.2. Analysis of Synergistic Value Creation Conditions in Game Balance

4.2. Analysis of Synergistic Value Creation Conditions in Game Balance. Whether an enterprise A chooses synergy or betrayal, it depends on the difference ΔG_A between its expected payment when it chooses synergy $(p = 1)$ and betrayal $(p = 0)$, because it has incomplete information for the enterprise and can only consider the problem from its own interests:

$$\Delta G_A = \sum_{i=1}^{4} G_{iA}(p = 1) - \sum_{i=1}^{4} G_{iA}(p = 0), \tag{7}$$

$$\Delta G_A = qI\left[a\eta(1+\theta)^{n-1} - 1\right]. \tag{8}$$

The condition for enterprise A to choose synergy is $\Delta G_A \geq 0$, and according to the above formula, there is $a\eta(1+\theta)^{n-1} - 1 \geq 0$, as $a \geq 0$, so

$$a \geq \frac{1}{\eta(1+\theta)^{n-1}}. \tag{9}$$

Based on the above model construction results, the following can be seen:

(1) When η and θ are certain, if the η value is relatively large, then a can be relatively small, and if the η value is small, then the requirement is relatively large. That, result of the first cooperation conditions show that the synergistic effect of enterprises of innovation, also willing to adopt cooperative behavior, and it suggests the less resources and ability to make synergistic value creation. The synergistic effect of innovation is small, and enterprises only adopt cooperative behavior when they are dominant in the process of innovation.

(2) When η is certain, if η and θ are relatively large, then a can be relatively small, and if η and θ are small, then the requirement is relatively large. Thus, the second cooperation condition is obtained:

When there are more times of collaboration and trust relationship is established, enterprises are willing to take cooperative innovation behavior even though they have less dominance in the innovation process. When there are fewer times of cooperation and trust relationship is not established, enterprise A is willing to take cooperative behavior only when they are dominant in the innovation process.

As mentioned above, in theory, the game behavior of enterprise B and the game behavior of enterprise A have the same rational choice in the same strategic environment. Therefore, it can be concluded that the conditions for enterprise B to choose synergy are as follows:

$$b \geq \frac{1}{\eta(1+\theta)^{n-1}}. \tag{10}$$

When $a = b = 1/2$, it means the two enterprises have equal input, equal undertaking of innovation risks, and equal separation of innovation benefits, and both parties have the

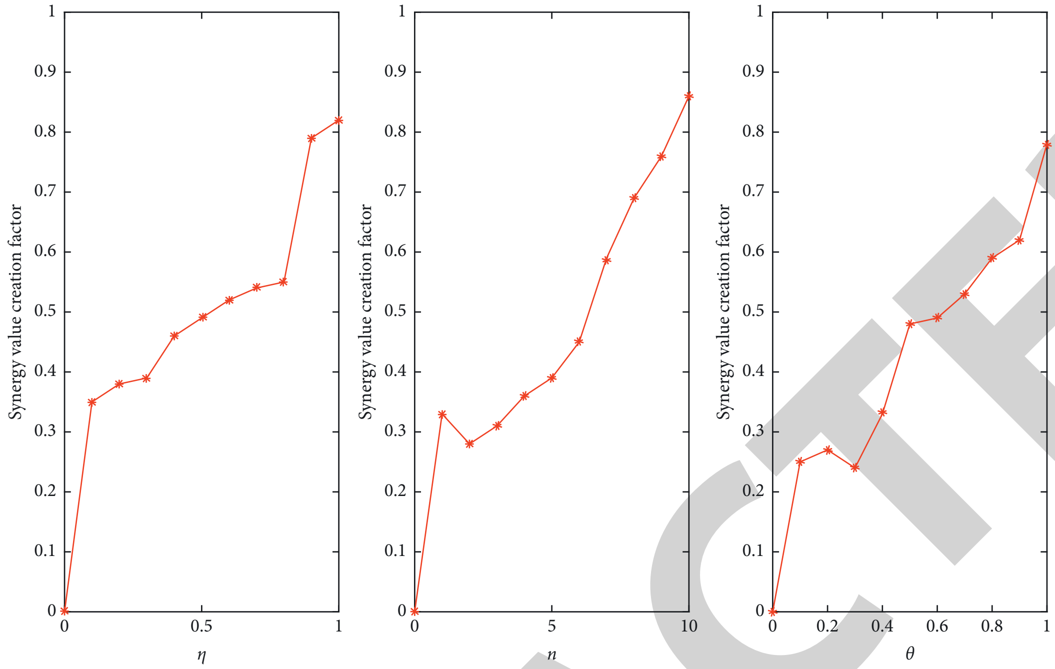

Figure 5: Comparison results of models with different η values, n values, and θ values.

Table 4: Results of network cooperation density under different ratios.

Ratios	Network cooperation density	Synergistic value creation goal probability
$a = 0 \cdot 1,\ b = 0 \cdot 9$	0.34	0.32
$a = 0 \cdot 2,\ b = 0 \cdot 8$	0.46	0.49
$a = 0 \cdot 3,\ b = 0 \cdot 7$	0.56	0.62
$a = 0 \cdot 4,\ b = 0 \cdot 6$	0.67	0.71
$a = 0 \cdot 5,\ b = 0 \cdot 5$	0.87	0.92
$a = 0 \cdot 6,\ b = 0 \cdot 4$	0.77	0.79
$a = 0 \cdot 7,\ b = 0 \cdot 3$	0.67	0.71
$a = 0 \cdot 8,\ b = 0 \cdot 2$	0.62	0.67
$a = 0 \cdot 9,\ b = 0 \cdot 1$	0.45	0.59

greatest desire to carry out long-term or repeated cooperative innovation.

4.3. Promotion Path and Experiment of Cooperative Competition Game Analysis. According to the above game analysis of collaborative competition, the essence of collaborative competition is incomplete information repeated game, so enterprises in emerging industries need to pay attention to balance. The comparison results of models with different η values, n values, and θ values are shown in Figure 5. The synergistic value creation of enterprises in emerging industries needs to start from the following aspects:

(1) *Improved η Value*. The higher the expected synergy coefficient between enterprises, the more inclined enterprises are to long-term synergy. The value can be improved by improving the way and structure of collaboration and strengthening the communication between enterprises in the process of collaboration.

(2) *Improved n Value*. In other words, the more times of synergistic value creation, the more mutual understanding and trust between enterprises, so as to establish a long-term stable synergistic value creation relationship.

(3) *Improved θ Value*. We should strengthen the information exchange of enterprises in emerging industries, establish the mechanism of equitable distribution of collaborative achievements, and develop a good collaborative institutional environment, legal environment, and cultural environment.

Table 5: Results of network cooperation density under different ratios based on empirical data.

Ratios	Cooperation density (2019)	Goal probability (2019)	Cooperation density (2020)	Goal probability (2020)
$a = 0 \cdot 1, b = 0 \cdot 9$	0.33	0.34	0.33	0.34
$a = 0 \cdot 2, b = 0 \cdot 8$	0.45	0.55	0.46	0.55
$a = 0 \cdot 3, b = 0 \cdot 7$	0.57	0.64	0.55	0.64
$a = 0 \cdot 4, b = 0 \cdot 6$	0.68	0.77	0.68	0.77
$a = 0 \cdot 5, b = 0 \cdot 5$	0.86	0.94	0.86	0.95
$a = 0 \cdot 6, b = 0 \cdot 4$	0.79	0.82	0.81	0.82
$a = 0 \cdot 7, b = 0 \cdot 3$	0.68	0.72	0.68	0.72
$a = 0 \cdot 8, b = 0 \cdot 2$	0.67	0.68	0.66	0.67
$a = 0 \cdot 9, b = 0 \cdot 1$	0.48	0.62	0.48	0.64

(4) *Improved q Value*. In other words, it can effectively promote the synergistic value creation of emerging industries by improving the potential synergistic benefits, asset complementarity, and synergistic atmosphere and increasing the punishment for betrayal.

Meanwhile, under different ratios of a and b, the synergistic value creation has different effects. The specific simulation results are listed in Table 4.

The empirical data selected in this study are the sample data of new energy emerging enterprises, and the times of synergistic value creation, degree of knowledge collaboration, and innovation data are collected. Innovation is based on patent data based on the Patsnap database. The sample data include a total of 200 enterprises from 2019 to 2020. Results of network cooperation density under different ratios based on empirical data are listed in Table 5.

Based on the constructed model and experimental results, it can be theoretically proved that when $a = b = 1/2$, two enterprises are most likely to adopt synergistic value creation behavior. In the same way, the case of individual enterprises can be deduced. When $a = b = c = \ldots = 1/n$, n, enterprises are most likely to adopt synergistic value creation behavior. Therefore, it is necessary to create synergy conditions so that enterprises in emerging industries can make an equal investment and equal separation of innovation benefits and risks.

5. Conclusions

Based on the complex network relationship and dynamic model of game evolution among multiple entities of value creation within emerging enterprises, the factors that affect the efficiency of synergistic value creation in the input, benefit assignment, and interaction mechanism are analyzed, and then the path of the promotion of synergistic value creation among the entities of new enterprises is proposed. The model test results show that the core enterprises play a leading role in the cooperation input among emerging enterprises, and if the balance of interests among cooperative enterprises is guaranteed, then the revenue effect is the best, and the network cooperation density is the strongest. To enhance synergistic value creation, it is necessary to improve the expected coefficient and number of synergies between enterprises and establish a mechanism for equitable distribution of synergies by strengthening information exchange among enterprises in emerging industries, so as to build an atmosphere of synergies, the complementarity of assets and synergies.

Finally, based on the above research findings and combined with the realistic situation, countermeasures and suggestions are provided for synergistic value creation of emerging enterprises in China, and reference basis is provided for the government to support the development of synergistic value creation activities of emerging enterprises. However, due to the lack of more data support and technical support tools, the subsequent research will combine the collaboration data of typical emerging enterprises for value creation data analysis.

Character relationships in literary works can be interpreted and analyzed from the perspective of social networks. Analysis of intricate character relationships helps to better understand the internal logic of plot development and explore the significance of a literary work. This paper attempts to extract social networks from Chinese literary works based on co-word analysis. In order to analyze character relationships, both social network analysis and cluster analysis are carried out. Network analysis is performed by calculating degree distribution, clustering coefficient, shortest path length, centrality, etc. Cluster analysis is used for partitioning characters into groups. In addition, an improved visualization method of hierarchical clustering is proposed, which can clearly exhibit character relationships within clusters and the hierarchical structure of clusters. Finally, experimental results demonstrate that the proposed method succeeds in establishing a comprehensive framework for extracting networks and analyzing character relationships in Chinese literary works.

1. Introduction

Classic literary works are passed down to the present day because imaginative virtual worlds created by the authors can reflect many characteristics of our society. Character relationships in a novel indirectly reflect the writer's experiences and feelings about social life, cultural beliefs, and habits. Traditional analysis tries to discover the value of a literary work and compares similarity between the social structure in the work and real-world structure. However, recent analysis paid more attention to social relationships of characters. For example, the relationships of characters portrayed by a novel often carry a large amount of social information which is important for scholars when interpreting a literary work. Hence, extracting a social network and analyzing intricate character relationships will help to better understand the internal logic of plot development and explore the significance of a literary work. For instance, it can ease the process of reading a novel with too many characters, because readers are often confused about complicated character relationships while reading a long novel.

This paper attempts to extract networks of character relationships for several Chinese literary works by performing network analysis, cluster analysis, and data visualization. By applying these technologies and refining shared features in literary works, we succeeded in building a framework for studying network extraction and character relationship analysis of the Chinese literature. Initially, a Chinese lexical analysis on the novel text is used to resolve character names. Co-word network analysis is then employed to extract a network of character relationships. By analyzing the created network, we are able to grasp the basic characteristics of important characters in the specified Chinese novel. Finally, a variety of data visualization techniques are proposed to display character relationships in the novel.

This article is arranged as follows: Related researches are discussed in Section 2. Section 3 elaborates the methodology of character relationship extraction and analysis in Chinese literary works. Datasets and experimental results are described in detail in Section 4. The conclusion is drawn in Section 5.

2. Related Work

Analyzing literary works quantitatively by using scientific tools is one of the current research hotspots. The research approach is mainly divided into three categories: language analysis, text analysis, and comprehensive analysis [1]. Experts in both literature and computer science have recently focused on comprehensive analysis, which will be the main direction for literary research in the future. Zhao et al. [2] established a model of character graphs based on emotional polarity and gave general procedures to comprehend the Chinese literature. Huang et al. [3] developed a Chinese person entity relation extraction technology utilizing distant supervision, which can automatically identify and extract semantic relationships. Li and Liu [4] divided the corpus of a classical Chinese novel into training data and test data. Based on an N-gram language model and a random forest algorithm, they extracted features and performed a classification experiment to identify the authorship of the novel.

Social networks have also been introduced to analyze literary works. A growing number of scholars have begun to research literary character relationships based on social networks. Muhuri et al. [5] devised a means of annotation and character categorization to extract social networks. They applied it to two Bengali dramas and successfully found the protagonist and antagonist in the literature. Chowdhury et al. [6] investigated character relationships in a novel and its adapted film based on social network. They exploited many network features such as centrality metrics to analyze the difference in the character categorization within two expressions of art. Wang et al. [7] utilized co-word and social network analyses to study old Chinese literature in the Qing Dynasty. Fan et al. [8] examined character relationships in a classical Chinese novel by combining social network and cluster analysis.

A scheme for constructing a social network is using the co-word analysis technique. It measures the strength of relationships by counting the co-occurrence of words in a text. In recent years, co-word analysis has been widely employed in several fields. Chen et al. [9] conducted research by collecting the scientific literature with the topic of medical image processing. In order to explore research hotspots in this field, keywords of papers were used for co-word and cluster analysis. Huang et al. [10] chose industrial symbiosis as their research topic, using co-word and social network analysis to evaluate the current status and trends. They found that this research direction showed an interdisciplinary characteristic. Another research [11] built and visualized a co-word network in the Night-Time Light remote sensing field according to data from the Web of Science. Hu et al. [12] adopted scientometrics and co-word analysis to study bibliographic data in food safety from 1991 to 2018. Their work focused on food safety in agriculture and industry and revealed global research trends in this field. Xie et al. [13] predicted the evolution of academic research and hotspots in bioacoustics and ecoacoustics based on bibliometric analysis and network-based methods such as co-word network analysis, co-author network analysis, and co-citation network analysis.

3. Methodology

Manual analysis is a choice when the number of characters is small in a literary work. Nevertheless, it is unacceptable to manually process a novel with hundreds and thousands of characters. Thus, this paper focuses on automatically extracting and analyzing character relationships with the help of social networks and natural language processing technologies. The main framework of character relationship analysis can be illustrated in Figure 1. At first, a corpus of the Chinese literature and its corresponding character name list are loaded. Chinese lexical analysis is then performed so that character names can be correctly resolved. After building a social network based on co-word analysis, we calculate the number of network features and implement the visualization of network data in many ways.

3.1. Preprocessing. Before preprocessing, a full-text collection of Chinese literary works has to be collected from open datasets on the Internet. A selected literary work should contain the standardized Chinese text with high quality. Besides, a corresponding character name list downloaded from the web has to be provided for co-word analysis. Data cleansing is also done to correct some mistakes and remove unclear data in a raw corpus.

A Chinese natural language processing tool, ICTCLAS (https://ictclas.nlpir.org/), was used to perform lexical analysis, including segmentation, part-of-speech (POS) tagging, and named entity recognition (NER). Combining the character name list and character names resolved by NER, we succeeded in preparing the data for constructing a character relationship network.

3.2. Network Extraction of Character Relationships. Literary character relationships can be described as an undirected network. The character name is recognized as the node, and co-appearance of two names in a sentence or a paragraph is deemed as the link. Then, the weight of a link can be calculated by counting the number of times that the two names co-occur in the text. By performing co-word analysis, we can extract a weighted network of character relationships for the Chinese literature.

When dealing with Chinese character names, it is necessary to identify a character with different types of names: full name, nickname, and abbreviated name. A powerful algorithm should handle it correctly and effectively. We set a series of rules to convert names of different forms into full names.

3.3. Network Analysis for Character Relationships. Performing network analysis requires calculating multiple network features. The network features involve degree distribution, density, clustering coefficient, average clustering coefficient, shortest path length, average shortest path length, diameter, and centrality.

The degree of a node represents the number of its neighbors in the network. Degree distribution [14] is defined

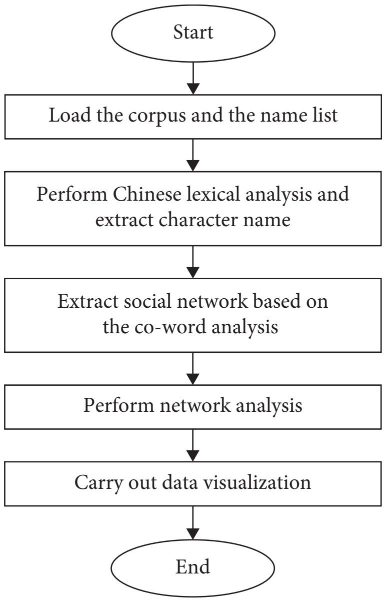

Figure 1: Research framework for analyzing character relationships in Chinese literature.

as the distribution of node degree, showing how links are distributed among nodes. Many researchers inspect whether a character relationship network has the power-law distribution, which is a common pattern discovered in numerous real networks [15].

Network density assesses the relative denseness of a network from the perspective of connected links. In a network, density is the portion of potential links which actually exist in the network [8]. It is often used in social networks to measure the intensity of social relationships and trends in evolution.

As a local feature of a network, the clustering coefficient [16] reflects the degree of clustering from the perspective of the nodes. It is the number of existing connections within a node's neighbors divided by the number of potential connections [17]. If all neighbors of a node are connected to each other, the clustering coefficient of this node will be 1. The average clustering coefficient, also known as the clustering coefficient of a network, is an average of all nodes' clustering coefficients. This value indicates the probability that friends of a person are also friends in real social connections.

The shortest path length [18] between two nodes refers to the number of links that connects two nodes by the shortest path. Thus, the average shortest path length is defined by the average number of links along the shortest paths. It measures information transmission efficiency within a network. Another indicator related to the shortest path is the diameter of a network, which is the maximum value of all shortest path lengths.

Centrality [15] is a measurement of significance for each node in the network. Three centralities are often discussed in network science involving degree centrality, betweenness centrality [19], and closeness centrality [20]. They are calculated based on the concept of degree, betweenness, and degree of closeness.

3.4. Cluster Analysis for Character Relationships. The weight of a link between two nodes in a social network can be used to represent the similarity of two characters. The larger the weight is, the more likely the two characters will be related to each other. At the beginning, a co-occurrence matrix is created by counting the weights of links, which are frequencies of character names appearing together. Furthermore, Ochiai coefficients [21] are calculated to implement the normalization of the co-occurrence matrix for the purpose of eliminating the influence of frequency of a character existing in a literary work. The formula of the Ochiai coefficient is described by

$$\mathrm{Och} = \frac{\mathrm{freq}\,(X \cap Y)}{\sqrt{\mathrm{freq}\,(X) \times \mathrm{freq}\,(Y)}}, \tag{1}$$

where $\mathrm{freq}\,(X)$ is the frequency of character X and $\mathrm{freq}\,(X \cap Y)$ is the frequency that X and Y co-occur in the literary work. In addition, a similarity matrix can be produced by applying the mathematical formula to the co-occurrence matrix. The elements of the similarity matrix range from 0 to 1. A large value implies a high similarity between the two characters, which means they incline to gather together in cluster analysis.

After taking the similarity matrix of character relationships as input, we exploit a bottom-up agglomerative hierarchical clustering method to organize characters into groups. The algorithm treats each character as a cluster at first. Two most similar clusters are merged at each iteration until only one cluster remains or it reaches the specified threshold. Finally, a hierarchical tree structure of character relationships is obtained through cluster analysis.

3.5. Data Visualization. Data visualization offers a graphical representation of data, helping us better understand the pattern within the data. Character relationships can be visualized in many different types. In this paper, clustering results of characters are portrayed in the form of a dendrogram. Since the output of hierarchical clustering is a binary tree, a tree-like dendrogram is an effective structure for visualizing character relationships.

Furthermore, the binary tree can be illustrated by a Venn diagram [22] as shown in Figure 2. In Figure 2, a red leaf node is also a node in the Venn diagram. The red node represents a character in the literary work, whereas a branch node stands for a larger group involving characters or small groups. Using the Venn diagram to display the result of hierarchical clustering has the following advantages: for one thing, nodes can be connected by links in the Venn diagram, which cannot be done in a tree structure; for another, the Venn diagram can clearly express a hierarchical structure. According to Figure 2(b), cluster A contains cluster B and character C, whereas characters D and E are included in cluster B.

However, application of a simple Venn diagram has some limitations. For instance, a novel with n characters incorporates $n-1$ clusters in the hierarchical clustering result. When the number of characters is too large, there will be a plethora of nodes and groups in the Venn diagram. It

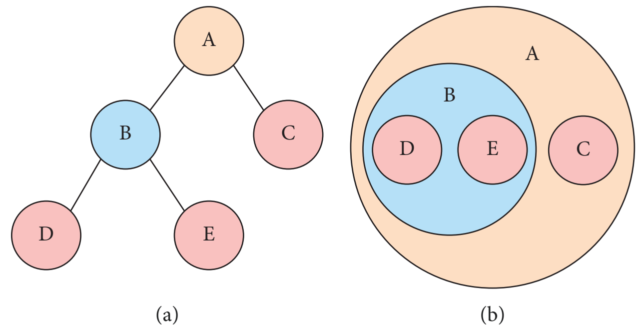

Figure 2: Visualization of the outcome of hierarchical clustering. (a) A binary tree. (b) A Venn diagram.

leads to a poor visualization of clustering results. There is no need to depict all clusters in the hierarchical structure, because researchers only pay attention to several important clusters. This paper improves the representation of target clusters by removing internal small clusters and retaining all character nodes. As shown in Figure 3, inner cluster B will be omitted if we are interested in cluster A, which results in a simplified visualization. The simplification of the Venn diagram is very useful when we visualize a multitude of characters with a small number of clusters.

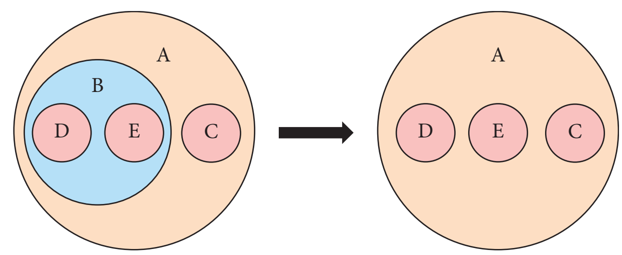

Figure 3: Removal of internal clusters in the Venn diagram.

4. Experimental Results

4.1. Datasets of Chinese Literary Works. A myriad of e-books of the Chinese literature can be downloaded from the Internet. In this paper, four classical Chinese novels are chosen as datasets to be analyzed. The novels' names and their abbreviations are presented in Table 1. Original texts are preprocessed to meet the experimental criteria. Cleaned data are available from the authors upon request. As character names are indispensable to extract social network from a literary work, character name lists of novels are also collected through the Internet. The number of characters for each novel is given in Table 1.

4.2. Results of Network Extraction and Analysis. Based on the character name list and co-word analysis, a social network of character relationships is extracted for each Chinese novel. Taking Demi-Gods and Semi-Devils (DGSD) as an illustration, a network with 169 nodes and 1,559 links is established in this paper. Figure 4 gives the visualization of the DGSD network by showing the top-50 nodes in degree distribution. It is a weighted undirected network where the size of a node denotes the frequency of a character name appearing in DGSD and the strength of a link represents the co-occurrence of two names in different semantic contexts.

The degree distribution of four networks and their log-log plots are depicted in Figures 5 and 6, respectively. According to the figures, only the degree distribution of the RTK network follows a power-law distribution—a significant property of the real-world network. In the log-log plot of Figure 6, we can fit a linear equation to the data of RTK well. However, other datasets of literary works fail to capture power-law properties because their authors only write a small number of core characters and neglect most low-frequency characters.

The average degree of a character relationship network means how many neighbors does a character connect on average. The indices for the 4 Chinese novels are listed in Table 2. The DRM network has the largest average degree. It means that characters in DRM are closely joined together in comparison with other novels. On the contrary, the RTK network has the smallest average degree because its author describes a large number of characters who appear only once or twice in the novel.

According to Table 2, densities of the four networks are less than 0.3, so they are sparsely connected networks, especially the RTK network. The average shortest path length is more than 3 for the RTK network but less than 2 for the DRM and LCH networks. Distribution of the shortest path length between two nodes is displayed in Figure 7. As for diameter which represents the distance of the largest-shortest path, only the RTK network has a diameter of 9, which is much larger than 4. Therefore, it has to afford a high cost of reaching another node in the RTK network in comparison with the other three networks.

The clustering coefficient reflects the local characteristics of a node. In a Chinese literary work, a character with the largest clustering coefficient does not necessarily have the most important role. The average clustering coefficients for 4 novels are given in Table 2. Moreover, we compare the character relationship network with a randomized version of a network with the same number of nodes and links, obtainable with a configuration model [23] that keeps the same degree distributions. This type of a random model is better than a simple ER model [24, 25]. From the results obtained in Table 3, the average shortest path length of each character relationship network is smaller than that of a random

Table 1: Four Chinese novels selected as datasets.

Number	Chinese novel name	Abbreviation	Number of characters
1	Dream of the Red Chamber	DRM	265
2	Romance of the Three Kingdoms	RTK	1,133
3	Legend of the Condor Heroes	LCH	90
4	Demi-Gods and Semi-Devils	DGSD	169

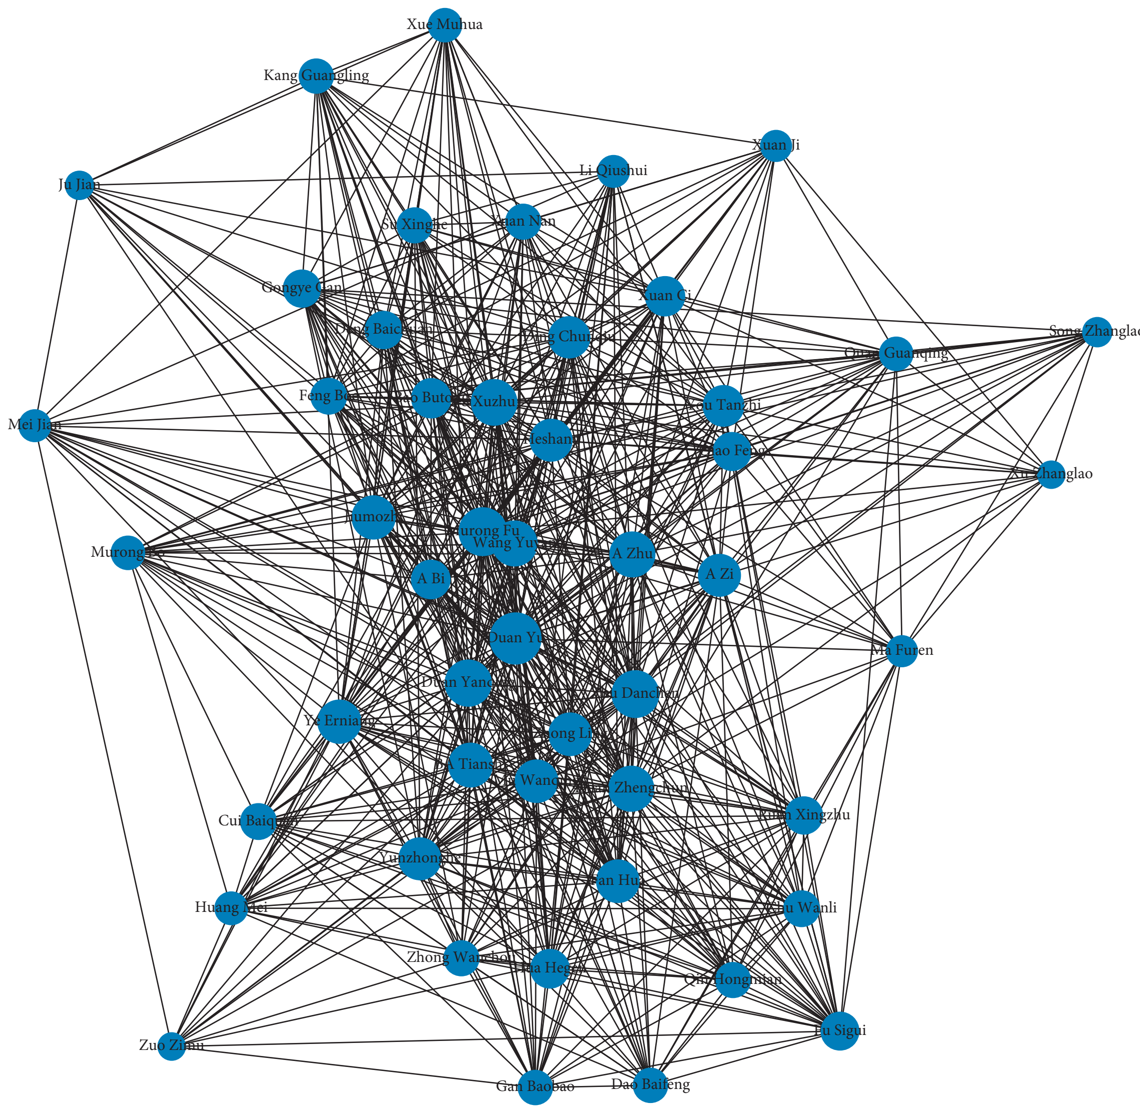

Figure 4: A visualization of the DGSD network with the top-50 nodes in degree distribution.

network except for the RTK network. The exception may be originated from an apparent three-group structure existing in the RTK network. All character relationship networks have larger average clustering coefficients. Hence, the social network of character relationships in a literary work is often a small-world network.

Three centralities can be calculated to measure significance of characters in a novel. Degree centrality is proportional to the degree of a node, which highlights the pivotal position of a node. Betweenness centrality reflects the "communication" ability of a node in the network. A high-betweenness node has a stronger ability to communicate with others. Closeness centrality represents the degree of accessibility from one node to other nodes in the network. Taking the example of DGSD, the top ten characters in centrality are shown in Table 4. Eight of the ten characters appear in three rankings, incorporating Duan Yu, Xu Zhu, Heshang, Murong Fu, Wang Yuyan, Qiao Feng, A Zhu, and A Zi.

4.3. Results of Cluster Analysis and Visualization. In order to discover clusters from data, the co-occurrence matrix should be first created by counting the weights of links. An example

	Random			2.1423	0.2690

of five characters in DGSD is presented in Table 5. The diagonal number is the frequency of a character's name appearing in the novel.

Normalization of the above co-occurrence matrix is finished by computing the Ochiai coefficient. Then, the co-occurrence matrix is converted into a similarity matrix as shown in Table 6.

Similarity of any two characters can be used for cluster analysis. In this research, a bottom-up hierarchical algorithm employing the similarity matrix is implemented to cluster character names in the literary work. As the result of hierarchical clustering is a binary tree, a dendrogram is drawn to describe character relationships in the novel. Figure 8 depicts a dendrogram of the clustering result for 33 main characters in DRM. Four large clusters can be identified by the clustering algorithm, including the Jia family of the Rongguo Mansion (H1), the Jia family of the Ningguo Mansion (H2), the Xue family (H3), and a group of noble people (H4). In our algorithm, H1 and H2 are clustered together in the hierarchy, which is called the "Jia family."

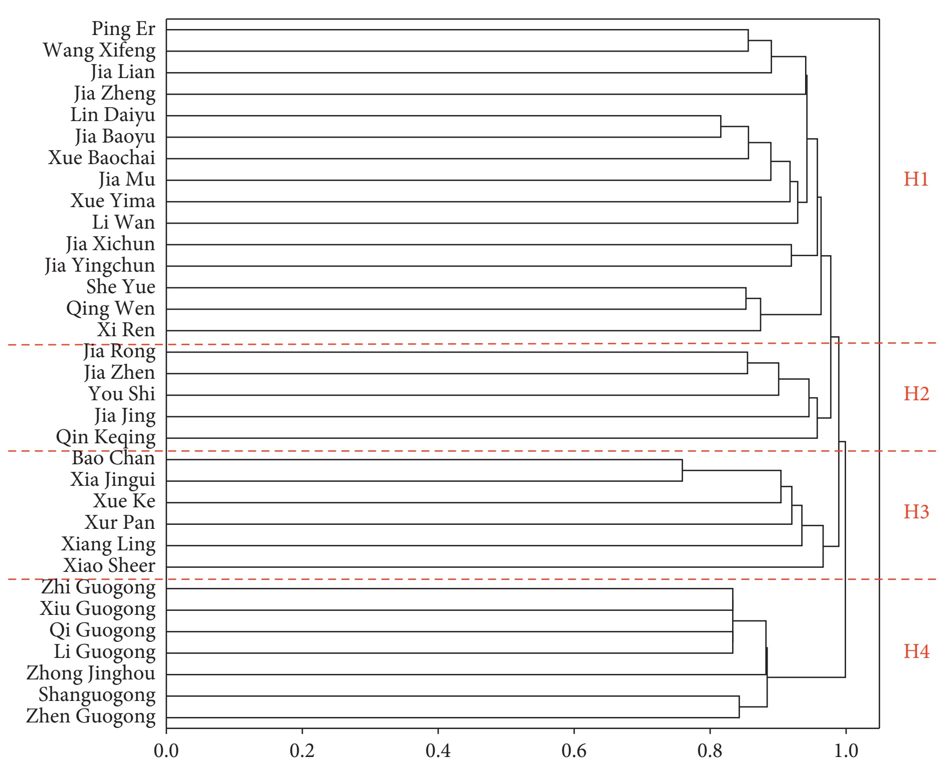

Figure 8: Dendrogram of clustering result for the DRM network.

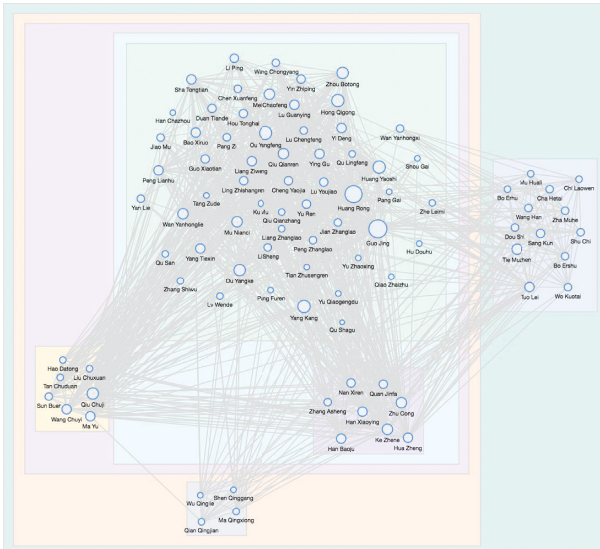

Figure 9: Improved Venn diagram visualizing the clustering result of LCH.

Furthermore, the Jia family (H1 and H2) and the Xue family (H3) are combined to form a bigger cluster due to marriage. H4 is a group of noble people with titles that are closely connected. Finally, all the clusters are aggregated into one cluster.

Besides the dendrogram, an improved Venn diagram is also proposed to depict the hierarchical clustering result. Figure 9 gives an instance of LCH using an improved method and reveals a visualization result by setting the number of clustering as 5. In this figure, small groups within 5 clusters are eliminated so that clusters can be clearly presented. Also, the hierarchical structure of 5 clusters is exhibited by filling different clusters with different colors. Moreover, we can control the number of clusters and merge nodes with the same cluster label in hierarchical clustering. The proposed visualization method can not only draw connections between nodes but also show the hierarchical structure of clusters. For example, four groups on the left side of Figure 9 are different gangs in mainland China. They cluster together to form a large group with leading Chinese characters. The group on the right side of Figure 9 is composed of Mongolian characters. Five groups are aggregated to build a small world of LCH with a hierarchical framework.

5. Conclusions

This article focuses on network extraction and analysis of character relationships in Chinese literary works. Four classical Chinese novels are selected as datasets to be analyzed. Initially, semantic segmentation and POS tagging were completed to process the raw corpus. A co-word analysis was then used to extract social networks of character relationships from Chinese literary works. Furthermore, a network analysis was performed by calculating degree distributions, network density, average clustering coefficient, centrality, and so forth. In order to implement cluster analysis, a co-occurrence matrix and similarity matrix were calculated to measure the similarity (or distance) between two characters in the network. Besides, data visualization was applied to explore character relationships. On the one hand, a tree-like dendrogram was used to display the result of hierarchical clustering. On the other hand, an improved Venn diagram was proposed to simplify graphical visualization. Finally, a dendrogram for DRM and a Venn diagram for LCH were visualized in our experiments.

In future, pronouns will be translated into character names using the coreference resolution so as to improve the extraction effect of character relationships. Introducing other network features and visualization approaches is another direction in the following research.

Plaque deposits in the carotid artery are the major cause of stroke and atherosclerosis. Ultrasound imaging is used as an early indicator of disease progression. Classification of the images to identify plaque presence and intima-media thickness (IMT) by machine learning algorithms requires features extracted from the images. A total of 361 images were used for feature extraction, which will assist in further classification of the carotid artery. This study presents the extraction of 65 features, which constitute of shape, texture, histogram, correlogram, and morphology features. Principal component analysis (PCA)-based feature selection is performed, and the 22 most significant features, which will improve the classification accuracy, are selected. Naive Bayes algorithm and dynamic learning vector quantization (DLVQ)-based machine learning classifications are performed with the extracted and selected features, and analysis is performed.

1. Introduction

Cardiovascular illnesses are the chief reason for death as per the World Health Organization. Accurate measurement and analysis of the carotid artery provide early identification of stroke and atherosclerosis diseases, which are caused by plaque deposit. In clinical diagnosis, plaque morphology and stenosis severity characterization may be diagnosed using noninvasive ultrasound imaging [1]. Experienced radiologists outline the layer thicknesses and plaque deposition buy may vary depending on the person. Automatic segmentation and classification of the carotid artery ultrasound images are necessary for accurate and early assessment of the disease.

Biochemical risk factors and vital signs include high C-reactive protein, glycohemoglobin, low-density lipoprotein cholesterol, serum creatinine, factor alpha, platelet-to-lymphocyte ratio, and neutrophil-to-lymphocyte ratio. Biomechanical risk factors include increased plaque area, low stenosis grade, increase in IMT, presence of in-plane curvature, abnormal shear stress, C-shaped ICA, low wall shear stress, and reversal flow. The related diseases because of plaque formation in the carotid artery are diabetes, hypertension, plaque hemorrhage, head and neck radiotherapy, chemotherapy, coronary artery diseases, peripheral artery diseases, and low ankle-brachial index [2, 3].

Feature extraction reduces the data dimensionality by removing the redundant features, hence improving the training and inference speed. Nonredundant significant features from the ultrasound images of the carotid artery are extracted and used by machine learning (ML) algorithms to classify the image as abnormal or normal. Using additional features might cause overfitting, and less count features may make the data underfit. A good machine learning model may be built with relevant extracted and selected features from the image. Blood flow features like end-diastolic height, resistivity index (RI), maximum systolic height, pulsatility index (PI), spectral broadening index, and height width index help in plaque identification. Texture, grayscale median (GSM), entropy, coarseness, Hurst coefficient, etc. are some of the useful features [4, 5]. The feature mapping to the classes in a computer-assisted diagnostic (CAD) system is called classification.

Loizou et al. proposed a texture feature variation in carotid artery ultrasound video to recognize the biomarkers of the plaque [6]. Followed by denoising and segmentation, the systole and diastole features were extracted from the video sequence. For the normal, symptomatic, and asymptomatic groups, a higher grayscale median was observed in systole and diastole cardiac cycles. Plaque texture features and grayscale median (GSM) were considerably diverse for the two classes. A multiresolution texture classification technique was proposed by Nikolaos et al. to classify the B-mode carotid artery ultrasound image as with or without plaque deposit [7]. Wavelet packet, stationary wavelet, discrete wavelet, Gabor transform, and other basis function decomposition schemes showed effectiveness in identifying the disease. Appropriate features were selected using deviation in values of the features and using a nonlinear correlation coefficient for thresholding. He proved that biomechanical forces affected texture analysis, and they showed horizontal directionality.

Prostate cancer inventions in transrectal ultrasound images by an automatic segmentation approach were proposed by Wang et al. [8]. The low layers of the convolutional neural network (CNN) are suppressed, and the prostate features in the deep layers are increased to identify, select, and influence the multilevel features from the various layers so that each layer features are enhanced. Layer-wise attention is used for enhancing the features in individual layers. The steps are generating attentive maps in layers, concatenate single-layer feature map to multilayer feature maps, and kernel arrangement in the three convolutional layers. The kernels used in the first two convolutional layers are $3 \times 3 \times 3$, and the last kernel has $1 \times 1 \times 1$ layer. From the learned samples in the folds, hyperparameters were identified by cross validation.

A feature-guided denoising CNN was proposed by Dong et al. [9] for removing noise and improving the image quality of portable ultrasound images. A feature masking layer was proposed for hierarchical noise removal in layers. Feature extraction was performed by an explainable artificial intelligence procedure. The highest important features were observed, and the other less important features were also partially preserved by guided backpropagation to map the neural network's choice. The feature images were combined with the Laplacian pyramid fusion method. BI-RADS feature extraction for characterizing the breast cancer lesion, which is continuously varying during the ultrasound sequence, was proposed by Sellami et al. [10]. The analysis was performed for the varying images with morphological and texture features. They concluded that the feature extraction should be performed in many slices of similar mass to get the optimal segmentation results. Slice selection depends on the radiologist, and another slice may have the necessary useful information, which should not be missed for diagnosis.

Siavash et al. proposed a method to quantify morphological features, which helped in classifying tumor cells and disease identification [11]. By conserving the bigger vessel trunks, morphological parameters like tortuosity were measured. They developed an approach to augment the tumor microvessels with ultrafast ultrasound imaging. Wang et al. used a pretrained deep convolutional neural network (DCNN) and developed a multinetwork feature extraction model, which also performed dimensionality reduction and trained an ensemble support-vector machine [12]. Followed by preprocessing of the histological data by scale variation and color improvement, features in many levels were extracted by four trained DCNN. Using dual-network orthogonal low-rank learning, feature selection is performed for overfitting modifications and performance boosting of the method.

Zhou et al. proposed an involuntary measurement with phase images for spine curvature using three-dimensional ultrasound volume projection images [13]. Bony feature extraction by twofold thresholding strategy with asymmetric and symmetric measures information using phase congruency was performed. When the signal Fourier components are hugely in-phase, they can extract Mach bands, roof, line edges, and step edges.

Li and Liu proposed a genetic algorithm using information flow for the Naive Bayes classifier. From the view of correlation and angle of causality, a new weight measure criterion is produced by information flow. The approach provided improved classification accuracy compared with other attribute-weighting approaches with Bayes classifiers. The first, third quartile, and median values were higher for the proposed classifier [14]. Zhang et al. proposed a LVQ with a modular reconfigurable pipelining architecture for object recognition and image compression [15]. The method was verified in a 65 nm CMOS prototype chip. Reduced computation time and integration density efficiency were achieved by the approach.

Feature extraction and selection of the carotid artery ultrasound images are performed to assist ML-based classification. The best significant features are selected by a divergence approach and principal component analysis (PCA). The images are classified as with or without plaque deposit, for early identification of the presence of stroke. This study's layout is as follows. Section 2 gives the methodology of feature extraction, selection, and classification, Section 3 explains the results and discussions, and Section 4 concludes the study.

2. Methodology

This segment describes the feature extraction of the carotid artery ultrasound images. Appropriate features are selected after extracting the image features. The selected features are classified using Naive Bayes and DLVQ machine learning algorithms, and the classification performances are analyzed.

2.1. Carotid Artery Ultrasound Images. Ultrasound imaging is economically affordable, noninvasive, and continuously improving in image quality that will provide early diagnosis of arterial disease. Intima-media layer thickness, lumen diameter, and texture characterization are necessary for the assessment of cardiovascular illnesses. The ultrasound images are affected by speckle noise and should be effectively denoised, so that image quality is preserved and the useful features are not lost. Curvelet decomposition-based denoising is performed for noise removal.

The carotid artery is an artery in the neck region, which transports pure blood from the heart to the brain and the front of the face. It contains the common carotid artery (CCA), which splits into external carotid artery (ECA) and internal carotid artery (ICA). Figure 1(a) presents the carotid artery structure, where ICA provides blood to face and ECA to the brain. The bifurcation is a more plaque-prone area.

Figure 1 presents the sample carotid artery ultrasound image with and without plaque deposit. The deepest smooth layer is intima, muscular middle layer media, and the outer layer is adventitia. Lumen is the inner core of the artery. Atherosclerosis is the narrowing of the artery lumen because of fat and calcium deposit in the artery wall, which may lead to thinning of blood flow as indicated. The local thickening in the artery because of fat deposition is called plaque formation. The intima-media thickness (IMT), lumen-intima (LI) interface thickness, and media-adventitia (MA) interface thickness influence the carotid plaque thickening. IMT measurements for a healthy person are from 0.2 to 0.25 mm.

Carotid artery disease identification includes plaque characterization and layer thickness measurements on age, gender, environmental conditions, and other habits of the person. The increased plaque thickness in the carotid is considered as an early indicator of future cardiovascular risks like stroke and atherosclerosis. The artery is at distance of 1 to 3 cm from the skin and so can be analyzed with imaging techniques.

2.2. Database Creation. Ethical clearance is obtained from SRM Medical College Hospital and Research Centre, Kattankulathur, Tamil Nadu, India, to get carotid artery ultrasound images. Carotid artery ultrasound B-mode image datasets are collected from SRM Medical College Hospital and Research Centre, Kattankulathur, Chennai, and Bharat Scans, Chennai.

Three hundred and sixty-one carotid artery ultrasound images were obtained, out of which 202 are normal images without plaque deposit and 159 images are with plaque deposit in the artery layers. About 75% (270) of data are used for training and 25% (91) for testing the machine learning algorithms.

2.3. Feature Extraction. Feature extraction and selection prevent overfitting of the training data and poor generalization of the new samples as given in Figure 2. Effective model construction for machine learning depends on the suitable optimized features. For a given feature set $F = \{f_1, f_2, \ldots, f_n\}$, the features to be selected should maximize the learner algorithms' ability to classify the carotid image as symptomatic or asymptomatic. F should be a function maximizing the scoring function. The features are normalized or translated in the range [0 1]. Thus, the data are aligned with similar distributions and help in model fit. Z score normalization procedure is used, which is a standard score technique. Population mean is deducted from the individual data and uniformly divided by the population standard deviation.

Despite variations in class, a useful feature should remain unchanged. Feature extraction categories are based on nontransformed and transformed structural characteristics, and structural and graph descriptors. For high-dimensional feature space, computational complexity increases [16]. A kernel function is made to record the nonlinear data into a higher dimensional space. Kernel is a dot product in high-dimensional space. Thus, all computations are made in the low space dimension. The kernel function is given by

$$K(x, x') = \vartheta(x)^T \vartheta(x)', \tag{1}$$

K is the inner product of the vectors x and x' in the low-dimensional feature space for a function ϑ. At an instant y, with slope w_0, the input's hyperplane is given by

$$y(x) = \operatorname{sign}\left[\sum_{i=1}^{M} y_i K(x, x') + w_0\right]. \tag{2}$$

Feature selection is to identify the relevant properties of the image for data reduction and reduction in feature set, and to improve accuracy for performance improvement and proper understanding of the data for image analysis. Features may be subdivided based on their relevance.

The extracted features may belong to any of the following categories, which assist in deciding whether it is a significant feature.

(i) A feature X_i is irrelevant for all the subsets belonging to S_i.

$$P\left(X_i, Y \mid S^{-i}\right) = P\left(X_i \mid S^{-i}\right) P\left(Y \mid S^{-i}\right). \tag{3}$$

These are the features with very less or zero probability calculated by Kullback-Leibler divergence.

(ii) A feature X_i is nearly unrelated with approximation value $\mu > 0$, for subsets S_i

$$\mathrm{EMI}\left(X_i, Y\right) \leq \mu. \tag{4}$$

For $\mu = 0$, the feature is surely irrelevant.

(iii) A feature X_i is separately inappropriate if the significance threshold $\varphi \geq 0$.

$$\mathrm{MI}\left(X_i, Y\right) \leq \phi. \tag{5}$$

(iv) A feature i is possibly nearly inappropriate based on D index computed with n number of examples, with approximation $\phi \geq 0$ and risk $\delta \geq 0$.

$$P(C(i, m) > \phi(\delta, m)) \leq \delta. \tag{6}$$

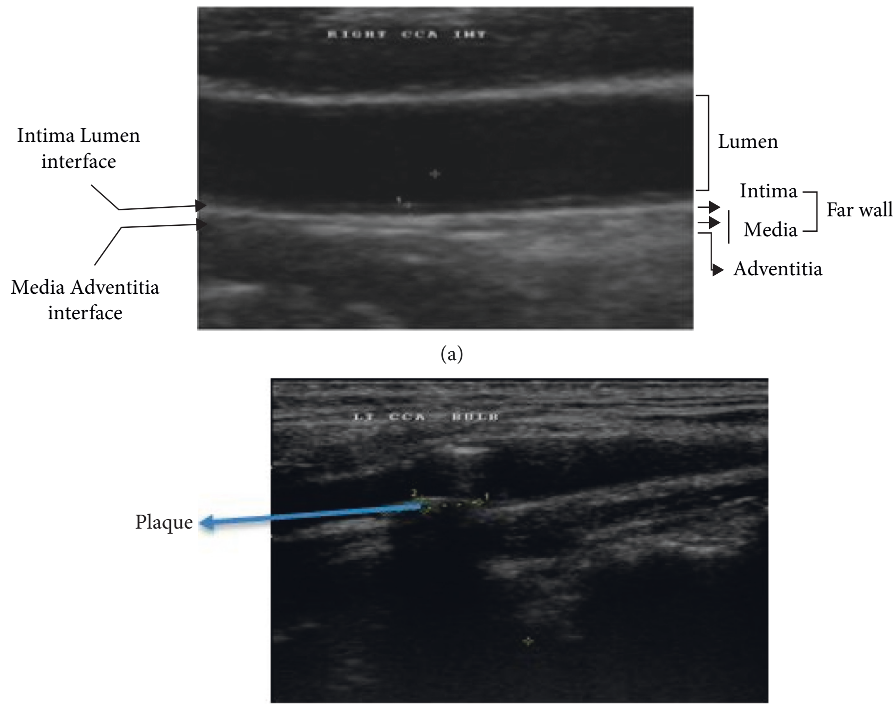

FIGURE 1: Sample carotid artery ultrasound image (a) with plaque and (b) without plaque.

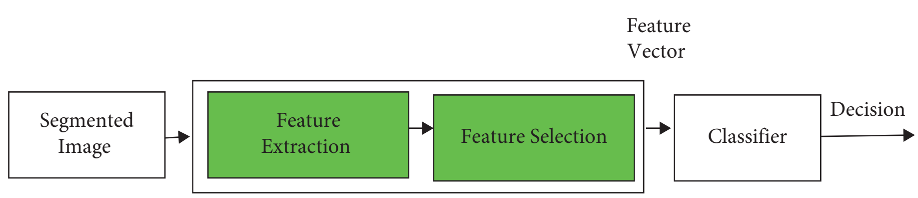

FIGURE 2: Block diagram of classification system.

(v) A subgroup V of features is certainly adequate if it also belongs to the complementary of the subset.

$$ {}^{i}_{v} P(Y \mid V) = P(Y \mid X). \tag{7}$$

(vi) A subgroup V of features is roughly adequate with approximation level $\phi \geq 0$ when

$$\mathrm{DMI}(V) \leq \phi. \tag{8}$$

If $\phi = 0$, the subset is surely sufficient.

(vii) A subset V of features is minimally approximately sufficient with approximation level $\phi \geq 0$, and other smaller subsets of ϕ does not exist.

From the carotid artery dataset, more artery characteristic-related features along with the standard features are extracted to analyze the image and identify whether the person has plaque deposit. The dataset was enhanced and labeled by radiologists for accuracy [17], and 63 shape, texture, morphology, histogram, and correlogram-based features are extracted and analyzed with the machine learning techniques.

Along with the existing features, plaque morphology-based features extracted are plaque power spectra for all the three intensity variations (low, medium, and high), namely, shape, connectivity, convexity, plaque size, lipid core, presence of intraplaque hemorrhage, smooth lumen surface indicating no risk, and rough lumen, which may lead to stroke and plaque volume. Figure 3 gives the procedure followed for feature extraction, selection, and classification of the carotid artery ultrasound images.

2.4. Extracted Features. Features are extracted from the carotid artery images in the database following preprocessing followed by segmentation steps. The image is noise-free and contrast enhanced, assisting in the quantization of the image features. The below sixty-three features are extracted from the carotid artery ultrasound image database.

Table 1 gives the list of the extracted features. Thirty-three texture features, five shape features, ten histogram- and

correlogram-based features are extracted. Fifteen plaque morphology-based features were extracted from the carotid artery ultrasound image database. A detailed explanation of the extracted image features is given below.

2.4.1. Texture Features. Texture in the image is computed from the gray-level co-occurrence matrix (GLCM), which uses spatial difference among the pixels, which are in pairs with a certain distance, relation, and direction [18, 19]. Inertia, energy, correlation, entropy, and homogeneity information are extracted from the matrix. It is proved that the directions 0°, 45°, 90°, and 135° are less dominant for GLCM in medical images, requiring less computation at these angles. For image $I(k, k)$, the co-occurrence matrix is given by

$$C_M = \sum_{i=1}^{k}\sum_{j=1}^{k}\begin{cases} 1, \text{ if } I(i, j) = k, I\left(j + D_x, j + D_y\right) = k, \\ 0, \text{ otherwise,} \end{cases} \tag{9}$$

where $D_x = D.\cos(\theta)$, and $D_y = D.\sin(\theta)$, θ being the offset defining matrix direction from the central pixel, and D, the distance from the central pixel. For the given angle θ, the parameters computed are as follows:

$$\begin{aligned} \text{contrast} &= \sum_{a=1}^{L}\sum_{b=1}^{L}(a-b)^2 C_M, \\ \text{correlation} &= \sum_{a=1}^{L}\sum_{b=1}^{L} C_M\left[\frac{\left(a-\mu_a\right)\left(b-\mu_b\right)}{\sqrt{\left(\sigma_a^2\sigma_b^2\right)}}\right], \\ \text{energy} &= \sum_{a=1}^{L}\sum_{b=1}^{L} C_M^2, \\ \text{homogenity} &= \sum_{a=1}^{L}\sum_{b=1}^{L}\frac{C_M}{1+|a-b|}. \end{aligned} \tag{10}$$

Gabor wavelet texture features are computed in precise directions and frequencies. Statistical features like mean, median, kurtosis, and skewness were computed. LBP gives the characteristics of the texture's spatial structure. GLCM analyzes the pixel pair's gray-level distribution and is known as a second-order histogram. Gray-level difference statistics (GLDS) extracts the texture features mean, entropy, angular second moment, contrast, and homogeneity representing the difference between the pairs of average gray levels. For $d = 1$, the mean displacement values were computed.

The following are the relation between texture and statistical characteristics.

(i) For dis-similar pixel pair in coarse texture region, contrast is high, representing considerable variation in gray level.

(ii) A high-energy feature value represents the textural uniformity of the image.

(iii) Uniform GLCM is represented by a large entropy value, which represents nonhomogeneity or degree of disorder.

(iv) Homogeneity of the pixel pair is small for different gray-level pixel pairs.

(v) Pixel's neighborhood influence represents the correlation.

The pixel statistical properties given by the statistical feature matrix (SFM) are coarseness, roughness, periodicity, and contrast. Pixel's self-similarity is represented by fractals in Euclidean space for a bounded set A for N overlapping copies of itself. For a scaling ratio s, the fractal dimension is given by

$$D = \frac{\log N(s)}{\log(1/s)}. \tag{11}$$

A rough texture has less fractal dimension texture analysis (FDTA) at image resolution 4. Radial and angular sum of discrete Fourier transform for Fourier power spectrum textural feature is computed [20]. The texture's visual properties are projected in the neighborhood gray-tone difference matrix (NGTDM), given by strength, complexity, coarseness, and contrast. The absolute gradient value is more when the pixel intensity moves from black to white, and it is less when it moves from dark gray to a lighter shade. Dark to light shade movement is indicated by a positive gradient, and light to dark shade is represented by a negative gradient [21]. Mean and variance are computed from the absolute gradient texture feature. It measures the mean gray-level changes through the image and how far the pixels are from the mean deviation. Pixels of the same gray level in a certain route are given by the run-length matrix.

2.4.2. Shape Features. Shape-based similarity among the pixels is extracted by shape features. It is a content description based on and performed by feature extraction and likeness measurement among the extracted features. Region-centered shape feature projects the contour characteristics in the entire image region, and contour-based shape feature gives the shape in the contour alone. Contour-based shape features extracted are sharpness, complexity, length irregularity, aspect ratio, and circularity. Contour detection from the edges is possible with these rotation, translation, and scale-invariant shape features [22–24].

$$\begin{aligned} \text{sharpness} &= \sum\frac{\max\left(0, 1-\left(\left(2|\theta-\pi|/\pi\right)^2\right)\right.}{n}, \\ \text{complexity} &= \frac{10^{-3}}{n}, \\ \text{length irregularity} &= \frac{\sum\left|L_i - L_{i+1}\right|}{K}. \end{aligned} \tag{12}$$

For $n > 3$, $K = 2P$ and for $n = 3$, $K = P$, which is the length of the polygon segment and the next segment.

$$\text{aspect ratio} = \frac{p_1 + p_2}{C},$$
$$\text{circularity} = \frac{4\,pA}{P^2}, \tag{13}$$

where the segment boundary enclosed polygon sides n, discontinuity angle θ, the perimeter of the polygon bounded by segment border P, and the most significant perpendicular distances to the boundary p_1 and p_2. X and Y coordinates of the picture frame, area of ROI, perimeter, and perimeter^2/ area of ROI were computed to find whether the complexity and size of the carotid image shape help in identifying plaque deposit.

2.4.3. Histogram and Correlogram Features. For the continuous pixel data, the histogram is its frequency distribution representation. Gray-level histogram of segmented ROI for the carotid image for thirty-two same width bins was computed. The plaque histogram feature effectively represents the plaque characterization. The multiregion histogram is computed for equidistant ROI to check whether the plaque outer region signifies disease progression. Grayscale median (GSM) derived from the histograms first-order statistics and entropy represents the echogenicity and arterial wall ROI's randomness. For the image array Y, T_2 histogram is computed for a known mean scalar A. Image data are obtained from the first-order histogram with n^{th} feature $y_n(i, j)$ in the local region M. Let us consider y_n constitute discrete values only. The distance vector, which is the gray-level difference between the two pixels, is given by

$$d = \left(\Delta_x, \Delta_y\right), \tag{14}$$

for integers Δ_x and Δ_y. At distance d, the gray-level difference is given by

$$Y(d) = |\, I(i, j) - I\left(i + \Delta_x, j + \Delta_y\right) |. \tag{15}$$

The HOG feature derived from DCT gives the details about corners and edges in the image. Gradient and orientation information of the artery layer localized region is extracted after separating the image into smaller regions. The histogram of each region is separately computed from the gradients and orientations of pixel values. For directions G_x and G_y, the gradient magnitude is given by

$$\text{gradient magnitude} = \sqrt{G_x^2 + G_y^2}. \tag{16}$$

The orientation of each pixel is given by

$$\tan\phi = \frac{G_y}{G_x}. \tag{17}$$

The number of HOG features is dynamic based on the size of each region. Based on the gradient and direction, the weighted HOG is generated. To prevent aliasing problems, in orientation and position centers, bilinear vote interpolation is performed.

Statistics and spatial distribution of the features are represented by a type of histogram called correlogram [25]. Pixel gray intensity from the center is computed to get the correlogram of the image. The distance of each pixel from the center is identified from which equidistant pixels histograms were computed. The calculated distance to the maximum distance difference is divided by the normalization factor, which gives the correlogram comparison. The texture and shape features are normalized, whereas histogram and correlogram features are used without normalization.

2.4.4. Morphology Features. The presence of structural elements at different scales is identified by morphological features. The near-isotropic detection structural elements are represented by + in the structural pattern of the plaque. At the two morphological sets, mean cumulative distribution functions (CDFs) and the mean probability density functions (PDFs) are computed. Plaque component-based multilevel decomposition describes the morphology of the image [26, 27]. The normalized image is thresholded at low, medium, and high intensities. The unstable plaque is indicated by low dark components, and the bright region indicates stable plaque. The plaque power spectra for all the three intensity variations are used as a feature for plaque classification. The hypergeometric function used to capture the morphology of the image by the n_{th}-order Krawtchouk classical polynomial k is given by

$$k_m(x; p, N) = \sum_{k=0}^{N} a_{k,m,p} x^k = \mathrm{aF}_1\left(-m, -x; -N; \frac{1}{P}\right). \tag{18}$$

For a given x, with $m = 0$ to N, $N > 0$, $p \in (0, 1)$ if the hyperbolic function F_1. This represents the geometrical structure of the artery and the carotid plaque with details of shape, connectivity, and convexity. Clinical diagnosis depends on the artery wall morphology as a weighted map of the weighted original image. If the segmentation results are poor, the contour morphology may miss some details, leading to improper diagnosis. The morphological stream of feature extraction selects all the morphological features required for learning and classification like plaque size, lipid core, and presence of intraplaque hemorrhage [28]. Plaque destabilization leads to plaque rupture, and the disrupted plaque constitutes a thrombus in the distal artery layers. The volume of plaque in the carotid artery is not a clear indicator of the degree of stenosis. Ischemic symptoms can be identified by the plaque morphological features. In spite of any stenosis degree, the features may cause stroke risk. Thus, the morphological features and the degree of stenosis together give the plaque vulnerability characteristics. A smooth lumen surface indicates no risk, and a rough lumen is considered to lead to stroke.

Blood pressure and plaque rupture cause intraplaque hemorrhage, and it is closely related to cerebrovascular events. The susceptible plaque has a thin fibrous cap, which covers a lipid-rich necrotic core containing inflammatory cells. The artery attempts to maintain a uniform plaque diameter concerning the lumen. Positive remodeling tends to increase the diameter, and adverse remodeling tends to decrease the diameter, which is called stenosis [29, 30]. Plaque volume is proved to be a more significant feature to identify the disease progression and vulnerability than the degree of stenosis.

Echolucent plaque, which contains big white blobs, is considered to be dangerous. Calcified and collagen-stuffed plaque is stable and has very less chance of rupture with a tiny high-intensity image. A lipid with scattered components in the low-intensity image can be characterized as asymptomatic. Thus, unstable plaque is an effect of the thin fibrous cap. From the morphological features extracted, it is understood that plaque instability may not lead to stenosis but reduces blood flow in the artery.

2.5. Feature Selection. A robust subset of the extracted features is selected to reduce computational complexity and improve classification accuracy. Feature selection aims at dimensionality reduction, retaining the discriminatory information from the images. The maximum discriminant features from the extracted features are carefully chosen depending on the subsequent method.

The distance among two classes for all the features are generated as below for mean m_1, m_2 and standard deviation σ_1, σ_2.

$$\text{distance} = \frac{|m_1 - m_2|}{\sqrt{\sigma_1^2 + \sigma_2^2}}. \tag{19}$$

Significant features are identified using the distance measure, and increased distance means more the significance. Sixty-five features are extracted, from which twenty-two most relevant features are considered for the classification process. Along with this method, the principal component analysis (PCA) method for the selection of features is performed. Eigenvalues are used for deriving the principal components. Uncorrelated feature set and principal components are achieved from the correlated ones, orthogonal transformation.

The steps in PCA feature reduction are as follows:

(1) The mean value of the dataset D is computed.

(2) A new matrix S is formed by subtracting the mean value from D.

(3) From S, covariance is estimated at $C = \text{AAT}$. For data 1 to l,

$$S_k \in R^N, \sum_{k=1}^{l} S_k = 0 \, \text{covariance c} = \frac{1}{l} \sum_{i=1}^{l} S_i S_i^T. \tag{20}$$

(4) Eigenvalues derived from the covariance matrix are $[V_1, V_2, \ldots, V_n]$.

(5) Eigenvectors are found from the covariance matrix.

(6) Vector $D - \overline{D}$, a linear function of eigenvectors, is given by

$$D - \overline{D} = b_1 u_1 + b_2 u_2 + \cdots b_n u_n. \tag{21}$$

The symmetric covariance matrix is $[V_1, V_2, \ldots, V_n]$.

(7) Large eigenvalues reduce the dataset to $D - \overline{D} = \sum_{i=0}^{l} b_i u_i$, $1 < N$.

For a normally distributed dataset, the principal components are independent. The PCA depends on the individual variable screening. The PCA reduces the dimensionality of the dataset and increases interpretability with a reduction in loss of information. The variances are maximized one after the other by developing variables, which are uncorrelated.

2.6. Classification. The extracted features were given to machine learning classification algorithms, namely, the Naive Bayes algorithm and dynamic learning vector quantization (DLVQ), for a more accurate classification of the carotid artery ultrasound images.

2.6.1. Naive Bayes Algorithm. Bayes theorem considers an event probability based on prior knowledge of the related conditions with statistical interference. The Naive Bayes classification algorithm is a supervised approach, which depends on the Bayes theorem and assumes that the occurrence of a feature is not dependent on other features in the image. Frequency tables are generated from the dataset, followed by probability-based likelihood table generation and posterior probability calculation based on the Bayes theorem that are performed. Since the dataset followed a normal distribution, Gaussian-based Naive Bayes classification is performed for the dataset images. Weighting the features and structure extension is used to overcome the drawback of the complete feature independence assumption. A kernel function is used to estimate the data distribution instead of following a normal distribution.

For the two-class problem C_1, C_2, samples are indicated by n dimensional vectors.

$\overrightarrow{Y} = \{Y_1, Y_2, \ldots Y_m\}$ containing m attributes A_1 to A_m projecting m measured values. $\overrightarrow{Y}$ needs to be found with the highest a posteriori probability. Y lies inside the class C based on the following condition.

$$P\left(C_i \mid \overrightarrow{Y}\right) = \frac{P\left(\overrightarrow{Y} \mid C_i\right) P(C_i)}{P(\overrightarrow{Y})}. \tag{22}$$

The numerator value should be maximized to get a higher probability, since the probability of getting the Y vector is a constant. The assumption that the classes are conditional independent is performed [31, 32].

$$P\left(\overrightarrow{Y} \mid C_i\right) \approx \prod_{s=1}^{m} P(Y_s \mid C_i). \tag{23}$$

The Y_1 and Y_2 probabilities can be obtained from the training set.

Since Naive Bayes assumes that all the dimensions are independent, the classification accuracy is minimum compared to the LVG algorithm.

2.6.2. Dynamic Learning Vector Quantization (DLVQ). The LVQ is a winner take all Hebbian learning-based supervised learning approach. The algorithm classifies the sample with the same label as the codebook prototype, similar to the nearest neighbor classification. In the training phase, LVQ iteratively goes through the training sample y_j, shifted to the nearest available prototype $n_{m(j)}$ nearer or farther from y_j. This depends on if the $n_{m(j)}$ is in the same class as y_j.

$$n_{m(j)} = \begin{cases} n_{m(j)} + \rho\left(y_j - n_{m(j)}\right), \text{if } n_{m(j)} \text{has label } x_j, \\ n_{m(j)} - \rho\left(y_j - n_{m(j)}\right), \text{otherwise}, \end{cases} \tag{24}$$

ρ is between 0 and 1, and it is a step size, which is monotonically reducing [33, 34]. An adaptive version of LVQ is DLVQ, which can acclimate the neuron count to the dataset. It is a computationally less cost approach that has two layers of the fully connected network. The output parallels to one of the classes and matches to a reference vector with weights assigned. The output value is the consolidation of the outcomes of all the output neurons, which signifies the distance between the input sample and the reference vector. The distance helps in weight updating during the training phase and assigning the neuron to the corresponding output during the classification [33]. The frequency-sensitive competitive learning approach is used for training the network. DLVQ is used with global average pooling so that the model parameter count is minimized, thus reducing overfitting.

3. Results and Discussions

For the carotid artery ultrasound images, feature extraction, selection, and classification are performed. The results are analyzed with the classification performance measures.

3.1. Feature Extraction and Selection. The features extracted from the carotid artery ultrasound images are normalized and plotted for normal images without abnormalities and abnormal images with plaque deposit. From the bar plot, if a particular feature records significant variation for normal and abnormal images, it is considered as a significant feature. If a feature does not show variations for normal and abnormal images, it is considered not a significant feature and is omitted.

Figure 4 shows sample discriminant features such as skewness, kurtosis, histogram, HOG, and correlogram. Features with more variance help in machine learning classification since the values are far apart for normal and abnormal cases. For sample features such as correlation, contrast, entropy, and variance, the normalized feature values are indiscriminate and are hence not useful for machine learning classification. Table 2 gives the selected features based on discriminant and PCA feature reduction technique for the carotid artery ultrasound images.

The statistical PCA model identifies the discrete pattern in the data and thus selects only the required features. The input neurons of the classification algorithms are powered by the potential features.

3.2. Classification Performance Measures. The selection of appropriate performance measures for evaluating the machine learning classification algorithms provides faith for its real-time application. Since the data are imbalanced, applying more measures provides a clear insight into the algorithm usage. Classification of the carotid artery ultrasound images is a binary class problem, correct classification as fitting to the class being true positive (TP), correct classification as not fit in the class as true negative (TN), wrongly categorized to a class false positive (FP), and misclassified to a class as false negative (FN). The general efficiency of the model is given by

$$\text{accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}}. \tag{25}$$

Agreement of the labels with positives is given by

$$\text{precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}. \tag{26}$$

Sensitivity and recall give the efficiency of identifying positive labels. The data out of the classifier and the positive labeled ones' relationships are measured by F score. Negative label identification performance is measured by specificity. Recall is given by TPR, and probability is given by FPR. Area under the ROC curve (AUC) gives false classification identification presentation of the model, where 1 depicts a *n* ideal model [35, 36].

$$\begin{aligned} \text{recall} &= \frac{\text{TP}}{\text{TP} + \text{FN}}, \\ \text{precision} &= \frac{\text{TP}}{\text{TP} + \text{FP}}, \\ \text{f score} &= 2 \times \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}}, \\ \text{specificity} &= \frac{\text{TN}}{\text{TN} + \text{FP}}, \\ \text{AUC} &= \left(\frac{1}{2}\right)\left(\frac{\text{TP}}{\text{TP} + \text{FN}} + \frac{\text{TN}}{\text{TN} + \text{FP}}\right), \\ \text{Accuracy} &= \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}}. \end{aligned} \tag{27}$$

These parameters denote the classification model performance. The classification models used ReLU activation function. ReLU is a nonlinear activation function, which does not activate all neurons at the same time. It is fast and easy and converges faster compared to other activation functions.

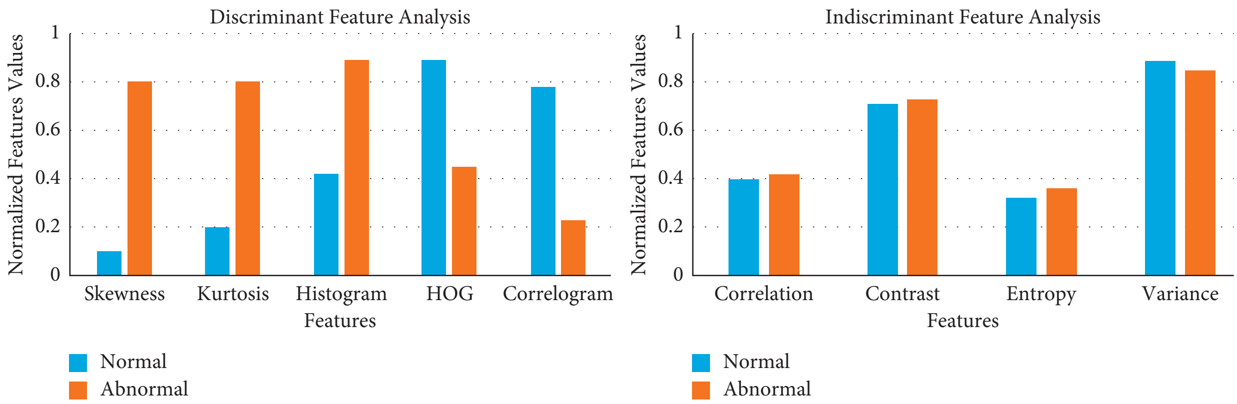

Figure 4: Feature analysis.

Table 2: List of selected significant features.

Sl. no	Selected features	Description
1	Texture	Spatial arrangement of image intensity
2	Spatial structure	Exploit location information
3	Skewness	Extent to which a distribution differs from a normal distribution
4	Kurtosis	Pixel intensity distribution
5	Histogram	Pixel distribution as a function of tonal variation
6	Correlogram	Spatial correlation of intensity changes with distance
7	HOG	Count incidences of gradient alignment in localized regions of an image
8	Gabor wavelet	Frequency-wise intensity variation check in specific direction
9	Angular 2nd moment	Textural uniformity in image
10	Shape	Shape characteristics
11	Sharpness	Degree of clarity in both coarse and fine image detail
12	Length irregularity	Irregularities of the length of structures in an image
13	Mean probability density function	Probability that the region brightness is less than or equal to a specified brightness value
14	Grayscale median	Median of grayscale intensities
15	Multiregion histogram	Checks whether plaque outer region signifies disease progression
16	Arterial wall ROI's randomness	Randomness present in the artery wall
17	Absolute gradient	Directional change in intensity
18	Angular and radial sum of discrete Fourier transform for Fourier power spectrum	Fourier power spectrum's Fourier transform
19	Coarseness	Type of texture feature
20	Convexity	Convex curves present in an image
21	Connectivity	Connectivity among pixels
22	Plaque volume	Plaque volume measure

3.3. Machine Learning. The database comprised of 202 normal images without any plaque deposit and 159 images with plaque deposit. The selected features are provided as the input neurons of the ML approaches. Box-Cox plot transforms the data so that it can be similar to a normal distribution. Considering the presence of normally distributed errors, a hypothesis test can be performed. The gain curve gives the performance of the machine learning models with randomly taken data. The curve analyzes the percentage of the target compared with a group with the highest probability. The receiver operating characteristic (ROC) curve provides the sensitivity vs. specificity relation for the

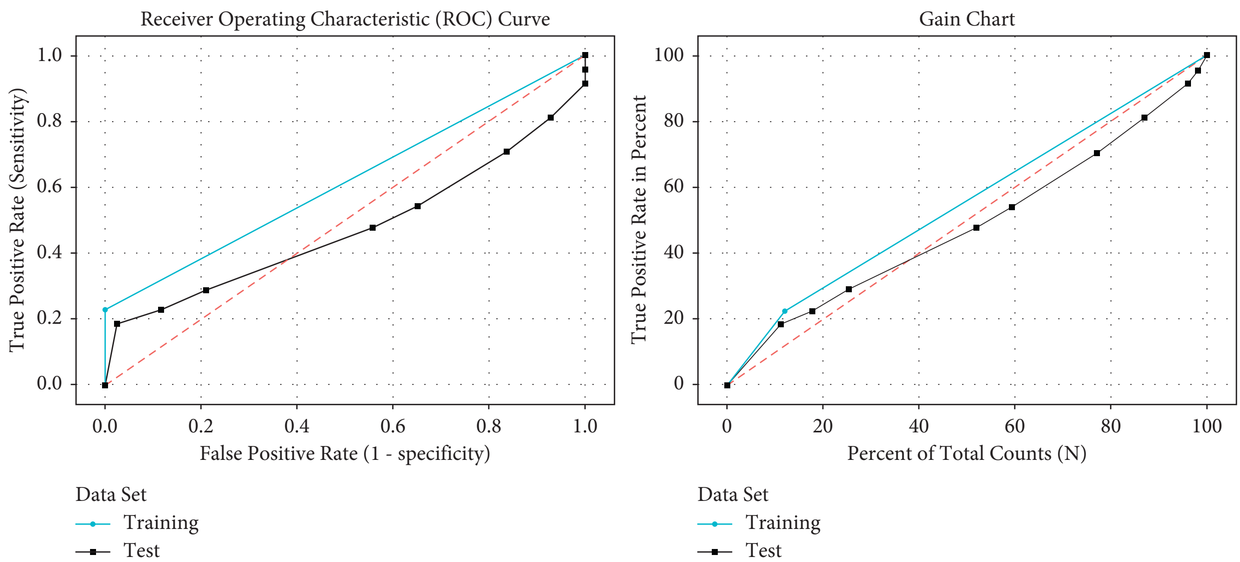

Figure 5: ROC curve and gain chart of Naive Bayes algorithm.

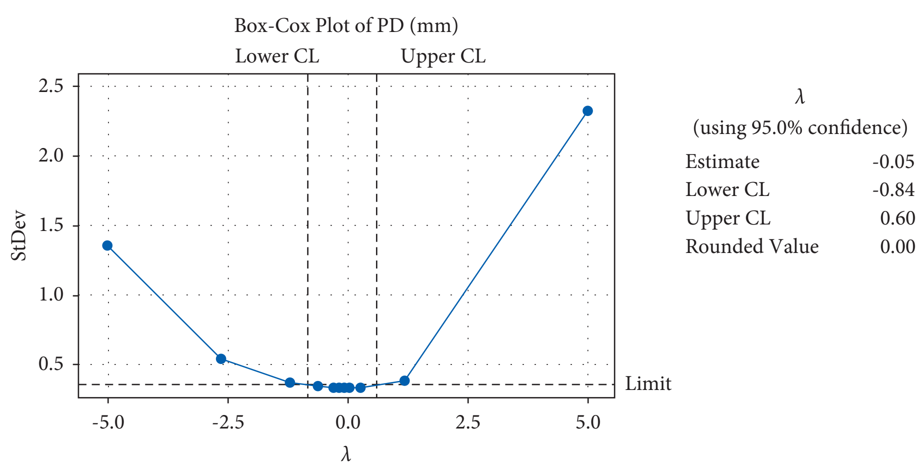

Figure 6: Box-Cox plot of plaque diameter.

probable cutoff values in all classification thresholds. The ordinal curve gives the contribution of the features and their significance. It helps in the data to rely on one final side.

Figure 5 gives the ROC curve and gain chart of the Naive Bayes classification. It has recorded an area under the curve training of 61.46% and 47.50% for testing. The gain chart gives the whole positive rate percentage to the total count percentage.

Figure 6 gives the Box-Cox plot for the plaque diameter, which is a linearity plot giving the correlation between the transformed StDev and the given lambda values. Figure 7 gives the pure ordinal curve for sample features meangl (mean gray level), kurtosis, contrast, and skewness.

Table 3 provides the confusion matrix of the applied ML techniques, namely, Naive Bayes and DLVQ, performed in 361 carotid artery ultrasound images.

Table 4 gives the comparison of the Naive Bayes and dynamic learning vector quantization approaches using the classification performance measures.

Table 5 separately gives the accuracy of the Naive Bayes and DLVQ algorithms with the extracted sixty-three features and the selected twenty-two features. Improved accuracy is found in both the machine learning algorithms on using only the selected features.

Classification of hard and soft plaques will aid in diagnosing dangerous plaque types and may be implemented as a

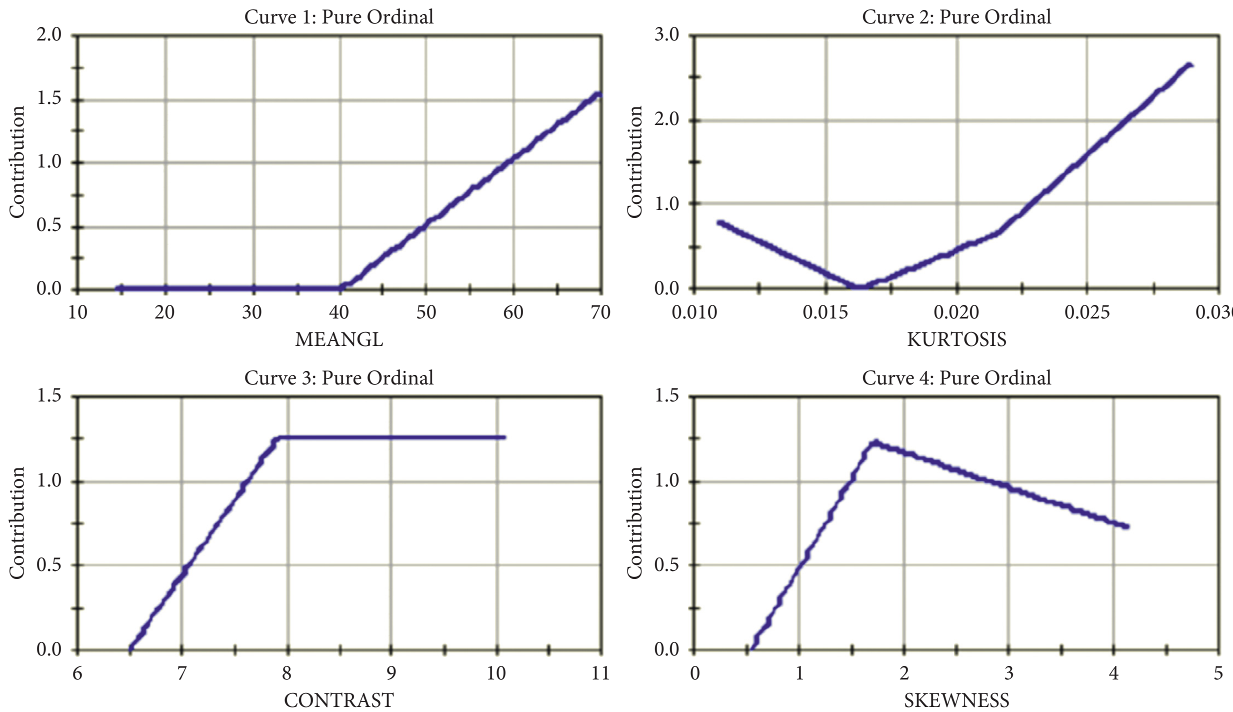

Figure 7: Pure ordinal curve.

Accuracy	With all extracted features	With selected features
Naive Bayes	80.91	82.82
DLVQ	88.72	91.68

future work. A patient-specific model with more measurements from a single patient including boundary conditions, pressure, geometry, 3D images, and thermal images may be implemented to improve diagnostic performance.

4. Conclusions

Sixty-three features consisting of texture, shape, histogram, correlogram, and morphology were extracted from the carotid artery ultrasound images. Principal component analysis (PCA) and feature analysis by feature significance-based feature reduction were performed to minimize overfit and underfit problems. The robust subset from the extracted features reduces model complexity and computation and improves the efficiency of the classification task. Classification of Naive Bayes and DLVQ algorithms is performed using the extracted and selected features. DLVQ with the selected features recorded an accuracy of 91.68%, specificity 98.51%, sensitivity 83.01%, precision 97.77, F score 89.78%, and AUC 98.14%. DLVQ has proven to give improved performance compared to the DLVQ classification approach, on using the selected extracted features.

Chinese classical dance is cut into the inner verve from a grasp of external form in dance instruction, and the aesthetic fashion and artistic norms of classical dance are established with historical depth. The "professional specificity" of characters and the "language description" of plots are eliminated in Chinese classical dance creation, highlighting the contemporary spirit of classical dance creation. Chinese classical dance was born during the early years of the People's Republic of China. The term "classical dance" did not refer to all Chinese classical dances at the time; rather, it referred to a dance form that embodied China's national spirit and had a classical cultural heritage based on Chinese traditional dance. The average frequency of step-over was 0.9, which was higher than the average rate of basic turnover of 0.75 and step-by-step turnover of 0.5, according to the results of the SPSS19.0 analysis. As a result, except for a few points with loud noise, it can be concluded that stepping over is an effective feature. The recognition model of the somersault posture of classical dance is studied in this paper, a database for real-time acquisition of three-dimensional data of human motion is established, and the Google model of human body characteristics is obtained based on feature plane matching of human body posture, all using motion capture technology and few-shot learning. The above data has good reference and application value for improving teachers' teaching level and arousing students' learning enthusiasm in the dance teaching process when applied to posture teaching and analysis. The captured data can convert human motion in real three-dimensional space into data in virtual three-dimensional space. Motion capture technology converts human motion information into a technology that can be recognized by computers.

1. Introduction

Chinese classical dance is made up of traditional Chinese opera, dance, martial arts, and ancient art resources that are mined, screened, and integrated. "Twist, tilt, circle, curve, form, spirit, strength, and law" are the overall requirements and prominent features of Chinese classical dance, and these eight words evolve into posture and movement law through waist movement [1]. Second, in dance creation, Chinese classical dance should be cut from the understanding of external form to the understanding of internal charm, and the aesthetic fashion and artistic norms of classical dance have been established with historical depth; third, in dance teaching, Chinese classical dance should be cut from the understanding of external form to the understanding of internal charm, and the aesthetic fashion and artistic norms of classical dance have been established with historical depth; and fourth, in dance creation [2, 3], Chinese classical dance should be cut from the "profession specificity" of character images and the " Opera," which contains the living fossil of dance inheritance, was studied and learned by the founders of Chinese classical dance. The development of opera is perhaps a tributary in the great Chinese culture, but it is the most clear and complete [4]. The origins of Chinese classical dance can be traced back to the early days of the People's Republic of China. At the time, the term "classical dance" did not refer to all Chinese classical dances; rather, it referred to a dance form that embodied China's national spirit and had a classical cultural heritage based on Chinese traditional dance. When we consider that history, we cannot help but think of Mr. Ouyang Yuqian. He actively advocated for dancers learning the fundamental skills of Chinese opera, as well as studying and distinguishing Chinese classical dance from basic opera dance, and this suggestion was taken into consideration and implemented in the curriculum of the first dance school in New China [5, 6].

Motion capture system can track, monitor, and record human motion data. At present, it has been preliminarily applied and developed in entertainment effectiveness, health record, rehabilitation training, and other aspects [7, 8]. Motion capture is a process of acquiring the size measurement, position, and direction information of moving objects so as to realize further research. Since the 1970s, motion capture has been an important method of photographic image analysis in biomechanics research, and since then, this technology has been more and more widely used in animation, robot control, human-computer interactive games, sports training, and other fields [9]. The motion capture system is mainly composed of sensors, signal acquisition equipment, data transmission, and data processing, including mechanical, electromagnetic, and optical. The adopted motion capture equipment is an optical motion capture system with high precision and good stability, which has achieved ideal results in the process of collecting Xinjiang Uygur dance data [10, 11]. The dance data collected by the motion capture system is input into the 3D animation software and can be displayed perfectly through the virtual display engine [12]. Motion capture technology is a rapidly developed technology in the last 20 or 30 years. Many domestic and foreign researchers have invested a lot of scientific research efforts in this field and obtained advanced scientific research results and rich theoretical support in many aspects, including the way and application of motion capture, the analysis of real-time motion data, and the analysis of motion posture.

This paper proposes to apply the motion capture technology to the tumbling posture recognition model of classical dance, establish a database to obtain the three-dimensional data of human motion in real time, and match the human posture based on the feature plane to obtain the Google model of human characteristics. Applying the above data to the posture teaching and analysis in the process of dance teaching is helpful to improve the teaching level of teachers, Mobilizing students' learning enthusiasm has good reference and application value [13, 14]. Human motion posture analysis first rose abroad. With the advent of the new century, Chinese domestic research experts also began the research and analysis of three-dimensional posture [15].

This paper studies and innovates the above problems from the following aspects:

(1) A writhing gesture recognition model of classical dance based on motion capture technology is proposed. This paper studies the identification model construction of the tumbling posture of classical dance. The combination of motion capture technology and the tumbling posture of classical dance will make up for the deficiency of traditional dance forms and has advantages that traditional dance does not have in the acquisition and transmission of movement skills. According to one's own state, one can study and demonstrate actions purposefully and then compare the analysis results of 3D motion data with the standardized action posture so as to correct the standardization of actions in time, which greatly improves students' learning and teachers' teaching efficiency.

(2) Build the database of the identification model of the tumbling posture of classical dance based on motion capture technology. Based on the application of motion capture technology to the identification of the tumbling posture content of classical dance, firstly, set the performer's dance movements and their range of motion; then, capture the three-dimensional data of the performer's dance movements and establish a three-dimensional dance teaching model database. Finally, make the dance movement database into a three-dimensional animation and apply it to the identification model of the tumbling posture of classical dance.

The paper is divided into five parts, and the organizational structure is as follows:

The first chapter introduces the research background and present situation of the tumbling posture of classical dance and puts forward and summarizes the main tasks of this paper. The second chapter introduces the domestic and foreign related work of the somersault posture of classical dance. The third chapter introduces the principle and model of motion capture technology. In chapter 4, the realization of the recognition model of tumbling posture of classical dance based on motion capture technology is introduced, and the performance of the model is compared through experiments. The fifth chapter is the full text summary.

2. Related Work

2.1. Research Status at Home and Abroad. Gaglio et al. proposed that the first trouble for Chinese classical dance to recognize the posture from opera is the contradiction between "stylized dance and functional training," which is the basic contradiction in the construction of Chinese classical dance teaching materials, which has not been completely solved until today [16]. TNA B proposed that the formation of "form" of Chinese classical dance was fundamentally influenced by ancient traditional concepts, mainly the concept of nature, and human natural activities affected the formation of artistic aesthetics and aesthetic ideas [17]. Shiqi et al. proposed that Mr. Mei Lanfang, an opera performing artist, is known as a male actress. When limited by certain clothing, props, and roles, how to shape the stage image of women's posture through a beautiful, "exquisite," delicate, and "language" orchid palm has become an art form integrating the song, dance, and music of the previous generation [18]. Nai et al. proposed that classical dance comes from the burst of emotion, and Oriental people have formed a unique way of posture expression under the influence of traditional ideas. Easterners are not used to expressing their feelings directly like the West, but in a gentle and implicit way, which stems from the naive, simple, and restrained emotional thinking of farmers in the bones of Easterners [19]. The authors proposed that Chinese classical dance is a genuine domestic product and a new kind of dance comparable to modern dance and ballet. Most of its soundtrack is played with musical instruments with Chinese characteristics, such as pipa, erhu, guzheng, and Xiao, and the clothing usually has a smell of ancient fragrance [20]. Deng et al. proposed that the historical and cultural spirit precipitated in opera and dance is in the same line with the spirit of China's 5000-year-old traditional culture. We absorbed the orchid palm from it and drew lessons from and cited the "nonphysical performance" in the drama dance performance, which uses hand movements and human body posture with eyes, body method, pace, and so on [21]. Pope et al. put forward that the traditional poetry contains the ancient people's aesthetic thought activities in the aspects of appreciation and creation, which has a certain influence on the formation and development of Chinese classical dance [22]. Maheu et al. proposed to stand on the vision of the discipline construction of Chinese classical dance. The original intention of the course construction of body rhyme is to deepen the national attributes of Chinese classical dance styles, but it is still the historical mission of the discipline to cultivate the actors' body posture, and it is also an important project for the discipline to continuously inherit and spread the faculty with cultural heritage and professionalism [23]. Christopher et al. put forward that "the basic ability training of Chinese classical dance refers to the basic ability training and special quality training of all parts of body posture." The basic skills training of Chinese classical dance mainly focuses on three aspects: strengthening the training of softness, training of quality and ability, and training of technical skills. From the ground, the lever, and the middle three parts, the soft opening strength of students and their technical skills can be solved [24]. Xuan et al. put forward that the body rhyme of Chinese classical dance should not only have the style of Chinese traditional body culture, but also conform to the scientific nature of human posture. Therefore, for the study of body rhyme of Chinese classical dance, discussing the principle of body rhyme capacity, the principle of style, and its practical application can provide important reference for the discipline to consolidate and deepen the theoretical foundation [25].

2.2. Research Status of Tumbling Posture Recognition in Classical Dance Based on Motion Capture Technology. This paper investigates the recognition of classical dance tumbling postures using motion capture technology. This paper examines the origin and transmission mechanism of the body rhyme movement power of Chinese classical dance from the perspective of human movement, in conjunction with traditional Chinese Dantian theory and the core of modern human physiological anatomy. This paper examines the principles of body rhyme movement in Chinese classical dance in terms of local form, overall movement law, and philosophical category from the standpoint of style; it then moves on to the application stage of action principle, which includes the application of principle in classroom teaching and the application of principle on stage. Human posture recognition and capture technology is currently the most widely used. The method for implementing it is to place the camera in a fixed position in space and then capture the object's real-time action and posture using light spots in this area. Classical art charm meets the rhythmic essence of traditional Chinese dance in China's classical dance. We must first determine the recognition target of human posture and the corresponding data acquisition scheme before recognizing the tumbling posture of classical dance. The main principle of attitude recognition and capture technology is to attach inertial sensors to the joints, such as a gyroscope and an accelerometer, to collect human attitude and action data, and then use data analysis and calculation to determine the amplitude and angle of human joint motion. The following are some of the advantages of this method: low price; there are no issues with the environment, such as light shielding, and the precision is excellent. This paper examines the significance of combining motion capture technology and dance teaching and verifies through experiments that using capture technology in teaching can improve students' subject status, as well as bring enlightenment and innovation to contemporary teaching research.

3. Principle and Model of Motion Capture Technology

The motion capture system records the movement process of moving targets using tracking devices with special marks placed at key positions. After that, computer processing is used to obtain three-dimensional space parameters, and finally, the matching of skeleton models used in animation is completed. The motion capture sensor's human behavior recognition technology is a multidisciplinary system that combines sensor technology, human dynamics, computer graphics, pattern recognition, and other disciplines. Front-end hardware and back-end software make up the technology. The front-end hardware's main functions and contents include gathering human motion data using motion capture sensors and transmitting that data to the computer. The back-end software's main purpose and content is to use the computer to efficiently process the collected exercise data so that the computer can automatically identify the action category of the captured object, allowing for action reproduction and human-computer interaction. First and foremost, the dancers' dance movements and range of motion should be established. The dance pose flowchart of the action capture technology of instructional design is shown in Figure 1.

While watching the animation, they draw posture movements in their mind. The actions that they do not understand or do not know can be demonstrated repeatedly from multiple angles. Secondly, students conduct practical demonstration, capture their own actions with high-precision three-dimensional camera, and compare them with teachers' standard actions. By comparing the dance movements with the teacher's standard movements in sections through the motion capture system, the shortcomings can be quickly found out, which is convenient for local correction.

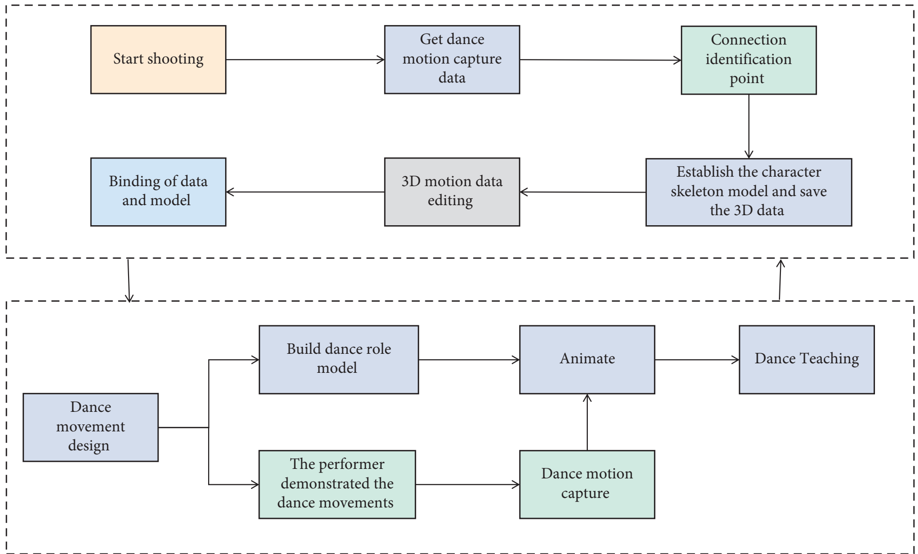

Figure 1: Dance posture flowchart of motion capture technology.

Motion capture technology is used to assist the teaching and research of dance. The early motion capture was proposed by American Polish Fisher in 1915. His "rotoscope" technology is considered to be the pioneer of motion capture technology. The main principle of this technology is to initially take the action video image taken in reality as the bottom sample of animation depiction, and then the animators depict the required actions frame by frame on this basis. The virtual display platform collects all kinds of dance materials, performs by actors, collects data through motion capture devices, and converts them into data recognizable by 3D animation software, and finally displays the dance content perfectly through the virtual display engine. The motion capture technology is applied to the data acquisition in the tumbling posture process of classical dance, the skeleton motion route of human body is extracted, and then the posture discrimination is obtained by using the feature vector matching method so as to establish the tumbling posture model of classical dance. It is easy to know that the depth of the whole bone tree is 3. The human body can be roughly divided into 11 bone trees, as shown in Figure 2.

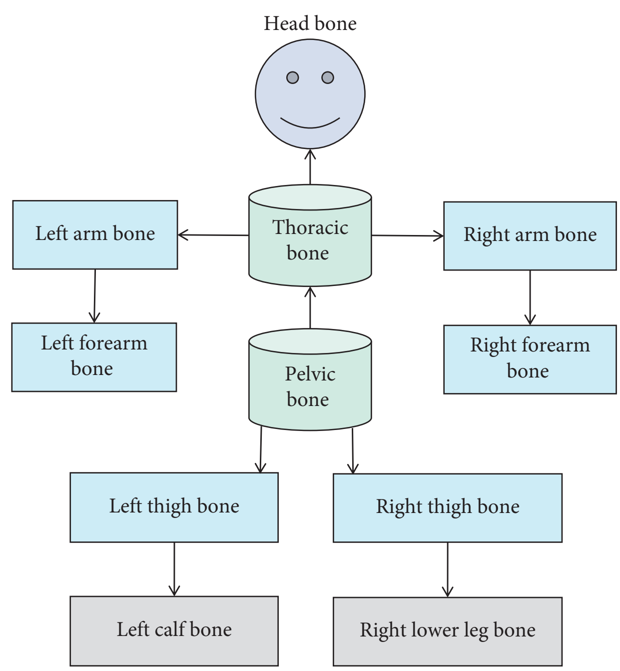

Figure 2: Basic skeleton structure of human body.

The matrix algorithm is proved to be a feasible BVH analytical algorithm, as shown in formula (1), on how to convert the correct position and dynamic of bones into animation.

$$v' = Mv. \quad (1)$$

Type v indicates said transformation point; v indicates the original point; and M indicates the transformation matrix.

This formula is especially important when the matrix multiplication is three independent Euler angles, which are not exchangeable to construct the rotation matrix. Rotation matrix R is based on the rotation parameters of each axis of the individual rotation matrix, R_x, R_y, R_z, as shown in formula (2), where the composition order is "XYZ."

$$R = R_x R_y R_z, \quad (2)$$

where R is rotation matrix; R_x $y$is$y$-axis rotation parameter; R_y $z$is$z$-axis rotation parameter; and R_z $x$is$x$-axis rotation parameter.

The movement of a single bone consists of translation, rotation, and proportional components, which can be combined together and transformed by using homogeneous coordinates. Unless otherwise stated, the order of combination of these different transformations is stated in the form that sufficient transformations will always follow, such as the following formula.

$$M = TRS. \tag{3}$$

Type S is said bone size and T is translation matrix.

In most motion capture file formats, the data is derived in a hierarchical way and formula, and formula (3) only gives the local transformation of a certain bone. The local transformation of the skeleton describes its direction in the local coordinate system, which in turn is influenced by the direction of its parent skeleton. Formula (4) lists this combination sequence, in which $n-1$ is the current bone, its mother bone is $n=0$, and EE represents the root bone of the bone hierarchy.

$$M_{\text{global}}^{n} = \prod_{i=0}^{n} M_{\text{local}}^{i}. \tag{4}$$

Using formula (4) and the derivation of local transformation, we can calculate the global position of the origin of each bone and obtain the position of the bone of the origin from the offset information of the hierarchy.

The function interval changes proportionally with the change of w, b, while the physical interval is fixed. When $\|w\| = 1$, the function interval is equal to the physical interval. The final optimization we need to complete is to select the classification plane that can maximize the minimum physical interval, as shown in

$$\begin{aligned} &\arg\max_{r,w,b} \frac{\hat{y}}{w}, \\ &s.t.\, y_n\left(w^T x_n + b\right) \geq \hat{y}. \end{aligned} \tag{5}$$

In the formula, *s.t.* is abbreviated as constraint condition, where $n = 1, \ldots, N$.

The direct operation here will be very complex. We set the function interval of the sample closest to the classification interface to 1 by using the characteristic that the function interval changes in proportion to the change of w, b without affecting the physical interval. Then, we transform the original problem into a quadratic programming problem that is easier to solve:

$$\begin{aligned} &\arg\min_{w,b} \frac{1}{2} w^2, \\ &s.t.\, y_n\left(w^T x_n + b\right) \geq 1, \end{aligned} \tag{6}$$

where $n = 1, \ldots N$.

To solve such problems, we usually combine the constraints and optimization problems into one formula through Lagrange factor. The Lagrange equation obtained is as follows:

$$L(w, b, a) = \frac{1}{2} w^2 - \sum_{n=1}^{N} a_n \left\{ y_n\left(w^T x_n + b\right) - 1 \right\}. \tag{7}$$

Pay attention to the order of solution here, which is still to get the minimum physical interval according to w, b first, and finally to maximize the minimum physical interval. First, we find the partial derivative of Lagrange equation to w, b and make it equal to 0. Get the following two equations:

$$\begin{aligned} w &= \sum_{n=1}^{N} a_n y_n x_n, \\ \sum_{n=1}^{N} a_n y_n &= 0. \end{aligned} \tag{8}$$

After the above two equations are introduced, we get the duality problem of maximizing the physical interval. This dual problem only contains a, and after solving a, we can get w^*, b^* by bringing it into the formula. The optimal interface is $w^{*T} x + b^* = 0$.

$$\begin{aligned} \hat{L}(a) &= L(w, b, a), \\ &= \sum_{n=1}^{N} a_n - \frac{1}{2} \sum_{n=1}^{N} \sum_{m=1}^{N} a_n a_m y_n y_m x_n^T x_m, \\ &s.t.\, a_n \geq 0, \\ &\sum_{n=1}^{N} a_n y_n = 0. \end{aligned} \tag{9}$$

Type middle $n = 1, \ldots N$.

Finally, the 3D data acquired by using motion capture technology needs to be presented on the computer in a concrete model, and animation is generated for teaching and playing. Students can compare the learned dance movements with the teacher's standard movements by segments through the motion capture system, which can quickly find out the shortcomings and facilitate local correction.

4. Design of Recognition Model of Tumbling Posture in Classical Dance

4.1. Tumbling Posture Recognition of Classical Dance Based on Motion Capture Technology. The data acquisition in the tumbling posture process of classical dance is done using motion capture technology, and the skeleton motion route of the human body is extracted, followed by posture discrimination using the feature vector matching method to create the tumbling posture model of classical dance. The different postures of the human body are divided into two categories: static posture and dynamic posture; the recognition process of static action and dynamic action is carried out in the second level, respectively. The disadvantage of this structure is that it has a problem with error transmission, which means that misclassification samples from the first level will flow into the second level, resulting in a second-level classification error. The key to solving this problem is whether the system's design fully considers the inherent differences between static and dynamic posture, as well as the relative ease with which they can be distinguished. It is possible to interpret and classify multiple sensors at the same time. The results show that the first-grade classification error can be largely ignored, effectively suppressing the error propagation problem. Install 20 data identification points on each part of the dance trainer's body; then start the high-speed 3D data dynamic capture system while remaining well within the preset space range. The controller recognizes that the trainer has completed all of the preprogrammed basic movements. The dynamic capture system will track the dance movements and match them to the model in this process. The real-time acquisition of human action is completed when the computer successfully identifies and enters 20 data acquisition points into the system.

Based on the application of motion capture technology to the identification of the tumbling posture content of classical dance, various postures of human body are divided into two categories: one is static posture, and the other is dynamic posture. In the second level, the recognition process of static action and dynamic action is carried out respectively. The writhing gesture recognition form of classical dance based on motion capture technology is the intersection of computer science, educational technology, and educational psychology. By absorbing and learning from new theories, technologies and methods in other fields, the disadvantages of traditional recognition mode can be solved. The virtual display platform collects all kinds of dance materials, performs by actors, collects data through motion capture devices, and converts them into data recognizable by 3D animation software, and finally displays the dance content perfectly through the virtual display engine. After the motion capture system is successfully matched, the data of human motion posture is recorded, and the natural characteristics of human motion from different perspectives can be analyzed by the system software. In this paper, the motion model database uses key joint points to mark the movement changes of human body. At present, the connection between key points is mainly rigid connection, which can ensure the stability of dance posture. By comparing the dance movements with the teacher's standard movements in sections through the motion capture system, the shortcomings can be quickly found out, which is convenient for local correction. Motion capture technology is used to assist the teaching and research of dance.

4.2. Experimental Results and Analysis. In this experiment, taking the left arm movement of the dance trainer as an example, taking the left arm characteristic plane p_1 as the basic calculation plane, three discriminant parameters $\{\mathrm{Sim}(V_1, V_{\mathrm{stand}}), \mathrm{Corr}(\theta_1), \mathrm{Corr}(\theta_8)\}$ can be obtained, respectively, and the overall motion posture of the left arm can be determined by the above three parameters. Experiments show that the calculation error is effectively reduced, and the results are shown in Table 1.

After completing all teaching hours, the learning situation of the two groups of students is verified through assessment. The college dance teacher scores the range, strength, consistency, and technical standardization of aerobics actions of the two groups of students. The results are determined by SPSS19.0 analysis. The test results are shown in Table 2.

p represents the significance of the experimental effect, and $p < 0.04$ is generally the most significant. According to the experimental results, the students who learn by motion capture have a better grasp of dance movements than those who learn by routine.

This experiment was completed on a PC with Core (TM) i5-34703.2 GHz CPU and 5 GB memory, and MATLAB was used as the development environment. The created motion database contains 20 sets of dance action segments, each of which has about 1,300 frames. The subjects are randomly selected college students, and all subjects have dance foundation. Three experiments were carried out respectively, and the difference of left arm movement posture was compared. From Figures 3–5, the difference between the movement to be measured and the standard movement was clearly seen.

Through the comparison and verification of the experimental results in Figures 3–5, using the feature plane similarity matching method to analyze the motion posture can clearly and efficiently detect the differences and standards between moving objects and has high robustness, which lays a foundation for the scientific training of dance. Coordination is the basic quality of a dancer. The teaching of turning over covers the correct turning of the waist, the orientation training of hand posture, and the joint cooperation of crotch, leg, knee, foot, and step below the waist. It is a great test and exercise for the cultivation of coordination. If the body, especially turning over, is difficult to complete without coordination; even if it is completed, it will lack the corresponding beauty. Therefore, the coordination of turnover movement training dancers is a key point. Physical training can be divided into three stages: initial stage, middle stage, and later stage.

In this experiment, the peak frequency points in the tumbling posture of classical dance, such as basic turning, step-by-step turning, and step-by-step turning, were compared in two experiments. The experimental results are shown in Figures 6 and 7.

From Figures 6 to 7, it can be seen that this feature shows a high degree of discrimination in the three categories of classical dance tumbling posture. At the 8th frame of the sample, the average frequency of step turn is 0.9, which is higher than the average rating of basic turn of 0.75 and that of point turn of 0.5. Therefore, it can be concluded that stepping over is an effective feature, except for some points with loud noise, which is generally stable. In the environment of motion capture equipment, students may have some adaptability problems, which are relatively restrained. However, students can make greater progress by simulating the posture of learning dance training and constantly revising their own learning process, especially in the standardization of dance movements, and students can realize their own shortcomings faster.

Table 1: Relevant parameters of left arm action attitude.

Experimental object	$Sim(V_1, V_{stand})$	$Corr(\theta_1)$	$Corr(\theta_8)$
Standard object	0.6847	0.9758	1.0124
Object to be tested	0.7125	0.8314	0.9847

Table 2: Comparison of experimental results.

Group	Movement range	Strength of action	Action coherence	Action standardization
General group	83.3 ± 6.5	79.7 ± 7.3	81.3 ± 7.8	78.5 ± 6.4
Experimental group	81.4 ± 6.8	81.7 ± 5.2	83.2 ± 3.3	82.3 ± 4.3
Significant p	0.032	0.027	0.024	0.041

5. Conclusions

The motion capture system-based tumbling posture recognition of classical dance will not only play an important role in the protection of national dance, but also in the long-term development of national dance. The display of dances from various cultures can help with dance research, learning, development, and application. This paper examines human motion posture using the real-time characteristics of motion capture technology, proposes a tumbling posture recognition model for classical dance based on motion capture technology, examines the characteristics of human motion posture, examines the development prospects and research significance of using motion capture technology in classical dance, and provides an effective theoretical basis for scientific training. The range, strength, consistency, and technical standardization of aerobics actions of the two groups of students were scored by the dance teacher. The average frequency of step somersault is 0.9, which is higher than 0.75 of the average evaluation rate of basic somersault and 0.5 of point somersault, according to SPSS19.0 analysis. In addition to the large noise, it can be concluded that the overall turning point is effective. The motion capture technology proposed in this paper can recognize basic classical dance tumbling postures with high precision. The system's ability to achieve higher-precision recognition of more types of posture on this basis is critical. Dance teaching and research benefit from the use of motion capture technology. The captured specific three-dimensional motion data is transformed into digital abstract motion, the three-dimensional human body motion posture database is established, and the teaching animation video is generated, which helps to optimize the traditional dance learning form, according to the characteristics of real-time tracking, detection, and recording of motion capture technology. The importance of improving educational quality cannot be overstated.

The main strategic direction of promoting rural revitalization is to achieve high-quality rural development, maintain the dominant position of farmers, and promote common prosperity of farmers. In recent years, the sustainable development of economy has raised farmers' awareness of starting their own businesses, and their entrepreneurial enthusiasm has been heating up. Based on the empirical survey data of typical rural areas in the Zhejiang Province and structural equation model analysis technology, this paper makes an empirical analysis of the relationship among network embeddedness, entrepreneurial resources, and entrepreneurial ability. The results show that knowledge resources have a significant negative impact on farmers' inclusive entrepreneurial behavior. The dual embedment of social network and industrial network has a significant positive impact on migrant workers' access to knowledge resources and operational resources needed for entrepreneurship, and the entrepreneurial ability of migrant workers mainly depends on operational resources. Under the background of common prosperity, we should continue to implement the policy of supporting farmers' inclusive entrepreneurship and encouraging industrial and commercial capital to enter rural areas, and at the same time, provide rural areas with agricultural knowledge, agricultural skills, and market guidance to promote employment.

1. Introduction

In China's "new normal" stage, entrepreneurship is one of the most important ways to promote the stable operation of the economic system and long-term economic development. However, as there is a common threshold for capital entry to participate in entrepreneurial innovation, the credit exclusion of countries and regions has become a key factor affecting the entrepreneurial activities of small- and medium-sized enterprises and ordinary families. Inclusive development combines economic development with the needs of vulnerable groups, putting people first and achieving social justice and fairness [1, 2]. Since then, "inclusive development" has supplanted "inclusive growth" as the compass for the new era's detailed economic development [3]. Inclusive innovation is defined as a type of innovation that promotes inclusive development, "reduces poverty," and it is "most directly related to the needs of the poor." The will, motivation, and vitality of rural entrepreneurship have been boosted to unprecedented levels by the Common Prosperity Strategy, and more rural entrepreneurs have emerged as the protagonists of poverty alleviation, industrial integration, social governance, and rural areas [4]. As a result, tapping the rural social network and understanding the impact of network embedding on the acquisition of entrepreneurial resources and the improvement of farmers' entrepreneurial ability is critical for farmers' employment and inclusive entrepreneurship.

Farmers' self-employment consciousness gradually emerges as the economy continues to develop. The development of this self-employment consciousness has a more positive impact on farmers' income and employment prospects. Farmers' needs for resources and employment methods in the process of starting their own businesses are also posing a challenge to China's original urban-rural dual system [5]. The revitalization of farmers and rural areas is an important part of common prosperity in the traditional concept, as well as the focus and difficulty of common prosperity [6]. According to Ma and others, China's rural governance should be focused on resolving interdependence and cooperation among people, resolving contradictions and conflicts, and improving people's public services [7]. In academic circles, most small-scale entrepreneurship research focuses on regional differences in small-scale entrepreneurs, as well as the impact of training and entrepreneurial intent on small-scale entrepreneurship. The government's role is to make timely and effective institutional arrangements to create and improve entrepreneurial conditions, optimize the entrepreneurial environment of microsubjects, and improve the overall quality of the entrepreneurial environment. Creating a strong entrepreneurial atmosphere and mature entrepreneurial conditions is the goal of creating an entrepreneurial environment. This paper makes some recommendations to the government based on the research on inclusive entrepreneurial paths to improve the overall entrepreneurial environment, promote the popularization of typical inclusive entrepreneurial paths, and improve the quality of rural entrepreneurial activities.

Highly developed social wealth and social productivity are the premise and foundation of common prosperity. It is difficult to achieve common prosperity unless productivity is highly developed. Despite the fact that farmers' wages and operating income have increased, the income structure still needs to be optimized. Wages and operating income are excessively high, and property income is also rising, however, it is rising only as a small percentage of total income. Supporting the entrepreneurial environment, encouraging farmers to start their own businesses, and focusing on optimizing the rural entrepreneurial environment are the keys to success. This paper can help farmers learn from the research results, obtain the most effective entrepreneurial resources in limited circumstances, maximize their abilities, and complete business creation with quality and policy support factors by studying and analyzing the impact of resource acquisition on farmers' inclusive entrepreneurial path.

The innovations of this paper are as follows:

(1) Innovation from the perspective of research: the evolution of entrepreneurial enterprises has its own life cycle. This paper examines a comprehensive entrepreneurial path based on the life cycle of entrepreneurial enterprises, i.e., selecting existing research from the perspective of enterprise life cycle will gain more targeted characteristics of inclusive entrepreneurial path.

(2) Innovation of research content: the existing research literature on farmers' entrepreneurship mainly focuses on the entrepreneurial environment, and the research on farmers' entrepreneurial access to resources is insufficient. Based on the household survey of typical farmers in the Zhejiang Province, this paper collected the data needed for the research. The form of investigation solves the limitation of time and space well. The investigation can be conducted in different places at the same time, and the quantity and quality of samples can be guaranteed using network tools.

The research framework of this paper consists of five parts, which are arranged as follows: the first chapter introduces the research background and significance, and then, it introduces the main work of this paper. The second chapter mainly introduces the related research status of inclusive entrepreneurship. The third chapter puts forward the concrete method and implementation of this research. The fourth chapter verifies the superiority and feasibility of this research model. The fifth chapter is the summary and prospect of the full text.

2. Related Work

2.1. Inclusive Entrepreneurship Research. Individuals who are entrepreneurs start businesses in one of the two ways: as new ventures or as derivatives of existing ventures. Early academic circles believed that the success or failure of entrepreneurs was determined by their personal characteristics and talents, however, later research has shown that it is the position of individuals in the organization, not the characteristics of entrepreneurs, that determines whether they seek opportunities and engage in entrepreneurial activities [8]. As a result, situational factors and mechanisms become the main ideas to explain entrepreneurial activities in the process of entrepreneurship, which is also the theoretical framework on which this paper is built, i.e., it examines the key features of the overall entrepreneurial process before moving on to the background factors that may influence entrepreneurial activities.

Yu and others believe that inclusive entrepreneurship is actually a collective entrepreneurial activity carried out by ordinary grassroots people in specific areas, and it is a self-employed group [9]. Essougong and others believe that a key feature of inclusive entrepreneurship is the realization of equal opportunities. Inclusive entrepreneurial opportunities are different from entrepreneurial opportunities in general sense. Opportunities appear in specific areas and are strongly influenced by background factors, such as regional cluster environment and government [10]. Oladele et al. think that natural conditions, history, accidental factors, economies of scale and externalities, enterprise organizational structure, competition, and innovation are the key factors for the formation of industrial clusters [11]. Deller et al. established the indicator system of inclusive development and found that inclusive development had an indirect impact on urban-rural income gap using the intergenerational overlap model [12]. From the perspective of microfamily, Ab et al. established a multivalue response model and analyzed inclusive finance from the supply side and demand side [13].

According to the empirical results, the optimal level of inclusive finance is not necessarily the same as the level of demand and supply and is also different from the macrolevel and microlevel. Nie et al. conducted a study based on panel data to further confirm the importance of entrepreneurship and policy support to long-term economic growth [14]. Therefore, although work experience has a positive impact on entrepreneurship, the influence of personal education and the family background of public officials on entrepreneurship is uncertain. Empirical research shows that households with high risk aversion are more inclined to choose agricultural entrepreneurship, households with risk preference are more inclined to start business in industry and commerce, and the income of industrial and commercial entrepreneurial enterprises shows a reciprocal U-shaped relationship.

2.2. Farmers' Entrepreneurship. In the process of farmers' entrepreneurship, farmers rely on family organizations (or informal organizations composed of relatives and friends) or create new organizational forms to form large-scale production and operation scale and pursue the growth and development of wealth. Zhao et al. divided small-scale entrepreneurship into group entrepreneurship and individual entrepreneurship and pointed out that the content of small-scale entrepreneurship referred to the expansion of processing agriculture, and so on [15]. Liu et al. regarded farmers' entrepreneurship as an unbalanced game process that involved the transformation of various resources, and it is also the decisive factor of policy and market in the game [16]. In terms of the influence of farmers' entrepreneurial behavior on society and economy, Phiri et al. explained the importance of farmers' entrepreneurial behavior to rural development [17]. Zhang and Han also made clear the strategic significance of farmers' entrepreneurial actions to the harmonious development of new countryside [18].

More academics are looking at the growth of migrant workers' entrepreneurship through the lens of the entrepreneurial network. The importance of enterprise growth includes scale expansion and capability improvement, and entrepreneurship can be divided into social networks and industrial networks. Shah et al. discovered that migrant workers who engage in growth-oriented and value-oriented entrepreneurship outperform migrant workers who engage in survival-oriented entrepreneurship, implying that higher value pursuit yields better results [19]. The number of families reduces the likelihood of migrant workers returning home to start a business, and the accumulation of family wealth (economic and social capital) has a positive impact on entrepreneurial performance. Sher et al. believe that because they have more knowledge and skills, better education and training, stronger adaptability to the environment, higher self-pursuit, and the new generation of farm tools, they are more willing to return home and start their own businesses [20]. Apart from the difficulty of policy factors, Blevins and Ragozzino have shown that human capital and the individual psychological state of entrepreneurs have a significant impact on farmers' entrepreneurial performance [21]. According to Gans et al., if a company's information capability is low, it will lack the necessary market information and information processing mechanisms [22].

3. Methodology

3.1. Theoretical Model. Entrepreneurship is a form of work that necessitates the development of management, organizational, and service skills, as well as the ability to think, reason, and make decisions. Entrepreneurship is a branch of business that studies how individuals create, discover, or create opportunities to create new things, and how they use those opportunities in various ways to produce different outcomes. With the continued development of our economy and society, an increasing number of people will join the middle class. Many farmers will be present, particularly those who are most likely to enter the middle class. To achieve universal prosperity, we must not only make rural residents the primary beneficiaries of common prosperity but also assist them in achieving material and spiritual prosperity.

Entrepreneurial motivation is the goal or vision that entrepreneurs demonstrate when starting a business based on their internal and external needs. It drives entrepreneurial behavior and influences entrepreneurial performance during the startup process. Regardless of the aforementioned influences on entrepreneurship, entrepreneurs decide whether to start a business based on their own internal needs. Furthermore, outstanding employees from successful peer companies frequently start their own businesses. They are well-versed in the industry's operations and are well-versed in the most critical aspects of the industry's operations. They can grasp the important points when starting a business and achieve twice the result with half the effort, lowering the cost of the enterprise's startup period. Entrepreneurs are well aware of the flaws and drawbacks of running a business, and they can avoid the risks of starting one as soon as possible.

However, unlike the inherent characteristics of other entrepreneurial groups' networks, migrant workers fall into the predicament of leaving the social and industrial networks in the process of entrepreneurship. As they are far away from their hometown, they are hard to integrate into the city, forming a social network, while migrant workers who return home to start their own businesses are far away from the city. Hence, it is difficult for them to obtain external economy in terms of industrial division of labor and cooperation through participation. The purpose of this study is to explore the influence path of dual networks embedded in farmers' inclusive entrepreneurial ability on the acquisition of entrepreneurial resources. Based on this, this paper puts forward the theoretical model as shown in Figure 1.

Entrepreneurship is the process of creating new products or services and realizing their potential value in the absence of resources. Except for the donation of entrepreneurial

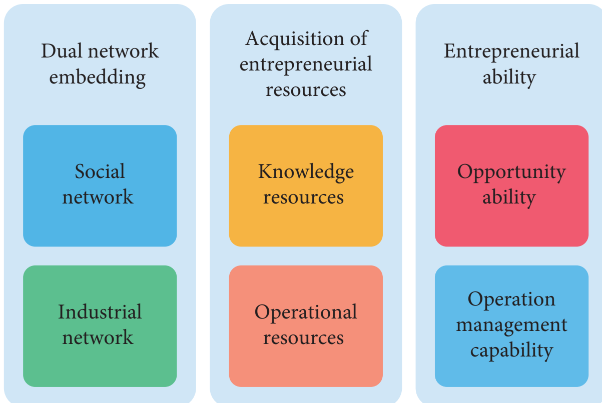

Figure 1: Theoretical model of farmers' inclusive entrepreneurial ability.

resources and entrepreneurial opportunities, entrepreneurs often have nothing. There is a "resource gap" between the huge number of resources needed for starting a business and the limited resources actually controlled by new enterprises. At the initial stage of entrepreneurship, the inherent resource holding of entrepreneurs in the entrepreneurial environment is the basis of entrepreneurial behavior, and the heterogeneity of resource holding composition determines the randomness and diversity of entrepreneurial behavior at the externalized microlevel. With the new creation of some entrepreneurs, the performance of enterprises is obviously better than that of other entrepreneurs. At this stage, entrepreneurs should have the following related skills: integrate resources and start and operate enterprises.

3.2. Life Cycle Model of Enterprise. The age of a company is the basis of its life cycle, which is mainly reflected in the relationship between two factors: adaptability and controllability. Adaptability refers to the response speed and controllability of enterprises to changes in internal and external environment. Controllability refers to the ability of a company to control its external and internal environment. The "youth" of an enterprise refers to its adaptability, which is relatively easy to change and adjust, however, its control is relatively small, and its behavior is generally unpredictable. Therefore, adaptability and controllability are two main factors. The growth of enterprises is the common growth of quality and quantity. Any model that only explains the growth of a company in terms of quality or quantity is one-sided and incomplete. In the three-dimensional enterprise life cycle model, the company life cycle is determined by the age and scale of the company. This model not only reflects the quality of enterprises but also reflects the change of enterprise scale. Hence, it can describe the growth trajectory of enterprises more comprehensively.

A typical enterprise life cycle refers to the whole continuous process of an enterprise from birth to growth, aging, and final decline, however, the enterprise is not an organism. Hence, we cannot apply the biological point of view. Theoretically speaking, it is meaningful to study the growth model of a company. Figure 2 shows the growth model of enterprises in the two models.

For a successful small company, it generally adopts the Ivy enterprise development model. A company can maintain adaptability and flexibility until its heyday. The company can maintain stable growth while extending its scale if it can achieve controllable equilibrium and keep up with the changing market (Figure 2(a)). There is also a meteor model. When a company's life develops to infancy or adolescence, the scale of the company expands rapidly and then suddenly dies, and the growth curve is like the trajectory of a meteorite falling from the sky (Figure 2(b)).

Every stage of the life cycle is very important. Enterprises have different strategic priorities at different stages, and failure at any stage will destroy entrepreneurial enterprises. During the growth of a new enterprise, there may be several problems one after another. Therefore, we need the influx of entrepreneurs, teams, resources, and other factors to constantly overcome various difficulties in the growth process of entrepreneurial enterprises. Entrepreneurs should constantly adapt to the environment, adjust team members, integrate accumulated resources, and improve the overall quality.

3.3. Data Source. The data of this paper comes from the survey of farmers' entrepreneurship and employment in the Zhejiang Province. In terms of regional selection, the survey samples are selected from farmer entrepreneurs in the typical villages of the Zhejiang Province. The questionnaire is distributed in-person and is filled on the spot. A total of 300 questionnaires were distributed and 285 were returned, with an effective rate of 95%. The contents of the survey mainly include personal and family information of farmers, characteristics of farmers' entrepreneurial environment, characteristics of farmers' entrepreneurial behavior, etc. When studying the personal information and family information of farmers, the most important thing is whether they will communicate with public officials and have good relations with state-owned banks and other government agencies to determine whether there are key factors for obtaining resources from resource acquisition. The main gender and age of entrepreneurs are shown in Figure 3.

3.4. Mathematical Model Establishment and Variable Selection. This paper aims to investigate how migrant workers' inclusive entrepreneurial activities can acquire the necessary knowledge and management resources for entrepreneurship via the dual embedding of social and industrial networks, as well as influence farmers' inclusive entrepreneurial ability. The structural equation model (SEM) is a multivariate statistical technique that combines factor and path analysis. It can incorporate some difficult-to-measure variables directly into the model for analysis, as well as analyze the complex relationship between multiple observed variables and latent variables all at once, which traditional regression analysis cannot. The structural model's formula is as follows:

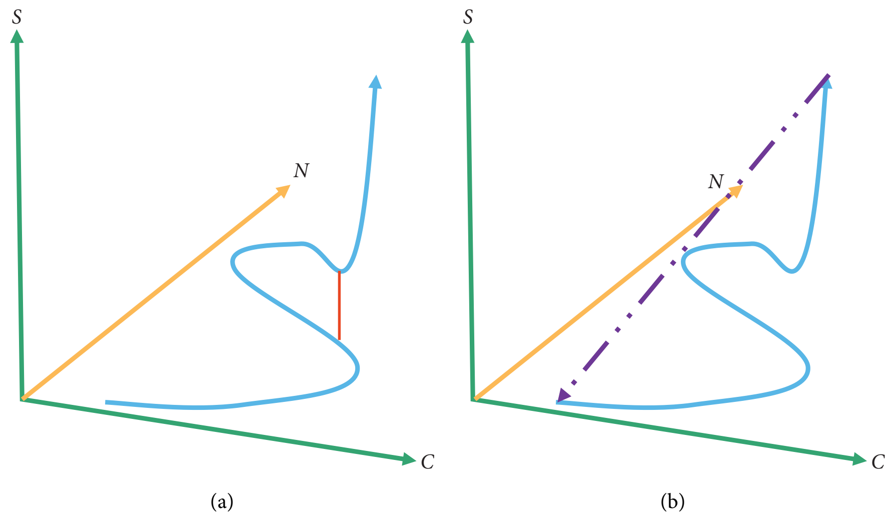

Figure 2: Enterprise growth model based on the (a) Ivy growth model and the (b) Meteor pattern.

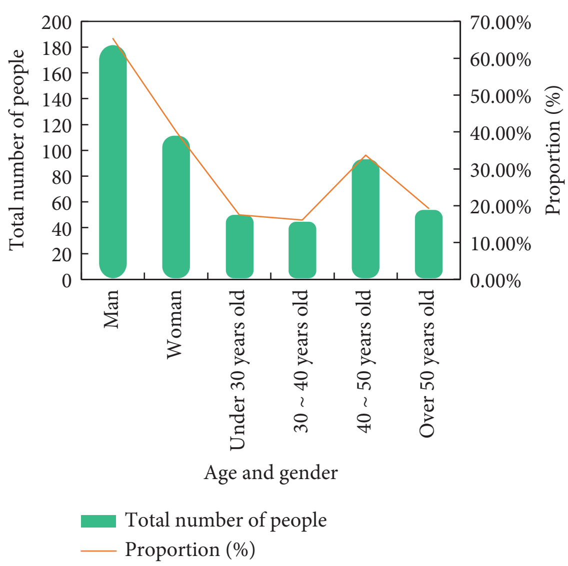

Figure 3: Basic information of sample farmer entrepreneurs.

$$X = \Gamma_X \xi + \sigma, \tag{1}$$

$$Y = \Gamma_Y \tau + \varepsilon. \tag{2}$$

Equations (1) and (2) are measurement models. Among them, X, Y represent exogenous and endogenous observed variables, respectively. ξ, τ, respectively, represent exogenous latent variables (i.e., potential independent variables) and endogenous latent variables (i.e., potential dependent variables). Γ_X is the relationship matrix between the exogenous latent variable and its observed variable, which is composed of a factor load of X on ξ. Γ_Y is the relationship matrix between the endogenous latent variables and their observed variables, which is composed of the factor load of Y on τ. σ, ε is the error term of the measurement model.

$$\tau = A\tau + \Lambda\xi + \gamma. \tag{3}$$

Formula (3) is a structural model in which A is the coefficient matrix of the endogenous latent variables, describing the relationship between endogenous latent variables, Λ is the coefficient matrix of exogenous latent variable, describing the influence of exogenous latent variable ξ on endogenous latent variable τ, and γ is the error term of the structure.

Farmers' entrepreneurial behavior has two possibilities: starting a business and not starting a business. However, in the existing regression model, the value range of dependent variable is between negative infinity and positive infinity, while the value range of the dependent variable affected by entrepreneurial behavior is within [0, 1]. The form of binary dependent variable model is as follows:

$$\hat{y}_1 = x_i\beta + \mu_i, \tag{4}$$

where μ_i is the interference term.

Assuming that $\hat{y}_1$ is greater than the critical value of 0, $y_i = 1$. When $\hat{y}_1 \leq 0$, $y_i = 0$. The relationship is as follows:

$$y_i = \begin{cases} 1 & \hat{y}_1 > 0, \\ 0 & \hat{y}_1 \leq 0. \end{cases} \tag{5}$$

Here, the critical value is chosen as 0. In fact, as long as x_i contains a constant term, the critical value is irrelevant. Hence, at this point,

$$\begin{aligned} P(y_i = 1|x_i, \beta) &= P(\hat{y}_1 > 0) = P(\mu_i > -x, \beta) = 1 - F(-x, \beta), \\ P(y_i = 0|x_i, \beta) &= P(\hat{y}_1 \leq 0) = P(\mu_i \leq -x, \beta) = F(-x, \beta), \end{aligned} \tag{6}$$

where F is the distribution function of μ_i, which requires that it is a continuous function and monotonically increasing. Hence, the regression model can also be regarded as follows:

$$y_i = 1 - F(-x, \beta) + \mu_i. \tag{7}$$

At this point, it becomes the mean regression model of y_i.

112 data obtained from the questionnaire were used as expert opinions. Establish fuzzy number $\widetilde{A}$.

$$\begin{aligned}\widetilde{A} &= (\alpha_i, \beta_i, \gamma_i),\\ \alpha_i &= \min\left(B_{ij}\right),\\ \beta_i &= \left(\prod_{k=1}^{n} B_{ij}\right)^{1/n},\\ \gamma_i &= \max\left(B_{ij}\right).\end{aligned} \tag{8}$$

In the above formula: i—Index number, $i = 1, 2, \cdots, n$; j—Expert number, $i = 1, 2, \cdots, n$; α_i—The minimum value of index i scored by experts; β_i—Geometric mean value of expert scoring index i; γ_i—The maximum value of expert's score on index i; B_{ij}—j expert's scoring value of index i.

When using the fuzzy Delphi method to evaluate risk indicators, we need to convert linguistic variables into fuzzy numbers. Hence, we import expert scoring data into our model and get triangular fuzzy numbers. The fuzzy number is obtained by inverse clearing triangular fuzzy number by the arithmetic average method.

$$A = \frac{\alpha_i + \beta_i + \gamma_i}{3}. \tag{9}$$

In this study, to ensure the validity and reliability of the measurement indicators, some items were modified and supplemented according to the characteristics and actual situation of farmers' inclusive entrepreneurs using the maturity scale used in existing domestic and foreign literatures. The questionnaire was designed by Likert's 5-point scoring method, and the description of the items was described as "strongly agreed," "comparatively agreed," "moderate," "slightly disagreed," and "very different," as shown in Figure 4.

3.4.1. Dual Network Embedding. As migrant workers start their own businesses mainly in industries with low skill content, it is difficult for new enterprises to have the power to establish cooperative relations with universities and research institutes. It represents a group of related partnerships among subsidiaries, financial institutions, intermediaries, and government agencies, excluding universities and scientific research institutions.

3.4.2. Entrepreneurial Resources. This paper investigates the acquisition of knowledge resources by farmers' inclusive entrepreneurs from four aspects: new product or service development, market development, production and management, and related policy system.

3.4.3. Operating Resources. The existing research mainly inspects business resources from the aspect of resource availability, focusing on whether entrepreneurs can obtain capital, human resources, technical resources, plant, equipment, and other physical resources at low cost.

3.4.4. Entrepreneurial Ability. This paper describes entrepreneurs' management ability from four dimensions: organizational ability, strategic ability, relationship ability, and commitment ability. Farmers' inclusive entrepreneurs should have the same relationship and commitment skills as other entrepreneurial groups, however, their newly started enterprises are small in scale and simple in organization, and their requirements for organizational and strategic capabilities are slightly lower than those of other entrepreneurs.

4. Experiment and Results

The estimated coefficients in the binary choice model cannot be interpreted as the marginal effect of symbols on dependent variables only. If the sign is evidence, the probability that the dependent variable is 1 increases. If the sign is negative, the probability that the dependent variable is 1 decreases. Considering that the dependent variable is the implementation of farmers' entrepreneurial behavior in variable selection, i.e., the dependent variable can take the values of "1" and "0" as "entrepreneurship" and "for entrepreneurship." In this study, resource acquisition mainly starts with policy resources, financial resources, and information resources. Hence, the selection of variables is shown in Table 1.

SPSS software is used to analyze the influence of resource acquisition on farmers' inclusive entrepreneurial behavior, and the regression results are shown in Figure 5.

$A4$ has a significant positive correlation with farmers' entrepreneurial behavior of acquiring information resources, which is significant at the statistical level of 1%. The regression coefficient is 0.196 and Exp(B) is 1.21, which means that the probability of farmers' entrepreneurial behavior will increase by 0.196 for each additional unit in contact with civil servants, other things being equal. At the level of 5%, $A1$ has a significant impact on farmers' entrepreneurial behavior, with the coefficient of 0.569 and Exp(B) of 1.806, which means that the probability of farmers' entrepreneurial behavior will increase with each unit of $A1$. Therefore, the probability of entrepreneurial behavior of married farmers is higher than that of unmarried farmers.

$A3$ has a significant negative impact on farmers' entrepreneurial behavior. It passed the 1% significance test, and the coefficient was −0.215 and Exp(B) was 0.774. It means that the higher the education level of farmers, the lower the possibility of entrepreneurial action. Studies have shown that industrial structure adjustment will affect regional innovation activities [23]. The research shows that the optimization and upgrading of industrial structure has a positive effect on inclusive entrepreneurship [16]. Research shows that the rapid change of industrial structure will affect entrepreneurship in the short term, however, it will promote local entrepreneurial innovation activities in the long-term [20]. Therefore, this paper selects the proportion of the tertiary industry in GDP to investigate to control the industrial structure of each region. Descriptive statistics of each variable are shown in Figure 6.

The scale design of this paper refers to the mature scale used by scholars in the past, which ensures the validity of the

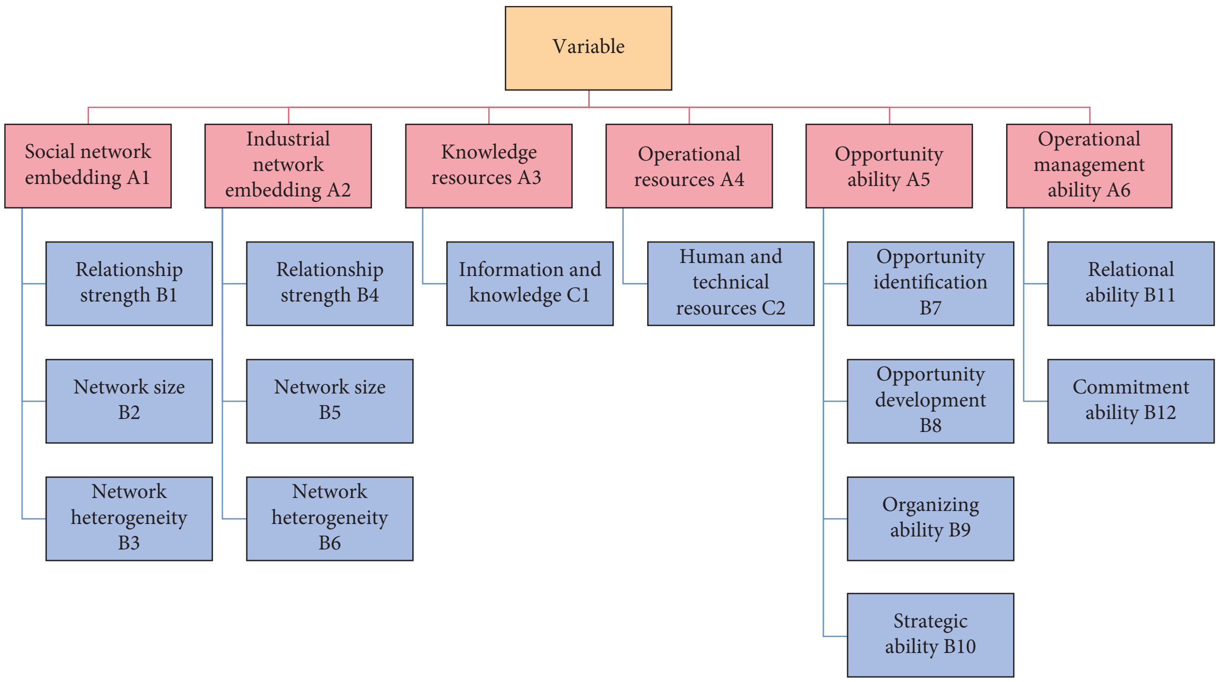

Figure 4: Variable measurement item.

Table 1: Selection of variables influencing access to resources on farmers' inclusive entrepreneurial path.

First-order variable	Secondary variable	Mean value
	$B1$	3.36
$A1$	$B2$	2.25
	$B3$	3.04
	$B4$	2.21
$A2$	$B5$	3.88
	$B6$	2.96
$A3$	$C1$	2.36
$A4$	$C2$	3.32
	$B7$	3.01
$A5$	$B8$	2.88
	$B9$	3.63
	$B10$	2.41
$A6$	$B11$	2.88
	$B12$	3.71

content of this scale. Constructive validity, also known as structural validity, is mainly used to indicate whether the actual measurement result of a scale is consistent with the research concept, which usually consists of convergence validity and discrimination validity. Specifically, $A1$ and $A2$ can extract three factors, $A3$ and $A4$ can extract a single factor, $A5$ can extract two factors, and $A6$ can extract four factors. These extracted factors are measured by a scale, and the variables are the same. At the same time, the factor loading values of all measures after orthogonal rotation are greater than the threshold value of 0.5, which indicates that the convergence validity of the measure scale is ideal. The discriminant validity test results (see Table 2) show that the square root of latent variables on the diagonal is larger than the correlation coefficient between latent variables on off-diagonal, which indicates that the scale has good discriminant validity.

The result of building structural equation model with AMOS is shown in Figure 7. All the test indexes of the overall goodness-of-fit of the model are higher than the threshold, which indicates that the overall goodness-of-fit of the model is good.

In this paper, SPSS20.0 statistical software is used to analyze the impact of resource acquisition on farmers' business performance. In the process of processing, firstly, all variables are introduced into the regression equation. Then, the significance test is carried out, and finally, the regression method is refitted, and this principle is repeated until the regression coefficient of each variable in the equation is significant.

We introduce all the above independent variables into the regression equation, as shown in Figure 8 below.

It can be seen in $A2$, $A4$ and $A6$, $B1$ that it is not obvious. After removing the above variables, a two-step regression analysis is introduced, which shows that insignificant variables are equal to $C1$ and $B10$. So far, in the third step, we used two variables $A1$ and $B9$ and brought all the remaining variables into the regression analysis method to continue the regression analysis. The regression results of the third stage model are shown in Figure 9.

It is significant with $B3$ at the level of 5% in the statistical test, and the estimation coefficient is positive. When other factors remain constant, contact with senior civil servants improves the effectiveness of farmers' entrepreneurial performance. The difficulty level of high government function, relevant market system establishment, market policy guidance, financing convenience, contact with bank staff, access to information from other channels, overall access to

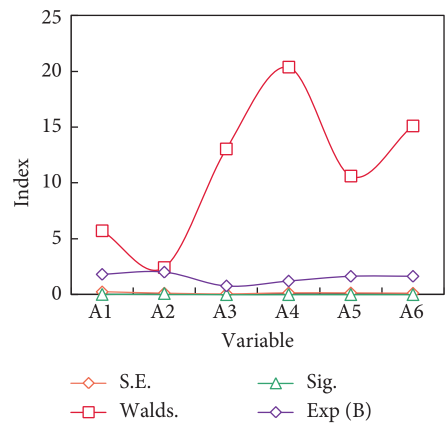

Figure 5: Influencing factors of various variables.

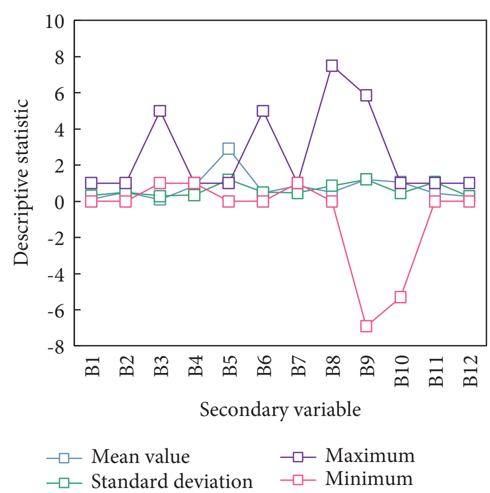

Figure 6: Descriptive statistics of related variables of secondary variables.

Table 2: Test results of discrimination validity.

Variable	*A*1	*A*2	*A*3	*A*4	*A*5	*A*6
*A*1	0.771					
*A*2	0.413	0.762				
*A*3	0.501	0.501	0.821			
*A*4	0.263	0.336	0.461	0.743		
*A*5	0.459	0.428	0.502	0.418	0.874	
*A*6	0.337	0.367	0.424	0.442	0.426	0.769

information resources, policy convenience, and no resources is significant and failed the test.

Farmers' entrepreneurs in China are clearly affected by information restrictions in the process of starting a business because of the limited information channels available to them and the high cost of obtaining information. Business operations and maintenance are no longer limited by information channels. The educational level is statistically significant at 10%. Information channels are becoming more diversified and efficient. The estimated coefficients of age and educational background are positive among the three variables, while the estimated coefficient of gender is negative. Farmers' entrepreneurial performance is significantly influenced by their representative life experience and accumulation of experience. Although operational resources serve a greater purpose than knowledge resources, both have a negligible impact. This result demonstrates that current migrant worker entrepreneurship is still survival-oriented, and the industry entry threshold is low. Inclusive entrepreneurs are relatively simple, and they have not yet attained

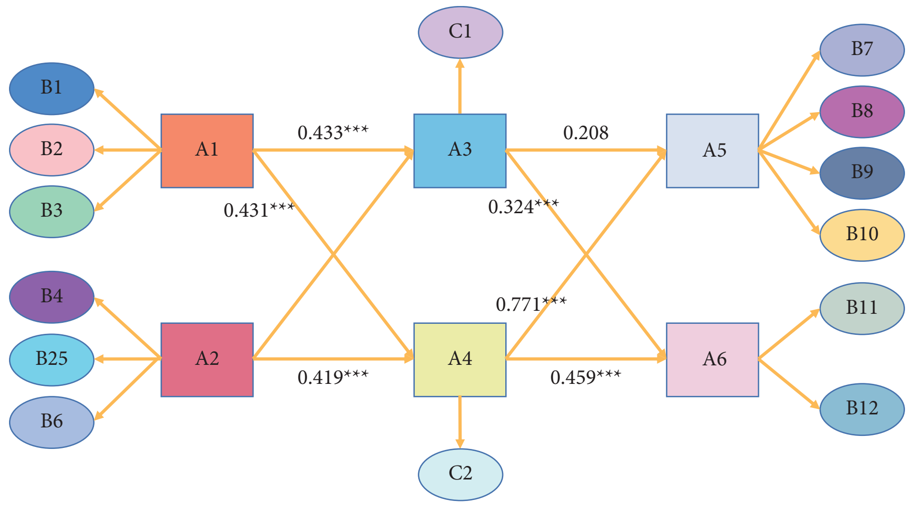

FIGURE 7: Structural equation model diagram of the influence of farmers' inclusive entrepreneurship.

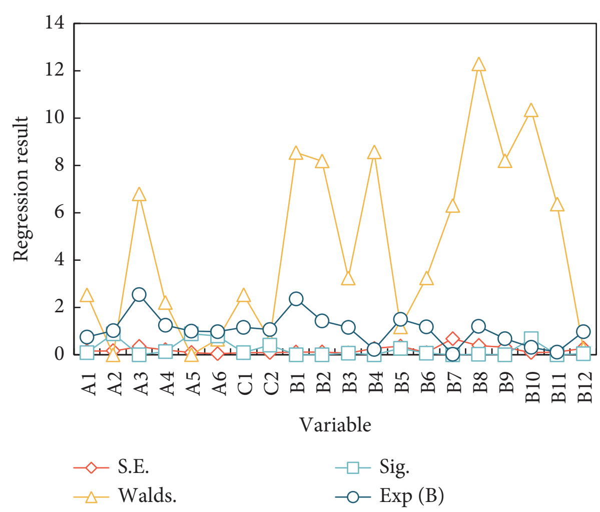

FIGURE 8: The first step model regression results.

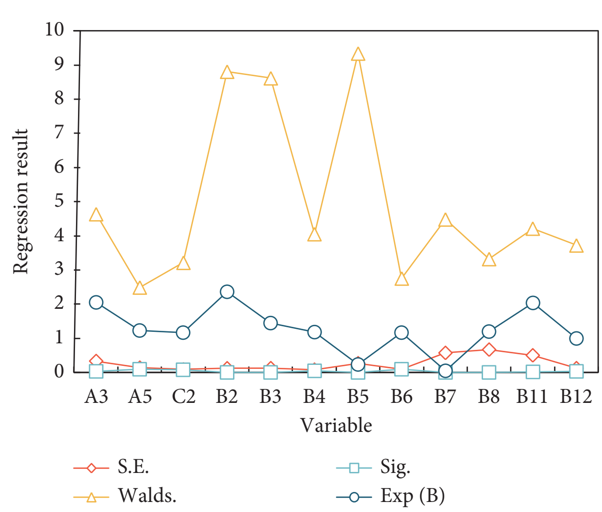

FIGURE 9: The third step model regression results.

the level of knowledge acquisition resources and operational resources required to improve a company's ability to operate and manage. At the moment, Chinese migrant workers are still self-employed, and their new entrepreneurial management mode differs significantly from the modern enterprise management mode that reflects migrant workers' entrepreneurial spirit.

5. Conclusions

Based on the empirical research data of typical villages in the Zhejiang Province, this paper analyzes and summarizes the process and mechanism of inclusive entrepreneurs' development path from the perspective of common prosperity. We find that there is a significant positive correlation between business resources and farmers' entrepreneurial behavior in obtaining information resources. At the statistical level of 1%, knowledge resources have a significant negative impact on farmers' entrepreneurial behavior. The dual embedment of social network and industrial network has a positive impact on migrant workers' acquisition of knowledge resources and business resources needed for starting a business, however, the acquisition of knowledge resources is mainly influenced by the embedded industrial network. Therefore, under the vision of common prosperity, when building various systems, the government fully considers the needs of people of different classes and actively introduces policies to encourage and guide farmers so that more farmers can choose entrepreneurship, employment, and settlement.

Rare earth is one of the most important strategic minerals in the world today. The wide application of new products and technologies in the global market has made the world's demand for rare earth resources grow rapidly. As an important basic resource of high technology, rare earth plays a significant role in national security and strategy. As rare earth mineral resources are irreplaceable in civil, military, and nuclear industries, they have become national strategic resources of various countries in the world. Although China's rare earth industry has occupied a leading position in the world, with the continuous expansion of the scale of the rare earth industry, the pollution problem of "three wastes" produced in the recovery of rare earth mineral resources is becoming more and more serious. From the perspective of resource endowment, China is rich in rare earth resources, but the declining trend of resource reserves is obvious, and the advantages and disadvantages of resources are more prominent. Based on the goal planning and few-shot learning, this paper studies the economic significance of rare earth resource development, aiming at solving some problems in the development of rare earth mineral resources in China, and thus promoting the scientific and healthy development of the rare earth industry.

1. Introduction

Rare earth elements have unique electronic structure, which makes them have excellent magnetic, optical, and electrical characteristics. They are widely used in metallurgical machinery, petrochemical industry, electronic information, energy and transportation, national defense and military industry, high-tech materials, and other industries [1]. As an important high-tech basic resource, rare earth plays an important role in national security and strategy. The most important feature of the raw material base developed so far in the world is that its structure is conducive to large or even super large deposits. China has basically formed a legal system for the protection and management of mineral resources guided by the Constitution and dominated by laws, administrative regulations and departmental rules, which provides a clear legal basis for the management of rare earth resources according to law [2]. Many experts believe that these deposits will be relocated according to the special characteristics of rare earth mineral composition [3]. Due to the progress of China's rare earth metallurgy technology and low cost, foreign rare earth smelting and separation enterprises have closed down one after another and the relevant research is gradually reduced [4]. Although China's rare earth industry has occupied a leading position in the world, with the continuous expansion of the scale of the rare earth industry, the pollution problem caused by the recycling of rare earth resources is becoming more and more serious [5]. This situation has affected the healthy, sustainable, and stable development of China's industrial system. It is urgent to develop an efficient and practical green mining and smelting process to solve the problem of environmental pollution caused by three wastes.

Rare earth is an indispensable strategic resource for countries all over the world to transform traditional industries and develop high-tech and cutting-edge national defense technology. We need to re-examine China's mineral resources legal system, explore the root causes of the problems from the theoretical basis and system design, and make up for the insufficient theoretical preparation and unreasonable system design [6]. Then, put forward the feasible countermeasures to improve China's legal system of mineral resources and then study the management of rare earth according to law [7]. China is not only a big country in rare earth resources but also a big country in rare earth production, export, and consumption in the world. Some countries and regions have listed it as a key element for the development of high-tech industries and a national strategic element, which is called an indispensable "industrial vitamin" [8]. From the perspective of resource endowment, China is rich in rare earth resources, but the declining trend of resource reserves is obvious, and the advantages and disadvantages of resources are more prominent [9]. Starting from the theoretical level, this paper abandons the theory that administrative license is the direct allocation of resources and insists that administrative license is only the franchise qualification granted by the government to the opposite party.

Heavy rare earth mineral raw materials mainly include phosphorus manganese ore, brown yttrium ore, ion adsorption rare earth ore, and uranium ore [10]. The rare earth industry is China's advantageous industry. The comprehensive management of the rare earth industry will greatly promote the healthy development of China's rare earth industry and better serve China's high-tech industry, new energy, aerospace, and national defense [11]. In the part of rare earth exploration license, closely follow the pace of China's geological exploration pattern reform, grasp the latest reform trends, put forward suggestions to speed up the establishment of mineral exploration financing market, and promote the exploration of rare earth and other strategic minerals [12]. As rare earth resources are irreplaceable in civil, military, and nuclear industries, they have become national strategic resources of countries all over the world [13]. Although China has obvious advantages in rare earth resources, due to lack of understanding, China's rare earth industry started late and the long-term development and management of rare earth resources are extensive [14]. In practice, the phenomenon of indiscriminate mining and blind competition among enterprises has become increasingly prominent, resulting in a large outflow of resources at low prices [15]. Based on the goal planning, this paper studies the economic significance of the development of rare earth resources, aiming to solve some problems in the development of rare earth resources in China, coordinate the development and utilization of rare earth resources with the ecological environment, and promote the scientific and healthy development of rare earth industry.

Section 2 analyzes the general situation of China's rare earth resources from two aspects: the characteristics of resource endowment and the characteristics of resource trade. Section 3 discusses the economic significance of rare earth resources through the goal planning method. Section 4 summarizes the content of the full text.

2. Overview of Rare Earth Resources in China

2.1. Characteristics of Resource Endowment. From the perspective of resource trade, the export-oriented and primary

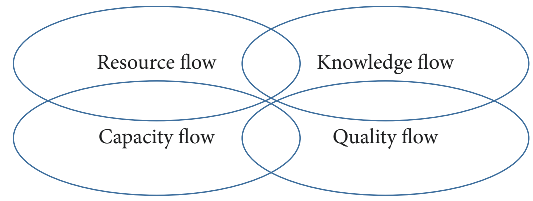

Figure 1: Extension Manufacturing Capability Unit model.

product-oriented trade structure has further weakened China's advantage of large quantity and variety of rare earth resources and intensified excessive competition in the rare earth industry. Between the upstream and downstream of the rare earth industry chain is a process of increasing value. At present, the profits of the rare earth industry are concentrated at the back end of its industry chain. Although rare, rare earth elements have not been known and used for a long time. It was not until the end of the 18th century that people discovered the existence of rare earth elements. Through research, people gradually realized its value and applied it to people's production and life. While China's rare earth is overexploited and its reserves continue to decline, foreign rare earth is being strategically protected and proven reserves are also increasing, leading to the gradual loss of China's rare earth reserve advantage [16]. Rare earth minerals in our country are mainly distributed in remote areas. A large number of small enterprises are engaged in rare earth resources development. The management mode is extensive and destructive mining, resulting in a large amount of rare earth resources loss and destruction [17]. Ultrahigh purity rare earth metals are the material basis for studying the intrinsic properties of rare earth and developing new rare earth materials. The purity of rare earth metals is also one of the key factors affecting and restricting the properties of rare earth functional materials.

With the increasing demand for rare earth resources in China's high-speed economic growth, the export volume of rare earth is decreasing year by year, but the export volume of rare earth and other dominant minerals in China still occupies an important position in the world mineral trade. The rapid establishment, integration, reconfiguration, and dissolution of the Extension Manufacturing Capability Unit, as well as the rapid diffusion, rapid remodeling, and rapid transformation of manufacturing capability. There are four kinds of flows in the diffusion process of the Extension Manufacturing Capability Unit. The combined effect of these four streams enables large engineering equipment manufacturing systems to emerge rapidly expanding manufacturing capabilities in a short time. Figure 1 is a model of the Extension Manufacturing Capability Unit.

The smuggling of rare earth resources in China is very serious, disrupting the order of the rare earth market, invalidating the national rare earth control policy, and failing to achieve industrial integration goals. Although rare earth resources are stored in large quantities in the world, due to the difficulty in industrial smelting and purification in practical applications, rare earth resources are still extremely rare. According to the geographical area, the geographical distribution of rare earth resources is broad and there is no

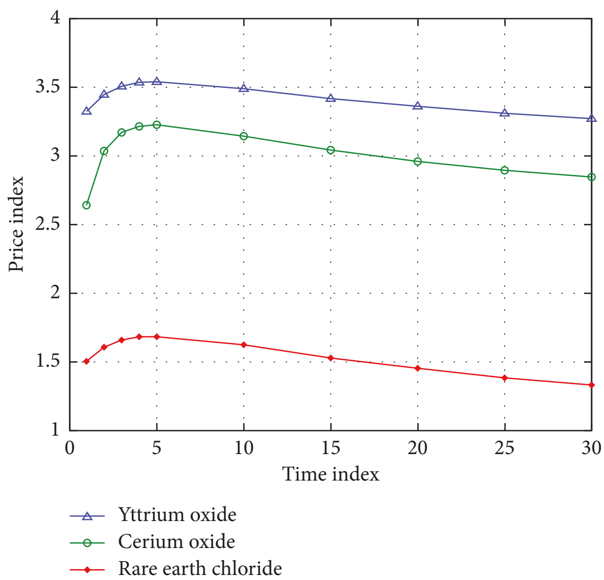

Figure 2: Changes in export prices of rare earth products.

monopoly of a certain region. Rare earth minerals are nonrenewable resources. Although major developed countries have been striving to develop alternatives, the harvests are minimal and some of the so-called alternatives are difficult to achieve the desired results in application. Therefore, rare earth resources are more precious [18]. The vast geographical distribution of rare earth resources determines that it is unrealistic to want to obtain a dominant say in rare earth resources for a long time by tightening supply ports. Compared with energy and basic metals, rare earthconsumption is very small and under the current visible application, the increment in various consumption fields is also limited. The strategic reserve system of resources should be implemented. Once the price of important mineral resources fluctuates abnormally and there is an interruption or shortage of supply, the strategic reserve resources can be put into the market to adjust the relationship between supply and demand in the market, thus greatly improving the right to speak on the price of mineral resources. Generally speaking, the price of rare earth resources has been low for a long time and the economic benefits are limited. At the same time, the environmental cost of rare earth resources development is high, which makes the overall benefits of rare earth resources export low. Figure 2 shows the changes in export prices of rare earth products in China.

There are n indicators for evaluating the independent innovation capability of rare earth enterprises. Based on this part of the indicators, the independent innovation capability of enterprises is quantitatively divided into T grades, which are described as the following quantitative comprehensive evaluation matter element models:

$$Q(u_{ij}) = \sum_{i=1}^{n} \underset{1\le j\le m}{\mathrm{Max}}\left\{g_{ij}(T)\right\}. \quad (1)$$

The matter-element model formed by the comprehensive evaluation of the independent innovation ability and the

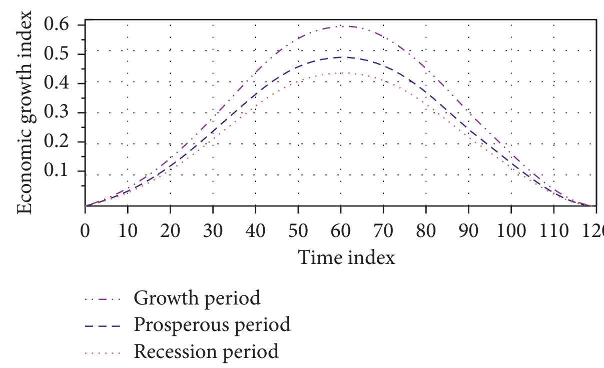

Figure 3: General law of resource-based urban development.

allowable value range of each indicator is called the domain matter element.

$$y_{f-n_m} = \sum_{i=1, i\neq n}^{N} \sum_{l=1}^{M} \sqrt{p_{i_l}} \mathbf{h}_{i,n_m}^{T} \mathbf{W}_{i,i_l} s_{i_l}. \quad (2)$$

For the enterprise to be evaluated, the data or analysis result obtained by the evaluation is represented by the matter element P.

$$P_{f-n_m} = \sum_{i=1, i\neq n}^{N} \sum_{l=1}^{M} p_{i_l} \left\| \mathbf{h}_{i,n_m}^{T} \mathbf{W}_{i,i_l} \right\|_2^2. \quad (3)$$

2.2. Characteristics of Resource Trade. A large number of foreign-funded enterprises have evaded the export quota of rare earth resources in China by investing in factories and other ways and have carried out predatory mining. Only simple processing can be exported, resulting in a large amount of waste of rare earth resources. The abundance of rare earth elements in the earth's crust is not barren, even relatively rich, and the abundance of some elements is higher than that of common metals such as copper and zinc. Rare earth elements are widely distributed in the Earth's crust and there are many mineral occurrences. However, there are no more than 30 large companies that control rare earth resources in the world. If you master the trends of these 30 companies, you can directly understand the global supply and demand of rare earth and the industrial chain [19]. The protection and management of rare earth resources in China have been gradually implemented with the breakthrough of rare earth application technology and the development of the rare earth industry. We should strengthen macrocontrol and give full play to the leading role of the government. The establishment of a rare earth industry enterprise alliance to control the price and usage of concentrate and to control the price and sales of primary products. Formulate relevant policies to encourage rare earth enterprises to go abroad and participate in or take control of the development of foreign rare earth resources, so that China's rare earth industry will truly go international.

Although China prohibits the export of rare earth raw ores, the economic benefits brought to China by the export structure dominated by rare earth separation products are

Table 1: Performance indicator structure parameter estimation and significance test.

Path description	t value	Path coefficient
Market learning ability ⟶ influence performance	3.46	1.57
Marketing ability ⟶ marketing performance	3.24	1.49
Customer management capabilities ⟶ marketing performance	4.37	1.45

Table 2: Characteristic values corresponding to each feature.

Features	A1	A2	A3	A4	A5	A6	A7	A8	A9
Characteristic value	75.6	88.5	87.3	95.2	74.8	74.7	86.2	91.7	76.5

relatively low, and rare earth smelting separation will cause serious pollution. From the beginning, two mechanisms with the nature of compensation and assistance were proposed, i.e., compensation mechanism for resource development and the assistance mechanism for declining industries. Sustainable development is based on natural assets and coordinated with environmental carrying capacity. Sustainable development aims at providing quality of life and is compatible with social progress. Research in any discipline or field should be supported by scientific methods that meet the needs of its research objects and contents and are determined by its research purposes. At the same time, any scientific research method is not exclusive but universal. Figure 3 is a schematic illustration of the general law of the development of resource-based cities.

The relevant data are substituted into the system to run, and the original model is repeatedly corrected to obtain a series of fitting indexes of the corrected model. When the significance level is low, the customer management ability has a relatively large impact on the marketing performance. However, the other two subindicators market learning ability and marketing promotion ability have a significant impact on marketing performance but to a lesser extent. In Table 1, the structural parameter estimation and significance test of performance indicators is shown.

Although the absolute amount of rare earth is large, the content is low and the average abundance in the Earth's crust is only 200 ppm, and the distribution is very uneven. In the matter element, A is an evaluation feature, that is, an indicator. Some feature values can be calculated by the system, and the feature values corresponding to each feature are shown in Table 2. Figure 4 shows the relationship between eigenvalues and matter elements in three sets of experimental data.

China's political system, economic system, and the development of the rare earth industry determine the legal system and policy measures for the management of rare earth resources. At present, almost all oxidizing roasting-hydrochloric acid leaching method is used in the industry. The rare earth ore is oxidized and calcined, and the bastnasite is decomposed to form rare earth oxide, rare earth fluoride, or rare earth oxyfluoride which is soluble in hydrochloric acid [20]. Rare earth elements are mostly in the form of oxides or symbiotic forms of oxoacid minerals, and the degree of enrichment is low. There are not many deposits with mining value at the current technical level, so rare earth

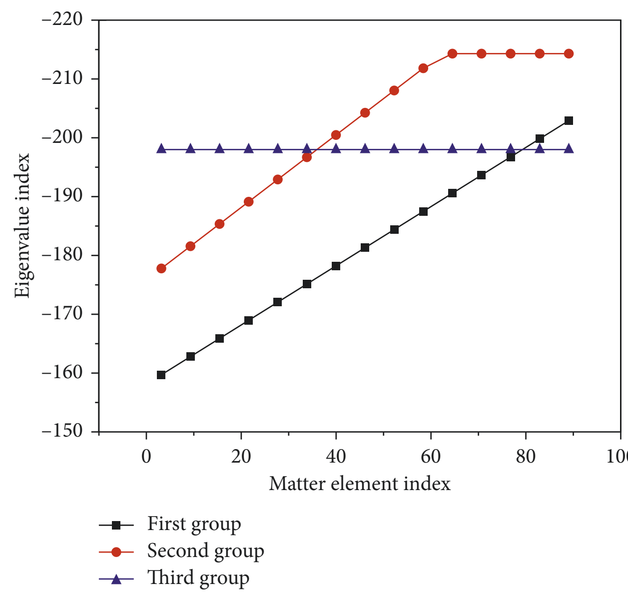

Figure 4: Relationship between eigenvalue and matter element.

resources have been proven in the world. The amount of exploitation is scarce. The in situ leaching process does not requires excavation of ore bodies, has little impact on the ecological environment, and has high resource utilization [21]. However, the in situ leaching process developed in the early stage is only applicable to mines with intact ore bodies. For mines with complex geological conditions, leaching liquid leakage often occurs, resulting in a significant reduction in rare earth recovery.

3. Economic Significance of Rare Earth Resources

Whether the political and legal system of rare earth resources protection and management can adapt to the development requirements of the rare earth resources industry determines the success or failure of China's rare earth resources strategy. Rare earth enterprises should develop new products to meet the domestic demand for rare earth consumption. Rare earth, as a special mineral resource, is greatly different from other mineral resources in terms of resource structure, resource use, and spatial distribution. In view of the problems of high consumption of chemical materials, the low comprehensive utilization rate of resources and serious pollution of the three wastes in the rare earth smelting and separation process, various research institutions, and enterprises have developed a series of efficient, clean, and environmentally friendly smelting and separation processes. In order to reduce dependence on foreign rare earth resources and prevent being controlled by others, some developed countries have begun to develop substitutes for rare earth resources. Judging from the current scientific and technological achievements, although some scientific and technological progress has been made, the results are not good. In order to better protect rare earth resources, China's established rare earth strategic resource reserve system should be implemented and perfected as soon as possible [22]. The unified export of rare earth products has also better maintained the reasonable price of rare earth, but there are also unreasonable problems, such as neglecting the management and protection of light rare earth and failing to adjust the relationship between rare earth development and environmental protection. Rare earth enterprises should seize the market opportunity, follow closely the market demand, and strive to develop the domestic market.

Under the current economic situation, small mining companies should adhere to the principle of large and small, superior and inferior, and follow the laws of the market economy according to the natural occurrence of resources. The social network formed by resource-based urban clusters is a complex and dynamic network. A social implementation mechanism such as a cluster network can establish a cluster trust mechanism to improve the resource environment. At different stages, the strength of urban cluster competitiveness and the specific performance of urban cluster competitiveness at different stages are shown in Figure 5.

The market learning ability has no significant influence on the accounting effect and brand assets. It actively promotes the construction of modern characteristic resource-based industries and the modernization of production methods, production methods, and production concepts. Speed up the transformation of industrial development mode, save natural resources and production factors, optimize the economic structure of resource-based cities, and realize sustainable development. Figure 6 is a schematic structure for strategic adjustment and guidance of industrial structure in resource-based cities.

The mode of unified purchase and sales of rare earth products was severely impacted by the market economy and withdrew from the historical stage. Therefore, the state's policy of controlling rare earth mainly focuses on mining and export. Through orderly mining, effective protection of resources is realized, and at the same time, local regional economic transformation and industrial upgrading are also supported. China's failure to enact a superior mineral protection law in time to meet the requirements of the development of the market economy has put the country's protection of rare earth resources into a dilemma. Most of the rare earth minerals in the world contain only a few rare earth elements, which are incomplete. The rest of the rare earth elements that do not exist still depend on imports [23]. China Nonferrous Engineering Design and Research Institute and Rare Earth Material Factory have improved the

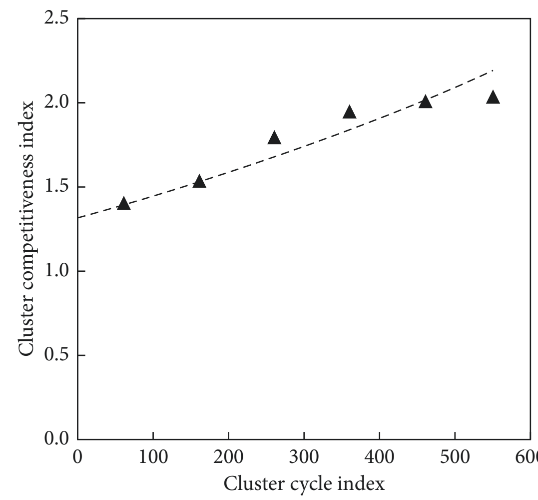

Figure 5: Trends in the competitiveness of resource-based clusters.

low-temperature roasting process to solve the problem of wall formation. Continuous low-temperature dynamic roasting can be realized by using low-temperature curing technology. Although the abundance of rare earth elements in the Earth's crust is not poor or even higher than that of some common metals, due to the technical conditions, some rare earth ores have low mining value and high cost, which are difficult to meet the mining standards and cannot be applied by human beings.

No resource can function independently as a factor of production. Only when natural resources are combined with social resources can they be transformed into productive forces with use value and value. Rare earth enterprises should base themselves on the domestic market and expand domestic demand. Figure 7 shows the contribution of different resources at different stages of economic development.

After the establishment of the comprehensive evaluation of the material-element model of independent innovation capability, it is necessary to evaluate the index value of each characteristic of the independent innovation capability of the enterprise and the approximation degree of each level. Applying the proximity of classical domain matter elements in the following extension set:

$$\mathrm{cell}_{ps-1} = \arg\max_{n} \left(\sum_{m=1}^{M} P_{f-n_m} \right). \tag{4}$$

The extension distance is

$$\mathrm{cell}_{ps-n_{s1}} = \mathop{\arg\min}_{i,i\neq \mathrm{cell}_{ps-1},\ldots,\mathrm{cell}_{ps-n_s}} \left(\sum_{m=1}^{M} \sum_{l=1}^{M} p_{i_l} \left\| \mathbf{h}_{i,ps-1_m}^{T} \mathbf{W}_{i,i_l} \right\|_2^2 \right). \tag{5}$$

Calculate the degree of association of the company to be evaluated with the weight coefficient of each feature.

$$R_{n_i}^{C} = \log_2 \left(1 + \frac{p_{\mathrm{mac},n_i} \left\| \mathbf{h}_{\mathrm{mac},n_i}^{T} \mathbf{W}_{\mathrm{mac},n_i} \right\|_2^2}{\sigma^2} \right). \tag{6}$$

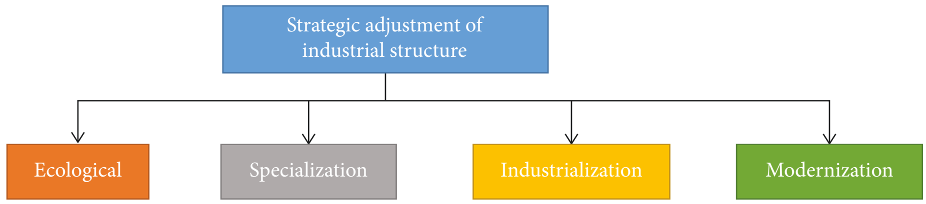

Figure 6: Strategic adjustment structure of the resource-based urban industrial structure.

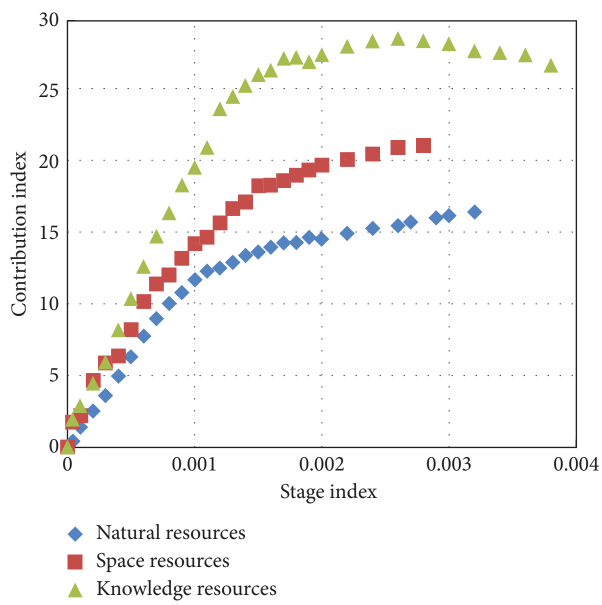

Figure 7: Different resources contribute to different stages of economic development.

Table 3: Price competition degree division.

Degree of decrease (%)	0–20	20–40	40–60	60–80	80–100
Normalized value	0.2	0.4	0.6	0.8	1

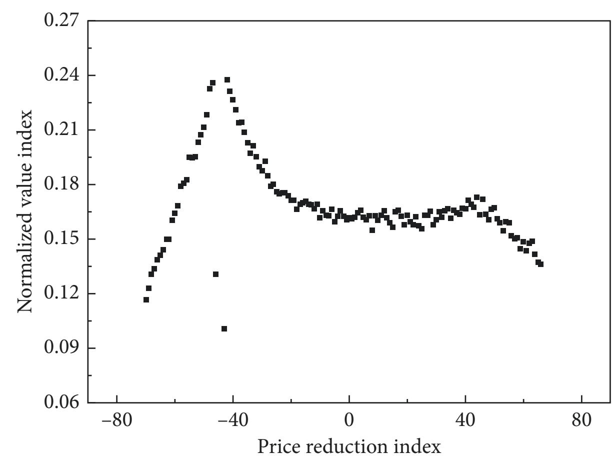

Figure 8: Relationship between normalized value and price reduction.

Through the deep processing of rare earth resources and the extension of the industrial chain, the pace of development of rare earth resources from upstream primary raw materials to deep processed products, high-tech new materials, functional components, and end-use products will be accelerated. After the various influencing factors have been uniformly measured to the four-point system, in order to better study the impact of price competition on various factors, the argumentation part adopts the idea of normalization of price competition. The price competition is divided into five sections, each of which has a length of 20%. The specific division is shown in Table 3. The relationship between the normalized value and the price reduction range is shown in Figure 8.

Sustainability is a measure of the sustainability criteria for resource-based urban transformation systems and the development of subsystems. Using the development rate of each subsystem as a measure, the following can be obtained:

$$Q\left(u_{ij}\right) = \sum_{i=1}^{n} \underset{1\le j\le m}{\mathrm{Max}}\left\{g_{ij}(T)\right\}. \tag{7}$$

Using the fuzzy membership function method to obtain the following:

$$y_{f-n_m} = \sum_{i=1,i\neq n}^{N} \sum_{l=1}^{M} \sqrt{p_{i_l}}\,\mathbf{h}_{i,n_m}^{T}\mathbf{W}_{i,i_l} s_{i_l}. \tag{8}$$

Calculate the trend degree as follows:

$$P_{f-n_m} = \sum_{i=1,i\neq n}^{N} \sum_{l=1}^{M} p_{i_l}\left\|\mathbf{h}_{i,n_m}^{T}\mathbf{W}_{i,i_l}\right\|_2^2. \tag{9}$$

In the impact on the other three indicators, although there is a certain degree of positive impact, but the impact is less than the customer management ability. But it is very close, so its impact on brand equity can not be ignored. The impact of marketing capabilities on customer value and product innovation is not significant, and the positive impacts on the other three indicators are significant. Similarly, the factor load of the corresponding indicators is also less than the factor load associated with the customer. The structural parameter estimation and significance test of the impact of marketing subcategories on marketing performance subindicators are shown in Table 4.

The selection of resource-based city indicators should cover the content of the evaluation as much as possible and comprehensively reflect all aspects of the city's sustainability

Table 4: Significant test of the impact of marketing subcategories on marketing performance subindicators.

	Value of customer	Competitive result	Brand equity	Product innovation
Market promotion ability	0.76	0.59	0.64	0.69
Customer management ability	0.37	0.44	0.49	0.51
Market learning ability	0.39	0.32	0.47	0.45

Table 5: Value of the correlation function of the evaluation level.

Grade indicator	1	2	3	4
S1	0.386	0.556	0.742	0.457
S2	0.943	0.796	0.297	0.362
S3	0.348	0.653	1.569	0.794

capacity. The correlation value of each level indicator is shown in Table 5.

To measure the degree of price competition between a company's homogeneous product and the market average price, you can simply write the price competition between a single company's product pricing and the market average price as follows:

$$c_1(t) = c_{11} + (c_{1T} - c_{11})\frac{t}{T},$$
$$c_2(t) = c_{21} + (c_{2T} - c_{21})\frac{t}{T}. \tag{10}$$

Initialize, calculate the connection weight and threshold, and assign any value.

$$I_i = \left[\sum_{j=1}^{p} \omega_j^m y_{ij}^m\right]^{(1/m)}. \tag{11}$$

Provide input samples and expected output to obtain the following equation:

$$I_\omega \ddot{\delta} = F_r d - K_\omega \dot{\delta} - C_\omega \delta - K_1 e \delta. \tag{12}$$

Calculate the output of each unit in the hidden layer.

$$T = \frac{M}{R} = \frac{i\eta_e M_e}{r}. \tag{13}$$

Enterprises need to improve their independent innovation ability and promote the upgrading of industrial structures. Strengthen the research on the development strategy of the rare earth industry and formulate policies and measures to further promote the development of rare earth technology and industry. Rare earth minerals are China's dominant mineral resources. In the early stage of reform and development, it is historically inevitable to obtain considerable economic income by supplying a large amount of rare earth products to the international rare earth market. Compared with the world's large multinational enterprises, China's enterprises in related industries are not strong in independent innovation, market competitiveness, and ability to resist international market risks. Cultivating a number of large enterprises with strong comprehensive strength is an important goal. Heavy and light rare earth products are sharply divided, and the proportion of heavy rare earth products in the mines that have been put into production is relatively low, so they cannot impact the medium and heavy rare earth market. China will continue to maintain its leading position in this field [24].

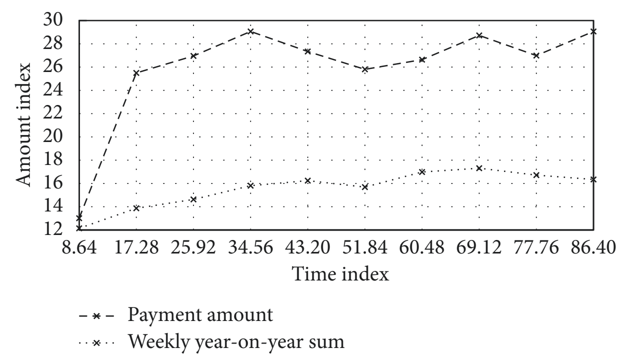

Figure 9: Preview of the transaction overview.

Rare earth resources are widely used in modern industrial development. Rare earth elements play a key role in some aspects. In the overall sales analysis, it is necessary to specifically analyze the customer unit price, year-on-year month-on-month changes, and other links. A preview of the transaction is shown in Figure 9.

China needs to fulfill relevant international commitments and obligations. The supply of rare earth products cannot be controlled by administrative means. Even through the means of environmental protection, its supervision system and law enforcement methods are not perfect and lack of supporting measures. The strategic value of rare earth resources is outstanding, and its supply directly affects the national defense industry, national competitiveness, and even the economic security of the entire country. The development of the rare earth resource industry not only provides a large number of jobs but also solves the problem of insufficient supply of mineral products in rapid economic development. In order to balance the interests of the central, local, and enterprise and properly handle the relationship between different regions and upstream and downstream industries, it is recommended to reconfigure mining licenses for state-led enterprises on the basis of the joint of national large-scale rare earth enterprise groups and resource regions [25]. We must first clearly understand the problems of China's rare earth resources in mining, processing, and export trade and find out the reasons through careful analysis and research, and then we can propose solutions to the problems. In order to enable China's rare earth industry to develop healthily and sustainably, it is recommended to increase investment in science and technology and environmental protection, strengthen research on efficient and clean production processes, industrial development and promotion, and strictly implement the "Rare Earth Industrial Pollutant Emission Standards." You can choose several key links for key management to effectively manage the valuable rare earth resources that protect the country.

4. Conclusions

Rare earth minerals are the strategic resources of the country. Therefore, the distribution and use of rare earth mining rights should not be allowed to be bought and sold arbitrarily as ordinary metal mining rights, so as to realize the effective control of rare earth strategic resources by the country. At a time when the socialist market economy system is gradually improving, the reimplementation of comprehensive planning and control of rare earth and other advantageous mineral resources no longer meets the fundamental requirements of the market economy era but also violates the basic development trend of mining development and operation mechanism and management system. While rare earth development benefits mankind, the accompanying problems of resources and environment are becoming increasingly prominent. With the in-depth development of economic globalization, China's international exchanges and cooperation in the field of rare earth resources are increasing day by day. At the system level, different legal procedures should be applied to the grant of rare earth development and management rights and the assignment of rare earth mining rights, respectively, to clarify the differences between the franchise rights and property rights. Mining rights can be taken as state-owned capital and included in the asset management scope of central enterprises. The exploration right should be granted to large enterprise groups on a regional, limited, and limited basis to avoid the loss of new rare earth resources. It is suggested that departments of land and resources at all levels should clean up and rectify their registration in the name of polymetallic minerals, actually demarcate rare earth mineral resources, and re-examine the exploration licenses and mining licenses that have been issued in rare earth mineral resources areas. In terms of process innovation management, China should attach importance to the nonrenewable nature of rare earth resources and increase the capital investment for rare earth deep processing and process innovation as soon as possible.

Academic Editor: Xin Ning

A master's degree program in "new liberal arts" is a great opportunity to strengthen cooperation between art colleges and universities, to promote the construction of product design and digital molding majors, and to promote teaching and research on the "integration" of the theoretical foundations of engineering intelligent manufacturing. To take advantage of cooperative universities' advantageous disciplines and professional platforms, we should construct new art and emerging interdisciplinary majors, as well as promote the construction and exploration of joint training of doctors and masters in relevant disciplines in the interdisciplinary direction of art and engineering. The foregoing approaches are intended to create a new "art and engineering" model for the establishment of a product design speciality at our university. In order to meet the requirements of "Art & Engineering" advocated by the national new engineering construction, art disciplines have their own inherent rules and characteristics. We should actively create disciplinary and professional characteristics, help universities cooperate with each other in high-quality development, and share and win together, in order to continuously achieve new academic results.

1. Introduction

China's "Six Excellences and One Top" Plan 2.0 was launched in Tianjin on April 29, 2019, with the goal of boosting universities' capacity to serve economic and social development by promoting the construction of new engineering, new medicine, new agriculture, and new liberal arts. When it comes to the growth of higher education, "new liberal arts" has become a subject that needs to be taken seriously [1].

It is necessary to grasp the new requirements for the development of philosophy and social sciences in order to strengthen the construction of new liberal arts. It is also necessary to cultivate new cultures with Chinese characteristics, such as Chinese style and Chinese style in the new era, as well as philosophical and social scientists. It is also necessary to establish a Chinese school of philosophy and social sciences in order to strengthen the construction of new liberal arts. The construction of "new liberal arts" has as its primary goal the adaptation to the new requirements of the development of philosophy and social science in the new era as well as the promotion of cross-fertilization between philosophy and social science with the new round of scientific and technological revolution and industrial change. As a result, the "new liberal arts" have emerged as a topic that must be properly studied and explored in the development of higher education in the contemporary day. For the "new liberal arts," efforts should be made to cross disciplines, form and expand new fields of knowledge at the boundaries between disciplines, particularly in conjunction with science and technology, and realize the intersection of arts and science. This, for the liberal arts, entails enhancing the scientificity of liberal arts and thus promoting the construction of "new liberal arts."

It was Bauhaus principal Walter Gropius who introduced the educational concept of "Art & Engineering" product design for the first time. Gropius insisted on the new unification of art and technology, which resulted in the formation of a new educational system that combined art education with handicraft. With its approach of merging "pure art" with "useful technology" [2, 3], the Bauhaus provided inspiration for the future "Art & Engineering" teaching model.

The term "engineering" in the "Art & Engineering" mainly refers to engineering in science, which is a discipline in which people study and apply theories and knowledge of natural science, sociology, economics, logic, and other disciplines to innovate or improve the design and use of solutions in various fields [4]. It also includes the meaning of "engineering technology," in which people use engineering technology to make practical objects or tools to extend or compensate for human capabilities and change people's way of life, with the intention of being practical.

Product design is a kind of industry that is about innovation, and without innovation, there is no vitality. The educational concept of product design should also include the concept of innovation. Since the Bauhaus pioneered the innovative educational concept and mode of "Art & Engineering," institutions across the world are following suit [5]. However, in this new era, if we adhere to this concept and follow the trend without seeking innovation, the design talents we cultivate will be out of step with the society. Based on the diversified, informative, and intelligent conditions of the times, the educational concept of "Art & Engineering" in product design must keep pace with the times and make the concept of design education have new thinking characteristics.

Rather than just rehashing the old buzzwords of "intersection of disciplines" or "intersection of arts and sciences," the concept of the new liberal arts should be understood from the perspective of China's intrinsic requirements for postsecondary education [6]. The investigation and practice of "Art & Engineering" of product design in the context of "New Liberal Arts" are still in the early stages of its development and implementation.

Problems

(1) The engineering technology category of product design majors does not have sufficient teaching qualifications, and it is difficult to connect the more artistic design majors with the more technical engineering technology at this time. Product design majors will concentrate on the design of rail transportation class and intelligent product class, which will be based on the application of big data, cloud computing, and artificial intelligence technology, allowing the design to be more scientific, rational, and extensive in the context of the "New Liberal Arts." As a result of this rapidly changing development environment, the knowledge structure, cognitive ability, and thinking mode requirements of designers will undergo significant shifts in the near future. As a result, design education will need to adapt quickly in order to meet the changing needs of society.

(2) There is a difference between the training for talents and the education of design as well as the most recent technology available on the market. (2) Product design teachers must convert their art backgrounds and engineering teaching concepts into product design teaching concepts. The talents cultivated by design education will be unable to meet the needs of social development and will eventually be eliminated if design education does not adapt to the changing times in order to adjust the goal of talent training and does not use engineering technology to complement the design practice. It will also be difficult to implement the employment of design education students. In order to better support product design teaching, it is urgently necessary to investigate how "Art & Engineering" can promote the reform of product design education from a systematic and holistic perspective as well as to clarify the ideas for "Art & Engineering" to better support product design education and cultivate more professional product design applied talents.

Solutions

(1) "Art & Engineering" should reflect the personalization and diversity of interdisciplinary

To further strengthen the construction of product design discipline, give full play to disciplinary strengths, and concentrate disciplinary characteristics; to strengthen interdisciplinary crossover and integration with art colleges and engineering majors and take the construction of a special master's degree in art as an opportunity to build the disciplinary characteristics of "Art & Engineering"; to do a good job of training product design talents with high quality and establish an application-oriented education training system that serves the needs of economic and social development.

(2) "Art & Engineering" should pay attention to talent training

To further boost the creation of product design majors and the training of future product design talent. Taking the construction of new engineering and new liberal arts as a model, establish and improve the dynamic adjustment mechanism of majors, optimize the structure and connotation of majors, expand the enrollment scale of majors, and establish new majors in art; concentrating on the cross-fertilization of art and engineering to form the cultivation characteristics of art and design talents, promote the in-depth reform of project-based teaching, and strengthening the internationalization of art and design talents; focusing on the cross-fertilization of it is necessary to continue to increase the construction of teaching staff at the "Art and Engineering" school. It is also important to develop a high-level professional teaching and research team with a worldwide perspective through training, further training, and study visits, in addition to expanding the channels for the entry of high-level talents into the product design industry.

(3) Research on the new platform of discipline construction in College of Arts and Design

> To adapt to the requirements of "Art & Engineering" advocated by the national new engineering construction, art disciplines have their own inherent rules and characteristics, should actively create disciplinary and professional characteristics, and help universities cooperate in high-quality development to help each other and share and win together, in order to continuously achieve new academic results.

At this stage of the school's development ideas and goals, the status of the School of Art and Design is increasingly important, directly related to the comprehensive and coordinated development of the school's related disciplines, the important indicators of the school's name change, and the core content of the school's future sustainable development. Therefore, the great development of art and design disciplines should fully rely on the school's traditional advantageous disciplines, build a new platform for discipline construction of the College of Art and Design, and strive to form a number of characteristic high-level research results around the direction of discipline construction of the College, with the common ideal of "building a first-class art and design college of the same kind with domestic influence and provincial status" [7, 8], form the mainstream value orientation common to all the faculty and students, and concentrate our efforts to create a college culture atmosphere that emphasizes discipline and professional development, academic research and artistic creation, harmonious construction and quality improvement, and continuous deepening, expansion, and ascension.

2. New Thinking and New Forms of Cultural Confidence Research of "Art & Engineering"

According to the "new liberal arts" theory and practice, the Jiangsu brand-product design major establishes a new pattern of "Art & Engineering" in accordance with the investigation and practice of the development of national first-class products. It will be developed in conjunction with the master's degree program at the College of Art and Design in order to strengthen cooperation between art colleges and universities, cooperation with engineering practice majors, and practical teaching of intelligent design and will strive to promote a close connection between knowledge transfer and production practice. It will also be developed in conjunction with the master's degree program at the College of Art and Design in order to promote "integration" of theory and practice in the field of product design and digital molding. It is necessary to establish a design research and development platform with innovation as the goal, a practical platform with engineering training as the means, and a social crowdfunding or school-enterprise cooperation platform with market demand as the guide in order to explore and practice "Art & Engineering" in product design education, resulting in the formation of a new way of thinking about and practicing "Art & Engineering" in product design education. It is shown in Figure 1.

As part of this effort, the college will make better use of the advantageous disciplinary and professional platforms of the partner institutions to carry out the construction of new art and emerging cross-disciplinary disciplines and professions. It will also work to promote the construction and exploration of joint training programs for PhDs, Master of Arts, and Master of Engineering degrees in relevant disciplinary fields as well as joint training programs in engineering-related cross-disciplinary directions. A number of initiatives will be undertaken by the two sides to benefit from their respective disciplines, such as the development of new art and emerging interdisciplinary disciplines and majors, the establishment and sharing of internship and practical training teaching practice bases, the cultivation of PhDs and Master of Art and Engineering-related interdisciplinary directions within relevant disciplinary fields, as well as the collaboration in the development of an innovative and entrepreneurial education system. The partnership will be translated into practical measures to support the development of the school in a timely manner, as well as to promote the quick expansion of the school's business, and work toward the establishment of a new pattern of "Art & Engineering."

2.1. Research on the Construction of Cultural Confidence Majors with "Art & Engineering"

(1) Research on new thinking and new forms of "Art & Engineering" in the era of "New Liberal Arts"

(2) Research on teacher training for "Art & Engineering" talents in the field of design in universities and research on leading the cultivation of product design talents

(3) Research on the construction of product design talent training objectives and curriculum system with "Art & Engineering"

2.2. Investigation into the "Art & Engineering" Teaching Mode and the Use of Abilities in Intelligent Design

(1) To investigate the current state of product design higher education in both China and abroad, as well as the characteristics and applications of intelligent technology, in order to predict the future development trend of intelligent product design education and to establish a fundamental theoretical system for intelligent product design education in China and abroad

(2) To redefine the training objectives of product design talents in the new liberal arts era, improve the talent training program, and establish the core curriculum system of "Art & Engineering"

(3) To study the changes in the teaching resource environment, teaching and learning methods, teaching management and evaluation methods, personalized teaching mode, and teacher training in the "Art & Engineering," to propose the reform direction of product design education, and then to build the education system of product design in the era of "New Liberal Arts"

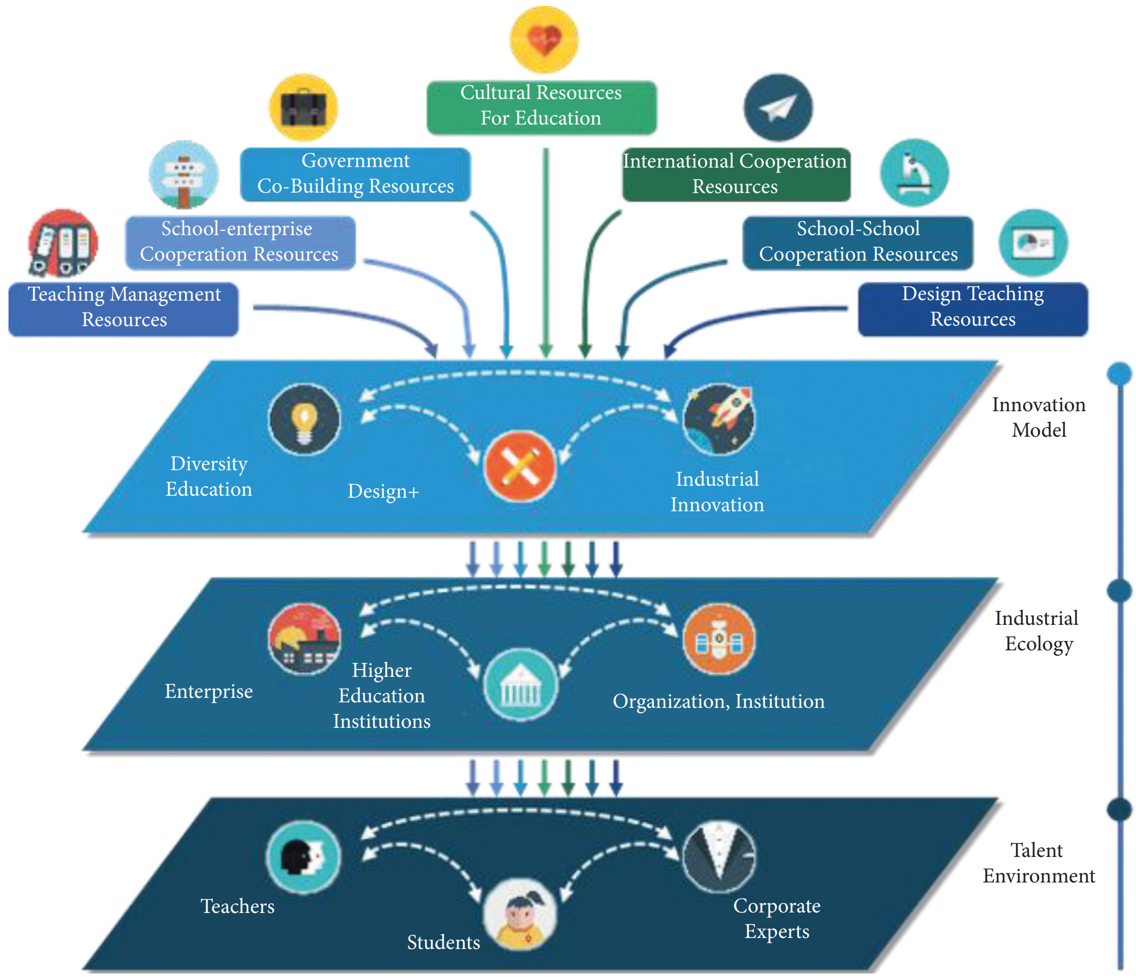

Figure 1: New thinking and new forms of education in "Art & Engineering" cultural confidence theory research.

2.3. Research on the Construction of a Teaching and Research Platform for Product Design and Digital Molding of "Art & Engineering"

(1) Research on courses that are closely linked to the "Art & Engineering": Human-Computer Interaction Design Research at master's level, Advanced Manufacturing Technology and Artistic Design, Thematic Studies in Electromechanical Product Design, Product and Interaction Design Project Practice, Design competitions and exhibitions.

(2) Research on computer-aided design series courses, product design series core courses, model making, thematic design series courses, CG production of animation characters, cultural and creative design of animation, model making of craft products, jewelry design, environmental model making, and many other professional basic courses and professional courses in the undergraduate stage of "Art & Engineering".

(3) Researchers at home and abroad are investigating intelligent educational platforms for "Art & Engineering" in a variety of contexts, including the platform characteristics and operation system of educational robots and platforms, teaching software and teaching tools, intelligent virtual assistants, among other things; they are also investigating the teaching and research platform of intelligent product design and digital molding.

3. Diversification of "Art & Engineering" Practice Research with Cultural Confidence

When placed in the context of the "new liberal arts," product design majors' educational thinking must seek innovation and keep up with the times; as a result, the educational mode of "Art & Engineering" tends to be market-oriented, internationalized, personalized, and manifesting the characteristics of regionalization [9–11].

3.1. Enhancing Students' Interest and Skills in "Art and Engineering" Intellectual Creation. Students' real-world experience with a variety of material processing techniques and skills is enhanced through the use of the basic molding system, which increases the means of expression and the ability of intelligent product design for art and design students, which is conducive to activating students' creative thinking, encouraging students to carefully observe the surrounding living environment and the current social situation, and combining objective natural laws and their own unique thin-film technology. The measures outlined above can assist us in cultivating a diverse pool of high-quality applied talents to satisfy the needs of economic and social development.

3.2. Improving the Quality of Talent Cultivation of "Art & Engineering" and Sharing Teaching Resources with Cultural Confidence. Students can conduct experiments at any time and from any location because of the development of this project, which overcomes the limitations of time and space. At the same time, the software has a variety of learning functions that allow pupils to practice over and over again. "Observation, recording, and combination-making exercises" [12] of virtual experimental items in a variety of virtual experimental contexts have helped students to improve their design skills. When this initiative is put into practice, it significantly improves the scientific approach to learning as well as the professionalization of students' practical skills. Using the Internet, participants can easily access and use large-scale class experiments, and the project is open to the general public as well as educators. As of now, not only do the virtual simulation teaching materials serve the staff and students at this college but they also assist in the virtual simulation experimental teaching of other related majors.

3.3. "Art & Engineering" Should Be Personalized and Diversified Teaching. When it comes to improving students' design ability, the design education process is critical because it cultivates strong hands-on practical skills while also growing high theoretical literacy and the capacity to make full use of regional cultural resources to enrich their design concepts. In addition, professional craftsmen who are engaged in design and production work in the field of traditional crafts should be hired to teach at the institution. At the same time, in order to realize the purpose of assisting social production, the school should develop an industry-university-research platform in collaboration with businesses. A design that has not been translated into a product and the value of that design has not been realized are impossible if pupils do not grasp the manufacturing process. Students from all directions study professional basic courses together in the freshman year, such as design aesthetics, design composition, design expression techniques, the history of world arts and crafts, the history of Chinese arts and crafts, and other basic courses [13–15]; in the sophomore year, we implement discipline subdivision and choose discipline direction, such as curriculum of ceramics, wood carving, leather design, furniture design, and other disciplines [16–18].

3.4. "Art & Engineering" Should Implement Industrialization. The industrial transformation of design works, as well as the capacity to follow up in the process of product manufacture, processing, and sales, is an important element of the product design profession and one that can drive students to pursue a degree in product design which includes: (1) establishing craft design factories or studios on campus, as well as crowdfunding platforms on various commercial websites to publicize the works and raise funds for the processing and production of design works; (2) establishing school-enterprise partnerships with enterprises, in which the school commissions enterprises to process design works and provide them with marketing, as depicted in Figure 2; and (3) establishing school-enterprise partnerships with enterprises, as depicted in Figure 2.

3.5. "Art & Engineering" Should Be Internationalized. Design, like art, has no geographical boundaries. It is also necessary to integrate and cross borders in the "Art and Engineering" approach to product design education in order to better portray the spirit of product design education. Internationalization of the "Art and Engineering" approach to product design education is recommended in order to establish a broader and more diverse sector of design education [16–18]. The process of "Art & Engineering" product design education, such as the teaching of ceramics courses, must combine ceramic engineering and art, and it is necessary to cultivate advanced composite applied talents who understand both ceramic engineering and have excellent artistic design ability in order to meet the needs of China's ceramic industry development. Studying abroad, getting to know oneself and one's adversary, and learning the essence are all essential for standing out in design education.

4. Innovation and Prospect of "Design+" Multidisciplinary Cross-Fertilization with Cultural Confidence

In the context of the "New Liberal Arts," the educational thinking of product design majors must be innovative and keep up with the times so that the educational mode tends to be industrialized, internationalized, and personalized in the market, as well as manifesting the characteristics of regionalization, as shown in the following diagram. It is necessary to establish a design research and development platform with innovation as the goal, a practical platform with engineering training as the means, and a social crowdfunding or school-enterprise cooperation platform with market demand as the guide in order to explore and practice "Art and Engineering" in product design education, resulting in the formation of a new way of thinking about and practicing "Art and Engineering" in product design education. The following are examples of specific innovations.

4.1. Research on the Innovative System of Cultivating Intelligent Applied Talents in Product Design under the "Art & Engineering". The product design major, which is a combination of art and engineering in the context of "New Liberal Arts," should adhere to the principles of moral education, establish cultural self-confidence, support the high-quality development of the regional economy, and cultivate innovative and applied product design professionals who can comprehensively develop "moral, intellectual, physical, aesthetic, and labor" and grasp the elements

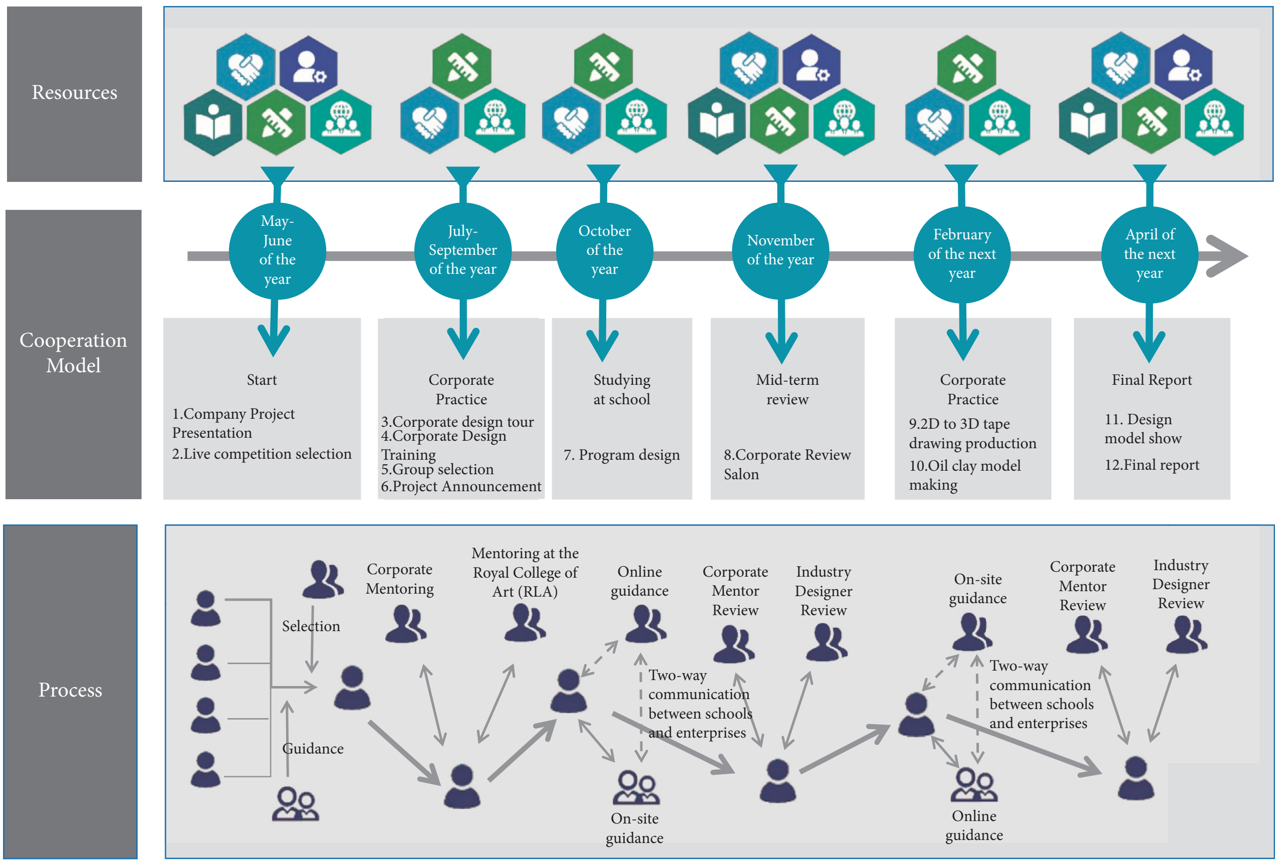

Figure 2: The "Art & Engineering" school-industry partnership project follows a logical progression.

of product function, form, material, structure, and color in the context of "New Liberal Arts."

(1) The practice of "Art & Engineering" product design and professional construction in the context of "New Liberal Arts" is being explored and researched.

It is necessary to emphasize the core purpose of "Art & Engineering" in design majors' curriculum and teaching system and introduce this learning concept to students early in the teaching process [19] so that students realize that they are product designers with comprehensive professional qualities rather than conceptual designers who can only draw concept drawings. We use the case analysis method to examine the current situation of product design education at home and abroad, as well as the nature, connotation, and construction ideas of the "New Liberal Arts." We also investigate the development trend of "Art & Engineering" in product design education, and we establish the fundamental theoretical system of product design education under the umbrella term of "New Liberal Arts."

(2) "Art & Engineering" is a teaching style that focuses on the application of intelligent design applied talents

When faced with the challenges of diversity, information technology, and intelligence, the education concept of "Art & Engineering" for product design majors must evolve to keep up with the times so that the design education concept possesses new thinking characteristics as well. By adopting a new model of product designers' "Art & Engineering" skills, we can reevaluate the training objectives of product design talents, improve the training program, and establish a core teaching model that meets the innovative consciousness and creative ability of "Art & Engineering" skills in the context of "New Liberal Arts."

4.2. Construction of Industry-Education-Research Platform for Product Design under the "Art & Engineering". As required by the discipline's talent cultivation goal, and in order to satisfy the needs of modern design and manufacturing firms, the College of Art and Design is collaborating with the College of Design to declare a master's degree in the field of art and design. A new teaching and research platform for product design and digital molding will be established in order to promote the "integration" of theory and practice in smart manufacturing. This will help to improve the quality of practical instruction while also promoting the close connection between knowledge transfer and manufacturing practice. The development of digital molding technology has altered the rigid standard of traditional manufacturing, allowing for greater design flexibility as the technology advances. In addition, the development of digital molding technology has increased the design dimension while

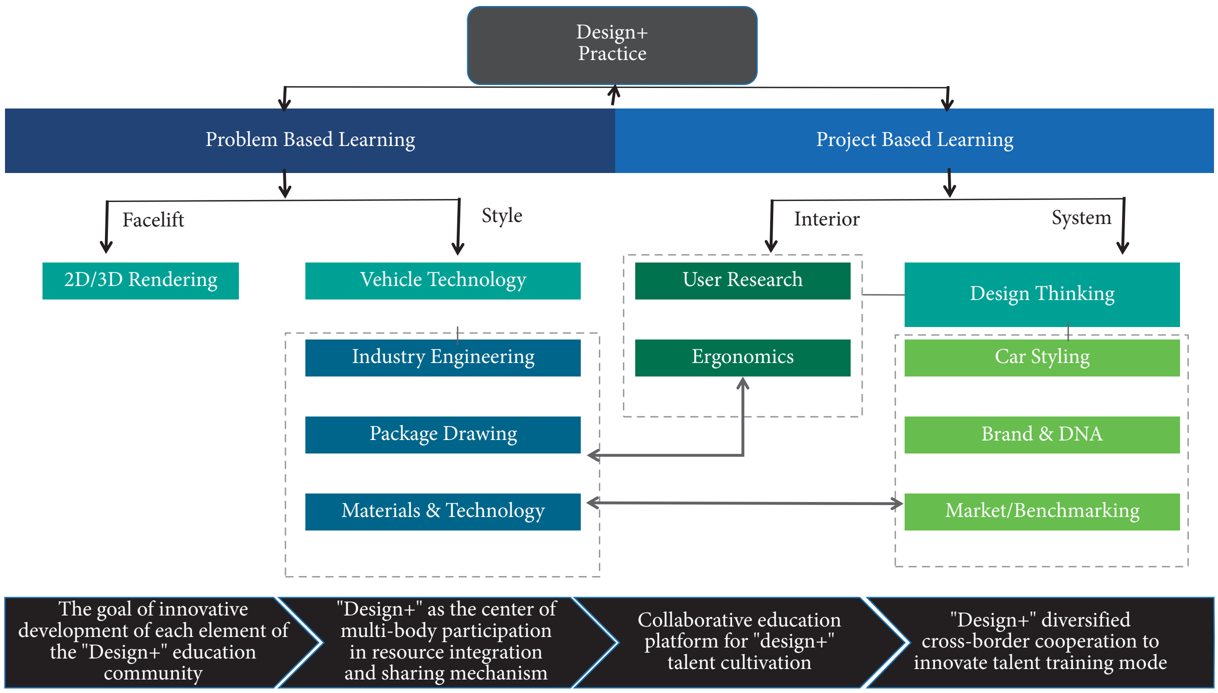

Figure 3: Reform and practice plan of design interdisciplinary graduate education.

simultaneously enriching the design means and presentation level. It encourages the development of teachers' scientific research abilities while also providing substantial technological and physical assistance for the collection of scientific research results in the classroom.

Innovative research on the construction of a teaching and research platform for product design and digital molding of the "Art and Engineering". An important feature of the product design profession and an important aspect that can motivate students to learn is the industrial transformation of design works and the ability to follow up during the production, processing, and sales of products. This teaching and research platform is composed of basic molding system, digital molding system, and reverse design system and is centered on three major master's specialties: product and interaction design, environment and landscape design, and visual and information design, to purchase relevant research instruments and equipment, create a research platform, support relevant basic theory and key technology research, promote the development of relevant disciplines in the university, and help local industries transform and upgrade.

4.3. Establishing a Design Education System of "Vision Sharing-Resource Sharing-Platform Building-Effectiveness Co-creation" as a Linked Evolutionary Mechanism. As a result of technological advancement, social transformation, and international rivalry, new needs for the growth of design education have been established. Specifically, we investigate the objectives, processes, methods, and resources of professional talent training for design graduate students. We also examine the elements and their mutual relationships among them; categorize the elements according to the logical relationship between the domain layer, platform layer, and subject layers [20, 21]; construct an interdisciplinary education system for design majors; follow the basic ideas of interdisciplinary professional construction; form the key tasks of profession; and make the interaction between the many levels of the system and the talent, industry, and innovation chains more comprehensible and understandable. A linking evolution mechanism of "vision sharing-resource sharing-platform building-effectiveness co-creation" is proposed to carry out professional education reform and practice, based on our findings. The reform and practice plan can be seen in Figure 3.

5. Conclusion

As our school's development ideas and goals progress, the status of our design majors has become increasingly important, as it is directly related to the comprehensive and coordinated development of the school's related disciplines, to the important indicators of the school's name change, and to the heart of the school's long-term sustainable growth. The great development of design interdisciplinary disciplines should, as a result, fully rely on the school's traditional advantageous disciplines, create a new platform for the construction of interdisciplinary disciplines in the college, and strive to form several characteristic high-level research results centered on the college's discipline construction direction. The common ideal of "constructing a first-class college of art and design with domestic influence and provincial status" should serve as a guide for all faculty and students, and we should concentrate our efforts on developing a college culture that emphasizes discipline and professional development, academic research and artistic creation, harmonious construction and quality improvement, and continuous deepening, expansion, and ascent. In addition, we will further explore how to combine the new teaching mode system of artificial intelligence in the near future.

Academic Editor: Xin Ning

With the popularization of 3D printing in the consumer goods field, there is a specific type of hole named annular hole in the narrow features, surface bumps, or folded parts of products. The traditional triangular mesh repair method is not effective for such holes. The structural characteristics of the annular hole are analyzed in this research, and the definition and identification method for annular holes is presented through the shape and position relationship of two closed hole lines. To improve the repair efficiency and the applicability of the algorithm, the traditional hole repair method and process are ameliorated. A repair strategy of hole boundary stitching and filling, triangulation optimization, implicit surface construction based on Radial Basis Function, and surface integral deformation is adopted to achieve a smooth joint of the repaired hole surface with the original triangular mesh surface. The method can ensure surface smoothness and accuracy. Finally, two experiments are carried out to verify the repair quality and efficiency of our method. Compared with Geomagic software, the proposed method can automatically identify and repair annular holes with fewer defects and similar efficiency. Compared with a traditional hole repair method, the evaluation results demonstrate that the proposed method is much faster, and the repair quality is higher without the influences of human operations. It is shown that our method can be applied to annular hole repair of 3D printing models without the participation of technicians.

1. Introduction

3D printing is an emerging manufacturing technology based on digital models, which manufactures physical items by stacked bondable materials such as powdered metals or plastics. Having made a profound impact on the traditional process, production line, factory model, and industry chain combination, 3D printing is a representative disruptive technology in manufacturing [1–3]. Currently, with the rapid development and popularity of 3D printing, consumers have also turned to and experienced 3D printing. For example, the platform created by Shapeways in the United States, which integrates design, customization, and sales, has more than 21,000 online stores, having served more than 1 million consumers and printed over 21 million products [4]; in China, Haier Group has built an online open innovation and entrepreneurship platform, which has more than 300,000 registered users and created successful cases such as the Tianzun air conditioner [5].

As 3D printing is applied in the consumer goods field, various types of holes often occur in constructing and acquiring mesh models, which would seriously affect the appearance and quality of 3D printed models. At present, the identification and repair of holes in triangular mesh models are mostly carried out through user interaction, which has low efficiency and requires certain skills of operators. However, most consumers do not have professional skills in hole identification and repair, which poses difficulties for the development of 3D printing in the consumer goods field. The repair of holes like simple holes and island holes has been focused on and researched, but the repair of specific annular holes in the consumer goods field has not been reasonably solved. To this end, it is necessary to research and classify the characteristics of annular holes according to their topology, and corresponding annular hole identification and repair methods could be provided with high repair quality and less professional operation requirement.

The paper is organized as follows. After reviewing some related work in Section 2, the main types and characteristics of annular holes are studied and an intelligent identification method for annular holes is proposed in Section 3. In Section 4, an improved implicit surface repair method for annular holes based on Radial Basis Function (RBF) is presented. In Section 5, compared with the results of internationally well-known commercial software and a traditional hole repair method, experimental results and discussion are given. Finally, our summary, evaluation, and direction for further research are discussed in Section 6.

2. Related Work

Originating as early as the 1980s, 3D printing has boomed again with the promotion of the Internet since 2010. Having made positive progress on the market application in fields including aerospace, automotive, and healthcare, it got started in 3D printed cars, airplanes, and artificial liver tissues. It can be seen that 3D printing is continuing to promote and expand its application. In 2012, the British Magazine the Economist evaluated 3D printing as "an important symbol of the third industrial revolution," which would become a new creative technology to change the future world [6]. Since then, 3D printing has also gained the attention of the average consumer. In October 2013, the world's first successful auction of a 3D printed artwork named "ONO God" was held [7]. 3D printed shoes, jewelry, dolls, and other products have also gradually entered the vision of ordinary consumers, as shown in Figure 1.

Along with the wide application of 3D printing, many scholars at home and abroad have researched the rapid reconstruction and repair of 3D printed models. The simple and flexible structure, high stability, and topology of triangular mesh models lead to the rapid and mature development of the hole-filling technique based on triangular mesh models [11]. A more typical repair method is the surface-based hole-filling algorithm, which repairs holes on the surface with the help of data near the holes by directly detecting and identifying the hole information of the input 3D model. It mainly includes the mesh growth method based on adding new sampling points and the method based on implicit surface fitting [12–14].

The mesh growth method based on adding new sampling points generates new sampling points from hole triangle boundaries to hole area and constructs new triangular patches by edge swapping and triangle refining until the whole hole is covered. Pernot et al. [15] proposed the curvature minimization principle to repair holes by adding new triangles under the premise of minimizing the curvature variation between the surrounding and inserted meshes, which is applicable to holes with a simple shape. Marchandise et al. [16] used the hole boundary points as well as the neighboring vertices as the basis for establishing surface patches and sampling on the surface patches. The method had a relatively high hole-filling accuracy, but it was not applicable to the case where the curvature variation of the hole area was large. Wang et al. [17] first repaired the hole with the advancing front method and then used the data such as normals of the boundary vertices to determine optimal vertices, so as to adjust the position of the pre-repaired hole triangular surface patch. However, for complex holes, especially for the hole boundary area with large curvature variation, the geometric features of the original model would be lost, and the repair result would be too flat.

The hole-filling algorithm based on implicit surface fitting repairs holes with an implicit surface established with original model data. Lévy [18] parametrized the entire model data to the plane for processing, and the algorithm is less efficient when the area of the repaired holes is small. and the number of triangles is large. Brunton et al. [19] first flattened the hole boundaries without self-intersection onto the reference plane for filling and then used the minimum energy method to embed the patched mesh back into the spatial mesh. Fortes et al. [20] proposed a shape feature determination method on top of Brunton's. Based on the minimization of an energy function, the holes were filled by inheriting the local information of the holes in the original model. The method required better local data quality of holes. Du et al. [21–25] all used RBF to fit the implicit surface of holes and then adjusted new vertices to the implicit surface. The method was suitable for repairing simple holes and island holes. For island holes with large curvature variation, a bridging method was proposed to connect the island boundary and hole boundary. Zhao et al. [26] carried out a preliminary repair with the advancing front method and then finished the repair by solving Poisson equation to adjust positions of added vertices. This method was not applicable to the repair of large holes.

Through the above analysis on hole-filling techniques, it is proved that the mesh growth-based repair method is a simple idea, easy to implement, and more effective for repairing holes in flat areas with simple structures and no significant features. The implicit surface fitting method produces a smoother repair surface, inherits the original mesh data information during the repair process, and has little interference with the original mesh model and more accurate repair results. However, it asks for a harsher scenario and would always smooth sharp features. Both methods can obtain ideal results for simple holes, but there may be mapping failure or mapping error for complex holes, resulting in poor hole-filling effects.

For the segmentation and repair of complex holes, Jun [27] proposed an algorithm to split a complex hole into simple holes and then fill each divided simple hole, which helped in triangulating and repairing holes with self-intersecting boundaries in the projection process but was not ideal in filling complex holes of other types, especially the problem of self-intersecting boundaries in the nonprojection process. Inspired by this method, Li et al. [28] presented an algorithm based on the concept of edge expansion to split complex holes into simple holes and then perform hole-filling with due consideration of the neighboring mesh morphology. Lai and Hsu [29] further considered the treatment of island holes and proposed a hole-filling algorithm based on B-sample surfaces to fit the vertices near the holes to the B-sample surfaces, emphasizing the topological accuracy and smoothness of the joint between the new mesh

Figure 1: 3D printed consumer goods [8–10]. (a) 3D printed shoes STRVCT. (b) Nike 3D printed football shoes. (c) Faux Russian big crown. (d) 3D printed table. (e) Custom doll. (f) Flower lampstand.

and the existing mesh. Feng et al. [30] introduced a fast filling method for triangular meshes based on hole size, which classified holes into small-sized, middle-sized, and large-sized holes according to their size and used different filling algorithms for different hole types. However, the classification method, which only considered the hole size and ignored the complex topological morphology, would hardly achieve satisfactory results in filling complex holes. Wen et al. [31] presented a surface-repairing method with automatic identification of defective holes and maintenance of detail features in the hole region, but the method was only applicable to repair defective holes in simply connected domains, ignoring the topology of complex missing regions. By analyzing the hole boundaries and topology, Li [12] classified holes into ordinary holes, interstitial voids, island holes, and semiclosed holes and proposed a hole-filling algorithm based on Poisson equation, which can repair large-scale complex 3D models containing a large number of holes and a variety of hole types. The method was applied to the restoration of heritage models with slightly insufficient repair efficiency. Centin et al. [32] proposed a Poisson-driven approach, which allowed to close complex holes, islands, gaps, and missing parts with a seamless integration of the patching triangles along the mesh boundaries, with guaranteed and homogeneous mesh quality. But its repair quality was seriously influenced by the boundary curves user selected. Based on the above analysis, the intelligent identification and repair method for annular holes is still a challenge.

3. Annular Holes and Their Intelligent Identification Method

3.1. Generation of Annular Holes. In the consumer goods field, due to the complex and varied structures of most products such as handicrafts, doll models, and bionic products, there are many narrow features, surface bulges, hollow-carved structures, or folds, as shown in Figure 2. They can easily cause fracture, local loss, or separation of the triangular mesh model during model construction, scanning, and acquisition. So, a specific type of hole always occurs, namely, an annular hole. Using the existing repair methods, it is easy to cause the fillings of hollow-carved structures or folds, and they lead to high differences from the original structure. In addition, most users for consumer goods are ordinary people lacking the ability to operate specialist repair software, so the result of hole repair is not satisfactory.

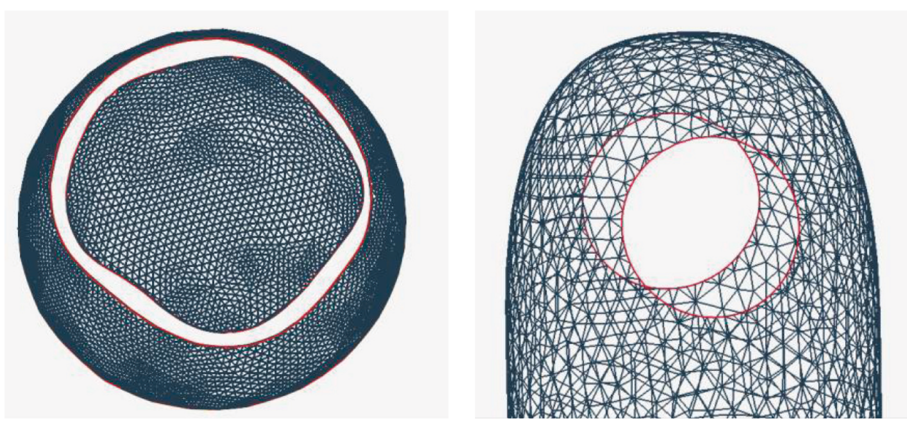
3.2. Annular Holes. The annular hole is formed by two boundary lines with similar shape and no common point, whose positional relationship is approximate coplanar or parallel, as shown in Figure 3. Annular holes are commonly found in sections, cross-sections, or folds of models. Two types of annular holes are summarized through analysis.

Coplanar annular hole: the positions of two annular closed curves are approximately coplanar, and the normal directions are similar, as shown in Figure 3(a). It is a common type of annular holes occurred in the surface bulges or hollow-carved structures.

Parallel annular hole: the positions of two annular closed curves are approximately parallel, and the normal directions are nearly contrary, as shown in Figure 3(b). It is an uncommon type of annular holes occurred in narrow features, hole features, and folds. There are few repair methods to deal with such holes.

The annular hole has two annular closed curves. The application of simple hole filling methods to an annular hole will repair all the interior of the two annular closed curves, resulting in a large number of self-intersecting patches. As for island hole repair methods, the number of internal triangular surface patches of annular holes is too large, and

FIGURE 2: The example products prone to annular holes.



(a) (b)

FIGURE 3: Two types of annular holes. (a) Coplanar annular hole. (b) Parallel annular hole.

the hole normal directions of parallel annular holes are nearly contrary. So, it is not appropriate to simply use the surface deformation repair method of deleting island fragments or selecting some islands as constraint points, which is easy to affect the repair quality or destroy the original structure of the model. For this reason, the repair of annular holes needs to be treated separately.

3.3. Intelligent Identification Method for Annular Holes. As the annular hole is made up of two boundaries that are similarly located and shaped, the hole connects two discontinuous triangular mesh sections of the model. The two boundaries of the annular hole can be identified by detecting the distance between the boundaries of different combinations of triangular facets; that is, an annular hole is composed of the free boundaries of two sets of triangular meshes. Therefore, the following determination method for annular holes is presented.

We set the hole boundary points as $P_1, P_2, P_3, \ldots, P_n$, and O as the gravity center of hole boundary points, i.e.,

$$O(\overline{X}, \overline{Y}, \overline{Z}) = \frac{1}{n}\sum_{i=1}^{n} P_i\,, \quad i = 1, 2, \ldots, n. \tag{1}$$

Using the coordinates of the hole boundary points and the gravity center O, a 3×3 covariance matrix C can be defined as

$$C = \begin{bmatrix} \mathrm{cov}(X,X) & \mathrm{cov}(X,Y) & \mathrm{cov}(X,Z) \\ \mathrm{cov}(Y,X) & \mathrm{cov}(Y,Y) & \mathrm{cov}(Y,Z) \\ \mathrm{cov}(Z,X) & \mathrm{cov}(Z,Y) & \mathrm{cov}(Z,Z) \end{bmatrix}, \tag{2}$$

where

$$\mathrm{cov}(X,Y) = \frac{\sum_{i=1}^{n}(X_i - \overline{X})(Y_i - \overline{Y})}{n-1}. \tag{3}$$

The eigenvalues and eigenvectors of the matrix can be calculated through Jacobi method. We set the three eigenvalues as the first vector $\overrightarrow{V_1}$ and the eigenvector corresponding to the smallest eigenvalue as the second vector $\overrightarrow{V_2}$. The eigenvalues and eigenvectors of the Jacobi matrix represent the distribution direction of the points, and the main feature that distinguishes an annular hole from an island hole is the approximation of the distribution pattern of the points between two boundaries. Therefore, the characteristic distance between two boundaries of the annular hole is defined as

$$Dis_{ab} = \overrightarrow{V_{a1}} \times \overrightarrow{V_{b1}} + \overrightarrow{V_{a2}} \times \overrightarrow{V_{b2}}. \tag{4}$$

In this equation, a and b represent the two boundaries of an annular hole. Dis_{ab} is the characteristic distance between boundaries a and b. $\overrightarrow{V_{a1}}$ and $\overrightarrow{V_{b1}}$ are the first vectors of boundaries a and b. $\overrightarrow{V_{a2}}$ and $\overrightarrow{V_{b2}}$ are the second vectors of boundaries a and b. Then, we screen a large number of annular holes and island holes and calculate their characteristic distances. An empirical value of the characteristic distance is found to distinguish an annular hole from an island hole. When $Dis_{ab} < 0.15$, an annular hole is formed between the two boundaries. At this point, the corresponding repair method can be used to achieve optimal results. Accordingly, an intelligent identification process for annular holes is planned as in Figure 4.

Step 1. Model preprocessing. Segment all the complex holes to single holes without common points.

Step 2. Calculate all the closed hole boundaries, and exclude crack holes and dislocation holes. The method in Steps 1 and 2 has been researched in another thesis [33].

Step 3. Judge whether the number of closed boundaries is less than 2. If yes, this indicates that there is no annular hole, and it ends; if no, proceed to next step.

Step 4. Calculate the nearest boundary of each boundary. It is measured by the distance between the nearest points between two boundaries.

Step 5. Judge whether they are mutually nearest boundaries, and the boundary feature distance is less than 0.15. Mutual nearest boundary means that the nearest boundary of boundary a is b, and the nearest boundary of boundary b is a. At the same time, in order to eliminate the case that two simple holes are adjacent (as shown in Figure 5), it is also necessary to meet the following conditions: on the fitting plane of the boundary, the gravity center of boundary a is within b, and the gravity center of boundary b is within a. If the above conditions are met, it is an annular hole. Otherwise, there is no annular hole.

Step 6. End.

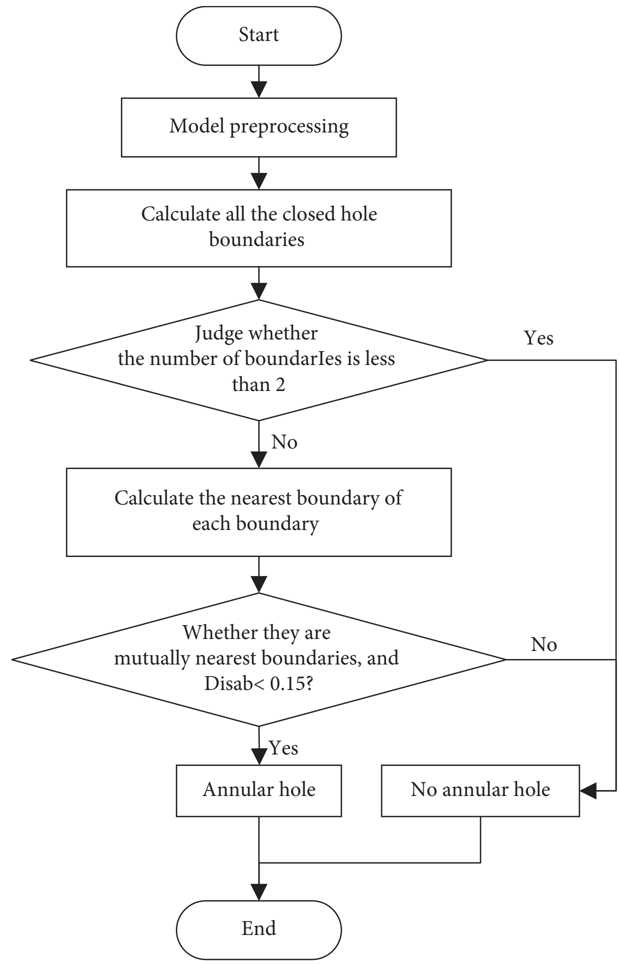


Figure 4: Intelligent identification process for annular holes.

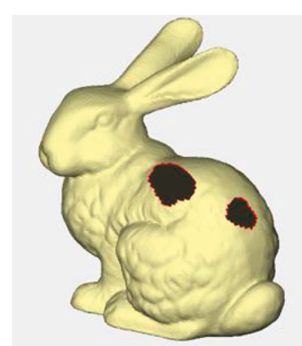

Figure 5: Example of adjacent simple holes.

4. Repair Method for Annular Holes

Traditional hole-filling methods generally require a process of surface fitting, surface cutting, and surface stitching. The annular hole has two boundaries and two sets of corresponding cutting and stitching boundaries, with narrow or flat hole lines and massive boundary points. Using traditional hole-filling methods, it always has low repair efficiency and a high failure rate. Besides, various consumer products lead to a variety of annular holes, and the systematicness and robustness of the above method are also insufficient. Therefore, we propose a method that stitches and fills the holes, optimizes the triangulation, constructs implicit surface, and finally carries out surface integral deformation. The method can solve the repair issue of diversified annular holes and extend the application range in consumer products.

4.1. Hole Boundary Stitching and Filling. First of all, an initial stitching surface patch is constructed as the basis for surface fitting. In this paper, the method of connecting the nearest points is used to stitch annular holes, as shown in Figure 6. The specific steps are described as follows.

Step 1. Reorient hole lines. As the two types of annular holes have different hole line directions, the two hole lines of an annular hole need to be adjusted to the same direction. The same direction refers to the fact that, on the best-fit plane of the two hole lines, the polygons formed by the projection of the hole lines are all clockwise or counterclockwise. Herein, the counterclockwise direction is taken as positive.

Step 2. Connect initial triangles. Start from the starting point P_0 of the hole line L_0 with fewer points, calculate the nearest point Q_0 of P_0 on the other hole line L_1, and connect P_0 and Q_0. Find the next point Q_1 of L_1 and its nearest point Q_2 on L_1, and connect P_1 and Q_2. Triangulate the area composed of P_0-P_1-Q_2-Q_0 to obtain triangles $P_0Q_1Q_0$, $P_0P_1Q_1$, and $P_1Q_2Q_1$.

Step 3. Connect the remaining triangles. Repeat the above steps for the points on L_0 until all boundary points on L_0 are calculated.

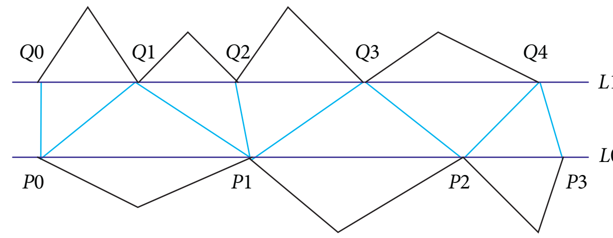

FIGURE 6: Stitch annular hole boundaries.

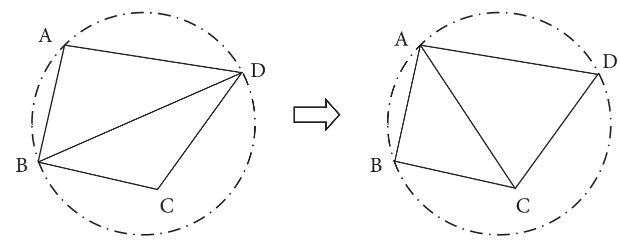

FIGURE 7: Illustration of the edge-swap method.

4.2. Triangulation Optimization. Before the surface is fitted, the stitched triangle patches need to be refined, so that it can be smoothly connected to the original model. The specific optimization principle and method are as follows: (1) for a triangular patch with an area larger than the specified area, divide the patch into three triangular patches by taking a point at the center of the triangle and connecting that point to its three vertices. (2) If two triangles are connected by an edge, and one triangle is inside the circumscribed circle of the other triangle, the edge is called a long and narrow edge. The edge-swap method should be used for optimization. Edge-swap is achieved by swapping the diagonals of the convex quadrilateral formed by two adjacent triangles, so that the narrow triangle converges to a positive triangle, as shown in Figure 7.

4.3. Implicit Surface Construction. The initial repair surface has been created by stitch and refined triangulation of the two hole lines of the annular hole, but it is not yet smoothly integrated with the whole surface. For that, the RBF is used to establish an implicit surface equation for annular holes, to ensure as much continuity and smoothness as possible between the repaired surface and the original surface.

Firstly, to ensure a smooth and continuous joint between the hole boundary and its surrounding original triangular surface, we use the vertex of the two boundaries of an annular hole and the multiplet neighboring points of its neighboring triangular patches (typically 3–5 multiplet neighboring points, depending on the size of the hole) to build a collection $V = \{P_i, i = 1, 2, \ldots, n\}$ (n is the number of hole boundary vertices and neighboring points) of interpolation constraint points. The interpolation constraint points on the surface satisfy

$$f(P_i) = 0, \quad i = 1, 2, \ldots, n. \tag{5}$$

In order to avoid useless solutions of $f \equiv 0$, while keeping the positions of the boundary points of stitched patches unchanged, we calculate the normal information of the refined mesh model boundaries and add additional constraint points in the normal direction. They are located in the inner or outer directions of the surface. The additional constraint points should satisfy

$$f(P_i + h_i N_i) = h_i, \tag{6}$$

where N_i is the normal vector of the surface located at the vertex P_i, and h_i is a normal constraint value with a small positive value. It can be assumed that all additional constraint points are located at the same distance from the surface, and they are on an equivalent surface to the hole surface. The value of the constraint does not affect the solution of the implicit equation for the hole surface, so the implicit equation for the hole surface can be taken to have a value of $h_i = 1$ at all additional constraint points.

From this, we combine all interpolated constraint points and additional constraint points to create a set of constraint points $V = \{P_i, i = 1, 2, \ldots, N\}$ (N is the number of all the hole constraint points) and form the following constraint:

$$f(P_i) = h_i, \quad i = 1, 2, \ldots, N. \tag{7}$$

From the constraint points, we can define the implicit surface equation $f(\mathbf{r}) = 0$. The energy function [22, 34] for a thin plate with its second-order differentiable function is

$$E=\int_{R^3}\left(\frac{\partial^2 f}{\partial x^2}+\frac{\partial^2 f}{\partial y^2}+\frac{\partial^2 f}{\partial z^2}+2\frac{\partial^2 f}{\partial x\partial y}+2\frac{\partial^2 f}{\partial x\partial z}+2\frac{\partial^2 f}{\partial y\partial z}\right)\mathrm{d}x\mathrm{d}y\mathrm{d}z. \tag{8}$$

This energy function reflects the smoothness of the function f in three dimensions, and it has lower energy values in regions of the surface where there are no sharp changes in curvature such as folds. The interpolation function is solved under the interpolation constraint of $f(P_i)=h_i$ such that the value of the energy function is minimized. At this point, the form of the interpolation function f is obtained as the RBF form [13]:

$$f(\mathbf{r})=\sum_{j=1}^{N} w_j\phi\left(\mathbf{r}-P_j\right)+Q(\mathbf{r}). \tag{9}$$

In this equation, $\mathbf{r}$ denotes any point on the generated surface, $\mathbf{r}=(x,y,z)$; P_j denotes the points defining the equation, $P_j=(P_j^x,P_j^y,P_j^z)$; w_j denotes the real weight corresponding to each constraint point; $Q(r)$ is a first order polynomial. For any point $\boldsymbol{r}$, the form of $Q(r)$ is $Q(r)=q_0+q_1x+q_2y+q_3z$, where q_0, q_1, q_2 and q_3 are real coefficients of the polynomial. $\phi(r-P_j)$ is the RBF. In three-dimensional space, as functions with three variables need to be fitted, the more effective form of RBF is a triharmonic spline function $\phi(\mathbf{r})=\mathbf{r}^3$.

In order to solve for the weights and polynomial coefficients, each constraint point must satisfy both the interpolation constraint and the orthogonality conditions.

$$\begin{gathered}f(P_i)=\sum_{j=1}^{N} w_j\phi\left(P_i-P_j\right)+Q(P_i),\\ \sum_{j=1}^{N} w_j=\sum_{j=1}^{N} w_jP_j^x=\sum_{j=1}^{N} w_jP_j^y=\sum_{j=1}^{N} w_jP_j^z=0.\end{gathered} \tag{10}$$

Let $\phi_{ij}=\phi(P_i-P_j)$. From the above conditions, we obtain the following set of linear equations:

$$\begin{bmatrix}\phi_{11} & \phi_{12} & \cdots & \phi_{1n} & 1 & p_1^x & p_1^y & p_1^z\\ \phi_{21} & \phi_{22} & \cdots & \phi_{2n} & 1 & p_2^x & p_2^y & p_2^z\\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \vdots\\ \phi_{N1} & \phi_{N2} & \cdots & \phi_{NN} & 1 & p_N^x & p_N^y & p_N^z\\ 1 & 1 & \cdots & 1 & 0 & 0 & \cdots & 0\\ p_1^x & p_2^x & \cdots & p_N^x & 0 & 0 & \cdots & 0\\ p_1^y & p_2^y & \cdots & p_N^y & 0 & 0 & \cdots & 0\\ p_1^z & p_2^z & \cdots & p_N^z & 0 & 0 & \cdots & 0\end{bmatrix}\begin{bmatrix}w_1\\ w_2\\ \vdots\\ w_N\\ q_0\\ q_1\\ q_2\\ q_3\end{bmatrix}=\begin{bmatrix}h_1\\ h_2\\ \vdots\\ h_N\\ 0\\ 0\\ 0\\ 0\end{bmatrix}. \tag{11}$$

For the annular hole repair surface, as the constraint points taken are data points around the hole boundary, the solution time is shorter with the Gauss elimination method, and a unique set of solutions $(w_1,w_2,\ldots w_N,q_0,q_1,q_2,q_3)$ can be obtained directly. Bring the obtained results into the interpolation function $f(\mathbf{r})$, and the implicit surface equation for the hole established by the RBF can be given as

$$f(x,y,z)=\sum_{j=1}^{n} w_j\left(\sqrt{\left(x-P_j^x\right)^2+\left(y-P_j^y\right)^2+\left(z-P_j^z\right)^2}\right)^3+q_0+q_1x+q_2y+q_3z=0. \tag{12}$$

4.4. Surface Integral Deformation. Once the implicit equation for the annular hole surface has been established, the vertices of triangular patches from the triangulation optimization in 4.2 need to be adjusted to the fitted implicit surface, that is, integral deformation of the surface. In this paper, the classical gradient descent method is used to adjust the vertices of triangular patches after triangulation, where all the repaired vertices of triangular patches are gradually approximated towards the implicit surface along the gradient direction of the implicit equation $f(x,y,z)$, until they are adjusted to the fitted hole implicit surface within the allowed error range.

Gradient descent is an iterative optimization-seeking algorithm for some criterion function. Let $f(r)$ be some criterion function and $\boldsymbol{r}$ a vector, and then the negative gradient direction of $\boldsymbol{r}$ is the direction, where $f(r)$ decreases fastest, along which the approximation point can be reached fastest [35]. The gradient of the implicit function $f(x,y,z)$ is denoted as $\nabla f=(\partial f/\partial x,\partial f/\partial y,\partial f/\partial z)$ [22]. From the implicit surface equation for holes, we get

$$\begin{aligned}\frac{\partial f}{\partial x}&=3\sum_{j=1}^{N} w_j\left(x-P_j^x\right)\sqrt{\left(x-P_j^x\right)^2+\left(y-P_j^y\right)^2+\left(z-P_j^z\right)^2}+q_1,\\ \frac{\partial f}{\partial y}&=3\sum_{j=1}^{N} w_j\left(y-P_j^y\right)\sqrt{\left(x-P_j^x\right)^2+\left(y-P_j^y\right)^2+\left(z-P_j^z\right)^2}+q_2,\\ \frac{\partial f}{\partial z}&=3\sum_{j=1}^{N} w_j\left(z-P_j^z\right)\sqrt{\left(x-P_j^x\right)^2+\left(y-P_j^y\right)^2+\left(z-P_j^z\right)^2}+q_3.\end{aligned} \tag{13}$$

Depending on the vertex of each triangulated patch, the new position to which it is adjusted needs to be calculated. Considering the iteration efficiency and the optimization effect, we chose the following equation as the iteration formula:

$$r_{k+1}=r_k-\frac{f(r_k)}{\left\|\nabla f(r_k)^2\right\|}\nabla f(r_k), \tag{14}$$

where k denotes the number of iterations. Calculate the difference $r_{k+1}-r_k$ between the new position of the vertex and the position before stretching. If $r_{k+1}-r_k\le\varepsilon$ (ε is a given limited error), it can be considered that the new position of the vertex r_{k+1} is on the hole surface and the iteration ends. Otherwise, r_{k+1} replaces r_k and the iteration continues.

The implicit surface equation of the hole describes the surface formed by the hole boundaries and their multiplet neighboring triangular patches, so the vertices of the

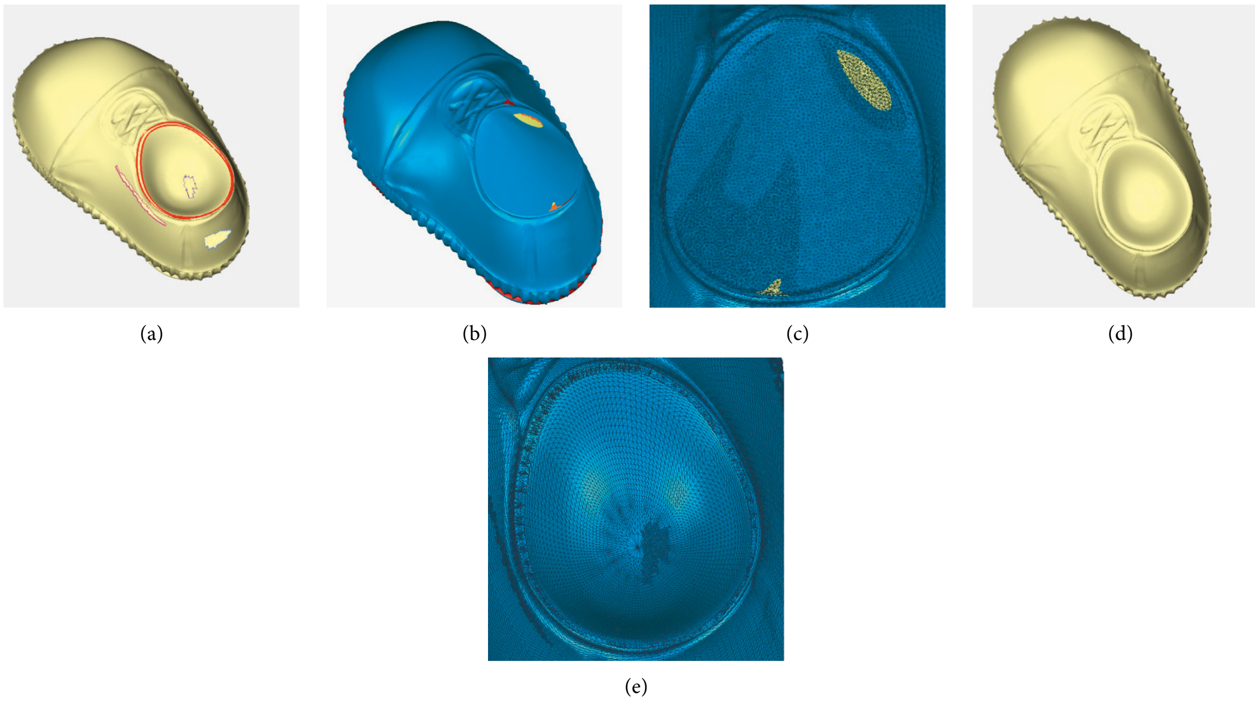

Figure 8: Comparison of repair effect of shoe model. (a) Original annular hole model. (b) Repair result of Geomagic. (c) Repair details of Geomagic. (d) Repair results of the proposed method in this paper. (e) Repair details of the proposed method in this paper.

adjusted triangles are located on the same surface as the vertices of the triangular patches around the hole boundary. It is ensured that the repaired hole surface is well stitched to the original triangular mesh surface and maintains a consistent surface form and continuity.

5. Experimental Results and Discussion

As few scholars have researched automatic identification and repair methods for annular holes, it is difficult to find a targeted algorithm for comparison. For this reason, this paper selects and compares the repair results with the well-known commercial software Geomagic and a traditional hole repair method to determine the identification and repair effect of the research method. All the developed algorithms were implemented in C++ by using Visual Studio 2013 and tested on a PC equipped with an Intel®Core i7-4790 processor and 8 GB of RAM on Windows 10. In the comparison process, three types of consumer-oriented models are selected, such as shoe, bone, and tooth, because these models are prone to the presence of annular holes.

Figure 8 compares the repair effect of shoe model between Geomagic and the proposed method. Figure 8(a) shows that an annular hole exists at the folding location of the shoe mouth, and the annular hole lines are indicated by red lines. When using Geomagic to repair, the two hole lines of the shoe model are repaired, respectively, resulting in the closure of the shoe mouth, and the repaired surface differs greatly from that of the original model, shown in Figures 8(b) and 8(c). With the proposed method, the annular hole of the shoe model is accurately identified and repaired between the hole boundaries, as shown in Figure 8(d). The repair details are displayed in Figure 8(e). It can be seen that triangular meshes are evenly divided, and the surface fitted between the two separated surfaces is smooth.

Figure 9 shows the comparison of repair effect of bone model. An annular hole exists at the fracture location of the bone, as shown in Figure 9(a), and the annular hole lines are also indicated by red lines. Geomagic repairs the broken holes, respectively, resulting in the formation of two independent parts, as Figures 9(b) and 9(c) depict. With the proposed method, the annular hole of the bone model is accurately identified and repaired, leading to regular triangular meshes and smooth surfaces, as shown in Figures 9(d) and 9(e).

When repairing the annular hole on the tooth surface, the result is similar to the shoe and bone models, as shown in Figure 10. Through the above cases, we can draw the following conclusions. Geomagic cannot automatically identify annular holes. Without human intervention, the software fills the inside of two closed hole boundaries, leading to discrepancies between the restoration and the actual requirements, and even to the separation of the model. Geomagic destroys the original structure of the model. With the proposed method, annular holes in the model are all accurately identified and repaired between the hole boundaries. As can be observed through the detailed graphs, the structures of the repaired model match the original models, and the triangular mesh density, the continuity with the edge meshes, and the smoothness are all ideal.

After repairing by the proposed method and Geomagic, the three repaired models were checked by a grid doctor. In terms of the six types of repair defects including nonmanifold

edges, self-intersections, highly-creased edges, spikes, small components, and small holes, Geomagic is found to have more defects like spikes, highly creased edges, and self-intersections, while the model repaired by the proposed method has fewer defects and higher repair quality. The repair time of our method is equivalent to Geomagic, so the repair efficiency is acceptable. Specific comparison information is shown in Table 1.

Table 1: Comparison of repair results after inspection.

Objects	Methods	Nonmanifold edges	Self-intersections	Highly creased edges	Spikes	Small components	Small holes	Repair time (s)

(a) (b)

Figure 11: Repair result of bone model with the method proposed by Centin. (a) The overall repair result of bone model with the method proposed by Centin. (b) Repair details of bone model with the method proposed by Centin.

The existing repair methods, when applied to the repair of annular holes, mostly require manual involvement. Taking the algorithms proposed by Centin [32] as an example, the user input for their method must be a set of boundary curves without defects, and holes or gaps, which are not selected should not be filled. So, the repair quality is seriously affected by the input boundaries. For the bone model, we selected boundaries with slight defects to repair. An obvious dent defect appeared, as shown in Figure 11(a). With their restricted Delaunay triangulation and tailoring routine, there is a high quality mesh in the repair area, as shown in Figure 11(b). But the repair time was significantly increased to 1.278 s without considering time spent on the manual selection of boundary lines, and our time was 0.062 s with the automatic identification of boundary lines. Therefore, our method has the advantage of high repair efficiency.

In summary, as repair algorithms or software like Geomagic cannot independently identify and process annular holes, manual repair method is needed. The use of manual repair requires the selection of two closed hole boundary curves, complex manual bridging, and splitting of annular holes into ordinary holes. The result and quality are affected by the skills of technicians, and the efficiency is drastically reduced, which also makes the operation difficult for average consumer users. Therefore, the above comparison shows that the proposed method can automatically determine whether two closed hole boundary lines form an annular hole by their shape and distance relationships and provide intelligent repair methods of stitching and filling, triangulation optimization, and surface integral deformation. The method can meet the repair needs of various types of consumer-oriented models, reduce the operational difficulties of nonspecialist technicians, and improve repair efficiency.

6. Conclusion

In the field of consumer goods such as handicrafts and bionic products, narrow features, surface bulges, and folds can easily lead to annular holes in the triangular mesh model during the process of construction, scanning, and acquisition. However, the traditional repair method for common holes is unsuitable for annular holes, which would cause defects such as self-intersecting patches, or even alteration of the original structure of the model.

To this end, we propose an intelligent identification and repair algorithm for annular holes. From the structural characteristics of the annular hole, we give the definition and the automatic identification method for annular holes through analysis of the shape and position relationships between the two closed hole lines. Referring to the traditional implicit surface repair method of single hole, we propose a new improved method. In order to optimize the systematicness and robustness of the repair method, we first stitch and fill the two annular hole lines, then optimize triangulation, construct a variational implicit surface based on RBF, and finally deform the surface integrally based on gradient descent. The proposed method achieves a smooth joint of the repaired hole surface with the original triangular mesh surface, and the repaired surface is smooth and accurate. Finally, we verify the feasibility of the method by examples, proving that it can replace the manual repair methods and significantly improve the repair quality and efficiency.

There are two important improvements in our method. Firstly, it retains all the facet information in the annular hole and stitches the facet between two closed hole lines, instead of filling a single hole boundary in sequence or using the artificial bridging repair method of technicians. The repair quality is also ensured. Secondly, the routine of stitching and filling, triangulation optimization, and surface integral deformation has higher repair efficiency. Especially for parallel annular holes, it avoids possible stitching errors caused by the inconsistent normal vectors of holes. But the errors always appear in other repair methods or software.

In the repair process, the implicit surface repair method based on RBF can obtain smoother repair surfaces, but it also smooths out sharp features. In the future, we will provide corresponding repair methods for more special features. The narrow features, surface bulges, hollow-carved structures, or folds occurring in consumer products will be identified and repaired more accurately. When the method is applied to the repair of 3D printed models in the consumer goods field, it will not require the participation of technicians. The easy operation characteristics of the method will attract the attention and attempt of a large number of consumers. It will promote the widespread use of 3D printing technology.
