Retracted: Design of Teaching Quality Analysis and Management System for PE Courses Based on Data-Mining Algorithm

Computational Intelligence and Neuroscience

Received 26 September 2023; Accepted 26 September 2023; Published 27 September 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Retracted: MOOC and Flipped Classroom Task-Based English Teaching Model for Colleges and Universities Using Data Mining and Few-Shot Learning Technology

Computational Intelligence and Neuroscience

Received 26 September 2023; Accepted 26 September 2023; Published 27 September 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Cardiac health diseases are one of the key causes of death around the globe. The number of heart patients has considerably increased during the pandemic. Therefore, it is crucial to assess and analyze the medical and cardiac images. Deep learning architectures, specifically convolutional neural networks have profoundly become the primary choice for the assessment of cardiac medical images. The left ventricle is a vital part of the cardiovascular system where the boundary and size perform a significant role in the evaluation of cardiac function. Due to automatic segmentation and good promising results, the left ventricle segmentation using deep learning has attracted a lot of attention. This article presents a critical review of deep learning methods used for the left ventricle segmentation from frequently used imaging modalities including magnetic resonance images, ultrasound, and computer tomography. This study also demonstrates the details of the network architecture, software, and hardware used for training along with publicly available cardiac image datasets and self-prepared dataset details incorporated. The summary of the evaluation matrices with results used by different researchers is also presented in this study. Finally, all this information is summarized and comprehended in order to assist the readers to understand the motivation and methodology of various deep learning models, as well as exploring potential solutions to future challenges in LV segmentation.

1. Introduction

The capability of a machine to simulate and impersonate human intelligence processes is referred to as artificial intelligence. Machine learning is a subbranch of artificial intelligence which is based on the idea to enable machines or computers to perform without being specifically programmed. The machine can learn from data and focus on the use of the pattern and experience to improve the performance of the computer in making decisions on its own. In this way, the machine becomes capable of developing analytical models to adopt new situations autonomously.

Deep learning (DL) is a subfield of machine learning associated with a process inspired by the formation and function of the brain called an artificial neural network (ANN). DL is concerned with the interpretation of data based on the mechanism of the human brain by developing and simulating the algorithm worked on human brain analysis and learning. The training data are fed into the algorithm as input, and the successive layers of the DL algorithm analyse the original data to extract the features required for the targeted task. The training data is fed into the algorithm as input, and the successive layers of the DL algorithm analyse the original data to extract the features required for the targeted task. The entire process is free of human manipulation. One of the earliest practiced DL techniques is ANN with a deep network structure [1]. The multilayer perceptron models [2] have been proposed with the rapid progress in the research areas of computer vision (CV) and human brain neurons. This yields the development of other classical models such as back-propagation neural network models, convolutional neural network (CNN) models [3], bidirectional recurrent neural networks [4], transformers [5], long short-term memory (LSTM) [6], and deep belief network [7] models.

These research findings have significantly helped the expansion of DL architectures, flooring the way for its substantial level applications in numerous areas, especially in image processing. Image classification, image registration, object detection, and image segmentation were among the main tasks performed by the DL algorithms very efficiently.

These image processing methods were applied in various fields such as surveillance [8, 9], intelligent transportation system [10, 11], wireless communication [12, 13], web mining [14, 15], robotics [16, 17], civil [18], and the most important in medical image processing [19]. In medical, DL is used for the segmentation of various structures from the medical images [20], detection of different diseases [21–23], and also for image registration to have a better view of images [24].

The cardiac images are one of the medical images used for the assessment of patient health. Different cardiac images are used for the analysis of cardiac function. Assessment of cardiac function performs an essential part in medical cardiology for patient supervision, risk estimation, disease analysis, and therapy evaluation [25, 26]. For cardiac diagnosis, digital images are the basic tool used for the computation of subsequent clinical indices from the shape and structure of the heart. From the structure of the heart, the assessment of the left ventricle (LV), right ventricle (RV), and myocardium (MYO) are the main assessments. LV is one of the central issues and the attention of cardiac function study and disease diagnosis. Delineation of LV boundary is of great clinical importance for the study of heart parameters such as the ejection fraction (EF), stroke volume (SV), LV mass (LVM), end-systolic volume (ESV), and end-diastolic volume (EDV) [27].

Some studies have reviewed the segmentation of medical and cardiac images. However, to the best of the author's knowledge, those investigations did not investigate LV segmentation solely and explicitly. Keeping in mind the importance of LV, the primary focus of this research is to review only the segmentation of LV using DL models. This paper provides a comprehensive overview of different DL architectures used for the LV segmentation. This review has been carefully summarized to present the state-of-the-art DL algorithms focusing on the LV segmentation task. To find out the quality research in the area, the Web of Science database was used as a search engine. The keywords, "left ventricle", "segmentation, and "deep learning" were used to find out the related papers. The articles which primarily do not emphasize LV segmentation were excluded because the scope of this review included an analysis of LV based segmentation. The review has been conducted using resources published between 2018 and onwards until December 2021.

In this article first, we discussed the three different imaging modalities used for the LV assessment in Section 2. Section 3 presents the basics concepts related to DL and CNN. Different DL architectures used for the LV segmentation are reviewed in Section 4. The section is subdivided based on the different approaches used with DL such as preprocessing, deformable models, and clinical indices calculation. The discussion about the architecture, hardware, software, and datasets used for training, and evaluation matrices used to analyze the performance of models is presented in Section 5. The complete structure of the article is depicted in Figure 1.

2. Medical Images for LV Assessment

Different medical imaging modalities were used for the assessment of LV. These modalities include magnetic resonance images (MRI), echocardiography, computer tomography (CT) scan, myocardial perfusion imaging, multiple gated acquisition scanning, gated blood-pool SPECT, and fusion imaging. However, the most used imaging modalities in literature for LV segmentation are MRI, US, and CT scans. The detail of these images is presented in this section.

2.1. Magnetic Resonance Images. MR imaging is a widely used technique in the cardiac armamentarium. The official name is recognized as "cardiovascular magnetic resonance (CMR)," when the MRI is employed on the heart or cardiovascular system. Its diagnostic precision has preceded it to become the gold-standard for heart analysis [28].

MRI is suitable for the evaluation of heart chambers [29, 30], size, and blood flow through major vessels [31], heart valves [32], and pericardium [33]. In addition, for LV size and mass measurement, the MRI is considered a reference standard [34, 35]. Its adaptability is incomparable to other different imaging methods. It provides not only precise anatomic information but also gives functional information that helps in finding patients at risk. Three-dimensional geometric analysis of the LV by CMR provided more appropriate information about the shape of the LV than the traditional echocardiography with high fertility and low variability [36]. CMR has also been successful in observing LV hypertrophy in patients with apparently normal echocardiographic results [37].

Besides these outstanding outcomes, a few important limitations of CMR need to be remembered. It faces problems with costs, limited availability, and lack of portability. These constraints prevent the use of CMR normally. Compared with other imaging modalities, CMR inspections

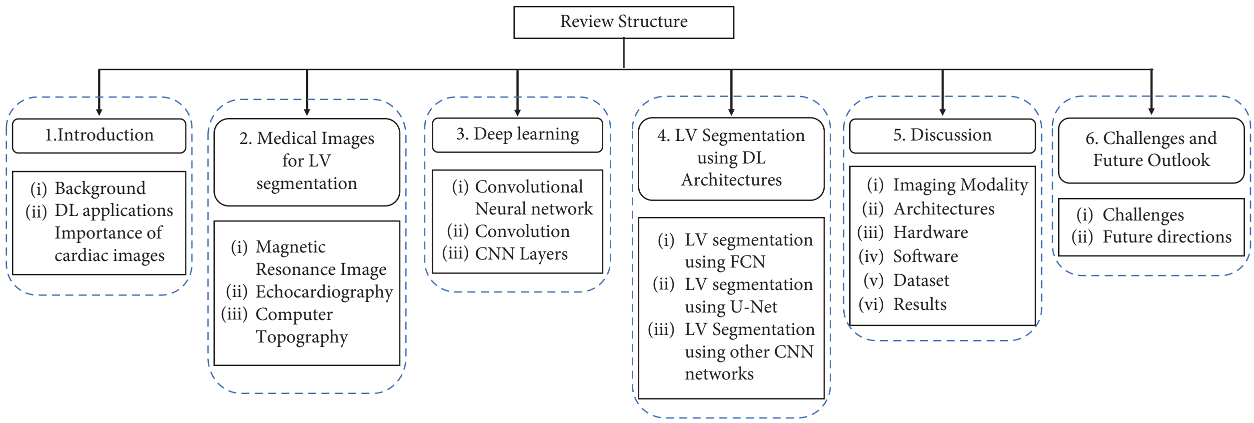

Figure 1: Article structure diagram.

are very costly and inadvisable for patients with metallic implants such as graft stents and cardiac pacemaker devices. Cardiac MRI may not be accessible immediately in all centers, and it can be a difficult instrument to work out in patients who require serial monitoring. Another condemnation of CMR is the period of examination to acquire LVM data. It also has some minor issues such as device incompatibilities and patient tolerance. Figure 2 shows LV segmentation in MRI images. The red area is LV segmented using a CNN. [38].

2.2. Echocardiography. Echocardiography used high-frequency ultrasound waves to produce anatomical images of the heart. That is why it is referred to as ultrasound (US) imaging. It is the largely used imaging modality for the examination of cardiovascular diseases [39]. Due to its easy accessibility, outstanding temporal resolution, real-time imaging, and noninvasive nature, the US is considered the basic imaging for measuring the LV function. US has become the primary preference for the analysis of LVM. A regular LVM calculation is an essential part of the US examination [40]. US imaging is also used in measuring the decrease in LVM after the treatment [41].

The most used US imaging is two-dimensional US (2DE) and three-dimensional US (3DE). An example of 2DE is shown in Figure 3 and the LV boundary is shown by the red line. Although M-mode US imaging is also in use, due to different limiting factors of M-mode such as it only identifies the function of the basal segment while 2D and 3D can perform the whole LV segmentation, the use of M-mode is very limited. Using the 2DE, LVM can directly be calculated. Similarly, by attaining the pyramidal image, we can look at the 3-dimensional image of the whole heart. The 3D imagining of heart anatomy can be obtained using 3DE and it has also overcome the limitation of 2D imagining. Therefore, 3DE has gained considerable importance over 2DE and M-mode in various patient populations [42]. Inadequately, 3DE is not commonly available and costly compared to 2D imagining. The other limitation of the US imaging is the speckle noise [43] and low contrast ratio [44], which limits its performance.

2.3. Computer Topography. A computed tomography (CT) scan of the heart provides a cross section of the structure of the heart. It characterizes the X-ray attenuation features of tissues being imaged [45, 46]. CT is a growing imaging method for the noninvasive computation of heart anatomy and function. LV size and mass estimation can be computed using the CT modality. CT is also found as a good alternative for the LV size and mass calculation for those patients who have contraindications to CMR [42]. The study in [47] compares CT and US and also finds that CT can be used as an alternative to the US.

Though CT has many advantages, a few constraints are not ignorable. CT cannot be employed as real-time intraprocedural assistance due to unavoidable ionization radiation exposure called a stochastic effect [48]. Repetitive regular use can raise the cancer risk. The increase in image quality results in a higher dose of radiation. The left part of Figure 4 is a CT scan of the heart and in the right part, the LV is highlighted. [49].

3. Deep Learning

DL can be defined as a machine learning algorithm that deals with neural networks. Neural networks with a deep structure or with more than 2 hidden layers are also referred as deep neural networks. A general architecture of DL is shown in Figure 4. DL is a representation learning (subtype of machine learning) with multiple levels of representation [50]. For the past several years, DL has been developed as a popular tool that attracts the attention of researchers from several fields. It helps to overcome the weaknesses of traditional methods and solve complex problems to achieve better results. The popularity of DL is doable due to large datasets, computational performance, training techniques (ReLu), and advanced networks (CNN). With the increase in databases, DL has exponentially achieved success both in commercial and academia. Not only the software base advancement help DL to achieve success, the latest hardware such as graphical processing units (GPU's) improved the ability of DL [51]. Deeper layers improve the system's experience by learning the features from data and making complex structures deeper and simple [52]. Therefore, it is a

novel discovery for solving problems in those areas which has high dimensional data. Inspired by brain function, deep neural networks are built from many hidden layers sandwiched between the input and output layers. The general architecture of a deep neural network is presented in Figure 5.

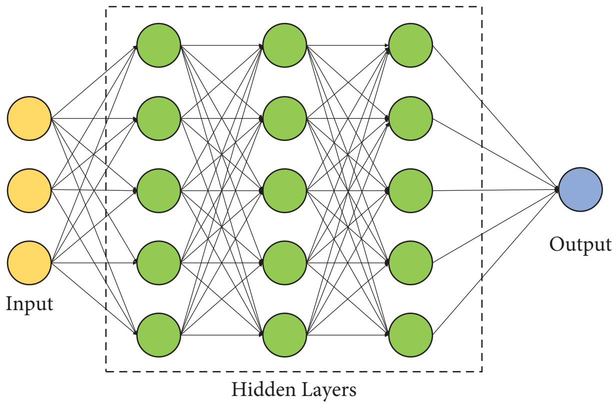

FIGURE 5: A general architecture of a deep neural network with three hidden layers.

3.1. Convolutional Neural Network. DL architectures are performing excellently in solving traditional artificial intelligence problems. The most established, progressive, and widely used is CNN. The following section discusses CNN, its variants, and its applications.

Among all the models of neural networks, CNN is the most dominant approach to solving problems of CV. The idea of CNN architecture was developed in the 1980s [53] but due to the lack of computational ability of hardware, high processing machines, and large storage devices to deal with big images, the idea did not flourish. The concept accelerated as the processing of machines increased in terms of computation and database to retrieve and store. Later in [54], CNNs were successfully applied in classification problems and performed brilliantly in CV applications. The gradient-based learning algorithm highly motivated CNN to produce optimized weights. CNN performed far better than other multi-layered perceptrons. The CNN weights are shared and are not needed to learn again for the same object at different locations. It recognizes visual patterns, directly from raw image pixels. This decreases the number of learnable parameters. CNN performance is impressive on 2D and 3D images. CNN model has minimized the preprocessing task and the back-propagation learning method improved the performance as it has provided a solution to deal with nonlinearity with the decrease in computation process due to a smaller number of weights. CNN has been producing better results in object recognition, behavior recognition, audio recognition, detection, recommendations localization, classification, and segmentation tasks.

3.1.1. Convolution. Convolution is a mathematical operation that involves the multiplication and addition (weighted average) of two functions. The first function (x) represents input data and the second function (w) represents kernel and together they produce the output, called feature maps. CNN is similar to neural networks that use weights and biases. It involves a convolutional layer in the neural network that applies to input data of an acceptable type. The CNN architecture is divided into two divisions: feature extractors and classifiers. Each convolution layer finds specific features from the input data using a shared weight called kernels, and with n number of kernels, the convolution layer determines n features. The input of each layer is the result of the previous layer. A simple CNN consists of a convolutional layer, pooling layer, rectifier unit, fully connected layer, and classifier. The convolutional layer is a building block of CNN. The input image convolves with the kernel (learnable filter). The kernel slides over the input image and the size of the kernel are somehow learned from the input image. Some parameters drive the size of output i.e., depth, stride, and padding. The CNN compresses the fully convolutional network by lessening the connections and sharing the weight of the edge.

Figure 6 shows a general CNN structure; the input image is convolved with kernels to extract the features. The result of convolution is then passed through the pooling layer (mostly Max pooling). The CNN extracts the features using these layers and finally a fully connected layer [55] gives the predicted output.

Convolution performs 3 main tasks: sparse interaction, parameter sharing, and equivariant representation.

(i) Sparse interaction: In a neural network, every output unit interacts with every input having separate parameters. These parameters help to determine the relationship or interaction between the input and output units. CNN uses kernels of different sizes which are smaller than input data in size. This reduces the number of learning parameters and the storage space and increases computation efficiency.

(ii) Parameter sharing: It uses the same parameter for more than one chunk. In convolution, each kernel value is used at every point of input other than boundary values. It helps CNN to use only one set instead of multiple parameters for every location. It reduces the storage requirement further.

(iii) Equivariance: It refers to the shift in the feature map by the same amount as the input shifts. Convolution does the same but not naturally [50].

3.1.2. CNN Layers. For the past few decades, CNN is performing intensely in CV (detection, recognition, tracking, estimation, processing, analysis, learning, restoration, and reconstruction) as the popular machine learning algorithm. The GPUs have also brought extra efficiency in their results. The boost CNN gain is through several factors such as a large labeled training dataset, rectifier linear unit, regularization (dropout), and augmentation. The strength of CNN is extracting discriminative features at different levels. The CNN architecture consists of a convolutional layer, a nonlinearity layer, and a polling layer followed by a fully connected layer.

(i) Input layer: This layer understands the input data. It gives the contents of input data and has no learnable parameters. So, this layer has nothing to do with learning.

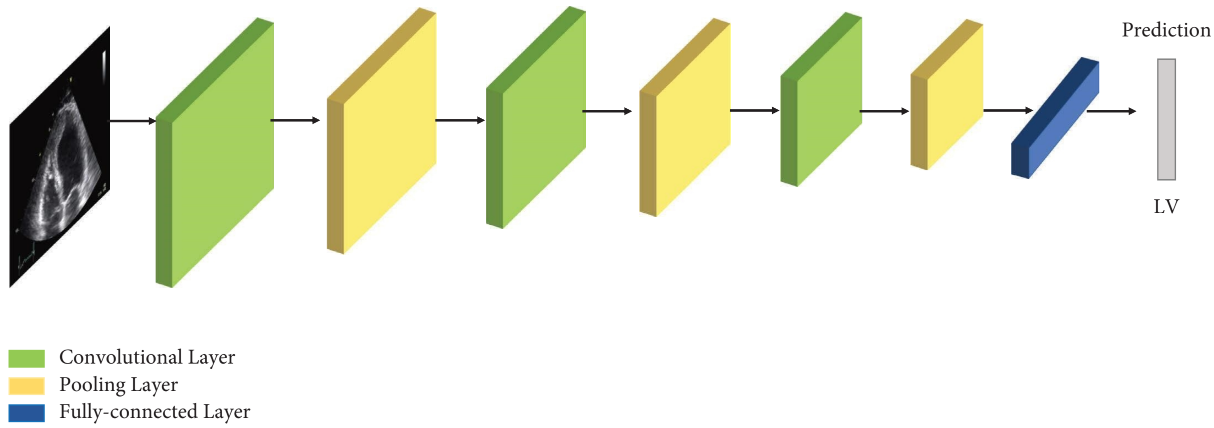

Figure 6: General structure of deep convolutional neural network.

(ii) Convolutional layer: Convolutional layer performs convolution operation which is the trademark of CNN architecture. This layer holds learnable parameters such as weights and biases. This layer contains filters or kernels, used to detect edges, shapes, and patterns of the given input image. Kernels are convolved with each input feature/image pixel to produce feature maps as an output. A dot product between each input and filter is performed, followed by summing each dot product output, and finally, a bias is added. Bias can be configured according to network requirements. The convolutional layer reduces the computational cost by reducing the input size:

$$Z_i^l = \sum_{J=1}^{K^{l-1}} W_{i,j}^l * Z_j^{l-1} + B^l. \quad (1)$$

The kernel computes the product of weight and input of kernel size. It also determines the desired features based on kernel weights. Equation (1) shows the operation of the convolutional layer, where Z_i^l and Z_i^{l-1} are the outputs of the current layer and previous layer, respectively, and $W_{i,j}^l$ and B^l represent filters and biases. Each neuron need not be connected to all other neurons in the preceding and following layer. The input is convolved with filters to produce an output where bias is added for nonzero value. The final output goes through a nonlinear activation function which activates the feature maps and forwarded the result to the next layer.

(iii) Pooling layer: The other name of this layer is the subsampling layer. This layer reduces the dimensions through downsampling operation. Average (uses the average value) and Max (uses the highest value) pooling are the two most used operations. The following subsampling function represents a pooling operation:

$$Z_i^l = Sub - Sampling\left(Z_j^{l-1}\right). \quad (2)$$

(iv) Nonlinearity layer: It applies the relevant nonlinear activation function. The most common functions are sigmoid, rectified linear unit (ReLU), hyperbolic function, and SoftMax:

$$a^l = f\left(Z^l\right). \quad (3)$$

(v) Dropout: This layer regularizes the CNN model, decreases computation, and increases the generalization. It randomly drops the units by assigning the zero weight to a set of units. This layer helps to avoid the overfitting problem.

Fully connected layer: This is a flattened layer with each neuron of the previous layer connected to each neuron of the current layer. Each neuron has a separate weight for each connection. This layer has the highest number of learnable parameters. The input data are linearly processed, passed through a nonlinearity, and then propagated to the next layer.

4. LV Segmentation Using DL Architectures

CNN has performed several CV tasks effectively and precisely, that is why it is a widely used DL technique for image segmentation, especially for medical images. In Section 4.1, several CNN architectures are reviewed which are used for the LV segmentation.

4.1. LV Segmentation Using Fully Convolutional Network. The fully convolutional network (FCN) [56] introduces the fully convolutional layers instead of fully connected layers. Therefore, FCN can handle the variable size of images and fewer parameters to be learned which also make the network faster. The FCN and its variants used for LV segmentation are explained below.

4.1.1. FCN with Pre/Postprocessing. A three-step (preprocessing, LV segmentation, and postprocessing) LV segmentation method is proposed in [57]. In the first phase, LV is localized using the over feat algorithm [58] to determine the region of interest (ROI) which is then fed to the next phase where the segmentation is performed using a temporal FCN (T-FCN) architecture. The CNN model is pretrained with GoogLeNet and fine-tuned using LV images. The T-FCN adds another hidden layer at the decoding path to restore the original size. The segmented LV boundary is further refined in the third phase by using one of the two algorithms: fully connected conditional random fields (CRFs) with Gaussian edge potentials [59] and semantic flow [60]. To train the network, the TWINS-UK database was used which consists of more than 12,000 images. The result showed that T-FCN with CRF performs better segmentation and achieved the dice similarity coefficient (DSC) value of 0.9815, average perpendicular distance (APD) of 6.2903, and conformity index of 0.9610. This work only focused on the LV segmentation.

One of the preprocessing methods is to crop the ROI first and then apply the segmentation to the selected ROI. This procedure for LV segmenting is presented in [61]. The clinical parameters such as LV volume (LVV), LVM, SV, and EF were also analyzed by estimating the size of LV from MRI images. The class imbalance challenge was tackled by first finding out the ROI using an FCN model. A new FCN model was applied to these ROI images for LV segmentation. Class entropy and radial distance were used as loss functions. The model is trained and tested using two datasets: the Automatic Cardiac Diagnosis Challenge (ACDC) 2017 publicly available dataset and a local dataset. The ACDC-2017 dataset consists of 150 patients' data, while the local dataset consists of almost 6000 images. The performance is evaluated using the DSC and Hausdorff distance (HD) for cross-entropy loss and radial distance loss. The model is analyzed for both datasets and achieves almost the same results, which yield that the model is generalized and applicable to any dataset. The proposed model attained better DSC and HD values than that of U-Net and ConvDeconv-Net. The DSC value for LV segmentation of the proposed model on the local dataset is 0.95 and ACDC dataset is 0.94. Similarly, the HD value is 9.31 and 11.21 for the local and ACDC dataset, respectively.

4.1.2. Improved FCN for Clinical Index Calculation. Chen Qin et al. [62] proposed a model that consists of two branches: the motion estimation branch and the segmentation branch. The unsupervised Siamese style recurrent spatial transformer network is utilized for motion estimation and FCN is used for the segmentation. Motion estimation is an unsupervised method that combined the motion estimation and segmentation layer which can also be referred to as a weakly supervised model. A total of 220 short-axis view subjects were obtained from a UK biobank study. The LV segmentation is assessed by separately segmenting the LV and also by combining the two models. The DSC value of 0.9217 is achieved for only segmentation, while 0.9348 is achieved for the combined model which depicts that the model performs better in combine mode.

Similarly, the LVV is calculated using MRI images in [63]. The volume of LV is a very important feature to evaluate the patient's cardiac health which requires LV segmentation. The method segments the LV for diastolic and systolic to calculate the volume of LV. The Sunnybrook dataset is used to train and test the model. Data augmentation is also applied by rotating the slice in different directions. The method used a local binary pattern in cascade to detect the ROI. Then, a CNN model is used to score the ROI and select the one with the maximum score. Finally, LV is segmented using hypercolumn FCN (HFCN) from the ROI. The HFCN features from different levels were concatenated to form a new layer, and segmentation was based on this new layer. The volume is calculated using both manual and HFCN. The variance estimation method is used to estimate the final prediction. This algorithm ranked fourth in the Second Annual Data Science Bowl competition organized by Kaggle. Although this algorithm performs very well in segmentation, still sometimes the model generated the irregular shape of LV as it does not use the prior knowledge of the 3D shape of LV.

The feasibility and accuracy of FCN to segment the scar tissues in LV were analyzed in [64]. The modified version of FCN, efficient neural network (ENet), is applied to cardiac images. The proposed network consists of 13 convolutional layers with a 3×3 kernel size and stride of 2, while a parametric rectified linear unit (PReLU) was used as an activation function. Cross-entropy was used as a loss function. The two protocols, protocol-1 and protocol-2, were used for the segmentation. In protocol-1, the ground-truth and original images were directly fed to the network for training and segmentation. Whereas, in protocol-2, the desired LV area was cropped before training the network. The images were cropped using Hough transform [65]. The dataset consists of 250 images of 30 patients which is further increased to 2000 images by applying the data augmentation technique. Protocol-1 and protocol-2 achieved the accuracy of 95.97% and 96.83%, the sensitivity of 97.31% and 87.89, the specificity of 68.77% and 88.07%, and the DSC value of 0.54 and 0.71, respectively. The result demonstrated that protocol-2 performs better than protocol-1, which depicts that cropping the ROI gives better results in segmentation.

4.1.3. Loss Functions and Optimization Algorithm. Until now, we have explained the FCN models and their performance based on preprocessing or by applying some changes in the model. Nevertheless, one very important parameter is the loss function. In [66], the updated model of FCN with different loss functions was analyzed. An iterative multipath FCN (IMFCN) segmentation model for LV, RV, and MYO from MRI images was proposed. To tackle the class imbalanced problem, searching for ROI was performed and images were cropped using the method proposed in [67]. The proposed model consists of an encoder, feature fusion, decoder, and deep supervision. Encoder part used s $[i]$ current slice, previous slice $s\ [i-1]$, adjacent slice $s\ [i+1]$, and already predicted segmentation $M\ [i]$ as input. These features are inserted into the encoder part to extract new features. The new features are fed to the feature fusion which consists of different convolution layers of different sizes. The output features from the fusion block are fed to the decoder block which has unsampled features. Finally, the deep supervision part performs the segmentation. The efficiency of the model is also compared using different loss functions. Batch-wise class reweighting mechanism and batch-wise weighted dice loss function were utilized for multiclass segmentation. The results of the proposed models were evaluated and compared with U-Net and LVRV-Net. To quantitatively evaluate the performance, three metrics: DSC, average symmetric surface distance (ASSD), and HD were employed. Batch-wise weighted dice loss function shows the best results among all loss functions. In this research, the most inaccuracies in segmentation have occurred in apical and basal slices. Additional processing mechanisms can lessen these errors.

The focal loss was analyzed with the four skip connections in the FCN model [68]. The model was referred to as the focal residual network (FR-net). RestNet50 was used as a backbone network. Cross-entropy loss was calculated across the predicted probability and labeling. Focal loss was applied to improve preliminary segmentation results. Sunnybrook dataset was used. DSC and APD were used to evaluate the performance. The model results were also compared with U-Net and FCN and other work based on the Sunnybrook dataset. The models attained the DSC value of 0.93 and APD of 1.41.

In addition to the loss function, the optimization algorithm is also a key feature of the CNN model. In [69], the performance of optimization factors was analyzed for the CNN model. Six different optimization algorithms, namely, stochastic gradient descent (SGD), nesterov accelerated gradient [70], RMSProp [71], Adam [72], AdaDelta [73], and AdaGrad [74] were implemented to train CNN model. A CNN model was proposed and trained separately using all six optimization factors. Sunnybrook dataset was used for training and testing. The best performance was obtained by the RMSProp optimization technique. The model achieved the DSC of 0.93, APD 2.13, and percentage of good contour (GC) 95.64 using RMSProp optimization.

4.1.4. Other FCN Techniques. One key limiting factor in DL is the amount of data. Training the FCN model using a large dataset for LV segmentation is studied in [75]. The FCN model is trained on the UK Biobank dataset. The images of 5,008 subjects (93,500 images) were used to train the model after data augmentation. The data were manually annotated by eight different experts. DSC, mean counter distance, and HD values of 0.94, 1.04, and 3.16 were achieved, respectively. The segmented LV is also used to measure the LV-EDV, LV-ESV, and LVM.

Another technique to enhance the model performance is to take advantage of the pretrained model. A pretrained VGG model (trained on ImageNet) was combined with FCN called FCN-all-at-once-VGG16 [49]. The model used skip connections to combine the hierarchical features from convolutional layers with different scales. Adam was used as an optimizer with an initial rate of 10^{-4}. A dataset of a total of 1100 subjects was used by splitting the dataset of 100 subjects into 50 training, 30 validations, and 20 tests images. The next 1000 cases (diastolic) are segmented using a trained model and compared by 1000 manually drawn by an expert technician. The manual drawing was performed using the in-house software (A-view Cardiac, Asan Medical Centre, Seoul, Korea). For quantitative analysis, sensitivity and specificity evaluation matrices were used. The method is limited when the number of pixels of background (i.e., image pixels other than the LV mask) is large. The model was evaluated using four performance indices, i.e., DSC, Jaccard similarity coefficient, mean surface distance (MSD), and HD.

FCN was also used with a graph matching algorithm. The motion estimation of LV from MRI images was studied in [38]. The method consists of four steps: (1) endocardial contours of the LV were predicted using a FCN, (2) features of points in short-axis cine MRI were extracted using an FCN feature descriptor, (3) the correspondence between contours of the LV myocardium was estimated by a novel graph matching algorithm, and (4) the correspondence between two LV contours and the LV motion field was estimated using the FCN feature descriptor into the graph matching algorithm. The Medical Image Computing and Computer-Assisted Intervention (MICCAI) 2009 challenge database and the 33 subject's database [53] were employed to evaluate the proposed method.

Consequently, FCN and its modifications show very decent results for LV segmentation. To enhance the performance different preprocessing and postprocessing techniques, loss functions, and data variability can be used. Figure 7 illustrates examples of segmented images generated by FCN models.

4.2. LV Segmentation Using U-Net. In medical images, the required area to be segmented consists of a small area of the entire image. The U-Net [76] has shown substantial results in the segmentation of medical images. This is possible due to the ability of U-Net to continuously suppress the background region in training and emphasis the required areas that need to be segmented. That is why the most used network for LV segmentation is U-Net and its modification models.

4.2.1. U-Net with Pre/Postprocessing. Studies applied the postprocessing or preprocessing with DL methods to yield good results. Guo et al. investigated the postprocessing effect on MRI images in [77]. Input Cardiac MRI is fed to U-Net and then labeling probabilities were generated. For the postprocessing Kernel cut, a segmentation technique was used. The output of U-Net is the input of continuous kernel cut which segments the desired part. LV, MYO, and RV were segmented using this approach. The result shows that, with less training data, reasonable segmentation results can be achieved.

The postprocessing on vivo diffusion tensor CMR was performed in [78]. A five-layer U-Net architecture is used to perform the LV segmentation followed by image registration. This helps to remove the bad images, and then, the final segmentation was applied. To increase the size of the dataset, data augmentation was used (translation and rotation).

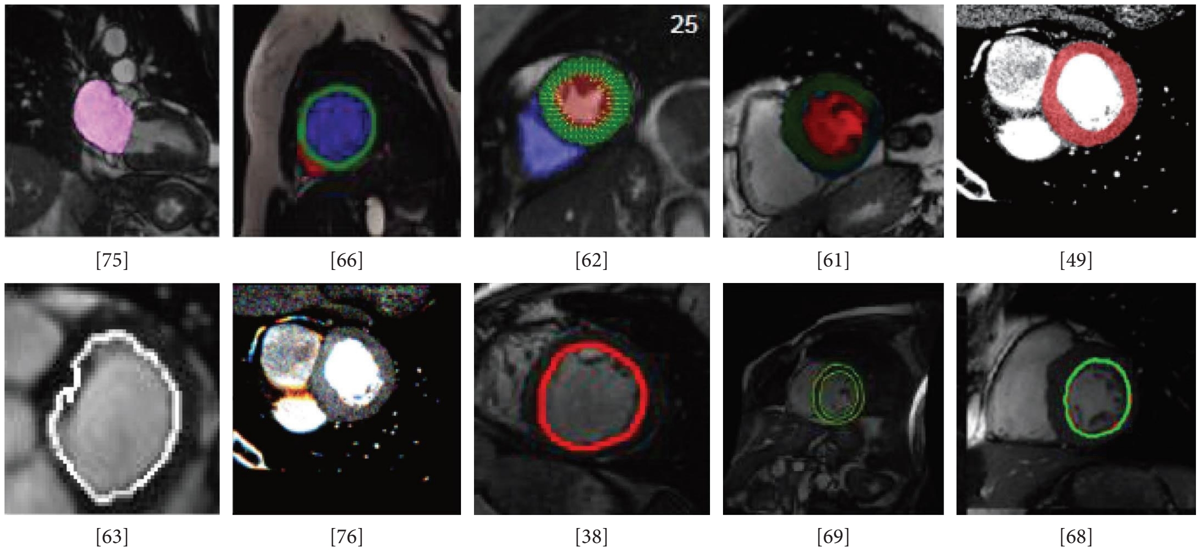

Figure 7: Sample of segmented images using FCN.

Batch normalization was used with U-Net to avoid overfitting. The model achieved a 0.93 median value of DSC.

The approach in [79] performs the preprocessing on the images by selecting the ROI by using the SinMod method. The ROI contains the desired part of the heart that is fed to the U-Net model for training. The curriculum learning (CL) strategy was utilized as a training strategy. The proposed methods were compared together with U-Net without CL, FCN (with and without CL), and hybrid gradient vector flow snake. The DSC, overlap, and mean average distance (MAD) were used as evaluation matrices.

In [80], the labeled images from the Kaggle database were used before training. The concept of transfer learning is utilized by pretraining the 3D U-Net model using Harvard data. The U-Net model was used to segment the LV, MYO, and RV. The DSC value achieved for LV segmentation was 0.87 without transfer learning and 0.95 using transfer learning.

The determination of ROI makes the segmentation task simple and accurate as the targets area is reduced to ROI instead of a complete image. This strategy was used in [81] and proposed for the three U-Net-based models. The proposed CNN architectures classify myocardial tissues and detect LV-ROI before LV quantification. For this experiment, the Sunnybrook cardiac dataset and the Cardiac Atlas Project (CAP) were used, which consists of 45 and 95 cases, respectively. Three new CNN architectures were proposed which are based on U-Net. The main purpose of the proposed models is to quantify the LV. Before LV quantification, LV-ROI detection and myocardial tissue classification were performed using the same U-Net architectures.

In the first proposed model, the encoding path comprises two 3×3 convolution operations, batch normalization, and residual learning. The 2×2 Max-pooling operation with stride 2 was performed after the residual learning [24]. The second and third proposed architecture is named as uInception and uXception. The network complexity was reduced in these networks. The SGD was used as an optimization factor and Jaccard distance as a loss function. The data augmentation was applied to increase the data size from 4,048 to 20,000. The segmentation accuracy was measured using the DSC and achieved 0.870, 0.869, and 0.868 for the proposed networks, respectively. Mean square errors of 0.0135, 0.0136, and 0.0138 were achieved while the mean absolute error was 0.0137, 0.0136, and 0.0138. Furthermore, EDV, ESV, SV, LVM, and EF were calculated as clinical indices.

4.2.2. U-Net with Deformable Model. The combination of DL and deformable models as postprocessing can be combined to segment the LV. Veni et al. trained the U-Net model for LV segmentation from the A4C chamber view of US [82]. The segmented output is further refined using the deformable model. Using this technique, high accuracy is achieved by training the model with a very fewer amount of data, i.e., 69 images. The DSC value of 0.86 ± 0.06 was achieved.

4.2.3. Improved U-Net for Clinical Index Calculation. Many studies focus on the calculation of various heart parameters such as EF, global longitudinal strain, or LVM, and for measurement of these parameters, LV segmentation is one of the primary tasks to be performed. A study was performed to validate that the DL methods can be used in real-time software that streams images directly from an ultrasound scanner [83]. A U-Net model was utilized for LV segmentation. The main goal was to calculate ventricular volume, EF, and mitral annular plane systolic excursion (MAPSE). All these parameters were based on the segmentation of LV. The accuracy of the model was evaluated by Bland–Altman analysis. The dataset of 75 patients was used and a value of $(-13.7 \pm 8.6)\%$ for EF and (-0.9 ± 4.6) mm for MAPSE was achieved for Bland–Altman. The results show that DL is a feasible solution for the real-time calculation of clinical indices used for cardio analysis.

Similarly, LV segmentation was also performed to measure the GLS. The work in [84] utilizes the standard U-Net architecture and performs the four tasks on US images: (i) classification of cardiac view, (ii) segmentation of LV from the cardiac view, (iii) estimates of the regional motion, and (iv) a fusion of measurement. The segmentation architecture comprises five levels of upsampling and downsampling. All levels consist of two convolution layers with filters ranging from 32 to 128. The 3×3 filter size, 2×2 Max pooling, and 2×2 equal stride were utilized. Dice was used as a loss function and Adam as an optimizer.

A method to achieve LV segmentation based on temporal area correlation was proposed in [85]. U-Net was used as a base CNN model, and then, the multitask module is utilized for epicardium and endocardium segmentations. The output of the multitask module was fed to recurrent neural network (RNN). The RNN performs the temporal area correlation optimization. The average DSC of 0.90 ± 0.05 and average HD of 7.6 ± 4.5 was achieved. The LVM and EF have also been calculated to cross-validate the results.

For the quantitative analysis of the LV, segmentation is performed before quantification of LV parameters (area and dimension) [86]. The segmentation provides the structural information of LV which is further used for quantification. Initially, U-Net architecture was used as a segmentation model. Furthermore, a Deep-CQ segmentation model was proposed for LV segmentation that comprises the proposed loss function. The binary classification of each pixel as LV or background was performed using the Gibbs distribution function [87]. The segmentation performance was evaluated using DSC matrices and achieved 0.893 ± 0.05 value for Deep-CQ models, while U-Net yields 0.897 ± 0.041. The main object of this research work is the quantification of LV, and the Deep-CQ model performed better than U-Net for quantification while U-Net performed better than the Deep-CQ model in segmentation.

Estimation of myocardial perfusion is an essential step to measure the blood flow through the heart muscle. The arterial input function (AIF) extraction is an important phase for calculating the myocardial perfusion. The AIF estimation is highly dependent on detecting the LV size accurately. The LV segmentation to measure the AIF was performed in [88]. A U-Net model based on RestNet was designed to segment the LV. RestNet consists of batch normalization, ReLU, and convolution layers. To estimate the output probability, sigmoid or SoftMax was used. The kernel size used was 3×3 with 1 stride and 1 padding in all convolution layers. A weighted sum of cross-entropy and IoU was used as a loss function. To find out the best hyperparameters, 45 training sessions were performed and the best hyperparameters were used for final training. The labeling of LV and RV was performed using an ad hoc algorithm and experts cross-check the labeling. The model was trained using two different sets of classes: (i) LV and background and (ii) LV, RV, and background. The model achieved DSC values of 0.87 ± 0.08 for three classes and 0.82 ± 0.22 for two classes. The performance of the model trained for three classes was better than two classes because the contextual information extracted from three classes improves the LV segmentation performance.

From an entire echo cine, automatic LV segmentation was performed in [89]. The US images and optical flow of US images were first fed to the temporal window. The optical flow was calculated by the Horn–Schunck algorithm. The output of US image and optical flow US images act as input to the two separate encoder parts of U-Net. The output of both the U-Nets was concatenated. In the third part of the model, the concatenated data were passed to the bidirectional LSTM. The U-Net decoder finally up-sampled and segmented the LV. The data of 563 patients were used with a training and testing ratio of 80 and 20, respectively. Dice was used as a loss function and Adam as an optimizer. Network performance was compared with U-Net and U-Net Bi-Conv LSTM using the DSC. The model U-Net optical Bi-Conv LSTM achieved the best DSC value of 0.936 and accuracy of 0.977.

4.2.4. Comparison of Different U-Net Models. The comparison of three well-known CNN architectures was performed by [90]. U-Net, wide U-Net, and U-Net++ were trained using the data of 94 patients. Data augmentation was used to increase the data size and to avoid the overfitting problem. The U-Net has 32, 64, 128, 256, and 512 feature maps, while the wide U-Net has 35, 70, 140, 280, and 560 feature maps. U-Net++ has an additional block of feature maps and skip connections. Exponential linear units (ELU) were used as an activation function in all layers except the last layer, where sigmoid was used. The model was trained using the original dataset and augmented dataset and the performance was assessed. The U-Net++ model performance was the best among the three models using an augmented dataset. The highest DSC value of 92.28 is obtained. Moreover, U-Net++ was less overfitted than U-Net and wide U-Net.

4.2.5. U-Net Performance Based on Dataset Properties. Although the comparison among different variants of U-Net was performed in [90], the training dataset and data variability also affect the performance of the network. The effect of training datasets from different variability on the performance of the CNN model was analyzed in [91]. U-Net architecture was used as a segmentation model and assigned the names CNN1, CNN2, and CNN3 based on the training dataset variability. Three different training sets were collected for this research experiment. CNN1 was trained using the data from single center and single vendors with 25,389 images. CNN2 was trained by the set consisting of images from multiple centers by the single vendor and 27,488 images, while multiple centers and multiple vendor data were used to train the CNN3 model with 41,593 images. The training images were preprocessed for normalizing the resolution, cropping the images to 256×256, and normalizing the signal intensity. APD was used as an evaluation metric. CNN3 had the largest number of training samples and the highest variability, and it has achieved the best performance on unseen heterogeneous testing data with the highest value of 1 mm for CNN3. While EDV, ESV, LVM, and EF were used as clinical indices.

Similar and detailed research to analyze the impact of the amount of data, quality of images, and influence of expert annotation on LV segmentation was executed in [92]. A US images dataset that is openly available was also introduced in this work. The dataset consists of an apical 4-chamber view of 500 patients and is called the Cardiac Acquisitions for Multistructure Ultrasound Segmentation (CAMUS) dataset. The authors compared the performance of different CNN models based on U-Net. The models used for LV segmentation were U-Net1, U-Net2, anatomically constrained neural network, stacked hourglasses, and U-Net++. All these architectures were based on encoder-decoder and the main difference among these architectures is the use of different layers and learning parameters. The U-Net2 yields the best segmentation results, and the performance was slightly better than U-Net1, but U-Net1 needs fewer parameters to learn, so the authors choose U-Net1 for further experiments. The model was trained to segment only LV and multistructure in which the model segments the LV endocardial (endo), LV epicardial (epi), and left atrium (LA). The model performance was consistent for both LV segmentation and LV segmentation in the context of LA.

The effect of image quality on training was also tested. Two different sets of images are given to the network for training. One set comprises only high-quality images while the other consists of high- and low-quality images. The output of both sets does not vary significantly. The author infers that the encoder-decoder-based techniques can cope with variability in image quality. The influence of the size of the training dataset on the performance was also tested. The U-Net1 model was trained by increasing the dataset from 50 patients to 400 patients. At each level, 50 more patients' data are added for network training. The results show that the performance of the model increases to 250 patients and slightly improved by increasing the training data further to 400. It is concluded that U-Net1 requires 250 patient data to attain a good promising result. The impact of expert annotation was evaluated by annotating the data by three different experts. The network was trained each time using the data of 50 patients labeled by every three different experts. The validation data were kept the same, and the model was tested by the remaining 400 patients' data. The network trained using the expert's data showed better results in testing. It is analyzed that the data contouring images are cardiologist dependent. Furthermore, the encoder-decoder network can learn a specific way of segmenting.

The labeling of large dataset problem was addressed in [93]. A model was proposed to generate the ground-truth images. Pseudoimages were generated using a graphical model such as the principal component analysis. The CycleGAN model was employed to generate the labeled images by using the pseudoimages and unlabeled original images. These labeled images were utilized to train a U-Net model. CAMUS dataset, EchoNet dataset, and synthetic dataset were used to train and test the model. The results show that the model trained using the synthetic data also performs very well.

4.2.6. Other Models Based on U-Net Architectures. Segmentation of LV, RV, and MYO from apical 2 chamber (A2C) view or apical 4-chamber (A4C) view has been implemented using DL methods [94]. In this work, neural network was tested to segment the LV, RV, and MYO from the apical long axis view (ALAX). In ALAX the main difference is the LV outflow tract (LVOT) which restricts the view. Four different approaches were used in this research. First, U-Net1 was trained from scratch and used to segment the ALAX. This model was referred as a baseline model in this work. Secondly, the baseline network was trained on A2C/A4C views, used as a transfer learning, and then trained for ALAX segmentation. Third, the baseline network was trained using A2C, A4C, and ALAX data. As ALAX data are less than A2C/A4C, so to compensate for this, ALAX data were repeated ten times in each epoch. In the fourth approach, the network was fed with US images and binary indicators. The purpose of the binary indicator is to inform the network about the input image whether it is ALAX or A2C/A4C. As the U-Net model has no dense layer, so an image is created from a binary indicator and fed to the network. The dataset of CAMUS challenge consisting of 500 patients was used for training, while for ALAX view, separate data of 106 patients were collected. The proposed multiview segmentation network achieved the best DSC value of 0.921.

To achieve the accurate and precise LV boundary and size, different studies modify the U-Net to elevate its performance. Gutierrez-Castilla et al. [95] improved the U-Net model by applying the changes in skip connections. The features' maps from each decoder layer were selected and upsampled according to the size of the final decoder output. After upsampling each decoder feature map, all feature maps were concatenated or added together. Using these dense skip connections, the decoder can flow directly to the final layer from each decoder layer. As no extra layers or filter is added, so this model does not add any extra parameters. For training, the model two datasets ACDC and Sunnybrook were used which consist of 150 and 45 patients' data, respectively. LV, RV, and MYO were segmented for diastolic and systolic. DSC and HD were used as evaluation matrices. As a clinical index, EF was also calculated by segmenting the LV for ED and ES. For ED, 0.968 and 4.855 (mm) values of DSC and HD were achieved, respectively. Likewise, DSC of 0.944 and HD of 6.254(mm) were attained for ES.

In the same way, a CNN model, named batch-normalization-U-Net (BNU-Net) was designed for LV segmentation from MRI images [96]. The proposed model was based on U-Net architecture, where the successive layers in the encoding path were followed by an ELU as an activation function and batch normalization was applied after convolutional filters. The BNU-Net has 4 layers in the contraction path and 7 layers in the expansion path. The 2×2 Max pooling was used after a pair of convolutional layers in the contraction path. The model was also trained using the

ReLU activation function and was found that the model gives better performance with the ELU activation function. The model was trained using the publicly available Sunnybrook dataset and the training data size was increased by applying the affine method for data augmentation. DSC and sensitivity matrices were used to compare the performance of BNU-Net with U-Net (with and without data augmentation). The BNU-Net performed better with data augmentation and gave a value of 0.93 for DSC and 0.97 for sensitivity.

Also, a novel U-Net-based method, CNN module, named the "OF feature aggregation network" (OF-Net) as integrated temporal information from cine MRI into LV segmentation [97]. The proposed model integrates the motion information with the U-Net model. Furthermore, two more CNN models were used to localize (ROI-Net) and then segment the LV (called attention module). The model is trained using a flying chair dataset and fine-tuned using the MRI datasets. Two different publicly available datasets, Statistical Atlases and Computational Modelling of the Heart (STACOM) and ACDC datasets, were used. Out of 100 subjects, 66 were used for training and 34 for testing. Total of 12,720 images for training and 6972 for testing (from the STACOM dataset). A DSC value of 94.8 ± 3.3 was achieved.

In [98], a graphical user interface is developed for LV segmentation from MRI images using PyQT libraries. Images were labeled manually, and the labeled LV images were fed to train the CNN model. A publicly available dataset and the internal dataset were used to train the model with 13,535 images and test the model with 4,148 images. The model achieved the DSC of 0.87 ± 0.02.

The sonographers also used the point-of-care ultrasound (POCUS), which is portable ultrasonography used for diagnosis. The feasibility of translating the POCUS echo images to the high-quality traditional echo images was studied in [99]. To improve the quality of POCUS data according to the level of cart-based US data, the mapping from POCUS images to cart-based US images was an obligatory task. To achieve this goal, the POCUS images were analyzed, compared, and mapped with the traditional US images. The dataset of 5000 POCUS images and 16000 US images was used for the mapping purpose. The anatomy of LV was extracted from POCUS (using A2C view) using the DL method and then mapped with high-quality US images. The images were classified as low quality (fair + medium) and high quality. This classification was performed based on the visibility of the anatomy of the desired region. Fully convolutional encoder-decoder networks based on U-Net architecture were utilized for the translation of images. The size of the input image was 128×128. The model comprises ten encodings and eight decoding convolutional layers. ReLU activation, batch normalization, and dropout with ratio = 0.2 were used. In the first layer, batch normalization was not employed. Max-pooling and transpose convolution layers with stride 2×2 were used in downsampling and expansive paths, respectively. The average DSC value obtained is 82.6 ± 12.3 and 88.3 ± 5.0 for low- and high-quality images, respectively. Similarly, 2.6 ± 2.7 and 1.9 ± 0.8 mm values of HD for low- and high-quality images.

Despite the several advantages of using the U-Net in medical images, it ignores the effects of features maps on different scales directly. To solve this problem, a pyramid network is combined with the dilated U-Net model and named as multifeature pyramid U-Net (MFP-UNet) [100]. In dilated U-Net model, two more downsampling layers were added to extract more dense details of an image. As the US images were usually low contrast images, the images were preprocessed to enhance the contrast of US images using Niblack's method for global thresholding. The model was trained using a self-collected dataset of 137 2D-US sequences which yields 1080 training images and 290 test images. Furthermore, the model was also trained using the publicly available CAMUS dataset. The proposed model did not only yield good segmentation results but also took less runtime. The model was compared with U-Net, dilated U-Net, and DeepLabv3. It takes about 1.2 sec for the classic U-Net, 1.33 sec for DeepLabv3, and 0.81 sec for MFP-UNet to segment a test image. DSC, HD, Jaccard distance, and mean absolute distance were used to compare the performance of the model.

Another concerning issue is, while computing the parameters, most of the DL models extract similar features at low levels. To avoid this problem, modification in the attenuation U-net model was proposed by introducing the attention gates mechanism [101]. This model focuses on the desired region of varying size and shape automatically. Furthermore, the class imbalance problem was addressed by introducing the Tversky loss. The model achieves 0.75, 0.87, and 0.92 for Jaccard index, sensitivity, and specificity, respectively.

One of the main problems which arise in DL architectures is gradient vanishing. The research [102] focuses on the gradient vanishing problem and proposed a model residual of residual (ROR) U-Net model. The encoding path of the proposed model is similar to ResNet-U-Net, but three shortcut levels are introduced in the ResNet-U-Net model. The First 3×3 convolutions and zero padding on the input image are applied. At the second level ResNet, the identity and convolutional blocks of ResNet are divided into three branches, while, at the third level, convolutional blocks and identity blocks are used. The proposed model was trained and tested using the Sunnybrook dataset and compared with U-Net and ResNet-Unet models. The 0.866, 0.926, 0.923, 0.120, and 0.945 of Jaccard index, DSC, precision, false positive rate (FPR), and recall are achieved by the model.

The study [103] used the unsupervised learning method to segment the LV, RV, and MYO. A U-Net model was trained using ACDC and tetralogy of fallot dataset (TOF) dataset on short-axis (SAX) view of MRI images. Then, using the transformation network, the model segment the LV, RV, and MYO from the SAX view. The model has never seen the SAX view of images before.

In [104], the localization and detection of the area containing LV and RV were performed by a network known as the Left Ventricle Localization NET (LVLNET). This model is a lightweight encoder-decoder such as CNN. This CNN model contains two 3×3 kernels, batch normalization, and Max pooling in each layer having four layers in total.

This localization model identifies the central part containing the LV and RV. The image is cropped and then pass to the next proposed CNN model called multigate dilated inception architecture (MGDIB). The MGDIB is based on U-Net architecture, but the kernel weights are expanded by the dilation factor and called a dilated convolution. The number of parameters does not increase using the dilated convolution. Two publicly available datasets, LV segmentation challenge (LVSC) + ACDC, were used. LVSC is used for the first part for localization while ACDC is for the segmentation of LV and RV. Different clinical measurements such as EDV, ESV, EF, and LVM are also calculated. DSC and HD values obtained were 0.900 and 0.910 for ED and ES, while HD values were 8.330 and 11.040 for ED and ES. Figure 8 depicts instances of segmented images by the U-Net model.

4.3. LV Segmentation Using Other CNN Networks. Several studies also used various CNN models other than FCN and U-Net. The detail of other CNN models utilized for LV segmentation is explained in this section.

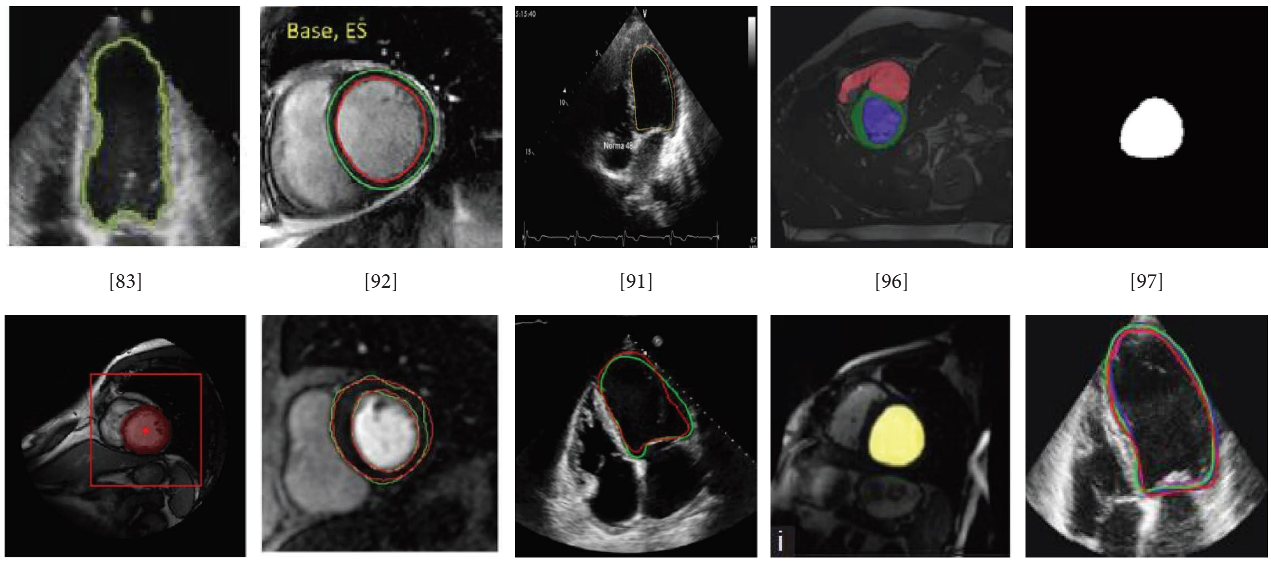
4.3.1. CNN Models with Preprocessing. US imaging was also used for the heart analysis of children. For this analysis, the segmentation of LV and LA was performed on the paediatric US images [105]. Preprocessing was applied to the images before the training. The meaningless background was removed by resizing the images to 512×512. Furthermore, image augmentation was also used by rotating, random cropping, using salt and paper, and speckle noise with a probability of 0.01. To extract the spatial features, a spatial path module was designed. The spatial path is a convolutional network consisting of three layers with stride = 2, followed by batch normalization and ReLU activation function. It extracts a large amount of low-level spatial information. A submodule spatial attention was added to exploit the interspatial information and it focused on the "where" information part. The second parallel part of the network extracts the contexture information using five convolutional layers. RestNet50 was used as a backbone network. The submodule contextual attention was used at the end of this part to refine the extracted information and to know the "what" information part in an image is important. The context attention submodule focuses on "what" to look at, whereas the spatial attention submodule focuses on "where." The authors compare the results of each submodule and conclude that "where" is more important in LV segmentation rather than focusing on "what." In the last part, the features of both the parts are fed into another module called feature fusion module that generates the final refine features. A self-collected dataset of 127 4CH videos (100 for training and 27 for testing) was used. Images were extracted from the videos and 3654 images were used for training and 831 for testing. The segmentation results were evaluated step by step by adding each model, and finally, full Attention-guided Dual-path Network shows the best result. Additionally, well-known CNN architectures (FCN, U-Net, DeepLab, PSP Net, and BiSeNet) were also trained and results were compared with the proposed network. The DSC coefficient achieved a score of 0.951 and 0.914, in the LV and atrium segments, respectively.

4.3.2. Hybrid Segmentation Methods. Some researchers analyzed the performance of hybrid CNN models for LV segmentation. The morphological models, snake models, and active shape model (ASM) were combined with CNN models in different studies. A hybrid model using DL and morphological methods was employed in [106]. The ROI was detected using a CNN model; then, LV was segmented using a multiscope CNN model. Three different patches were used for training the network, i.e., 8×8, 16×16, and 24×24, covering different scopes. Finally, morphological filtering was used to refine the boundary segmented by CNN. The LUMC dataset was utilized for this work. The model achieved the DSC value of 0.71.

Another hybrid approach based on CNN and the double snake model was proposed to segment the LV from MRI images [107]. A SegNet architecture was used for the initial segmentation result. Then, ROI was plotted around the coarsely segmented region taking the center point of the segment object and rectangular ROI was formed using polar transform. Output from SegNet was fed to the snake models which perform the final segmentation of LV. For training, the model 45 subjects were used and accessed from the MICCAI challenge. The DSC value of 0.96 and 0.97 was achieved for endo and epi. EF and LVM were calculated as clinical indices. Additionally, regression and Bland–Altman analysis was also performed.

Similarly, the work in [108] combines the ASM and neural network to segment the LV. A diffusion filter was applied to the images as a preprocessing step before feeding the data to the model. This filter used eight neighboring edges to preserve the edge information along with noise removal. A CNN architecture, Faster-RCNN, was used to determine the position of LV, and ASM used this location to segment the LV. As the ASM needs the initial position of the object to determine the position, so the region proposal network (RPN) was used to propose the regions that might contain the LV. Then, Faster-RCNN located the LV in the proposed ROI. Both RPN and Faster-RCNN were fine-tuned with ImageNet. The dataset of 30 patients was used for this work. The DSC, MAD, and HD were used to evaluate the performance. Furthermore, the models were also compared with other models proposed in the literature. The proposed model yields a DSC value of 0.921, MAD 1.95, HD 6.29 mm, and Jaccard 0.86.

One more hybrid approach was proposed consisting of the CNN model and dynamic programming [109]. Initially, SegNet [110] with 17 stacked convolution layers was used for coarse segmentation which segments the boundaries of LV. The batch normalization, ReLU activation function, and four MaxPool layers were used after the first four convolution layers. Secondly, the segmented results from SegNet were refined for endocardial contour. In the last step, a dynamic programming model was used to calculate the epicardium and endocardium of the heart. The 900 subjects from Hubei hospitals were used for this study. Jaccard and DSC were



[83] [92] [91] [96] [97]

[82] [99] [101] [103] [90]

FIGURE 8: Sample of segmented images using U-Net.

used for the evaluation. The DSC of 0.90 (0.03) and 0.93 (0.02) were obtained for endo and epi, respectively. Similarly, 0.80 ± 0.06 and 0.76 ± 0.09 average value of Jaccard was obtained. The LV-EDV, LV-ESV, SV, EF, LVM in the diastolic phase, and LVM in the systolic phase were also measured. The Bland–Altman analysis was performed for the comparison of these clinical indices.

4.3.3. CNN + LSTM. A combination of encoder-decoder network and LSTM was used in [111] with Fire dilated and D-Fire dilated layers as a replacement for standard convolutional layers. The Fire dilated modules add an extra dilation rate in the kernel by inserting zeros between the consecutive values of the kernel and skip connections were applied to keep the temporal information of the image. Using the Fire dilated module, the network extracted more image information by adding extra parameters. Between the encoder and decoder, an LSTM module is added which is a special RNN structure. LSTM along with propagating the characteristics also captures the temporal dependencies between consecutive frames. Images were preprocessed by cropping the image based on ROI and resized to 80×80. A total of 2900 images from 145 subjects were used to evaluate the performance of the model and two experts manually labeled the images. DSC, Jaccard distance, accuracy, and positive predictive value (PPV) were used as evaluation metrics. The model achieved the DSC 0.960, Jaccard 0.903, accuracy 0.991, and PPV of 0.960 for LV. The proposed model was compared with simple Conv-Deconv, SegNet, FCN, and U-Net architectures.

A segmentation-based deep multitask regression learning model (Indices-JSQ) was proposed in [112]. The model is mainly divided into two parts. The first part is a segmentation network named Img2Contour and the second part is a multitask regression model (Contour2Indices). The segmentation model is based on deep convolutional encoder-decoder architecture with three convolution layers. The ReLU activation function along with Max-pooling was employed. Feature maps were generated by the use of the convolution layers with the kernel size of 5×5. This part segmented the LV and then passed the information to the next part of the model. The second part consists of RNN with LSTM. Three parallel CNN architectures were used that differ in kernel size and pool size. For the 1st CNN model, kernel size and pool size were 3×3 and 2×2, the 2nd model was 3×3 and 5×5, and the 3rd model have the same size of kernel and pool, i.e., 5×5. The dropout layer was used to avoid the overfitting problem. Information was passed to the LSTM which further quantifies the indices. A total of 2900 short-axis views of 145 subjects were used for training. DSC and mean absolute error (MAE) were used for the performance evaluation, and the performance is compared with other CNN models. Area, dimension, and wall thickness were also calculated as clinical indices. The proposed model automatically calculates these indices which is one of the major contributions of the model.

The tumor extraction using the convolutional LSTM network was performed in [113]. To prove the generalization of the proposed ST-ConvLSTM model, it was applied on 4D ultrasound for LV segmentation. The model was trained on the publicly available 3D + time ultrasound dataset challenge on Endocardial Three-dimensional Ultrasound Segmentation (CETUS) consisting of data from 15 patients. The proposed model achieved the DSC of 0.868 and 0.859 for ED and ES phases, respectively.

The classification and segmentation of LV from multiview (A2C, A3C, A4C) US images were implemented in [114]. Initially, pyramid dilated dense convolution (PDDConv) was used to extract multilevel and multiscale features. PDDConv network consists of batch normalization, ReLU, and dilated convolution. After extracting the features, hierarchical convolutional layers with LSTM recurrent units (hConvLSTM) were used for segmentation. The fully connected layers were used to perform the classification task using 3DCNN. Data of three different views, i.e., A2C, A3C, and A4C with 150 patients for each view yielding a total of 450 patients' data consisting of 13,500 frames, were utilized for training and testing. Furthermore, the model was trained and tested using the publicly available CAMUS dataset which has 1800 frames. To evaluate the performance of the models, MAD, DSC, and HD matrices were used. DSC of 0.92 for all A2C, A3C, and A4C views was obtained. The mean HD of 6.06 mm, 5.96 mm, and 6.06 and mean MAD of 2.80 mm, 2.77 mm, and 2.83 were achieved for A2C, A3C, and A4C views, respectively. The proposed model was compared with U-Net, ACNN, and U-Net++ and achieved better results. The EDV, ESV, and EF for the CAMUS dataset were also estimated using the segmented LV.

4.3.4. Alternative CNN Models. A DL model was proposed to segment the LV and calculate such as cavity area, MYO area, cavity dimension, and wall thickness [115]. The model is named cascaded segmentation and regression network (CSRNet) and has two parts: a CNN model that segments the LV and a regression model to quantify the LV metrics. The dense connected convolutional neural network (DenseNet) was employed to reduce the number of learning parameters. The network mainly consists of three dense and three transition blocks. It generates three different probability maps for background, MYO, and cavity. Output from the last layer was fed to the regression component and passes to a CNN model with three convolution layers and two fully connected layers. To train the network, 2900 images (145 subjects) were used. These images were parted into 2320 training and 580 for testing. Several preprocessing methods such as landmark labeling, rotation, ROI cropping, and resizing were also applied to the images. DSC is calculated and compared with U-Net. The performance of DenseNet was better and achieved 0.989, 0.886, and 0.959 for background, MYO, and cavity. Similarly, the number of parameters, training, and testing time of CSRNet were compared with U-Net and DenseNet. The CSRNet has 0.6 M learning parameters with 17.62 training time and 1.20 sec testing time in 100 epochs.

A good initialization is a key parameter that optimizes the CNN model quickly. In [116], an initialization method was designed for the DCNN model to segment LV using MRI images. The model was trained and tested using two initialization methods: random initialization and Gabor filter initialization. Gabor filters can provide an accurate description of most spatial characteristics of simple receptive fields. Furthermore, spectral and spatial domains were simultaneously optimized in these filters which minimized the number of features. The authors demonstrated that using Gabor filter initialization requires less amount of training data and less complexity due to lower parameters. The York Cardiac Segmentation database (5011 images) was used for training. The model achieved the DSC of 0.798 with random initialization and 0.80 with Gabor initialization, while if Gabor filtered was maintained, the value further increased to 0.803.

A dense V-Net model was proposed which is based on V-Net architecture [117]. Few dense layers were added to the original V-Net model to improve the performance. For training, 30 patients' data (86 frames and each frame containing 73 images) were collected and manually labeled by 3 experts. The improvement of the proposed model was shown by comparing it with U-Net, FCN, and V-Net. The proposed model achieved a DSC of 0.90.

A transformers-based [5] DL model was designed to handle the sequential data. Transformers were mainly used for natural language processing and in [118] it is used to learn the image parameters. In the first part, 3D LV volume was passed to the transformer net which consists of 3D Conv layers, batch normalization, ReLU, Max-pooling layers, and fully connected layers. These layers extracted the transform parameters from the LVV and were inserted into AtlasNet, a new shape generation framework. The Atlas network has several advantages such as improved precision and generalization capabilities, and the possibility to generate a shape of arbitrary resolution without memory issues. AtlasNet consists of deformable layers and generates the 3D LV shape using the parameters achieved from the transformer. DSC, MSD, and HD were used for evaluation and achieved 0.91 ± 0.027, 1.99 ± 0.64, and 8.92 ± 7.16 respectively.

The CNN models such as FCN and U-Net focused on single-frame image processing. While, in the study [119], a dense RNN was proposed to segment the LV from a four-chamber view of the MRI time sequence. RNN can deal with sequential information. In RNN, information from the previous cell was transmitted to the next LSTM cell, but the first cell does not get any previous information. The proposed model used the two RNN models. The first layer of the second RNN model, which performs the segmentation, receives the information from the first RNN model. In this experiment, data from 137 patients were used. The performance of the model was compared with state-of-the-art CNN models. The proposed model achieved the IoU of 92.13%. Few examples of the segmented LV by CNN models are depicted in Figure 9.

5. Discussion

The performance of DL methods depends on various parameters, and the time for the data processing is based on hardware. The details of the several modified models and proposed architectures are explained in Section 4. Here, in this section, some important data from the reviewed literature are presented. The section is divided into five sections and conveyed in a tabular form so that readers can have an overview of all important information related to hardware, software, imaging modality, database, architecture, and results.

5.1. Imaging Modality. For the analysis of cardiac diseases, different imaging modalities have been used such as the US, CT scan, and MRI. Due to its high resolution, MRI is the gold

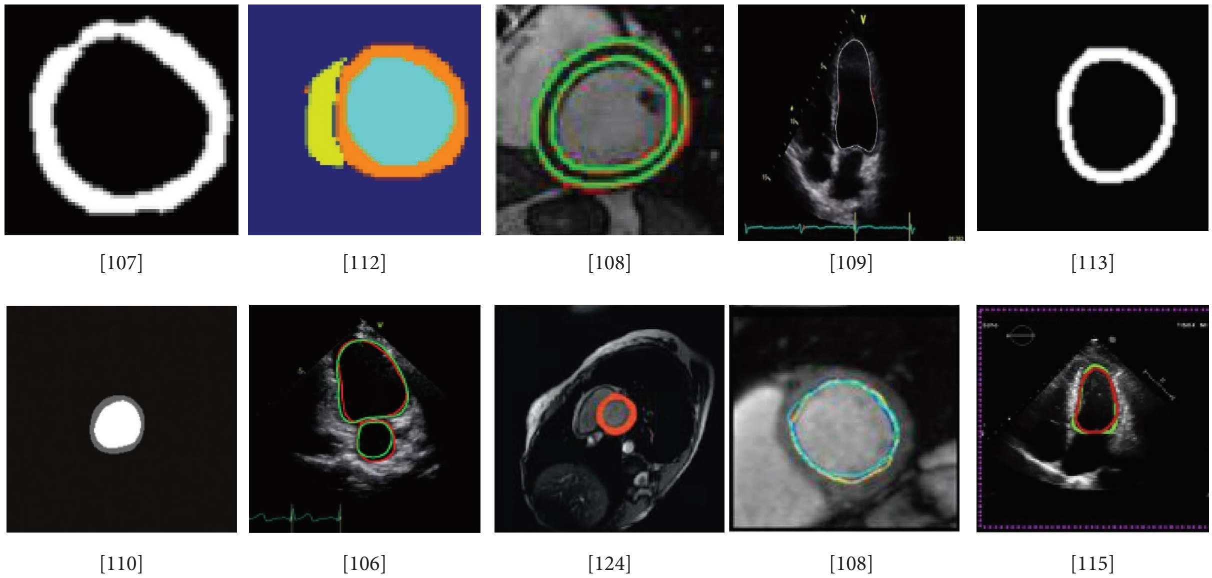


Figure 9: Sample of segmented images using other CNN models.

standard and is mostly used. On the contrary, US images are also highly recommended due to their ease of use and low cost. The third type of image used for the cardiac analysis is CT.

5.2. Architectures. Several CNN architectures are used by researchers for LV segmentation. The U-Net architecture is specifically designed for medical images; therefore, the use of U-Net and its variants are mostly used for the segmentation of LV. Besides U-Net architecture, FCN is the second most used network architecture for LV segmentation. Table 1 shows the CNN architectures used for LV segmentation.

5.3. Hardware. During the training process, the neural networks learn millions of weights. It may take several days to train such a huge number of weights on CPUs. The training time taken by the machine is one of the parameters to be focused on while implementing the models. Therefore, for the processing of DL models, hardware configuration plays an important role. A striking option for DL is a GPU. The use of GPUs makes the training and testing process fast, and results can be attained and compared in a short time. Hardware configurations used by authors for LV segmentation are listed in Table 2.

5.4. Software. An appropriate software framework is necessary to execute the complex DL architectures. Various frameworks have been used to implement the LV segmentation through DL architectures. These frameworks are generally used in Python programming. Python is an open-source programming language; furthermore, it supports a remarkable set of easy to utilize library functions for the execution of DL models; therefore, Python is widely used in DL-based applications. The software frameworks described in this section are primarily developed in Python language. The most general among them are TensorFlow, Theano, Keras, CAFFE, Torch, and Deeplearning4j. Few researchers have also used MATLAB as a programming language. Software used by researchers is enlisted in Table 3.

Table 1: Studies used different CNN models for LV segmentation.

Architecture	Study
FCN	[38, 49, 49, 57, 61–63, 66, 68, 69, 75]
U-Net	[77–86, 88–104, 120]
Other CNN models	[64, 105–109, 111–119, 121, 122]

5.5. Dataset. The performance of DL models is highly affected by the dataset. The number of images or number of patient data used to train and test the model is one of the key attributes of LV segmentation. Most researchers have used self-collected data, but, at the same time, several public datasets are also available. The details of the datasets are explained below and summarized in Table 4.

Data are from the 2009 Cardiac MR Left Ventricle Segmentation Challenge, often known as the Sunnybrook Cardiac Data. The data collection includes 45 cine-MRI images from a variety of different people and pathologies.

After registering on a website dedicated to the online evaluation, the ACDC database is made accessible to participants through two datasets. One dataset, referred to as the training dataset, contains 100 patients and manual references based on the study of one clinical expert. Second is a testing dataset consisting of fifty additional cases without manual annotations.

The MICCAI 2009 database contains 45 samples of short-axis cine MR images, 15 training cases, 15 test cases, and 15 online cases, which are randomly divided. The MICCAI 2018 challenge dataset comprises 145 participants'

processed CMR sequences. The ages of the individuals range from 16 to 97, with an average of 58.9 years.

The CAMUS dataset includes clinical exams performed on 500 patients at the University Hospital of St. Etienne (France). The LVSC dataset is accessible to the general public as part of the 2011 STACOM short-axis cine MRI semi-automatic LV myocardial segmentation challenge. This dataset is comprised of 200 individuals with myocardial infarction and coronary artery disease.

The short-axis steady-state free precession cine MRI from the Cardiac Atlas Project database is used to make up the STACOM dataset. In total, 100 individuals with post-myocardial infarction and coronary artery disease are included in the dataset. Every image contains a ground truth annotation.

The TWINS-UK is a volunteer register consisting of more than 12,000 twins. One thousand four hundred and sixty eight consecutive female volunteers (mean age 62 9 years) were recruited for this investigation. Each dataset had 12 to 14 short-axis cine that were continuous and evenly spaced from the atrioventricular (AV) ring to the apex, covering both ventricles.

The UKBB dataset is comprised mostly of a large number of healthy volunteers. By stacking a series of 2D cine images, 3D images of the LV and RV were created. LV, MYO, and RV were manually segmented in the ES and ED phases by 8 observers under the direction of 3 lead investigators, and hundred subjects were chosen.

The Cardiac Atlas Project offers CMR for 95 individuals with coronary artery disease and mild-to-moderate left ventricular dysfunction from prospective, multicenter, and randomised clinical studies. Sufficient slices along the short axis were collected to cover the whole heart in SAX. Also included in these acquisitions was the manual segmentation of the myocardium. The CETUS dataset came from 15 patients. Each patient had 13–46 3D volumetric imaging sequences, and each sequence had two manually segmented volumes at the end-diastole (ED) and end-systole (ES) phases. Figure 10 is an illustration of original and labeled image taken from four distinct datasets.

5.6. Results. The segmentation performance of models is evaluated using well-known evaluation matrices such as DSC, HD, and Jaccard distance, although some authors also used other matrices for accuracy, sensitivity, etc.

The DSC [123] is overlap based and calculated using equation (1). In the equation, S_{GT} represents the ground-truth image that represents the original LV size and boundary. S_{Seg} is the segmented mask by the model. To calculate the DSC, the intersection region of two masks is divided by the total region of both masks. The range of DSC is 0 and 1, where 0 represents no similarity or overlap and 1 represents exact overlap:

$$DSC = \frac{2\left|S_{GT} \cap S_{Seg}\right|}{\left|S_{GT}\right| + \left|S_{Seg}\right|}. \tag{4}$$

The HD [124] is a spatial distance-based index to measure the "closeness" of two sets of points. The HD between two-point sets A and B is defined by equation (2).

$$d_H(A, B) = \max(h(A, B), h(B, A)), \tag{5}$$

where $h\ (A,\ B)$ is direct Hausdorff distance, and it can be calculated by equation (3).

$$h(A, B) = \max_{a\epsilon A} \min_{b\epsilon B} \|a - b\|, \tag{6}$$

where $\|a - b\|$ is any norm value, e.g., Euclidean distance.

The Jaccard distance [123] can be calculated using the formula presented in equation (4).

$$J = \frac{|X \cap Y|}{|X\, U\, Y|}, \tag{7}$$

where X and Y are the ground-truth and segmented output images, respectively.

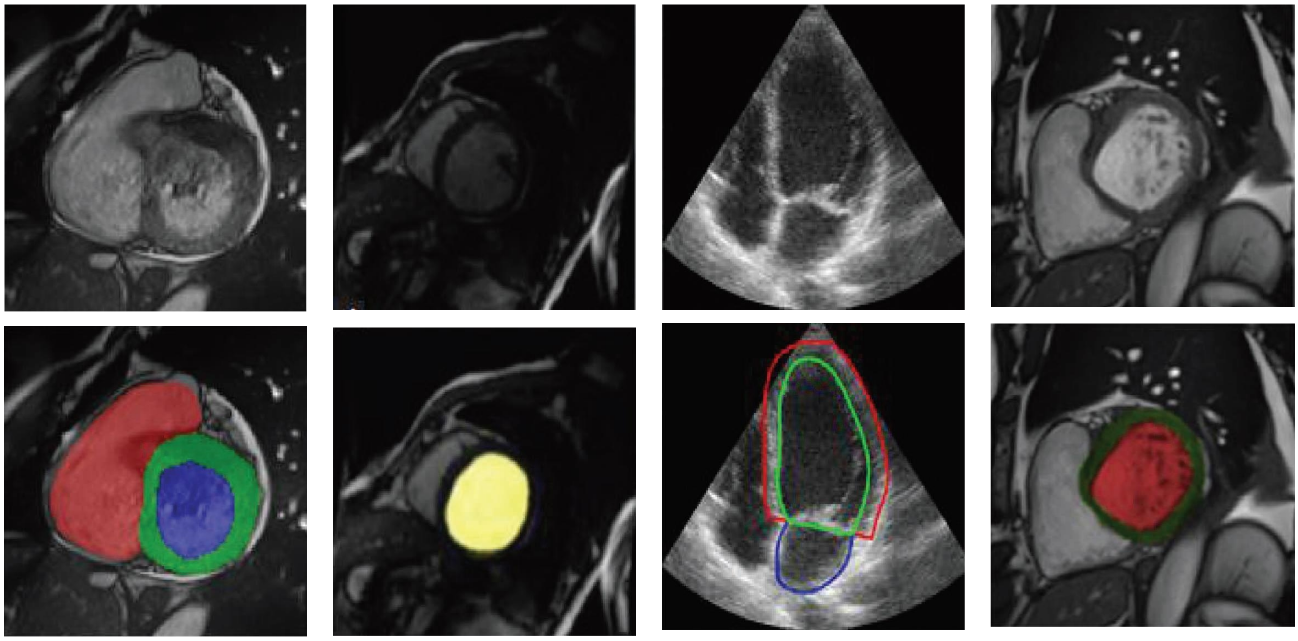

Figure 10: Example of the original image (top) and ground truth (bottom) of (a) ACDC, (b) Sunnybrook, (c) CAMUS, and (d) MICCAI datasets.

Similarly, the precision, specificity, and IoU can be computed with the use of equations (5)–(7), respectively:

$$\begin{aligned}\text{Accuracy} &= \frac{TP+TN}{TP+TN+FP+FN},\\ \text{Specificity} &= \frac{TP}{TP+FP},\\ \text{IoU} &= \frac{\text{overlapping area}}{\text{combined area}}.\end{aligned} \tag{8}$$

The assessment matrices and theoretical values attained by researchers are shown in Table 5.

6. Challenges and Future Outlook

The article shows that DL approaches have equally performed or outperformed the previous state-of-the-art LV segmentation techniques. DL algorithms are expected to completely replace the current LV segmentation techniques. Given this, it is reasonable to consider whether DL techniques can be directly applied to real-world applications to reduce medical practitioners' workload. However, there are still challenges to make the existing DL methods viable for real-time applications.

In medical images and, particularly, cardiac images, acquiring the annotated images is the most prevalent challenge. As this article demonstrates, most of the research employed supervised learning, which necessitates the usage of a significant number of annotated images. To properly label, the LV needs both specialised knowledge and a significant investment of time. As a result, the datasets of the annotated LV are quite limited in comparison to other publicly available datasets in other fields, such as natural images.

Moreover, the performance of DL on data that differs from the training dataset is another challenge. Even though the trained DL model is tested on unseen data, the training and testing data are received from the same source, such as the same sort of scanner. The model does not provide the anticipated outcome if new types of data, e.g., from multiple scanners or different disease patients, are used to test the model. A few studies have utilized training data for LV segmentation from different sources and scanners to train the model to get over this problem.

Also, the DL performance is highly dependent on the quality of the training images. Many imaging modalities such as CT and US are of low quality due to many factors such as speckle noise and poor contrast ratio. To produce high-quality images, many researchers use some sort of data preprocessing.

Therefore, further studies are required to investigate the methods to improve the image quality. Therefore, the efficiency of the DL model and the accuracy of LV segmentation may be significantly boosted by improving the image quality. There is a significant demand for a DL-based system that has the ability to improve image quality in an efficient and effective manner while simultaneously reducing noise. Therefore, the LV segmentation will be considerably more accurate when the segmentation and enhancing methods are combined.

In addition, the integration of LV segmentation algorithms with additional patient data, such as patient history, age, and demographics, is an important area of the article

that might further improve the performance of clinical decision making and assist physicians in calculating clinical indices.

As discussed above, one of the main challenges is the availability of large datasets, and there is abundant new research aimed at levitating the limited dataset size problem, and some LV datasets are publicly available. There is a pressing need for architectures and algorithms that have been purposed and built for the segmentation of medical images and, therefore, LVs, and that can also perform admirably when applied to limited datasets.

7. Conclusion

In this article, a comprehensive review of the literature focused on the analysis of cardiac images using DL for LV segmentation is presented. In the field of image processing CNN, a subbranch of DL has shown very promising results for different types of identification including classification, object detection, and segmentation. CNN is also seen as a futuristic approach specifically in image processing. The application of CNN in medical images is extensive. Therefore, this work details and summarizes the uses of CNN for LV segmentation. The most common imaging modalities (MRI, US, and CT scan) were briefly introduced in the article. The basics of CNN architectures were also discussed to have a better understanding of these models. Among the different CNN models, FCN, U-Net, and modified model two are mostly used for LV segmentation. This work also gives a detailed discussion of hardware, software, and dataset used for LV segmentation. The different evaluation matrices used for the performance analysis of the models were also discussed. A comparative summary was tabulated to ease the comparison for the readers. This work lays a foundation for the readers for an instinctive understanding of DL methods used for LV segmentation specifically for medical and cardiac images.

Data Availability

All the data used to support the findings of the study are included within the article as references.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

Retracted: Decision-Making Application of the Cloud-Fog Hybrid Model Based on the Improved Convolutional Neural Network in Financial Services in Smart Medical Care

Computational Intelligence and Neuroscience

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

In order to alleviate the "difficulty in seeing a doctor" for the masses, continuously optimize the service process, and explore new financial service processes for admission and discharge, this study proposes a cloud-fog hybrid model UCNN-BN based on an improved convolutional neural network and applies it to financial services in smart medical care. Decision-making applications: this research improves and designs the UCNN network based on AlexNet and introduces small convolution layers to form convolution groups, making the network more adjustable. The network structure is simpler and more flexible, and it is easy to adjust the algorithm. The number of parameters is small, and it can be directly superimposed without having to add new network hidden layers. The experimental results show that the recognition rate of the UCNN network on the FER2013 and CK+ datasets is higher than that of other recognition methods, and the recognition rates on the FER2013 and CK+ datasets are 98% and 68.01%, due to other methods. This shows that the improved convolutional neural network used in this study for financial services in smart medical care has certain applicability, and small convolution kernels help to extract more subtle features, so as to identify more accurately.

1. Introduction

In the 1990s, two scholars, Michael Hammer and Jame Champy, put forward the theory of "business process reengineering" [1]. The core of which is to use advanced information technology and modern management methods to reengineer business processes to improve service quality and efficiency. Business goals [2]: the First Affiliated Hospital of Wenzhou Medical University applies the concept of "smart medical care" to the reconstruction of the financial service process of admission and discharge. With the help of information technology, a new model of financial service for admission and discharge is constructed, and the financial procedures for admission and discharge are directly handled by the nursing staff in the ward. Through the new model, the financial procedures for admission and discharge have been optimized, the waiting time of patients in line has been shortened, hospital costs have been reduced, and patient satisfaction has been significantly improved [3]. Smart healthcare consists of three parts, namely, the smart hospital system, the regional health system, and the family health system. The smart hospital system consists of a digital hospital and an improved application. The regional health system consists of a regional health platform and a public health system. The home health system is the health protection closest to the citizens, including those who cannot be sent to the hospital for mobility problems.The home medical system is suitable for chronic diseases, remote care of elderly and young patients, health monitoring of mentally retarded, disabled, infectious diseases and other special groups, and video medical treatment for patients. Its intelligent medication system can automatically prompt medication time, contraindications, remaining medication, etc.The financial part of this study belongs to the family health system.

Computing technology is already a very mature technology in today's computer market, and cloud computing service products produced by using cloud computing also play an important role in today's markets in various fields.

There are many large, medium, and small enterprises in various fields using cloud computing products. Cloud computing can provide enterprises with functions such as information storage, management, and maintenance [4] and can also simplify the investment of enterprises in building networks, software, and systems. Human resources and the number of customers using cloud computing technology products are increasing, and it has been expanding from enterprise customers to individual users. Also, because of the increasing market demand, more and more information technology companies are moving their research centers to cloud computing technology research and product development. Major domestic and foreign information companies, including communication companies, are making efforts in this regard. Some researchers [5, 6] described the application of fog computing in IoT systems and its application characteristics; Pang et al. [5] placed computing at the edge of the cloud computing network to improve the availability and scalability of the system architecture and reduce transmission load and cloud processing burden. Rabinovich et al. [7] and Vaquero and Rodero-Merino [8] studied key technologies such as sensor network, peer-to-peer network, network virtualization in cloud-fog hybrid computing, and the main challenges faced by cloud-fog fusion. Zao et al. [9] studied the multilayer cloud and fog computing infrastructure and linked data network and its possible future intelligent environment in terms of the wearable user interface. Zhu et al. [10] studied the data access and interaction mechanism of edge network edge devices in fog computing. Giordano et al. [11] studied the layered distributed architecture of fog computing and its resource advantages in large-scale distributed computing based on the big data interference problem brought by the Internet of Things. Cloud computing is becoming an important force for change, but due to the proliferation of access devices and limited network bandwidth, the combination of fog computing or cloud-fog computing may bring about real computing changes.

A convolutional neural network is a method that can automatically extract object features, and feature extraction and feature classification are a simultaneous process (Ying et al.). AlexNet is one of the classic convolutional neural networks. AlexNet is deeper than LeNet in terms of network depth. It uses the combined structure of the convolutional layer and pooling layer to obtain features of graphic images. This research mainly explores the decision-making application of the cloud-fog hybrid model based on the improved convolutional neural network in financial services in smart medical care, so as to optimize the financial procedures for admission and discharge through the new model and shorten the patients' wait in line, reduce hospital costs, and improve patient satisfaction.

2. Model Introduction

2.1. AlexNet Network. As a commonly used convolutional neural network for deep learning [12, 13], AlexNet is improved based on the classic network LeNet, and on this basis, it can obtain more deep image features by extending the depth of the network. AlexNet is deeper than LeNet in terms of network depth and uses the combined structure of the convolution layer and pooling layer to obtain the features of graphic images [14]. At the same time, AlexNet also uses dropout regularization to suppress overfitting and uses the ReLU function instead. The sigmoid function is used as the activation function of the convolutional neural network, and the results prove that the ReLU function performs better in the deep convolutional neural network and also solves the problem of gradient dispersion and gradient disappearance caused by the sigmoid function (A et al., 2021), and the ReLU function has a faster learning speed. AlexNet has a total of 8 layers of network structure. The first 5 convolutional layers include 1 11×11 convolutional layer, 1 5×5 convolutional layer, and 3 3×3 convolutional layers, with 2 maxpool and 3 FC layers.

2.2. BN Normalization Algorithm. The role of the BN (batch normalization) layer is to prevent the gradient from dispersing and disappearing [15] so that a larger learning rate can be set when training the network, which significantly improves the training speed of the network model so that the model training does not rely too much on parameter initialization. To some extent, it reduces the dropout layer in the convolutional neural network [16]. So, its importance is the same as other structural layers in the network, and it is also an important structural part of the convolutional neural network. In general, the design of convolutional neural networks is more inclined to place the BN layer after the convolutional layer and the fully connected layer; of course, it can also be placed before the activation function [17]. The principle is that when each layer of the network is input, another normalization layer is inserted, that is, a normalization process is performed first, and then the next layer is entered, and it is a learnable one with parameters (γ, β) of the network layer. Assuming the input is n-dimensional, the normalization formula is as follows:

$$X = \left(x^{(1)} \cdots x^{(n)}\right). \tag{1}$$

Normalize each dimension, then

$$x = \frac{x^{(1)} - E\left[x^{(k)}\right]}{\sqrt{Var\left[x^{(k)}\right]}}. \tag{2}$$

If you just use the above normalization formula to normalize the output of a certain layer of the network and then send it to the next layer, this will affect the features learned by the output data of the previous layer, so the transformation and reconstruction method is introduced. The idea is to introduce the learnable parameters γ and β, and the formula is as follows:

$$\begin{aligned} y^{(k)} &= \gamma^{(k)}\widehat{x}^{(k)} + \beta^{(k)}, \\ \gamma^{(k)} &= \sqrt{Var\left[x^{(k)}\right]}, \\ \beta^{(k)} &= E\left[x^{(k)}\right]. \end{aligned} \tag{3}$$

It can be seen from the above formula that by reconstructing the parameters γ and β and learning these two parameters, the original features learned by a certain layer in the convolutional neural network can be recovered. However, in the actual test, the following formula is still used:

$$\hat{x} = \frac{x - E[x]}{\sqrt{Var[x] + \varepsilon}}. \tag{4}$$

2.3. Cloud Model. Since the concept of cloud computing appeared in 2006, the two IT technologies of computing and network have been continuously integrated and then coexisted with each other, which has effectively promoted the development of the information society [18]. In these IoT scenarios, a more secure, faster, and more stable computing mode is required, and at the same time, computing needs to have better mobility support [19]. The above requirements cannot be met for cloud computing with high latency, low security, and reliability. Therefore, the concept of fog computing emerges as the times require.

Fog computing was proposed by Cisco in 2011. It deploys a large number of micro-fog node data centers with limited computing and storage capacity between the cloud and the object to disperse the computing pressure of the cloud center and reduce the amount of data transmitted to the remote network [20]. Due to the limited computing power of fog computing itself, it cannot replace cloud computing, but expands and supplements it. The integrated use of these two technologies not only retains the powerful computing and storage advantages of the cloud layer but also expands the scope of network computing. At the near-user end, that is, the network edge, network computing has lower latency and higher location awareness [21]. The benefits brought by fog computing have made a huge impact in the IT industry. In 2015, IT industry leaders such as Cisco, Dell, and Intel jointly established the OpenFog Consortium to promote the rapid development of cloud-fog hybrid computing. Today, more than fifty institutions from North America, Asia, and Europe have joined the Open Fog Alliance [22]. In 2018, the National Institute of Standards and Technology restandardized the definition of fog computing on the basis of Cisco's years of fog computing research: fog computing is a combination of smart devices and traditional cloud data centers. A horizontal computing model combines physical and virtual resources. With the standardization of fog computing-related concepts, the technical architecture of cloud-fog hybrid computing has become increasingly mature [23].

2.3.1. Cloud Computing Center Layer. In the cloud-fog hybrid computing model, the traditional cloud computing center is retained. The cloud computing center uses a large number of virtual resources and provides extremely strong computing power and storage capacity with the help of task scheduling, load balancing, and parallel computing technologies to meet the processing of complex computing tasks. In the Internet of Things scenario, the cloud computing center is suitable for intelligent analysis and learning of large data volume information and storage of historical data, which is a supplement to the computing capability of the fog layer.

2.3.2. Network Layer. The network layer includes the access network layer and the core network layer. The access network layer mainly connects end-user equipment and fog layer node equipment through network equipment, which includes both wired and wireless networks. The core network connects the cloud computing center and the fog layer computing nodes through the wired network.

2.3.3. Fog Computing Layer. The introduction of the fog computing layer is the core of cloud-fog hybrid computing, which requires certain business processing and data computing capabilities. At the same time, the fog computing layer also needs to be able to cooperate with the cloud layer to carry out reasonable network control and resource scheduling to complete more complex computing and storage tasks. In addition, the scale of computing nodes in the fog computing layer may also become huge due to business requirements, and the hardware and software costs of a single computing node are relatively low. In order to meet the above functional requirements, in terms of hardware, the fog computing layer can be composed of general-purpose servers, white-label switches, routers, and other devices. In terms of software, in addition to the software system responsible for business computing and processing, it is also necessary to introduce software defined network (SDN) technology responsible for network traffic control and forwarding, and network functions virtualization (NFV) responsible for providing virtual network functions. Table 1 shows the main software and hardware resources required for the general fog computing layer.

Building fog computing nodes is an important part of fog computing layer construction. The Central Office Rearchitected as a Datacenter (CORD), DC transformation of network computer room, project promoted by the Open Network Alliance (ONF) basically meets the requirements of fog-layer computing nodes. The CORD platform integrates SDN, NFV, and other technologies and provides the possibility of fog-layer computing, traffic control, and network services with the help of hardware resources such as general-purpose servers and white-brand switches. If business services are added to it, it will become a suitable fog layer-compute node.

2.3.4. End User Layer. In the era of the Internet of Things, there are more and more types of devices in the end-user layer, including smartphones, computers, smart wearable devices, and various sensors. In order to realize the vision of the Internet of Everything, these intelligent terminal devices are connected together through wired or wireless networks, thus creating the necessity for the development of cloud-fog hybrid computing. In cloud-fog hybrid

Table 1: Comparison of classification accuracy on FER2013 and CK+ datasets during model improvement.

Ways to improve	Precision	
	Dataset of FER2013	Dataset of CK+
Introduce 4 convolution groups	67.80	96.55
Introduce 3 convolution groups	68.55	97.51

computing, the intelligent terminal device is the initiator of the task, and the task is forwarded to the corresponding fog computing node after being scheduled by the network device in the access network. After the task is processed by the fog layer and cloud layer, the processing result will be sent back to the terminal device through the network.

3. Network Improvements

3.1. Improvement Method. In this section, the UCNN network is designed on the basis of AlexNet, and the convolution group structure is introduced into the AlexNet network, that is, the convolution group convset of the small convolution kernel. The advantage of this structure design is that it is convenient to adjust the algorithm, and the convolution group can be directly added [24]. In this convolution group, there is a 1×1 convolutional layer at the beginning and the end, which can be connected with convolutional layers of any scale. A 3×3 convolution kernel and a 5×5 convolution kernel are used in the middle. The structure is shown in Figure 1.

A convolutional neural network is mainly composed of the input layer, convolution layer, activation layer, pooling layer, and fully connected layer. The network model in this paper introduces more than 3 of the above convolution groups to replace the 11×11 large convolution kernels in the AlexNet network. Each convolution group introduces 4 3×3 convolution layers and 2 max-pooling layers and then adds a batch normalization layer (BN layer), which can speed up the convergence of the model.The convolutional layers are supplemented with 0 to prevent edge pixels from being omitted when the convolution kernel performs convolution calculations. Using dropout regularization, all neurons are discarded according to the probability of 0.3, which simplifies the entire network model, suppresses overfitting, and further improves the classification ability of the model [25].

Dropout regularization can effectively suppress the phenomenon of overfitting. The main idea is that a part of the neurons in each layer of the network is randomly discarded, and the probability of random discarding is set according to the training situation of the model. This paper has carried out many experiments, starting from the probability of 30%, 40%, and 50%. The experimental results show that the random discarding of neurons with a probability of 0.3 is the best. Therefore, this paper sets the dropout regularization parameter to 30%, which simplifies the network structure while suppressing overfitting.

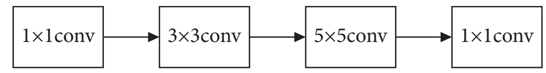

Figure 1: Structure of convolution group convset.

In this paper, the main idea of improving the AlexNet network structure is to replace the 11×11 large convolution kernel with a convolution group of small convolution kernels to extract more subtle features in smart medical financial services, and other convolution layer parameters are set the same. In the overall network structure improvement, convolution groups with small convolution kernels have been introduced 4 times. The two improved methods are given in Table 1. Figures 2 and 3 are the experimental results of the recognition accuracy of the two design methods on the FER2013 and CK+ datasets, respectively.

The results of the cubic and quaternary convolution groups are studied. From Figures 2 and 3, it can be found that the cubic convolution group has higher accuracy than the quaternary convolution group, and the accuracy rate of the quaternary convolution group is higher. In FER2013 and CK+, the two datasets used in this experiment are always slightly lower than the cubic convolution group. In the following fitting, the cubic convolution group is selected.

3.2. UCNN Network Structure. Compared with the classification accuracy, the effect of introducing 3 convolution groups is better, so this paper finally adopts the introduction of 3 convolution groups as the final network model, named UCNN (Unit CNN) network. Figure 4 shows the whole improved network model diagram.

4. Simulation Results and Analysis

This section first introduces the dataset used and then performs data enhancement on the dataset. The improved network model in this paper is used to train and test the expression dataset and compared with a variety of newer expression recognition methods; the comparison results show that the improved network model is more effective. The experimental environment of this paper is a Windows system, the deep learning model is Pytorch, the CPU is Intel i59600kf, and the GPU is NVIDIA GTX1080ti.

4.1. Dataset Processing

4.1.1. FER2013 Dataset. The FER2013 dataset is a commonly used identification research dataset, which itself has been divided into a training set, validation set, and test set. Among them, there are 28,709 training sets, 3,589 validation sets, and 3,589 test sets.

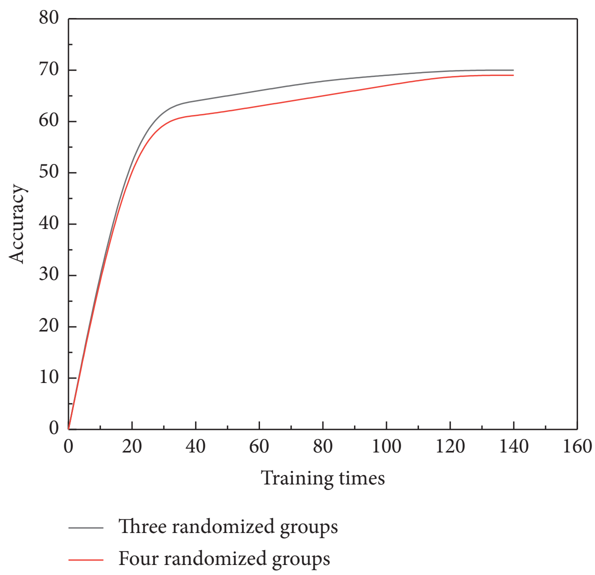

Figure 2: Comparison of two networks on FER2013 dataset.

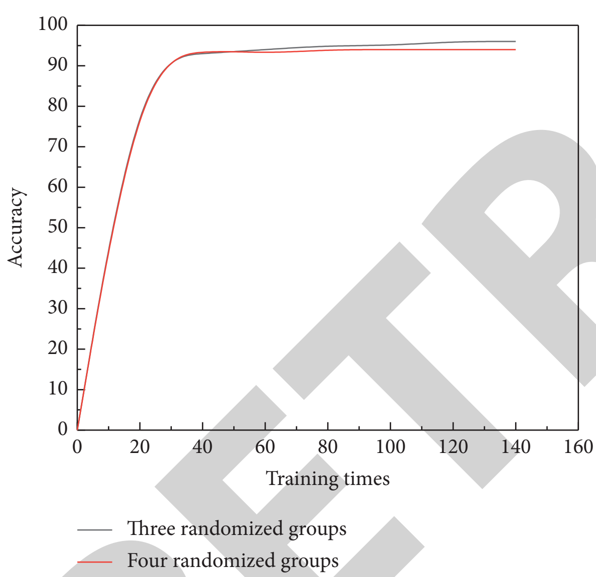

Figure 3: Comparison of two networks on CK+ dataset.

4.1.2. CK+ Dataset. The CK+ dataset was released in 2010. It is a dataset with a larger amount of data obtained by expanding the dataset on the CK dataset. In this paper, 30% of the dataset is divided into the test set, and 70% is divided into the training set.

4.2. Data Augmentation. Convolutional neural networks are often supported by a large number of parameters. Some large neural networks, such as GoogleNet, even have millions of network parameters. To make these huge network parameters work properly, a large amount of data is required. Train the network for a long time. However, the reality is that there is not that much data to work with. Therefore, data augmentation plays a great role in network training. It can expand the amount of data, improve the generalization

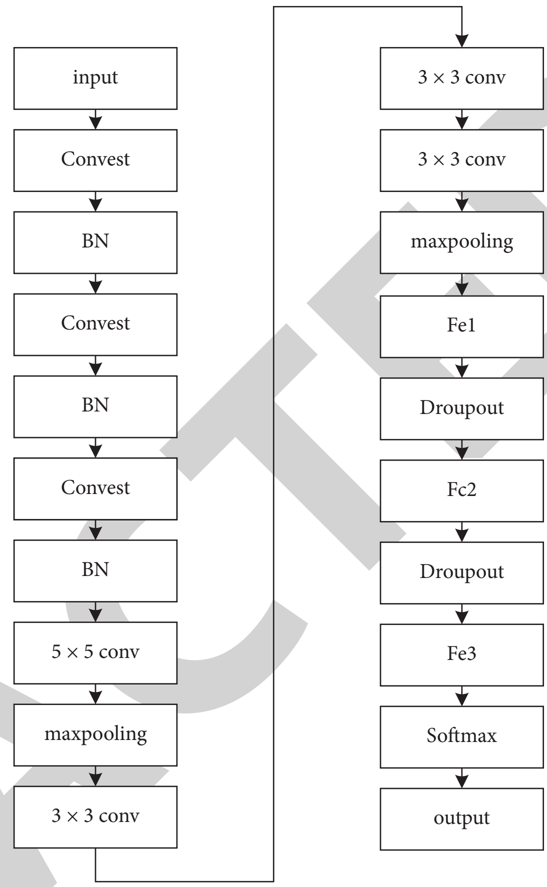

Figure 4: UCNN network structure.

ability of the model, and improve the robustness of the model. The data augmentation method used in this paper is random sampling.

4.3. Improved Analysis. This paper improves the original AlexNet, introduces three convolution groups with small convolution kernels to replace the 11×11 convolution kernels in the original AlexNet, constructs a new network UCNN, and uses the UCNN network on the FER2013 dataset and CK+ dataset, respectively. Train and test: the dataset has been expanded, and the CK+ dataset has been expanded to 2000, of which 70% are used as training sets and 30% are used as test sets. The FER dataset is not expanded, because the amount of data in the original dataset itself is relatively large.

Figures 5 and 6 show the training accuracy and test accuracy of the improved network UCNN on the CK+ dataset and the FER2013 dataset. It can be seen that the UCNN network performs well on the two datasets, where the dotted line represents the training accuracy. The solid line represents the test accuracy, which reached the recognition rate of 98% and 68.01% respectively, and there is no obvious overfitting phenomenon, indicating that the network in this paper has a relatively good generalization ability.

On the FER2013 and CK+ datasets, other network models are used for testing, and compared with the UCNN network, the results are shown in Figures 7 and 8.

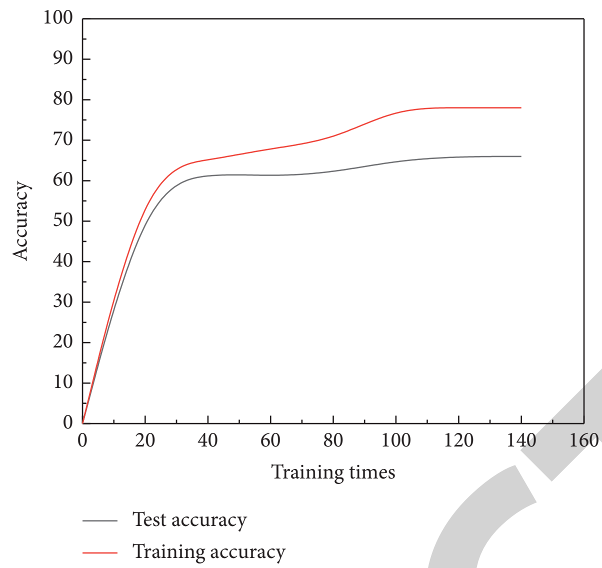

Figure 5: Training and test performance of the UCNN network on FER2013 dataset.

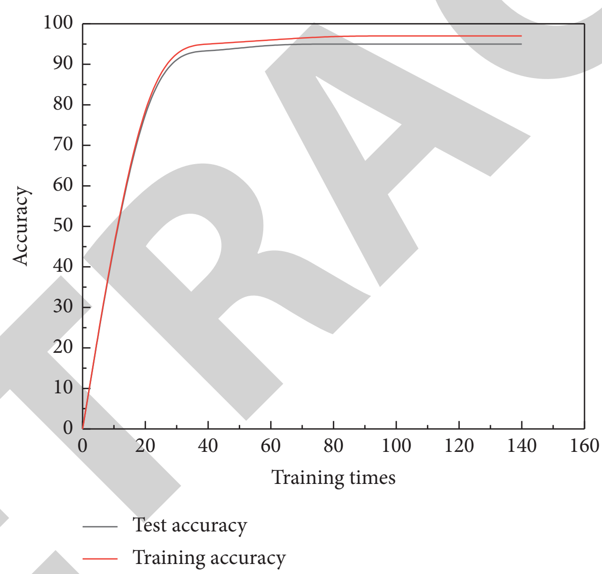

Figure 6: Training and test performance of the UCNN network on CK+ dataset.

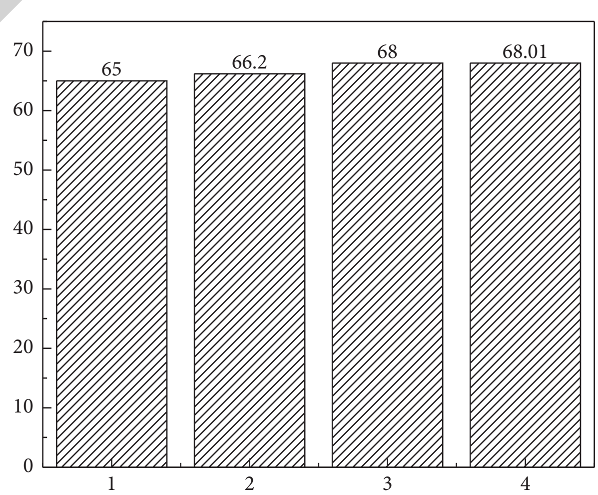

Figure 7: Comparison of training and test performance of recognition rate between this method and other methods on FER2013 dataset.

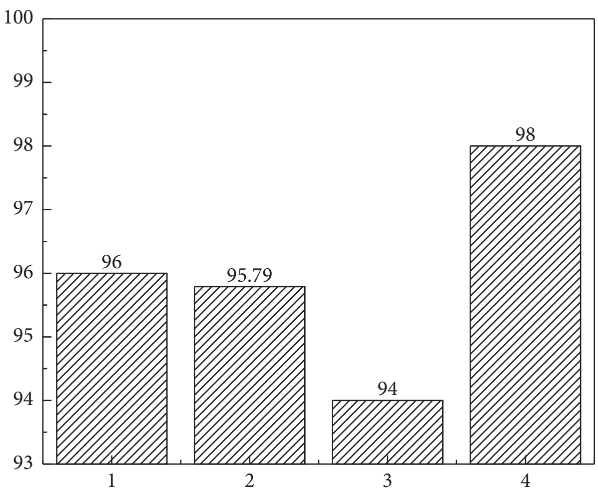

Figure 8: Comparison of recognition rate between this method and other methods on CK+ dataset.

Reference [26], reference [27], and reference [28] all conducted experiments on the FER2013 dataset, and reference [29], reference [30] and reference [31] all conducted experiments on the CK+ dataset. As can be seen from the chart, the method in this paper performs the best on both datasets.

5. Conclusion

The information system compiled according to the internal control requirements objectively enforces and regulates the operation behavior of operators, eliminates arbitrary and subjective factors, and is an important means to reduce the risk of errors and fraud. Aiming at the low utilization rate of small and medium-sized convolutional neural networks in smart medical financial systems, this study designs the UCNN network, which uses the convolution group of small convolution kernels to replace the 11×11 large convolution kernels in the AlexNet network. Small convolution kernels help to extract more subtle features of the original data, thereby improving the recognition rate. A BN batch normalization layer is added after each convolution group to prevent the gradient from disappearing and improve the training speed of the network. In order to reduce the network parameters, a fully connected layer in the original structure is removed, and dropout regularization is added behind the remaining two fully connected layers to further prevent overfitting. During the training process, the dataset was enhanced to solve the problem of insufficient data. The research results are as follows: (1) the improved network UCNN based on AlexNet designed in this paper has a simpler structure, fewer parameters, faster model convergence speed, and higher recognition rate compared with the current newer methods; FER2013 and CK+ datasets achieved recognition rates of 98% and 68.01%, respectively; (2) compared with the quadruple convolution group, the cubic convolution group has higher accuracy, and the accuracy of the cubic convolution group is higher than that of the quaternary convolution group by 67.80% and 96.55%; (3) data enhancement significantly expands the data volume, improves the generalization ability of the model, and improves the robustness of the model [32].

Retracted: Study on the Global Stability for a Generalized SEIR Epidemic Model

Computational Intelligence and Neuroscience

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

In the current study, a generalized SEIR epidemic model is studied. The generalized fractional-order SEIR model (susceptible-infected-recovered (SIR) epidemic) model differentiated the population into susceptible population, exposure population, infected population, and rehabilitation population and has fundamental mentoring importance for the forecast of the probable outburst of infectious ailments. The fundamental duplicated quantity R_0 is inferred. When $R_0 < 1$, the disease-free equilibrium (DFE) is particular and tending towards stability. When $R_0 > 1$, the endemic equilibrium is sole. In addition, certain circumstances are set up to make sure the local progressive stability of disease-free and endemic equilibrium. Considering the influence of the individual behavior, a broader SEIR epidemic model is raised, which classified the population into susceptible, exposure, infected, and rehabilitation. What is more, the basic reproduction number, that regulates whether the infection will die out or not, is obtained by the spectral radius of the next-generation matrix; moreover, the global stability of DFE and endemic equilibrium are analyzed by a geometry method.

1. Introduction

Nowadays, some infectious diseases are still aimed at large populations [1, 2]. They are regarded as the potential causes of death, particularly in numerous developing countries [3, 4]. As a result of this, mathematical modeling in epidemiology plays a more and more important role in public health research [5, 6]. This academic subject facilitates interpreting the studies in epidemiological phenomena and catch the distinctive elements that could result in a serious epidemic or even to a hazardous pandemic in the world [7, 8]. The established susceptible-infected-recovered (SIR) epidemic model was firstly described by Kermackin 1991 [9].The infection latency often needs a long-time range [7] In the meantime, an incubated individual is still latent but hasn't contagious [10]. Consequently, another type of exposed individuals might be supplemented to SIR and the novel epidemic model SEIR was introduced by Ricardo [11]. This SEIR model with treatment and offeredcertain adequate conditions to certify the local stability of equilibrium points. Additionally, epidemiological studies have exposed that mutation leads to more and more unaffected viruses offering the emergence of numerous new damaging epidemics or even new hazardous pandemics [12]. The laws of disease spreading should be urgently investigated because of infectious diseases bring disaster to human health and might provide a theoretical basis for the infection prevention and control [13]. Due to infectious disease existing certain latency before its breaking out, the SEIR epidemic model was researched in a latent period. As described in the study [14], Zhang, Li, and Ma et al. analyzed an SEIR epidemic model with the immigration of different compartments and adequate contact rates and proved the overall stability of the system by variable transformation. In addition, Meng, Chen, and Song introduced the delayed SEIR epidemic model with perpendicular propagation and pulsed vaccination [15].They considered the infection-free periodic solution, which was globally attractive under some appropriate conditions; furthermore, time delay, pulse vaccination and vertical transmission brought obvious efforts to the dynamics of the model. The previous research [16] contained random agitations into SIR and SEIR epidemic models with saturated incidence and set that the solution under some conditions had ergodic property by utilizing the stochastic Lyapunov function. Li and Chen discussed an age structured SEIR epidemic model with vertically and horizontally transformation. They established the threshold of endemic existence and showed threshold parameters usually computable in [17]. Chen et al. [18] investigated an SEIR epidemic Model with a non-monotone incidence, then obtained the global stability. It's worth repeating: the morbidity provides further data about the disease broadcast. Therefore, the overall incidence characteristic has as aim of denoting a big collection of infection incidence rate. Meng group, Michael Y. Li, and Ke Wang in [19] considered an SEIR epidemic model for the dynamic transmit of communicable disease that propagate in population by connecting to hosts and analyzed a geometric method to global stability. A great deal of processes of mutation was detected in a large number of communicable diseases. Due to this reason, the multi-strain SEIR epidemic model is a critical tool for investigating a number of communicable diseases that comprise a lengthy incubation period and also diverse infection strains. The correlation of learning multi-strain models is finding out the diverse situations allowing all operating strains to coexist. The global dynamics of the SEIR model is the focus of numerous explorations by studying bilinear or nonlinear incidence. In the current study, a comprehensive SEIR epidemic model is studied, and the threshold is obtained. By the method of geometric approach, global stability of disease-free equilibrium (DFE) and endemic equilibrium are analyzed; furthermore, the infection will die away if $R_0 < 1$, or become endemic if $R_0 > 1$.

2. Preliminaries and Model Derivation

The incidence provides further evidence about the spread of the disease [20] Therefore, the goal of the general incidence rate function is to characterize the incidence rate of a large group of infections. Consequently, the aim of this study is to summarize the earlier models by thinking over a SEIR model with general prevalence rate. Therefore, this current study would be carried out on the subsequent comprehensive SEIR epidemic model:

$$\begin{cases} \dfrac{dS}{dt} = A - f(S, I) - dS, \\[2ex] \dfrac{dE}{dt} = f(S, I) - \varepsilon E - dE, \\[2ex] \dfrac{dI}{dt} = \varepsilon E - \delta I - dI, \\[2ex] \dfrac{dR}{dt} = \delta I - dR, \end{cases} \tag{1}$$

where (S)is the numbers of susceptible population; (E)is the numbers of each latent individual's class;(I) denotes the amount of communicable population;(R) is the amount of deleted population; With regard to the issues coping with population dynamics, all the variables might be positive. We would suppose firstly that all the model indicators are positive. The paraments A is positive constant, which represents the birth rate of the population. The paraments d is positive invariable too, which represents the death rate of the population. The non-negative constant ε describes the transfer rates from exposed to infected, and the non-negative constant δ describes the transmission rates from infection to recovery. The function f (S, I) represents the ratio of new infection and is expected to be sufficiently smooth to ensure the existence and uniqueness of solution to the system (1) with non-negative initial situations. By the functional framework of basic theory of differential equations, we verify that there is a particular local solution to the issues. To verify the positive results, we would demonstrate that any settlement beginning from positive orthant. To meet biological sense, the function f (S, I) is assumed to fulfill the conditions as below for all S ≥ 0, I ≥ 0:

(a) $f(0,0) = f(S,0) = f(0,I) = 0$,
(b) $f(S,I) > 0$ for $S > 0$, $I > 0$,
(c) $\partial f(S,I)/\partial S \geq 0$, $(\partial f(S,I)/\partial I) > 0$,
(d) $I(\partial f(S,I)/\partial I) \geq f(S,I)$,
(e) $I(\partial f(S,I)/\partial I) - E(\partial f(S,I)/\partial S) - f(S,I) > 0$.

The total population $N = S + E + I + R$ satisfies $N' = A - dN$ may vary in time. It is easy to see the population scale N converges to (A/d) without disease, thus we study system (1) in the following feasible region:

$$D = \left\{(S, E, I, R) \in R_+^4 \colon S + E + I + R \leq \frac{A}{\mathrm{d}}\right\}. \tag{2}$$

Which is a positive invariant set in R_+^4, represents the border and inner of D by ∂D and D° respectively.

The condition (a) ensures the existence of unique DFE $P_0(A/\mathrm{d}, 0, 0, 0) \in \partial D$ for system (1). Setting the right-hand sides of the last three equation to zero, and the sum of the first two equation to zero, it is easy to obtain a particular endemic equilibrium $P^*(S^*, E^*, I^*, R^*)$, where,

$$\begin{aligned} S^* &= \frac{A\varepsilon - (\mathrm{d}+\varepsilon)(\mathrm{d}+\delta)I^*}{\mathrm{d}\varepsilon}, \\ E^* &= \frac{\mathrm{d}+\delta}{\varepsilon}I^*, \\ R^* &= \frac{\delta}{\mathrm{d}}I^* \end{aligned} \tag{3}$$

Simultaneously obtained

$$\begin{aligned} f(S^*, I^*) &= \frac{(\mathrm{d}+\varepsilon)(\mathrm{d}+\delta)}{\varepsilon}I^*, \\ \frac{\partial f}{\partial I}(S^*, I^*) &= \frac{(\mathrm{d}+\varepsilon)(\mathrm{d}+\delta)}{\varepsilon}. \end{aligned} \tag{4}$$

3. The Basic Reproduction Number

In this section, the basic reproduction number R_0 is studied. R_0 is clarified as the spectral radius of next-generation matrix in [7], i.e.

In this section we study the fundamental reproduction number R_0, R_0 is expressed as the spectral radius of next-generation matrix in [7], i. e. $R_0 = \rho(FV^{-1})$. In system (1), only E and I is directly related to epidemic. There followed the way of van den driessche and Watmough, that is

$$\begin{pmatrix} \frac{dE}{dt} \\ \\ \frac{dI}{dt} \end{pmatrix} = \begin{pmatrix} f(S,I) \\ \\ 0 \end{pmatrix} - \begin{pmatrix} (d+\varepsilon)E \\ \\ -\varepsilon E + (d+\delta)I \end{pmatrix},$$

$$F = \begin{pmatrix} 0 & \frac{\partial f}{\partial I}\left(\frac{A}{d},0\right) \\ \\ 0 & 0 \end{pmatrix}, \tag{5}$$

$$V = \begin{pmatrix} d+\varepsilon & 0 \\ \\ -\varepsilon & d+\delta \end{pmatrix},$$

then $V^{-1} = (1/(d+\varepsilon)(d+\delta))\begin{pmatrix} d+\delta & 0 \\ \varepsilon & d+\varepsilon \end{pmatrix}$

The next-generation matrix is

$$FV^{-1} = \frac{1}{(d+\varepsilon)(d+\delta)} \begin{pmatrix} \varepsilon \frac{\partial f}{\partial I}\left(\frac{A}{d},0\right) & (d+\varepsilon)\frac{\partial f}{\partial I}\left(\frac{A}{d},0\right) \\ \\ 0 & 0 \end{pmatrix}. \tag{6}$$

Hence the fundamental reproduction number as,

$$R_0 = \frac{\varepsilon}{(d+\varepsilon)(d+\delta)} \frac{\partial f}{\partial I}\left(\frac{A}{d},0\right). \tag{7}$$

4. Global Stabilities of Disease-free Equilibrium (DFE)

The disease-free equilibrium (DFE) is characterized by the demising of the infecting, and the sickness could not attack the individuals. The DFE first nonzero component is determined by the infant natality and mortality of the predisposed population and does not rely on the morbidity functional indicators. The infection disappeared, the susceptibility gets their greatest numerical, and the rest of variables eliminate. In this paragraph, concentration might be concentrated to the statistical stability of this DFE. In fact, we could suppose the stability of DFE when the fundamental reproduction quantity is less than the unified value. This makes us to seek for the proper model indicators to inspect statistically the steadiness of the original stable status.

By the framework of van den Driessche and Watmough [21], we immediately obtained the following local asymptotical stability of DFE:

Theorem 1. *Allow R_0 be defined in (7), the unique DFE of system (1) is local asymptotical stability provided that $R_0 < 1$ and unsteady provided that $R_0 > 1$.*

To explore the global stability of DFE, the following result explained in [22]is needed:

Lemma 1. *Take into account a model expressed in a form*

$$\begin{cases} \frac{dX_1}{dt} = F(X_1, X_2), \\ \\ \frac{dX_2}{dt} = G(X_1, X_2), G(X_1, 0) = 0, \end{cases} \tag{8}$$

where $X_1 \in R^m$ represents the amount of population without infection and $X_2 \in R^m$ represents the sum of infected population containing potential, infectious, etc; $X_0 = (X_1^*, 0)$ indicates the DFE of system (8).

Also suppose the conditions (H1) and (H2) as following:

(H1) For $dX_1/dt = F(X_1, 0)$, X_1^* is global asymptotical stability.

(H2) $G(X_1, X_2) = AX_2 - \widehat{G}(X_1, X_2)$, $\widehat{G}(X_1, X_2) \geq 0$ for $(X_1, X_2) \in \Omega$, the Jacobian matrix $A = (\partial G/\partial X_2)(X_1^*, 0)$ is an M-matrix and Ω is the feasible region.

Then the DFE $X_0 = (X_1^*, 0)$ is global asymptotical stability if $R_0 < 1$.

Theorem 2. *The DFE of system (1) is global asymptotical stability if $R_0 < 1$.*

Proof. In system (1), permit $X_1 = (S, R)^T$,$X_2 = (E, I)^T$, the uninfected model is

$$\begin{pmatrix} \frac{dS}{dt} \\ \\ \frac{dR}{dt} \end{pmatrix} = F(X_1, X_2) = \begin{pmatrix} A - f(S,I) - dS \\ \\ \delta I - dR \end{pmatrix}, \tag{9}$$

the infected model is

$$\begin{pmatrix} \frac{dE}{dt} \\ \\ \frac{dI}{dt} \end{pmatrix} = G(X_1, X_2) = \begin{pmatrix} f(S,I) - (d+\varepsilon)E \\ \\ \varepsilon E - (d+\delta)I \end{pmatrix}. \tag{10}$$

and $G(X_1, 0) = 0$.

Next requireto verify the conditions (H1) and (H2).

When $X_2 = 0$, i.e. $E = I = 0$, the model (9) is

$$\begin{pmatrix} \frac{dS}{dt} \\ \\ \frac{dR}{dt} \end{pmatrix} = \begin{pmatrix} A - dS \\ \\ -dR \end{pmatrix}. \tag{11}$$

And the solution of system (11) is $S(t) = A/d - (S(0) - (A/d))e^{-dt}, R(t) = R(0)e^{-dt}$.

It is easy to see $S(t) \longrightarrow A/d, R(t) \longrightarrow 0$, as $t \longrightarrow +\infty$. Hence $X_1^*(A/d, 0)$ is global asymptotical stability. The condition (H1) is verified.

$$G(X_1, X_2) = \frac{\partial G}{\partial X_2}(X_1^*, 0)X_2 - \widehat{G}(X_1, X_2)$$

$$= \begin{pmatrix} -(\mathrm{d}+\varepsilon) & \dfrac{\partial f}{\partial I}\left(\dfrac{A}{\mathrm{d}}, 0\right) \\ \varepsilon & -(\mathrm{d}+\delta) \end{pmatrix} \begin{pmatrix} E \\ I \end{pmatrix} - \begin{pmatrix} I\dfrac{\partial f}{\partial I}\left(\dfrac{A}{\mathrm{d}}, 0\right) - f(S, I) \\ 0 \end{pmatrix}, \tag{12}$$

obviously $A = (\partial G/\partial X_2)(X_1^*, 0)$ is an M-matrix. According to assumption (d) we obtain $\widehat{G}(X_1, X_2) \geq 0$. The condition (H2) is verified.

According to Lemma 1, The DFE $P_0(A/\mathrm{d}, 0, 0, 0)$ of system (1) is global asymptotical stability if $R_0 < 1$. □

5. Global stabilities of endemic equilibrium

Theorem 3. *There exists a unique positive endemic equilibrium for system (1) if $R_0 > 1$, and no positive endemic equilibrium if $R_0 < 1$.*

Let $F(I) = f(S^*, I)/I = f(A\varepsilon - (d+\varepsilon)(d+\delta), I/d\varepsilon, I)/I$, $y = (d+\varepsilon)(d+\delta)/\varepsilon$. Let y=F(I)

$$f\left(\frac{A\varepsilon - (\mathrm{d}+\varepsilon)(\mathrm{d}+\delta)I}{\mathrm{d}\varepsilon}, I\right) = \frac{(\mathrm{d}+\varepsilon)(\mathrm{d}+\delta)}{\varepsilon}. \tag{13}$$

It is clearly to see $F(I) = 0$ at $I = (A\varepsilon/(\mathrm{d}+\varepsilon)(\mathrm{d}+\delta))$, then

$$F(I) < \frac{(\mathrm{d}+\varepsilon)(\mathrm{d}+\delta)}{\varepsilon}. \tag{14}$$

with the help of inequality (d)

$$\lim_{I\longrightarrow 0^+} F(I) = \lim_{I\longrightarrow 0^+} \frac{f(A/\mathrm{d}, 0)}{I} = \frac{\partial f}{\partial I}\left(\frac{A}{\mathrm{d}}, 0\right) > \frac{(\mathrm{d}+\varepsilon)(\mathrm{d}+\delta)}{\varepsilon}. \tag{15}$$

The equation y =F(I) has unique solution if and only if $\partial f/\partial I(A/\mathrm{d}, 0) > ((\mathrm{d}+\varepsilon)(\mathrm{d}+\delta)/\varepsilon)$, then $\varepsilon\partial f/\partial I(A/\mathrm{d}, 0)/(\mathrm{d}+\varepsilon)(\mathrm{d}+\delta) > 1$, namely $R_0 > 1$.

Clearly $R_0 > 1$, there is a unique positive endemic equilibrium for system (1), and no positive endemic equilibrium for $R_0 < 1$.

Theorem 4. *The unique positive endemic equilibrium of system (1) is local asymptotical stability provided that $R_0 > 1$.*

Proof To study the local asymptotical stability, the equivalent system of (1) is researched

$$\begin{cases} \dfrac{dS}{dt} = A - f(S, I) - dS \\ \dfrac{dE}{dt} = f(S, I) - (d+\varepsilon)E \\ \dfrac{dI}{dt} = \varepsilon E - (d+\delta)I. \end{cases} \tag{16}$$

The Jacobian matrix of system (16) is

$$J = \begin{pmatrix} -\dfrac{\partial f}{\partial S}(S, I) - d & 0 & -\dfrac{\partial f}{\partial I}(S, I) \\ \dfrac{\partial f}{\partial S}(S, I) & -(d+\varepsilon) & \dfrac{\partial f}{\partial I}(S, I) \\ 0 & \varepsilon & -(d+\delta) \end{pmatrix}, \tag{17}$$

and the characteristic equation at $P^*(S^*, E^*, I^*, R^*)$ is

$$\mathrm{Det}\,(\lambda E - J) = \lambda^3 + a_1\lambda^2 + a_2\lambda + a_3 = 0, \tag{18}$$

where $a_1 = 3\,d + \varepsilon + \delta + (\partial f/\partial S)(S^*, I^*) > 0$, $a_2 = (\partial f/\partial S(S^*, I^*) + d)(2\,d + \varepsilon + \delta) > 0$,

$$a_3 = \varepsilon\frac{\partial f}{\partial I}(S^*, I^*)\frac{\partial f}{\partial S}(S^*, I^*) > 0. \tag{19}$$

In order to prove all roots, have negative real parts, using (4) and obtain $a_1 > d + \varepsilon$, $a_2 > \partial f/\partial S(S^*, I^*)(d+\delta)$, $a_3 = (d+\varepsilon)(d+\delta)\partial f/\partial S(S^*, I^*)$, therefore $a_1a_2 - a_3 > 0$.

According to Routh-Hurwitz theory the unique positive endemic equilibrium of system (1) is local asymptotical stability provided that $R_0 > 1$.

Theorem 5. *The unique positive endemic equilibrium of system (1) is global asymptotical stability provided that $R_0 > 1$.*

Proof In line with Theorem 1 the unique DFE of system (1) is unstable provided that $R_0 > 1$, and $P_0(A/\mathrm{d}, 0, 0, 0) \in \partial D$, then system (1) is uniform persistence [23], i.e. $\exists c > 0$, $\lim_{t\longrightarrow\infty} \inf\{S(t), E(t), I(t)\} > c$. Uniform persistence implies the presence of compact subsets $K \subset D$. It is easy to see system (1) satisfies the conditions in [24].

Next, we only need to prove the Bendixson criterion $q < 0$.

The Jacobian matrix of system (16) is (17), and the associated second compound matrix is,

$$J^{[2]} = \begin{pmatrix} -\dfrac{\partial f}{\partial S}(S, I) - (2\,d+\varepsilon) & \dfrac{\partial f}{\partial I}(S, I) & \dfrac{\partial f}{\partial I}(S, I) \\ \varepsilon & -\dfrac{\partial f}{\partial S}(S, I) - (2\,d+\delta) & 0 \\ 0 & \dfrac{\partial f}{\partial S}(S, I) & -(2\,d+\varepsilon+\delta) \end{pmatrix}. \tag{20}$$

Let the matrix function $P(S, E, I) = \mathrm{diag}(1, E/I, E/I)$, then

$P_fP^{-1} = \mathrm{diag}(0, (E'/E) - (I'/I), (E'/E) - (I'/I))$, matrix $B = P_fP^{-1} + PJ^{[2]}P^{-1}$ can be written in the form

$B = \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix}$ where $B_{11} = -(2\ d + \varepsilon) - \partial f/\partial S(S, I), B_{12} = [\partial f/\partial I(S, I)I/E, \partial f/\partial I(S, I)I/E], B_{21} = [\varepsilon(E/I), 0]^T$,

$$B_{22} = \begin{pmatrix} \frac{E'}{E} - \frac{I'}{I} - (2\ d + \delta) - \frac{\partial f}{\partial S}(S, I)0 \\ \\ \frac{\partial f}{\partial S}(S, I)\frac{E'}{E} - \frac{I'}{I} - (2\ d + \varepsilon + \delta) \end{pmatrix}. \tag{21}$$

We define a norm $\|(u, v, w)\| = \max\{|u|, |v + w|\}$ for any vector (u, v, w) in R^3, and $\mu(B)$ denote the Lozinskil measure with respect to this norm. Using the valuation method in [25] we have $\mu(B) \leq \sup(g_1, g_2)$, with $g_1 = \mu_1(B_{11}) + |B_{12}|$, $g_2 = |B_{21}| + \mu_1(B_{22})$. $|B_{12}|$, $|B_{21}|$ are the matrix norm about l_1 vector norm, μ_1 is Lozinskil measure about l_1 norm. For example, $|A| = \max_{1\leq k\leq n} \sum_{i=1}^{n} |a_{ik}|, \mu_1(A) = \max_{1\leq k\leq n}(a_{kk} + \sum_{i=1, i\neq k}^{n} |a_{ik}|)$ for any matrix $A = (a_{ij})_{n\times n}$, then

$$\begin{aligned} \mu_1(B_{11}) &= -(2d + \varepsilon) - \frac{\partial f}{\partial S}(S, I), |B_{12}| = \frac{\partial f}{\partial I}(S, I)\frac{I}{E}, |B_{21}| = \varepsilon\frac{E}{I}, \\ \mu_1(B_{22}) &= \frac{E'}{E} - \frac{I'}{I} - (2d + \delta). \end{aligned} \tag{22}$$

Hence

$$\begin{aligned} g_1 &= -(2\ d + \varepsilon) - \frac{\partial f}{\partial S}(S, I) + \frac{\partial f}{\partial I}(S, I)\frac{I}{E}, \\ g_2 &= \varepsilon\frac{E}{I} + \frac{E'}{E} - \frac{I'}{I} - (2\ d + \delta). \end{aligned} \tag{23}$$

From system (16), we obtain $I'/I = \varepsilon(E/I) - (d + \delta)$ and $-(d + \varepsilon) = (E'/E) - (f(S, I)/E)$, then $g_2 = E'/E - d$ and $g_1 = ((E'/E) - (f(S, I)/E) - d - (\partial f/\partial S)(S, I) + (\partial f/\partial I)(S, I)(I/E))$, by assumption (e), $g_1 = ((E'/E) - d - (\partial f/\partial S)(S, I) < (E'/E) - d)$, then $\mu(B) \leq \sup(g_1, g_2) = (E'/E) - d$.

Since system (1) is uniform persistence, there is $\xi > 0, T > 0$ so that when $t > T$, $E(t) > \xi, I(t) > \xi$ for all $(S(0), E(0), I(0)) \in K$, we have $1/t \ln(E(t)/E(0)) < \mathrm{d}/2$, then $1/t \int_0^t \mu(B)\mathrm{d}s \leq (1/t)\ln E(t)/E(0) - d < -(\mathrm{d}/2)$, namely

$q = \lim_{t\to\infty} \sup \sup_{x_0\in K} 1/t \int_0^t \mu(s, x_0)\mathrm{d}s < -(\mathrm{d}/2) < 0$, thus, the associated second compound matrix is local asymptotical stability, verified the proof.

6. Discussion and conclusion

It is well described that the spreading of a contagious illness implicates disease-related elements including infectious mediator, route of broadcast, latent period, infectious stage, susceptivity, and resistance [26]. Infectious disease model defining a spread mediators in an enclosed population and containing susceptible (S), infectives (I), and recovers (R) were introduced by Kermack in 1927. According to the Kermack model, diverse epidemic models have been advanced in current periods, such as SIR, SIS, SEIR models [27]. Functional form of the incidence rate plays a critical role in of epidemic model. Several previous studies highlight that the route of disease transmission might have a nonlinear incidence ratio [28]. To explore the effect of the non-linearity, Korobeinikov take into account diversified models with the incidence and set up Lyapunov functions that make them to create global properties for SEIR model. Thereafter, Korobeinikov proven global properties for multiple epidemic models with incidence of a more commonformula [29].

In the current study, we have explored the global stability of the generalized SEIR model with quantitative overview of the complex analysis and certain qualitative characteristics of the SEIR model have been discussed. This model included some compartments, namely the susceptible, exposing individuals, infecting individuals, and the removal individuals. We have created the existence, positivity and boundedness of settlement which ensure the well-formedness of the SEIR model. To validate our distinctive results theoretically, numerical simulation is carried out. It is measured that the model with extensive association capabilities contains many typical correlation features, which could better understand the equilibrium stability. The long-term forecast desires to amend the model properly based on the alteration of strategic and medical aspects. We might talk about this in the future work.

In order to explore the real effect of art mental health therapy, this paper proposes a feature selection algorithm based on genetic algorithm. The algorithm takes college students as the research object and discusses the effect of psychotherapy on college students through painting art therapy. The results showed that there were extremely significant differences in EPQ extraversion factors among the people treated with the educational intervention of art psychology course ($P < 0.01$), and there was no significant change in other factors ($P > 0.05$). There was no significant change in total depression score and depression index ($P > 0.05$). There were significant differences in social avoidance factors and social anxiety ($P < 0.05$), and there were relatively significant differences in the total score of sadness ($P < 0.01$). It is concluded that the use of artistic elements can effectively help people express themselves and express their psychological emotions, which has a certain effect in mental health treatment.

1. Introduction

Before the formation of language and words, early human beings mainly used graphics and painting to record events in life and through graphics to reflect emotions and ideas of colossus. Therefore, the artistic expression in the form of graphics and painting is the innate instinct of human beings. The key point of artistic therapy is to effectively integrate different forms of art types into psychotherapy and, at the same time, use artistic media such as painting, music, and dance to promote the growth of people's mind and cure people's psychological problems in a supportive environment. Therefore, art psychotherapy is also a process of discovering and expressing oneself with the help of art forms derived from the depths of emotion. And in the process of self-psychotherapy using art forms, people usually do not pay too much attention to the beauty of visual art, the grammatical arrangement of words, and the harmony and fluency of songs. They just use art to release, express and relax, and obtain insight by studying symbolic and metaphorical information to achieve the effect of psychotherapy, as shown in Figure 1.

2. Literature Review

Modern psychotherapy with speech as the medium has a good effect in correcting irrational cognition and thinking, but it is powerless in dealing with psychological problems with emotional distress as the main symptoms, such as emotional disorder and traumatic experience. In brain science, emotion and art (painting, music, etc.) are controlled by the right hemisphere at the same time. Therefore, even speech therapists with rich clinical experience do not despise the excellent effect of painting in dealing with emotional distress. A large number of studies abroad have proved the artistic way of using the right hemisphere to deal with emotional disorder [1].

Children with family and development problems were treated with spontaneous painting creation method. It was found that painting therapy can alleviate the pressure from family and society, express anxiety, and strengthen the self-concept of visitors [2]. Individual and group painting therapy was carried out for children with learning disabilities. It was found that, in the treatment, children and peers

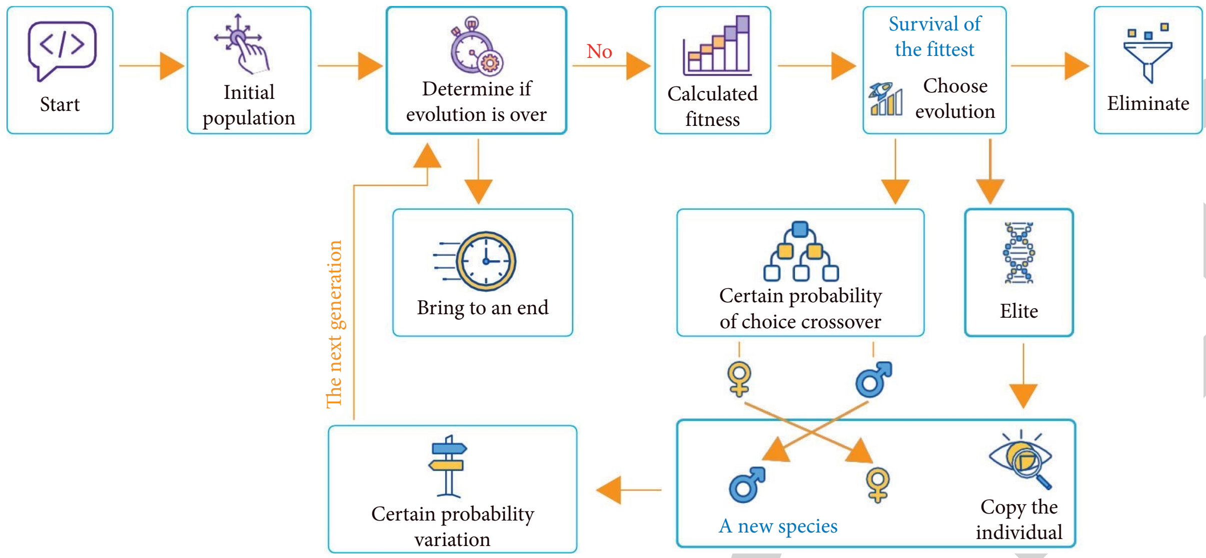

Figure 1: Comprehensive evaluation model of artistic psychotherapy health based on genetic algorithm.

promoted the development of social skills through interpersonal interaction and finally improved individual self-esteem. Babin applied painting psychotherapy to 3 women with anorexia and 3 women with obesity. The results showed that the self-concept of 5 women was significantly improved [3]. It is found that painting intervention can promote homeless women to improve their sense of self-esteem and self-awareness. The research of some scholars has found a physiological basis for painting to promote the improvement of self-esteem. He found that fluctuations in the amount of neurotransmitter serotonin in the brain can affect the quality of movement and the level of self-esteem. The high content of serotonin is related to self-affirmation and movement control, and the low content is easy to lead to anger and impulsive behavior. Human life depends on movement, and effective and elegant movement produces a sense of satisfaction. The training provided by art happens to produce such skill movements. The display of these movements leads to positive feedback among people, thus strengthening self-esteem [4].

Since the 1940s, psychologists have also developed a variety of painting projection techniques for psychotherapy and testing, but basically painting projection techniques can be divided into three categories: free painting, painting with specified content, and painting techniques in between. The first is free painting technology. The stimulation given is only paper and pen, giving the visitor the greatest freedom to express the inner world he is most eager to express. However, analysts need extensive knowledge background and rich analysis experience, which makes it difficult to quantify and ensure reliability and validity. The second category is the painting technology that specifies the content. Fang Shuren painting test is the most comprehensive and widely used typical representative. It gives standard guidelines and has certain provisions on content, tools, and location, which is more conducive to the popularization of experience and application in experimental research. The last one is between the two. It gives a certain stimulation, but it does not regulate what content to paint at the same time. In addition, the final analysis of this technology is not for the painting content of the subjects, but for the nature of the changes made by the subjects on the given stimulus [5].

Domestic painting psychotherapy has also achieved some applied research results in the treatment and diagnosis of mental disorders, special groups such as intellectual disabilities, crisis intervention and psychological education, and group psychological counseling and treatment [6].

In the study of a case of children's depression, painting image was used to regulate children's depression, and the effect was remarkable. This paper discusses the application of painting therapy in middle school students with emotional disorders and uses the room tree person test method to treat 6 middle school students who come to psychological counseling. It is found that the use of painting therapy can better understand the causes of middle school students' emotional conflict and has played a good effect in the process of psychological counseling. The study tried to use painting projection technology, free association, and positive imagination in a psychological counseling case of depression to fully present the patient's past experience, internal image, and unconsciousness and communicate the patient's consciousness and unconsciousness. The results show the patient's inner growth and development, and the performance has been changed and transformed in real life. Through the experimental treatment of college students' depressive symptoms through painting aesthetic treatment activities, the results show that the design can significantly improve the level of college students' depressive symptoms, promote the college students with depressive symptoms, and significantly improve the overall mental health level of the subjects. Its effect is mainly reflected in the significant improvement of four factors: somatization, interpersonal sensitivity, psychosis, and paranoia [7].

A team explored the effect of group painting art therapy on the rehabilitation of physiological, psychological, and social functions of schizophrenic patients. The results show that group painting art intervention can alleviate the mental symptoms of schizophrenic patients and promote the improvement of patients' self-concept and quality of life. The application of painting therapy in interpersonal group counseling is an effective method for college students with development crisis, personality problems, and international communication problems. Through group counseling, the self-acceptance of members can be improved, the sense of self-harmony can be enhanced, and the level of self-esteem can be improved to varying degrees. Group counseling promotes the personality growth of members as a whole and improves their mental health level. Collective painting therapy starts from the two points of collectivity and painting to easily create a treatment environment and guide most people. Patients talked about its novelty and being easy to understand after treatment. As an auxiliary form of psychotherapy, painting therapy has its uniqueness [8].

3. Unsupervised Feature Selection Algorithm Based on Genetic Algorithm

3.1. Feature Selection Algorithm. Feature selection, at first, is a technology in the classification problem. The purpose is to find out which features have a great influence on the label, minimize the influence of irrelevant features in the classifier training process, and avoid overfitting and high time complexity. From the definition, the process of feature engineering is mainly composed of the following aspects, as shown in Figure 2.

Feature selection algorithms often use some evaluation criteria to measure the candidate subsets. The evaluation criteria are divided into two categories according to whether they are related to the subsequent machine learning model. One kind of evaluation criteria is independent of the learning model and evaluates the feature selection as an independent process. This feature selection algorithm is called filter algorithm. This feature selection process is shown in Figure 3 below.

The other is called wrapper algorithm. In this algorithm, the evaluation criterion is the performance of the subsequent machine learning model. In this process of machine learning, feature selection is a part of the establishment of machine learning model [9]. For each candidate feature subset, the model needs to be retrained. The specific process is shown in Figure 4.

In the field of practical application, when the feature dimension is high and there are many redundant features, these two hybrid strategies are often used for feature selection. Firstly, the independent evaluation criterion algorithm is used to preliminarily evaluate the features and quickly eliminate most irrelevant features. Then, the encapsulated feature selection is carried out for the remaining few features to obtain the feature subset with the best neutral energy for the subsequent machine learning model [10].

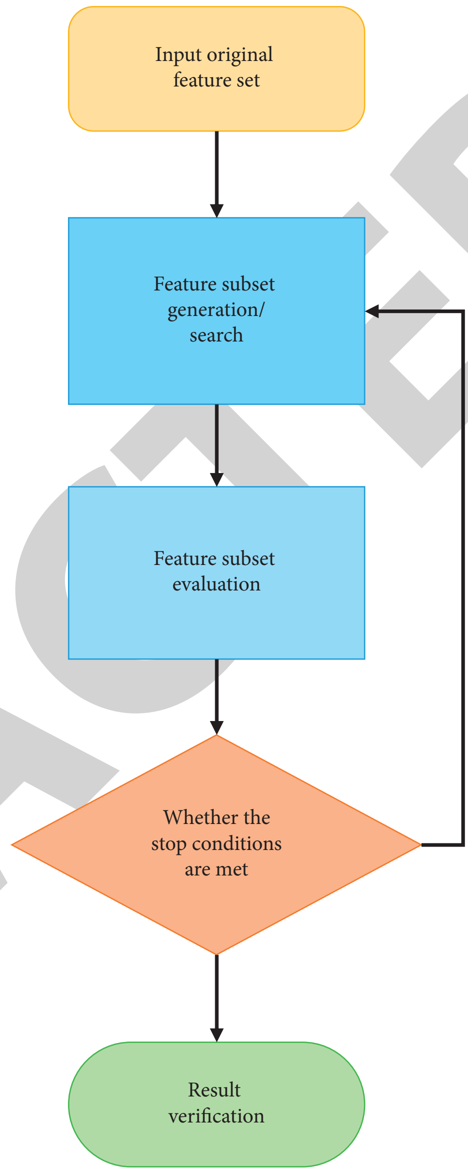

Figure 2: Feature selection process.

3.2. Genetic Algorithm

3.2.1. Conceptual Process. The core idea of the algorithm is to characterize the iterative process of the solution of the optimization problem by the heredity of genes in the population. Among them, the population represents the set of all feasible solutions, and each individual gene in the population represents a feasible solution. By artificially setting a natural environment (fitness function, or evaluation function), the way of survival of the fittest in nature is simulated. Filter the individuals in the population that are not suitable for the natural environment and inherit the individual genes suitable for the environment. Through the characteristics of gene crossover and variation in the genetic process, the offspring population can not only retain the characteristics of good solutions in the previous generation population, but also retain the possibility of producing better solutions

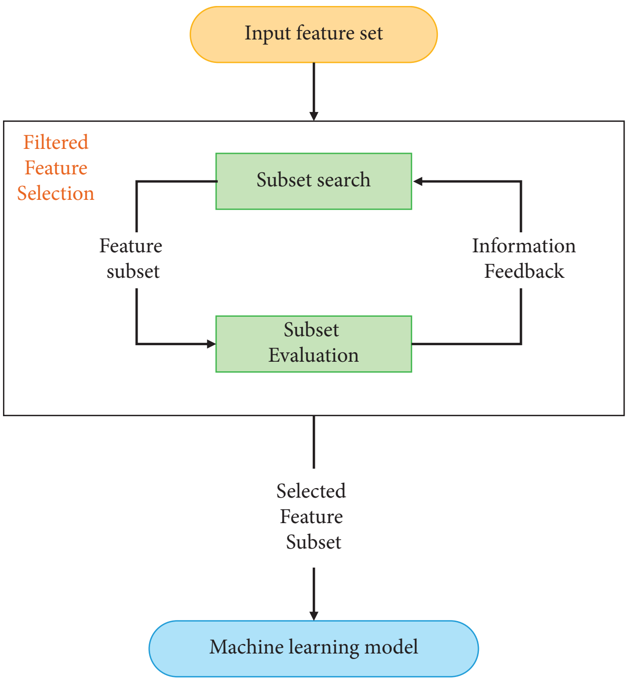

Figure 3: Filter feature selection process.

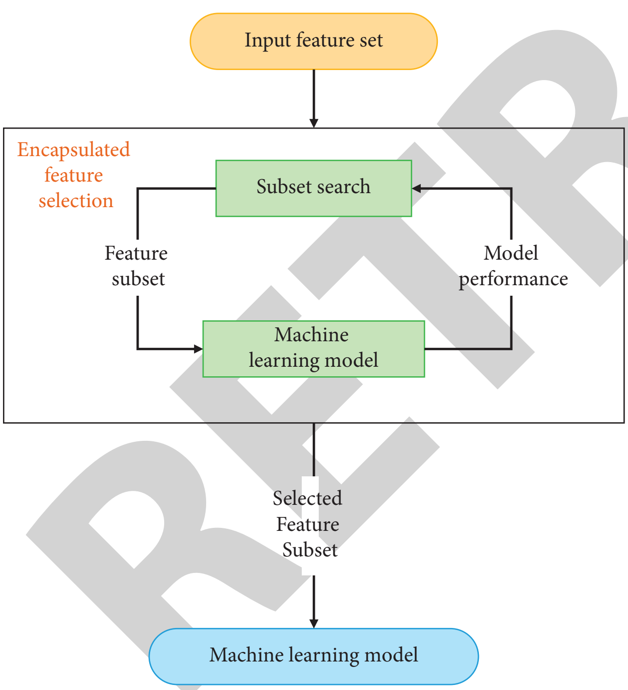

Figure 4: Wrapper feature selection process.

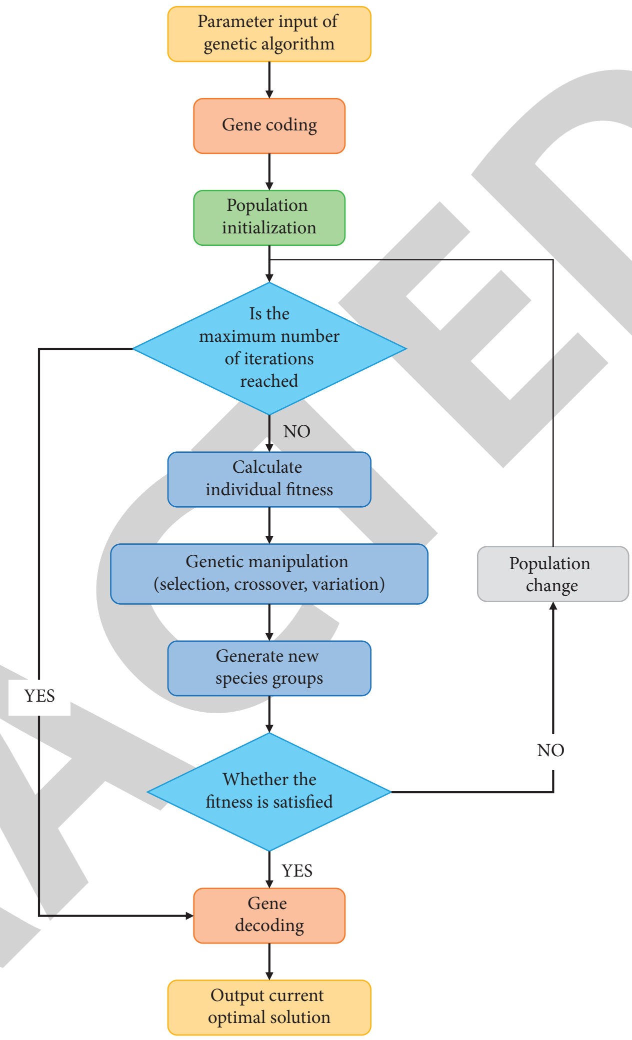

Figure 5: Principle of genetic algorithm.

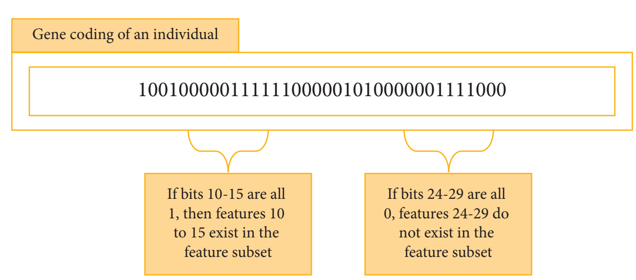

Figure 6: Coding of a gene.

[11]. The flow of genetic algorithm is shown in Figure 5 below.

In the feature selection problem, as shown in Figure 6, for a data set with feature number n, a binary gene sequence with length n is usually used to represent a feasible solution. In each gene, 0 indicates that the feature is not in the individual, and 1 indicates that the feature exists in the individual. Each coding sequence represents an individual [12].

3.2.2. Definition of Population Genetic Mode. Roulette selection algorithm: roulette selection algorithm comes from roulette gambling. The main principle is that, on the roulette surface, regions with different angles have different probability of being selected; that is, the larger the proportion, the easier it is to be selected. In the feature selection algorithm, the higher the fitness, the easier it is to be selected. In a population with N individuals, for individual x_i, given its fitness $f(x_i)$, the probability of individual selection is carried out according to the following algorithm:

(1) Use formula (1) below to calculate the individual fitness ratio, which is similar to the ratio of different areas on the roulette.

$$p(x_i) = \frac{f(x_i)}{\sum_{j=1}^{N} f(x_i)}. \tag{1}$$

(2) Calculate the cumulative fitness distribution from x_1 to x_N, similar to the probability distribution function, as shown in formula (2) below:

$$q_i = \sum_{j=1}^{i} p(x_i). \tag{2}$$

(3) Take random number as shown in formula (3):

$$r \in (0, 1). \tag{3}$$

If the following formula is satisfied, it is shown in formula (4):

$$q_{i-1} < r q_i > r, i > 1. \tag{4}$$

Then select individual x_i; otherwise select individual x_1. It can be seen that, in the roulette algorithm, the third step is more likely to select individuals with high fitness.

Random traversal sampling algorithm: this algorithm is similar to roulette selection algorithm. The first two steps are also to calculate the individual fitness proportion and fitness distribution. However, in the third step, random traversal sampling adopts the concept of equidistant sampling. Assuming that the number of individuals in the population is N and the number of individuals to be selected is d, the selection sequence is as shown in formula (5):

$$\{r_1, r_2, \ldots, r_d\}, \tag{5}$$

where r_1 is the random number between $(0, 1/d)$; it is shown in formula (6):

$$r_j = r_{j-1} + \frac{1}{d}. \tag{6}$$

Tournament selection method: different from the first two, the tournament selection method does not need to calculate the probability distribution function but selects individuals by simulating the way similar to the group competition, which is mainly divided into three steps:

(1) Determine the scale of each competition; for example, select 30% of the individuals in the original population to compete.

(2) Select the champion (with the highest fitness) among the individuals who meet the number by random sampling.

(3) Repeat steps 1 and 2 until a sufficient number of individuals are selected.

Crossover refers to the process of hybridization of parent individuals to produce offspring, which is divided into single point hybridization and multipoint hybridization, as shown in Figure 7.

3.3. Clustering Algorithm

3.3.1. Algorithm Process. Clustering technology, also known as cluster analysis, is a technology to analyze the data according to the correlation between the data itself in the absence of prior knowledge. Therefore, clustering is an important part of unsupervised learning, and it is also widely used in pattern recognition, machine learning, and other fields [13].

In cluster analysis, there are two cases—a single data belongs to and only belongs to one category or may belong to multiple categories, corresponding to hard clustering and fuzzy clustering, respectively. In the hard clustering model, the clustering results are shown in formula (7):

$$U = \begin{bmatrix} u_{11} & u_{12} & \ldots & u_{1n} \\ u_{21} & u_{22} & \ldots & u_{2n} \\ \ldots & \ldots & \ldots & \ldots \\ u_{k1} & u_{k2} & \ldots & u_{kn} \end{bmatrix}, \tag{7}$$

where U is the $k \times n$ matrix, where k is the number of clusters, n is the number of samples, and u_{ij} indicates whether sample i belongs to cluster j, which satisfies the following formula, as shown in formula (8):

$$u_{ij} \in \{0, 1\}, 1 \le j \le k, 1 \le i \le n. \tag{8}$$

In hard clustering, sample i either belongs to cluster j or does not belong to cluster j, and there is no value between 0 and 1. In fuzzy clustering, the formula should be modified as shown in formula (9):

$$u_{ij} \in [0, 1], 1 \le j \le k, 1 \le i \le n. \tag{9}$$

In the two different clustering methods, u_{ij} is also constrained by formulas (10) and (11):

$$\sum_{j=1}^{k} u_{ij} = 1, 1 \le i \le n, \tag{10}$$

$$\sum_{i=1}^{n} u_{ij} > 0, 1 \le j \le k. \tag{11}$$

In fuzzy clustering, the sum of distribution probability of samples in all clusters is 0. Formula (11) imposes a basic constraint on the cluster capacity; that is, any existing cluster has at least one sample that belongs or has a probability of belonging to it; otherwise the cluster does not exist [14].

3.3.2. Algorithm Evaluation Index. The following is a brief introduction to these evaluation indicators: CA: judge whether all samples in the cluster are classified into appropriate clusters by giving a label, and evaluate the clustering effect by statistical accuracy. The calculation is shown in formula (12):

$$CA = \sum_{i=1}^{K} \frac{\max(C_i|L_i)}{|\Omega|}. \tag{12}$$

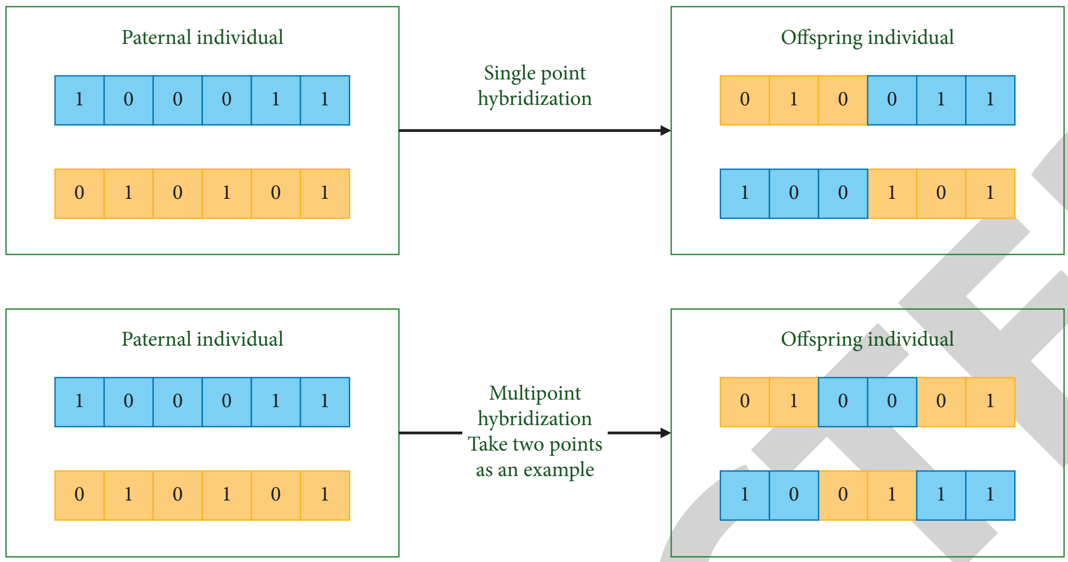

FIGURE 7: Two hybridization methods.

RI and ARI: given the sample label, all point pairs can form four indicators, the same label but belonging to different clusters, the same label and the same cluster, the same cluster of different labels, and different clusters of different labels, as shown in Table 1.

TABLE 1: Corresponding table of cluster labels.

	Homocluster	Different clusters	Total
Same label	a	b	a + b
Different labels	c	d	c + d
Total	a + c	b + d	a + b + c + d

Then the RAND coefficient is calculated with formula (13):

$$RI = \frac{a+d}{a+b+c+d}. \tag{13}$$

In the case of random, the ARI value is close to 0. With the improvement of clustering index, the ARI value is closer to 1. Its calculation method is shown in formula (14):

$$\mathrm{ARI} = \frac{RI - E[RI]}{\max(RI) - E[RI]}. \tag{14}$$

The value range of ARI becomes [−1, 1]. The larger the value, the closer the clustering effect to the real data distribution.

NMI: mutual information (MI) is a concept in information theory, which is mainly used to evaluate the correlation between the distribution of two random variables. There are two random variables X, Y, $p(x)$ is the edge distribution of x, $p(y)$ is the edge distribution of y, and $p(x, y)$ is its joint distribution; then MI is calculated as formula (15):

$$MI(X,Y) = \sum_x \sum_y p(x,y) \log \frac{p(x,y)}{p(x)p(y)}. \tag{15}$$

Standardized mutual information (NMI) is also called normalized mutual information; that is, standardize the value of mutual information to between [0, 1] through the standardization method, as shown in formula (16):

$$\mathrm{NMI}(X,Y) = 2\frac{MI(X,Y)}{H(X)+H(Y)}, \tag{16}$$

where $H(\cdot)$ represents the information entropy of random variables, and the calculation is shown in formula (17):

$$H(X) = \sum_{k \in S} p(x) \log_2 p(x). \tag{17}$$

Through the above formula, the mutual information between two random variables is normalized to [0, 1]. At the same time, NMI can also correct the bias of MI for more variables.

CP and SP: compactness CP refers to the average distance from each point in the cluster to the cluster center; that is, the smaller the CP value, indicating that the closer the distance within the cluster in the clustering model, the smaller the CP value in theory, the better. The tightness calculation can be calculated by formulas (18) and (19).

$$CP = \sum_{i=1}^{k} CP_i, \tag{18}$$

$$CP_i = \left(\frac{1}{|C_i|} \sum_{k \in C_i} d^p(x, c_i) \right)^{(1/p)}. \tag{19}$$

DBI index: due to the limitations of CP and SP, it is easy to fall into the local optimal solution when using CP or SP alone to evaluate the clustering model, while DBI balances the two and defines the performance of the clustering model on its basis. The calculation method can be determined by formula (20):

$$\mathrm{DBI} = \frac{1}{k}\sum_{i=1}^{k}\max_{j\neq i}\left(\frac{CP_i + CP_j}{\left\|c_i - c_j\right\|_2}\right). \tag{20}$$

Here is the DBI index description of Euclidean distance. From the definition of DBI, we can see that it takes into account the benefits of CP and SP for the quality evaluation of clustering model. The smaller the DBI value in application, the better.

4. Research on Comprehensive Health Evaluation of Art Psychotherapy

4.1. Research Assumptions. The purpose of this study is to compare the experimental effects through quantitative analysis. In the research, mainly guided by the viewpoint of "post-modern experiential art creation," the intervention group and control group were designed, and the pretest was conducted for group A and group B to ensure the equality of grouping. SPAT group psychological counseling was carried out. After the intervention, the experimental effects of the following aspects were analyzed and compared to explore its internal mechanism [15].

According to the above specific research purposes, the overall research assumptions of the intervention results in the second part of the study are as follows:

Experimental preconditions: equal histochemical design Pre A = Pre B.

Expected results of the experiment: paired samples of pretest and posttest in the same group: *t*-test: Post A > Pre A.

Analysis of variance of posttest comparison of differences between different groups: Post A > Post B.

The specific meanings of the general assumptions are described as follows:

Hypothesis a: compared with before and after intervention group A, spat group counseling (intervention group A) has significant differences in six aspects: self-harmony, depression, Eysenck personality type, social avoidance and anxiety, life orientation, optimism, and trait coping style [16].

Hypothesis AB: compared with control group B, spat group counseling has significant differences in six aspects: self-harmony, depression, Eysenck personality type, social avoidance and anxiety, life orientation, optimism, and trait coping style [17].

4.2. Implementation Process. The research object of this study is college students. Due to the particularity of the course, after consultation and discussion with relevant teachers and departments before the course, it is possible to implement a unique teaching form of comprehensive painting therapy in a college students' mental health course. The educational intervention of spat curriculum in this study was undertaken by an associate professor of psychology and one of the authors of this paper. The professor has 20 years of teaching experience in psychology. The author is a graduate student majoring in psychology and obtained the qualification certificate of national second-class psychological consultant and secondary vocational teacher. The author is responsible for preparing all the art media required for the course before class. In addition to reading a large number of relevant literature before the course, the interveners also discussed the spat course education plan in detail to ensure the quality of course education [18].

The course site is a fixed large classroom to meet the needs of activities in the course. The selection of specific art media, evaluation tools, and data processing are basically the same as the group counseling part of the second research. It should be noted that the love attitude scale (LAS) used in this study has good structural validity through confirmatory factor analysis. There are 22 items in 6 subscales, and the reliability of each subscale is between 0.706 and 0.818. The concept of love composed of six love styles: romance, game, companion, reality, possession, and dedication also exists among college students in mainland China. The view of love is a multidimensional psychological value. The initially formed love attitude scale can be used as a tool to evaluate the tendency of college students' view of love [19].

Comprehensive painting art therapy is committed to the unified and coordinated development of students' cognition, emotion, behavior, and personality as a whole. Therefore, different art experience activities such as painting are designed from different levels, and the curriculum education implementation plan is finally determined in combination with the basic teaching content of mental health curriculum [20]. The number of students in this course is 116, collectively known as the intervention group. There are ten courses, one hour and 30 minutes each time. See Table 2 for the specific contents of the curriculum education program.

Comprehensive painting art therapy is committed to the unified and coordinated development of the three levels of cognition, emotion, behavior, and personality of group members. Therefore, different painting and other art experience activities are designed from different levels. At the same time, the group counseling activity plan of this study is finally determined by referring to the existing painting art treatment group plans at home and abroad and under the guidance of professionals [21]. SPAT group psychological counseling activities were carried out for 9 times, once a week, about 2 hours each time. The control group did not intervene. See Table 3 for the specific contents of the activity plan.

The measurement part of the questionnaire is the reevaluation of the psychological scale. Fill in the self-compiled feedback form of group counseling effect, and then give full feedback and discussion between the instructor and members. Finally, the team farewell activity is called "big reunion." The purpose is to bid farewell to the group in a

Table 2: Implementation plan of SPAT mental health course.

Course time	Course unit topics	Course implementation process and method	Remarks: art media
1 March 1, 2010	Purpose of family formation: to understand the course form, eliminate the strangeness among members, understand each other, and form a small family Establish reasonable coping styles before, after, or after falling in love	(1) Course introduction: introduce the course content, form, and teaching methods (2) The first test of psychological scale is the pretest (3) Warm-up activities: use the Gestalt grouping method to group according to age, zodiac, and exchange personality characteristics with each other (4) Group grouping "simulated family": divided into 10 small families, with more than 11 people in each group. Each group selects two principal and deputy parents to be responsible for management and gives a sentence of "who is (she)," and finally shares it (5) Situational drama activities: the performance of "the development process of love emotion" in situational drama, that is, acquaintance, development, conflict, redevelopment, and decision, who is most able to think about their own pursuit and ideas, emotional needs, and how to actively guide	A4 sketch paper, Hb pencil, eraser, etc. Zhi, glue, scissors, self-brought pictures, and photos related to love, etc.
9 May 10, 2010	Emotional integration purpose: to integrate friendship, family affection, and love emotion from the level of knowing and doing	(1) Introduction to the course: the explanation of love sentiment, that is, sense of reason, aesthetics, and morality (2) Emotional test and case discussion and explanation (3) Painting and story analysis: "future life—a better tomorrow" nine-division painting and story sharing, according to the operation steps of the nine-division integration painting method (4) Viewing of audiovisual materials: emotion and marital emotion	24 color watercolor pens, oil painting stick, color pencil, A4 sketch paper, Hb pencil, eraser, etc.
10 May 17, 2010	The purpose of personality integration: members share deeply, integrate the curriculum harvest, and integrate into personality	(1) Course introduction: course summary (2) Personal painting: "a growing tree of life" and sharing (3) Group painting: "emotional garden," small family as a group, using large rice paper (4) Explore the future career blueprint, discuss, and share (5) After the second test of the psychological scale, the students bid farewell to each other	Watercolor pen, oil painting stick, watercolor pigment, rice paper, A4 sketch paper, pencil, eraser, etc.

warm, sweet, and cohesive situation, go to life, and leave a beautiful and unforgettable memory.

4.3. Research Results and Discussion

4.3.1. Comparison of Pretest Results of Psychological Measurement between SPAT Group Psychological Counseling Intervention Group and Control Group. Before spat group counseling, the intervention group and the control group were measured with the professional psychological scale. The analysis of variance showed that there was no significant difference between the intervention group and the control group in these aspects. The specific test results on different scales are shown in Table 4.

4.3.2. The Influence of Educational Intervention of SPAT Course on the Types of Love Attitude. In order to investigate whether there are statistically significant changes in students' love attitude before and after the educational intervention of spat course, the *t*-test of paired samples of "pretest and posttest" is carried out. The results are shown in Table 5.

Table 3: SPAT group psychological counseling program.

Activity name	Activity objectives	Process and method	Art media
(1) A new family 2010.03.04	(1) Clarify the objectives of the group and the formation of the group (2) Be familiar with team members and art media (3) Build trust and warm group atmosphere	(1) Introduction and discussion on the content and form of group activities (20 minutes) (2) Psychological scale measurement and signing informed consent (20 minutes) (3) Warm-up activities—social measurement and body bumper car (20 minutes) (4) Set up three small families to discuss and display "family name," "family number," "family song," and "family dance" (25 minutes) (5) Nine-cell emotional painting (20 minutes) (6) End sharing (15 minutes)	Watercolor pen, color pencil, oil painting stick, color small cardboard; psychological scale and informed consent
(2) Who am I 2010.03.11	(1) Emphasize group commitment and enhance group motivation (2) Improve self-awareness	(1) Group dynamic reconstruction (15 minutes) (2) Self-portrait painting (30 minutes) (3) Music image painting (30 minutes)	2B pencil, eraser, A4 sketch paper: oil paint, rice paper, brush, platter;

Table 4: Results of pretest ANOVA of psychological scale in intervention group and control group.

Scale and its factor name	Group	N	Mean	SD	Variance homogeneity test			Analysis of variance results
					Levene statistics	Sig. (P value)	F value	P
Disharmony factors of SCCS self and experience	Intervention group A	15	41.470	6.543				
	Control group B	15	46.070	10.879	2.430	0.130	1.802	0.190
SCCS self-spirit	Intervention group A	15	21.730	3.918				

Table 5: T-test results before and after spat curriculum education intervention love attitude scale.

Paired comparison of pretest and posttest differences			T-test results	
Scale and factor name	Mean	SD	T value	P
Romantic love	0.257	2.557	1.030	0.305
Game love	−0.124	3.021	−0.420	0.675
Companion love	0.705	3.079	2.346	0.021*
Possessive love	−0.114	2.569	−0.456	0.650
Realistic love	−0.105	2.382	−0.451	0.653
Give love	−0.057	2.541	−0.230	0.818

$^{*}P < 0.05$, $^{**}P < 0.01$.

It can be found from the data in the table that, before and after the experiment, there is a significant difference in the peer love factor in the pretest and posttest results of the intervention group ($P < 0.05$), and there is no significant difference in other factors. There was no significant difference in other factors. This shows that spat curriculum intervention can enhance the tendency of "peer love" and has a positive effect on improving the types of love attitudes of college students. The ternary theory of love holds that love should have three core points: intimacy, passion, and commitment. "Peer love" is the love for intimate partners formed by the combination of intimacy and commitment. This kind of love is characterized by mutual respect and trust between the two sides. What people experience is more a sense of trust and dependence on each other. This type of love will be concentrated in a long and happy marriage. Although the passion is gone, common ideals, common interests, common values, tolerance, and habits can better maintain good feelings. Therefore, more guidance should be given to college students.

4.3.3. Influence of Educational Intervention of SPAT Course on Eysenck's Personality Type Characteristics. In order to investigate whether there are statistically significant changes in the factors of students' Eysenck personality type before and after the educational intervention of SPAT course, the t-test of paired samples of "pretest-posttest" is carried out. The results are shown in Table 6.

It can be found from the data in the table that, before and after the experiment, there is an extremely significant difference in EPQ extraversion factor in the pretest and posttest results of the intervention group ($P < 0.01$), and there is no significant difference in other factors. This shows that spat curriculum intervention can significantly improve the extraversion of college students' personality types. The reason may be that the curriculum education improves the openness of members, stimulates their internal spontaneity and initiative, and is willing to show more characteristics such as good communication, enthusiasm, and impulse. Fang

Table 6: Results of t-test before and after the short EPQ scale of educational intervention in SPAT course.

Paired comparison of pretest and posttest differences			T-test results	
Scale and factor name	Mean	SD	T value	P
EPQ psychoticism factor	−0.123	1.357	−0.935	0.352
EPQ extraversion factor	−0.686	2.105	−3.339	0.001**
EPQ neuroticism factor	−0.019	2.780	−0.070	0.944
EPQ masking factor	0.076	1.895	0.412	0.681

*stands for $P < 0.05$, $^{**}P < 0.01$.

Paired comparison of pretest and posttest differences			T-test results	
Scale and factor name	Mean	SD	T value	P
Total score of LOT-R life orientation scale	−0.029	3.712	−0.079	0.937

$^{*}P < 0.05$, $^{**}P < 0.01$.

Table 8: T-test results before and after TCSQ of educational intervention in spat course.

Paired comparison of pretest and posttest differences			T-test results	
Scale and factor name	Mean	SD	T value	P
TCSQ negative coping style factor	−0.038	5.932	−0.066	0.948
TCSQ positive coping style factor	−0.419	6.978	−0.615	0.540

$^{*}P < 0.05$, $^{**}P < 0.01$).

Shuren depicted in the curriculum intervention is a specific image and a psychological "self-sufficiency," resulting in no significant change before and after the educational intervention LOT-R. The comparison results before and after the educational intervention LOT-R are shown in Table 7.

4.3.4. The Influence of Educational Intervention in SPAT Curriculum on Trait Coping Style. In order to investigate whether there are statistically significant changes in students' trait coping styles before and after the educational intervention of spat course, a paired sample t-test of "pretest and posttest" was carried out. The results are shown in Table 8.

It can be found from the data in the table that there is no significant difference between the pretest and posttest results of the intervention group in the negative and positive factors of trait coping style before and after the experiment. The reason may be that the students participating in the curriculum intervention do not have coping style problems, and there is no significant change before and after.

5. Conclusion

From the overall results of this study, compared with the control group, spat group psychological counseling significantly enhances college students' self-flexibility, improves the degree of self-harmony, reduces college students' social avoidance tendency, improves college students' extraversion of personality types, has a more positive effect on reducing personality concealment, and can improve college students' optimistic attitude. The positive coping style factor increased, and the scores of other depressive tendencies, neuroticism factors, negative coping styles, and social anxiety factors decreased, which is in line with the initial assumption of this study. The specific research conclusions are as follows:

In the rehearsal group discussion, there was a difference in personal transformation between this group (sampan) and other groups before and after the experiment ($P < 0.05$). There was no significant difference in group B before and after the experiment ($P > 0.05$). After the experiment, there was a significant difference in individual stereotype types between the affected group and the control group ($P < 0.05$), and there was no statistical difference between the other groups ($P > 0.05$).

In the group discussion of art design improvement, there was a significant difference in EPQ concealment ($P < 0.01$) and a significant difference in EPQ extroversion factor ($P < 0.05$) before and after the experiment, but there was no significant difference in the control panel. After the experiment, the difference in EPQ extroversion between the control group and the control group was statistically significant ($P < 0.05$).

In the group discussion of art deco, there was a significant difference between the groups of avoidance before and after the experiment ($P < 0.05$), and there was no significant difference with other groups. After the experiment, there was a significant difference in the total stress score between the control group and the control group ($P < 0.05$).

In the art deco group discussion, the LOT-R life orientation total score listed in the group was significantly different before and after the experiment ($P < 0.05$), but there was no significant difference in the control group. After the experiment, there was a statistically significant difference in the total score of life direction between the affected group and the control group ($P < 0.01$).

In the group discussion of decorative art design, the adverse effects of TCSQ on the intervention process were significantly different in each group before and after the experiment ($P < 0.05$), but there was no significant difference in the control group. After the experiment, there was no significant difference between the intervention group and the control group in both adverse and positive performance.

With all the benefits of this study, the spat data reported effects on improving college students' romantic behaviors, increasing college students' extroversion, reducing underlying behaviors more effectively, and lowering student relationships and stress. Other factors did not change significantly, but scores increased on positive thinking for good solution quality and positive behavior and increased on other stressors, mental disorders, neurotic factors, and poor resolution, consistent with the original theory. The main points of the special research are as follows:

In the research on the effect of layered art, the point-to-point interaction before and after the experiment was

It is thought to be an effective technique to handle the problem of educational data explosion and lack of information by identifying potential relationships between data and directing decision-makers through the extraction, transformation, analysis, and modeling of educational data. Based on this, this research constructs a data analysis model for education evaluation using the K-means clustering technique in DM. The weight of each index of students' comprehensive quality is calculated using AHP, and the value of the weight is used to determine whether the index is the important feature of analysis system mining. Improved sampling technology is used to deal with the representation of large-scale data sets; a sample partition clustering technique is proposed as a general framework. The best accuracy of this method, according to experimental data, is 95.6 percent, which is 12.1 percent greater than Mi cluster algorithm and 6.8 percent higher than DRCluster algorithm. The K-means clustering analysis technology is used to analyze students' comprehensive evaluation data in this paper, with the goal of determining the regularity of data implication, accurately diagnosing learning problems, and providing the foundation for developing effective student management strategies.

1. Introduction

With the implementation of teaching reform, enrollment continues to rise, and a large number of children face significant obstacles in terms of school construction, teaching management, and teacher management [1]. Schools have amassed a considerable amount of complex student data, such as student status information, accomplishment information, specialty information, and moral information [2]. It has been challenging to adapt the old management mode to the large student population and data management. How to properly utilize and analyze massive raw data and turn it into useable knowledge and value has become an important topic of common concern at home and abroad to tackle the difficult problems in educational data processing [3]. The introduction of information management technology to tackle data problems produced by the influx of students in the field of education has played a major role in the construction of schools [4], thanks to the rapid development of Internet technology. It is vital to acquire the necessary data for evaluating education. Researchers gradually find that the collection channels are restricted and that there are a lot of unstructured data when they collect data. It takes a long time to store meaningful data, and it is far more difficult to acquire timely information feedback [5]. Faced with these growing issues, a variety of educational applications and platforms to assist teachers in collecting and analyzing data arose and are now extensively used [6]. The rise of information technology has aided educational research by allowing for the collecting, storage, analysis, and decision-making of data and allowing for the timely collection of student studies. Simultaneously, it gives data support for teachers to properly and timely analyze students' development and change their own teaching style [7]. The introduction of information technology may not only remove a lot of repetitive manpower and increase staff efficiency, but it can also play an essential role in the collaborative administration of schools due to its fast information transmission mechanism.

DM (data mining) is also called knowledge discovery in database. DM is the process of discovering hidden, regular, and unknown but potentially useful and understandable information and knowledge from a large number of incomplete, noisy, fuzzy, and random practical application data. Cluster analysis is an important and active research field in DM [8]. As an unsupervised learning method, clustering is essentially a density estimation problem. The data to be clustered are not labeled with its category in advance and can be generated by a mixed model. Its main idea is to divide data into several classes or clusters to maximize the similarity of data objects within clusters and minimize the similarity of data objects between clusters [9]. The clustering algorithm can be selected by the data type of field attributes in the database and the characteristics of objects operated by clustering. Common clustering algorithms include partition-based clustering algorithm, hierarchical clustering algorithm, density-based method, grid-based method, model-based method, and constraint-based method. At present, large-scale data sets frequently emerge in the field of education, which poses new challenges to data analysis and research. In the face of large-scale data, traditional analysis algorithms are no longer as "handy" as small- and medium-sized data, but there are many problems such as difficult processing, long processing time, difficult parameter determination, low efficiency, and low clustering quality. Moreover, the collection content of evaluation data is single, and the analysis method lacks a certain depth. For the current situation of education data analysis, this paper introduces K-means clustering algorithm to analyze the education evaluation data. The innovations of this paper are as follows:

(i) From the perspective of cognitive learning theory, this paper aimed to address the current educational data's long processing time, uncertain parameters, and low clustering quality; the collection content of evaluation data is single, and the analysis method lacks certain depth and many other issues. To analyze the education evaluation data, the K-means clustering algorithm is introduced. The proposed approach is suitable for large-scale DM, according to a series of experiments. For relevant researchers, this has some reference and guiding relevance.

(ii) In this paper, the data are cleaned, integrated, and transformed into data storage format, and the input data fulfilling the K-means algorithm are created, with the goal of solving problems such as data duplication, missing data, and inconsistent storage kinds. We may also uncover commonalities between students using the K-means technique to cluster and analyze their comprehensive evaluation results. Students are categorized based on their commonality, allowing student managers to provide tailored education management for various types of students.

2. Related Work

In these years of rapid DM growth, various disciplines' research topics are continually presented, including data retrieval technology, artificial intelligence, neural networks, virtual reality technology, and associated basic mathematical theories. Simultaneously, DM's applicability in the realm of education is expanding. DM has been used by a number of academics to analyze educational data in recent years.

Kelly et al. proposed a fast relaxed clustering algorithm based on graph theory. The asymptotic time complexity of this algorithm is linearly related to the data capacity when applied to larger-scale datasets [10]. Charles et al. proposed an efficient K-means clustering algorithm, which uses precomputed distances between points and dormant clusters to reduce the amount of distance computation, greatly reducing the running time and space used [11]. Rosenkranz et al. believe that the current educational data statistical analysis platforms and tools have been promoted and applied in school teaching, but there are still many problems in how to effectively analyze and use these data [12]. Scott and others believe that in the process of education, educational evaluation data occupy a large proportion, and it clearly shows the actual learning situation of students, which plays an important guiding role in teachers' teaching. Therefore, from the perspective of teachers, it uses the "Jike Big Data" system to optimize the use of educational evaluation data [13]. Hopper et al. studied the related problems of teaching optimization based on the analysis of educational evaluation data. It proposes to use educational evaluation data to determine the learning starting point of learners, design quantifiable learning goals, select learning content suitable for learners, and accurately evaluate teaching quality, and conduct personalized learning analysis and feedback in a timely manner [14]. Wolbring et al. pointed out that the collection and analysis of educational evaluation data are not only a reflection of students' learning achievements but also a reflection of teachers' teaching effect [15]. Goldberg et al. used the ideological and moral quality, intellectual education quality, physical and mental quality, and development ability quality indicators to evaluate and subdivided the indicators into multiple secondary indicators. The evaluation adopts evolutionary algorithm, fuzzy comprehensive evaluation, multivariate statistical analysis method, etc., to obtain effective weights, and the data items are summed according to the weights to obtain the quantitative score evaluation value [16]. Kang et al. selected some data from a large-scale data set, used these data to construct an adjacency matrix, and obtained eigenvectors by eigendecomposition of the adjacency matrix, and finally used Nyström to approximate the eigensolution of the original matrix [17]. Aiming at the main methods of DM, Hou et al. studied the ideas and applications of related algorithms, analyzed the advantages and disadvantages of existing methods and compared them. Based on this, a data analysis method based on the optimal decision tree algorithm is proposed [18]. Lavelle et al. analyzed and designed an evaluation database based on the functional requirements of the school education and teaching situation evaluation system. It can realize functions such as maintenance of basic information, statistics, and query of evaluation data [19]. Wang et al. proposed a new fuzzy clustering algorithm based on genetic algorithm, which realized the clustering analysis of characteristic data with mixed attributes. By introducing the genetic algorithm into the algorithm, the global optimal solution can be obtained quickly and effectively, and it does not depend on prototype initialization at all [20].

Based on these studies, this paper proposes an educational evaluation data analysis method based on K-means clustering algorithm to solve the problems of difficult processing, long processing time, and difficult parameter determination. In this paper, firstly, the cluster analysis method in DM technology is applied to establish a model to quantitatively analyze the indicators and their values of objects, and then, a new comprehensive evaluation method for students combining quantitative analysis with qualitative analysis is proposed. Then, AHP is used to calculate the weight of each index of students' comprehensive quality and judge whether the index is the key attribute of analysis system mining according to the value of the weight. Finally, the improved sampling technique is used to deal with the representation of large-scale data sets. A general framework of sampling partition clustering algorithm is proposed. The validity of the framework is verified by implementing K-means and k-medoids algorithms. It is proven that this method is practical and feasible.

3. Methodology

3.1. DM-Related Technology. With the gradual development of educational big data, artificial intelligence, learning analysis, and intelligent network learning platform, learners' whole-process learning data can be recorded. At the same time, with the rapid development of DM, artificial intelligence, and other technologies, these educational data can be automatically and deeply analyzed and processed, and learners can be personalized analyzed and diagnosed. The core function of DM technology is to discover potential rules from large-scale data. DM (data mining) is a specialized technology for mining extraordinary knowledge from large-scale data. It is a process of mining useful information from incomplete, massive, noisy, fuzzy, and random data that people do not know in advance. DM is a process of discovering potentially useful information or knowledge in reality. This process is essential for discovering knowledge in the database, in which knowledge discovery is a process of converting raw data into effective information that can be used for analysis. DM is a process of selecting, exploring, and modeling a large amount of data to discover unknown rules and relationships in advance. The purpose of DM is to get clear and useful results for the owner of education database. The DM process generally consists of business object determination, data preparation, DM, and result analysis.

Cluster analysis in DM is an active and challenging research field. In recent decades, its importance and cross characteristics with other research directions have been widely recognized by people. It plays a very important role in identifying the internal structure of data and has become one of the important research contents of DM, machine learning, and pattern recognition. The differences between groups are obvious, and the data in the same group are as similar as possible. Data clustering divides physical or abstract objects into several groups. Within each group, there is high similarity between objects, but low similarity between groups. It is the same as and different from classification. The same thing is that the data source is divided into several parts. The difference is that it is a kind of unsupervised learning, and it does not know the final grouping number and grouping standard. As a classical clustering algorithm, K-means mainly realizes different classifications of data sets through an iterative process. This algorithm has the advantages of simplicity and strong scalability. In DM field, the typical requirements for clustering mainly include the following aspects: ① scalability, ② ability to handle attributes of different data types, ③ any shape cluster can be found, ④ insensitive to the entered record order, ⑤ high dimension, ⑥ minimization of domain knowledge for determining input parameters, ⑦ ability to effectively deal with noise and abnormal data, and ⑧ availability and interpretability. In DM stage, the task or goal of mining is determined, and the mining method is selected, to implement DM operation and obtain useful patterns. The specific DM application requirements are determined, the goal of mining is cleared, and the effect that can be achieved after the system is completed. The application field background is analyzed, and the problem objective is determined. The background knowledge of related fields is understood, the needs of users are made clear, and data are collected to solve problems, and services are provided for the follow-up work. Traditional data analysis is a kind of verification analysis. It is a kind of user-driven data analysis, focusing on describing the facts that have happened in the past. DM is to mine information and discover knowledge without hypothesis. The obtained information has three characteristics: effective, unknown in advance, and practical. It is to predict the future situation and explain the factual reasons of the past. To obtain potentially effective information to meet the needs of users, it is required to fully mine the surface information, remove redundant data, and visually display key data to users. Prediction and description are the two goals of DM. Prediction refers to the use of some information fields and variables in the database to predict the hidden useful information, and description refers to the description of data as an understandable pattern. There are two aspects to consider when choosing an algorithm: first, according to the different characteristics of different data, the algorithm is selected related to it to mine; second, according to the needs of users or the actual operation of the system. This stage is the core and difficulty of knowledge discovery process.

3.2. Big Data of Education and Educational Evaluation. This paper holds that educational big data refer to the data collection generated in the whole process of educational activities and collected according to educational needs, which is used for educational development and can create great potential value. Big data for education are a subset of big data, and it is a collection of data generated throughout the educational process and collected based on educational needs, which is utilized for educational improvement and has a lot of potential value. Schools have purchased or adapted educational administration systems to better handle

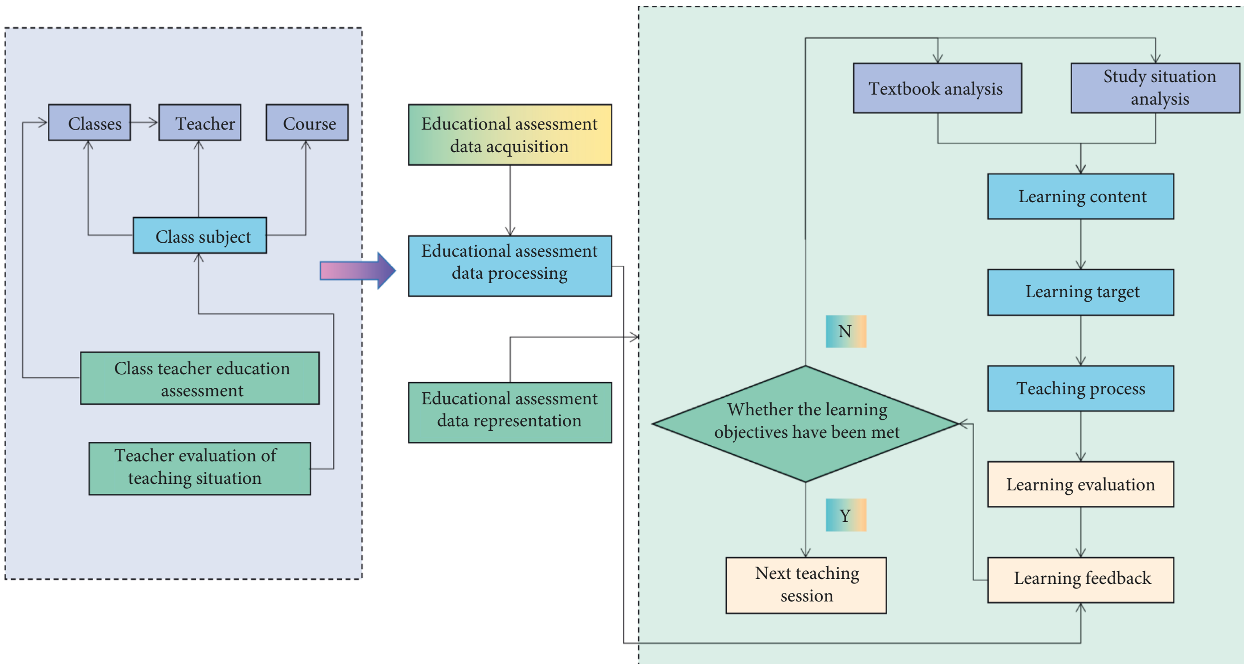

Figure 1: Teaching optimization method based on educational evaluation data.

students' information as the student population has grown. The system's principal purpose is to keep track of pertinent information about pupils' academic achievement, for example, students' test scores and grade points, information about their curriculum, examination schedules, attendance, and information regarding rewards and discipline violations, among other things. All of this is educational big data. Different classification standards exist for big education data, depending on the perspective. Teaching data, management data, scientific research data, and service data can all be found in the data sources. According to the degree of organization, it can be separated into structured data, semi-structured data, and unstructured data. It can be separated into process data and result data at the collection stage. Process data are information gathered during the teaching process that is difficult to quantify directly. Quantifiable data are referred to as result data.

A huge education database is built to collect massive student data, including students' test scores, social activities, class attendance, and hobbies. Relying on tens of millions of data collected by the database can help students in various universities to do data analysis, help them find out the reasons why they cannot improve their grades, and help them adjust their learning styles or change their lifestyles in time to avoid dropping out of school. The data collected in each evaluation are defined as educational evaluation data in this paper, and the data types are mainly data generated in the learning process including the knowledge points, questions, difficulty, discrimination, learners' right and wrong situation, grades, and ranking. At present, the application value of educational evaluation data is mainly reflected in six aspects, namely, promoting more scientific teaching management, promoting the innovation and reform of teaching mode, promoting the realization of personalized learning, promoting the reconstruction of educational evaluation system, promoting the successful transformation of scientific research paradigm, and promoting the humanization of educational service. Educational evaluation refers to the process of scientifically measuring and judging various educational activities, educational processes, and educational results using certain technologies and methods under the guidance of certain educational values and according to established educational goals. At present, the research in the field of basic education has just started, and the data analysis platform of education evaluation has not been able to provide accurate education decisions for teachers and personalized teaching services for students. Therefore, the research on educational big data needs to be strengthened. Figure 1 is a teaching optimization method based on educational evaluation data.

Education evaluation data are the data fact obtained for the education effect or the development of students in all aspects, and education evaluation is the process of value judgment based on these data. Student evaluation data are one of the subsets of educational big data that educators are most familiar with. Its sources are abundant, including formative evaluation, unit test, midterm and final test, and large-scale regional test. There are various types of data, including test scores and teacher evaluation. When confronted with diverse and customized student groups, fixed, homogenous, and dogmatic educational and administrative systems have revealed numerous flaws. To reform educational techniques and management modes, we should begin with the dominant position of students and provide tailored instruction based on their qualities. In school education, evaluation data are regarded as the most important indicator of educational and teaching improvement. These data are mainly test scores gathered through measurement, and

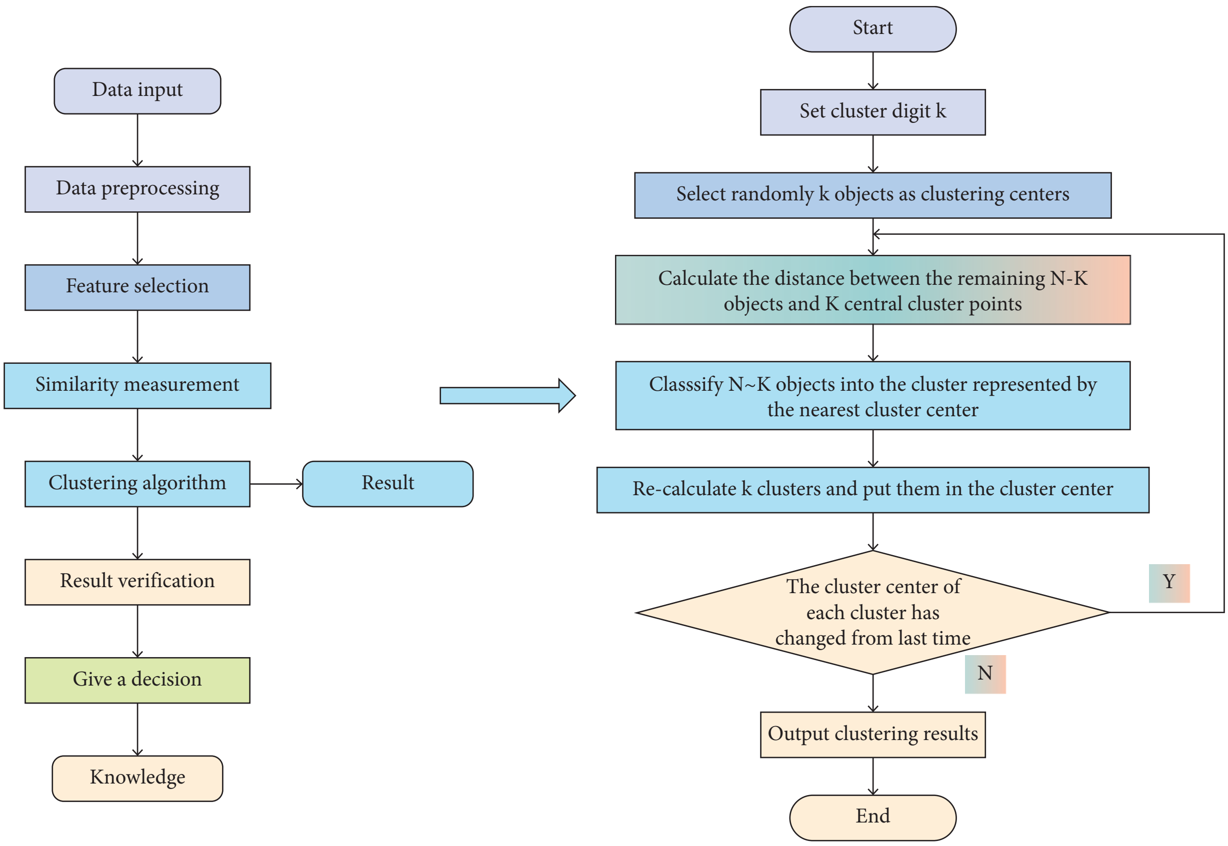

FIGURE 2: General flow of K-means clustering algorithm.

careful collection, categorization, sorting, statistics, and analysis can turn them into very valuable big data in education. Teachers are the leaders of pupils in the sphere of education. The more they know about students, the better they can choose the most appropriate learning content in class, set the most precise learning objectives, conduct objective learning evaluations and provide timely learning feedback, provide students with personalized guidance, and help them develop their abilities to their full potential. The use of educational evaluation data analysis software or tools in the teaching process, as well as the routine collecting and analysis of these data, is critical to maximizing the value of evaluation data. Teachers can stay on top of changes in their students' knowledge, help them modify their learning speed, and continually enhance and optimize the instructional design process.

3.3. Educational Evaluation Data Analysis Based on K-Means Algorithm. Data integration, data selection, and data preprocessing are the three sub-steps of data preparation. Data integration unifies data from numerous files or databases, cleans it, and resolves semantic ambiguity. The goal of data selection is to figure out what the operation object of the discovery task is, which is the target data, which is a collection of data taken from the original database to meet the demands of users. The goal of data preparation is to convert raw data into a format that can be analyzed. Data preprocessing entails combining data from several sources, eliminating duplicate data values and noisy data, and screening out data sets and feature qualities that are not relevant to present DM activities. K-Means uses the rule algorithm to compute the distance between data items and then iteratively calculates the grouping situation of the obtained data objects until the center does not move, resulting in K clustering outcomes. The general algorithm flow is shown in Figure 2.

After the DM stage, the obtained result patterns are usually redundant or do not meet the user's requirements, so it is necessary to delete, filter, or return to the previous stage according to certain standards and reselect data and methods to obtain meaningful patterns and knowledge. In the course of the task, different data sources and different formats of the collected data are also different, so different data should be integrated and cleaned and processed. The general process of clustering includes feature selection, similarity measurement, clustering algorithm, result verification, and decision-making. K-Means algorithm is simple and efficient. However, there is no clear standard definition for the clustering number k and the selection of the center point of the algorithm, and most of them are given randomly, which will easily cause great influence on the algorithm results. Therefore, a selection method to solve the initial value k is used. Given a set of n data points:

$$X = \{x_1, x_2, x_3, \ldots, x_n\}. \tag{1}$$

The algorithm is to find a partition of X, $P_k = \{C_1, C_2, C_3, \ldots, C_k\}$, which minimizes the value of the objective function J.

$$J = \sum_{i=1}^{k} \sum_{x_j \in C_i} \left| x_j - o_i \right|^2, \tag{2}$$

where o_i represents the center point of class C_i. The Euclidean distance between two p-dimensional data points x_i and x_j is set, as in formula:

$$\begin{aligned} x_i &= \left(x_{i1}, x_{i2}, x_{i3}, \ldots, x_{ip}\right), \\ x_j &= \left(x_{j1}, x_{j2}, x_{j3}, \ldots, x_{jp}\right), \\ d\left(x_i, x_j\right) &= \sqrt{\left(x_{i1} - x_{j1}\right)^2 + \left(x_{i2} - x_{j2}\right)^2 + \ldots + \left(x_{ip} - x_{jp}\right)^2}. \end{aligned} \tag{3}$$

The average distance of all samples is determined as follows:

$$\text{Meandist}(S) = \frac{2}{n(n-1)} \times \sum_{i \neq j, i, j=1}^{n} d\left(x_i, x_j\right). \tag{4}$$

The square error criterion function for determining the objective function is as follows:

$$\sigma_i = \sqrt{\frac{\sum_{i=1}^{n_i} \left(x_i - c_i\right)^2}{C_i - 1}}. \tag{5}$$

In the formula, c_i is the centroid point of the same category of data. The c_i calculation formula is defined as follows:

$$c_i = \frac{1}{\left|C_i\right|} \sum_{x_i \in T_i} x_j. \tag{6}$$

In the formula, $|C_i|$ is the number of C_i-like data objects; c_i represents the ith cluster center.

Data cleaning is the process of cleaning problematic data. Its task is to clean the data that do not meet the requirements, usually deleting or modifying, but not simply modifying. Data that do not meet the requirements are redundant, missing, and wrong data. Data cleaning mainly includes standardization of format, removal of abnormal data and duplicate data, and correction of error data. It is necessary to clear some duplicate data in the test data management system and obtain data of other dimensions from other systems to supplement the whole database. The purpose of data cleaning is to ensure the accuracy and validity of data, to ensure good mining efficiency in the process of mining. At the same time, data cleaning is the foundation to complete the whole mining work. Given data input as information, features are extracted to represent the whole data set, so that redundant information can be reduced as much as possible. Then, according to the similarity between data points, a specific clustering algorithm is applied to the data set, and the cost function usually determined by the similarity of data points is reduced to the minimum. When the algorithm converges, it will return the output cluster. Clustering is very complicated. Different clustering analysis is applied to the same data, and the results are completely different, and the definition of clustering is usually relative. There are different clustering methods for the same group of objects, and different clustering of the same data probably corresponds to different applications.

Based on the minimum distance principle, we classify the data points x in the remaining datasets into the current cluster, namely,

$$c = \arg\min\left(\left|x - \mu_j\right|^2\right), \tag{7}$$

where μ_j is the centroid of class C_j and c is the class assigned to the data. Once new data have been assigned a class label, the cluster centroids are updated iteratively until all data points have been processed:

$$\mu_j = \frac{\mu_j m_j + x}{m_j + 1}, m_j = m_j + 1. \tag{8}$$

The data in the assessment system can be separated into two groups: one that can be represented using mathematical language and another that can be stated using words. The language's data can be examined and sorted, and DM technology's decision tree, correlation analysis, and cluster analysis methods can be used to create a model to quantify the analysis object. Because of the irregularity of data acquired from various sources, data conversion is required to develop a process suitable for DM. The quality of K-means clustering is insecure when dealing with huge data sets. As a result, this study introduces a sampling strategy to make the partition clustering algorithm acceptable for large-scale data sets. The simplest way is to choose numerous partitions at random from the original large-scale data collection. Each partition employs a clustering technique, with clustering results that are both reliable and capable of representing the entire data set. Input data are information saved on various digital media in various formats, such as an electronic report or a data relation table. These data might be kept in centralized databases or distributed site systems.

4. Result Analysis and Discussion

This study investigates the impact of data analysis on education evaluation using the K-means algorithm, as well as conducting teaching trials. The similarities between students are discovered through clustering analysis of students' comprehensive evaluation scores using the K-means technique. Students are categorized based on their commonality, allowing student managers to provide tailored education management for various types of students. The evaluation findings and learners' understanding levels are assessed before and after deployment, and the learning effect provided by this model is tracked. During the experiment, learners were interviewed and given questionnaires to gain feedback and suggestions for optimizing and refining the model, which was then iteratively improved to measure its overall performance. Finally, a feedback questionnaire is created to assess the model's use feedback across several

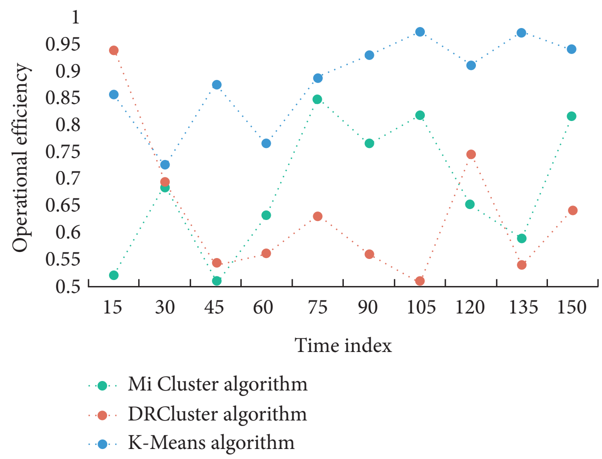

Figure 3: Running efficiency of different algorithms.

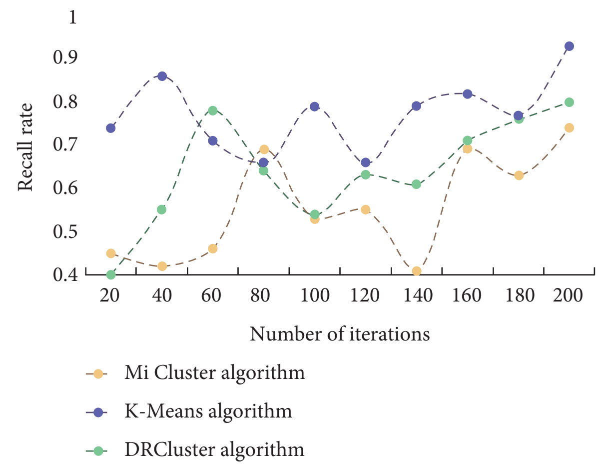

Figure 4: Recall of different algorithms.

dimensions. To begin, this section compares and contrasts the efficiency and effect of the DRCluster and Mi cluster algorithms with this algorithm, as well as analyzes and evaluates their biological importance. The running efficiency of different algorithms is shown in Figure 3. The accuracy of different algorithms is shown in Figure 4.

It can be seen that the running efficiency of this algorithm is high, and the running efficiency of DRCluster algorithm and Mi cluster algorithm is lower than that of this algorithm. In terms of recall rate, this method also has certain advantages, and the recall rate of this method is better than the other two algorithms. This conclusion also verifies the superior performance of this algorithm. To further evaluate the mining effectiveness of the algorithm, different algorithms are used for biclustering mining of six data sets, and the number of biclusters they can find is compared. Table 1 shows the number of double clusters that the three algorithms can mine in six data sets.

It can be seen from the table that the Mi cluster algorithm can find the least number of double clusters, which is mainly related to the differential support defined by the algorithm. However, the algorithm in this paper adopts effective support degree, transformation into differential weight graph, effective pruning strategy, and so on, which makes the number of mining biclusters the largest. A significant amount of experimental data are analyzed in this section. The software Office Visio was used to create the expert knowledge structure map and the student knowledge structure map. The Questionnaire website was used to gather and evaluate student feedback questionnaires, which were then analyzed using SPSS. The educational administration employees should compile the basic data needed for the evaluation and keep track of pertinent information such as the classes participating in the evaluation, the class teachers, the class subjects, and the teachers prior to the evaluation. Second, a system is set for students to rate their teachers and classmates. Finally, the evaluation is questioned by leaders and teachers. The analysis and application of educational evaluation data will examine every student's homework, test, and examination, transforming diagnostic evaluation into process evaluation and allowing teachers to grasp students' learning progress and place in time and reflect and adjust their teaching accordingly. Figures 5 and 6 depict the outcomes of clustering data sets using the DRCluster algorithm, Mi cluster algorithm, and this algorithm mode, respectively.

The test results reveal that the suggested method has a high level of accuracy, with an error rate of less than 2% over time. In these three modes, the K-means clustering algorithm suggested in this paper is valid. Routine exercises and examination evaluation tasks are carried out by students. Explicit data are the result of statistically studied evaluation data, such as score ranking, true or false situations, and answer time. Qualitative outcomes that require more examination, such as knowledge structure and comprehension level, are referred to as implicit data. The thorough evaluation score sheet includes factors such as ideological quality, cultural and athletic activity innovation, and academic accomplishment. All scores are in percentages, with a minimum scoring unit of 1 and no order of magnitude difference. The existing data dimension table is separated into three categories, and the values are taken according to the supplied weight coefficient, to compare with the current measurement and quantification result data. Students' evaluation data collection uses marking instrument and extreme class big data platform, and teachers use extreme class big data platform to arrange knowledge unit test papers, print them into papers, and distribute them to students. The test paper scanner is used to collect students' evaluation data, and the students' evaluation data are stored in the polar class big data platform. The evaluation data are analyzed, and the achievement of learning goal A of a class after the implementation of targeted education management is analyzed as shown in Table 2.

It can be seen that the total success rate of the class is 92.14%. The overall average score rate of the class is higher than that of the grade, which indicates that the class has a good grasp. Using K-means algorithm, DRCluster algorithm, and Mi cluster algorithm, the comprehensive evaluation scores of students are clustered and analyzed, respectively, and then, the changes in students' test scores after implementing targeted education management for different types of students are shown in Figure 7.

Table 1: Comparison of algorithm effectiveness.

Data set	Number of genes	Number of samples	Mi cluster algorithm/ number of biclusters	DRCluster algorithm/number of double clusters	Number of algorithms/ biclusters in this paper
Yeast	21498	297	30	139	254
Lymphoma	11024	209	37	131	167
Breast	3014	184	42	126	326
Live	4125	99	51	154	312
Lung	54926	82	15	142	106
Path_ metabolic	801	73	9	136	89

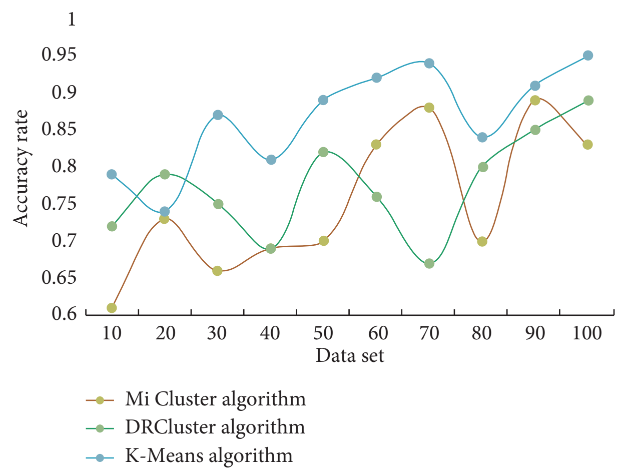

Figure 5: Accurate recognition rate.

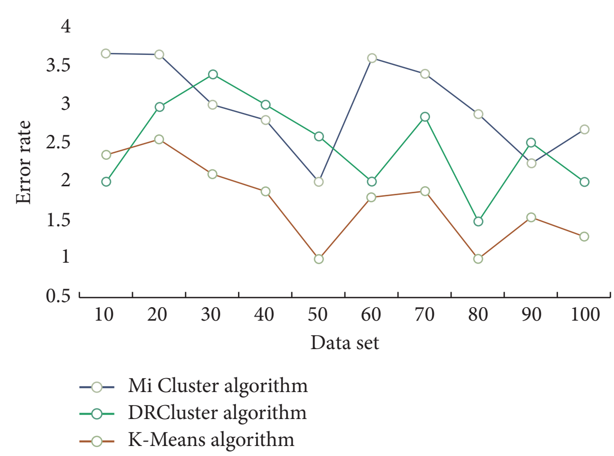

Figure 6: False recognition rate.

Table 2: Analysis of the achievement of students' learning objective A.

Student number	Students should meet the standards	Actual score rate of students	Determine whether students meet the standard	Class should meet the standard (%)	Actual score rate of class (%)	Actual grade score rate (%)	Probability of reaching the standard (%)
1	72%	80%	Yes				
2	75%	90%	Yes				
3	88%	100%	Yes				
4	90%	95%	Yes	80.57	92.75	88.69	92.14
5	93%	100%	Yes				
6	96%	100%	Yes				
...	...	...	...				

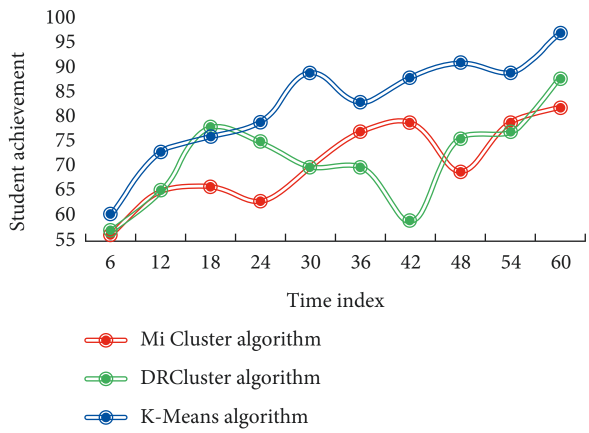

Figure 7: Changes in student achievement.

From the data analysis in Figure 7, it can be seen that after the analysis and targeted teaching management with this method, the students' scores show an obvious upward trend. Its influence on the improvement of students' grades is far greater than the other two methods. This result shows that this method is effective and feasible.

5. Conclusions

E-learning institutions contain a lot of useful information. Many educators are grappling with how to accurately uncover the important knowledge concealed in school evaluation data in the midst of such a massive amount of data. This work creates an educational evaluation data analysis model based on the K-means clustering method from the perspective of cognitive learning theory, based on existing research and application of educational evaluation data analysis at home and abroad. The model generates corresponding categorization rules based on a large number of students' educational assessment data; the main factors that can affect students' overall quality are determined based on the study of these rules. In addition, the K-means clustering algorithm is used to statistically assess the indicators and their values of the objects, resulting in the proposal of a new comprehensive student evaluation technique that combines quantitative and qualitative analysis. Experiments demonstrate that this method can achieve a maximum accuracy of 95.6 percent, which is 12.1 percent higher than Mi cluster and 6.8 percent higher than DRCluster. This method efficiently solves the drawbacks that traditional algorithms have, such as low processing per unit time, high processing times when dealing with big amounts of data, and difficulty in attaining the desired results. It has some practical and theoretical value in the field of data analysis, as well as some reference value for other academics. Despite the fact that this study accomplished certain research outcomes, numerous influencing factors and controls were not taken into account in the design process due to time constraints and a lack of understanding. The analysis technique will be improved in the future to improve the educational evaluation data analysis model. [21].

In the modern environment, visual communication design has become a comprehensive subject that combines technology and art. The development of various technologies has promoted the emergence of new design art forms, and at the same time, it has also promoted the change of design concepts and thinking modes. Visual representation, as a representation practice to express the meaning of information in the form of visual symbols, is a method and means to realize information visualization. Based on visual interface design, this article takes interactivity and user experience as innovation points and digs into the design process of interactive information visualization to achieve the purpose of information transmission. By analyzing the cognitive tasks of users in each stage of visual thinking activities in visual terminals, this article proposes to optimize the interactive design of visual communication from the key points of attention, consciousness, and memory. In order to verify the feasibility of the interactive mode of visual communication based on information visualization theory, this article has carried out several comparative experiments with different models. Experimental results show that this algorithm has a faster convergence speed and a greater generalization ability, the accuracy of the algorithm reaches 96.03%, and the highest evaluation of user satisfaction is 95.93%. The interactive mode of visual communication in this article can provide means and reference value for the development direction of visual communication design.

1. Introduction

Computer science was the first field to use visualization. It entails transforming a substance into a medium that can be seen with the eyes, that is, the object can be seen and understood through the eyes of the audience [1]. Its goal is to improve the audience's information knowledge and comprehension. In the field of computer graphics, information visualization is a significant accomplishment. Information visualization has long been thought of as a method and tool for helping people understand and analyze large amounts of data. The data age is currently in full swing, and humans are confronted with not only "anything is possible," but also unprecedented challenges [2]. Visualization technology has been pushed from the laboratory to a broad terminal market as information visualization has gradually branched out from scientific visualization. The research will focus on the analysis of information experience and the availability of information services against the backdrop of the information age. Information visualization is a new subject field that combines multidisciplinary theories and methods from a variety of disciplines, including communication, psychology, statistics, and design [3]. Information visualization typically focuses on assisting expert users in performing complex data exploration and analysis tasks as efficiently and effectively as possible, thanks to its historical roots in scientific reasoning, computer graphics, and algorithm optimization. This advanced data visualization technique is frequently regarded as a scientific tool [4]. At the moment, simply improving visualization quality through advanced technical means is insufficient to meet users' information needs. In order to improve information visualization more comprehensively, it is necessary to fully comprehend users' cognitive processes from perceptual experience to rational thinking.

The research object of information visualization can be divided into three aspects as an interdisciplinary field: data, visualization technology, and visualization performance [5]. People in the information age not only passively accept information, but also actively produce and disseminate it, resulting in a shift in their visual concepts. Image and symbolic information provide obvious visual pleasure to the audience, which provides a good audience foundation for the design and communication of visual communication [6]. Humans organize various visual elements such as words, images, colors, and other elements to achieve the dissemination of public information through visual communication design. It is a type of design that uses visuals to communicate. Visual communication is the process by which the designer transforms ideas and concepts into visual symbols, whereas visual communication is the process by which the receiver transforms ideas and concepts into visual symbols. Visual communication design is a type of design that communicates through visual symbols. The sender of information is the designer, and the receiver of information is the object of communication [7]. An urgent problem is how to make visualization technology better serve information users through a visual communication scheme, make information users understand and process information more easily, and improve the interactive effect of visual communication [8]. Visual representation design of information refers to a designer's visual representation design of information based on the subject of information visualization, using visual communication design knowledge, in order to make the audience easily obtain effective information in the era of big data and achieve maximum dissemination of information. Based on the information visualization theory, this article makes an in-depth study on the interactive mode of visual communication, and its innovations are as follows:

(1) Based on the existing theoretical basis of information visualization and visual communication, this article studies the relationship among information visualization, visual representation, and visual communication design and analyzes the communication mechanism of visual representation of information visualization. In the application innovation of dynamic visual innovation and multisensory interactive experience in visual communication design, some typical cases under new technologies are used for research, trying to explore new ideas and methods through case analysis.

(2) Based on the existing research results, this article puts forward new views, discusses the visual cognitive representation of information visualization, and broadens the research field of information visualization. According to the existing mode of thinking, combined with our own practice, a systematic design method of visual communication of information visualization is constructed. The effectiveness of this method is verified by experiments, and the superiority of dynamic visual communication in information dissemination is analyzed. In the future, visual communication design in other fields can provide a reference basis.

This article's research content and structure are as follows: Section 1 introduces the article's research context, significance, and organizational structure. Section 2 is primarily a summary and review of relevant domestic and international literature. It also introduces the research and innovation methods used in this article, which are based on these related literatures. Section 3 focuses on information visualization theory and related issues of visual communication interaction mode as well as the interactive information visualization design process. Section 4 details on the experimental analysis. The actual test is carried out in this section, and the test results are obtained, based on the relevant data. The algorithm's performance is evaluated in comparison to the experimental results of other methods. Section 5 concludes the study. This section primarily summarizes the research's main points and findings, summarizes the research conclusions, and suggests future research directions.

2. Related Works

Information visual design is a unique discipline that cuts across many industries and is a design category with a wide range of applications. Nowadays, relevant researchers in the field of information visualization have their own unique knowledge and understanding from their respective perspectives as well as a level of depth. Simultaneously, as the vocabulary of media grew, many design firms and avant-garde designers began to experiment with digital multimedia to express creativity and convey information. Visual communication design, as part of the creative field, is attracting increasing attention from all walks of life, playing an increasingly important role in people's lives, and defining the function of information transmission.

Papasarantou et al. examined the often-overlooked appeal of visual appeal in information visualization and discussed the broader role of emphasizing visual communication design principles in the design process [9]. Vera believed that improving the efficiency of visual thinking in processing information and reducing the cognitive load in this process can allow more cognitive costs to be allocated to later abstract understanding and decision-making. Therefore, they conducted research on finding ways to optimize the design of information visualization by understanding the characteristics of visual thinking activities [10]. In order to further understand and engage in scientific information visualization and visual communication design methods, Wu et al. proposed a mutual learning strategy of art and practice [11]. Combined with the development characteristics of information visualization under the background of experience economy, Li and Liu et al. explored solutions to improve the quality of visualization services from the perspective of information users and provided useful suggestions for the research of information visualization in visual communication design and visual effect evaluation [12]. Kosara and Mackinlay used a large number of cases to conduct an in-depth exploration of the practical innovation of visual communication design, thus confirming the two main visual expressions of visual language in new media—one is dynamic and the other is multisensory humanization of interaction [13]. Winstel pointed out that the visual communication design under information technology should not only stay in the traditional design under the influence of technology, but should focus on the "new communication" and "new language" of visual design, and new forms of expression and specific applications in new media are studied in-depth [14]. Compared with other disciplines, visual communication design occupies a pivotal position in information design by Pfeffer. The communication of visual graphics vocabulary is the key to information design and the most basic requirement of visual information construction. On this basis, with the expansion of the application field of information design, its design concept affects business planning, cultural construction, and audience visual interaction experience [15]. Reif et al. obtained the commonality and individuality of digital visual communication design and print design through the comparative analysis of digital visual communication design; and then combined with examples to analyze the immaterial, interactive, and multidimensional language characteristics and dynamics of digital visual communication design, multimedia, and interactive communication characteristics [16]. Haustein et al. took visual communication as the main body of their research and explored the communication mechanism of visual representation of information visualization and the corresponding design method of visual communication of information visualization [17]. Estrada et al. believed that the current design forms for information dissemination only pay too much attention to design symbols, ignoring the psychological needs of the audience and the process of information dissemination, resulting in the inability to maximize the dissemination of information [18]. Han and Deng focused on new media and visual communication design and analyzed the occurrence of new media and its characteristics of the times. At the same time, the connotation and development process of visual communication design are explained in simple terms, and it is concluded that the change of media technology is the main reason for the evolution of visual communication design [19].

In this article, some viewpoints and ideas are put forward based on previous studies on visual communication. On the basis of visual interface design, and taking interactivity and user experience as innovation points, the design process of interactive information visualization is deeply explored. Combining theory with practice, this article explores a systematic design method of visual representation of information visualization. According to the application of design thinking and design methods, the simulation experiment is carried out, and all kinds of boring data information are presented through visual symbols, which eliminates the obstacles between the public and all kinds of information and improves the effectiveness of visual communication interaction.

3. Methodology

3.1. Information Visualization Theory and Visual Communication Design. Information is defined as meaningful data that can express the objective facts that the data describe. The data that have been organized and sorted have relevance and have become information, but it remains data for those who are not experts in this field and cannot comprehend the meaning expressed by these data. Information visualization is the use of effective visual expression to assist users in reading, identifying, and interpreting data subjectively in order to provide them with access to critical data. More personalized and customized information visualization works have been published through the Internet platform since the arrival of the experience economy, which not only benefits users' information quality but also poses new challenges to information visualization design. The visualization product should be able to reach the brain via human vision, hearing, touch, and even other senses, and instantly understand a large amount of data [20]. Information visualization emphasizes people's receptivity while also incorporating psychology, visual design, human-computer interaction, business methods, and other disciplines. The symbolic design in the practice of visual representation is the reason why the visual view of information can convey information to the public. The ability of the audience to interpret the meaning of symbols provided by designers determines the effectiveness of information communication. Information communication is ineffective if the audience does not understand the meaning of the symbols.

Information visualization has been adopted by many media and educational, government, and corporate organizations due to its understandable visual form and inherent ability to present complex data. When users contact the information visualization platform, one of the most common cognitive activities is visual thinking. Visual thinking, in contrast to other abstract thinking activities, is based on perceptual experience and can complete a variety of cognitive tasks. The disseminator, receiver, information, and carrier are all involved in the visual representation of information, which is a two-way interaction between coding and decoding in information dissemination. At the same time, the information visualization view is a type of construction, with the representation being the representation that is dependent on the construction, and the construction being the construction that requires representation, all of which combine to form the information visualization view's meaningful communication. Information can be visualized while being read to alleviate the pressure of a "information explosion" caused by a large amount of data. When creating information graphs, the accuracy of information visualization is critical. Before beginning the design, it is necessary to have a solid foundation of theory, science, and technology, and the resulting infographic must be completely accurate. When designing infographics, this is where designers can easily make mistakes. In comparison to large data sets generated by scientific calculations and engineering surveys, information visualization resources are nonphysical and abstract, with no obvious spatial characteristics. The information visualization process and system structure are shown in Figure 1.

With the gradual expansion of the scope of modern design, digital technology and network technology have penetrated into all fields of visual communication design, and the influence and participation of multimedia technology on art and design are getting deeper and deeper, which makes visual communication design step onto a brand-new stage. Information design and graphic design serve different purposes: the former is concerned with "effective information transmission," while the latter is concerned with "exquisite artistic expression." The visual effect is more innovative and unique because the image generation technology for information visualization is not complicated, and its expression methods are diverse. Individuals, businesses, and even countries can be clients of information visualization. These forms are important, but the service content is what matters most. Information visualization covers a wide range of disciplines and application fields as an important method in information design. It can be used to solve specific professional problems. The faster and more agile the visual thinking can respond to the input visual information, the more accurate and reasonable the visual communication of information is. Information visualization examines the data visualization presentation results, extracts the hidden value from the data, and assists in making sound decisions. Because this type of decision is not invariable in a constantly updated data environment, information visualization is a continuous process that allows users to discover potential problems and improve the final decision in stages over time. In the visual communication design of information visualization, color serves as a classification and emphasis tool. Color distinguishes primary and secondary relationships and categories. In visual perception, color is the most intuitive, and information can be obtained without using logic.

Computer science research [21, 22] in information visualization mainly focuses on solving users' functional requirements. This technical research can reduce the impact of other problems such as aesthetics or user experience [23]. Visual communication design always takes the audience's acceptance of visual information through their own aesthetic judgment as the ultimate goal, and visual communication design always pursues and yearns for a rational interaction with the audience, thus turning the communication of visual information into effective communication with people. Interaction is a convenient way for users to operate content and its attributes. Interaction is a technology that can easily explain products and make the audience feel relaxed when reading information. The two-way interactive communication mode of visual information makes the new media visual communication design pay more and more attention to the audience's necessity and "participation" in the design. On the contrary, more and more people are looking forward to bringing their ideas and wishes into the design, which promotes the formation of interactive design. As information visualization design is a very wide range of disciplines, in the process of visualization, the application of visual communication design has a transformational impact on the ways and means of attaching importance to teaching and carrying out information visualization research. Graphic symbols account for the largest proportion in information view, which is the soul of visual representation of information. Graphic symbols include pictures, theme graphics, attached icons, charts, and characters. This article analyzes and summarizes the classification of graphics, the effectiveness of attached icons, the model construction of charts, and different types of characters. The more and faster cognitive tasks are accomplished by visual thinking, the more cognitive costs can be allocated to abstract thinking activities, thus improving the efficiency of people's deep understanding of information and making decisions.

3.2. Interactive Design of Visual Communication Based on Information Visualization. Graphic symbols are image materials generated by various graphic software, and their visual representation differs from that of words and languages. Graphics, which are the main visual representation symbol in information visualization design, can be copied in large quantities using various methods. Because the main graphic symbol is so closely linked to the information visualization theme, it can be said that the main graphic symbol is the information theme's mapping. Visual communication design in the modern world is interactive design with people that emphasizes the audience's active cognition in the process of receiving information and selectively accepts visual information based on their own aesthetic demands and wishes. The more experience and knowledge an information user has with information acquisition and understanding, the faster and more accurately he can extract the information content he needs from the visual interface and the more effectively he can dig out the connotation and relationship of information and find solutions to problems. Tagged words are concise, clear, and easy-to-understand that appear in the view as expressive keywords. The introduction or explanation of a specific piece of information or a group of related pieces of information is included in descriptive text. The orderly arrangement of some data and information in the information view, which makes the information more intuitive and reduces the audience's visual pressure, is known as organized text. A basic visual model is chosen to express it is "representation." This step essentially determines the nascent form of the visualization effect, and it is necessary to consider the appropriate representation method based on the data dimensions, such as a list, tree structure, or other methods. The goal of "decoration" is to make information expression simple and clear while also being rich in connotation, practical, and beautiful. To create a logical structure, the information hierarchy must first be divided. After grouping and classifying the data, graphic design is used to convey information of various dimensions, such as category, attribute, degree, orientation, etc., and data of all types and dimensions are sorted according to the information needs of users to highlight the most pressing issues. Figure 2 depicts an interactive

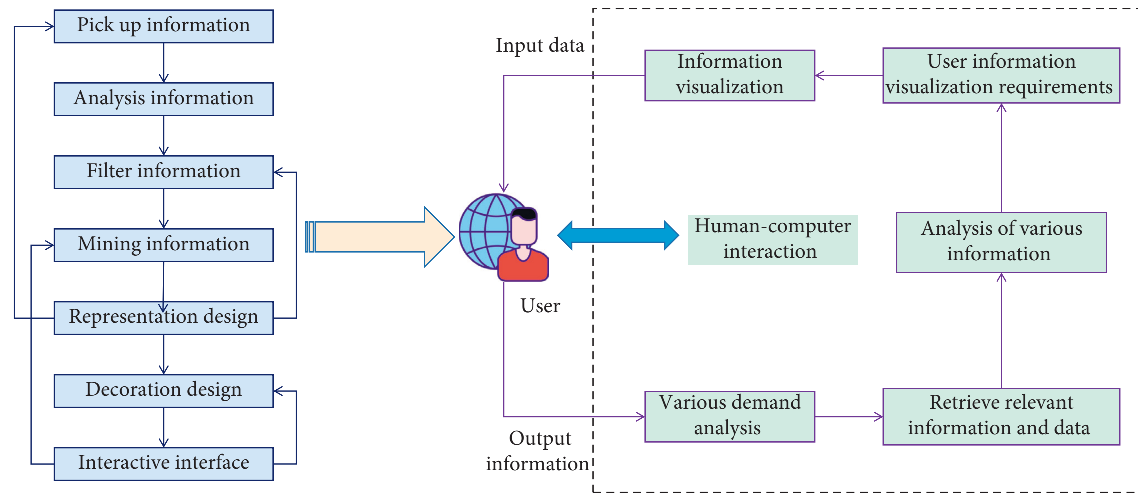

FIGURE 1: Information visualization process and system structure diagram.

design diagram of visual communication based on information visualization.

Abstract graphic symbols are completely out of the natural form, and it is impossible to extract a specific image from them, so it is necessary for viewers to create graphics with their imagination. Figurative figure is a form that is close to the viewer's daily life and the objective facts. It can reproduce the features of things and is direct, vivid, clear, and easy to identify. Dynamic visual symbols can attract more attention from the audience, which also makes the new media visual communication design not only need to pay attention to the expression form of plane visual elements, but also consider its animation effect in the picture. The difference of visual information determines its "pop-up effect." The better the pop-up effect, the easier it is to pay attention to screening. Therefore, the target information can be "popped up" from the background or nontarget information by changing the visual features such as color, size, position, and shape. Data mining or statistical methods are used to analyze the data format or put the data in a mathematical environment. Its purpose is to find some rules in a pile of chaotic data, so as to provide organized raw materials for subsequent data representation. Visual representation is the method and way to realize information visualization. It refers to the multi-method of "visualization" for information representation, so that the represented information can be "visualized," and finally the information can be optimized, so as to promote the public's acceptance and understanding of information, maximize the information dissemination, and innovate the information dissemination process.

If the coordinate of the root node is (X_0, Y_0), the selected radius is r; the number of direct child nodes is count. Then the formula for calculating the coordinate (X_i, Y_i) of the ith child node is as follows:

$$X_i = X_0 + r^* \cos\left(\frac{2p^* i}{\text{count}}\right), \tag{1}$$

$$Y_i = Y_0 + r^* \sin\left(\frac{2\pi^* i}{\text{count}}\right). \tag{2}$$

If the coordinate of A is (X_0, Y_0), and the included angle of A on its concentric circle is initAngle, the formula for calculating the coordinate (X_i, Y_i) of the ith child node in the next layer of A is as follows:

$$\begin{aligned} \text{initAngle} &= \arctan\left(\frac{Y_0}{X_0}\right), \\ X_i &= X_0 + r^* \cos\left(\text{initAngle} + 2p + \frac{i}{\text{count}}\right), \\ Y_i &= Y_0 + r^* \sin\left(\text{initAngle} + 2\pi + \frac{i}{\text{count}}\right). \end{aligned} \tag{3}$$

It is possible to improve the quality of the user experience by creating a favourable situation. Information visualization design can incorporate materials related to users' knowledge base, life experience, and personal details. The arrow is the most widely used directional symbol in the visual representation design of information visualization, and it has various meanings in various contexts. Computers perform the majority of the design work. The user's status shifts from passive to active in the interactive stage, from acceptance to discovery and consideration. The ability to control and explore data through interface interaction allows them to truly combine computer and human intelligence. The visible part of the user's interface is called the man-machine interface. Communication and operation with the system require a man-machine interface. Under new media technology, it is the most unique design language in visual

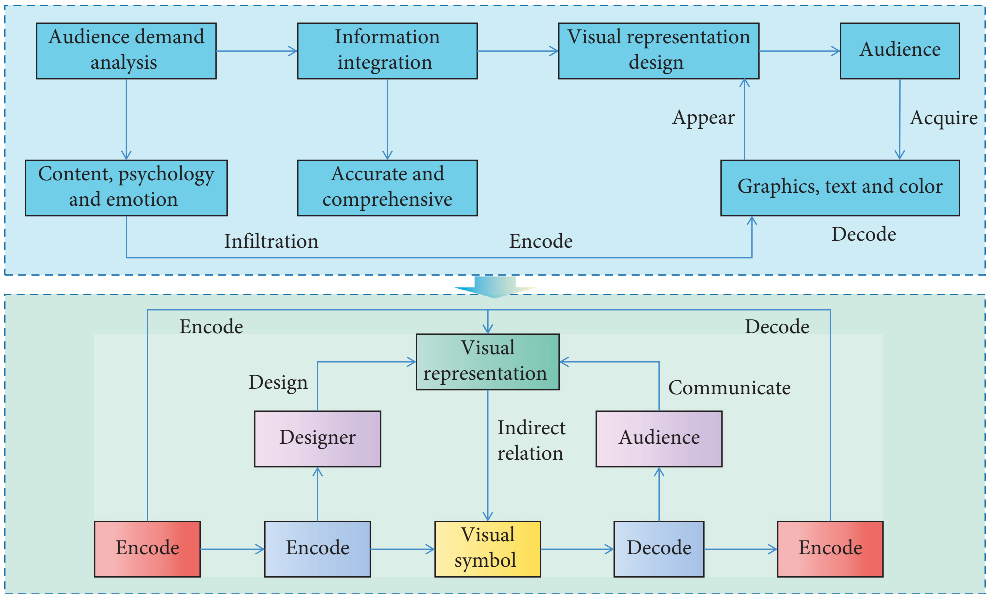

FIGURE 2: Interactive design of visual communication based on information visualization.

communication design, and the interactivity of visual communication design has been fully demonstrated in a variety of design practices. Expert users can understand and analyze data at a deeper level thanks to interaction. For obtaining implicit data knowledge, an interface is required. The introduction of a comprehensive digital network has created unprecedented opportunities for interaction and the collection of a wide range of data, including text, image, and sound. Information users are surprised and their knowledge and experience are challenged as expressive methods of information visualization evolve. As a result, appropriately adding guidance or comments in the visual interface will help users understand information better. Aside from formal symbols, the design should also conform to the audience's visual experience, place the core information content in the center, and guide the reading sequence with flow symbols like arrows to improve reading efficiency.

Class perception is used to measure the perceptual strength of the color and spatial distribution of each class. For any point p in class c^m, the perception degree V_p of this point is calculated by the following formula:

$$V_p = w_p S_p, \tag{4}$$

where w_p refers to the weight of point p in class c^m, and the weight is determined by the neighbor points of point p. S_p refers to the significant value of p. This value is obtained by formula (2). S_p expresses the color difference between point p and its surrounding neighbors.

$$\begin{gathered} S_p = \Delta\varepsilon\left(C_p, \frac{1}{N_p} \sum_{q \in N_p} C_q\right), \\ \Delta\varepsilon(x, y) = \sqrt{\left(\Delta L^{*2}\right) + \left(\Delta a^{*2}\right) + \left(\Delta b^{*2}\right)}, \end{gathered} \tag{5}$$

where

$$\begin{aligned} \Delta L^* &= L_x^* - L_y^*, \\ \Delta a^* &= r_x \cos\theta_x - r_y \cos\theta_y, \\ \Delta b^* &= r_x \sin\theta_x - r_y \sin\theta_y. \end{aligned} \tag{6}$$

Assuming that X is divided into C classes, and each x_i corresponds to a class label $I(x_i)$, then the data of class c are expressed as

$$\{X_1^c, X_2^c, \ldots, X_n^c\}, \tag{7}$$

where n is the number of data in the c class, $c \in \{1, 2, \ldots, C\}$. The data of different classes are divided as much as possible, and the objective function is as follows:

$$\max tr \frac{P^T S_b P}{P^T S_w P}, \tag{8}$$

where S_b and S_w represent the class spacing dispersion and the intra-class distance dispersion, respectively, and the specific definitions are as follows:

$$S_b = \sum_{C=1}^{C} n_c (u_c - u)(u_c - u)^T,$$
$$S_w = \sum_{C=1}^{C} \sum_{i}^{n} (x_i^c - u_c)(x_i^c - u_c)^T, \quad (9)$$

where $u_c = \sum x_i^c / n_c$ is the mean value of the cth data; u is the mean value of all data, the center point of all data.

The purpose of data analysis is to concentrate, extract, and refine a large amount of hidden information of data to find the inherent laws of the research objects, so that people can understand, judge, and make corresponding decisions and actions faster and better. On the one hand, information visualization should try to call the familiar visual features of users to construct the visual effect of information; and on the other hand, frequent visual thinking training can enrich information users' experience and knowledge stored in their brains and make visual thinking activities more efficient. In information visualization, it is not to look for symbols with specific meanings to represent, but to consider the whole information view, combine information content and context, and adopt the "proper principle" to represent with visual symbols. The modern environment provides a space for innovation and breakthrough in the design thinking and concept of visual communication design. We can make visual creation according to this selective way of reading information, so that the audience can fully participate in the whole design process, thus obtaining a more humanized visual experience.

4. Result Analysis and Discussion

With the progress of society, the carrier of visual information dissemination is constantly changing with the development of technology, which all affects the expression of visual information such as graphics, characters, colors, etc. in visual communication design, and also affects the change of thinking mode of design creation. In the practice of visual representation of information visualization, the construction of information model refers to the selection of appropriate organization arrangement. Visual representation design of information is a process of rational and perceptual thinking. Rational information model construction plays an important supporting role in visual representation design of information visualization. Human-computer interaction plays an important role in information visualization, and a large amount of data can only be perceived through human-computer interaction. Man-machine interaction transmits information naturally and efficiently, and allows users to get a good understanding. Good interactive mode and simple user interface can help people get relevant information quickly. Figure 3 shows the convergence of the three algorithms as the number of iterations increases.

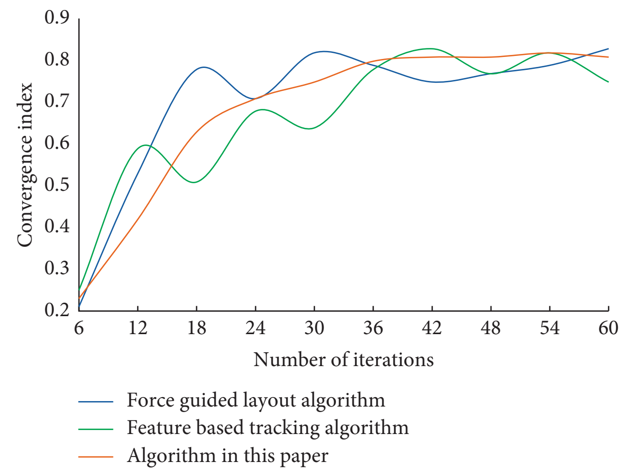

FIGURE 3: Convergence of algorithm.

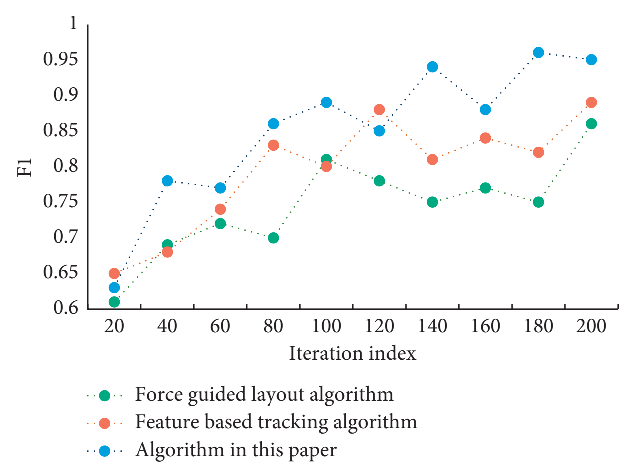

FIGURE 4: Experimental results of F1 value of algorithm.

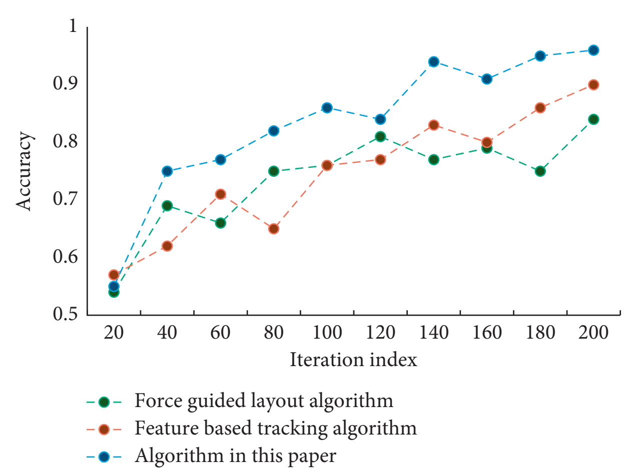

FIGURE 5: Experimental results of algorithm accuracy.

It can be seen that the algorithm in this article gradually converges with the increase of iteration times. This is due to the difference of objective functions of different methods. The four elements of visual design, such as text, graphics, color, and layout, are the foundation of information design, and the accurate application of them will help the accurate expression of information design. Timeliness is the main feature of dynamic visual design. From graphic design to dynamic design, the form of font design changes from a

Table 1: Experimental results of each index.

Algorithm	Average absolute error	Recall rate	Accuracy rate
Grid layout algorithm	0.373	0.874	0.798

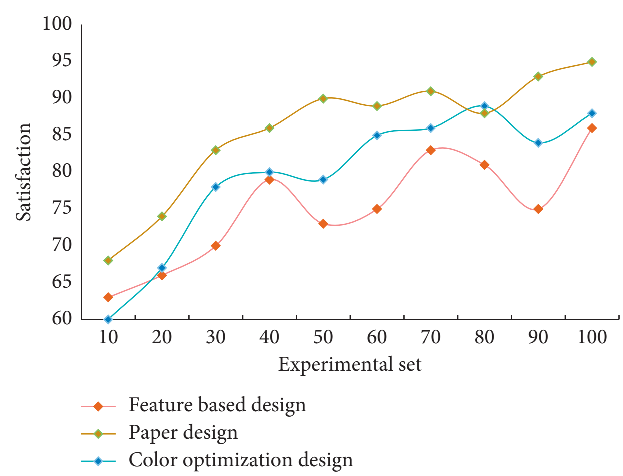

Figure 7: User satisfaction results.

static entity to a digital virtual scene based on the concepts of time and space. Visual information from the physical world is detected visually, and then the target information is screened by visual attention mechanism, and it is decided which information needs to be processed by consciousness and which can be directly reflected. Consciousness will further process the input information, eventually forming empirical knowledge and storing it in memory for later advanced rational cognition. In order to verify the performance of this algorithm, we selected F1 value and precision as two indexes for many experiments. The experimental results of F1 value are shown in Figure 4, and the precision results are shown in Figure 5.

Systematic design method includes two processes: analysis and synthesis. Analysis precedes synthesis, and existing data information is improved after analysis to achieve new synthesis. For graphic information integration design, it is required to link the analysis and integration methods, start with the whole system, analyze and extract effective data information, and synthesize it into information visualization presentation form. In dynamic design, the development of digital technology and information technology makes it possible for the spatial attribute of characters. Time and space are two inseparable concepts in the movement. In the transformation of space, we can constantly experience the visual experience brought by movement and feel the flow of time, so as to better receive information. The interactive infographic is programmed by software such as Flash or Dreamweaver, integrates the data that have been converted into graphic language, and presents it in the form of aesthetics according to scientific data. Its presentation form is not only a moving picture, but also viewers can interact with short films on the media with their own concerns, which is more flexible than video infographics. In this chapter, several experiments are carried out to verify the feasibility and practicability of this algorithm. The experimental results of different indexes of the algorithm are shown in Table 1.

Parametric design is a term used in the design world to describe the process of establishing a specific relationship. Other elements change when one changes. Because of its various meanings and postures, each font has a unique emotional effect. Fonts are valuable due to their diverse personalities. As a result, understanding the expression of words for the transmission of information is critical in visual communication design. Consciousness will focus on dealing with new and different information, learning and adapting as a result, and the information processed by consciousness will be stored in memory as a new source of knowledge. As a result, based on visual objectives, information visualization should provide a reasonable explanation or cognitive clues to some strange and novel information, and then assist consciousness in better completing cognitive tasks. Figure 6 depicts the effectiveness assessment of visual communication interaction design.

From the data in Figure 6, it can be seen that this design is effective and practical, which can enhance the perception of visual trajectory. Long-term memory, like a permanent box, holds a large amount of information and can extract activation information at any time. This requires a series of structures in the design process to conform to cognitive thinking and human cognitive behavior, so that the design activities can be carried out according to evidence and in the right direction. The survey results of audience demand satisfaction of visual information communication design are shown in Table 2.

The “dynamic design” in interface design has been paid more and more attention by visual design practitioners. The unique dynamic design can express the distinctive personality of the software and create fascinating effects. At the same time, it can also appease users through the use experience, so that the audience can get a relaxed and pleasant feeling when reading information, thus truly achieving humanization. Figure 7 shows the survey results of user satisfaction with different design methods.

From the survey results of user satisfaction, it can be seen that users are more satisfied with this design method. This chapter carries out a lot of experiments and analyzes and summarizes the superiority of visual communication design in information transmission. Through research, it is found that the accuracy of this algorithm is 96.03%, and the highest evaluation of user satisfaction is 95.93%. This algorithm has faster convergence speed and greater generalization ability.

5. Conclusion

In the field of information visualization, visual communication design is becoming more and more involved. It is an essential component of the development of data visualization. Information visualization will develop in a more personalized and customized direction in the future, with the arrival of experience economy and the rapid development of Internet applications, and the presentation form of information visualization will not be limited to two-dimensional plane, but will pay more attention to integration with interactive experience. Through the power of images, information visualization brings dull data to life, allowing readers to grasp information quickly and leave a lasting impression. Relevant personnel should concentrate on the visualization form and mode of interaction when dealing with information visualization design. With the help of psychology and communication knowledge, this article examines the kernel of information visualization and visual representation. The audience “decodes” information through visual symbols to obtain information, according to this study. Simultaneously, it is proposed that by expounding on the concept of information visualization and analyzing the cognitive tasks and characteristics of each stage of visual communication, information users can be effectively assisted to acquire and understand information better by lowering the cost of information users in the visual thinking stage and improving their visual thinking response efficiency. Many tests show that the algorithm has a faster convergence speed and a greater ability to generalize. This algorithm has a 96.3% accuracy rating and a 95.93% user satisfaction rating. This research has certain reference value. However, due to the limitation of knowledge level and research time, there are still some problems in this article. This article is only a preliminary study of information expression, and there are still a lot of research on the details of expression and visual elements. The research of visual information interaction mode has sustainable attention and exploration significance in the future academic research and production practice and should be deeply discussed and studied.

Based on a machine learning algorithm, this paper deeply explores the privacy protection of personal information. In this paper, the definition of the machine learning algorithm is put forward, the design idea of privacy protection in joint machine learning platform is studied, and the architecture model and model parameter updating strategy of joint machine learning under privacy protection are designed. To protect the privacy of personal information, this paper also proposes a data homomorphic verification mechanism to prevent the global parameters from being tampered with by malicious cloud servers. In order to verify the performance of the models constructed in this paper, the comparative experiments of different models are carried out. The experimental results show that this algorithm has a fast convergence speed, and the average error rate decreases by 4.17% compared with the traditional algorithm. Moreover, the accuracy of this algorithm reaches 95.37%, which is about 8.76% higher than the previous algorithm. This model is applied to the field of personal information privacy protection, which can provide a safe and reliable environment for personal information privacy and effectively protect the privacy of data owners. And, means and reference value is provided for the development direction of privacy protection.

1. Introduction

The amount of data generated by all walks of life is exploding as we enter the information age, thanks to the development of information technology such as the Internet; with the enhancement and aggravation of online data behavior, the protection of personal information and privacy is particularly prominent in the contemporary era [1]. As a result, the purposeful collection, investigation, utilization, transmission, disclosure, and sale of personal information via the Internet has reached an unprecedented level. Although easy-to-obtain personal data have become a staple of academia and industry, the process of data collection, publication, processing, and storage will be aided by a slew of third-party service providers, expanding the number of possible data sources [2]. Personal data collection, expansion, mining, and use for more precise business marketing activities have gradually become a new focus of business development for traditional businesses, Internet businesses, data-related businesses, and so on. With business's continued growth and prosperity, it also brings with it potential conflicts of interest and hidden risks for various individuals [3]. In addition, due to the prevalence of online fraud, user privacy breaches do occur from time to time. Personal privacy protection has become one of the problems brought on by the information society in the network environment. Despite the fact that the definition of privacy is complex and varied, personal information plays an important role in privacy [4]. The abuse and control of information is a major concern in today's world of privacy. People are gradually becoming more aware of personal privacy as big data-related technologies advance. As a result, countries' focus in formulating laws and regulations on privacy protection has shifted to how to properly protect privacy without impeding network development.

The content of privacy right is extensive, including the information secret of a natural person's personal life, the peace of his personal life, and even his own decision on private life. Therefore, from the content, the right to privacy can be said to be a collection of rights [5]. Personal information may be infringed in the commercial data behavior of Internet enterprises, that is, personal information risk; that is, personal information may be harmed as an Internet user. In the traditional differential privacy model, data from different sources are concentrated in the central server, and then the data are treated with privacy protection, and the central server publishes the inquiry information satisfying the differential privacy [6]. However, in the process of data collection, third-party service providers are often uncontrollable, which easily leads to privacy leakage [7]. The characteristics of diverse data sources, fragmented information, and personalized and differentiated privacy requirements lead to the risk of privacy leakage when multi-party data are merged. At the same time, the separation of data ownership and storage rights, multi-source, high-dimensional, and dynamic characteristics aggravate the risk of privacy leakage in the process of data sharing and pose new challenges to privacy protection technology. Personal information, as an original part of "privacy," has become a prominent contemporary problem in the background of the increasingly prosperous enterprise data behavior [8]. At the same time, data privacy has become the core issue of machine learning, especially when using some sensitive data in cloud computing, the cloud is not completely trustworthy. Therefore, privacy protection and machine learning algorithms must be designed for the cloud. Machine learning provides a potentially powerful framework for automated perception and reasoning. However, a good machine learning framework still needs a large number of data sets to fully realize its potential of perception and reasoning. In this paper, a personal information privacy protection model based on a machine learning algorithm is constructed, and its innovations are as follows:

① This paper studies the structure design and working mechanism of distributed machine learning system under privacy protection and analyzes the design strategy of privacy protection in a distributed machine learning system. Aiming at the privacy protection of personal information, this paper designs a data homomorphic verification mechanism to prevent the global parameters from being tampered by malicious cloud servers.

② This paper investigates vector addition, number multiplication, linear transformation, and weighted inner product homomorphism operations using vector homomorphism encryption; this allows the vector homomorphic encryption scheme to meet the basic operations in machine learning. A local differential privacy data stream protection protocol is proposed that can provide data stream privacy while also ensuring high data availability and requiring less storage and computing power.

This paper mainly explores the privacy protection of personal information, which is divided into five sections. The specific research framework is as follows:

Section 1 is the introduction. This part introduces the research background, significance, and methods of this paper and gives the innovation and organizational structure of this paper. Section 2 is a summary and research of related literature at home and abroad and introduces the research methods of this paper. Section 3 mainly constructs the privacy protection model of personal information based on a machine learning algorithm. Among them, Section 3.1 analyzes the concept connotation of privacy protection and machine learning and summarizes the related basic theories. Section 3.2 focuses on the construction method and implementation of the personal information privacy protection model. Section 4 is the experimental analysis. In this part, many experiments are carried out, and the experimental results of other models are compared to analyze the performance of the models. Section 5 is the conclusion and prospect. This part mainly reviews the main contents and results of this research, summarizes the research conclusions, and points out the direction of further research.

2. Related Work

The arrival of the information age has brought about changes in all aspects of our lives, and profound business changes have taken place in the global society. With the rapid growth of intelligent terminal devices, massive data are generated anytime and anywhere. These data have profound value, and all kinds of enterprises and institutions begin to collect personal data on a large scale and analyze and mine the collected data. While enjoying the convenience brought by information technology, information security and privacy have become the focus of people's attention. Therefore, many researchers have made relevant explorations on data search and personal information privacy protection technology.

Ocansey et al. [9] proposed a fully dynamic fully homomorphic encryption scheme that no longer limits the number of allowable parties [9]. Wang et al. [10] propose an outsourced secure multi-party computation framework. The scheme uses two noncollusion cloud servers, one for storage and computing, and the other contains the master private key that can decrypt user data and realizes computing outsourcing by constructing a secure protocol [10]. Wang et al. [11] proposed a security outsourcing detection system, the system classification is completed by the support vector machine algorithm, and privacy protection is achieved by designing a secure multiparty protocol [11]. Yin et al. [12] focused on data outsourcing services on the basis of analyzing the risks of privacy leakage in the stages of data release, storage, and search and combined with the multiparty requirements for data privacy protection granularity, data availability, timeliness, and other dimensions at different stages. Research on key technologies of data privacy protection under the mode [12]. Reza et al. [13] took the hybrid cloud as the data bearing platform, proposed a data segmentation technology based on the k-anonymity criterion, and designed a complete set of data anonymity segmentation scheme to solve the balance of data privacy protection and availability when the set-valued data is released [13]. Wei et al. [14] believe that attackers can obtain data privacy by filtering random noise. Furthermore, random perturbations may expose the privacy of outliers when attackers have access to external information, i.e., published data about individuals may contain quasi-identifier properties that may be linked to public databases to reidentify individual records [14]. Liu and Zhou [15] proposed a privacy protection scheme based on differential privacy, and its protection of data privacy has nothing to do with the background knowledge mastered by the attacker. This scheme ensures that statistical queries on the target dataset and on datasets that differ by only one record are identical in results [15]. Ke et al. [16] proposed the use of differential privacy computing to achieve privacy-preserving mining of joint datasets [16]. Barni et al. [17] proposed a distributed algorithm, which assumes that the same record has a unique global identifier in a vertically divided data environment, and all parties involved in data fusion only have data with partial attributes; the original information is hidden in the communication process, and the privacy protection of the data fusion process is realized by constructing a complete anonymity table to determine whether the anonymity threshold is met [17]. Hu et al. [18] proposed an algorithm for users to learn game equilibrium. The classifier built by this algorithm enables each user to strike a balance between the accuracy of the classification task and data privacy [18]. Xie et al. [19] proposed an abstract model to support databases with any number of public and private variables and formulated application-independent privacy protection granularity and utility metrics, where privacy protection granularity was quantified by ambiguity, and data utility was measured by Fidelity to quantify [19].

Based on research on privacy protection of personal information in related literature studies, this paper proposes a new research approach and method. Using the machine learning architecture model, this paper creates the overall architecture of the joint machine learning platform, as well as the key structure of the central server. A fast synchronous random gradient descent method is designed for a heterogeneous multiclient situation to ensure fast training and convergence of the model, as well as to improve the generalization ability of the existing model. The traditional disturbance mechanism is used to protect the key attribute data, with noise satisfying the definition of local differential privacy added to the model's local update. As a result, the aggregation operation can be used to initialize the global model parameters, resulting in fewer model training communication rounds. Experiments show that the model is stable and reliable, as well as that it performs as expected.

3. Methodology

3.1. Privacy Protection and Machine Learning. As a contributor of individual knowledge and content, participate in knowledge creation and sharing in the information age. At the same time, with the help of the Internet, individuals can realize some or all activities or projections in reality and conduct business transactions, self-construction, social interaction, information acquisition, and other actions. At present, the collection, expansion, mining, and use of personal information for more accurate business marketing activities has gradually become a new focus of business development for traditional enterprises, Internet companies, data-related enterprises, and so on [20]. With the continuous development and prosperity of business, it also brings potential conflicts of interests and risks of different individuals. Internet privacy refers to the right that a natural person enjoys on the Internet that his personal affairs are not publicly publicized, his private life is not disturbed, and his personal information related to online activities is protected from being illegally collected, known, utilized, and disclosed by others. In the information age, massive data have brought obvious privacy security problems in the practical application of machine learning. Users' personal highly sensitive data are collected and kept in commercial companies indefinitely. Users can neither delete these data nor restrict the use of them by commercial companies. Considering the privacy and security of data, many data holders are reluctant to share their data sets, so they can not directly use the joint data sets of participants for machine learning [21]. As an important component of the original concept of privacy, personal information will face more prominent and severe challenges in the information age and networking. The new emphasis of network privacy in the era lies in the problem of "privacy digitalization" brought by network society. This is the core issue of "privacy" in the information age.

In the information age, the right of network privacy should include the following aspects: ① the control of personal information. ② The right to be free from interference when individuals conduct online behavior. ③ The obligee's knowledge of the use and collection of personal information on the Internet by others, and his request to withdraw from deletion, etc. In the network society, the mass production of personal information and the precipitation of structured and unstructured data make it possible to use data to analyze consumer behavior and preferences and increasingly move towards accurate consumer description and database marketing. The more accurate you understand the marketing audience, the more you can achieve the marketing management goal of low cost and high return. With the development of cloud computing technology, it has gradually become a trend for enterprises to go to the cloud [22]. Personal information such as users' personal photos, home address, contact information, etc., may be permanently stored in the company server of the cloud service provider, which is beyond the control of the owner. The violations of users' privacy rights involved in the management of network resources mainly include improper use of network users' personal information, privacy of personal activities, traces of personal networks, and infringement of personal cyberspace. The collected person of personal information has the right to ask the collector to take necessary and reasonable measures to protect the security of his personal data. First of all, you can ask the website to take certain technical measures and policies to keep the collected data; secondly, their personal data shall not be transmitted or disclosed to any third party; finally, within the network service group, we should also pay attention to the disclosure of relevant information. On the user side, the user's cognition, attitude, and behavior of personal information risks when participating in interaction are the basic elements to be included in the interaction model to protect the user's personal privacy information. On the enterprise side, the appropriateness of its data behavior and the integrity of its protection are feasible and effective guarantees for the protection of personal privacy information. The data mining model of personal privacy protection is shown in Figure 1.

The data provider has shifted from service organizations to individuals as a result of the rapid adoption of personal smart devices, and traditional privacy protection methods are no longer adequate for the protection of personal privacy data. To achieve effective personal information protection, we must first clarify the most basic data behavior and provide the most practical reference from the enterprise behavior and regulation level. To solve the problem of personal data protection in particular, we must first address the problem [23]. The method of data encryption encrypts data while also completing complex calculations with the help of secure multi-party protocols, as the name implies. The difficult assumption of encryption algorithm and protocol construction underpins security. In academia and industry, the privacy difference is the most common method for protecting data privacy and the evaluation standard for privacy schemes. This model assumes that the adversary has sufficient background knowledge and that the addition or deletion of any record has no impact on the query's final result. Differential privacy protection technology is a well-defined privacy protection model that can withstand all attacks based on assumptions about background knowledge. Its main principle is to achieve privacy protection by adding random noise to distort the original data while maintaining the original data's statistical characteristics. Differential privacy mainly distorts data by adding noise to protect privacy. Privacy difference is independent of the background knowledge of the adversary, and it can provide a stronger privacy protection ability than the traditional anonymous protection mechanism. However, the differential privacy protection technology is difficult to be applied to the application scenarios where multiple data owners do not collude.

The server aggregates the user's personal disturbance reports from the client and decodes them to obtain valuable statistical information, while local privacy sets the privacy protection mechanism directly at the client. To avoid the privacy leakage of the untrusted third-party server, this process does not need to collect the client's real original data information, and it can be applied to a variety of complex collection scenarios. Although differential privacy protection technology improves privacy protection to some extent, noise introduces changes in the original data distribution, reducing the accuracy of results and data availability. Differential privacy technology can be used to store databases, effectively resolving the local storage privacy security problem [24]. Differential privacy, on the other hand, resolves the local storage privacy leakage problem. Secure multiparty computing is based on the assumption that multiple service users who do not trust each other exchange data information via secure multiparty protocols, allowing each service user to perform distributed machine learning tasks based on their own data. Federated learning, as a distributed machine learning framework, aims to train a high-quality centralized model while keeping local training data distributed on clients and allowing multiple users to train the same learning tasks at the same time. Each user downloads the global model, calculates the local model's update using the local data set, and uploads the update to the central server at the end of each training round. To calculate a new global model, the central server combines the local updates from clients.

3.2. Construction of Privacy Protection Model Based on Machine Learning. Machine learning is a branch of artificial intelligence. Machine learning is a scientific study of algorithms and statistical models used by computer systems to gradually improve the performance of specific tasks. The machine learning algorithm is a mathematical model based on the so-called "training data set." It can complete forecasting or decision-making problems without the guidance of a specific program. Most of the traditional machine learning training algorithms are only suitable for single machine learning. Therefore, machine learning in the distributed environment needs the corresponding distributed machine learning platform to complete. Machine learning algorithms are closely related to computational statistics. Machine learning problems can often be attributed to an optimization problem. The theory of optimization provides a theory and method for machine learning. In machine learning security, the adversary model is often used to describe the strength of an adversary. Distributed machine learning has three advantages: ① using data distributed in different nodes to train the model together increases the accuracy of the model. ② Storage units distributed in different nodes are used to store data, which increases the data set capacity for model training. ③ The computing units distributed in different nodes are used for training, which enhances the computing ability of the system itself. Machine learning is widely used in data mining, computer vision, e-mail filtering, detection of credit card fraud, and medical diagnosis and analysis. While machine learning is widely used in various fields, it also brings many threats to security and privacy. Generally speaking, learning in machine learning can be divided into three categories: supervised learning, unsupervised learning, and reinforcement learning. In supervised learning, the machine learning algorithm is based on a set of data sets with standard input and output. Supervise the use of data of known labels or classes. In unsupervised learning, the algorithm establishes a mathematical model of a set of data, which only contains the input but not the expected output. Reinforcement learning is based on the maximization of some scalar reward goals, based on data and some future rewards. However, this type of learning is limited to dealing with a small number of key parameters. The general process of personal information processing is shown in Figure 2.

Vector homomorphic encryption is a homomorphic encryption scheme for vector encryption. In machine

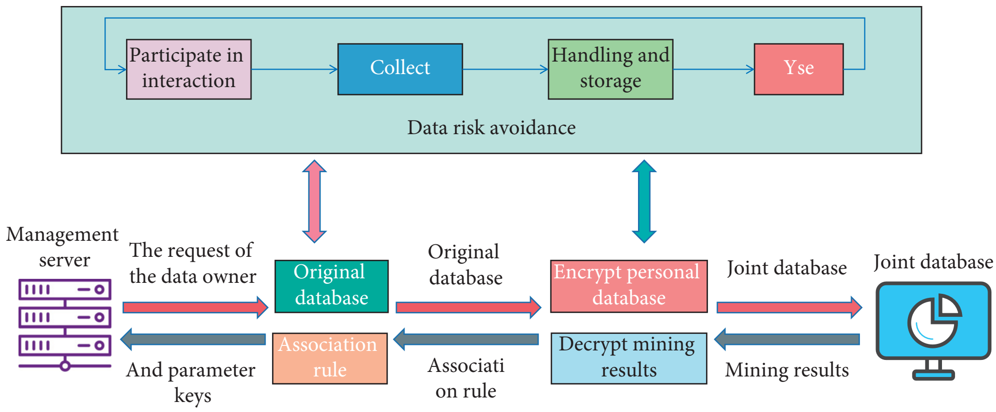

Figure 1: Data mining model of personal privacy protection.

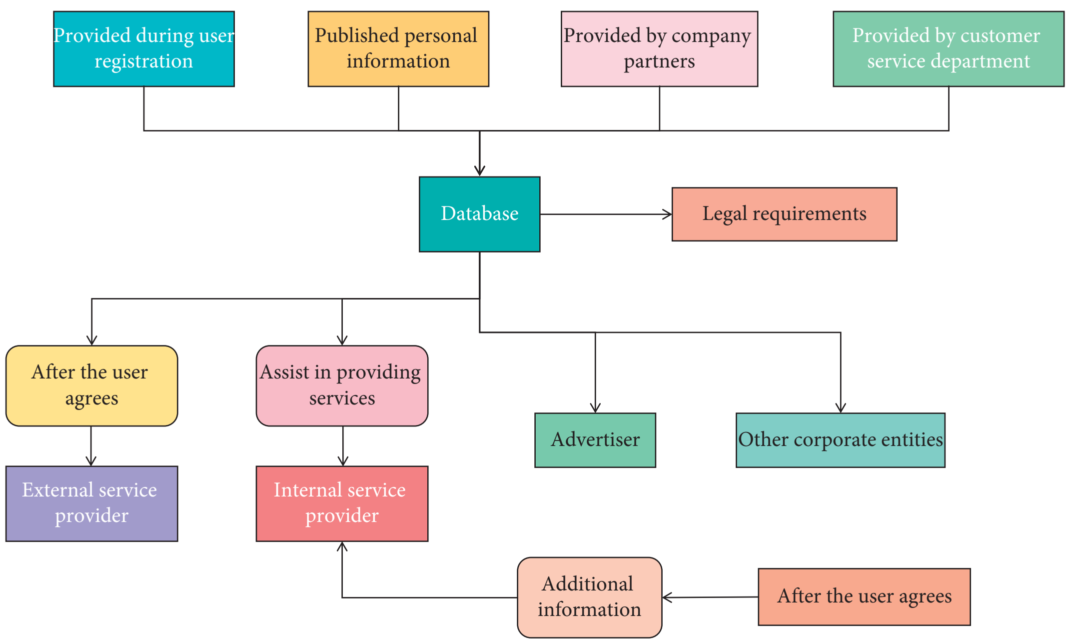

Figure 2: Flow chart of personal information processing.

learning, there are many operations for vectors. Therefore, a vector homomorphic encryption scheme is very important for machine learning. Homomorphic encryption technology is a kind of public key encryption system, which encrypts the original data to protect the privacy of data. Homomorphic encryption has its natural advantages, which makes it one of the candidates for privacy protection solutions in the era of big data. Its main advantage is that it can make the third-party complete homomorphic operation of data without decryption. The security of a homomorphic encryption algorithm is based on the difficulty assumption of the algorithm, which can provide a good security guarantee. Homomorphic encryption can encrypt both local data and model parameters. Using homomorphic encryption to support ciphertext calculation can solve the problem of machine learning by combining multiple participants' data sets and provide a data security guarantee for machine learning in a big data environment. The algorithm framework is divided into two parts: initialization and classification. Initialization includes the following steps: data preparation and data uploading; Classification includes the following steps: query matrix generation, secure similarity calculation, and secure multiparty calculation to obtain results. The homomorphic properties of subtraction and scalar multiplication of the algorithm are shown in the following formulas:

$$\begin{aligned}
&((c_1 - \ldots - c_n) - 2l_1 Z_1)\bmod p_3 \\
&= s^d (r_1 p_2 + km_1 + l_1 e_1) - \ldots - (r_n p_2 + km_n + l_n e_n) \\
&- (2r' p_2 + 2l_1 e_1)\bmod p_3 \\
&\triangleq s^d (r p_2 + k(m_1 - \ldots - m_n) - \varepsilon p_1)\bmod p_3 \\
&(N \times C_T)\bmod p_3 = \left(N \times s^d (r p_2 + kT)\bmod p_3\right) \\
&\triangleq s^d (r p_2 + kNT)\bmod p_3,
\end{aligned} \tag{1}$$

where N is a positive integer; $Z_1 = Enc_K^{e_1}(0)$ is a publicly available value generated by the first data owner.

The correctness of decryption is guaranteed by the following formula:

$$x = \left|\frac{S_c}{w}\right|_q = \left|\frac{S(M_x + e)}{w}\right|_q = \left|x + \frac{S_e}{w}\right|_q. \quad (2)$$

To recover plaintext x from ciphertext c and key S, the condition $|S_e/w| < (1/2)$ needs to be satisfied. Because there is the following formula:

$$\sum_{i=1}^{m} |S| e_i < \frac{w}{2}. \quad (3)$$

Going a step further e is

$$|e| < \frac{w}{2m|S|}. \quad (4)$$

The following formula can be obtained:

$$S_c = wx + e. \quad (5)$$

Before clients share local parameters, the parameters are processed by a privacy-protecting and verifiable mechanism, and the processed data is shared with the cloud server, obfuscating each client's local gradient and making it difficult for the cloud to extract any useful information from the collected gradient. Furthermore, a verifiable mechanism ensures the accuracy of transmission results, allowing for the effective detection of false results produced by malicious clouds. Due to the introduction of noise, the support vector machine algorithm scheme based on differential privacy protection alters the distribution of original data, lowering the accuracy, and usability of the results. Individual user data will never leave the device if local differential privacy is used. The proposed protocol strengthens data stream privacy protection, reduces attackers' options for destroying privacy and collects useful statistical data. The central idea of this paper is to query data sets in batches. Because the homomorphic encryption scheme supports homomorphic linear transformation operation, all query vectors can be placed in the same linear transformation matrix to achieve the purpose of the simultaneous query. In order to adapt to the distributed characteristics of the system, the system adopts the distributed selection random gradient descent method to update the model parameters. The core of the distributed random gradient descent method is the distributed and cooperative deep learning protocol.

If $pk_{l,i} = pk_{l,j}, sk_{l,i} = sk_{l,j}$, then $i = j$. At this time, the ciphertext polynomial kernel function of the data object m_i and the support vector g_j can be expressed as follows:

$$\begin{aligned} p_{j,i} &= K\left(SV_j, C_i\right) \\ &= \left(s_{j,i} + c(1)\right)^u \\ &= \left(\sum_{z=1}^{d}\left(c_{jz}^{*} \otimes c_{iz}\right) + c(1)\right)^u. \end{aligned} \quad (6)$$

Evaluate all ciphertexts $c_{ij}\,(j = 1, 2, 3, \ldots, l_i)$ of the i th data owner as follows:

$$\begin{aligned} c_i &= Eva\left(c_{i1}, \ldots, c_{il_i}\right) \\ &= \sum_{j=1}^{l_i} Enc_K^{e_i}\left(m_{ij}\right) \underline{\Delta}\, s^d \left(r_i p_2 + km_i + l_i e_i\right) \bmod p_3. \end{aligned} \quad (7)$$

Evaluating the ciphertext $c_i\,(i = 1, 2, 3, \ldots, n)$. for all n data owners is

$$\begin{aligned} c &= Eva\left(c_i, \ldots, c_n\right) \\ &= \sum_{i=1}^{n} s^d \left(r_i p_2 + km_i + l_i e_i\right) \underline{\Delta}\, s^d \left(r p_2 + km + \varepsilon p_1\right); \varepsilon \in Z. \end{aligned} \quad (8)$$

The correlation error is used as a measure of an average calculation error, while MAPE is used as a measure of frequency estimation error. The absolute value of the predicted value minus the actual value divided by the actual value is the correlation error. The following is the definition of the relevant error:

$$\text{Related error} = \left|\frac{y_i - x_i}{x_i}\right| \times 100\%. \quad (9)$$

The absolute value of the difference between the estimated and real frequencies is known as MAPE. Divide the absolute value by the real frequency, then add these numbers together and divide by the data range's length. The following is the MAPE definition:

$$\text{MAPE} = \frac{\sum_{i=1}^{|D|}\left|(y_i - x_i)/x_i\right|}{|D|} \times 100\%. \quad (10)$$

The ciphertext of personal data is of no use to individuals and needs to be kept confidential to other data owners. Therefore, the decryption algorithm of the ciphertext of personal data is abandoned in the design. In this paper, the algorithm classifies the test data set by calculating the similarity between the test data set and the training data set. The test data set selects the most similar k data from the training data set, and these k data confirm the label of the test data by voting mechanism. Privacy difference realizes privacy protection by adding noise to the survey results, and the added amount of noise not only protects users' privacy but also keeps data availability, so sensitivity becomes the key parameter of noise control. In local differential privacy, the concept of sensitivity is based on any two pieces of data. The mining sharing method similar to secret sharing in the algorithm is to prevent the fall and conspiracy attacks. The sharing method ensures that different data owners have different personal keys. Therefore, only when the databases of all the data owners participating in the mining are spliced into a joint database can the ciphertext mining results be decrypted correctly.

4. Result Analysis and Discussion

The privacy stream is released in real time using sliding window technology in this paper. It lowers computing and storage costs while also lowering privacy budget

Table 1: Anti-attack performance of different security schemes.

Serial number	Attack type	Secure data aggregation scheme	Secure data mining scheme on vertically partitioned database	Mining scheme on horizontal partitioned database	The security data mining scheme in this paper
1	Ciphertext-only attack	Can defend	Can defend	Can defend	Can defend
2	Known plaintext attack	Can defend	Unprotectable	Unprotectable	Can defend
3	Select plaintext attack	Can defend	Unprotectable	Unprotectable	Can defend
4	Selected ciphertext attack	Unprotectable	Unprotectable	Unprotectable	Unprotectable
5	Unauthorized mining attack	Can defend	Unprotectable	Unprotectable	Can defend
6	Forgiveness attack	Can defend	Unprotectable	Unprotectable	Can defend
7	Unauthorized decryption attack	Unprotectable	Unprotectable	Can defend	Can defend
8	Owner fall	Unprotectable	Unprotectable	Unprotectable	Unprotectable

consumption when compared to traditional privacy protection methods. The proposed protocol adaptively determines the window length of the stable subdata stream, detects significant movement, opens a new window in time, and captures the trend and distribution of the data stream to further reduce storage space and better allocate the privacy budget. This section examines the antiattack performance of this scheme as well as several comparison schemes in order to verify the security of this method. The performance of these schemes against attacks is detailed in Table 1.

It can be seen that this scheme can defend against more types of attacks and has higher security. In the distributed selection random gradient descent method, a small number of local model parameters are selected to update in each iteration, and this selection process is completely random. The distributed random selection gradient descent method assumes that there are two or more participants, who are independent of each other and participate in the training in parallel. After each round of local training, participants share the gradients of the calculated parameters, and each participant completely controls which gradients to share and how often to share them. To verify the impact of privacy budget on usability in real data sets, different algorithms are used to conduct experiments on real data sets. Figure 3 shows the impact of the privacy budget on evenly distributed data sets. Figure 4 shows the impact of the privacy budget on real data sets.

Experiments show that under different privacy budgets, the usability of this algorithm is higher than that of the other two algorithms, which proves that this algorithm is also feasible in practical application. The data encryption stage is a constant complexity operation. After the encrypted data is processed, the future expenses mainly come from the data query users. As for secure multiparty calculation, the steps to obtain the results are clear and simple, so the efficiency is very high. In the comparative evaluation stage, this paper does not consider the two stages of data preparation and secure multiparty calculation to obtain the results. Different schemes are applied to personal information privacy protection, and their security performance is compared. The results are shown in Figure 5.

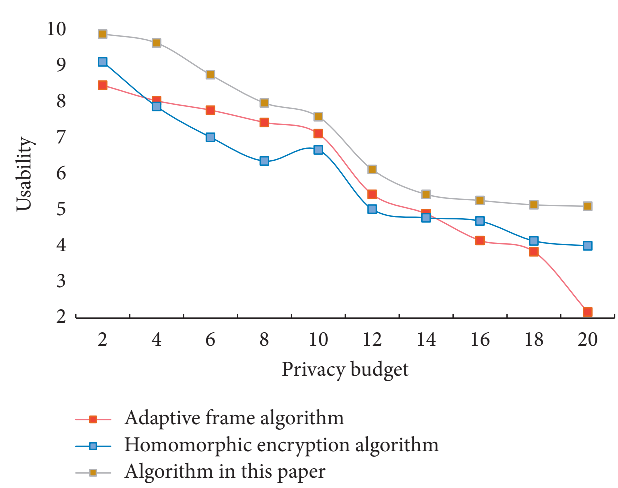

Figure 3: The influence of privacy budget on evenly distributed data sets.

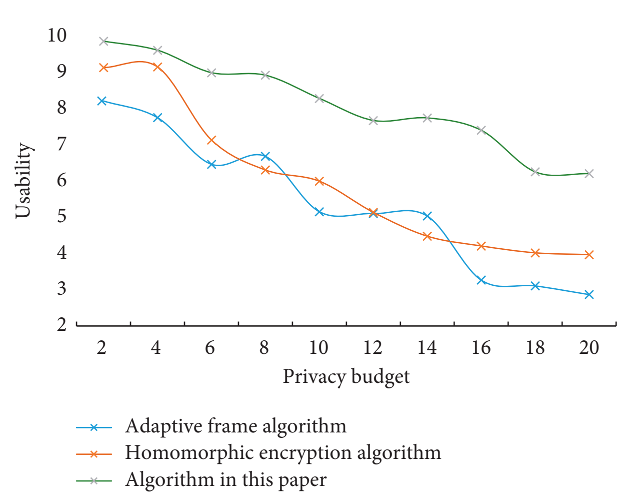

Figure 4: The impact of privacy budget on real data sets.

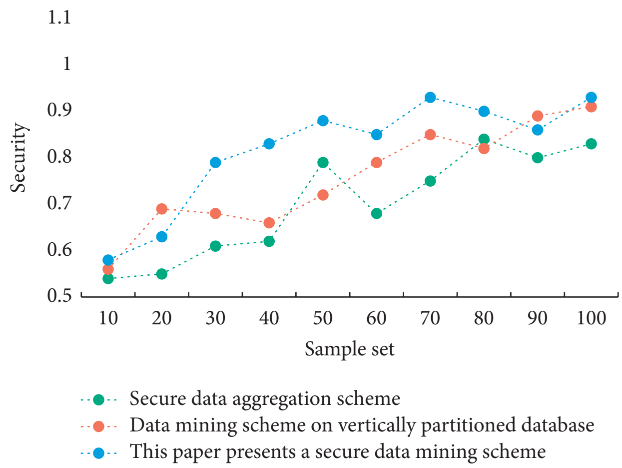

Figure 5: Security comparison of different schemes.

The method in this paper is safe and has some practical application value, according to the data in Figure 5. Significant movement in the data stream indicates the occurrence of a new event or trend. The newly observed tuples can be added to the current window to form a stable subdata stream if they maintain the current window's stability. A new window should be opened if new trends in the data stream emerge. Table 2 compares the results of various algorithms in terms of performance.

It can be seen that the performance of this algorithm is generally better than other comparison algorithms. Many participants in the system participate in the training on the same combined data set to complete machine learning and ensure that no local information of the participants is leaked to the central server during this process. Figure 6 is the simulation diagram of the secure distance calculation protocol.

From the data analysis, it can be seen that the decision-making process of the scheme classification in this paper is completely outsourced, and the data belonging to the master only needs to undertake the encryption in the initial stage and the decryption in the result acquisition stage. Comparing the adaptive framework algorithm and homomorphic encryption algorithm with the algorithm in this paper, the accuracy of different algorithms is shown in Figure 7.

It can be seen that the accuracy of this algorithm is higher than that of the adaptive frame algorithm and homomorphic encryption algorithm, and it has a certain superior performance. The experimental results show that the proposed protocol has high practicability, which is applicable to both numerical attributes and classified attributes and can keep its practicability under different distributions and data stream sizes. This algorithm has a fast convergence speed, and the average error rate decreases by 4.17% compared with the traditional algorithm. Moreover, the accuracy of this algorithm reaches 95.37%, which is about 8.76% higher than the previous algorithm. The scheme proposed in this paper has obvious advantages. At the same time, it realizes multidata ownership setting, complete outsourcing calculation, and zero communication consumption. At the same time, it supports the inner product kernel function and polynomial kernel function classification. This scheme can not only protect the privacy of the stream, but also ensure high practicability, and the overhead of storage and computing power is small.

Table 2: Performance comparison results of different algorithms.

Algorithm	Average error	Recall rate	Accuracy rate
Distributed privacy protection algorithm	0.548	0.874	0.862
Adaptive frame algorithm	0.496	0.887	0.894
Homomorphic encryption algorithm	0.217	0.926	0.918
K-means clustering algorithm	0.301	0.894	0.901
Algorithm in this paper	0.131	0.963	0.954

5. Conclusions

In view of the threats to personal information privacy, we need to further explore the defense technologies against poisoning attacks, confrontation attacks, and other attacks, improve the robustness of the model, and study the defense means against stronger attacks. In this paper, aiming at the existing privacy protection of personal information, combined with the research status at home and abroad, the machine learning platform and homomorphic encryption scheme are studied, respectively. By observing the characteristics of big data and the new publishing mode, this paper analyzes the potential risks of privacy leakage caused by data association analysis. Then, the privacy protection criterion matching its characteristics is studied, and the user's demand for data privacy protection and data availability is understood, and a privacy protection model based on machine learning is constructed. A privacy protection mechanism based on elliptic curve and homomorphic encryption is designed to cover the local gradient of each client, which makes it difficult for malicious adversaries and semitrusted cloud to reason the original information of the data set. The proposed privacy protection mechanism keeps the high prediction accuracy of the training model and balances the security and efficiency well. In this paper, based on vector homomorphic encryption, the similarity measure of vectors under ciphertext is designed. It has the advantages of low interaction cost, safety, and high efficiency. In order to verify the performance of the algorithm, a lot of experiments are carried out. The experimental results show that this algorithm has a fast convergence speed, and the average error rate decreases by 4.17% compared with the traditional algorithm. Moreover, the accuracy of this algorithm reaches 95.37%, which is about 8.76% higher than the previous algorithm. Although this paper has achieved some research results, there are still some shortcomings and places to be improved in the research process. For example, the low efficiency of the data fusion operation of local model parameter group ciphertext will be improved in the followup work.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

Retracted: Image Recognition of Sports Athletes' High-Intensity Sports Injuries Based on Binocular Stereo Vision

Computational Intelligence and Neuroscience

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Sports athletes are prone to certain injuries during high-intensity exercise training. In the process of treating an injury, images of the injury site need to be collected and identified. However, the traditional recognition method cannot effectively extract the features of the image. At the same time, it ignores the optimization of the damage image recognition results, resulting in low recognition accuracy and poor efficiency. Binocular stereo vision technology can quickly and accurately detect moving objects. Therefore, in order to more accurately identify high-intensity sports injury images, this study takes the high-intensity sports injury images as the basic research object. Several processes of image processing based on binocular stereo vision are analyzed, and the vulnerable parts of the body in high-intensity sports are also studied. Finally, the method in this study is verified. The experimental results show that the method proposed in this study reduces the average error rate by 0.19% compared with the traditional recognition method. It can effectively identify and detect injury images, thereby improving the accuracy and stability of sports injury image identification. The identification time is also shortened accordingly, which has certain practicability and feasibility. In addition, the binocular camera used in this study has high accuracy, and the obtained images of sports injuries are of good quality, which lays a foundation for image detection and recognition.

1. Introduction

Athletes who participate in high-intensity and technically difficult sports are more likely to sustain injuries during exercise, such as cervical spine and lumbar spine injuries. Binocular stereo vision closely resembles how the human eye processes images. It is a very dependable and simple algorithm that has proven its worth in a variety of fields. As a result, this study proposes a binocular stereo vision-based recognition method for high-intensity sports injury images, which is critical for the repair and treatment of injured athletes' parts.

Timely detection and identification of injury sites in athletes can more accurately diagnose the type and severity of injuries. Some scholars have conducted some studies on the identification of sports injuries. Prabhu et al. discovered that diffusion tensor imaging, magnetic resonance spectroscopy, and fMRI can detect changes in encephalopathy. The pathological examinations he performed documented progressive neuronal degeneration of the tau protein. It was found that prevention, early diagnosis, and appropriate treatment are the recommended methods for the treatment of these diseases [1]. Zhu et al. used a research method based on big data technology and CNN-based computer vision technology and theoretical analysis related to sports mechanics and image recognition. His research provided technical support for injury risk prediction in athletes [2]. Wang research purpose is to find how to intelligently process images of soccer games based on computer intelligence techniques. First of all, he identified and processed the dynamic images of sports and collected static and dynamic images of football. The experimental results showed that the systematic error of the auxiliary identification technology based on the Internet of things is 0.63. So, his proposed algorithm and the obtained experimental results effectively demonstrate the reliability of using intelligent image recognition techniques for soccer sports image recognition [3]. Based on the characteristics of athletes, Ma et al. developed and designed a C/S mode athlete training process monitoring system, using GPS to obtain real-time position information of athletes. In order to reveal the changing laws of various indicators of athletes under training, he followed a series of physical conditions of the athletes, such as the characteristics of physical functions, training programs and arrangements, the status of brain functions, routine physiological and biochemical indicators, and basic conditions of injuries [4]. The above researchers have combined the treatment and prediction of sports injuries with intelligent technology, which has played a certain role in promoting the recovery of athletes, but they did not put it into practice and lacked reliability.

Binocular stereo vision technology is a high-speed, high-precision noncontact measurement method. For this technology, many scholars have conducted research. Lin et al. aimed to develop a 3D image reconstruction method based on laser line scanning (LLS) technology to establish a binocular stereo vision system for preliminary research on obstacle detection technology for autonomous underwater vehicles (AUVs). Therefore, the results of the stereo vision system evaluation demonstrate the reliability and performance of the tank [5]. Based on the binocular stereo vision measurement principle and wireless sensing theory, Li and Zhang studied the measurement and analysis method of the athlete's movement displacement parameters. He developed a noncontact displacement measurement system. The experimental results showed that the integrated displacement measurement system designed in this study has high precision and good stability [6]. Lin et al. discussed one of the foundations of 3D reconstruction methods in binocular stereo vision, that is, feature matching. He studied the operation principles, feature matching algorithms of binocular stereo vision system, and 3D reconstruction system. Based on these studies, he proposed a set of more feasible algorithms to improve the effect of 3D reconstruction [7]. Sun et al. established a perspective projection model of any section of the elbow. Based on this model, he proposed a method to locate the precise projected position of the on-axis point on the image plane and reconstruct the 3D coordinates of the on-axis point using binocular stereo vision. He measured three bends of different diameters. Compared with the classical method, this method effectively reduced the reconstruction error [8]. The abovementioned scholars used this technology to analyze their research objects and proved the reliability and stability of this technology, but they did not conduct experiments on its application and lacked data support.

After a series of experimental analysis, it can be concluded that the error of the method in this study for the coordinate positioning of the damage image is less than 0.5 mm, and the error rate is less than 2%. This shows that the method in this study can locate the damage target more accurately. The recognition rate of the method in this study is significantly higher than that of other methods, and the lowest is more than 60%, which proves the operability of the method. In addition, the method proposed in this study consumes the shortest time when the number of recognized images is different, and the lowest is 0.5 seconds. This also shows that the recognition rate of this method is the highest, and it has great advantages over other methods. As the number of experiments increases, the error rates of different methods show different trends. The error rate of the method proposed in this study is much lower than other methods, with an average of about 0.06%, and that of other methods is about 0.25%. This shows that the method proposed in this study can reduce the error to a relatively low level when recognizing sports-impaired images.

2. Binocular Stereo Vision, High-Intensity Sports Injury, and Image Recognition

2.1. Binocular Stereo Vision. There are many ways that humans get information, and 70 percent of it comes from what people see. Therefore, vision has played an extremely important role in the process of people observing the world and understanding the world. Studies have shown that when people see things with the left eye and see things with the right eye, their perception of distance and spatial perception of objects will become different. The reason for this phenomenon is that the positions of the two eyes of human beings are different, which makes the things and images seen by the left eye and the right eye different. However, when the left and right eyes look at things at the same time, the neural tissue of the brain will fuse the received image information to form a sense of space for the object. This formation process is called binocular stereo vision. It is generally called BSV, that is, binocular stereo vision. Binocular stereo vision is an important part of computer vision [9–11].

The theoretical basis of binocular stereo vision technology is parallax theory (as long as the parallax angle and the baseline length are known, the distance between the target and the observer can be calculated). The main purpose of this technology is to restore and reconstruct the depth information and three-dimensional geometric coordinates of pixels, the purpose of which is mainly achieved by acquiring images. The "image" here is based on the simultaneous acquisition of the left and right perspectives, so it has certain passivity. With this technology, the real three-dimensional world can be quickly restored, providing the user with a description of the location of the target during the navigation process. Binocular stereo vision technology is more comprehensive, and it contains a variety of subject knowledge, such as optics, physics, and computer science. The most difficult and critical component of binocular stereo vision technology is the process of camera position calibration and feature matching. The model structure based on binocular stereo vision is extremely simple, and the operation efficiency is also very high, so its application prospect is very broad. In particular, this model is widely used in the automated production of factories. The human eye is capable of perceiving three-dimensional objects in three dimensions, and binocular stereo vision systems mimic this criterion. The simulation process is based on the principle of triangulation. This system uses imaging equipment and a computer to perform a series of processing on images. The system is generally divided into four functional modules, as shown in Figure 1.

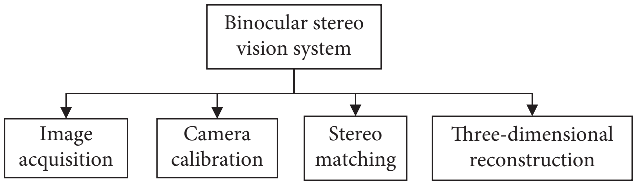

Figure 1: Functional modules of the binocular stereo vision system.

Next, the binocular stereo vision system will be introduced in detail. It consists of three components, namely a binocular camera, a frame grabber, and a computer. First, as the name implies, the binocular camera has two cameras, which also allows it to collect two images of the detected object from different positions. Second, the image acquisition card is connected to the camera and the computer, and the specific process is as follows: first, the binocular camera collects the image signal. Then, the acquisition card converts the collected signal into a digital signal and then transmits the digital signal to the computer. The computer saves it to the hard disk. Third, the computer mainly completes a series of tasks through algorithms, including image preprocessing and segmentation, feature extraction, and stereo matching, to calculate the three-dimensional geometric information of the detected graphics and reconstruct the three-dimensional scene. The basic principle of binocular stereo vision is shown in Figure 2.

The image processing process of binocular stereo vision will be introduced in detail as follows:

(1) *Image Preprocessing* [12, 13]. The camera can capture the image of the detected object, and then, the capture card transmits the image captured by the camera to the computer. In this process, it is easy to be subject to various interferences, which leads to the degradation of image quality and brings certain difficulties to subsequent image recognition. Therefore, image preprocessing becomes a necessity. The main purpose of image preprocessing is to remove the interference factors in the transmission process and enhance the pixels of the detected object in the image. If this task is done well, it will be more conducive to feature extraction and stereo matching of detected objects. In addition, this process can operate in both spatial (the two-dimensional plane where the image plane is located) and frequency (the spatial frequency of the gray value of the image pixel changing with the position) domains simultaneously, so it can also effectively reduce noise.

(2) *Selection of Color Space*. When processing more complex images, people usually select the part they are interested in and extract the feature information of this part. This process is called image processing. The basic flow of general image processing and recognition is shown in Figure 3. The result frame of image recognition based on binocular stereo vision is shown in Figure 4. For image information of different difficulties, it is necessary to select an appropriate color model, so as to facilitate its analysis, and also help computer equipment to quickly identify the characteristic information of the image. There are many general color models. Among them, hue, saturation, and intensity (HSI), luminance a and b (Lab), cyan, magenta, and yellow (CMY), red, green, and blue (RGB) are relatively common, which have different characteristics.

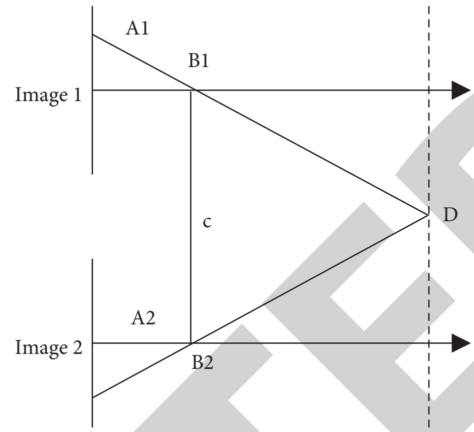

Figure 2: Basic principle of binocular stereo vision.

(3) *Image Segmentation*. Image segmentation [14, 15] refers to dividing the basic information of an image into several parts according to different characteristics. These parts are called image elements. The advantage of doing this is that it is conducive to fast matching of features. Each image element has its own characteristics, so they are also very easy to identify and distinguish. The advantage of image segmentation is that it can greatly reduce the workload of computers and administrators, thereby further improving the recognition efficiency of computers [16]. In general, there are various methods and classification criteria for image segmentation, mainly because the basis of segmentation is different. Among them, there are mainly three segmentation methods based on gray threshold, region growth, and edge detection. Among them, the first method is further divided into the maximum value method, the average method, and the weighted average method, as shown in Table 1.

(4) *Extraction of Image Features*. What this process needs to do is to compare the different features of the two images, so that the coordinates of the same point in the three-dimensional space in the two different images can be obtained. The features of images can be divided into local features (points, lines, surfaces) and global features (polygons, images) according to different classification [17] criteria, which can also be divided into color, texture, shape, spatial relationship features, etc. Different features use different algorithms.

(5) *Stereo Matching Process*. Stereo relative refers to two images taken by two cameras in a binocular camera

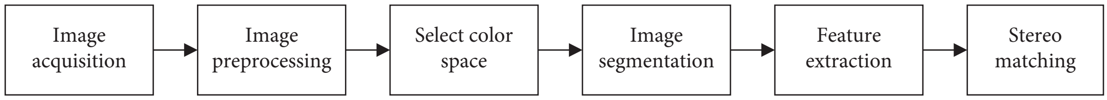

Figure 3: Basic flow chart of image recognition.

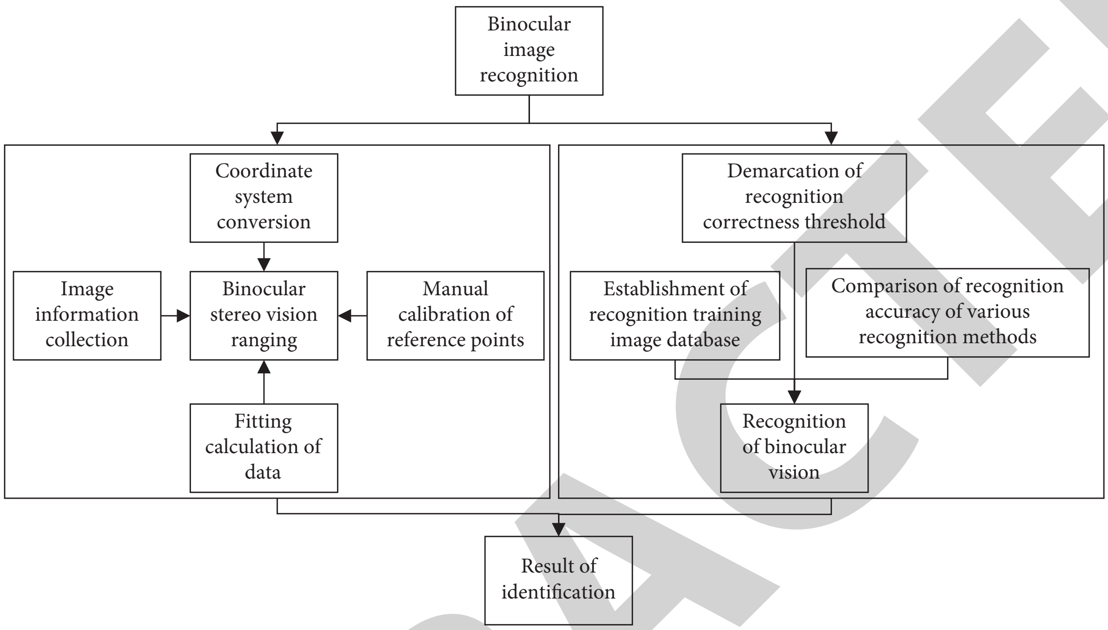

Figure 4: Structural framework of image recognition based on binocular stereo vision.

Table 1: Commonly used segmentation methods.

Segmentation method	Operation	Effect
Segmentation method based on gray threshold	Grayscale processing	Reduce redundant information
Segmentation method based on region growth	Split by pixel	Complete image extraction
Segmentation method based on edge detection	Split according to contour	Image segmentation

of the same object. The purpose of stereo matching is to discover and find the coordinates and relationships of the corresponding points in the two images, which is also the focus of 3D reconstruction. Stereo matching is also known as disparity estimation, or binocular depth estimation. Two algorithms are available for this process, that is, local descriptions based on invariants and statistical learning methods. This process is unique and reproducible, with some physical meaning.

2.2. High-Intensity Sports Injuries. High-intensity exercise training can greatly enhance the function of the human body, so that the maximum oxygen uptake of the organism can be improved, and myocardial functions such as heart rate, speed, and endurance can be improved [18]. The main characteristics of high-intensity exercise training are shown in Table 2. Under normal circumstances, the main contents of high-intensity exercise training include running and leapfrog, as shown in Table 3.

Sports injuries are clinically manifested as pain, swelling, etc., at the injury site of different severities. High exercise intensity is more likely to lead to muscle damage. As the name suggests, sports injuries refer to various injuries suffered by athletes during sports training [19]. Sports injuries are closely related to a series of factors, such as the intensity of sports, the type of sports, training environment, and sports auxiliary equipment. The specific classification of sports injuries is shown in Table 4.

Table 2: Basic parameter information of high-intensity exercise training.

Items	Remarks
Environment	Aerobic environment
Maximum load intensity	75%–80%
Heart rate	About 140 times/min
Oxygen supply method	Intermittent load method

In real life, injuries to athletes are unavoidable because most high-intensity sports involve relatively intense confrontation. With the passage of time, the injury develops concealment and long-term characteristics, causing permanent damage to the athlete's body. Abrasions, sprains, strains, and joint injuries are all common types of injuries

Table 3: Basic content of high-intensity exercise training.

Serial numbers	Contents	Exercise intensity
1	800 m jogging	6 min to complete
2	5 times × 5 m turn back to run	3 groups, rest 2 min between groups
3	50 m run	5 groups, rest 1 min between groups
4	Leapfrog	3 groups, each group 20 times, rest 3 min between groups
5	Squat	
6	Relax and stretch	5 min

Table 4: Basic classification of sports injuries.

Division angle	Classification	Remarks
Damage property	Chronic injury	Heavy local body load
	Acute injury	Muscle strain
Damaged tissue structure	Skin, muscle, joint, and nerve injury	
Damage degree	Mild injury	No effect on normal training or competition
	Moderate injury	Affect normal training or competition for over 1 day
	Severe injury	Need hospitalization

Table 5: Causes of sports injuries and their prevention strategies.

Reason	Specific description	Preventive measure
Psychological quality	Focus on tactical skills	Psychological counselling and mental health education Psychological supervision
	Less training	Soothe and regulate emotions Raise awareness of prevention
Physical quality	High physical consumption	Strengthen physical fitness and strength training Develop training programs
	High demand for strength	Improve basic physical fitness Standardize and correct tactical actions
Objective reasons	Improper infrastructure maintenance	Strict requirements and specifications Check the equipment regularly
	Clothing discomfort	Meet reasonable requirements Check and prevent damage

[20]. Abrasions are common in sports with more physical contact. Scratches can occur as a result of falls caused by low friction on the ground or excessive slippage, or as a result of collisions or scratched fingernails as a result of physical contact between athletes. Second, some high-intensity sports have an excessive range of motion, resulting in injuries to the athletes' soft tissues and ligaments, particularly in the ankle, knee, and waist joints. Third, one of the most common causes of injury is athletes' lack of warm-up and preparation. If the preparation is insufficient, the muscles, including the thighs, calves, shoulders, and backs, will not stretch. Fourth, if a joint injury, such as the metacarpophalangeal joints, ankle joints, or knee joints, persists, it is likely to become an old injury. Joint injuries are difficult to treat and can lead to complications.

According to the above analysis, the reasons for the injury can be summed up in three points, namely psychological reasons, physical quality, and objective factors. There are also some preventive measures and strategies for these three points, as shown in Table 5.

2.3. Image Recognition and Processing of High-Intensity Sports Injuries. To identify the injury image, the main cause of sports injury must first be determined. The formula for calculating the injury rate of each sport in high-intensity training is as follows:

$$\Delta\Delta\Delta\mathcal{E}_{\mathcal{B}}(\mathcal{Y}) = \frac{\sum_{i=1}^{\Delta}\mathcal{C}_{\Delta\Delta\Delta}(\Delta_{\Delta\Delta})}{\mathcal{L}\times\beta_{\Delta}}. \quad (1)$$

In formula (1), β_{Δ} refers to the parts of the body that are easily damaged during high-intensity training; $\mathcal{L}$ refers to the maximum heart rate before high-intensity exercise; and $\Delta_{\Delta\Delta}$ refers to the severity of the injury. $\mathcal{C}_{\Delta\Delta\Delta}$ refers to different sports, and Δ refers to the number of vulnerable parts.

All factors that contribute to an athlete injury are as follows:

$$\mathcal{S} = \frac{\mathcal{E}_{\Delta}(\mathcal{Y})\cdot\mathcal{R}'}{\Delta\times\mathcal{Y}_{\ell\Delta\Delta}\cdot\Delta_{\Delta}}\cdot\mathcal{B}_{\ell\Delta\Delta}. \quad (2)$$

In formula (2), $\mathscr{B}_{\ell\Delta\Delta}$ refers to the various causes of damage; $\mathscr{Y}_{\ell\Delta\Delta}$ refers to the probability of various damage types; and $\mathscr{E}_{\Delta}(\mathscr{Y})$ refers to the law of damage.

The relationship between high-intensity exercise training intensity and injury is as follows:

$$\mathscr{K}_{\alpha} = \frac{\Delta\Delta\Delta\mathscr{G}_{\mathscr{B}}(\mathscr{Y})}{\mathscr{S} \times \mathscr{B}_{\ell\Delta\Delta}} \Delta\mathscr{S}_0. \tag{3}$$

In formula (3), $\mathscr{S}_0$ refers to the probability of injury to various joint parts of sports players.

The relationship between sport and injury severity is as follows:

$$\mathscr{P}_{(\Delta)} = \frac{\Delta_{\Delta} \cdot \Delta_{\Delta}\phi(\Delta_{\Delta})}{\beta_{\Delta}} \times \frac{\mathscr{L}(\Delta, \Delta_{\Delta})}{\Delta_{\Delta\Delta}} + \Delta. \tag{4}$$

In formula (4), Δ_{Δ} refers to the injury site; ϕ refers to the general pattern of the injury; and Δ_{Δ} refers to the duration of the sportsman's exercise. Δ refers to the important part of the injury. $\mathscr{L}(\Delta, \Delta_{\Delta})$ refers to the proportion of the number of people injured in each sport.

The statistical formula of the injured parts that sports athletes are prone to produce in the process of high-intensity sports training is as follows:

$$\mathscr{X}_{\Delta}^{\mathscr{M}} = \frac{[\Delta_{\ell}(\Delta_{\Delta}) \cdot \Delta_{\Delta}(\Delta_{\Delta})]}{\mathscr{R}_{\mathscr{J}\Delta\Delta\Delta\Delta} \cdot \mathscr{R}_{\Delta\Delta\Delta}} \cdot \frac{\phi}{\mathscr{P}_{(\Delta)}}. \tag{5}$$

In formula (5), Δ refers to the cumulative number of injuries in sports athletes. $\Delta_{\ell}(\Delta_{\Delta})$ refers to the type of cause that causes the injury, and $\Delta_{\Delta}(\Delta_{\Delta})$ refers to the ratio of various causes of injury. $\mathscr{R}_{\mathscr{S}\Delta\Delta\Delta\Delta}$ refers to the joints that are susceptible to injury, and $\mathscr{R}_{\Delta\Delta\Delta}$ refers to the joints with the highest proportion.

The main factors of sports athlete injury are as follows:

$$\mathscr{E}(\mathscr{A}) = \mathscr{X}_{\Delta} \frac{\mathscr{A}\mathscr{P}_{(\Delta)}}{\mathscr{Q}_{\Delta\Delta}} \times \mathscr{Y}. \tag{6}$$

In formula (6), $\mathscr{Y}$ refers to the detection of high-intensity exercise training intensity.

The basic law of the formation of the main factors is as follows:

$$\mathscr{N}_{\omega} = \frac{\Delta(\mathscr{B})\Delta\gamma}{\beta \times \omega \cdot \alpha}. \tag{7}$$

Here, γ refers to the maximum speed and endurance of the athlete, and β refers to the characteristics of the injury. ω refers to the probability of an injury occurring, and α refers to the severity of the injury.

The main factors of the injury are classified, the formula of which is as follows:

$$\Delta\Delta\mathscr{Y}_{\Delta} = \Delta_{\Delta}\Delta_{\Delta} \cdot \frac{\Delta\Delta - \Delta_{\Delta\ell}}{(\Delta(\gamma) * \chi)} \cdot \alpha\mathscr{N}_{\varphi}. \tag{8}$$

In formula (8), $\Delta(\gamma)$ refers to the variability of injuries among sports players, and α refers to the type and severity of injuries. $\Delta_{\Delta}\Delta_{\Delta}$ refers to the injury probability of each part; $\Delta_{\Delta\ell}$ refers to the probability of injury caused by strains and sprains; and χ refers to the training volume of athletes.

Then, the sports injuries and their causes are classified and counted. The formula is as follows:

$$\mathscr{U}_{\Delta\Delta}(\Delta + 1) = \frac{\mathscr{V}\mathscr{U}_{\Delta\Delta} + \mathscr{B}_{\Delta}\Delta_{\Delta\Delta}(\Delta) - \mathscr{Y}_{\Delta\Delta}(\Delta)}{\mathscr{Y}_{\Delta\Delta}(\Delta) + \sqsupset \cdot \Delta_{\Delta}} \Delta\Delta_{\mathscr{Y}_{\Delta}}. \tag{9}$$

In formula (9), $\sqsupset$ refers to training phases with different intensities; Δ_{Δ} refers to training time; and $\mathscr{U}_{\Delta\Delta}$ refers to the speed of the athlete. $\mathscr{Y}_{\Delta\Delta}$ refers to the endurance time of athletes; $\mathscr{B}_{\Delta}$ refers to the weight of the cause of injury; and $\Delta_{\Delta\Delta}$ refers to the injury rate caused by the characteristics of different sports. (Δ) refers to the training level of the athlete.

The relationship between the training history process and the probability of sports injury is expressed as follows:

$$\mathscr{G} = \frac{\theta}{\Delta_{\Delta}\Delta \cdot \delta} \mathscr{P} * \mathscr{U}_{\Delta\Delta}(\Delta + 1). \tag{10}$$

In formula (10), θ refers to the historical process of an athlete's injury; Δ_{Δ} refers to the injury samples collected; and $\mathscr{P}$ refers to the basic situation and data information of the athlete.

After analyzing the cause of the injury, the grayscale conversion operation on the image of sports injury can be performed. If the motion-impaired image is colored, its pixels are represented by three bytes, which correspond to the brightness generated by the three components of R, G, and B. The formula for grayscale conversion is as follows:

$$\mathscr{G}\Delta\Delta\Delta(\Delta, \Delta) = \mathscr{S}(\Delta, \Delta) + \mathscr{F}(\Delta, \Delta) + \mathscr{A}(\Delta, \Delta). \tag{11}$$

The converted grayscale image is represented by a 24-bit image, which can effectively improve the recognition efficiency of high-intensity sports injury images. To further improve the recognition effect of sports injury images, it is necessary to extract the basic contour of the injury site. According to the characteristics of the damage image itself, the curve fitting method (substituting the existing data into a mathematical expression through mathematical methods) is used to obtain the final damage contour.

To make the model of the damaged contour reach a state where the active contour converges on the edge of the damaged part, the contour energy is calculated. Its formula is as follows:

$$\mathscr{F}(\mathscr{B}) = [\beta\mathscr{F}_{\Delta\Delta}(\mathscr{B}) + \alpha\mathscr{F}_{\Delta\Delta}(\mathscr{B})]\mathscr{G}\Delta\Delta\Delta(\Delta, \Delta). \tag{12}$$

Here, $\mathscr{F}(\mathscr{B})$ refers to the energy value of the broken contour, and $\mathscr{F}_{\Delta\Delta}(\mathscr{B})$ refers to the internal energy value of the active contour. $\mathscr{F}_{\Delta\Delta}(\mathscr{B})$ refers to the external energy value of the active contour. β and α refer to the weight coefficient.

The image is divided to get the center of the target contour. The formula is as follows:

$$\overline{\Delta} = \frac{1}{\Delta} \sum_{\Delta=1}^{\Delta} \Delta_{\Delta}, \tag{13}$$

$$\overline{\Delta} = \frac{1}{\Delta} \sum_{\Delta=1}^{\Delta} \Delta_{\Delta}. \tag{14}$$

After the basic contour of the damage is extracted, the transformation analysis method is used to initially identify the damage site. The digital matrix is constructed according to the obtained number and information of the pixel points of the damaged position. To improve the recognition accuracy, the length pattern with the feature vector of sixty-four is selected. The mean of the image population vector is as follows:

$$\lambda = \frac{1}{\Delta}\sum_{\Delta=1}^{\Delta}\Delta_{\Delta}\cdot\mathscr{F}(\mathscr{B}). \tag{15}$$

In formula (15), Δ refers to the number of sports injury images.

Next, a matrix $\mathscr{B}$ is set and the eigenvectors of the covariance matrix are calculated. The formula is as follows:

$$\Delta_{\Delta} = \mathscr{B}\frac{1}{\sqrt{\mu_{\Delta}}}\mathscr{Y}\cdot\Delta_{\Delta}\cdot\lambda. \tag{16}$$

Here, Δ_{Δ} refers to the eigenvector values of the matrix and μ_{Δ} refers to the nonzero eigenvalues of the matrix. Δ_{Δ} refers to the vector corresponding to the nonzero eigenvalues.

All training samples and image samples are projected into eigenspace $\mathscr{T}$, and the projection coefficient is calculated. The formula is as follows:

$$\Delta_{\Delta} = \mathscr{T}^{\mathscr{S}}\cdot\Delta_{\Delta}. \tag{17}$$

Next, the Euclidean distance is used to calculate the minimum distance, which is the initial recognition result of the image sample. The calculation formula is as follows:

$$\Delta(\Delta,\Delta) = \left[\sum_{\Delta=1}^{\Delta}\left(\Delta_{\Delta}-\Delta_{\Delta}\right)^{2}\right]^{1/2}. \tag{18}$$

Here, $\Delta(\Delta,\Delta)$ refers to the Euclidean distance (the straight-line distance between two points in Euclidean space) between image samples and training samples, and Δ refers to the number of training samples.

Next, the binocular stereo vision algorithm is used to further identify it, and the area of the damaged part is calculated. Then, the function of the position target of the camera can be expressed as follows:

$$\mathscr{K}_{\Delta} = \sum_{\Delta=1}^{\Delta}\mathscr{U}_{\Delta} - \Delta_{\Delta}^{2}\cdot\Delta(\Delta,\Delta). \tag{19}$$

Here, $\mathscr{U}_{\Delta}$ refers to the pixel cluster center, and Δ refers to the number of pixel cluster centers of the camera. Δ_{Δ} refers to the clustered object, and the minimum value of $\mathscr{K}_{\Delta}$ is the best clustering point, that is, $\Delta\Delta\Delta_{\mathscr{K}_{\Delta}}$.

Combined with the above analysis, the relative area of the damage image can be calculated, namely as follows:

$$\mathscr{A}\Delta\Delta\Delta_{\ell\Delta\Delta\Delta\Delta} = \left(\frac{\mathscr{V}'}{\mathscr{C}'}\right)\cdot\left(\frac{\mathscr{G}'}{C'}\right). \tag{20}$$

Here, $\mathscr{V}^{*}$ refers to the number of long pixels in the lesion image; $\mathscr{G}^{*}$ refers to the number of wide pixels in the lesion image; and $\mathscr{C}^{*}$ refers to the resolution of the image.

After segmenting the image, the absolute area of the damaged image is as follows:

$$\mathscr{A}\Delta\Delta\Delta_{\Delta} = \frac{\mathscr{Q}}{\mathscr{Q}'}\cdot\mathscr{A}\Delta\Delta\Delta_{\Delta\Delta\Delta\Delta\ell}\cdot\Delta\Delta\Delta_{\mathscr{K}_{\Delta}}. \tag{21}$$

Here, $\mathscr{A}\Delta\Delta\Delta_{\Delta}$ refers to the pixel area of the damaged part; $\mathscr{Q}$ refers to the total number of pixels in the damaged part; and $\mathscr{Q}^{*}$ refers to the total number of image pixels.

3. Comparison of Recognition Effects of Different Damage Detection Methods

To identify images of sports injuries, it is first necessary to locate the injury target. Next, some samples of sports injury images are selected, and then, three-dimensional reconstruction is performed on the coordinates in the samples, to perform the localization test of the method proposed in this study. The result obtained is shown in Figure 5.

According to Figure 5, it can be known that the error between the method in this study and the actual value is less than 0.5 mm, and the error rate is less than 2%. This shows that the method in this study can locate the damage target more accurately. Next, to verify the overall performance of high-intensity sports injury image recognition based on binocular stereo vision proposed in this study, one hundred athletes are selected, whose specific conditions are shown in Table 6.

Then, the instrument of the binocular stereo vision system is used to collect the data of the injured part of the subject. It is compared with other injury detection methods, to verify the recognition efficiency and time-consuming of the method in this study. Other damage detection methods include linear discrimination, ultrasound image features, and improved spectral clustering. For the convenience of expression, these methods are abbreviated as linear discriminant (LD), UIF, and ISC, respectively. Figure 6 shows the recognition rate results of different methods of damage detection.

It is obvious from the experimental data in Figure 6 that the recognition rate of the first two methods is an inverted U-shaped curve, and the recognition rate is relatively low as a whole. The recognition rate of the third method fluctuates greatly and is extremely unstable, so it is not very feasible. The recognition rate of the method in this study is significantly higher than other methods, and the lowest is more than 60%, which proves the operability of the method. In fact, the number of images to be recognized also has a certain impact on the recognition rate. Therefore, the selection of the detection method is adjusted, and the improved spectral clustering is replaced by the wavelet coefficient Hu; that is, the LD, UIF, WCHU, and the method in this study are compared. The results are shown in Figure 7.

According to the data in Figure 7, it can be seen that the method proposed in this study consumes the shortest time when the number of recognized images is different, with a minimum of 0.5 seconds. This also shows that the recognition rate of this method is the highest, and it has great advantages over other methods. Next, different times of

experiments are carried out, and the recognition error rates of these methods are compared. The comparison results are shown in Figure 8.

According to the data in Figure 8, it can be seen that with the increase in the number of experiments, the error rates of different methods show different development trends. The error rate of the method proposed in this study is much lower than other methods, about 0.06% on average, and about 0.25% for other methods, which shows that the method proposed in this study can reduce the error to a

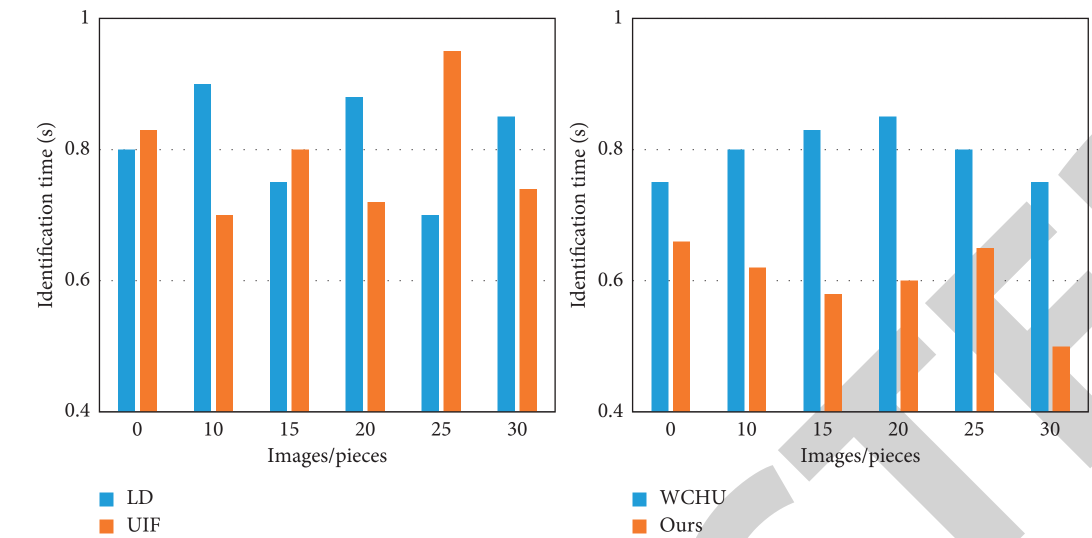

FIGURE 7: Time-consuming comparison of identification of different damage detection methods.

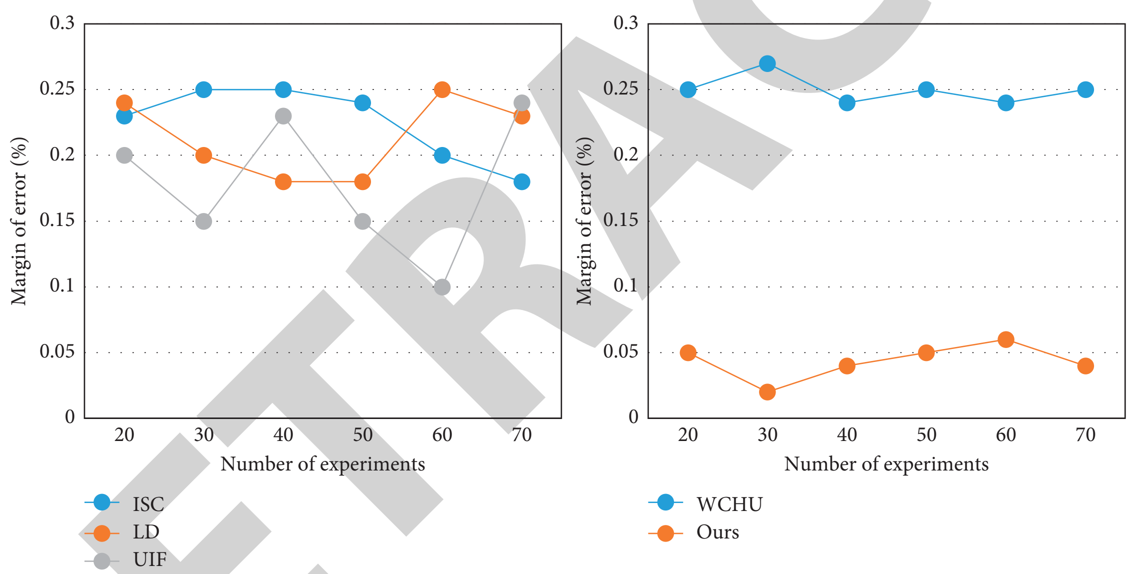

FIGURE 8: Comparison of error rates of different damage detection methods.

relatively low level when recognizing images of sports injuries.

4. Conclusions

High-intensity sports injuries can take a variety of forms. The longer a training period lasts, the more likely an athlete's body part will sustain repeated injuries. As a result, current research is focusing on how to reduce sports-related injuries by identifying injury images. There have always been issues with low recognition precision and frequent occurrences of errors in the process of recognizing damage images. This study proposes a binocular stereo vision-based method for high-intensity sports injury image recognition, and the damaged images are processed, including contour extraction of damaged parts and pixel calculation. The experimental analysis demonstrates the method's reliability and applicability, which is embodied in high recognition accuracy, short recognition time, and high recognition performance. However, there are some drawbacks to the method proposed in this study. The recognition accuracy and speed of the method in this study need to be improved for images of damaged parts with less obvious edge features. In the future, more research into this area will be conducted.

Academic Editor: Xin Ning

Food safety is a major concern that has an impact on the national economy and people's lives. The food industry has grown in quality and innovation in tandem with the rapid development of the economy and society. The emergence of new food technologies, as well as changes in dietary habits, has increased public concern about food safety. With the emergence of various counterfeit and substandard products, food quality and safety testing have become even more important. Traditional testing methods rely on sensory analysis and physical and chemical analysis. This approach is subjective and poorly adapted to the general public. It requires a high level of technical operation and is difficult to carry out on a large scale. To address this situation, this paper proposes an intelligent approach to food safety quality testing. The core idea is, first, to use sensors to collect data on the various components of the sample to be tested. Second, the random forest (RF) model used in this paper is trained. Third, the trained model is used to classify and identify the test samples. Based on the classification results, a conclusion is drawn as to whether the food product is a variant or a counterfeit. The advantage of this study is that the training model used is a weighted RF algorithm based on mutual information. The correlation between any two decision trees is calculated using mutual information, and for the more correlated decision trees, only the one with the highest evaluation accuracy is retained to form a new RF, and the evaluation accuracy is converted into voting weights, resulting in an RF model with less redundancy and higher evaluation accuracy. The experimental results show that the method used in this paper can successfully identify spoiled or counterfeit products and has good practicality.

1. Introduction

Food safety usually means that the items people consume are nontoxic; that is, they do not cause any harm to the body after consumption, and they provide the body with the nutrients it needs [1, 2]. Food safety is not just something that the producer needs to be aware of since there are multiple components involved in the process of food from production to consumption. Food safety is a matter that is jointly guaranteed in many fields. Eating is one of the most important things for human beings. Therefore, food safety and security are of the utmost importance. With the development of technology, many unscrupulous businessmen use high technology to make some poor-quality food products for sale to earn high profits. The packaging of these foods often looks attractive, and the food looks fresh and tasty. In order to achieve the purpose of attracting customers, unscrupulous businessmen will use some ingredients that are toxic and harmful to the human body. And consumers often focus only on the packaging or indication of the food and lack of food safety awareness. Consumers should therefore increase their awareness and knowledge of food safety, develop a healthy and scientific view of consumption, and actively participate in the regulation of food safety to ensure food safety and health. The protection of food safety is the legal responsibility of all food producers and operators, governments at all levels, and relevant regulatory agencies. Regulation should be continuously strengthened to promote a steady improvement in the internal management capacity of producers and operators by enhancing constraints from society. At the same time, the whole community must take an interest in and maintain food safety and support the work of the government. At present, many consumers have little awareness of the importance of safety management in food businesses, knowledge of consumer culture is still lacking, and the basis for social development of food safety is still not strong. When we are in food safety and find illegal problems, we should take positive action and take the initiative to report them to the regulatory authorities, rather than just complaining and grumbling, not to mention creating false information out of thin air, which will only interfere with normal regulatory work and bring about consumer panic, with the ultimate victim being the consumer.

Food quality and safety are very important, and the government is also the introduction of relevant policies to protect the quality of food. The current policy is mainly from the following aspects. The first is to strengthen the quality control of food sources and strict food into the market trading system. Food safety must start at the source, from planting, breeding, production and processing, wholesale and retail, and consumer four links to carry out a full range of supervision. The use of computers and other modern technical means is to establish a series of systems such as commodity labeling and quality tracing. The second is to establish an industry self-regulatory mechanism to ensure food safety. The credit self-regulation of food production and operation enterprises is particularly important to ensure food safety. Therefore, it is necessary to accelerate the construction of a food safety credit system and establish industry credit standards for food distribution enterprises. We should strengthen the legal system construction and integrity education for operators and urge enterprises to improve their awareness of integrity, quality, and legal operation. The third is the establishment of food safety standards and inspection and testing systems. Product and health standards are established comprehensively related to food safety, and a food safety standards system is built. At the same time, the food safety testing system is improved to ensure that the hygienic quality of food listed for sale meets the requirements of health standards. Fourth, a traceability system that can be traced back to the source is established. Food safety is a complex process that must consider all stages of the food chain, from farm to fork.

The government has given a series of safeguards from the production of food to its final consumption in people's mouths. The most important part of the whole safeguarding process is the occasional inspection of food quality. Traditionally, food quality checks have relied on manual inspection by quality inspectors, which is both energy and time consuming and inefficient. As a result, in recent years, smarter methods of food quality inspection have emerged one after another. The core idea is to identify the quality of food by recognizing the taste of the food. Reference [3] proposed an improved K-means algorithm for detecting spoiled food. The core idea of the study is to segment the pictures of food products in order to determine the degree of spoilage. Reference [4] uses deep learning algorithms based on computer vision techniques to detect and analyze the quality of complex food products. Reference [5] devised a relationship between food quality and preservation conditions based on Fourier's law of conduction. Reference [6] proposed a quality inspection technique for frozen foods. The core technique used in this study was Raman spectroscopy. Reference [7] introduced blockchain technology for the storage and preservation of food products, thus guaranteeing food quality and safety. Reference [8] summarizes a variety of deep learning techniques applied to the inspection of food quality such as fruits, vegetables, and meat. Reference [9] uses image processing techniques applied to the detection of egg quality. The study combines hyperspectral imaging, multivariate analysis, and image processing to identify the freshness of eggs as well as the breakage of eggs. Experimental results showed that this aspect was able to achieve a detection rate of over 97%. For quality detection of palletized packaged food, reference [10] used a deep neural network based on a principal component analysis network. Experiments were conducted using support vector machines (SVM) [11] as well as K-nearest neighbours (KNN) [12] for experimental comparison, which showed that the study has advantages not only in terms of detection accuracy but also speed. From the above studies, it can be seen that for food quality inspection, more and more scholars are introducing intelligent algorithms such as machine learning algorithms [13–15] and deep learning [16–18] algorithms. The use of intelligent technologies has indeed improved the efficiency and accuracy of food quality inspection and saved human and material resources. In this paper, RF algorithm is introduced for food quality inspection based on taste analysis. Experiments on vinegar demonstrate the effectiveness of the method in this paper.

2. Relevant Knowledge

2.1. Taste Analysis Methods. It is well known that the taste signals received by the human brain are produced by taste receptor cells in the mouth (mainly the tongue). These taste receptor cells interact with specific chemicals in food. Different types of taste cells are sensitive to specific flavour substances. This property enables humans as well as animals to recognize different tastes. Early artificial taste systems used generic sensors or methods to recognize the physicochemical properties of food. For example, for salty tastes, they can be measured using conductive agents, and for sour tastes, their pH can be measured directly to characterize the acidity. The most primitive calibrations were obtained using a comparison of the human evaluation of salty and sour flavours and the quantitative values detected by the sensors. AsHumans have vague descriptions of taste, e.g. "a little sour", "very sour." The machine, on the other hand, obtains precise measured values. This method therefore only yields results that are not uniform. Later research, towards multisensor multicomponent analytical chemistry methods, which rely on specific chemical sensors, is difficult to implement and difficult to generalize.

On the other hand, there is ongoing research into the underlying perceptual mechanisms of the taste nerve. It has been found that taste cells are not actually sensitive to only one chemical substance but respond to a variety of substances. At the same time, when different taste nerve cells perceive a stimulus at the same time, they transmit their respective signals to the center, which ultimately decides what type of taste stimulus to receive. A diagram of this process is shown in Figure 1. This mechanistic understanding is the cornerstone of modern taste sensing and analysis, resulting in the approach of cross-response sensor arrays. That is, a small number of types of sensors, through a mechanism similar to that of a neural network, are ultimately able to identify a larger number of types of taste stimuli. The number of stimulus types is an order of magnitude greater than the number of sensor types. Importantly, this approach draws on bionic ideas and breaks through the constraints of strongly selective taste sensors.

The traction in this mechanistic understanding has led to a move away from reliance on specific taste sensors for taste sensing. Tests have been carried out using less selective sets of sensors, which are analyzed by chemical analysis methods as well as by pattern recognition methods. This approach allowed pattern recognition to be used naturally in taste recognition scenarios. This was followed by the development of artificial taste sensing. And nowadays, the conceptual definition of taste sensors and electronic tongues and the mathematical processing methods used have gradually become clearer. With the development of materials, computers, and physical-chemical testing techniques, more sensors are available, and the accuracy and range of tests have advanced dramatically. A schematic representation of modern methods of artificial taste analysis is shown in Figure 2.

2.2. Application of Taste Analysis Methods. With the rapid development of electronic tongues and taste sensors, the recognition of types of taste is no longer limited to the recognition of simple basic characteristics such as sweet, sour, bitter, spicy, and salty. Application scenarios now include flavour and quality recognition, such as flavour recognition of alcohol and beverages, determination of the quality of liquid and solid foods, and can even be used to distinguish minor differences between different manufacturers' brands of the same type of food. More work has been carried out on the artificial taste analysis of liquid beverages than on the taste analysis of solid foods. A large body of literature deals with, for example, fruit juices, alcoholic beverages, and liquid flavourings. Reference [19] used multiple sensors to capture the composition of red wine in order to correctly differentiate the taste of red wine. Pattern recognition techniques were also used to perform operations such as preprocessing and classification of the collected data from the red wines. The experimental results show that the method used in this literature can successfully identify red wines as well as nonred wines. Reference [20] used a highly cross-selective sensor to capture the composition of red wines and combine it with principal component analysis and clustering algorithms to model and identify changes in the taste of red wines during storage. Reference [21] used an electronic tongue to capture the concentration of bisulphite in wine and trained a prediction model using the PLS method. The results showed that the method was effective in predicting the bisulphite concentration. PLS combined with linear discriminant analysis (LDA) was used in reference [22] to determine the taste of yellow wine (a Chinese rice wine). The data were used to analyze the taste characteristics of yellow wine from various regions.

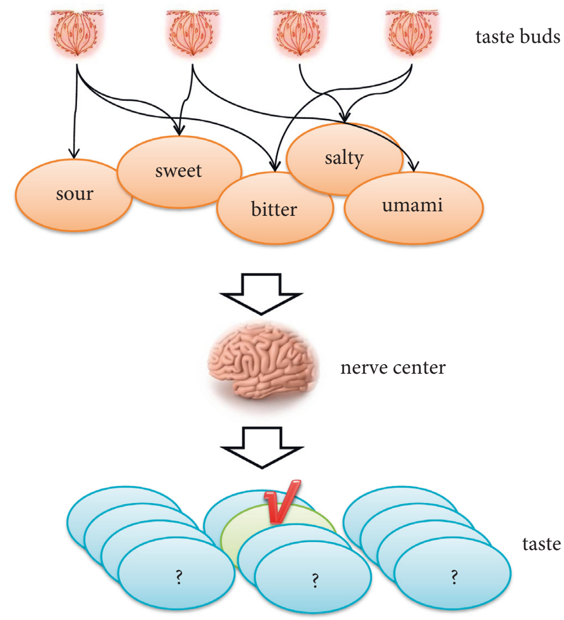

Figure 1: Nerve center determines taste stimuli.

3. Improved RF-Based Food Quality Detection Algorithm

3.1. Traditional RF. In the 1980s, Breiman et al. developed the classification tree algorithm, which was much less computationally intensive than repeatedly dichotomizing data for classification or regression. Breiman combined the classification trees into an RF in 2001 by randomly generating many classification trees and then aggregating the classification tree results. RF improves prediction accuracy without requiring significantly more computing power. RF is considered one of the best current algorithms because they are insensitive to multicollinearity. RF can deal with noisy and unbalanced data very well, which is one of the important reasons why the algorithm can be widely used.

RF selects n samples from the N training samples, which are typically much smaller than N, and repeats the process C times to generate C decision trees. When splitting each node of the decision tree, d attributes are chosen at random from all D attributes, and the best attribute from the d attributes is chosen as the splitting attribute. The CART algorithm is commonly used to select the splitting attributes. The Gini index can determine the splitting attributes in this algorithm. The Gini value of V is calculated by (1). Assuming that the proportion of the i-th category in the current sample set V is s_i, where $S_i = 1$ and k denotes the total number of categories.

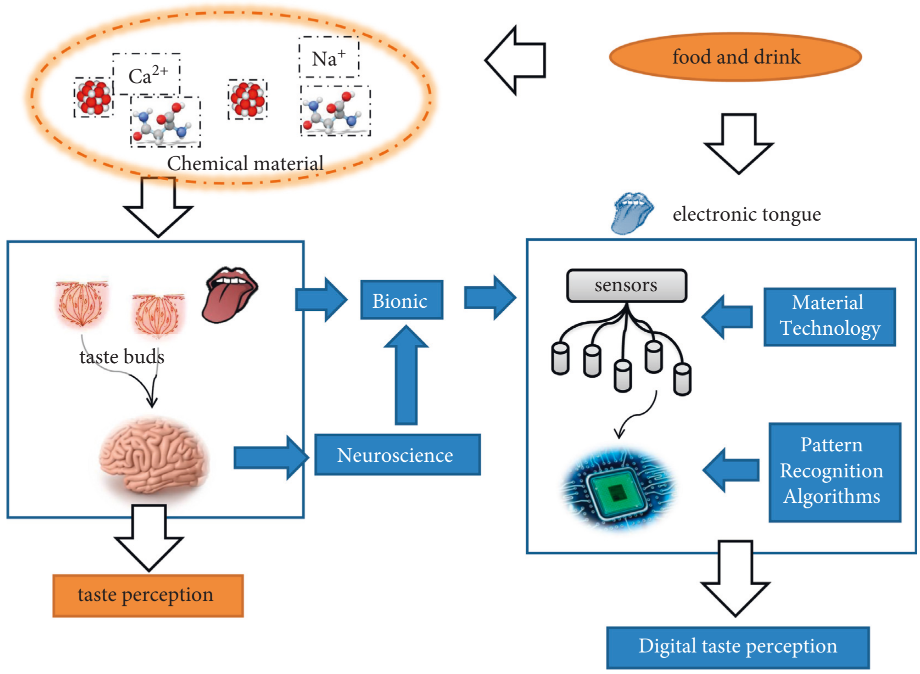

Figure 2: Artificial taste analysis.

$$\mathrm{Gini}(V) = 1 - \sum_{i=1}^{|k|} s_i^2. \quad (1)$$

The Gini value is taken to be between 0 and 1. The test attribute β is used to dichotomize the random variable V into two categories V_1 and V_2, and then, the Gini index for attribute a is calculated as follows:

$$\mathrm{Gini}(V,\beta) = \frac{|V_1|}{|V|}\mathrm{Gini}(V_1) + \frac{|V_2|}{|V|}\mathrm{Gini}(V_2). \quad (2)$$

Assuming that the set of candidate attributes is $(B = \beta_1, \beta_2, \ldots, \beta_d)$, then the attribute that minimizes the Gini index after division is selected as the optimal divided attribute.

$$\beta^* = \arg\min(\mathrm{Gini\_index}(V,\beta)). \quad (3)$$

3.2. Improving RF. Traditional RF generates decision trees with high similarity, rendering the trained model obsolete. Furthermore, in the voting process, all decision trees are given the same weight by default, ignoring any differences in performance between different decision trees. To address these issues, this paper proposes IRF that incorporates mutual information and a weighting strategy to optimize the RF. The correlation between any two decision trees is calculated using mutual information, and only the one with the highest evaluation accuracy is retained for the more correlated decision trees, forming a new RF and converting the evaluation accuracy into voting weights to obtain a RF model with less redundancy and higher evaluation accuracy.

Mutual information is used to measure the interdependence between two variables. For two sets of given random variables X_1 and X_2, their mutual information is expressed as

$$\begin{aligned} MI(X_1, X_2) &= L(X_1) \sum_{x_1 \in X_1} \sum_{x_2 \in X_2} p(x_1, x_2) \log \frac{p(x_1, x_2)}{p(x_1)p(x_2)}, \\ &= L(X_1) + L(X_{21}) - L(X_1, X_2), \end{aligned} \quad (4)$$

where $p(x_1, x_2)$ is the joint probability distribution of X_1, X_2, $p(x_1)$ and $p(x_2)$ are the marginal probability distributions of X_1, X_2, respectively, and $L(X_1)$ is the information entropy of X_1, which is calculated as

$$L(X_1) = -\sum_{x_1 \in X_1} p(x_1) \log p(x_1), \quad (5)$$

where $p(x_1)$ denotes the probability of event x occurring; $L(X_2)$ is the information entropy of X_2, and $L(X_1, X_2)$ is the joint entropy, which is calculated as

$$L(X_1, X_2) = -\sum_{x_1 \in X_1} \sum_{x_2 \in X_2} p(x_1, x_2) \log p(x_1, x_2). \quad (6)$$

For a decision tree l_i $(i = 1, 2, \ldots, C)$ in a RF, $MI(l_i, l_c)$ $(c \neq i)$ represents the mutual information of the decision tree l_i and l_c. In this paper, $MI(l_i, l_c)$ $(c \neq i)$ is used to calculate the correlation between decision trees l_i and l_c. The formula is

$$MI(l_i, l_c) = MI(z_i, z_c), \quad (7)$$

where z_i $(i = 1,2, \ldots, C)$ is the i-th decision tree's output state. The greater the value of $MI(l_i, l_c)$, the greater the correlation between the two decision trees, and the greater the degree of information overlap. A group of decision trees with mutual information values greater than a threshold ε will be combined by calculating the mutual information of any two decision trees. $MI(l_i, z)$ represents the mutual information between the decision tree l_i and the actual label z, that is, the correlation between the decision tree l_i's output evaluation result and the actual evaluation result. The equation is

$$MI(l_i, z) = MI(z_i, z). \tag{8}$$

The larger the value of $MI(l_i, z)$, the higher the evaluation accuracy of the decision tree l_i. Finally, the decision trees with less correlation and higher accuracy are formed into an IRF. The steps of IRF implementation are as follows:

(1) Step 1: get the training set $X = \{(x_1, y_1), (x_1, y_1), \ldots, (x_N, y_N)\}$, validation set $X' = \{(x_1, y_1), (x_1, y_1), \ldots, (x_L, y_L)\}$, x_i is the sample, and y_i is label.

(2) Step 2: draw n samples from X by bootstrap sampling and repeat T times to obtain T training sets.

(3) Step 3: for each internal node of the decision tree, d attributes are randomly selected from the sample D attributes, and the best splitting attribute among the d attributes is chosen as the test attribute of the node.

(4) Step 4: generate T completely random decision trees to form a RF $R = \{l_1, l_2, \ldots, l_t\}$.

(5) Step 5: input the validation set X′ into R to get the result.

(6) Step 6: based on the results, the correlation between each decision tree and the rest of the decision trees is calculated in turn. All the decision trees with $MI(l_i, l_c)\,(i \neq c)$ greater than the threshold ε are combined into one decision tree group. If the correlation between h, and all other decision trees is less than or equal to the threshold ε, then the decision trees are grouped separately.

(7) Step 7: repeat step 6 for the out-group decision trees in order until all decision trees are grouped.

(8) Step 8: obtain the decision tree with the highest accuracy in each group based on the accuracy $MI(l_i, z)$.

(9) Step 9: form a new RF from the obtained decision trees $R' = \{l_1', l_2', \ldots, l_t'\}$.

When evaluating the input sample data, the traditional RF has the same voting weight for each decision tree, which ignores the influence of the evaluation accuracy of different decision trees on the final result and reduces the evaluation accuracy of the RF as a whole. In order to increase the number of decision trees with high evaluation accuracy and reduce the influence of decision trees with low evaluation accuracy on the final evaluation results, this paper proposes a weighted voting method to convert the evaluation accuracy into the voting weights of decision trees. After the traditional RF is streamlined, the evaluation accuracy matrix A of decision trees in the IRF is

$$A = \begin{bmatrix} a_{11} & a_{11} & \cdots & a_{11} \\ a_{21} & a_{22} & \ddots & a_{2c} \\ \vdots & \vdots & \ddots & \vdots \\ a_{G1} & a_{G2} & \cdots & a_{GC} \end{bmatrix}, \tag{9}$$

where a_{gc} denotes the evaluation accuracy of the c-th decision tree for the g-th running state, where $c = 1,2, \ldots, C$, $g = 1,2, \ldots, G$, G is the number of classes of evaluation results, and C is the number of improved decision trees which obtained by substituting the validation set X' into IRF and calculating the correctness of the output of each decision tree for each class.

Based on the evaluation accuracy matrix, the weight matrix Q is defined as

$$Q = \begin{bmatrix} q_{11} & q_{11} & \cdots & q_{11} \\ q_{21} & q_{22} & \ddots & q_{2c} \\ \vdots & \vdots & \ddots & \vdots \\ q_{G1} & q_{G2} & \cdots & q_{GC} \end{bmatrix}, \tag{10}$$

where Q_{gc} is the weight of the p th tree for the g-th running state, which is calculated as

$$q_{gc} = a_{gc}. \tag{11}$$

The specific flow of the IRF is shown in Figure 3.

4. Experimental Analysis

4.1. Experimental Background. In recent years, there has been an increase in the number of counterfeit and shoddy products. These products often have identical outer packaging, but the quality of the product varies. This paper uses a taste-based food quality detection method. To verify the effectiveness of the method, data from different brands of vinegar are collected and analyzed, and the brands of the respective products are identified. If the results obtained by the RF algorithm for a product captured do not belong to an existing product class, this indicates that there is a problem with the quality of the product. Based on this idea, a Chinese food product vinegar was experimentally analyzed in the experimental part. The evaluation metrics used during the experiments to quantify the effectiveness of the classification models used in this paper are shown in Table 1.

Since the sample size collected during the experiment was not very large, a 5-fold cross-validation method was used to ensure the validity of the experiment, and 60% of the sample overview was selected as the training sample and 40% of the sample as the test sample. The comparison algorithms used were all classical classification algorithms, mainly SVM [23], RF (RF) [24], radial basis function neural network (RBFNN) [25], and Naive Bayes (NB) [26].

4.2. Vinegar Quality Inspection Experiment. The taste of different types of table vinegar is different because the raw materials and processes used to make them are different. Edible vinegar is an acidic condiment that is often used when people cook ingredients. Protein, fat, carbohydrates, ash, water, energy, riboflavin, sodium, potassium, calcium, magnesium, iron, manganese, zinc, copper, phosphorus, and selenium are the main components of table vinegar. Leucine, isoleucine, lysine, methionine, cystine, phenylalanine, tyrosine, threonine, tryptophan, arginine, histidine, alanine, valine, glycine, proline, glutamic acid, serine, and aspartic

$F1$ score	$F1 = 2^{*}\text{Precision} * \text{Recall}/\text{Precision} + \text{Recall}$

Table 2: Quantitative indicators for table vinegar.

Index\Type	Vinegar 1	Vinegar 2	Vinegar 3	Vinegar 4	Vinegar 5
$I1$ (%)	3.86 ± 0.57	7.55 ± 0.73	14.51 ± 0.28	14.64 ± 0.63	7.17 ± 0.81
$I2$ (%)	4.82 ± 0.62	6.46 ± 1.03	5.45 ± 0.53	5.35 ± 0.55	4.65 ± 1.02
$I3$ (%)	0.94 ± 0.38	1.28 ± 0.84	1.82 ± 0.44	1.79 ± 0.84	1.42 ± 0.87
$I4$ (%)	0.80 ± 0.92	1.17 ± 091	2.66 ± 0.38	2.74 ± 0.97	1.54 ± 0.53
$I5$	2.53 ± 0.86	2.49 ± 0.40	3.32 ± 0.64	3.54 ± 0.63	3.38 ± 0.62

acid are all found in it. In this paper, a total of five types of edible vinegar were selected: white vinegar, rice vinegar, aged vinegar, balsamic vinegar, and sugar vinegar. The quantitative indexes of each edible vinegar are shown in Table 2. $I1$, $I2$, $I3$, $I4$, and $I5$ represent total soluble sugar, total acid, salt, sugar-acid ratio, and pH, respectively. The sugar-acid ratio was determined by averaging total sugar and total acid.

Principal component analysis was conducted on the five component indicators of the above five types of vinegar, and the principal component score plots are shown in Figures 4 and 5. The variance contribution of the first principal component was 56.28 percent, the variance contribution of the second principal component was 25.93 percent, and the cumulative variance contribution of the first and second principal components was 83.54 percent, explaining the majority of the variance. Therefore, the first 2 principal components can only represent 82.21% of the information contained in the original 5 physical and chemical indicators. In addition, the five types of samples could not be well separated on the first principal component score axis, only white vinegar and sugar vinegar could be distinguished from the other types of vinegar, and there was great dispersion between the different brands of rice vinegar, while aged vinegar and balsamic vinegar were seriously confused with each other, which indicated that aged vinegar and balsamic vinegar had some similarity, while white vinegar and sugar vinegar were very different from the other types and showed specificity, and the samples of rice vinegar were more different from each other. It is difficult to group them together because of the relatively large differences between the samples of rice vinegar. This indicates that the first principal

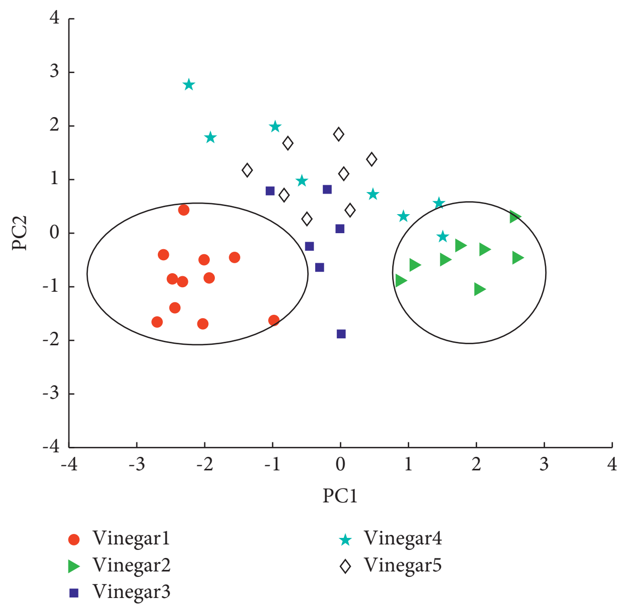

FIGURE 4: Schematic diagram of principal component analysis of component indicators.

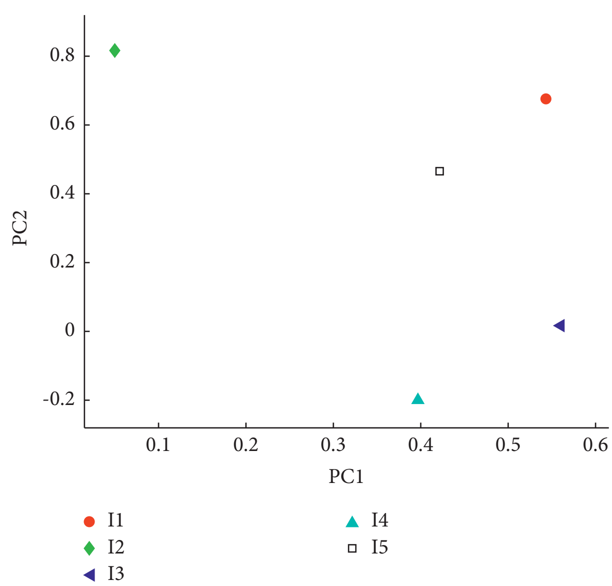

FIGURE 5: Factor loading diagram.

component obtained from the physicochemical indicators can be interpreted as the sugar content (sweetness) and that the first principal component is positively correlated with the sugar content. Furthermore, the distribution from left to right is roughly in the ascending order of the sugar-acid ratio, indicating that the first principal component can also be interpreted as the sugar-acid ratio and that the first principal component is positively related to the sugar-acid ratio. On the second principal component score axis, the five types of samples are also differentiated, and intuitively, the five types are distributed on the second principal component score axis from bottom to top in an ascending order of total acidity, which indicates that the second principal component

TABLE 3: Classification results of different models for vinegar.

Model\Index	Accuracy	Precision	Recall	*F*1
SVM	71.49%	67.35%	78.10%	72.33%
RBFNN	75.87%	67.99%	76.25%	71.88%
NB	78.83%	70.89%	71.92%	71.40%
RF	90.53%	81.93%	74.03%	77.78%
IRF	100%	99.83%	96.47%	98.12%

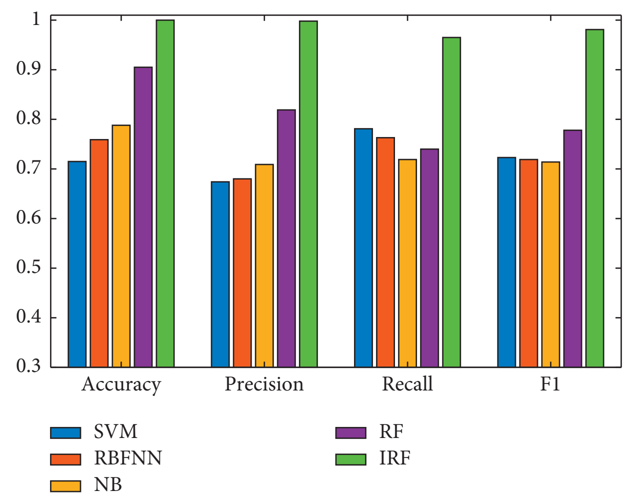

FIGURE 6: Comparison of classification results of different models.

obtained from the physicochemical indicators can be interpreted as acidity (sourness) and that the second principal component is positively correlated with acidity. In general, the results of the principal component analysis obtained from the physicochemical indicators were mainly related to the brix and acidity characteristics of vinegar, which is not unrelated to the fact that vinegar is an acidic condiment. However, these five physicochemical indicators alone are not sufficient to distinguish the different types of vinegar.

Sixty samples were taken from each category of edible vinegar. The total number of samples was 300. Eight indicators were collected for each type of edible vinegar. These 8 indicators were collected by 8 sensors. The size of the samples was $300 * 8$. Since there were 5 types of edible vinegar in total, the number of categories was 5. The results of the experiment are shown in Table 3 and Figure 6.

In terms of recognition accuracy, the IRF method used in this paper improves 0.40, 0.32, 0.27, and 0.10 compared to other SVM, RBFNN, NB, and RF. The improvement ratios fully demonstrate the superiority of this method. In terms of accuracy, the IRF method improves 0.48, 0.47, 0.41, and 0.22 over SVM, RBFNN, NB, and RF, respectively. The high *F*1 scores indicate that the model used in this paper has a good recognition rate for both positive and negative samples. The value range of the four indicators used in this paper is between 0 and 1. The larger the value, the better the performance of the model. The experimental results show that the IRF algorithm has the largest value on the four indicators and is far ahead of other comparison models. The experimental results verify the effectiveness of the IRF algorithm in the detection of edible vinegar quality.

5. Conclusion

There have been numerous issues with food quality and safety in recent years. Although the government has introduced relevant policies, it has not been able to eliminate all kinds of counterfeit and shoddy products. On the other hand, many food products are prone to deterioration during storage. If people do not detect these food products in time, they can be harmful to their health. This paper proposes the use of an improved RF algorithm to improve the speed and accuracy of food quality detection. The algorithm uses mutual information to calculate the correlation of any two decision trees, and for the more correlated decision trees, only the decision tree with the highest evaluation accuracy is retained, thus forming a new RF, converting the evaluation accuracy into voting weights, and finally obtaining an RF model with less redundancy and higher evaluation accuracy. The experimental results show that the method used in this paper can successfully identify spoiled or counterfeit products. However, although the algorithm in this paper is more intelligent than traditional food detection methods, there are some problems. One is that the model used does not achieve the desired results for high-dimensional data. Second, it is unknown how well the food testing method proposed in this paper can detect the quality of other food products, as the core ingredients of different food products are different. The determination of the core components has a great impact on the final identification effect. For the above two problems, this paper will be followed by an in-depth study.

This paper constructs a SDN network traffic prediction model based on speech recognition and applies it to the educational information optimization platform. By analyzing the influencing factors of SDN network equipment, communication links, and network traffic, this paper constructs the initial index set of SDN network traffic situation. In the data plane of SDN, the queue management algorithm is used to control the flow. On this basis, an IRS mechanism is proposed based on the advantages of SDN centralized control and the difference of transmission performance requirements between large and small streams. For the transmission of large traffic, IRS adopts greedy routing and multipath routing based on the remaining bandwidth to make the traffic evenly distributed in the network, and IRS adds the scheduling strategy based on IP addressing to avoid packet disorder. Simulation results show that the effectiveness of this algorithm can reach 95.67% at the highest, and the MSE convergence is 0.0021 at the lowest. At the same time, this method completes the quantitative evaluation of SDN network traffic situation, effectively solves the problem that SDN traffic situation labels cannot be determined, and opens a new vision of global state observation for SDN network management. This research can provide some technical support for the educational information optimization platform.

1. Introduction

In the knowledge economy era, education directly transforms into the mechanism for resource formation and allocation as well as the capacity to possess and distribute capital. An unstoppable trend of networked development of global information resources has been brought about by the quick development of information technology [1]. The main resource in modern society is information. It will be challenging to maximize economic and social benefits if resource development and use are not brought into the economic operating system. With the assistance of the development of deep NN (neural network) technology [2–4] in the new century, speech recognition technology has achieved ground-breaking successes. Speech recognition's primary function is to translate the data present in a speech signal into the corresponding text data. The ultimate objective is not to translate speech into words. Making machines understand humans is the aim of speech recognition. Future research may focus more on how to integrate semantic understanding with speech recognition. The four main components of the speech recognition framework are the decoder, language model, acoustic model, and feature extraction and processing module of the speech signal. Information technology professionals are currently considering how to better apply speech recognition technology to the field of education and teaching due to the technology's rapid development. The phonetic teaching approach is straightforward and effective in the educational setting. As a result, research into the use of phonetic recognition in the educational setting has gained importance and drawn a lot of attention from scientists. Economic and social benefits are very likely to result from it. With the general advancement of artificial intelligence, speech recognition technology will inevitably become more sophisticated. To advance the deep integration of information technology and education and teaching, speech recognition technology will be extensively applied to all facets of teaching and learning in the future. Studying the use of SDN network traffic prediction based on speech recognition in the educational information optimization platform is therefore important from both a theoretical and practical standpoint.

The importance of traffic control engineering as a mechanism for enhancing network performance has grown as a result of the diversified development of network applications, the expansion of services available over networks, and the constant rise in bandwidth demand. In addition, the unit integration mechanism used by traditional network management is unable to accurately describe the network traffic situation, and network resources have subpar global performance capabilities [5]. The question of how to increase network throughput, decrease network delay, and implement flexible scheduling to solve the traffic optimization problem of the data center network has become urgent due to the increase in traffic volume, the number of application deployments, and the increased requirements for service quality. OpenFlow, an SDN technology that has recently emerged, has created a new opportunity to address this issue [6]. A new network architecture called SDN divides network control and forwarding tasks. It can make network administration easier and increase the network's programmability and flexibility. SDN networks are continuously being developed on the foundation of traditional networks, and they have the potential to significantly increase network resource utilization [7]. SDN is a concept rather than a specific technology that refers to designing network architecture with the separation of forwarding and control. It plans the relationships and interfaces between each level of the network's hierarchy. Uneven traffic distribution in the data center network is one of the factors contributing to network congestion, which can be minimized by using a routing strategy that distributes traffic evenly among several accessible paths [8]. Currently, most multipath routing strategies use static hashing or shunting to divide data streams among different paths, which is easily problematic and can result in issues like large stream conflicts or packet disorder. This paper suggests a speech recognition-based SDN network traffic prediction model based on this and applies it to the platform for optimizing educational information. The innovation of this paper is as follows:

(1) This paper summarizes the application of speech recognition technology in the optimization of educational information resources. By analyzing the influencing factors of SDN network equipment, communication links, and network traffic, the initial index set of SDN network traffic situation is constructed. In the data plane of SDN, this paper uses queue management algorithm to perform flow control. The same set of parameters is used to implement the same management strategy for different data stream packets, and the influence of packet arrival and departure in buffer area on queue length is also considered. Experiments show that the network parameters calculated according to this model can meet all kinds of network requirements.

(2) In this paper, the data acquisition module in the SDN controller is designed, and the SDN network platform is built, which realizes the data acquisition and storage of traffic situation indicators. Aiming at the problems of packet disorder, this paper proposes an IRS mechanism based on the advantages of SDN centralized control and the characteristics of different performance requirements of large and small streams. For large streams, IRS uses greedy routing and multipath routing based on remaining bandwidth to make the traffic evenly distributed in the network, and IRS adds a scheduling strategy based on IP addressing to avoid packet disorder.

This paper will be broken up into five sections in accordance with the needs of the research. Each section contains the following primary work and organizational structure. Introduction is the first section. This section explains the background of the research, the research's subject matter, its originality, and its organizational design. The second section provides an overview of the state of research both domestically and internationally before moving on to discuss the research's main points and ideas. The third section is divided into two sections. The optimization of educational information and network traffic forecast are related topics that are covered in Section 3.1. Using speech recognition, Section 3.2 creates a model for SDN network traffic prediction. The model that was built in this paper is repeatedly simulated in Section 4, and the outcomes are examined. Summary and prospects are covered in the fifth section. It mainly elaborates on the research findings from this paper and anticipates the challenges ahead as well as the work that will come after.

2. Related Work

Shu et al. explored the working method of speech recognition technology and its teaching application, and emphatically introduced several main forms of speech recognition technology in the field of education and teaching. The current problems of speech recognition technology and the feasible way for future development to mature are discussed [9]. Ji et al. combined rough set analysis, DL (deep learning), and other methods to evaluate and predict the SDN network traffic situation [10]. The experimental results show that the model has high prediction accuracy. Chan et al. proposed an optimization algorithm based on color grouping for the data layer [11]. The model classifies different kinds of data streams, marked with different colors. Jha et al. proposed a new SDN network traffic situation assessment method [12]. This method uses the AK-means clustering method to determine the decision-making attributes of the traffic situation factor matrix and constructs a rough set analysis information system for situation information reduction and attributes importance to calculation and finally generates an unsupervised traffic situation assessment model. Konstanteli et al. conducted an in-depth analysis of network traffic control methods and proposed an algorithm-based traffic control model [13]. It points out the deficiencies in the flow control of the network from the control layer and the data layer. Liu et al. designed a multitenant-oriented network resource allocation and management platform based on SDN [14]. The platform provides its own view interface for different tenant networks and implements tenant resource allocation and traffic isolation. Based on the SDN network structure, Fabrizio et al. proposed the main functional modules of the SDN network traffic situation assessment and prediction system, including the data collection module and the situation assessment and prediction system module, and introduced the functions and implementation methods of each module in detail [15]. Chun et al. proposed a new model of SDN traffic control, which is based on the multicommodity flow algorithm and queue management algorithm to control SDN network traffic more finely [16]. Qi et al. proposed a maximum entropy network traffic prediction and controller predeployment model based on hidden Markov optimization [17]. The model classifies SDN traffic according to the type of protocol, uses the captured historical data flow, uses the maximum entropy algorithm to predict the distribution of future data flow, generates the predeployment scheme of various controllers in the control plane, and joins the hidden Markov chain which optimizes the timeliness of the forecast plan. Compared with the SVR model, this model has higher prediction accuracy, and the generated predeployment scheme can adapt to the dynamic changes in the complex SDN environment.

This paper builds an SDN network traffic prediction model based on speech recognition and applies it to the educational information optimization platform using research from related literature. This paper builds the initial index set of SDN network traffic situation by examining the influencing factors of SDN network hardware, communication links, and network traffic. This paper suggests an IRS mechanism based on the benefits of SDN centralized control and the characteristics of various performance requirements of large and small streams in order to address the issues of packet disorder. In order to evenly distribute traffic across the network for large streams, IRS employs greedy routing and multipath routing based on available bandwidth. Additionally, IRS incorporates a scheduling strategy based on IP addressing to prevent packet disorder. In this paper, flow control is implemented in the SDN data plane using a queue management algorithm. Studies reveal that the network parameters computed using this model can satisfy a variety of network needs.

3. Methodology

3.1. Application of Speech Recognition Technology in Optimization of Educational Information Resources. The ultimate goal of the application of modern information technology in education is to improve the educational efficiency. The utilization rate of educational resources has been improved, and the number of people enjoying educational information resources has increased geometrically. Education is essentially the process of information transmission [18]. The extensive, continuous, and in-depth influence of modern information technology on education has created a brand-new educational form-information education. At present, in the field of information research, the optimal allocation and efficient development of educational information resources is one of the frontiers and hotspots, and it is of great practical significance to implement it in the subject practice of educational scientific research. Educational information resources under modern information technology refer to the collection of useful information that is selected, organized, and ordered by human beings and is suitable for learners to effectively develop among themselves. With modern information technology, educational resources all over the world can be connected into an information ocean for the majority of educational users to share [19]. The educational information environment includes four elements: people, educational information resources, educational information technology, and educational information norms. These four elements and their many factors constitute a sustainable and dynamic educational information environment system. The effective use of educational information can help students to effectively reconstruct their knowledge structure, strengthen their self-learning and self-management, and at the same time help teachers and administrators to conduct in-depth research in teaching management. The content of modern information resources is very rich, among which network education resources are the most important part of modern education information resources. It has many types, including educational websites, e-books, electronic journals, virtual libraries, virtual software libraries, news groups, and electronic encyclopedias. Computer network technology is increasingly infiltrating into people's daily life, and digital survival has become a brand-new way of life. While people enjoy the surprises brought by the information society, they also expose their poor adaptability to the information society. This is manifested in students and teachers who generally lack the knowledge and experience of information retrieval, identification and integration, and the concept of online security is also very indifferent, and they do not know how to consciously abide by the norms of online behavior. Speech recognition technology is a technology that converts speech signals into corresponding commands so that computers can understand them. With the rapid development of speech recognition technology, the application scenarios of speech recognition have become more extensive, and it has different tasks and functions in various fields, resulting in different design schemes for different application scenarios, but the speech recognition systems all have the same overall structure.

The process of simulating human information exchange by using a computer mainly goes through the following processes: (1) natural language generation, (2) speech synthesis, (3) speech recognition, and (4) natural language understanding. The main task of speech recognition is to identify the information contained in the speech signal into the corresponding text information. The three main components of speech recognition are feature extraction, pattern matching, and reference pattern library. Although phonetics has been around for a while, it has not been widely used because of the difficulty of the corresponding model base and phonetic knowledge. The process of fairly classifying, organizing, managing, and processing the gathered complex information is known as information architecture. Its primary

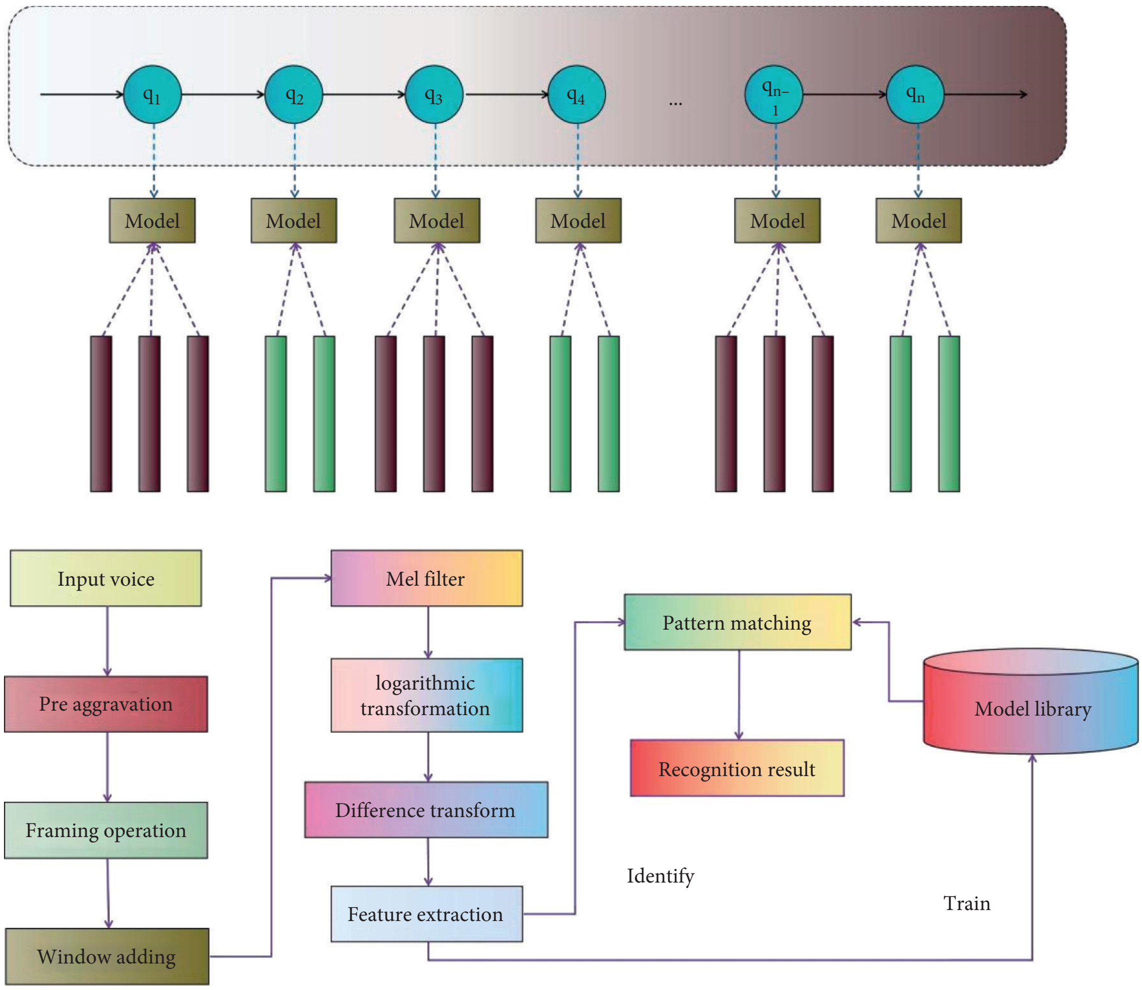

FIGURE 1: Framework and process of the speech recognition system.

responsibility is to combine the components of information expression, determine its course, and edit the expression's content in order to create a cognitive link between users and the data. Academic and industrial researchers are enthusiastic about DL theory due to its superior modeling capability for complex data. The performance of models based on DL has also significantly improved in many real-world application fields, particularly in speech recognition [20]. The computer will automatically produce the recognition results following preprocessing, feature extraction, training, pattern matching, and other units. From this procedure, it is clear that speech recognition is essentially a pattern recognition system and that the effectiveness and precision of recognition depend on the quality of the speech template and algorithm. Network media's ability to disseminate information quickly and with a wide range of influence is improved by the network's rapid growth and update frequency. Because educational information resources are highly time-sensitive, it is important to gather, process, and use educational information as soon as possible. The framework and process of speech recognition system are shown in Figure 1.

Although teaching itself is a systematic process with a clear goal, producers and consumers of educational information frequently do not interact directly, and many producers frequently produce educational information in accordance with their own intentions. Speech recognition technology has undergone significant technological changes recently due to the growth of the DL field, and the acoustic model has gradually shifted from the conventional Gaussian mixture model to the NN model [21]. The NN model significantly boosts the speech recognition system's recognition performance, enhancing its ability to support human daily life and industrial production. People are accustomed to understanding information in the context of their interpersonal relationships, and they selectively gather, arrange, and assess the information's relevance in light of their own needs. The degree to which information resources are accepted by learners and how well they are accepted by them largely depend on how well the information resources correspond to the learners' own concepts and knowledge bases. The speech recognition industry currently uses a lot of NN-based speech systems. Neurons, the training algorithm, and the network structure make up the majority of NN. Speech recognition suffers greatly from noise and interference, which lowers the rate of recognition. Due to the issues of comprehensive teaching content, rich and diverse speech expressions, and relatively small speech data sets in the educational scene, applying speech recognition to the educational scene is still a difficult research project. The high recognition rate is currently stuck at the "near-field speech recognition" stage and is unable to advance to the stage of "far-field speech recognition," which is the mode of natural man-machine interaction. The proliferation of inaccurate information and the challenge of finding high-quality resources are issues that we must simultaneously address despite the fact that education technology expands the learning environment for students. The environment for educational information needs to be optimized. A complete speech recognition system usually consists of three parts: (1) the speech front-end processing part responsible for processing speech signals, (2) the language model and acoustic model, which are trained by text corpus and voice data set, and (3) speech recognition, that is, pattern matching.

3.2. Construction of the SDN Network Traffic Prediction Model Based on Speech Recognition. Traditional network has been restricted in function expansion and network configuration. In order to make network management more convenient, SDN network has begun to appear in public view. SDN is a new network architecture that separates network control and forwarding functions, which can simplify network management and improve network programmability and flexibility. SDN can maximize the utilization of network resources, restrain the unlimited expansion of network infrastructure, and shield the complexity of the underlying network for the upper users. It simplifies the configuration and management of the network and promotes the innovation and development of the network. SDN network is continuously developed on the basis of traditional network, and the utilization rate of network resources can be greatly improved through SDN network. The latest development of SDN network and switching technology can make the network protocol stack abstract from the physical topology level to the flow level for business control. SDN carries the idea of designing network architecture for forwarding and control, rather than a specific technology. It plans the hierarchical structure of the network and the relationships and interfaces among all levels. With the popularization and development of this concept, different participants have further enriched its content, and they have different understandings of it from different angles. Network traffic will change with time and space. In the time dimension, the network traffic will change with different time periods of the day, for example, the traffic in the daytime is higher than that in the night. In addition, the network traffic may change dramatically in a very short time. SDN network is characterized by hierarchical design of data forwarding and network control. The SDN controller is interconnected with each switch, and control information is uploaded and sent through OpenFlow protocol. SDN network is divided into three layers: application layer, control layer, and data layer. It includes commercial applications used by users in the application layer through which network services can be provided to end users. The control layer consists of one or a group of controllers and connects the data forwarding layer with the application layer through an interface. The control layer has mastered the core, can obtain the global topology of the whole network, and design strategies to control the transmission path of the data layer. The data forwarding layer is composed of switches, hosts, and other underlying network devices, which is the realization of the data plane. The data layer does not have the function of selecting the forwarding path but can only transmit information according to the forwarding path provided by the control layer. The network structure of SDN is shown in Figure 2.

SDN network breaks through the limitation that the service interfaces of traditional network hardware devices cannot be configured and adjusted uniformly and in real time. Its advantages are mainly reflected in two aspects: (1) SDN separates the control plane and the data plane of the current network; the data plane is simply forwarded by the actual network equipment, and the control plane is controlled by a logically centralized controller. This simplifies the implementation and optimization of the strategy and the configuration of the network. (3) SDN improves the programmability of the network system by providing developers with powerful and extensible programming interfaces. Network flow is a dynamic variable that is constantly changing from a fine-grained perspective, but it is comparatively stable over time. If the load balancing model only takes into account this change based on the current time point, without taking into account the change trend of the future data flow, it may result in low cost performance controller migration. However, this migration cannot guarantee the overall improvement of the network performance in a specific amount of time, as it only supports the current burst network data flow, which may increase the overall network delay. Additionally, the load flow may exceed the network capacity when the SDN network uses the optimized routing configuration, particularly when the network experiences burst flow. In order to prevent this kind of congestion, which is the main goal of traffic control, we must allocate suitable transmission resources for data traffic in accordance with its transmission requirements and restrict some traffic flows from entering the network at the bottleneck links. Hedera, a dynamic traffic scheduling strategy that can sense the traffic size, is a representative scheme for addressing the issue of network congestion brought on by heavy traffic collision in an SDN-based data center network. Hedera's strategy is to use centralized scheduling for large flows with long durations and small quantities and default ECMP routing for small flows. To determine the flow rate and size of the large flow in this routing scheme, the edge switch using OpenFlow technology first counts the data of the flow generated by the source.

From the perspective of communication theory, obtaining the best decoded word sequence in speech recognition needs to be transformed into a pattern recognition problem. The core idea of solving the word sequence with the highest probability is to adopt the maximum posterior probability discrimination, and its calculation formula is as follows:

$$\widehat{W} = \underset{W}{\operatorname{argmax}}\, P(W|X). \tag{1}$$

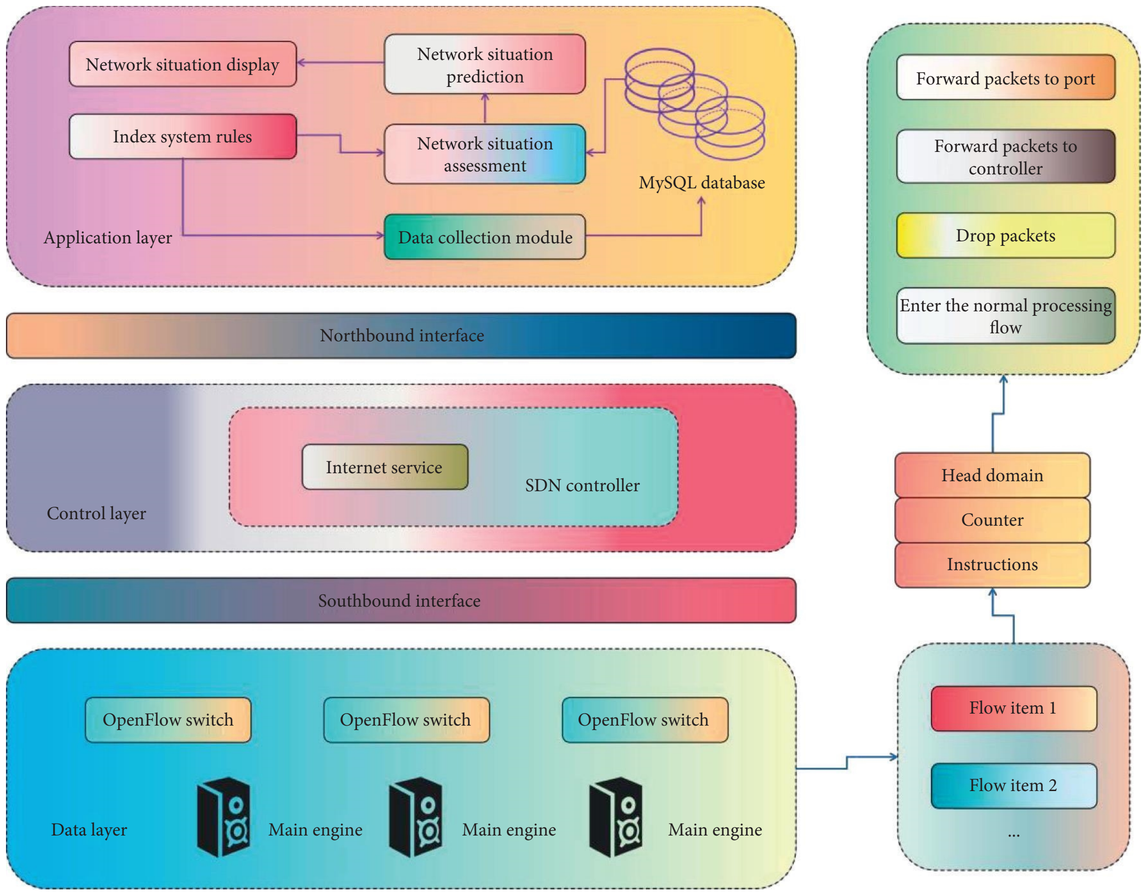

FIGURE 2: SDN network structure.

In the speech recognition problem, $P(W|X)$ is difficult to calculate directly, and it can be converted into the following formula by using the Bayesian formula:

$$\begin{aligned}\widehat{W} &= \underset{W}{\operatorname{argmax}} \frac{P(X|W)P(W)}{P(X)} \\ &= \underset{W}{\operatorname{argmax}} P(X|W)P(W),\end{aligned} \tag{2}$$

where $P(X)$ represents the prior probability of the feature vector, which is a constant for all word sequences, so it can be discarded. $P(X|W)$ represents the probability of using a given word sequence to generate the corresponding acoustic feature vector, which is modeled and calculated by the acoustic model. $P(W)$ is the prior probability of the word sequence, which can be modeled and calculated by the language model. After framing the speech signal, it is necessary to continue windowing the speech signal to deal with the nonstationary characteristics of the speech signal. The most commonly used window adding methods are the rectangular window and Hamming window. The definition of rectangular window function is shown in the following formula:

$$w(x) = \begin{cases} 1, & 0 \le n \le N-1, \\ 0 & \text{other}. \end{cases} \tag{3}$$

Define the currently available bandwidth $c(p)$ for path p:

$$c(p) = \min_{e \in p} c(e). \tag{4}$$

In the formula, $c(e) = x(e) - u(e)$, which is the remaining bandwidth of link e. Define the vulnerability of path p as $\alpha(p)$:

$$\alpha(p) = \max_{e \in p} \alpha(e). \tag{5}$$

In the formula, $\alpha(e)$ is the number of paths in different $p_1 s$ passed on the link e:

$$\alpha(e) = \sum_{l=1}^{L} \delta_l(e). \tag{6}$$

Among them,

$$\delta_1(e) = \begin{cases} 1, & \text{if } p \in p_1^k,\ e \in p, \\ 0, & \text{else}. \end{cases} \tag{7}$$

Network bandwidth utilization refers to the average of the ratio of link load to link bandwidth of all links in the recent period. The calculation formula of network bandwidth utilization is

$$\text{Link\_utirate}(t) = \frac{\sum_{l=1}^{L}\left(\text{portBytes\_}Rx_l(t) * 100\%/\text{bandwidth}_l\right)}{L},\quad L = 1,2,3,\ldots,L. \tag{8}$$

Among them, bandwidth_l refers to the bandwidth of the lth link, that is, the maximum number of bits that can theoretically be transmitted by the physical channel per unit time. $\text{portBytes\_}Rx_l$ represents the number of bits transmitted by the sender of the lth link. The link transmission delay refers to the maximum value of the communication delay from the sending port to the receiving port of all links. The calculation formula is

$$\text{Link\_delay} = \max_i\{p\text{topDelay}(i)\}. \tag{9}$$

Among them, the network delay can be calculated by the maximum transmission delay of the link, that is, the maximum time interval $p\text{topDelay} = T_2 - T_1$ between the time T_1 of the transmission data packet leaving the source point and the time T_2 arriving at the destination in the network; $p$topDelay represents the end-to-end delay. Network throughput refers to the total number of bytes passing through the switch port connected to the host in unit time without packet loss. It can be calculated by the total number of bytes imported and exported, namely,

$$\text{Net\_throughput} = \frac{(\text{dataBytes\_inNum} + \text{dataBytes\_outNum})}{T}. \tag{10}$$

Among them, T represents the sampling interval; dataBytes_inNum represents the number of incoming bytes connected to the host; and dataBytes_outNum represents the number of exported bytes connected to the host.

In this paper, the machine learning algorithm is used to compare the actual data stream with the predicted data stream, and if the deviation is greater than the set threshold, the deployment scheme is regenerated. Otherwise, the old scheme is still adopted. During the running of the scheme, the controller does not migrate any more to reduce the impact of migration on network performance. In an SDN network, all network resources are pooled together, and the controller distributes path and bandwidth resources evenly among the network's data streams. The data streams processed by the switch will be stored in the buffer area for transmission, and its only responsibility is to forward the data streams in accordance with the controller's defined policies. The network topology discovery module's network topology information and the network monitoring module's link remaining bandwidth information are used by the large flow routing calculation module in the SDN controller to determine the convergence layer link pair of the large flow's source and destination using the greedy algorithm. In this paper, the situation is assessed using a model based on rough sets and clustering [22], which can improve decision tables and assess the current network traffic situation in accordance with the decision rules derived from rough set analysis theory. The historical situation value and current situation value in the SDN network operation process are finally obtained by investigating the calculation method of situation index weight based on attribute importance, allowing for an intuitive and unmistakable understanding of the global network view and network operation trend through the situation value.

Table 1: Parameter setting of the simulation experiment.

Serial number	Parameter	Set up
1	Link bandwidth	10 Mbps
2	Link delay	3ms
3	Sending node	S1, S2
4	Receiving node	D1, D2
5	Minimum threshold	50
6	Maximum threshold	100
7	Maximum packet loss probability	0.2
8	Weight	0.03

4. Result Analysis and Discussion

Through Hurst index calculation of the SDN network traffic situation value, the sequence H value is 0.88, which indicates that the situation value sequence has strong self-similarity and long correlation. In order to verify the effectiveness of SDN network traffic prediction model based on speech recognition, this paper designs several simulation experiments on the MATLAB simulation platform. The platform can automatically configure network controllers, switches, etc., and execute protocols. In the simulation experiment, the controller with visual boundary is installed as the control layer of the network. Based on Python programming language, network switches and terminals can be easily configured on Floodlight. At the same time, in this chapter, a large number of comparative experiments are made between the prediction model in this paper and other different prediction models including the convergence of training iteration of traffic situation, the relative error of situation value prediction, the influence of super parameters of the model, and the generalization ability of different data sources. The simulation parameters are shown in Table 1.

When a large number of data flows pass through SDN network, network congestion will occur. On this basis, this chapter simulates and analyzes the pet control algorithm based on queue management. Because the network flow is complex and changeable, and many artificial subjective predictions are difficult to be verified, constructing the probability matrix through objective historical data to obtain the probability matrix under the condition of maximum entropy as the prediction result at that time can maximize the accuracy of the prediction. During the experiment, the training sample group is input to train the prediction model, and the maximum number of iterations is set to 2000. The change of training MSE (mean square error) in the network training iterative process is shown in Figure 3.

It can be seen that the MSE is decreasing from the initial 0.08 or so, and it reaches convergence after 600 iterations, and the MSE at convergence is 0.0021. This shows that with the increase of iteration times, the weight update can

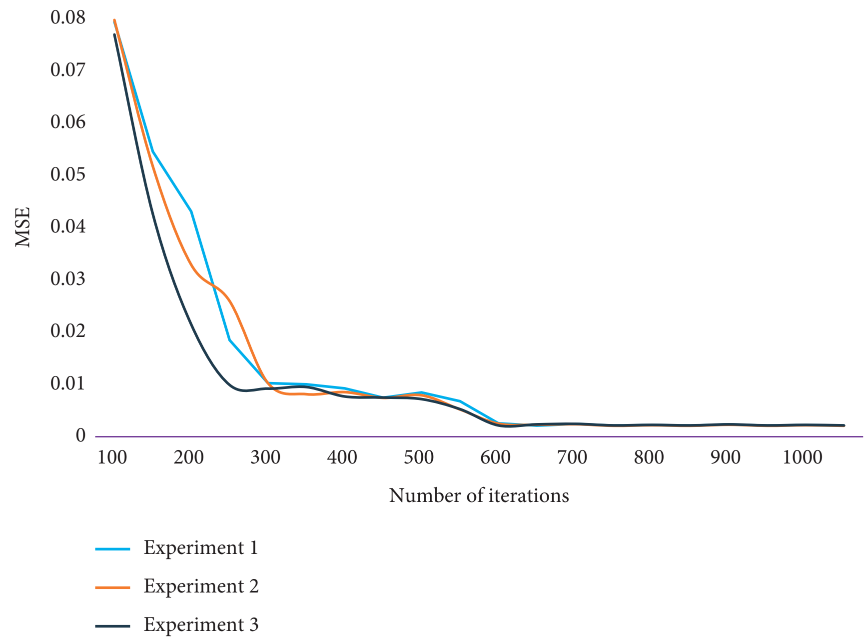

Figure 3: Changes of training MSE in the iterative process of network training.

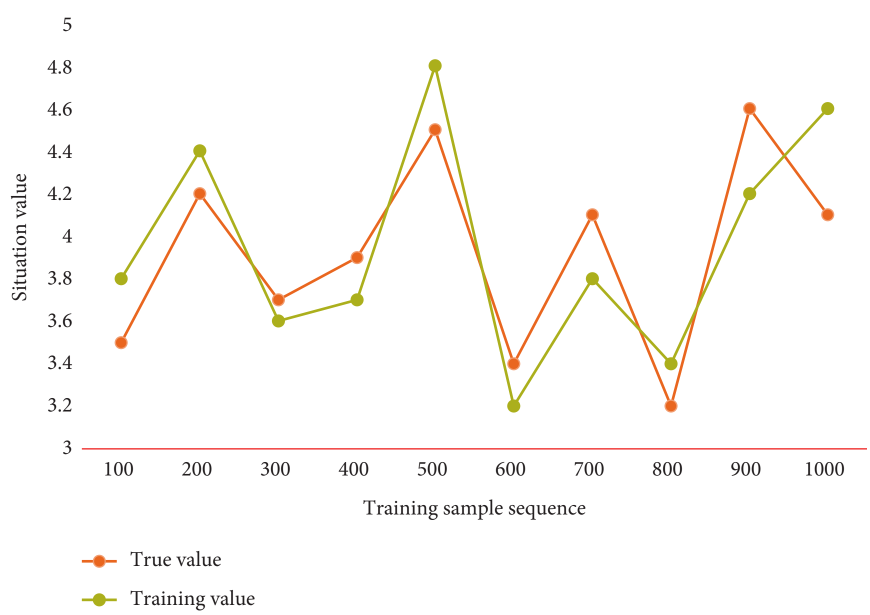

Figure 4: Effect of network training.

converge in the process of gradient descent, and the convergence speed is faster.

First, the parameters are compared and analyzed. Then the maximum and minimum threshold values are changed, and the performance parameters of each packet are further analyzed. Under the condition that the buffer size is constant, this chapter changes the minimum threshold of queue length. The network training effect is shown in Figure 4.

For this paper, the main factors that affect traffic prediction are the number, time, and protocol type of packets. Therefore, the model takes packet size, packet protocol name, and time as eigenvalues and generates the network flow data matrix by sorting the data. The trained network model is used to predict 20 groups of untrained samples. The prediction effect is shown in Figure 5.

It can be seen from Figure 5 that the prediction model can achieve good prediction results for any group of traffic situation samples to be predicted, and the relative error of prediction is basically controlled within 15%. In this paper, network throughput, average flow completion time, the remaining bandwidth jitter in Pod and remaining bandwidth jitter in the core layer are selected as performance evaluation indexes. Among them, the average stream completion time refers to the average time taken to complete

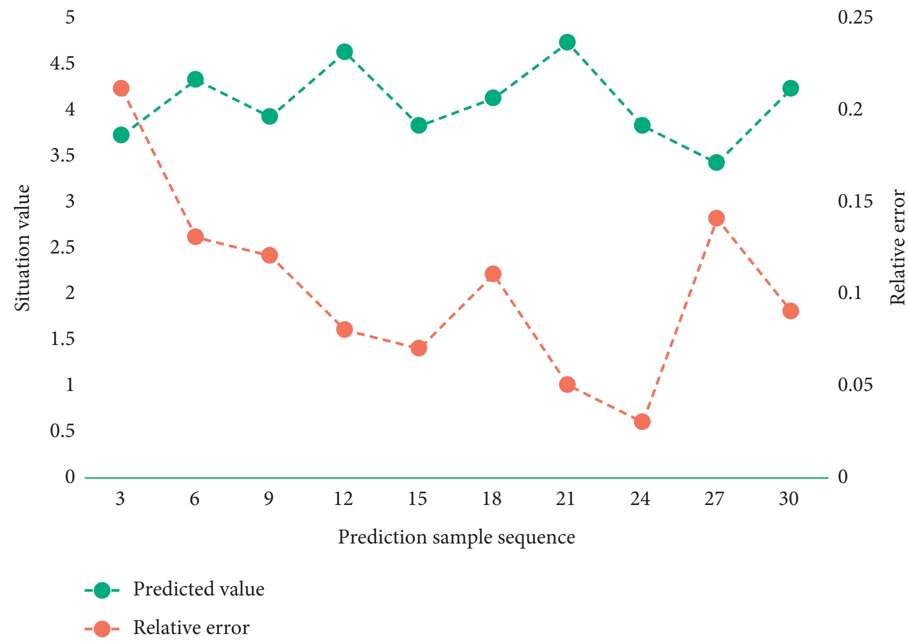

Figure 5: Prediction effect of the model.

Table 2: Test results of each index.

Index	IRS	ECMP
Network throughput	1058	957
Average flow completion time	48	53
Remaining bandwidth jitter of Pod link	26	30
Core layer link remaining bandwidth jitter	20	24

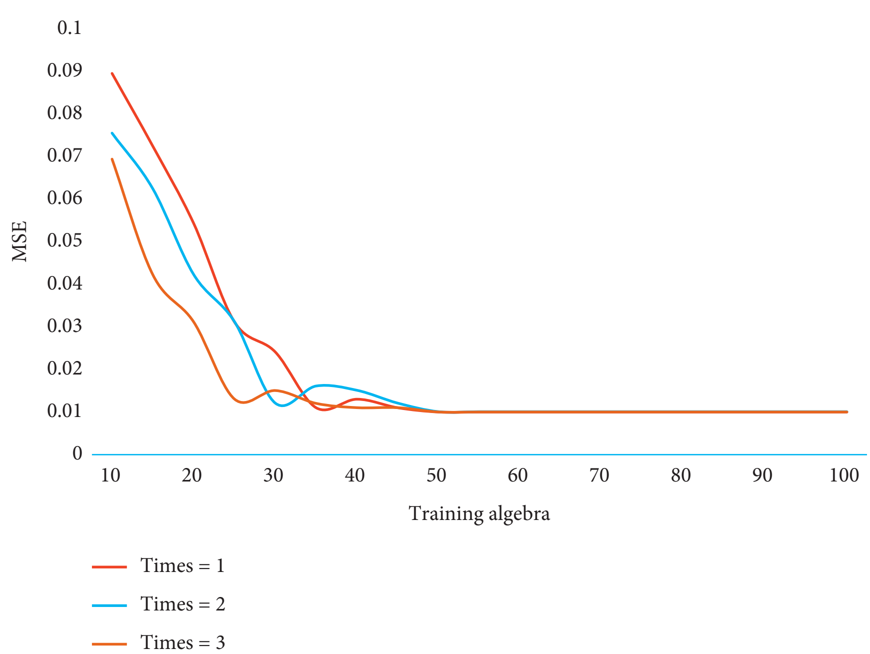

Figure 6: Comparison of the iterative convergence effect.

all 100 MB data block transmissions, and the smaller the time, the better the performance. Network throughput refers to the amount of data transmitted and successfully accepted through the network per unit time in the network. The larger the data, the better the performance. The jitter of the remaining bandwidth in the Pod and the jitter of the remaining bandwidth in the core layer refer to the standard deviation of the remaining bandwidth of each link in the Pod

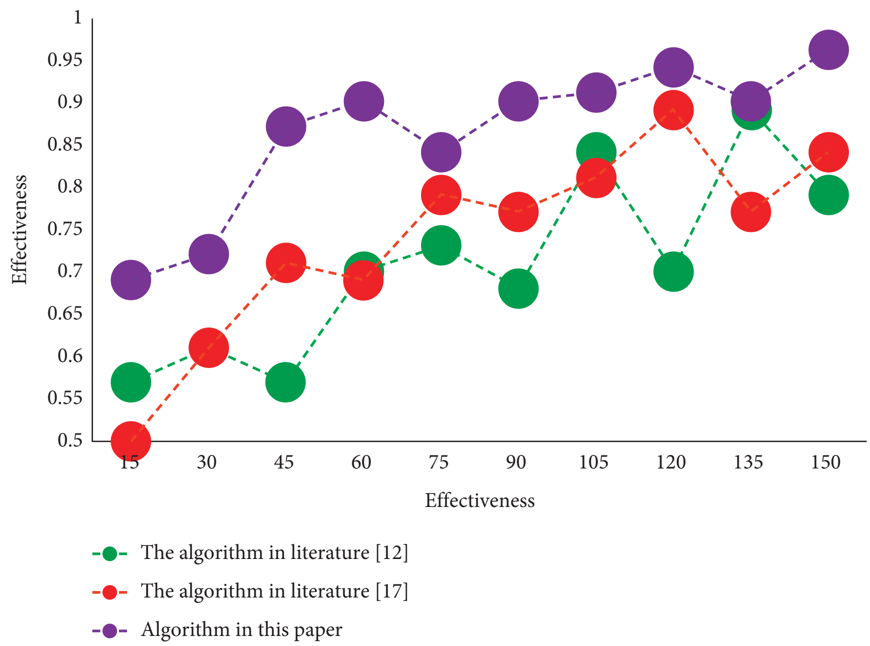

Figure 7: Effectiveness test results of the algorithm.

and the core layer, respectively. The smaller the jitter, the better the equalization performance. Table 2 shows the test results of each index.

On the whole, the traffic balancing effect of IRS is better than that of ECMP, which is mainly because IRS uses the dynamic routing method based on the remaining link bandwidth in convergence layer of the network, and large flows are always routed to low-load paths. Moreover, IRS uses the shunting method to route large flows in the core layer, which further balances the load in the network. Because the model uses random initial weights to initialize the network, different initial weights may have different effects on the network iterative convergence. In this paper, the results of three experiments are compared. Times means times, and the values are 1, 2, and 3. The iterative convergence effect is shown in Figure 6.

From the comparison results of curve slopes, it can be seen that the convergence speed of this model is faster than that of the other two models in the three experiments. At the same time, the initial MSE of this model is obviously better than the other two models. It shows that the algorithm in this paper can effectively improve the convergence speed of network model, and the training effect is better. The SDN controller only selects the forwarding path for the new flow injected into the network according to the usage of the remaining flow table of the switches on the feasible path in the current tenant network. The effectiveness test results of the algorithm are shown in Figure 7.

In order to verify the effectiveness of SDN network traffic prediction model based on speech recognition, this chapter designs several simulation experiments on the MATLAB simulation platform. Experimental results show that the effectiveness of this algorithm can reach 95.67% at the highest, and the MSE convergence is 0.0021 at the lowest. The results show that this model has faster iterative convergence speed, better training effect, and higher prediction accuracy.

5. Conclusions

The development of voice technology will further help education and teaching, improve teaching efficiency and teaching effect, and promote the overall development of artificial intelligence technology. Based on the research of related literature, this paper constructs a SDN network traffic prediction model based on speech recognition and applies it to the educational information optimization platform. In this paper, the data acquisition module in the SDN controller is designed, and the SDN network platform is built, which realizes the data acquisition and storage of traffic situation indicators. Aiming at the problems of packet disorder, this paper proposes an IRS mechanism based on the advantages of SDN centralized control and the characteristics of different performance requirements of large and small streams. For large streams, IRS uses greedy routing and multipath routing based on remaining bandwidth to make the traffic evenly distributed in the network, and IRS adds a scheduling strategy based on IP addressing to avoid packet disorder. Simulation results show that the effectiveness of this algorithm can reach 95.67% at the highest, and the MSE convergence is 0.0021 at the lowest. The algorithm can effectively realize the relative priority of each packet queue without reducing the utilization of network resources and can smoothly upgrade and downgrade the priority. On the whole, this model has faster iterative convergence speed, better training effect, and higher prediction accuracy. This research can provide some technical support for the educational information optimization platform. Although this paper has achieved some research results, the research is still shallow, and there are still many places that need to be improved and supplemented. In the future research, we should find a unified solution in different algorithms so that the performance of packet delay and system throughput is better and the utilization of network resources is maximized.

Due to the limitation of sports movement, the current simulation technology of sports entities is prone to deficiencies in capturing dynamic motion figures and is prone to lack of accuracy. It is also affected by external noise and brightness. To solve these problems, this paper proposes a sports entity simulation based on the fish swarm algorithm and compares the figure effectiveness, figure segmentation, core point, and noise reduction effect of the two in the shooting figure. Through the comparison, it is found that the figure is more appropriate to the real moving figure, the motion capture is more accurate, and the number of core points is related to the accuracy of motion capture. The more core points, the more accurate the motion capture, and the noise reduction effect is also increased by 20.3%, which reduces the impact of brightness on the motion simulation. The difference in the effect of the traditional simulation technology (particle swarm algorithm) and the entity simulation based on the fish swarm algorithm was also compared. The combination with the artificial fish swarm algorithm is to simulate the moving entity and learn from some reference data. By comparing the data between the two after the experiment, it is concluded that the fish swarm algorithm is more effective in the simulation of sports entities.

1. Introduction

The physical simulation of sports is recorded by sensors, and then the movement information in the space is transmitted to the processing center of the computer and processed by computer to get the basic three-dimensional human body model. On this basis, the human body frame is drawn to realize the physical simulation of sports. At present, the main technologies used to capture sports movements include optical capture, mechanical capture, and electroacoustic capture. Mechanical and electroacoustic capture methods are limited by sports and have a relatively broad acquisition range. However, the accuracy of motion capture is not enough. The advantage of the optical capture method is that it will not be blurred, but the number of captured points is not enough to meet the requirements of moving entities, and the collection location is affected by the brightness, and the equipment itself is also easily affected. It is easy to cause the external light data to interfere with the motion data, resulting in confusion in the analysis of the equipment during operation, and it is more complicated to deal with. Although electroacoustic capture has low operating costs, the capture accuracy is not enough. In this regard, motion capture technology is not satisfactory. In this paper, the simulation calculation of moving entities based on fish swarm algorithm is introduced.

In this paper, based on the fish swarm algorithm, the sports motion detection system is compared. By simulating the irregular images under human body dynamics, through the corresponding tools, under the condition that the background is not set, the influencing factors existing in sports are removed, background, shadows, brightness, noise, and so forth, and the main moving points of the human body under sports are extracted and simulated, which is of great significance to the improvement of simulation technology.

In this paper, a physical simulation of sports based on fish swarm algorithm is proposed. By comparing the figure effectiveness, figure segmentation, core point, and noise reduction effect of the two in the shooting figure, it is found that the figure is more appropriate to the real moving figure, the motion capture is more accurate, and the noise reduction effect is also increased by 20.3%. By comparing the data between the two after the experiment, it is concluded that the fish swarm algorithm is more effective in the simulation of sports entities.

2. Related Work

With the gradual acceleration of urbanization, people's quality of life has gradually improved. Every household has begun to prepare a car as a means of transportation, and the problem of urban traffic has gradually become more and more serious, and it is easy to cause congestion. The urban green wave traffic control system is one of the effective means to solve the problem of urban traffic congestion and reduce vehicle delays. In response to the problem of green waves, Ma C investigated the causes of congestion in the city through the fish swarm algorithm and found that the irregular movement of the crowd, the irregular parking of vehicles, and people's traffic awareness are the main reasons for the impact [1]. The progress of industrialization has brought about changes in weather, increasingly serious smog pollution, and a significant decline in air quality. Zhu X proposed a haze prediction method based on multifractal dimension (MFD) and coevolutionary discrete artificial fish swarm algorithm (CDAFSA). Using CDAFSA, MFD, and extreme learning machine (ELM), the algorithm population is initialized through good point set theory; the swarming, chasing, and foraging behaviors are improved by introducing the swimming speed of artificial fish; the algorithm is discretized; and competition and cooperative operation are introduced. Second, the haze dataset is reduced by CDAFSA and MFD; finally, a haze prediction model is established by using ELM. The experimental results show that the proposed prediction method is superior to the traditional method and has high stability and credibility [2]. The accurate prediction of wind power in wind farms is of great significance to the economic operation of wind farms and the safe operation of power grids. The randomness and volatility of wind in wind farms make wind power forecasting more difficult. Based on the characteristics of wind in wind farms, combined with relevant meteorological data such as wind speed, temperature, and humidity in wind farms, Zhai built the ultimate learning machine model (ELM) for wind energy forecasting and established an artificial fish swarm algorithm (AFSA) for rapid optimization. The constructed model is trained and predicted by the actual meteorological data and wind data of the wind farm. The results show that this method has higher predictive ability than the wind power prediction model of particle swarm [3]. The fish swarm algorithm is not only used in green waves, air quality surveys, and wind farms but also gradually used in sports.

Simulation technology, which is essential to virtual reality, has been extensively applied in the study of physical education. This ground-breaking programme has had a profound effect on conventional teaching methods and ways of thinking, and it has created enormous opportunities for the advancement of physical education. Yili examined the use of simulation technology and stimulus-response theory in the field of physical education with a focus on the drawbacks of the conventional physical education teaching method. This served as the foundation for the invention of the teaching method for physical education. The findings demonstrate that auxiliary teaching can enhance students' theoretical and practical understanding of physical education, enhance their academic performance and learning enthusiasm, and serve as a useful benchmark for physical education teaching innovation [4]. The active safety capabilities of cars have evolved into a crucial criterion for assessing their quality as the automotive industry continues to grow. The antilock braking system is an important tool to increase the active safety of the vehicle and prevent the wheels from locking. It does this by adjusting the torque to ensure that the vehicle slips at the ideal rate. It can still turn even when braking hard, cutting down on braking distance and time to lessen tyre wear. Song conducted research on an antilock braking system based on simulation technology on the basis of examining the pertinent principles. A simulation model for the antilock braking system in cars has been developed. It simulates the simulation model. According to the findings, antilock braking systems on vehicles perform better than conventional braking systems at maintaining slip rate, braking distance, and braking time [5]. During the wiring process of complex mechatronic products, the spatial pose and shape of the flexible wiring harness are prone to change. As a result, the sampling information of the wiring harness is inaccurate during the wiring process, which seriously affects the wiring efficiency. Wang proposed a physical property modeling and deformation simulation method of flexible cable harness based on the exact Cosserat model. The physical property model of the wiring harness based on the exact Cosserat model was established, and then the dynamic balance formula of the flexible wiring harness was constructed [6]. Simulation technology is an emerging technology in the field of system modeling and simulation research in recent years, and it has always been the focus of research. According to the simulation technology requirements of battlefield command decision-making, equipment task planning, and equipment maintenance support, the outstanding problems of existing simulation technology are summarized. That is, the domain model is stable and has no self-evolution ability. Ge put forward the concept of equipment parallel simulation technology and pointed out its characteristics. It systematically introduces its theoretical origin and research status of related technologies and discusses the main modeling technologies such as online perception of equipment degradation status and establishment of equipment degradation [7]. Simulation technology has been widely used now and is a milestone technology for the country to enter into rapid development.

3. Simulation System Description and Key

3.1. Simulation System. The simulation system must go through a standard motion figure processing stage before capturing, simulate the dynamic figure data in the computer body, and maintain the background's original state. Additionally, noise interference may get in the way of capturing.

The image cannot be captured directly as the background because the brightness in the capture space is also subject to slight variations, which will influence the capture [8]. The flow figure of system processing is shown in Figure 1.

Because the light intensity needs to be processed, it is necessary to extract new data from the background image and replace the previous background image. The replacement condition requires that the previous background image be relatively stable, and there is not much numerical deviation. When replacing, it cannot be said to be a complete replacement but only covers the previous information with part of the information and uses the difference algorithm between the sports image and the replaced background image to obtain the required background image. Through color processing, the image color is converted to the original gray. Then, the image data is differentiated through the threshold algorithm, and differential processing can identify differences in the background and quickly fill in the blanks. The differentiated data is used to complete the empty space in the replacement in a dynamic mathematical way, and a relatively complete three-dimensional map of sports points is obtained. 3D map is the basis of human motion contour and the most basic step of simulation technology. By extracting the edge points of the three-dimensional image [9], it will not be completely closed under normal conditions. By connecting the edge points, the key points of human body movement can be obtained, and the direction or position of other movements can be obtained instantly. The motion data outline will also coincide with the connected line segments. Through the obtained key points, the outline of human motion can be realized by drawing and 3D construction through simulation technology.

3.2. *Influence Points of the Realization System*

3.2.1. Background Extraction. There are many algorithms for background extraction. For example, there are interframe difference method, background difference method, ViBe algorithm, ViBe + algorithm, and so on. In this paper, the traditional fish swarm algorithm and the improved artificial fish swarm algorithm are used. Before extracting the background, the captured image points need to be sorted in a certain order. It is concluded that the sorted image is different from the previous background image and becomes cluttered. In ascending order from small to large, the pixel of the first image is the minimum value in the image. Similarly, the pixel value of the last image is the maximum value. Assuming that all image pixels are L, the noise interference is placed next to the background image, and the pixels arranged in the middle are used as the background, which can also prevent the pixels from being too large or small, resulting in the confusion of the entire image. The value of L in the system is selected as 9, and then the fifth figure is the background image. For the value of L, its size also has certain requirements. If it is too large, it will easily lead to too much calculation and affect the result. If it is too small, it cannot handle noise. Background extraction is the first shot of motion capture, but it cannot be captured as soon as it is turned on. Because of direct capture, the figures returned by the system are inconsistent, or there is a delay, or there are other cases where the pixels are not clear. This needs to be prepared in advance before capturing. When the figure reaches 25 frames, it will gradually stabilize. When the system is running, the previous frames can basically be abandoned directly, and the figures are the main ones, which are stabilized images. The frame rate is also a point to consider, because VC++ is used in this article as an auxiliary tool, the camera is the main sensing instrument, and the control instrument is a computer. Because, during image processing [10, 11], for image capture, the computer processing time is assumed to be t, if the T value is very large, the processing time of each photo is too long, which is not considered in this article, and does not meet the actual operation purpose. If the value of T is small, assuming that it is 0.01 s, it means that the computer needs to process hundreds of figures per second. But, for sports, the magnitude of the change is only a few microseconds, and the images in the vicinity of a few microseconds are similar, and there is not much difference. The general camera frame rate is 20–120 Hz. If the value of t is smaller, more images will be processed, and the situation of half-image will easily appear when the computer processes it. Get either the image of the upper half frame or the image of the lower half frame, or even there may be no figure. In order to ensure validity and accuracy, the processing frequency of the computer must be less than the capture frequency of the camera.

3.2.2. Human Motion Detection. There are three methods currently used for detection, the difference detection method [12], the background difference method, and the optical flow method [13]. The difference method is used in this paper. For the difference method, the background image and the previous frame image are determined through the calculation of the difference image, but it cannot be directly used in the background image because the image has color difference [14]. There are many influencing factors in the image, the color difference of the image, the scene of brightness, the number of recorded frames, and so forth, which cannot be directly used as the data information of the movement. The pixels are mainly formed in three ways, and the relationship between them is

$$\text{Gray} = 0.3R + 0.6G + 0.1B. \quad (1)$$

In the above formula, R, G, and B are the main paths of pixels. The color of the background is converted into the original gray through color, and the image data is differentiated through the threshold algorithm. Finally, the irrelevant points in the image are eliminated by the erosion algorithm. After adjusting and shrinking the image, the adjusted image is calculated, connected, and filled to supplement the empty points [15].

3.3. *Motion Profile and Straight Line Fitting.* First, the data points of the obtained foreground image are connected by line segments. Because the obtained image is a binary image,

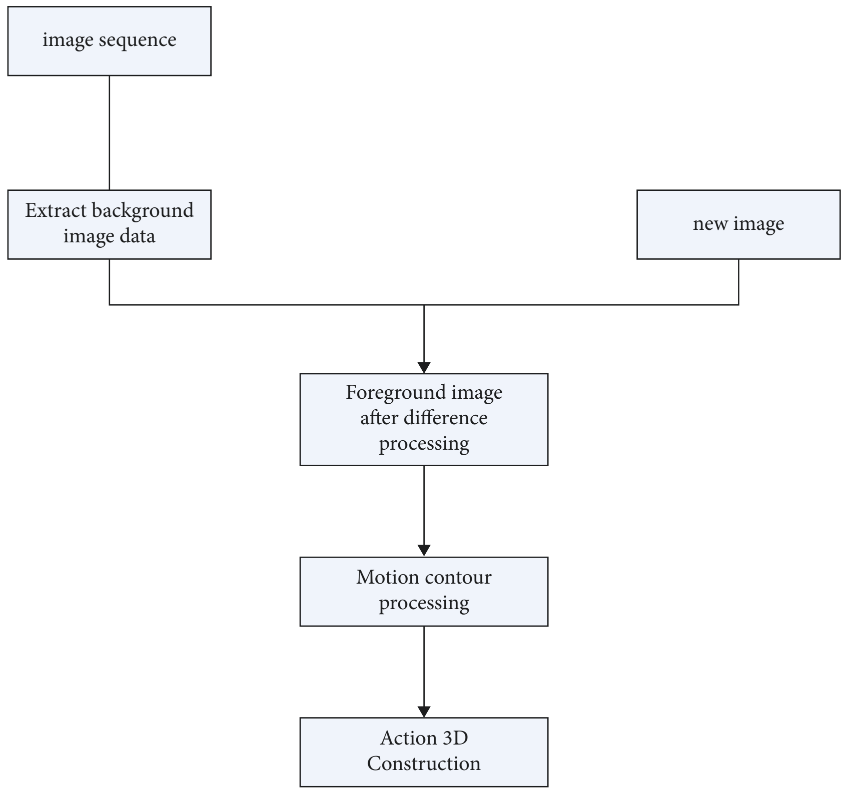

Figure 1: Flowchart of the simulation system.

the edge points need to be eliminated by tools. Connecting the points whose edges conform to the outline, the pixels slowly form a spatial figure, and these points are saved in ascending order to remove the useless line segments that are spent separately. Finally, the multisegmented lines are formed into the core, and the core is found to realize the fitting. The obtained image data is arranged and combined in space through pixels to form a mathematical problem, which is also conducive to finding the position of pixels. Drawing through spatial coordinate points, in order from small to large, the order of connections is very important for image formation. If the order of connections is wrong, it may not be possible to form the outline of the human body, and you need to start from the first step. Because the contour line segments of the image are not necessarily all closed, there will be some redundant points to form connecting line segments. These useless line segments need to be removed, which can prevent subsequent processing [16]. The traditional simulation technology to realize the influence points of the system is not perfect, and the artificial fish swarm algorithm is introduced to improve the imperfect points.

3.4. Artificial Fish Swarm Algorithm. Chinese researchers proposed an intelligent calculation technique called the artificial fish swarm algorithm. The algorithm uses the various locations of the artificial fish as potential answers and the amount of food the fish can detect as the importance of the response. By simulating fish swimming, foraging, gathering, and tail-chasing, the best solution can be found. Figure 2 [17] depicts the various states that fish schools could be in. In this study, cloud theory is applied, cloud learning and cloud variation factors are incorporated into a single artificial fish, and a cloud-based artificial fish swarm algorithm is proposed to address potential issues with artificial fish calculation [18].

In traditional fish swarm algorithm, assuming that the number of fish schools is S, the number of experiments is C, the fish school detection distance is D, the step size is L, θ is the proportion of fish in the artificial pond, and the interval between each fish is X, the food visibility of the artificial fish pond is

$$Q = f(x). \tag{2}$$

In the above formula, Q is the value of the correlation function. For the four behaviors of the fish school, the expressions of tail-chasing, foraging, gathering, and swimming are as follows.

As regards rear chasing behavior, when the status of artificial fish breeding is W_i, find the most suitable W_j within the detection distance [19], and the proportion of fish in the artificial pool is less than θ, and move W_i to W_j by one step. According to the following formula, if not executed, foraging behavior will be performed.

$$W_i = W_i + L \times \text{rand} \times \frac{W_j - W_i}{\left\| W_j - W_i \right\|}. \tag{3}$$

Considering foraging behavior, when the state of artificial breeding is W_i, the most suitable new state is W_j within

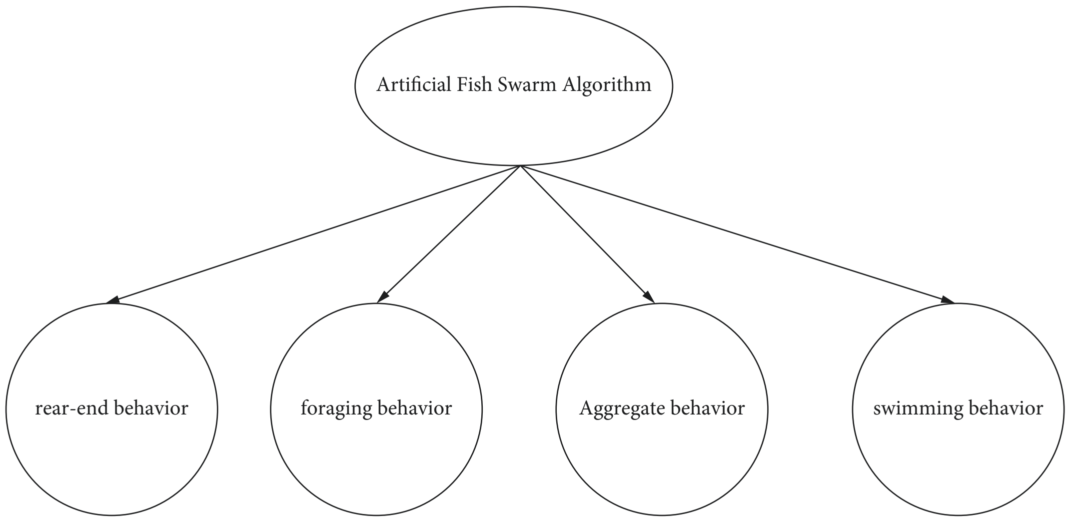

Figure 2: Fish presence status.

the detection distance. If suitable W_j is found, the artificial fish will move to W_j; if no suitable W_j is found, then W_i will continue to find the most suitable W_j and move towards W_j; after C times, if no suitable W_j is found, the following formula is performed:

$$\begin{aligned} W_j &= W_x + (2\text{rand}() - 1) \times D, \\ W_x &= W_x \times (1 + (2\text{rand}() - 1)) \times L). \end{aligned} \tag{4}$$

For aggregation behavior, when the status of artificial fish breeding is W_i, find the most suitable W_c within the detection distance, and the proportion of fish in the artificial pool is less than θ, move W_i to W_c by one step, and gradually form aggregation. If aggregation is not achieved, foraging behavior will be performed [20].

$$W_i = W_i + L \times \text{rand} \times \frac{W_c - W_i}{\left\| W_c - W_i \right\|}. \tag{5}$$

For swimming behavior, when the state of artificial breeding fish is W_i, and it swims freely within the detection distance, this behavior can be regarded as foraging behavior or free swimming behavior.

From the four modes of fish swarms, the tail-chasing behavior indicates that there is an intersection of answers in the process of finding a solution, the foraging behavior is on the way to find the optimal solution, and the aggregation behavior is that the answer to the optimal solution is very close, and swimming behavior indicates no solution. It can be understood that the traditional artificial fish swarm algorithm strengthens the aggregation of fish swarms but reduces the role of individual fish in the swarm. The free swimming of the fish will lead to a larger range of results in the subsequent algorithm, which in turn affects the foraging behavior of the fish [21]. When seeking the optimal solution, it enters a local circle, which is not perfect enough. Therefore, in this paper, the fish swarm algorithm of cloud theory is combined, and the two are modeled, which is also called Zhengtaiyun. Introduce cloud learning factors and cloud variation factors to improve algorithm learning ability in self-learning algorithms. The improved algorithm will be obtained, by comparing the behavior of the fish before with the individual fish, which can greatly improve the degree of learning identification, reduce the free swimming behavior of fish, enhance the aggregation of the optimal solution, and make it possible to search for the optimal solution more quickly [22]. The density here is the function corresponding to the best solution in the largest fish group. When finding the smallest solution, it can be obtained by the inverse of the maximum value. Assuming that the current position of the artificial fish is (x_i, y_i) and the density value is (F_x, F_y), there can be

$$\begin{aligned} R_x &= \frac{F_x}{F_x + F_y} \times x_i + \frac{F_x}{F_x + F_y} \times y_i, \\ R_n &= \frac{D}{L_1}, \\ H_e &= \frac{R_n}{L_2}. \end{aligned} \tag{6}$$

The cloud variation factor is the transformation of a single fish individual into an individual under the new model under the condition of Zhengtai cloud. Let the current position of the artificial fish be x_i and the density of a single artificial fish be F_x, which can be expressed as

$$\begin{aligned} R_x &= x_i, \\ R_n &= \frac{D}{L_3}, \\ H_e &= \frac{R_n}{L_4}. \end{aligned} \tag{7}$$

The random distribution certainty of random fish swarms can be achieved through Zhengtaiyun, which is denoted by G in the text. This is a vague concept that has a certain relationship with probability. In the improved artificial fish swarm algorithm, the distance of fish with high density is small, so as to obtain a suitable specified value, the range of G needs to be dynamically processed by the objective function, and there are two processing methods [23].

Randomness X-condition cloud generator method is expressed as follows:

$$R_x = F_{\max}\text{: } R_n = \frac{F_{\max} - F_{\min}}{L_5}\text{: } H_e = \frac{R_n}{L_6},$$
$$R'_n = \operatorname{randn}\left(R_n, H_e\right)\text{: } G = e^{\left(F' - R_x\right)/-2R'_n\left(F' - R_x\right)/R'_n}. \tag{8}$$

In the X-condition cloud generator, three special values are assigned, which are R_x, R_n, and H_e, and the influence value drop(x_0, G_i) is formed.

Deterministic linear function method is expressed as follows:

$$G = G_{\max} - \frac{F_{\max} - F'}{F_{\max} + F_{\min}}\left(G_{\max} - G_{\min}\right). \tag{9}$$

In the above formula, $F_{\max}$ is the maximum fish school fitness, $F_{\min}$ is the minimum fish school fitness value, $G_{\max}$ is the maximum fish school density due to external influence, and $G_{\min}$ is the minimum fish school density. In general, $G_{\max}$ is within (0.93–1), $G_{\max}$ is selected as 0.96, and $G_{\min}$ is selected as 0.19, which is also a conventional value. It can be seen from the above that the fitness value of the individual fish is inversely proportional to the search range. The larger the value, the smaller the range. When the fitness is the largest, $G = 1$. After the processing operation is carried out, it is brought into (7), and the result is unfavorable for population diversity. When G is 0.95, according to R_n, the value of L_5 is less than 4, which is 3.7. In the normal range, the result of L6 is 5–15, and the value of L6 is 10. Although R_n and H_e play a key role in the model, when multiple calculations are performed, replacement iterations will be performed to replace the previous data, so this has little effect on the values in the following text.

3.5. Segmentation of Sports Images Based on Fish Swarm Algorithm. The pixels of the image are arranged in order from low to high, and the image formed by the pixels needs to be segmented to obtain the core points. Then separate the multiple images of the movement, and segment them from the background image. When the color difference between the background image and the required image is obvious, when the computer processes as high values on both sides, this is the best separation period. If the computer processing is not at the highest level, no image segmentation is required. In this paper, threshold image segmentation is used. In this paper, threshold image segmentation is used. Through the thresholds U and $U \in (0\ ,\ L-1)$, the figure can be divided into two parts, and the background and positioning are B and W, respectively. Assuming that P is the probability of the original gray in Figure 2, $P_t = \sum_{i=0}^{t} p_i$, and then the entropy function is

$$H(t) = H_B + H_W,$$
$$H_B = -\sum_{i=0}^{t}\frac{p_t}{P_t}\ln\frac{p_t}{P_t},$$
$$H_W = -\sum_{i=t+1}^{L-1}\frac{p_t}{P_t}\ln\frac{p_t}{1-P_t}. \tag{10}$$

When $H(t)$ is the maximum value, t^* is the optimal solution. When there are K thresholds in the thresholded image, which is t^K, the entropy function can be calculated to obtain the maximum value; then there are

$$H\left(t_1, t_2, \ldots t_k\right) = -\sum_{i=0}^{t_1}\frac{p_i}{P_{t_0}}\ln\frac{p_i}{P_{t_0}} - \sum_{i=t_1+1}^{t_2}\frac{p_i}{P_{t_1}}\ln\frac{p_i}{P_{t_1}}$$
$$-\cdots\sum_{i=t_k+1}^{L-1}\frac{p_i}{P_{t_k}}\ln\frac{p_i}{P_{t_k}}. \tag{11}$$

The same as above, when $H(t_1, t_2, \ldots t_k)$ is the largest, $t_1^* t_2^* \ldots t_k^*$ is the best solution obtained.

The threshold image segmentation in the artificial fish school is calculated by the maximum value of the entropy value function of the artificial fish school in the original gray image. The threshold value map optimization process of the artificial fish school is shown in Figure 3.

(1) Fish swarm initialization. Suppose that the number of fish schools is S, the number of experiments is C, the fish school detection distance is D, the step size is L, and θ is the proportion of fish schools in the artificial pool.
(2) Calculate the fitness of each fish in the fish group by calculating the entropy function, and arrange the fitness values in order, from small to large; and change the information value at any time, and keep abreast of the dynamic maximum $F_{\max}$ and minimum $F_{\min}$ adaptive value.
(3) Randomly perceive the surrounding of the nth artificial fish, find the optimal artificial fish, and judge whether there is a rear-end relationship between the two. If not, go directly to the next step. If there is, follow the rear-end execution.
(4) Perform processing W_n on a single artificial fish; if the n value is lower than 0.62 k, perform cloud mutation processing on the fish, and if it is greater than 0.62 k, perform a cloud learning phase.
(5) Replace the maximum and minimum fitness values and update them on the dynamic board at any time.
(6) After processing all the individual fish, go to the next step. If not, continue to repeat the previous steps.
(7) Compare the number of updates with the set number of experiments. If the number of updates is greater than the set number, the algorithm terminates; otherwise, the second step is performed. Continue to find the fitness of the fish.

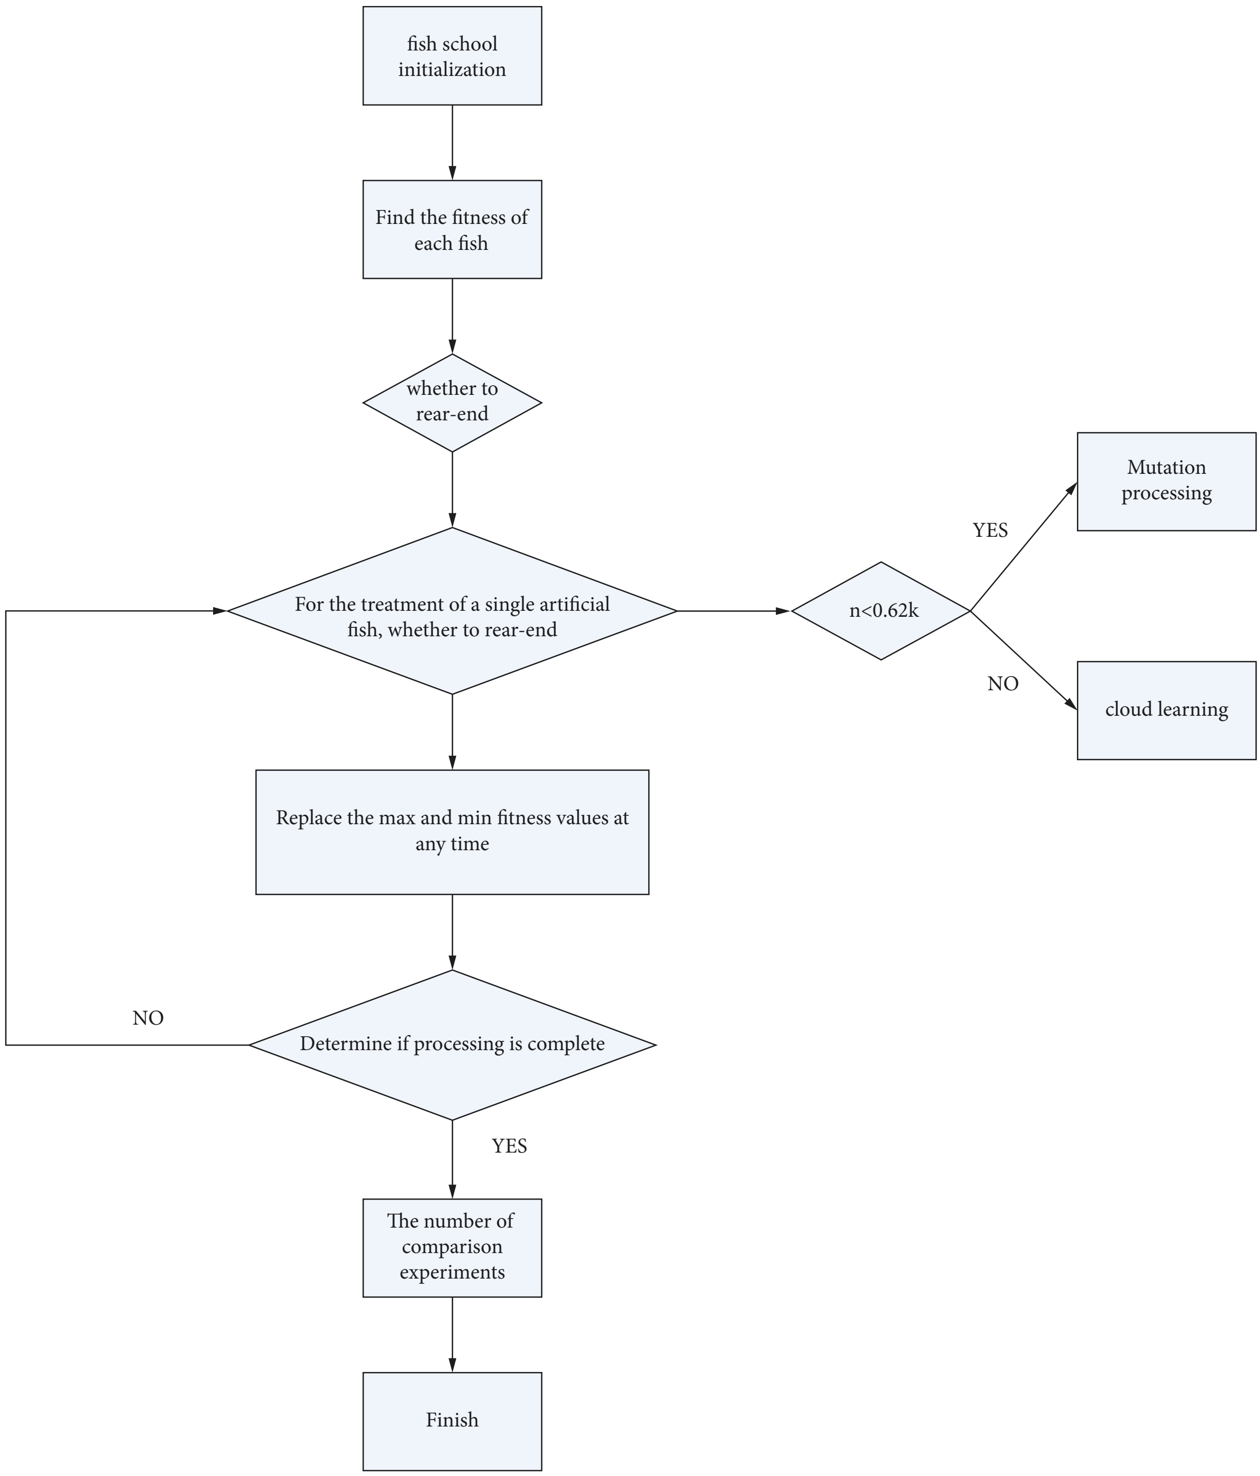

Figure 3: Flowchart of threshold map optimization for artificial fish swarms.

4. Simulation Experiments

In order to verify the effectiveness of the method, the paper uses different emphases as the experimental objects and compares the artificial fish swarm algorithm with particle swarm and genetic algorithm. The traditional motion simulation uses the particle swarm computing method. The experimental equipment and materials were the following: computer with Windows 10, Intel 10, Core(TM) i8-3632QM CPU, and 8G running memory, and the translation tool was Matlab (R2017b). Through many experiments, the effectiveness of the image entity simulation image under human motion, the segmentation of the image processing, the number of core points, and the noise reduction effect are compared. The experimental data are as follows.

Table 1: Initial parameter table.

Evolutionary algorithms	Parameter settings				
CT-AFSA	$S = 22$	$C = 100$	$D = 12$	$L = 10$	$\theta = 0.75$
Related data 1	$S = 22$	$C = 100$	W (min) = 0.38	W (max) = 0.92	Expansion factor
Related data 2	$S = 22$	$C = 100$	Code length = 10	Crossover probability = 0.65	Mutation probability = 0.1

Figure 4: Captured image comparison.

Figure 5: Apple image segmentation comparison.

The two algorithms to be compared need to be compared through a threshold before calculation. In order to ensure consistency, the threshold is uniformly set to 3 in this paper. The reference data obtained in the literature are obtained after experiments and have practical significance. The data sheet is shown in Table 1.

4.1. Captured Moving Images. In the first step, an image of human motion needs to be taken, because the original color hierarchy of the background image and the foreground image is easier to distinguish, so the image is used as a contrast image. The comparison of the captured images is shown in Figure 4.

The comparison in Figure 4 shows that the particle swarm algorithm has no way to clear the background and target of the shooting, and there is chromatic aberration, and the background processing is simple. The fish swarm algorithm can see obvious foreground, background, and color, and, in Figure 4, the distinction of brightness is also more obvious.

4.2. Monotone Background Image. As shown in Figure 5, the apple image of 512×384 is selected because the background is relatively monotonous, and the foreground and background are easier to separate when pixels are separated. From the comparison of the figures, it can be seen that the particle swarm algorithm does not distinguish the background and the foreground clearly, and it is basically impossible to see it. However, the image after the fish swarm algorithm can save the original image information, and, for

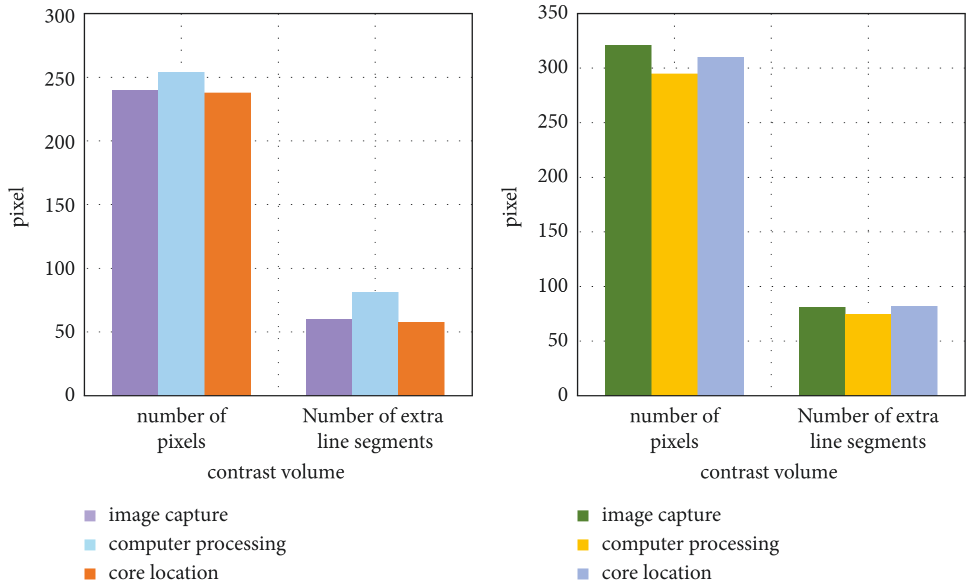

Figure 6: Core point comparison of pixel points.

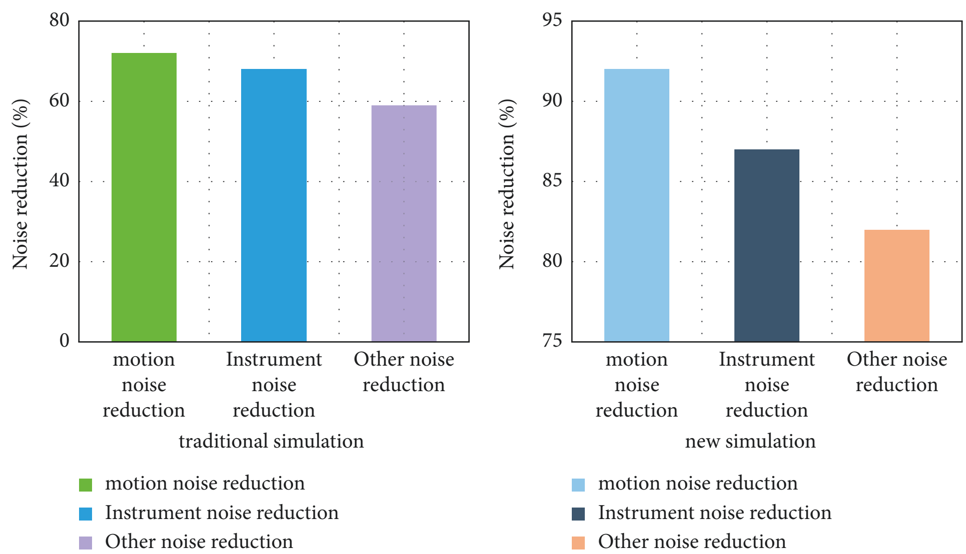

Figure 7: Comparison of traditional simulation and new noise reduction.

the information expression of the foreground edge, the particle swarm algorithm is not easy to distinguish between the foreground and the background, which is not conducive to the expression of the internal and edge information of the image.

For the physical simulation of human motion, the arrangement of the pixel points is arranged according to certain rules. However, in the physical simulation of traditional sports, there will be redundant line segments, the core points of the pixel points are judged by the number of line segment connections, and the number of core points is judged by the data of the two physical simulations, as shown in Figure 6.

Through comparison, it is found that the pixel core point of the traditional entity simulation is lower than that based on the fish swarm algorithm, and it is increased by about 35% on the traditional basis. The image obtained in this way is also more vivid, and there is no rough room. The core point reflects the key position of sports. The more core points, the more accurate the capture of sports.

When capturing moving images, it is necessary to remove the external sound and then better input into the system for information processing. After processing by the computer, ensure the stability of the computer, because the information with sound is entered into the system will have an impact on the simulation model. The noise reduction comparison between the two is shown in Figure 6. The simulation paper based on the fish swarm algorithm becomes a new type of simulation, as shown in Figure 7.

By comparing the noise reduction effect between the two, it is found that the simulation calculation based on the fish swarm algorithm is 20.3% higher compared to the traditional simulation. At the same time of simulation, it also restores the real motion, well preserves the integrity of the information input to the computer, and also has a good effect on noise reduction of other effects and has obvious optimization in traditional simulation technology.

5. Conclusions

In this paper, the physical simulation of traditional sports is compared through sports based on fish swarm algorithm. Through the shortcomings of traditional simulation, the moving entity simulation technology of fish swarm algorithm is introduced. By comparing the effectiveness of the simulated image under human motion, the segmentation of the image processing, the number of core points for the 3D model, and the noise reduction of the two in computer processing, the results found that the physical simulation based on the fish swarm algorithm is more restored on the image, and the captured figures are more segmentable, and the more core points, the more accurate the 3D model, and the noise reduction effect is also improved by 20.3%. The inadequacy of this paper is that the physical simulation is not verified by other algorithms, and only the fish swarm algorithm is verified in the physical simulation. The data referenced in this article also has a certain year, and there may be some errors in the experimental data. With the gradual development of current science and technology, the simulation technology for moving entities will become more mature, and more and more suitable algorithms will be used in entity simulation. The obtained data will also be more accurate, and the influence of external factors on the simulation entity can be excluded. This paper studies the physical simulation of sports, which has certain reference significance for the physical simulation technology.

In recent years, with the rapid development of a new generation of artificial intelligence technology, how to deeply apply artificial intelligence technology to physical education and break through the limitations of time-space scenarios and knowledge transfer methods in traditional models has become a key issue in intelligent physical education in the era of artificial intelligence. In order to realize the online monitoring of wearable devices with artificial intelligence in sports and overcome the problem of low recognition accuracy of electrocardiogram, blood oxygen, and respiratory signals in many cases, this paper proposes a combination of variational modal decomposition based on the maximum envelope kurtosis method. Long-short-term neural network (VMD-LSTM) monitoring method for wearable sports equipment. Through experimental analysis and verification, the current signal of the VMD model shows a trend of fluctuating from large to stable and then to large with motion, while the training accuracy of LSTM after the 150th iteration is 94.09%, which shows that the coupling model VMD LSTM can better predict the direction of sports artificial intelligence. In addition, although the training time of the BP neural network is shorter than that of the LSTM model, there is a large gap between the recognition effect and the LSTM, and there are also large differences between different neural network structures. This shows that the VMD-LSTM model has broad application prospects in such models.

1. Introduction

Artificial intelligence (Artificial Intelligence, referred to as "AI") is a discipline that studies how to make machines do things that humans need intelligence to accomplish [1]. Artificial intelligence has experienced the early game, expert system, and other algorithmic models and has developed to the current research direction of machine learning and deep learning [2]. Artificial intelligence is essentially a branch of computer science. With the rapid iterative update of computer technology, it shows stronger intelligence and practicability and is generally accepted by the public. My country's artificial intelligence started late, and there is still a certain gap compared with developed countries such as the United States. Physical education is one of the important contents of the implementation of comprehensive quality education in my country, and it has a basic supporting role in improving the national physique and improving the quality of life [3]. In recent years, the rapid development of a new generation of artificial intelligence technology has had a significant impact on the content, mode, method, and system of traditional physical education [4]. How to deeply apply artificial intelligence technology to physical education and break through the limitations of time-space scenarios and knowledge transfer methods in traditional models has become a key issue in intelligent physical education in the era of artificial intelligence.

In recent years, sports artificial intelligence research, the main subject is computer science, and the algorithm empirical research of basic theory is preferred [5]. It mainly involves the use of neural network-based machine learning-related algorithms, involving sports performance prediction [6], human action recognition and evaluation [7], technical and tactical decision support, sports injury assessment, etc.

[8, 9], [10] As the most important research direction in the field of artificial intelligence in recent years, deep learning (Deep Learning) is a kind of intelligent learning algorithm based on deep neural network and representation level, so as to obtain humanlike analytical learning ability, thus promoting the progress of artificial intelligence related technologies [11, 12]. Among them, the human posture recognition technology in deep learning is a technology that can accurately describe the posture and behavior by sensing the structural parameters of human limbs through sensing signals, images, and other data [13]. Detection of human skeleton joints is the core problem of pose recognition [14]. Since 2012, the rapid development of deep learning technology has promoted the continuous improvement of the detection effect of human skeleton joints [15].

Aiming at the lack of error correction design in the traditional Long and Short-term Memory Network (LSTM) structure [16], a sports artificial intelligence based on Variational Modal Decomposition (VMD) was proposed. Intelligent models [17, 18]. Combining the new ideas of "artificial intelligence" with the needs of sports provides a beneficial guarantee for meeting the needs of scientific training. Based on the VMD-LSTM model and the design and use of portable equipment, this paper constructs a sports monitoring service system, which combines a new method of artificial intelligence to analyze the real-time parameters of the sports process. By establishing this service model, the physical activity of athletes can be monitored.

2. Principles and Methods

2.1. Metamorphic Mode Decomposition. Variational mode decomposition is an adaptive signal processing method proposed in 2014. By iteratively searching for the optimal solution of the variational mode, the modal function and center frequency are continuously updated to obtain several modes with a certain bandwidth function [19]. Variational modal decomposition is an improvement of the EMD algorithm, which has the advantage of better avoiding modal aliasing and end-point effects [20]. Metamorphic Mode Decomposition.

Variational mode decomposition decomposes wearable sports equipment into several eigenmode functions (IMFs) with center frequencies on the premise that each decomposed eigenmode function has a limited bandwidth, by constructing and solving a variational problem to find each eigenmode function and its center frequency [21]. The VMD method decomposes the signal into predefined K eigenmode components IMF, where the IMF is redefined as an AM-FM signal.

$$u_k(t) = A_k(t)\cos(\phi_k(t)). \tag{1}$$

The accuracy of the decomposition result of the VMD algorithm depends on the number of modes K and the value of the penalty factor. If the value of K is too large, it will cause excessive signal decomposition, so that a component determined by the center frequency will be scattered in different eigenmode components; while the value of K is too small, it will cause modal aliasing, that is, different centers. The frequency signal components are in the same eigenmode component after being decomposed by VMD, resulting in components that have no practical significance. Both of these cases can lead to inaccurate results of the decomposition. The value of α will affect the frequency bandwidth of each modal obtained after the signal is decomposed by the variational modal decomposition algorithm, the degree of modal aliasing and the speed of the algorithm. If the value of the penalty factor α is too small, the bandwidth of each frequency is too large, and similar frequencies are mistaken for the large bandwidth part of the same center frequency so that they are decomposed into the same component, and the problem of modal aliasing occurs. When the value is too large, part of the bandwidth is reduced, which may cause the signal to be overresolved and spurious components appear. Therefore, the selection of appropriate parameter values is crucial to the accuracy of the PPG signal decomposition results [22].

2.2. LSTM Model. Long Short-Term Memory (LSTM) is a temporal recurrent neural network [2]. The outstanding contribution of this network lies in the use of the self-loop design, and the weight of the self-loop can also be updated in each loop iteration, thus cleverly avoiding the gradient dispersion problem that occurs when the recurrent neural network model updates the weights [23].

Each hidden node of the LSTM network model contains a storage unit, and the entrance of the storage unit is controlled by some logic units. These control units are generally called "gates." At the entrance of each hidden unit, there are three gates, namely, input gate, output gate, and forget gate [24]. The input gate is used to selectively save the input data, the output gate is used to determine when to output the value, and the forget gate is used to determine when the value should be memorized or forgotten [25]. Hidden nodes are shown in Figure 1. In the whole model, the parameters of the input gate, output gate, and forget gate in each hidden node are learned during the training process [26]. The calculation formulas for the three gates are as follows:

$$\begin{aligned}
\mathbf{i_t} &= \boldsymbol{\sigma}(\mathbf{W_{xi}x_t} + \mathbf{W_{hi}h_{t-1}} + \mathbf{b_i}),\\
\mathbf{o_t} &= \boldsymbol{\sigma}(\mathbf{W_{xo}x_t} + \mathbf{W_{ho}h_{t-1}} + \mathbf{b_o}),\\
\mathbf{f_t} &= \boldsymbol{\sigma}(\mathbf{W_{xf}x_t} + \mathbf{W_{hf}h_{t-1}} + \mathbf{b_f}),\\
\mathbf{c_t} &= \mathbf{f_t c_{t-1}} + \mathbf{i_t}\,\mathbf{tanh}(\mathbf{W_{xc}x_t} + \mathbf{W_{hc}h_{t-1}} + \mathbf{b_c}),\\
\mathbf{h_t} &= \mathbf{o_t}\,\mathbf{tanh}(\mathbf{c_t}).
\end{aligned} \tag{2}$$

3. Experimental Procedure and Result Analysis

3.1. Feature Extraction Using VMD Method. The maximum envelope kurtosis method is used to determine the optimal decomposition level K of the VMD, randomly extract several groups of current signals from the first group, and use the maximum envelope kurtosis method for analysis. By observing the variation trend of the local maximum envelope

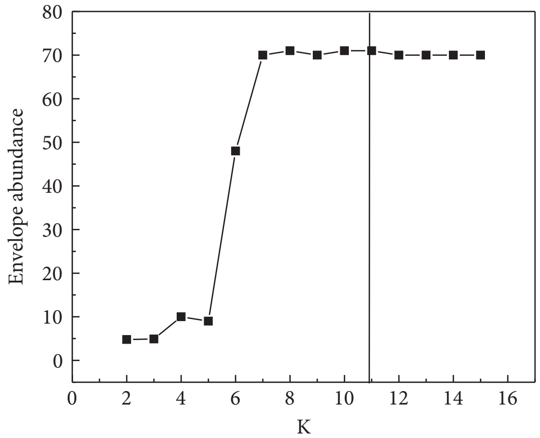

Figure 1: Variation Trend of maximum envelope kurtosis.

kurtosis in Figure 1, it can be found that the envelope kurtosis is the largest when $K = 11$.

So take $K = 11$ VMD for current signal processing. It can be seen from the decomposed current signal that IMF1, IMF2, and IMF3 are low-frequency signals, the frequency components are relatively single, and the main frequency components of the current signal are concentrated in the low-frequency current signal. Therefore, the features of the first three IMFs can be directly extracted to represent the movement and detect changes in parameters. There are interference signals such as noise in the high-frequency signal of the current signal, and after calculation, the signal-to-noise ratio in the high-frequency signal is less than 0, which is dominated by noise, and the soft threshold denoising method needs to be used for denoising. The original signal can be regarded as the sum of the decomposed IMFs, so the high-frequency signal can be simplified as follows:

$$\mathrm{IMF}_h = \sum_{i=4}^{11} \mathrm{IMF}_i \, i = 4, 5, \ldots, 15. \tag{3}$$

It can be seen from the calculation that the amplitude of the curve of the denoised signal is smaller than that of the high-frequency signal, which means that some noise is removed and the characteristics of the tool wear signal are preserved. The signal-to-noise ratio of the high-frequency signal before denoising is 6.581 dB, and the signal-to-noise ratio after denoising is improved to 2.024 dB.

Since it is difficult to find the relationship between the signal and sports parameters by directly observing the signal, the original signal is processed to extract features that are related to the body motion parameters. This paper extracts 7-dimensional time domain features, including mean, root mean square, peak value, standard deviation, variance, and kurtosis factor, margin factor; 2-dimensional frequency domain feature, including barycentric frequency and frequency energy value, extracting the mean, root mean square, and peak value of 3 low-frequency IMFs, and one high-frequency IMF, a total of 21 dimension features. Since the classification of sports parameters under multiple working conditions in this paper needs to consider the influence of parameters such as heart rate on the current signal, the three sports parameters are also classified as features, with a total of 24-dimensional features. The model training speed will be slowed down due to too many feature dimensions, and there may be features that are not related to motion parameters in these features. In this paper, the SelectKBest class in the feature-selection of the Python library is combined with the mutual information method to filter the features, and the 6-dimensional features plus 3 cutting parameters are selected from the 21-dimensional feature parameters as the model input.

3.2. Validation of Model Recognition Effect. A total of 921 groups of experimental data were collected in this experiment, and the number of experimental data in each group. Taking the first group as an example, the current signal is divided into three stages, the initial stage of exercise, the middle stage of exercise, and the later stage of exercise. The variation trend of the current signal eigenvalues with motion is shown in Figure 2.

It can be observed from Figure 2 that in the initial stage, the current signal fluctuates greatly, because the body movement state is good, and the body function parameters have not yet adapted to the body. In the normal stage, the current change is relatively gentle, and in the severe stage, it rises sharply, which is caused by the sudden strengthening of the exercise state after the exercise adaptation.

3.3. Normalization. Since there are few initial and late samples in each group of experiments, normal samples occupy the vast majority, and unbalanced samples will affect the final classification effect. Therefore, the SMOTE algorithm is used to oversample the interval with fewer samples. This method is used in minority samples. New sample points are generated on the Euclidean distance [27]. After dividing the 4 groups of experimental data into 3 intervals, the training set and the test set are divided according to the ratio of 3:1. For the multiclassification model, the output label corresponding to each state needs to be coded. In this paper, the One-Hot coding method is used. The data set composed of features after optimization needs to be normalized before classification, and the normalization formula is

$$x = \frac{x - x_{\min}}{x_{\max} - x_{\min}}. \tag{4}$$

As a variant of Recurrent Neural Network (RNN), LSTM can better avoid the problem of gradient disappearance and can effectively deal with the long-term dependency problem [1]. Due to the small number of samples collected, this paper designs a model with only a single LSTM layer, the number of LSTM neural units is set to 30, the batch size is set to 32, the cross entropy is selected as the loss function, and the Adam optimization algorithm is used to optimize the model parameters [28], and the structure of the LSTM model is shown in Table 1.

Figure 3 shows the accuracy and loss curve of the LSTM model training process. It can be observed from the figure

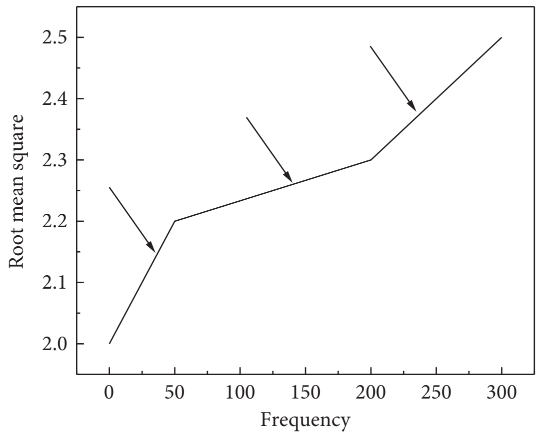

Figure 2: Trend chart.

Table 1: Inspection and test results of external wall damage.

LSTM model structure	Neurons of each layer quantity	Incentive at all levels function	Input of each layer dimension<
Input layer	Feature dimension	—	(None, 1)
LSTM layer	30	Sigmoid	(None, 30)
Full connection layer	8	ReLu	(None, 8)
Output layer	3	Softmax	(None, 3)

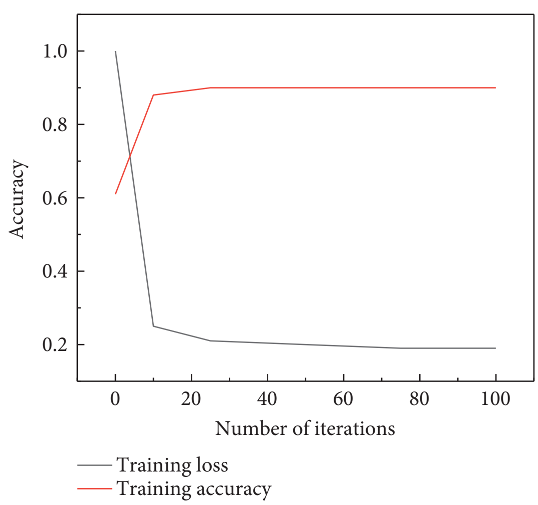

Figure 3: Model accuracy training and loss curve.

that the training accuracy value and loss tend to converge after the 150th iteration, and the training accuracy during the training process reaches 94.09%. The classification accuracy rate on the test set reached 92.44%. The loss rate is another way of expressing the accuracy. The loss rate in Figure 3 is stable at about 10% after multiple iterations, which indicates that the model selected in this study has good accuracy and strong applicability. It can be concluded that the model has high recognition accuracy and strong generalization ability, which can meet the recognition requirements of actual motion state parameters. The selected features can better characterize the change of motion state, which is similar to the research results of some scholars [29].

In order to verify the superiority of the model in this paper for the recognition of motion states under multiple working conditions, this paper uses empirical mode decomposition (EMD) and ensemble empirical mode decomposition to construct different feature vectors for the same sample set [28] and uses the LSTM model for Classification [30], the final result is far from the method in this paper, and the accuracy is not high. And, this paper compares the LSTM model with the traditional machine learning method Support Vector Machine (SVM) and BP neural network, in which the kernel function parameter σ and penalty factor C of SVM use particle swarm optimization algorithm to find the best parameters, respectively, are 11.580 and 12.926. The BP neural network adopts the structure of $30 \times 8 \times 3$, and the number of iterations is 500 times. In order to avoid experimental chance, each model was tested 5 times to take the average of the accuracy of the test set. Table 2 shows the test results of the model.

It can be seen from the table that the training time of SVM is longer than that of LSTM, and the accuracy of the test set is lower than that of LSTM. The data samples in this paper are changed from 921 to 1851 groups after sample synthesis. Efficiency is lower. Although the training time of the BP neural network is shorter than that of the LSTM model, there is a big gap between the recognition effect and LSTM, and there are also big differences between different neural network structures, which is similar to the research results of some scholars [31].

4. Model Predictions

In the research on the physical health of different groups of people, intelligent wearable devices based on machine learning and deep learning algorithms can identify, monitor, and analyze the muscular endurance and physical activity status of people with different physical fitness, including children, adolescents, and adults. Proposing exercise methods suitable for individuals with different physical conditions can promote the formation of healthy living habits.

In the monitoring test, there are many factors that affect the effect of sports wearable devices, including respiratory rate, heart rate, and real-time measurement of hemoglobin. The measurement of respiratory rate is affected by detection time and exercise intensity. Therefore, to obtain accurate respiratory frequency measurement, it is necessary to remove the influence of clutter on the respiratory measurement results. The least mean square can solve the respiratory frequency well, so the system decides to use the least mean square respiratory signal filtering algorithm as the main technology of this module. If all the influencing factors are considered, the experiment becomes very complicated and requires a huge cost. Therefore, the simplified variables in this paper are the fluctuation of electrocardiogram, respiratory signal, and monitoring of blood oxygen concentration.

Table 2: Model test results.

Classification model	Test set average classification accuracy (%)	Optimal classification of test set accuracy (%)	Train time (S)
LSTM	93.78	94.02	83.35
PSO-SVM	90.43	91.67	89.49
BP neural network	88.59	89.21	39.86

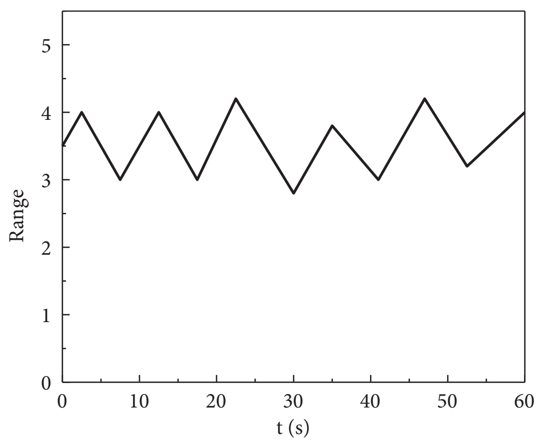

Figure 4: Respiratory signal after filtering respiratory signal using least mean square.

The electrocardiogram is an electrical activity process that reflects the excitement of the heart. It has important medical reference significance and reflects the activity process of the human body's electrocardiogram. It has considerable medical and sports measurement importance. In the ECG monitoring part, the system uses textile electrodes as the main material, because when the material contacts the skin, an equivalent capacitance C1 will be generated, which can achieve signal impedance matching and improve the sensitivity and accuracy of signal detection. The single-lead ECG measurement module made of textile electrodes is placed at two points on the surface of the human body. By measuring the potential difference between the two points, the signal can be transmitted to the analog ECG signal conversion interface through the wire, as shown in Figure 4.

The respiratory signal spectrum after filtering processing has regular breathing fluctuation as a whole, and the fluctuation is stable. The maximum amplitude of the fluctuation is 1.5 V, which occurs between 21 and 29 seconds. Within seconds, it can be seen that the monitored exercise participant's breathing is stable, the exercise training intensity is reasonable, and there is no need to adjust the amount of exercise. The least mean square can solve the respiratory frequency well, so the system decides to use the least mean square respiratory signal filtering algorithm as the main technology of this module. The least-mean-square respiratory signal filtering algorithm consists of five operating modules, firstly measuring n times of inhalation signal x, then measuring n times of exhalation signal e, and then adding the two different signals to calculate the sum signal frequency value, then the three-axis acceleration and the breathing signal are input into the digital filter together, and the breathing signal processed by the digital filter is then output for correlation detection. In square algorithm operation, the operation result will be input into the digital filter again, so as to reciprocate until the error is wirelessly reduced and the error is corrected continuously, so as to obtain the accurate respiratory data measurement signal. Capture, the process of data capture is the real-time measurement of human body functions such as heart rate and hemoglobin by wearable devices, so the monitor of the wearable device becomes the key device for this step.

5. Conclusion

Based on the perspective of the era of intelligence, on the basis of traditional sports and with the help of deep learning technology in the field of artificial intelligence, this research proposes an intelligent evaluation algorithm for sports wearable devices. Sports smart wearable system. In order to realize the online monitoring of wearable devices with artificial intelligence in sports and overcome the problem of low recognition accuracy of electrocardiogram, blood oxygen, and respiratory signals in many cases, this paper proposes a combination of variational modal decomposition based on the maximum envelope kurtosis method. Long-short-term neural network (VMD-LSTM) monitoring method for wearable sports equipment. Through experimental analysis and verification, the following conclusions are drawn: (1) in the early stage of the exercise, the current signal fluctuates greatly, and the current changes relatively gently in the normal stage, and then rises sharply in the severe stage; (2) after the 150th iteration, the training accuracy value, and the loss tends to converge, in which the training accuracy reached 94.09% during the training process, and the classification accuracy of the model on the test set reached 92.44%; (3) the training time of SVM is longer than that of LSTM, and the testing time is longer than that of LSTM. The accuracy rate of the set is lower than that of LSTM, and the efficiency of using SVM is relatively low; (4) although the training time of the BP neural network is shorter than that of the LSTM model, the recognition effect has a large gap with LSTM, and there are also differences between different neural network structures.[32], [33].

Objectives. Measuring anatomical parameters in fetal heart ultrasound images is crucial for the diagnosis of congenital heart disease (CHD), which is highly dependent on the clinical experience of the sonographer. To address this challenge, we propose an automated segmentation method using the channel-wise knowledge distillation technique. *Methods*. We design a teacher-student architecture to conduct channel-wise knowledge distillation. ROI-based cropped images and full-size images are used for the teacher and student models, respectively. It allows the student model to have both the fine-grained segmentation capability inherited from the teacher model and the ability to handle full-size test images. A total of 1,300 fetal heart ultrasound images of three-vessel view were collected and annotated by experienced doctors for training, validation, and testing. *Results*. We use three evaluation protocols to quantitatively evaluate the segmentation accuracy: Intersection over Union (IoU), Pixel Accuracy (PA), and Dice coefficient (Dice). We achieved better results than related methods on all evaluation metrics. In comparison with DeepLabv3+, the proposed method gets more accurate segmentation boundaries and has performance gains of 1.8% on mean IoU (66.8% to 68.6%), 2.2% on mean PA (79.2% to 81.4%), and 1.2% on mean Dice (80.1% to 81.3%). *Conclusions*. Our segmentation method could identify the anatomical structure in three-vessel view of fetal heart ultrasound images. Both quantitative and visual analyses show that the proposed method significantly outperforms the related methods in terms of segmentation results.

1. Introduction

It is reported that the annual birth rate of congenital heart disease (CHD) in children is 0.8–1% [1, 2], and the incidence rate has ranked first among all birth defects. At present, fetal echocardiography is an important medical imaging technology and most used for prenatal detection and diagnosis of CHD. Well-trained and experienced doctors can make a reliable diagnosis of 80–90% CHD by fetal echocardiography, while the diagnostic accuracy of doctors who lack experience in fetal echocardiography operation and diagnosis is significantly decreased [3, 4].

The three-vessel and trachea (3VT) view is one of the fetal echocardiography views, which was introduced by Yagel et al. [5] as a complementary cardiac view to easily assess the aortic arch anomalies. Gireadă et al. [6] performed a retrospective study on 1,596 unselected pregnant patients presenting at 11–37 weeks of gestation for a routine anomaly scan and analyzed the performance of the four-chamber (4C) view and 3VT view in detecting CHD. The results demonstrated 4C view detected 47.8% of all CHD, going up to 71.7% by adding grayscale 3VT view. The 3VT view is deemed desirable if technically feasible by both International Society of Ultrasound in Obstetrics and Gynecology (ISUOG) and American Institute of Ultrasound in Medicine (AIUM) screening guidelines [7, 8], especially due to its utility in detecting outflow tract anomalies [9–11].

Automatic image segmentation can guide operators to standardize and serialize the display and analysis of fetal echocardiography data. Semantic segmentation has been extensively studied for natural images and is expected to be applied to medical images to assist in diagnosis. However, unlike natural images, medical images are often more difficult to acquire and annotate, which results in a small amount of annotated data. In addition, the special imaging modality (e.g., ultrasound) of medical images produces images of low quality with noises and blurred boundaries. These factors often lead to unsatisfactory segmentation of images. For the segmentation of three-vessel view of fetal heart ultrasound images, we collected a total of 1,300 annotated images, which is completely incomparable to large natural image segmentation datasets.

Recently, machine learning methods have widely used in fetal image processing or ultrasound image processing, such as quality assessment [12–14], detection, and segmentation [15–17]. In the field of vessel image processing, physical models or properties are sometimes introduced to simulate realistic environment to obtain higher evaluation accuracy [18–20].

In this paper, we propose to utilize the channel-wise knowledge distillation [21, 22] technique toward fine-grained segmentation of three vessels in the 3VT view of fetal heart ultrasound images. Particularly, we first train a teacher model whose training data is precisely cropped to a region of three vessels. Such a teacher model enables fine-grained segmentation because it focuses only on the target region. However, such a model cannot be directly applied to the test data because we are not able to crop the test image to the target region before prediction. To this end, we train the student model by distilling the knowledge of the pretrained teacher model using full-size training data. This allows the student model to have both the fine-grained segmentation capability of the teacher model and the ability to handle full-size test images. Experiments show that the proposed method outperforms the most widely used existing methods by a significant margin.

2. Methods

2.1. Channel-Wise Knowledge Distillation. Knowledge distillation was originally designed for model compression: a compact student model is trained to perform better under the supervision of a large teacher model [23–25]. A subsequent study [26] has also shown that a student model with the same configuration as the teacher model can even exceed the performance of the teacher model. In this work, we employ the channel-wise knowledge distillation method, as it was shown to be more effective than the pixel-wise knowledge distillation that simply aligns point-wise classification scores per pixel [27, 28].

Channel-wise knowledge distillation was first introduced by Zhou et al. [21]. Its basic idea is to convert the feature map on each channel to a probability map and then align the channel-wise probabilities of the teacher model and the student model. The corresponding channel-wise distillation loss $\mathscr{L}_{CD}(\cdot,\cdot)$ is defined in the form of a KL divergence:

$$\mathscr{L}_{KD}\left(y^T, y^S\right) = \frac{\tau^2}{C}\sum_{c=1}^{C}\sum_{i=1}^{W\cdot H}\phi\left(y_{c,i}^T\right)\cdot\log\left[\frac{\phi\left(y_{c,i}^T\right)}{\phi\left(y_{c,i}^S\right)}\right], \tag{1}$$

where T and S denote the teacher and student models, $y^{(\cdot)}$ denotes the predicted logits of size $H \times W \times C$; i indexes the spatial location of pixels, where W and H are the width and height of the predicted logits; $c = 1, 2, .., C$ indexes the channel, where C is the number of classes including the background; τ is a hyperparameter called distillation temperature; $\phi(\cdot)$ is a channel-wise softmax function which converts the logits on each channel into a soft probability distribution, defined as

$$\phi\left(y_{c,i}\right) = \frac{\exp\left(y_{c,i}/\tau\right)}{\sum_{i=1}^{W\cdot H}\exp\left(y_{c,i}/\tau\right)}. \tag{2}$$

2.2. Our Method. In this paper, we use a model of the DeepLabv3+ [29] architecture with channel-wise knowledge distillation to segment three vessels in 2D fetal heart ultrasound images.

DeepLabv3+ is an encoder-decoder network designed for segmentation tasks. A modified aligned Xception model is used as the encoder, while the Atrous Spatial Pyramid Pooling (ASPP) layer is used as the decoder as the default setting of DeepLabv3+.

As shown in Figure 1, the teacher and student networks use the same architecture. According to the groundtruth label masks, we crop the region of interest (ROI, i.e., the region of three vessels) from full-size images to train the teacher model. Meanwhile, we record the coordinates of cropped regions to restore them to the corresponding spatial location in the full-size image afterwards. After training teacher network with cropped inputs, its logits output is used to distill knowledge on channels for student model training. This allows the student model to have the same ability to segment the ROI as the teacher model. For the training of the student model, we use full-size images as input and align the logits of the teacher model to the full-size ones as additional knowledge. The loss of our network is made up of three components:

$$L = \alpha\cdot\mathscr{L}_{CE}\left(y_{gt}, y_{\text{pred}}\right) + \beta\cdot\mathscr{L}_{\text{Dice}}\left(y_{gt}, y_{\text{pred}}\right) + \gamma\cdot\mathscr{L}_{KD}\left(y^T, y^S\right). \tag{3}$$

Here, $\mathscr{L}_{CE}(\cdot,\cdot)$ and $\mathscr{L}_{\text{Dice}}(\cdot,\cdot)$ denote cross-entropy loss and dice loss, respectively, y_{gt} is the groundtruth label mask, and y_{pred} is the predicted probability map showing the probability that each pixel being categorized in each class. $\mathscr{L}_{KD}(\cdot,\cdot)$ is defined in Section 2.1. Note that for the teacher network, γ is set to 0, since no knowledge distillation is used.

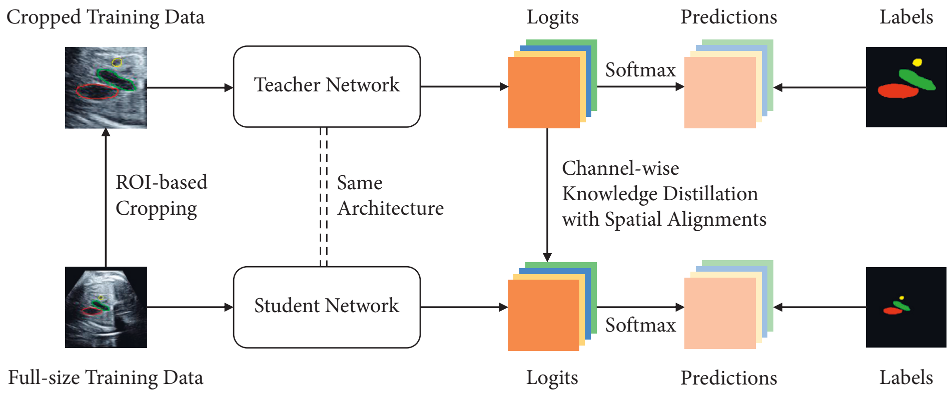

Figure 1: Overview of the proposed channel-wise knowledge distillation method.

2.3. Materials. 1300 pregnant women who underwent fetal echocardiography examination in Sir Run Run Shaw Hospital from 2016 to 2021 were randomly recruited. The gestational age was 20 to 40 weeks. The inclusion criteria were as follows: (1) normal fetus without heart or noncardiac malformations, especially there has no abnormality in the nine standard fetal echocardiography views posted by ISUOG; (2) low risks of chromosome abnormalities were confirmed by early NT and maternal serological examination, or amniocentesis and umbilical cord blood puncture; (3) gestational weeks estimated by ultrasound were consistent with those calculated by menopause history (difference <2 weeks); and (4) the mothers who had no diabetes, hypertension, or pregnancy complications. All pregnant women were informed the purpose of this study and agreed that their fetal heart ultrasound related data should be used for scientific research, and consents should be signed.

Philips IE33 (Philips Medical Systems, Bothell, WA, USA) color ultrasound diagnostic instrument was used, with S5-1 2D imaging probe and a frequency of 1~6 MHz. Firstly, the fetal echocardiography mode was used to comprehensively evaluate the structure and function of the fetal heart, clearly displaying the standard three-vessel view images and storing the original data. Pregnant women are requested to hold their breath or reduce the range of breathing as much as possible during the whole collection process.

Seven experienced doctors annotated and reviewed the collected fetal heart ultrasound images. They annotated the pulmonary artery (PA), aorta (AO), and superior vena cava (SVC) regions on each image as the groundtruth. The resolution of the original image is 1024×768. All images are simply center-cropped and resized to 512×512 as full-size training data in the student network. The ROI-based cropped images described in Section 2.2 are generated by padding the annotated three-vessel region with 50 pixels per edge and resizing them to a square region of size 512×512. We selected 1040, 130, and 130 images in all experiments for training, validation, and testing, respectively.

Figure 2 shows two examples of the fetal heart ultrasound images, as well as their corresponding full-size labeled images and ROI-based cropped images.

2.4. Training. The proposed method is implemented on an NVIDIA RTX 3090 GPU using the Keras and TensorFlow frameworks and trained using the Adam optimizer. We train the network through two stages:

(1) During the first stage, the initial learning rate is 0.0005 and the parameters are initialized by pretraining on the PASCAL VOC 2012 [30] dataset. All parameters of the Xception backbone are frozen. We set $\alpha = 1$, $\beta = 1$, and $\gamma = 0$. Since the main purpose of this stage is to speed up the training, we do not use the channel-wise knowledge distillation here. The batch size is set to 8.

(2) During the second stage, the initial learning rate is 0.00005 and all layers are trainable. We set $\alpha = 1$, $\beta = 1$ for both teacher and student models, while the hyperparameters of the channel-wise knowledge distillation are $\gamma = 3$ and $\tau = 4$ and are used only in the student model. In equation (1), $C = 4$ as we have 4 classes including the background, PA, AO, and SVC. The batch size is set to 2, since backpropagation to the backbone layers requires a larger amount of GPU memory.

In both stages, we set the decayed learning rate as $lr = lr_{\text{init}} \cdot 0.92^{\text{iterations}-1}$ and train for 50 epochs with an early stopping setting when the validation loss stops decreasing.

The following random data augmentation methods are used in the training: scale transformation, displacement, flip, rotation, and color jittering.

3. Results

To evaluate the performance of the proposed method, we compare with the most used existing methods, including U-Net [31] and the original DeepLabv3+. U-Net is a classical network and is widely used in medical image segmentation. The original DeepLabv3+ is also adopted as our teacher network; we train it on full-size images for performance comparison. For ablation study, we train the models for comparison by using a combination of cross-entropy loss and dice loss without the knowledge distillation.

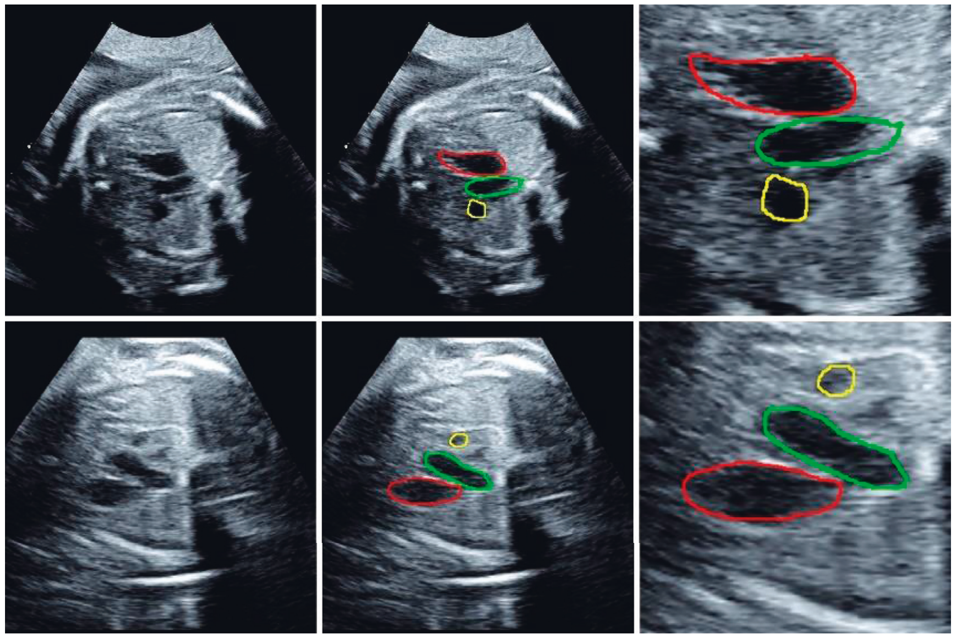

Figure 2: The 1st column shows original 3VT view of fetal heart ultrasound images. The 2nd column shows full-size labelled images, the red region is pulmonary artery (PA), the green region is aorta (AO), and the yellow region is superior vena cava (SVC). The 3rd column shows ROI-based cropped images, which are cropped from full-size images.

To quantitatively evaluate the segmentation accuracy, we use three evaluation protocols: Intersection over Union (IoU), Pixel Accuracy (PA), and Dice coefficient (Dice).

IoU:

$$\mathrm{IoU} = \frac{|S_a \cap S_b|}{|S_a \bigcup S_b|} \times 100\%. \quad (4)$$

PA:

$$PA = \frac{|S_a \cap S_b|}{|S_a|} \times 100\%. \quad (5)$$

Dice:

$$\mathrm{Dice} = \frac{2 \cdot |S_a \cap S_b|}{|S_a| + |S_b|} \times 100\%. \quad (6)$$

Here, S_a is the predicted segmentation result of the network and S_b is the groundtruth.

Table 1 shows the performance of our method. We present the IoU, PA, and Dice for each class evaluated on the test data. The mean value over three vessels' segmentation accuracies is shown in the bottom row. The mean IoU, PA, and Dice of the proposed method are 68.6%, 81.4%, and 81.3%, respectively.

Table 2 shows the comparison of three methods. The displayed measurements are the average of the three vessels' segmentation accuracies from all test data. It is evident that the proposed method performs better than the other methods.

To intuitively demonstrate the effectiveness of our results, we plot segmentation contours of the listed methods in Figure 3.

Table 1: Performance of the proposed method.

	IoU (%)	PA (%)	Dice (%)
Pulmonary artery (PA)	71.2	83.5	83.2
Aorta (AO)	69.7	82.8	82.1
Superior vena cava (SVC)	64.9	77.8	78.7
Mean	68.6	81.4	81.3

The segmentation accuracies of three vessels and their mean values are shown.

Table 2: Performance comparison to existing methods.

	IoU (%)	PA (%)	Dice (%)
U-Net	62.4	77.5	76.9
DeepLabv3+	66.8	79.2	80.1
Ours	**68.6**	**81.4**	**81.3**

The mean segmentation accuracy of three vessels over all test data is shown.

Specifically, we observed that when using existing segmentation methods, the SVC vessel is sometimes undetected or incorrectly segmented due to its small size. In addition, since the three vessels occupy only a small portion of the image, the existing methods only produce rough and incorrectly segmented boundaries.

4. Discussion

The incidence of birth defects in China is about 5.6% and the number of new birth defects is about 900,000 every year [1]. Amongst them, there are about 250,000 cases of birth defects that can be observed clinically at birth. Birth defects are the main causes of early abortion, stillbirth, perinatal death, infant death, and congenital disability, which not

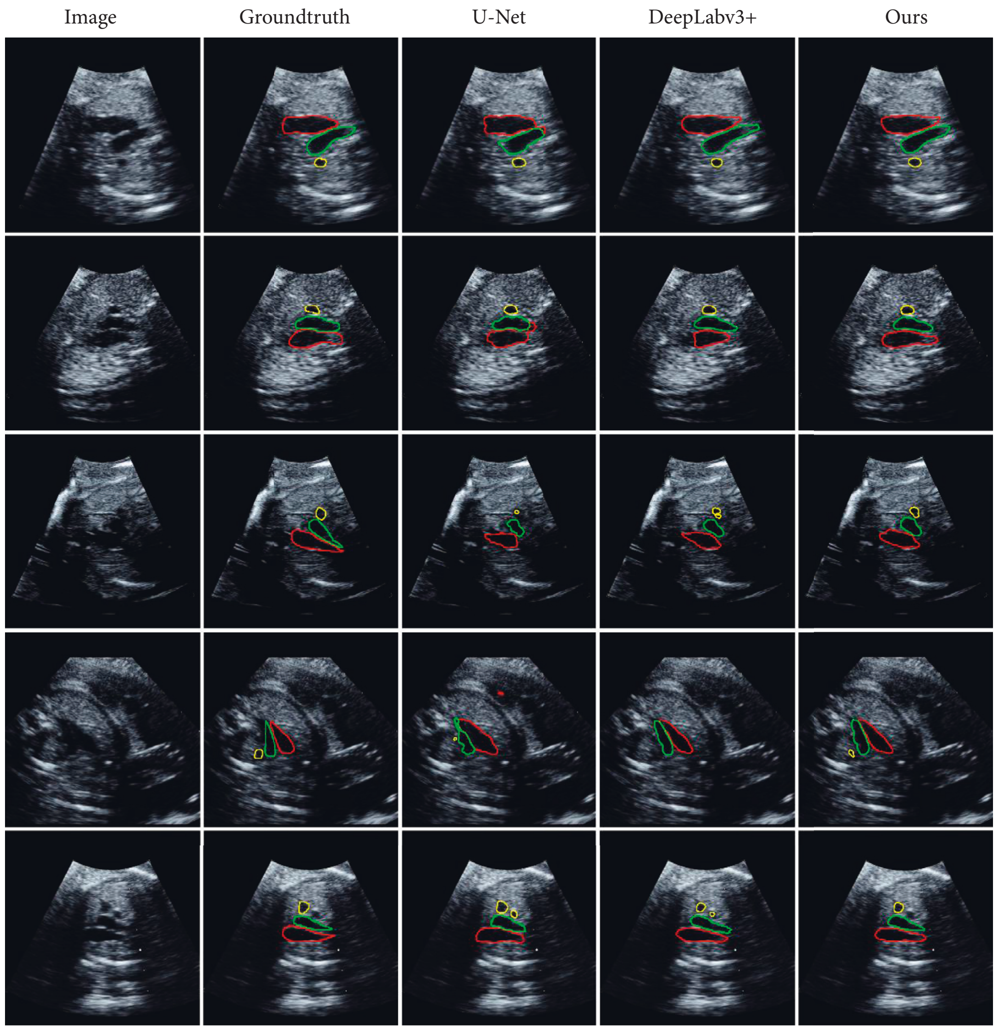

Figure 3: Segmentation results of different methods. The original 3VT view of fetal heart ultrasound images are shown in the first column and the groundtruth are shown in the second column. The segmentation results of U-Net, DeepLabv3+ and our proposed method are shown in the last three columns, respectively.

only seriously harm the survival and quality of life of children but also affect the happiness and harmony of families. It will also lead to potential life loss and increasing social and economic burden. Accurate prenatal diagnosis can significantly improve the perioperative treatment effect of CHD and the success rate of operation and reduce neonatal mortality.

Many studies have shown that improving the ability of routine obstetricians to recognize CHD is the most important issue to improve the successful rate of CHD prenatal diagnosis. However, doctors who complete obstetrical ultrasound diagnoses in their daily medical work are always lacking the diagnostic basis and evaluation experience of complex CHD, and it is difficult to obtain all basic views needed for CHD diagnosis [32–35], including four-chamber cardiac view, left and right ventricular outflow tract view, and three-vessel view, so it is difficult to make reliable display and diagnosis of CHD. As a result, CHD has become the most easily missed structural abnormality in prenatal routine ultrasound examination.

As we know, the 4C view is the most commonly used and easily obtained basic view in fetal heart examination. The acquisition rate at 16–40 weeks is around 95–99.5%, but four-chamber abnormalities only account for 48–63% of congenital cardiovascular malformations. A variety of fetal congenital cardiovascular malformations do not show abnormal shape of the four-chamber heart, including tetralogy of fallot, persistent truncus arteriosus, aortic valve stenosis, pulmonary valve stenosis, transposition of great arteries, and double outlet of ventricle. The extended basic views include three-vessel view, three-vessel trachea view, aortic arch view, pulmonary artery-ductus arteriosus arch view, and vein-atrium connection view. The detection rate of congenital cardiovascular malformation can be increased from 48–63% to 83–86%. Amongst which, the number, internal diameter, course, vascular arrangement, and abnormal blood flow direction of the major vessels can be clearly observed in the three-vessel and three-vessel trachea view, which plays an important role in the screening of fetal cardiac macrovascular malformations. Therefore, it is clinically important to collect and identify the three vessels, and the automatic segmentation algorithm could help doctors to easily operate and accurately diagnose CHD.

Automated segmentation of fetal heart ultrasound images is a challenging task due to low signal-to-noise ratio, low contrast, and blurred boundaries. Collecting and accurately annotating the data is also a difficult task. We believe that the performance of the proposed model can be further improved by using a larger and more standard dataset. Nonetheless, we achieved better results than DeepLabv3+ on all evaluation metrics, with performance gains of 1.8% on mean IoU (66.8% to 68.6%), 2.2% on mean PA (79.2% to 81.4%), and 1.2% on mean Dice (80.1% to 81.3%).

5. Conclusion

In summary, we propose a fully automated segmentation method for fine-grained segmentation of three vessels in the 3VT view of fetal heart ultrasound images using a channel-wise knowledge distillation technique. We design a teacher-student architecture to distill channel-wise knowledge from ROI-based cropped images to full-size images. The logits output of the teacher model empowers the student model with fine-grained segmentation capability. In this way, we obtain more accurate segmentation boundaries. Both quantitative and visual analyses show that the proposed method significantly outperforms other methods in terms of segmentation results of the three vessels in the 3VT view of fetal heart ultrasound images.

Small and medium-sized enterprises (SMEs) play an indispensable role in China's national economic system, and they can play a critical role in promoting economic growth and full employment. The main reason for the disruption and impediment to the development of SME clusters is that the enterprises in the clusters are experiencing a "capital shortage," as a result of the double contradiction between the clusters' financial benefits and the difficulties in financing. Grey theory is a relatively new concept in the field of information processing. It proposes theories and methods for processing and analyzing incomplete information systems using mathematical methods. This study uses finance in supply chain as a new research perspective to investigate the effectiveness of finance in supply chain in resolving SMEs' financing problems using the Grey theory model, with the goal of resolving SMEs' financing problems. When comparing the results of the Grey theory model and the regression analysis model, the relative error of the Grey theory model is on average 12.2% lower than that of the regression analysis model, indicating that the Grey theory model greatly improves accuracy. As a result, using the Grey theory model to solve supply chain financing and SMEs' difficulties can share risks, share credit, reduce transaction costs, weaken information asymmetry, and achieve mutual benefits and a win-win situation. It is expected to promote the development of the finance in supply chain model, mobilise enterprise enthusiasm for using finance in supply chain, improve finance in supply chain operational efficiency, and promote finance in supply chain development.

1. Introduction

At present, financing for SMEs is one of the major concerns of the whole society, and "supply chain financing" is a hot topic in the banking industry [1]. At present, with the improvement of capital market access standards, it is difficult for many enterprises to raise funds by issuing stocks or bonds, and in this case, the main way for enterprises to obtain sufficient funds is from banks [2]. Although the state has introduced support and incentive policies for SMEs, the effective implementation of the policies has a certain time lag effect and the effects that take time to appear [3]. In the development of SMEs, there are many problems, and the most important of which is the financing problem [4]. Domestic and foreign industrial competition is becoming increasingly fierce, and the development of SMEs is increasingly constrained by factors such as resource scarcity, energy shortage, and environmental damage [5]. The deep-rooted contradictions in the development of SMEs are becoming increasingly prominent, and the survival of SMEs is facing enormous pressure and challenges [6].

Finance in the supply chain is an important tool for SMEs to overcome their financial difficulties [7]. Corporate mergers and acquisitions are increasingly being used by companies to expand their business scale and change their development direction because of their multifaceted impact [8]. The practice and development of domestic commercial banks' supply chain finance have provided a good solution to the SMEs' financing problem [9]. This business model has broken the constraints of traditional financing and greatly expanded the credit market for SMEs, which has been recognised and imitated by an increasing number of commercial banks [10]. Although the state has eased SMEs' access to the market, it has not provided more preferential policies to help them grow [11]. In this case, establishing a special mechanism to create a new financing model to meet the financial needs of SMEs through collaboration among multiple participants or stakeholders in the credit market would be a more effective approach [12].

Grey theory [13] uses the similarity of the various factors affecting the system to determine the degree of relevance of various factors. The development of the system can be quantified by analyzing and comparing various factors to determine the most important factors in the system's and things' development [14]. Small businesses are constrained by their own capital in the continuous production process, making it difficult to organise the optimal production scale in accordance with market demand and maximise profits [15]. As a result, the preliminary work of planning the company's M&A financing, the basis of financing decision, will directly affect the ultimate success or failure of the company's M&A. Correct judgement of the macrorisks of financing and comprehensive risk analysis of the available financing methods is the preliminary work of planning the company's M&A financing, which will directly affect the ultimate success or failure of the company's M&A. According to Grey theory, the prediction of a system with both known and unknown or uncertain information is the prediction of a time-related Grey process changing in a particular direction.

The innovative points of this study are as follows:

(1) It is of great practical significance to assess whether finance in supply chain can promote the development of SME clusters. The study provides a theoretical basis for it by establishing a mathematical model.

(2) Focusing on the unique advantages of finance in supply chain financing model to solve the financing difficulties of SMEs, it directly reflects the specific effectiveness of finance in supply chain in the actual operation process and the inherent advantages of risk control.

(3) Combining the characteristics and coupling relationship between finance in supply chain and SME clusters, a new "$1+N$" pooled invoice financing method of finance in supply chain is proposed. It is innovative to connect SME cluster financing with finance in supply chain to improve financing efficiency.

This study's research framework is divided into five sections, which are organised as follows: the first section of this study introduces the research background and significance before moving on to the main work. The second part introduces the work done in supply chain finance to solve SMEs' financing issues, as well as the Grey theory model. The method of establishing the Grey theory model and the development model of finance in supply chain is sorted out in the third section, so that readers of this study can have a better understanding of the concept of analyzing finance in supply chain based on the Grey theory model to solve the financing of SMEs. The thesis' core section describes the use of the Grey theory model to analyze small business financing problems from two perspectives: serial Grey correlation analysis and sliding Grey correlation analysis. The thesis concludes with a summary of the entire work.

2. Related Work

2.1. Financial Supply Chain Financing for SMEs. With the deepening of reform and opening up, China's economy has developed rapidly and SMEs have also started to develop rapidly, becoming an indispensable and important part of China's economic system. Despite their increasingly prominent role in promoting the stable development of the national economy, fostering scientific and technological innovation, and providing a platform for employment, the number of SMEs is also increasing. However, their growth environment is not ideal, and the problem of having financial difficulties is particularly prominent. The rise of finance in supply chain has made it possible for this idea to become a reality.

Kouvelis et al. pointed out that in the UK financial system, SMEs still face financial difficulties in raising the necessary long-term capital. With the outstanding contribution of SMEs in expanding employment, solving the imbalance of regional economic development, and ensuring sustainable and stable economic growth, SMEs have become an important driving force of China's market economy [16]. According to Gaea, SME clusters create a good "green" environment for the development of finance in supply chain, and finance in supply chain provides a guarantee for the realization of the financial strategy of SME clusters [17]. Abbasi et al. proposed the net income theory, the net operating income theory, and the intermediate tradition theory as the initial theory of capital structure [18]. Luca et al. argue that various types of SMEs within an industrial cluster form an integrated supply, production, and marketing supply chain through a clear division of labor and mutual cooperation. The objective conditions are created due to the frequent capital transactions between the participants [19]. Sun et al. argued that SMEs inevitably encounter financial difficulties due to factors such as low credit levels, lack of collateral, and inadequate small and medium-sized guarantee institutions [20].

Finance in supply chain is a new financing model that has taken the world by storm in recent years. It unites core enterprises and upstream and downstream enterprises to provide flexible financing methods and effectively alleviate the financial difficulties of SMEs. Rather than assessing the production and operation status and credit risk of individual enterprises in isolation, finance in supply chain studies the financing needs of SMEs from the perspective of the whole industry chain, taking into account the core enterprises and upstream and downstream enterprises. It also considers logistics, capital flow, and information flow to achieve efficient connection.

2.2. Grey Theory Model. It is difficult to obtain a more complete and accurate understanding of complex systems due to the limitations of people's level of understanding, their ability to obtain information, and the existence of interactive interference between different types of information. The main characteristics of SMEs are small size, flexibility, and vitality, but they face difficulties in the development process in terms of capital, talents, and information. How to effectively extract, filter, and process information has attracted widespread attention and great importance, so Grey theory is a new discipline that has emerged.

Yao and Zhu introduced the concept of buffer operator and proposed a new method to attenuate serial shock perturbations and improve the prediction accuracy [21]. Zhou classified the expected returns of assets into two categories: risk-free returns and risky returns. The risk-free return is the risk-free rate in the capital market, and the higher the risky return is relative to the overall market risk, the higher the risk-return ratio needs to be achieved [22]. He uses function transformations to normalize the raw data and further improve the smoothness of the raw data stream. Also, theory and examples show that this mathematical transformation method is highly advantageous for improving the smoothing of the series [23]. Liu treats real security returns as the result of changes in many factors in the economy and assigns corresponding weights to each variable, assigning higher weights to factors with greater influence and less influential factors to those with greater influence [24]. Ning used the buffer operator forecasting principle to make short-term forecasts of Chinese energy consumption using a second-order weakening operator acting on the original series [25].

Under the effect of financial disincentives, there will be a "capital gap" in SME financing, resulting in an imbalance between supply and demand for capital. In the absence of supply chain support, enterprises in the group are likely to produce homogeneous and indistinguishable products, leading to fierce competition among enterprises. Based on the Grey theory model, through the coordination and integration of capital flow, logistics, and information flow, the smooth operation can be effectively ensured.

3. Based on the Grey Theory Model, The Idea of Finance in Supply Chain to Solve the Financing Problem of SMEs Is Analyzed

3.1. Establishment of Grey Theory Model. In cybernetics, things can usually be represented visually in different colors depending on the amount of information and whether the information is clear or not [26]. For a thing, if its information is informative and clear, then it can be said to be white [27]. If a thing has very little information and the information is vague, then it is black. What is in the middle is called Grey [28]. When considering a Grey theory model, sometimes the occurrence of certain events can lead to certain fluctuations in the returns of the event window. Therefore, the impact of events on the return must be fully considered in the Grey theory model, and the return forecasting method is shown in Figure 1.

First, to bring our Grey portfolio-based investment model closer to the real market, we refer to semiabsolute diversification risk in measuring risk. The process of model modeling involves using the original data series as solutions of the differential equation and modeling the approximate differential equation for those series that can approximately satisfy the conditions of the differential model. Assume that $S = S(i)$ represents the consumer or investor surplus of a financial product and $\Pi = \pi(i)$ represents the profit of a financial firm, both of which are functions of financial market prices. Then, the political production function is as follows:

$$M = M(S, \pi). \tag{1}$$

A necessary condition for the formation of SME clusters is the degree of association between enterprises. The characteristics, status, and role of each enterprise in the cluster, as well as the cooperative relationship between related enterprises, determine the network structure of the cluster [29]. Since many SMEs have an inadequate management system, the company's management system is not well developed and the disclosed operational information is not very complete. In this case, an information asymmetry is created [30]. Therefore, by borrowing from core enterprises and funding the actual transactions with them with supply chain financial services, we can effectively help SMEs to obtain the required loans at a lower cost and alleviate the problem of insufficient capital liquidity. In particular, when it is difficult to determine the optimal structure through visualization, comparative methods and quantitative analysis are used to determine the nuances of different structures in order to achieve the differentiation of structural strengths and weaknesses. Currently, in the actual operation of Chinese banks, together with the adoption of the receivables financing commitment method, the flowchart of the receivables financing model is shown in Figure 2.

The second is to mainly consider the case where the investor's expected return is uncertain; that is, the return on investment is represented by a Grey number. Since the expected return on assets of investors may fluctuate within a certain interval, the interval Grey number is used to represent the return on assets. In practical applications, when shock perturbations have a distorting effect on the original data stream, the buffer operator can be given priority to act on the original data stream to attenuate the perturbation distortion. The residual is the difference between the actual value and the simulated value, and the residual test actually tests the degree of deviation of the simulated value from the actual value. Let the original and simulated data be

$$\begin{aligned} x^{(0)} &= \left\{x^{(0)}(1), x^{(0)}(2), x^{(0)}(3), \ldots, x^{(0)}(n)\right\}, \\ \hat{x}^{(0)} &= \left\{\hat{x}^{(0)}(1), \hat{x}^{(0)}(2), \hat{x}^{(0)}(3), \ldots, \hat{x}^{(0)}(n)\right\}. \end{aligned} \tag{2}$$

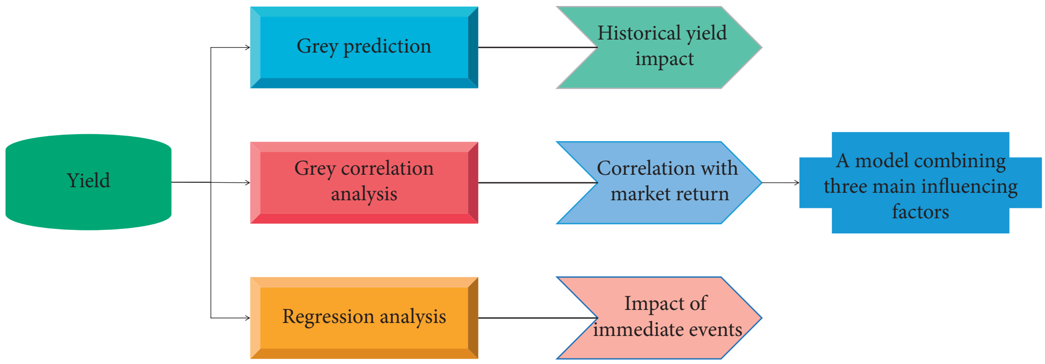

Figure 1: Forecast method of yield.

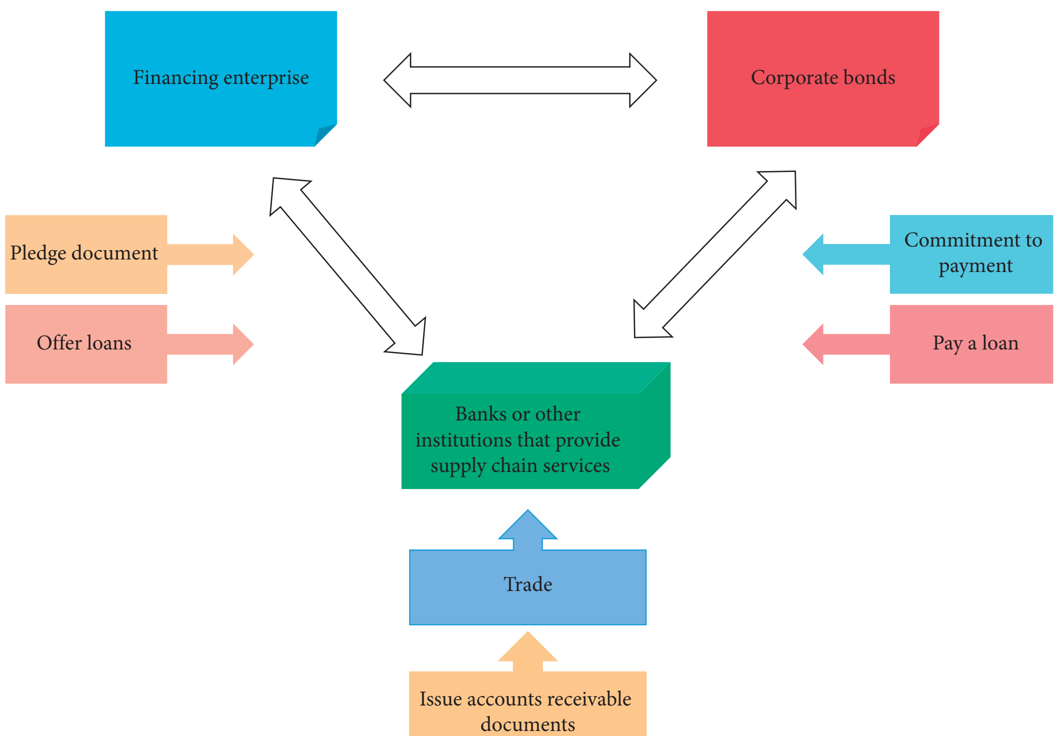

Figure 2: Flowchart of accounts receivable financing mode.

The residual sequence is as follows:

$$\begin{aligned} E &= (e(1), e(2), \ldots, e(n)) \\ &= X(0) - \widehat{X}(0). \end{aligned} \tag{3}$$

Among them

$$e(i) = x^{(0)}(i) - \widehat{x}^{(0)}(i), \quad (i = 1, 2, \ldots, n). \tag{4}$$

The cluster is a gathering place of many highly related industries, with clear division of labor and close connection, forming a "sub-network" of the supply chain. For the non-negative discrete series, the current theory describes the model by approximating the exponential form of the first-order differential equation to the exponential form of the first-order differential equation. The first stage is the primary stage, in which bank credit is introduced in the supply chain business cooperation to improve the business credit and stability of the whole supply chain. It also encourages upstream and downstream SMEs to establish long-term and stable strategic cooperation with leading enterprises to improve the operational efficiency and competitiveness of the whole supply chain. Let $X(0) = (x^{(0)}(1), x^{(0)}(2), \ldots, x^{(0)}(n))$ be the sequence of system behavioral characteristics, and the observed data sequence of system behavioral characteristics is as follows:

$$\begin{aligned} X(x(1), x(2), \ldots, x(n)) &= \big(x^{(0)}(1) + \varepsilon_1, x^{(0)}(2) \\ &\quad + \varepsilon_2, \ldots, x^{(0)}(n) + \varepsilon_n\big) \\ &= x^{(0)} + \varepsilon. \end{aligned} \tag{5}$$

Finally, the risk of the model is represented by a Grey number on top of the expected ROI, so that only one Grey number is needed for the whole model. The SMEs in the cluster have their own supply chains, distributed in various nodes. Due to the complexity of their internal relationships, the supply chains of SMEs can be single or multiple chains, cooperating and competing with each other. Grey theory defines the temporal measure of the sequence based on the open set topology and then defines the information density, the Grey derivative, and the Grey differential equation. In the finance in supply chain model, financial institutions such as banks no longer focus on individual financial companies, but on the risk of the entire supply chain and its transactions.

3.2. Supply Chain Financial Development Mode-"1 + N" Financing Service Mode. In the production and operation processes of SMEs, due to the time lag effect between the purchase of raw materials requiring prepayment, the sale of enterprise inventory products, and the recovery of sales payments, the enterprises have high capital flow requirements, and capital shortages occur from time to time. The development mode of finance in supply chain has innovated credit technology by providing overall service to the supply chain, integrating logistics, and information flow and closed operation, which has improved the efficiency of financial services, eased information asymmetry, and reduced transaction costs, and provided new ideas and ways to solve the financing problems of SMEs. According to the financing stage, the establishment of a more stage-specific financing risk evaluation index system provides a system guarantee for the evaluation and control of multistage financing risk, and the flowchart of comprehensive evaluation of financing risk is shown in Figure 3.

To begin with, due to a lack of short-term funds, downstream purchasers (financing companies) prefinance by confirming business on the assumption that the supply chain's presales company will buy back, relieving the pressure on downstream companies' procurement funds. Risk-averse investors are more concerned about investment risk and prefer to invest in a portfolio with a lower risk. Low risk, of course, entails a low reward. This financing model takes into account the cluster and supply chain as a whole, not only to solve individual company financing issues but also to provide financial support to individual company's upstream and downstream customers. Let the stochastic process $\{X_n, n \in T\}$, whose parameter set T is a discrete set in time, that is, $T = \{0, 1, 2, \ldots\}$, and whose state space consisting of the entire set of possible values of the corresponding X_n is a discrete set of states $I = \{i_1, i_2, i_3, \ldots\}$. If any integer $n \in T$ and any $i_0, i_1, i_2, \ldots, i_{n+1} \in T$, then the conditional probabilities satisfy the following equation:

$$\begin{aligned} P\{X_{n+1} = i_{n+1} | X_0 = i_0, X_1 = i_1, \ldots, X_n = i_n\} \\ = P\{X_{n+1} = i_{n+1} | X_n = i_n\}, \end{aligned} \tag{6}$$

$$\sum_{j=1}^{\infty} P_{i,j}(m, m+n) = 1, \quad i = 1, 2, \ldots, n. \tag{7}$$

Throughout the loan financing process, the principal is the debtor of the receivables and acts as a guarantor for the upstream company, providing collateral to the bank. Once the borrower defaults on the loan, the principal firm must take over the responsibility of repaying the loan. Starting from the framework of the multivariate Markov model, it is assumed that the financial position of the firm at the time of i, t and its financial position at the time of $t + 1$ satisfy the following recursive relationship:

$$x_{t+1}^{(i)} = \sum_{j=1}^{N} \lambda_{i,j} P^{(i,j)} x_t^{(j)}, \quad i = 1, 2, \ldots, N. \tag{8}$$

Here, $x_{t+1}^{(i)}$ is the probability vector of financial status.

Second, considering the conversion of existing inventory goods or operational raw materials into collateral that banks are willing to accept is a new idea for SMEs to recover bank loans. According to the evaluation criteria of indicators determined by the banking system, the evaluation indicators are graded based on the collected data and expert evaluations, so as to obtain the sample whitening number matrix for general risk assessment of supply chain financing. For the original data series with a high growth rate in the first half of the data series and small growth rate in the second half, the actual simulation error is smaller after modeling, and the construction operator attenuates or weakens the effect of the data distortion phenomenon caused by the shock perturbation shock. $X = (x(1), x(2), \ldots, x(n))$ is the data series of system behavior characteristics, and the data series of X after the effect of the operator D is noted as follows:

$$XD = (x(1)d, x(2)d, \ldots, x(n)d). \tag{9}$$

At the same time, the financial support provided by the bank can enhance the cohesion among the companies in the cluster and make transactions more convenient. However, when choosing Greyscale generation, attention needs to be paid to choosing the appropriate Greyscale generation operation based on known data characteristics and paying attention to choosing Greyscale generation with less error.

Finally, during the sales stage, SMEs can use large parent company accounts receivables as collateral to obtain funds from banks and other financial institutions. A linear whitening weighting function is constructed based on the actual situation of supply chain financing to classify its risk into three equal low risks: low risk, average risk, and high risk. Due to the fact that the core company is a market leader with a high credit rating and good operating condition, the default risk will be reduced. The receivables generated during the subject's participation in the transaction are not invoiced, so this model is essentially indirect financing. The bank will take on the entire supply chain, including

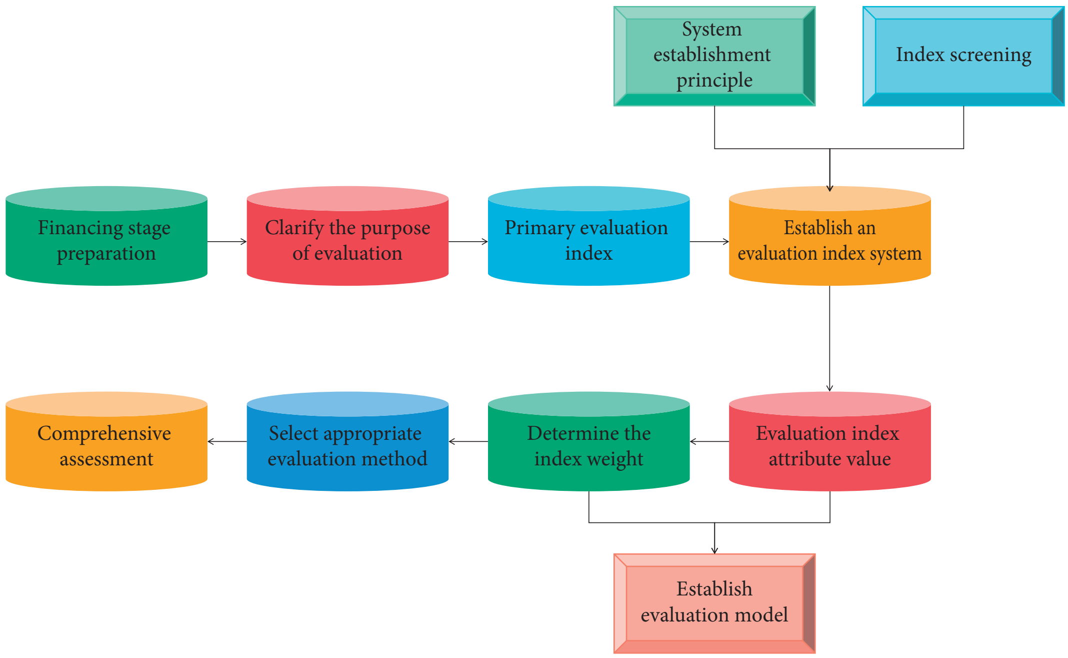

Figure 3: Flowchart of comprehensive evaluation of financing risk.

manufacturers, suppliers, and vendors, as a part of supply chain financing. This combined transaction operation eliminates many unnecessary losses and improves the fund setting. Inventory financing, also known as supply chain finance, enables SMEs to convert movable assets that banks are hesitant to accept into asset collateral via core business collateral, logistics, and storage supervision.

4. Application of Grey Theory Model in Analysis of Financing Problems of Small Enterprises

4.1. Sequence Grey Correlation Analysis. Grey theory provides a method for collecting and processing known information about systems and things in order to explore their corresponding patterns of development and change. The correlation test is a geometric test that examines the similarity between the model value curve and the actual value curve used for modeling.

The average relative error and the predicted value are obtained by comparing the corresponding time functions after the action of the no-buffer operator and the action of the buffer operator, calculating the simulated predicted value and comparing it with the actual value, which are shown in Figures 4 and 5, respectively.

First, the method of characterizing the geometry or the dynamics of how things develop between sequences in terms of the degree of velocity difference is called absolute correlation. The degree of speed difference here is also known mathematically as the first-order slope difference. For banks, most of them choose to increase the input cost when lending to SMEs in order to reduce the risk problem, thus improving the information collection and supervision of SMEs. The predicted values of the model for 2021 after the first-order weakening of each buffer operator are listed in Table 1.

In general, the closer the geometry and the closer the trend of change, the greater the degree of correlation. The step test is a point-by-point test, the correlation test is a test of the approximation of the model to the specified function, and the posterior difference test is a test of the stochastic properties of the step distribution. The test uses the relative error size test method, which is an intuitive comparative and point-by-point arithmetic test. The predicted data are compared with the actual data to see if the relative error meets the actual requirements.

Second, all the Greyscale information described by the sequences can be used to highlight the “white part” and weaken the “black part” to highlight the regularity between the sequences, which establishes the optimal solution model of the whitening equation. The whitening portfolio model is a multiobjective planning problem. Therefore, the multiobjective planning model of the first whitening equation, the second whitening equation, and any whitening equation is transformed into a single-objective planning model. The supply chain financing is designed by a certain operation model so that the business income of the trust company automatically returns to a specific credit-granting bank account, which in turn repays the loan or is repaid as collateral to reduce the credit risk of the bank. A method of whitening the Grey process in the generation process has the effect of attenuating or weakening the randomness of the original data stream and plays an extremely important role in the Grey modeling process. Interval values are necessary for the theory of interval Grey number prediction, and it is necessary to provide not only the possibility of converting fuzzy numbers into interval values but also the corresponding

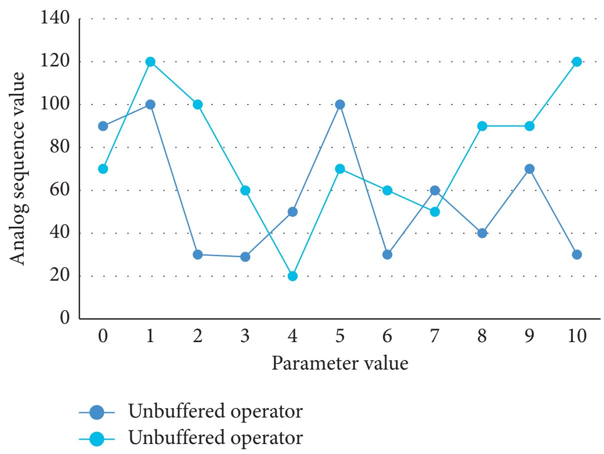

Figure 4: Simulation sequence diagram with or without buffer operator.

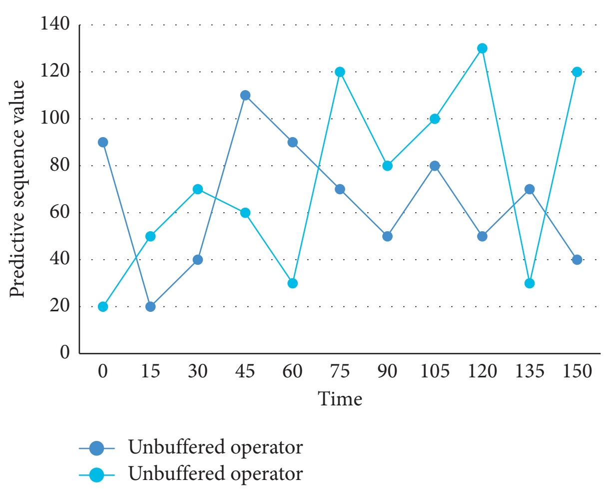

Figure 5: Prediction sequence diagram with or without buffer operator.

Table 1: Predicted values of each buffer operator after first-order weakening.

Sequence	Average relative error	Estimated value (10,000 people)
X	2.89	122
XD_1	4.82	371
XD_2	6.77	658

conversion methods and algorithms. When the development coefficients take different values, the accuracy curves of the Grey theory model, the original GM model, and the improved GM model are shown in Figure 6.

Finally, the Grey series is transformed into the underlying data reflecting the essential intrinsic characteristics, that is, achieving the so-called dimensionlessness, for comparison between pairs. The risk acceptance coefficients are determined according to the different risk acceptance levels of different investors, solving the single-objective planning problem of the whitened portfolio model, and finally determining the optimal solution of the model.

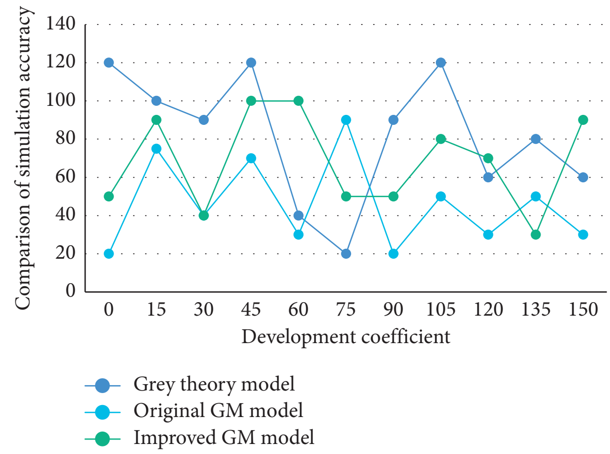

Figure 6: Comparison of simulation accuracy of three types of models with different development coefficients.

Cumulative generation is the accumulation of data between each series at each moment to get a new data series. Finance in supply chain integrates information, capital, logistics, and other resources, which is a scientific, personalized, and targeted financial service process. It takes the illiquid assets and the future cash flow generated by the assets in the supply chain operation link and certainty as the source of repayment and enhances the coordination of the supply chain to reduce its operation cost. From the calculation of the correlation coefficient, we can get the correlation coefficient values of the comparison series, that is, the model value series and the reference series, that is, the actual value series, which have many results at each point, and the information is too sparse to facilitate comparison. The correlation coefficient is embedded in a value, which is the sequence space before the accumulation of Greyscale correlation, called the original sequence space, and the sequence space formed after the accumulation of new data is called the generated sequence space.

4.2. Sliding Grey Relational Analysis. One of the most important indicators of national economic development is gross national product or GDP, which can reflect whether a country's economy is in the development stage or the recession stage. Due to the characteristics of Grey correlation, it makes up for the shortcomings of some mathematical and statistical methods, which are equally applicable to the sample size and whether the sample is regular or not, and the calculation is small and very convenient. At the development coefficient of 0.5 and 1, the multistep prediction accuracy of the Grey theory model is compared in the experiment, and the experimental results are shown in Figure 7.

First, things that have some factors in common with existing things are searched for and asynchronous comparisons are made between the factors. Therefore, the concept of sliding Grey correlation is proposed to project the trend by comparing the series of different time periods (looking for analogies). In practical applications, the Grey character of portfolio investment uncertainties, the variance of risk, and expected return of portfolio investment ranges from light numbers in the classical

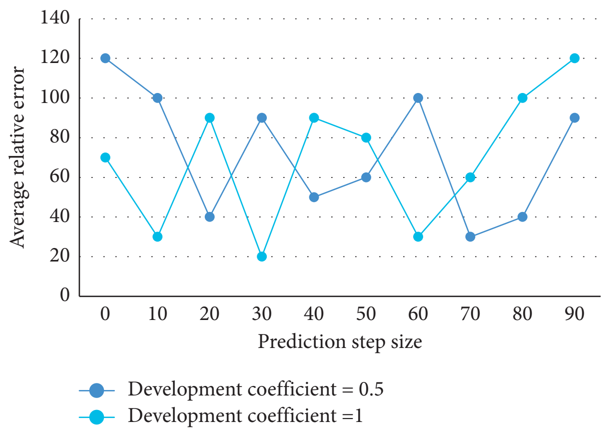

Figure 7: Comparison of multistep prediction accuracy of grey theory models with different development coefficients.

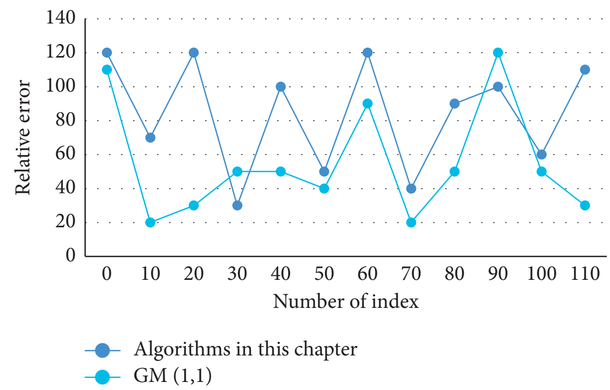

Figure 8: Comparison of simulation residuals between the GM (1, 1) model and the proposed model.

model to interval Grey numbers are considered, as the model is closer to the real situation. The higher the smoothness of the data stream, the higher the accuracy of the established model, and vice versa, the accuracy of the model is difficult to achieve satisfactory results. Therefore, the effective evaluation coefficients of each criterion in the criteria set need to be given to increase the stability of voting and the scientificity of evaluation to obtain a more accurate ranking of the importance of members. The unbiased GM (1, 1) model eliminates the exponential bias inherent in the traditional GM (1, 1) model and the distortion of the data series when the original data series is perturbed by shocks in the traditional GM (1, 1) model. The main reason is that the unbiased model avoids jumping from the difference equation to the differential equation when modeling the GM (1, 1) model. A comparison of the simulated residuals of the GM (1, 1) model and the proposed model in this study is shown in Figure 8.

Second, the amount of the slider on the left represents the time series' advancement, while the amount of the slider on the right represents the time series' lag. Because interval Grey numbers were introduced, any set of interval Grey number whitening values in the model corresponds to a possible scenario, and the results are unreliable and could be good or bad. In general, cumulative generations can give data a degree of regularity, and if that is not enough, the number of cumulative generations can be increased. Although the requirements for meeting multiple sets of criteria are more stringent, the affiliation metric quantified values combining group consensus and individual understanding can be more accurately reflected among multiple sets of criteria, and the discriminative ability will improve. We choose the Grey theory model for forecasting and the regression analysis model for forecasting three stocks of the same type, assuming no events will affect the stock price during the forecast period. The relative errors are compared in Table 2.

Comparing the results of the Grey theory model and the regression analysis model, we can see that the relative error of the Grey theory model is on average 12.2% lower than that of the regression analysis model, which greatly improves the measurement accuracy.

Table 2: Error comparison of different methods.

Stock		Stock 1	Stock 2	Stock 3
Grey theory model	Estimated value	0.152	0.162	0.186
	Relative error	15.4%	12.9%	11.6%
Regression analysis model	Estimated value	0.231	0.243	0.267
	Relative error	1.56%	1.29%	0.98%

Finally, overruns and lags are unique time-series properties that are only used as reference indicators during the correlation investigation process and do not represent good overruns or lags. The processed generative series are used to create a Grey generative model, which is then compared to the GM (1, 1) model created directly from the original data. The simulated prediction series can be obtained after recovering the model. To understand the decision risk, it is necessary to find the best and worst solutions for linear interval planning problems, as well as provide decision-makers with a range of effective solutions under certain conditions. Although some generative models have high prediction accuracy for Greyscale generated series, after recovering the original series, the prediction accuracy may be low, so the type of Greyscale generation used has an impact on the prediction accuracy. As a result, the dominance measure must take into account all of these factors in order to construct a reasonable set of evaluation criteria, and it is also necessary to consider the overall impact of different criteria sets on the evaluation problem and change the content of the criteria sets as needed to suit different evaluation criteria.

5. Conclusions

In the increasingly competitive modern market economy, the competition among enterprises is changing into the competition among supply chains. The development of finance in supply chain has brought hope to solve the financing problems of many SMEs in China. Finance in supply chain has fully integrated financial resources and realized model innovation, and the service scope has been extended to SMEs. The difficulty of SME financing is a classic issue with complex historical and objective reasons, while finance in supply chain is a newly emerged financing model in recent years, and it is the entry point of this study to crack the old problem with a new model, which is also the main purpose of this research. This study takes the financing of SME clusters as the research object and makes comprehensive use of theoretical knowledge such as the Grey theory model and finance in supply chain to conduct an in-depth study on the current situation of SME cluster financing. Using the Grey theory model to analyze the finance in supply chain has the unique advantage in solving the financial difficulties of SMEs. Introducing the Grey theory model can effectively weaken the information asymmetry between banks and SMEs and increase the possibility of banks to provide credit to SMEs. The Grey theory model can not only make a reasonable and accurate assessment of the overall risk situation of finance in supply chain but also predict the future development trend of the supply chain by comparing the risk levels of various indicators.

China's development is inseparable from the reform of education, so ECE is very important in the development of Chinese society. Based on this reason, this paper introduces the three reform waves of communist Chinese society under the influence of western culture. Because the professional level of kindergarten teachers does not match the concepts and requirements of the three preschool curriculum reforms in Chinese society, this paper analyzes the solutions based on this problem and holds that the leadership of kindergarten teachers should be vigorously developed.

1. Introduction

China has long recognized the important role of ECE in children's development [1]. Under the mutual influence of Chinese local culture and western culture, China's ECE has experienced many landmark changes. This paper introduces the changes of Chinese social culture under the influence of Chinese traditional local culture and western culture under communism. There have been three reforms of preschool education. For more than a century, China's educational practice has been influenced by Chinese traditional culture and Soviet thoughts, and it is also hoped to learn from advanced western educational ideas and methods and actively explore educational practices suitable for China. Although the third comprehensive reform of ECE has made great progress and had a wide impact on society, there are still many problems. One of the outstanding problems is that the quality of kindergarten teachers does not match the idea and demand of education reform. Some experts point out that teachers play an important role in the new curriculum reform. Focusing on the development of teachers' leadership is the most reliable solution under the mutual influence of Chinese native culture and western culture.

2. The Current Situation of ECE and Care in China

Preschool education refers to the education of children from 0 to 6 years of age. In recent years, the age range of children enrolled in kindergartens in some provinces has also begun to expand, meaning that children aged 2-3 can also enter the kindergarten [3].

In China's education system, ECE belongs to basic education, but not to nine-year compulsory education (six years of primary school and three years of middle school), which will get more education budget from the government. In all the stages of basic teaching, the budget for ECE is the least. For example, ECE has received only 1.3-1.4% of the national education budget in the last 17 years in China [4].

With the Third Plenary Session of the Eleventh Central Committee in 1978, China began to implement the policy of internal reform and opening to the outside world. Under the influence of the reform and opening-up policy, all walks of life in China have undergone earth-shaking changes, including preschool education, and the reform results of preschool education are the most remarkable [5]. As a result, there has been noticeable and dramatic improvements in ECE. However, there were still many challenges and difficulties to be solved by Chinese early education professionals [6]. One of the prominent issues was that the professional development level of most early childhood educators cannot meet the requirements of the reform. In response to this phenomenon, this paper attempted to propose the advocacy from the social and historical aspect of ECC reforms and the influence of the hybrid of three cultures on the reform.

3. A Social and Historical Aspect of ECC Reforms in China

In the past decades, under the interaction between Chinese local culture and foreign culture, especially western culture, a series of tremendous changes have taken place in ECE in China. In China, ECE is a full-time program of primary education for children. Generally speaking, the need to verify the quality of ECE starts with examining the characteristics of the curriculum, which is the key core of education [7].

In the development of ECE in China, the early childhood curriculum (ECC) reform mainly went through three stages, which were, respectively, affected by the social development and cultural characteristics at that time. The three stages of ECC reform, along with the historical process of major social changes of different origins, took place in 1920s to 1940s, 1950s to 1960s, and 1980s to the present, respectively [8].

3.1. The ECC Reform from 1920s to 1940s. The formal development of ECE in China began in the early 20th century. In 1903, China's first kindergarten was established in Wuhan (Zhu & Zhang, 2008), which copied the Japanese education model from the content and methods to the toys and facilities [9]. At that time, the influence of western missionaries was very extensive, and China's ECE also received its influence.

The May 4th New Culture Movement broke out in 1919, created conditions for the spread of various western educational thoughts in China, and had a profound influence on the reform of modern education in China, among which the ideological influence of John Dewey was particularly obvious [10]. In addition, the famous western scholars of ECE at that time, such as German Froebel and Italian Montessori, and their ECC models also became the object of imitation and learning for Chinese teachers [11].

However, local Chinese educators such as Chen Heqin, Tao Xingzhi, and Zhang Xuemen also had insight into the disadvantages brought about by copying foreign countries in ECE, which did not adapt to the social and cultural conditions in China at that time, and put forward the idea of starting with ECC reform to make ECC scientific and localized [12]. A curriculum called "unit integrated curriculum" was implemented in Nanjing in 1923, which initiated the first ECC reform (1920s–1940s) in China. In theory, it confirmed the subjectivity of children in the curriculum, and the curriculum should include all activities of children in kindergarten.

3.2. Full Acceptance of Soviet Theory (1950s–1960s). After the founding of the People's Republic of China in 1949, under the background of comprehensive learning from the Soviet Union, ECC also fully accepted the theory and practical experience of the Soviet Union. In the 1950s, China began the second ECC reform. Although the Chinese ECC no longer used the word "curriculum," it actually reflected a narrow understanding of the curriculum at that time, that is, the curriculum was regarded as a subject, and children were educated through the teaching of various subjects in kindergartens [13]. The Chinese Ministry of Education had completely rejected the previous practice, requiring kindergartens to systematically teach young children through "homework," emphasizing the leading role of teachers, and attaching importance to the learning of knowledge and skills for young children.

From 1966 to 1976, the "Cultural Revolution" occurred in China, which made China's education suffer a catastrophe, and ECE was no exception. That period was known as the dark period of ECE in China [14].

3.3. Progress for the Third ECC Reform (1980s to the Present). After the ten-year Cultural Revolution from 1966 to 1976, Chinese leader Deng Xiaoping put forward the famous reform and opening-up policy [15]. This reform has changed China's traditional education concept and made China's ECE go out of the dark period and turn into the golden period of ECE. After about 30 years of efforts, China's ECE reform has made great achievements [16].

Since the 1980s, Chinese early childhood educators have launched a large-scale ECC reform movement with ECC reform as a breakthrough point. Various foreign child development and education theories, such as Montessori, Dewey, Bronfenbrenner, Bruner, and especially Piaget's ideas, began to spread widely, and the thoughts of modern educators in China, especially those of Chen Heqin, were emphasized again, which provided theoretical background for the ECE reform since the 1980s [11]. Since then, the influence of the Soviet Educational theory on ECE in China has gradually weakened.

The third ECC reform started from the spontaneous experiment of China's kindergartens and played a great role in promoting it. In 1989, China's education authorities issued the Kindergarten Work Regulations (trial version). Since then, ECC reform has been transformed into a "top-down" reform led and promoted by the national administrative power [17]. In order to further deepen this reform, in 2001, the Ministry of Education issued the Supplementary Guidelines for Kindergarten Education Practice (trial version). These reforms and policies are aimed at the previously long-existing teacher-centered curriculum system, which has shifted to emphasizing the development of children and taking plays as basic activities [18]. The Supplementary Guidelines issued in 2001 reflected the core concept of ECC reform to provide integrated, situational, and life-oriented experience for children. Taking the five fields of "health, language, society, science, and art" as examples, the curriculum objectives, contents, and requirements as well as guiding points were elaborated [19].

Furthermore, during this reform period, some well-known western curriculum models such as Project Approach in the United States, Reggio Emilia Practice in Italy, and Montessori curriculum mode in Italy were widely known by Chinese ECE scholars and gradually localized in some kindergartens [20]. In addition, Chinese early education experts have also developed local curriculum based on China's national conditions and social needs, such as the theme-based integrated curriculum led by Zhu Jiaxiong [21], and the Anji Play Approach developed by Cheng Xueqin [22].

The reform in this stage is still going on, and its scale, length of time, and amount of resources are unmatched by previous ECC reforms. However, with the development of society and the passage of time, people began to evaluate this reform from multiple perspectives and put forward many problems at the conceptual and practical levels [23].

4. A Mixture of Three Cultures in China

China's ECC reform in these three stages happened to be accompanied by great social changes, and all of them were influenced by foreign cultures without exception. Unfortunately, the introduced curriculum did not necessarily meet the needs of Chinese children nor did ECE teachers in China have the expertise to handle it. This also reflects the need to pay enough attention to cultural compatibility in the ECC reform in China [24]. That is to say, the mixture of three cultures: Chinese native culture, Soviet Union (communist) culture, and western culture, has an indelible impact on China's social changes, including different aspects of ECC reform [25].

As is known to all, Chinese native culture originated from Confucianism, which had exerted a far-reaching and comprehensive influence on the Chinese people. The impact on education lied in the emphasis on repetition and memorization of individuals rather than encouraging and fostering creativity and flexibility. In the ECC reform, although Chinese teachers accepted the curriculum or pedagogies of foreign culture, they still adopted traditional teaching methods in practice because of the long-term influence of deep-rooted Confucianism [26].

The influence of Soviet culture is mainly reflected in China's second-stage ECC reform, which was generally stable and smooth. Traditional Chinese culture and communist culture were compatible to a certain extent because both value centralized management, planning systems, learning outcomes, clear goals, and teachers' guidance.

As a representative of western culture, the United States put forward a famous open door policy. Under the influence of this policy, the advantages of other cultures also had an impact on the third reform of China's preschool education. Although many ECE practitioners in China imitate the western education methods and try to change the traditional teaching methods from adult-centered to child-centered, they find that there are still many shortcomings to be improved in the process of teaching practice, and these problems cannot be solved in a short time [27].

The influence of these three cultures on ECE is not immutable, but developed dynamically, and each one had an impact on different aspects of ECC. Sometimes two cultures could produce a combined influence, for example, the commonality of Chinese native culture and communist culture strengthened the authority of teachers, and sometimes the influence of two cultures would offset each other to a certain extent, for instance, collectivism in Chinese native culture was the exact opposite of the cultivation of individuality in western culture.

5. One Noticeable Issue in ECC Reform: EC Teachers' Professional Level Did Not Match the Requirement

As mentioned above, EC teachers in China have been fully affected by the ECC reform. They have recognized the importance of learning child-centered educational theories and also have tried to change the traditional education system centered on knowledge transfer and skill acquisition, but it was still difficult to get rid of the old curriculum mode and traditional teaching methods in practice [28]. Early educators want to achieve results in the reform of ECE, so they can learn about the children's experiences, interests, and wants of the objects of education before teaching practice, which is very significant for the improvement of teaching effect [22]. With the advancement of the third phase of ECC reform, many methods and practices in the field of early education have been implemented, but few have achieved success, especially in developing regions of China. New cognition may not necessarily have an impact on traditional teaching methods.

In the exploration of preschool teaching reform, many preschool teachers are not clear about the main purpose of teaching, and the meaning of teaching is rather vague, especially in the complicated and changeable teaching environment at that time [29]. With the development of preschool education reform, preschool education requires higher and higher professional level of preschool teachers. However, the current problem is that the professional level of preschool teachers cannot meet the requirements of preschool education reform, which is the most important problem to be solved in preschool education reform and the key to the success of the reform.

The ultimate goal of the reform is to make both teachers' teaching and students' learning meaningful. As the first contact with children, teachers have the most say in the practicality and effectiveness of the curriculum. Therefore, in the development and implementation of a new curriculum, teachers should also have certain decision-making power, which requires them to achieve more professional levels [30]. The Chinese government is launching actions to promote EC teachers' professional development. One of its views is that EC teachers should participate in school-based research and reflect their own classroom behavior and be able to strike a certain balance between their preset learning tasks and activities of interest to children.

The main problems in the third reform of ECE in Chinese society are that the professional level of early childhood teachers cannot meet the requirements of the latest early childhood teaching level and the number of early childhood teachers is insufficient. To make the teaching reform successful, we must put forward concrete and effective solutions to these two problems. In order to solve these two main problems, the Chinese government has set up three levels of training programs for preschool teachers, namely, the national level, the provincial level, and the municipal level [31]. The kindergarten teachers who receive training have different teaching levels and regions, so different types of training programs should be set up according to different kindergarten teachers' needs. However, at present, most preschool teaching and training programs are not aware of this problem but blindly study the western preschool teacher training courses. As the training courses for preschool teachers are not targeted, the training effect for preschool teachers is not very satisfactory at present. Therefore, there is still a certain gap between the overall professional level of preschool teachers and the professional level required by preschool education reform. The third preschool education reform in China has not achieved obvious results [32].

6. Developing Teacher Leadership as a New Direction for the ECC Reform

At present, as the connection between countries in the world is increasing, if you want to gain an advantage in the competition in this era of globalization, you must make teaching develop with the times. So, countries all over the world have started their own educational reforms. Southeast Asian countries have borrowed the teaching mode of distributed leadership from the ECE reform in western developed countries. It can be seen that teacher leadership is very similar to distributed leadership, which is another form of distributed leadership.

Relevant scholars have found in the exploration of ECE reform that teacher leadership plays a crucial role in the quality of teaching and the success of teaching effect. Although teacher leadership is a decisive factor for the success of teaching, there is no unified explanation for the definition of teacher leadership in the field of early childhood teaching reform. The term "agent" means "a person or group responsible for leading change at the school level." Relevant scholars involved in the reform of ECE think that teachers who are "agents" can be divided into two different leadership roles in performing administrative and teaching duties, namely, formal leadership role and informal leadership role. Teachers' role in schools has been expanded, and they participate in school-related affairs, including curriculum development, staff training, school improvement, personnel affairs, school management, and decision making, instead of being confined to classroom teaching.

Ho Tikly (2012) found that in the process of preschool education reform, preschool teachers who have been receiving professional training have realized their leading role in the education process. However, under the influence of this out-and-out educational reform and innovation and different cultures, at present, the professional level of most preschool teachers still cannot reach the level required by preschool education reform, so there is still a long way to go for the success of preschool education reform in China. This paper holds that promoting the development of teachers' leadership can make preschool teachers change from passive recipients to initiators of preschool education reform, which will achieve more effective results in solving the above problems.

7. Conclusion

Under the guidance of the reform and opening-up policy, the Chinese government has learned from the west, making various fields develop towards diversification. Through the combination of the three ECE reforms and the latest ECE reform and development goals proposed by the Chinese government, the development of preschool teachers' leadership can enable them to have more opportunities to participate in the decision making of teaching reform and thus have more active decision-making power, which has a very significant effect on mobilizing the enthusiasm of preschool teachers. This may be a feasible method for improving the professional level of teachers under the specific cultural soil and era background.

The essential issue in music understanding and dance synthesis research is how to improve the degree of matching between dance motions and music rhythm elements. The matching model of dance movements and music rhythm features is created in this study based on human posture estimation research to tackle the problems that existing matching methods are prone to rapid changes in movements and cannot keep the original movement features. The rhythm properties of movement and music data are first analyzed, and then the degree of matching between movement and music pieces is measured using a dynamic time warping technique. A constraint-based dynamic planning approach is also used to synthesize the dance action sequence that best matches the supplied music. Experiments reveal that this model has a matching accuracy of 95.1 percent, which is higher than the two comparative models' matching accuracy of 5.2 percent and 7.6 percent, respectively. The matching score of this paper is high, reaching around 94 percent, according to the user research results. The method suggested in this work has apparent advantages in that it may efficiently help users in the arrangement of desired dance moves or backing music, and it can be applied in the field of actual choreography and scoring.

1. Introduction

Music, as we all know, has the power to inspire people and to express themselves in various ways. "Rhythm" [1] is the element of music that has absolute appeal to individuals. The duration of music and the intensity of timbre make up rhythm [2]. The length relationship between the action and the time value in the process of completing the dance action is referred to as dance rhythm. Long, short, strong, and weak, and their relationships create dance movements' regularity through alternation, repetition, change, and contrast [3]. You may communicate the rhythm, melody, mode, and emotion of music through dance. Human beings' evolved artistic expression is dance with music. When listening to music, many people may unconsciously dance [4]. Professional dancers will carefully control their dancing with the music based on their previous expertise, in order to more accurately represent the feelings expressed in the song. The emotions portrayed by music in dance might be playful and attractive, gorgeous and elegant, joyous and vibrant, or vigorous and unrestrained, all of which have specific dancing qualities. At the same time, the dancer's mastery of "rhythm" is reflected in his or her sense of rhythm. The dancers' perception and presentation of dance are directly affected by the rhythm. Professional dancers will tightly manage their dancing during a stage performance according to the melody, pace, and intensity of the music, in order to more accurately portray musical feelings through dance. Professional choreographers frequently create tight rules for the synchronization of dance and music. Choreography is a difficult and talented job that requires this type of dance design effort.

Although a skilled dancer can match music and dance movements manually, it takes a lot of time. And compared with the editor of solo dance, everyone's posture in group dance is different, and the editing work will be more complicated. Therefore, it is of practical value to make the computer match the characteristics of dance movements and music rhythm, and its intelligence and automation are of certain practical value to dance arrangement. Action and music are time-series signals of two different perceptual channels. In order to properly evaluate the matching degree between them, it is necessary to establish a reasonable matching model between dance action and music rhythm. Human pose estimation is the basis of many tasks in the computer vision field [5–7]. It involves many disciplines, such as pattern recognition, image processing, computer vision, and artificial intelligence. It can be used in human-computer interaction, motion analysis, motion recognition, and other fields [8, 9]. At present, in the field of human posture estimation, convolutional neural network, as a representative algorithm of deep learning, has the ability of representation learning. Compared with traditional computer vision technology and expert system, it has better performance in target detection and recognition, natural language processing, and other fields. Therefore, this paper applies convolutional neural network to human posture estimation and constructs a matching model between dance movements and music rhythm features based on human posture estimation. Its innovations are as follows:

(1) Based on the motion capture data, this paper constructs a motion database to store the rhythm and intensity characteristics of each motion segment. And in order to synthesize the dance action sequence that best matches the input music, a constraint-based dynamic planning process is introduced. Thereby, improving the matching degree of music and dance features and the smoothness of the resulting action sequence.

(2) The pyramid pool layer is utilized at the end of the feature extraction module to consider the features of multilayer convolution more thoroughly. The attention network based on time dimension features is added after the pooling layer, the relevance weight is added to the features in the video frame, and the weight of the features is updated through iteration of the attention mechanism. Simultaneously, the upgraded 3D network is trained on the input data using various combinations of diverse data, and the best input data format is chosen by assessing the trial outcomes of various groups. Experiments suggest that this strategy can significantly increase the network's accuracy.

2. Related Work

In modern music, the matching of dance movements and musical rhythm features has been widely used in choreography and score, and the practical value of all aspects and the complexity of technology have become a problem worthy of further study. Many scholars have studied the feature analysis and feature matching of dance and music. The research contents and emphases are also different.

Romina et al. first extracted musical features such as rhythm, beat position, and dynamic features, and then controlled the actions of character animations according to predefined feature mapping criteria. This method can realize the synchronization of music and dance movements, but due to the limitation of mapping criteria, the generated dance movements are relatively monotonous, and cannot reflect the intrinsic connection between music and dance [10]. Nabila et al. took the different movement rhythms and bouncing techniques of dance as the research objects, and took the students of a dance art school as the experimental objects; from the various processing methods of the action rhythm, they showed different bouncing techniques, showing different dances or dance styles, and the matching relationship between dance and music was studied [11]. Vincent et al. used machine learning to construct the mapping relationship between movements and music from a database of samples and proposed a method to create dance movements based on the emotion and content of the music [12]. Jola et al. took the rhythm pattern of the movement as the main feature of the movement and combined the speed curves of the hands, feet, and center of gravity of the body when analyzing the rhythm of traditional dance [13]. Yu et al. proposed a rhythmic feature-based action-music matching model. However, the model ignores other features than rhythm, and the generated dance movements need to be improved in terms of globality and coordination [14]. Zhang et al. propose a rhythm analysis method. In this method, the extreme point of joint angular velocity is taken as the candidate point of the segmentation rhythm, and then it is refitted into the action characteristic curve according to the distribution of the candidate points [15]. In terms of music feature analysis, Xue et al. comprehensively analyzed the rhythm of music with features such as note onset, chord change, and drum pattern and used information such as music playback speed and tempo as the main music features [16]. In order to synthesize dance movements, Zhu et al. first analyzed the music and extracted the music beats, and then, based on the original movement database, they used the movement generation method to generate new movement data. The method for music and dance synthesis is based on the beat of the music, ignoring other musical features [17]. Burnett et al. believe that dance is an orderly organization of basic movements according to a certain theme. And by setting several basic movements and scheduling rules to generate music-independent dance sequences, and then editing the dance appropriately when it matches the music [18]. Govindan et al. proposed a method to synthesize music and dance synchronously according to the rhythm and intensity characteristics of movements and music. The main idea is that musical rhythm is strongly correlated with action rhythm, and the musical intensity that represents musical mode is also strongly correlated to the action intensity that represents action strength [19]. Mir et al. proposed a genetic algorithm to match rhythms. The genetic algorithm modifies the movements based on the generated movements to improve dance diversity. This method searches for candidate actions by constructing action graphs in advance, which improves the search efficiency of the choreography system. However, this method only utilizes rhythm matching and does not fully exploit other relevant features of actions and music [20].

This paper makes an in-depth study of related literature, summarizes the shortcomings and advantages, and constructs a matching model of dance movements and music rhythm features based on human posture estimation. Firstly, the underlying features of music and action are extracted, and some feature pairs are excluded by correlation analysis. Then, genetic algorithm is used to optimize and select the corresponding relationship between matching accuracy and operation speed. At the same time, in order to obtain the mapping relationship between movements and music, we train the sample data and get the evaluation function of the matching degree between dance and music. Based on the rhythm and intensity, the feature matching analysis of music segments and action segments is carried out, and according to the rhythm matching, the most matched action segments are screened out for each music segment. Then, connectivity analysis is carried out on adjacent action segments, and a plurality of result action sequences are obtained according to the connectivity, and then the most matched action sequence is obtained according to intensity matching. Finally, the experimental comparison with other different models shows that the performance of this model is better. This method is feasible and practical.

3. Methodology

3.1. Analysis and Extraction of Rhythm Characteristics of Dance and Music. It is a common feature of rhythm, dance, and music. First, select a set of optimal motion and music features, which should be able to reveal the features of motion and music data most effectively, thus facilitating the analysis of the relationship between music and motion. In order to fully tap the local correlation between music and dance and improve the richness of generated dance, this paper does not match the input music directly with the actions in the action database. Instead, the target audio is segmented first, and then feature matching is performed for each music segment and action segment. Therefore, the music needs to be segmented. The average length of the movements and music pieces used in this paper is about 2 seconds. Cutting the data into action segments can not only fully mine the features in finer granularity but also greatly facilitate the reuse of action data.

Assuming that the overall music sequence is denoted as M, after the music is segmented, m music segments are obtained, and denoted as

$$\begin{aligned} &M_1, M_2, \ldots, M_m, \\ &M = [M_1, M_2, \ldots, M_m]. \end{aligned} \tag{1}$$

The extraction of music features is all based on music segments, and the music segments $M_i\,(1 \le i \le m)$ mentioned later all refer to the music segments in the music sequence M. The music features extracted by the music fragment M_i are recorded as

$$\text{Music}\,Feature(f) = \begin{bmatrix} F_R^{\text{Music}}(f) \\ F_I^{\text{Music}}(f) \end{bmatrix} \quad f \in M_i. \tag{2}$$

Among them, f is the frame number of the music segment M_i, and F_R^{Music} and F_I^{Music} are the rhythm and intensity features of the music segment, respectively.

For the vast majority of music segments, the quarter-note position of a music bar is often the starting point of all kinds of notes, and it is also the stress of the music, so the quarter-note position often coincides with the beat position of the notes. Music spectrum analysis provides the basis for music segmentation, music rhythm extraction, and music intensity extraction. Since the feature matching of music and action is based on the common features of music and action, namely rhythm and intensity, it is necessary to extract the rhythm and intensity features of music. In this paper, we adopt the following eight basic audio features: amplitude envelope, spectrum, cepstrum, spectrum histogram, periodicity histogram, fluency pattern, root-mean-square energy, and low-energy rate. The original music signal is a waveform signal in the time domain, but in order to extract richer information of music, such as rhythm and intensity, it is necessary to transform the music signal from the time domain to frequency domain and then analyze it. In order to ensure the stability of music rhythm and match with the internal structure of action bars, this paper only selects 4/4 beats of music pieces, and the music sequence is divided into music nodes according to bars. The map and workflow of this model are shown in Figure 1.

The mannequin used in this paper is a skeleton structure of human body, and the skeleton is composed of joint points that make up the human body. Human joints include head, hip, shoulder, chest, upper limbs, and lower limbs. These joint points constitute the human skeleton model according to the hierarchical relationship, with the hip as the root node, and other joint points are represented by rotation and displacement relative to their parent nodes. The orientation change of the rotation sub-joint point relative to the joint point is defined, and the displacement represents the spatial distance between the joint point and the sub-node. Each of the correlation coefficients may be the clue of the mapping relationship between action and music. However, considering all the coefficients at the same time will bring a very heavy amount of calculation. And some coefficient components will bring noise to the correlation between mining action and music. Therefore, this paper adopts the optimal feature selection algorithm to extract a representative feature subset, which should effectively represent the relationship between action-music and reduce unnecessary noise. Since the feature matching of music and action is based on the common features of music and action and rhythm and intensity, it is necessary to extract the rhythm and intensity features of action. In order to fully mine features in finer granularity and facilitate the reuse of action data, actions are segmented. The action mode is the same as the music segmentation mode above.

The action speed m_velocity of the joint point refers to the displacement of the joint point of the human body in unit time, and its calculation method is as follows:

$$m\_velocity = \frac{f_i(j+1) - f_i(j)}{\Delta t}, \tag{3}$$

wherein, $f_i(j)$ represents the position of the joint point i at the jth frame; $f_i(j+1) - f_i(j)$ represents the position change of the joint point i at the frame j; Δt is the time length

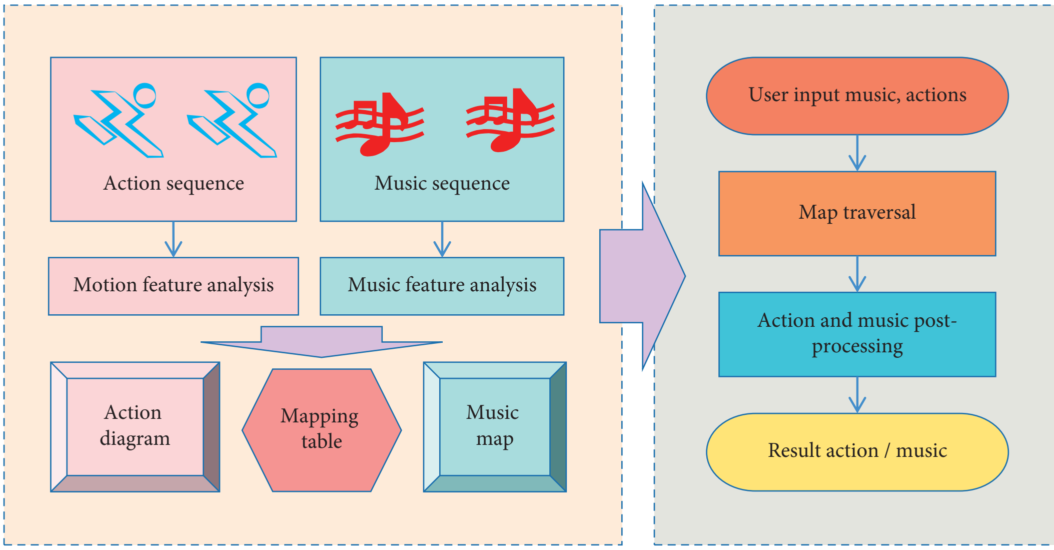

Figure 1: Workflow of the model in this paper.

of the jth frame. The formula for calculating the acceleration of the action is as follows:

$$m\_acceleration = \frac{v_i(j+1) - v_i(j)}{\Delta t}. \tag{4}$$

Among them, $v_i(j)$ represents the velocity of the joint point i at the jth frame. The formula for calculating the action distance is as follows:

$$\begin{aligned} C_i &= \frac{1}{N}\left(\sum_{j=1}^{N} f_i(j)\right), \\ m\_\text{span} &= \sum_{i=2}^{n}\sum_{j=1}^{N}\left|f_i(j) - C_i\right|. \end{aligned} \tag{5}$$

Among them, C_i is the center position of all positions of the ith joint point of the human body in the action clip, N represents the number of frames in the action clip, and n represents the number of joint points used in the human body model.

Because every joint point of an action segment can construct a cosine curve, in order to fully express the characteristics of the whole action, it is necessary to compound the curves of specific joint points that users are interested in, and the compound curve obtained by weighted average of each curve is the whole action curve. Static features are used to describe the pose characteristics of human characters. The static features extracted in this paper include motion spacing, motion density, arm shape, foot footprint, and balance. Traditional rhythm extraction methods that only aim at certain types of dance movements have great limitations. Because the feature extraction of the motion data is preprocessed and stored in the motion database, it can be extracted manually by its suitable rhythm extraction algorithm according to the dance style.

3.2. Construction of the Match Model between Motion and Music Features. Human pose estimation can be simply regarded as the combination of feature extraction [21] and classifier recognition. From preprocessing to feature selection, human motion information is extracted from the underlying data, and then classified by classifier to complete motion recognition. The process of human body motion recognition is the process of acquiring high-level motion information through the underlying data, thus learning the motion characteristics and finally realizing the motion classification. When estimating the human posture, the input data are the video frame sequence, so we need to consider not only the spatial representation of actions but also the sequence of atomic actions in the video frame sequence. There are three types of motion feature extraction based on nondeep learning algorithm: low-level features, middle-level, and high-level features and silhouettes. Low-level features usually refer to spatio-temporal interest points and dense optical flow. And middle-level features, mainly long-term tracking track or semantic representation. The premise of recognizing human movements by silhouette features is to assume that human movements are regarded as a continuous process of body posture. The learning process is extracted from a series of silhouettes, and then the traditional classifier is used to identify human movements. According to different application requirements, some researchers use single-view data, but the results are often vague. Especially in the method based on target silhouette, the system falls into local minima because multiple poses correspond to the same silhouette. Moreover, the traditional 2D convolution network cannot deal with the sequence of atomic actions when dealing with motion recognition in video, which has great limitations. This problem can be solved in 3D convolution network.

Assuming that the neuron has three input values: x_1, x_2, x_3, and the output is as follows:

$$h_{W,b}(x) = f\left(\sum_{i=1}^{3} W_i x_i + b\right), \tag{6}$$

where W_i and b are the neuron parameters at the input and $f(\cdot)$ is the activation function. Sigmoid function

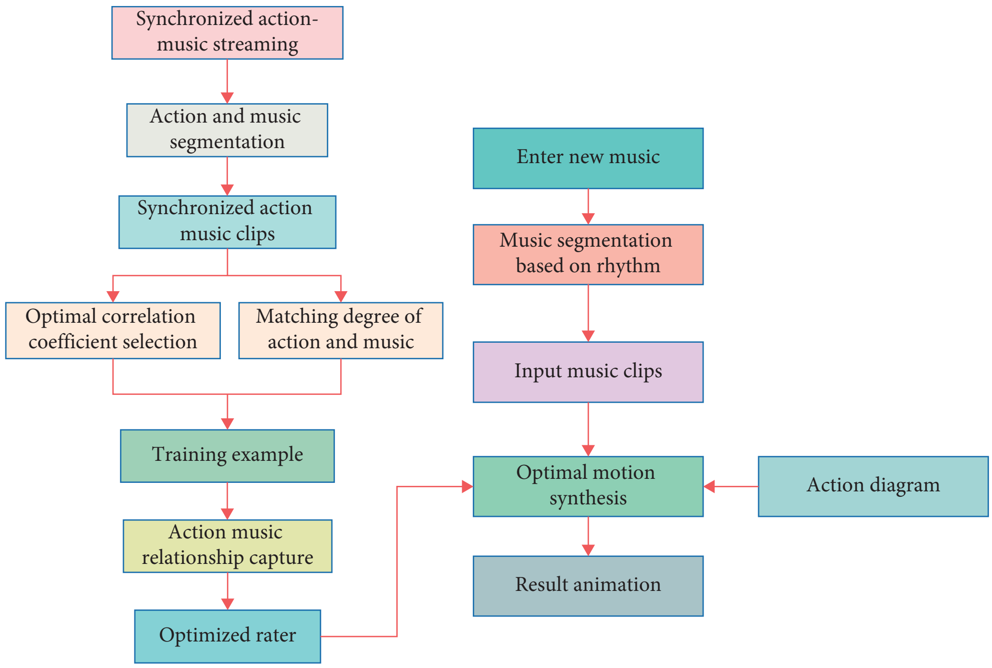

Figure 2: Algorithm flow.

$$\sigma(x) = \frac{1}{1 + \exp(-x)}. \tag{7}$$

Hyperbolic tangent tanh function

$$\tanh(x) = \frac{e^{x} - e^{-x}}{e^{x} + e^{-x}}. \tag{8}$$

The rhythm of the dance is synchronized with the music. Dancers always step on the rhythm points of the music when dancing, similar to clapping and beating, which can be roughly regarded as the coincidence of the stop action and rhythm points of the dancers. For each action and music segment combination, we extract 40 music features and 455 action features. Through correlation analysis, a correlation coefficient can be obtained, which together form a correlation coefficient matrix. Theoretically, the rate of change of eigenvalues can better reflect the development and change of things than the eigenvalues themselves. For a given well-matched action and music piece, the greater the change of the action part, the worse the matching degree with the original music piece. Feature matching is mainly based on rhythm and intensity matching. However, in order to ensure that the action segments can finally be connected into a coherent and natural dance action, it is necessary to analyze the connectability between every two adjacent action segments whose rhythm matches each music segment. In this chapter, the connectability analysis controls the current action and the previous action. When the adjacent action is the same action, the action distance between them is set to infinity, so that when the adjacent action is the same action, the two actions cannot be connected. The algorithm flow is shown in Figure 2.

In order to obtain positive training samples, all matching action-music piece combinations can be selected as positive training samples. We randomly chose a clip from all captured action footage and coupled it with a music clip to collect examples of negative training. The algorithm is used to determine the combination's matching score for each action-music piece combination. We can discover the best matching K music nodes for each action segment by comparing the scores, and these matching results will then be placed in an action-music mapping table. Similarly, a tag is provided for rhythm matching of dance action database with strong rhythm for music.

Let $\{v_{i1}, v_{i2}, \ldots, v_{iK}\}$ and $\{v_{j1}, v_{j2}, \ldots, v_{jK}\}$ be the set of K music nodes that best match u_i and u_j obtained from the map, respectively. Then, the music edges corresponding to u_i and u_j are the directed edges v_{im0} and v_{jn0} with the smallest distance in the music graph in

$$\begin{aligned} v_{im0} &\in \{v_{i1}, v_{i2}, \ldots, v_{iK}\}, \\ v_{jn0} &\in \{v_{j1}, v_{j2}, \ldots, v_{jK}\}. \end{aligned} \tag{9}$$

Therefore, the music nodes v_{im0} and v_{jn0} can be used as the background music corresponding to the action nodes u_i and u_j, respectively. The corresponding dance moves are calculated in the same way. The matching error of the action and the music is estimated as follows:

$$L(A_j, M_j) \triangleq 1 - \exp\left(-\text{Dist}_m\left(M_i, M_j\right)\right). \tag{10}$$

In this paper, we choose a specific correlation coefficient for each dance. The termination condition of feature coefficient selection is that when six new correlation coefficients are allowed to be selected into this subset, the accuracy should be increased by at least 4%. Start with an empty feature subset and add new features to the set until the termination condition is not met. The size setting of threshold is a measure of cohesion and connectivity. If the threshold setting is small, the adjacent actions are very similar, and the cohesion is very coherent, but the connectible action sequences will decrease accordingly. Anyway, if the threshold setting is large, the adjacent actions will be connected without being very similar, resulting in poor connection, but the connectible action sequence will increase accordingly. In addition, threshold setting has different requirements for different action types. Music-action correspondence is a set of music-action feature pairs, which is used for the matching calculation of music and dance. The music features and action features that make up the feature pair are in one-to-one correspondence and have high correlation characteristics.

In order to extract connectible actions based on connectivity, this section proposes a graph-based depth-first traversal algorithm for extracting connectible actions. Each action segment is regarded as a node, and a directed edge is established according to whether adjacent segments are connected or not. If adjacent segments are connectible, a directed edge is established; On the other hand, if the adjacent segments are not connectible, there is no directed edge in the adjacent segments. According to the best matching path of the sequence of motion and music feature points given by this algorithm, the motion (music) segment can be deformed to map the motion (music) feature points to the corresponding music (motion) feature points, thus further improving the matching degree between the motion and music segments.

4. Result Analysis and Discussion

The algorithm proposed in this paper is tested on multiple sequences, including synthetic and real data. The configuration of the experimental platform is Intel Pentium D2.80 GHz CPU, 16 GB memory, and uses QT4.2 and MatLab development environment. Dance sequences were acquired at a frame rate of 30 fps using a motion analysis optical motion capture device. The size of the voxels in the experiment is set to $18 \times 18 \times 18$. The dance movements used are recorded as movement data in BVH format. The data have 65 degrees of freedom, which contain 24 joint points, each joint point has about 2 degrees of freedom. The actions are recorded to the file at a frame rate of 35 frames per second. The accompanying background music is all single-channel music with a sampling frequency of 45 kHz. The sampling rate of the motion data is 35 Hz. The music in WAV audio format is extracted from the video file by the software Adobe Premiere, and the parts without sound at the beginning and end of the video are manually removed. In the experiment, an action graph containing 1069 nodes is constructed, and each node corresponds to an action segment. The total node length is about 726 seconds. The comparison results of the corresponding relationship accuracy of the underlying features and the corresponding relationship accuracy of the high-level statistical features are shown in Table 1.

From the experimental data in Table 1, it can be seen that, compared with the high-level statistical features, using the low-level features to construct the music-action correspondence can get higher accuracy. While the accuracy of

Table 1: Comparison of the accuracy of the corresponding relationship between low-level features and high-level statistical features.

Music number	Low-level feature correspondence accuracy	High-level statistical feature correspondence accuracy		
		SHI	KIM	SMS
1	77.6	67.2	70.9	69.8
2	75.4	60.3	67.5	71.4
3	76.3	64.7	65.9	72.3
4	74.5	71.3	70.5	69.4
5	76.8	68.4	69.7	62.8

the correspondence of high-level statistical feature is relatively low. In order to test the rationality of matching the characteristics of music rhythm and intensity with those of dance movements, several experiments were designed. In order to evaluate the effectiveness of the method proposed in this paper, the F1 index, which can comprehensively reflect the performance of the algorithm is selected to experiment the algorithm in this paper and compare different algorithms, and the result shown in Figure 3.

In practical application, the action map and music map in the action-music map are mostly composed of the same kind of dance, so the matching quality of the result animation created by the system when the action map and music map are constructed by the same kind of dance is evaluated. Every time it is necessary to determine an action segment from the candidate action set, the action segment with the best coherence is the first. Then randomly choose one of them as the action segment of the matching music. All initial postures are chosen from the live dance of motion capture. From the existing music-action database, based on the music similarity and the input music, the music-action data with corresponding matching are obtained, and the path of its action data is extracted as the reference path. When the action map part and music map part of the action-music map are composed of different dance types, the difference of style between the action bar and the music bar may lead to the change of algorithm performance. This paper also evaluates the matching quality for this situation. The accuracy of matching dance movements with music rhythm features by different methods is shown in Figure 4.

The matching action sequences can be counted, and if a certain number of values are reached, the traversal can be terminated. Because every time an adjacent point is visited, the adjacent point with the best rhythm is preferentially visited, so the action sequence obtained in priority matches the rhythm of the input music signal better. This paper puts forward the definition of fluency function and uses quantitative data to objectively analyze the connection between dance movements and music matching. The cohesion of dance movements using different matching methods is shown in Figure 5.

It can be seen that the dance movement cohesion of this matching method is obviously higher than that of the other two methods. Table 2 shows the time performance evaluation in this chapter. In this test, the time performance

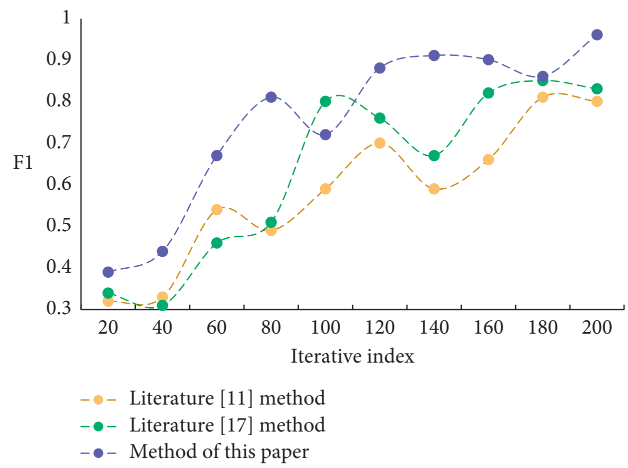

FIGURE 3: F1 value comparison.

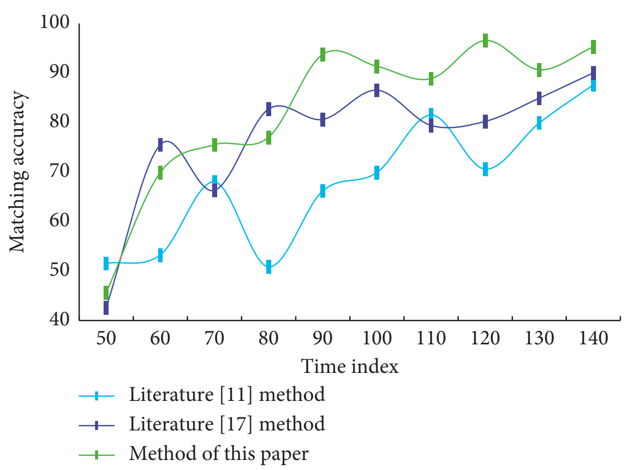

FIGURE 4: Matching accuracy of different methods.

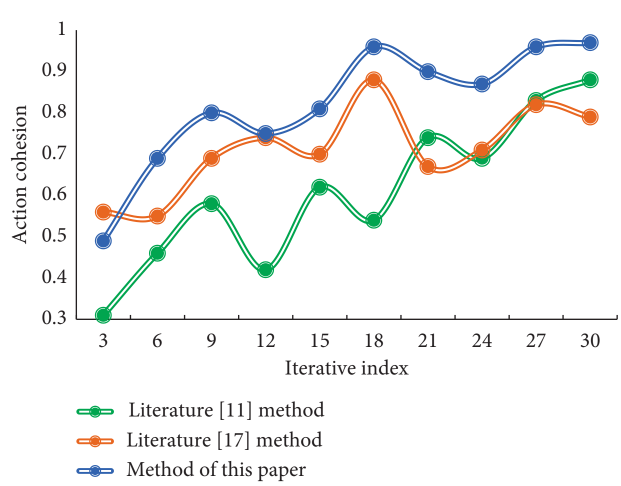

FIGURE 5: Dance movement cohesion results of different matching methods.

differences of the method in reference [11] and the method in reference [17] are compared.

In the methods of literature [11] and literature [17], it is important to traverse the music or action graph for each action or music segment to locate the best matching music node. We simply need to query the map for the best matched node in our function. As a result, our method's search speed is substantially faster than the other two techniques. 150 students were asked to complete a user experience research in order to objectively evaluate and test the model's performance. A user ability test was conducted prior to the experiment to guarantee that the participants could actually identify whether the action matched the music. Experimenters who did not have a strong musical background or who had difficulty appropriately perceiving the movement-music connection were removed. The user research study drew a total of 100 participants. Figure 6 depicts the pleasure of these 100 students with various model matching results.

In order to give more credibility to the evaluation results, we will compare the degree of difference between human and machine ratings. The results of automatic scoring by the algorithm are shown in Figure 7.

From the comprehensive analysis of the data in the two figures, it can be seen that the result of manual scoring is very similar to that of algorithm scoring. This also verifies the reliability of the score and draws the conclusion that the dance movements of this paper match the rhythm features of music to a high degree. According to the experiments in this chapter, the matching accuracy of this model is as high as 95.1%, which is higher than 5.2% and 7.6% of the two comparative models, respectively. This model effectively improves the efficiency and accuracy of the choreography and score system. And the matching score of this paper is high, reaching about 94%. It can be used in the field of actual choreography and score.

5. Conclusions

This is the law according to which rhythmic sequence and movements develop. Based on the estimation of human posture, this paper constructs a feature matching model of dance movements and music rhythm, which solves the problem of matching movements and music well. Firstly, based on the synchronization number of rhythm points of music and dance movements in time, the paper carries out rhythm matching. And in order to ensure the cohesion of adjacent action segments, the connectability analysis of adjacent action segments is made based on the action distance. At the same time, in order to generate the optimal dance action sequence, a dynamic planning process based on constraints is introduced. This process takes into account both the matching degree between actions and music and the coherence degree between actions in the result. The experimental results show that the matching score of this paper is high, reaching about 94%. And the matching accuracy of this model is as high as 95.1%, which is higher than 5.2% and 7.6% of the two comparative models, respectively. From the database point of view, this model effectively improves the efficiency and accuracy of the choreography and score system. The integration of movement and music has always been a difficult problem, which needs to be improved and dealt with at a deeper level. Although some research achievements have been made in this paper, the score algorithm of this paper has not considered enough the harmony of the transition between music pieces, and this content will be studied in depth in the next step.

Under the present background, optimizing the existing urban rail transit network is the focus of urban rail transit construction at present. Based on DL, this paper constructs the optimization algorithm of urban rail transit network route planning. According to the current urban layout and urban planning, build a suitable rail transit network line form; according to the function, the types of urban rail transit stations are divided, and the optimization of urban rail transit network lines is realized. In addition, according to the K short path algorithm, this paper calculates the effective path between any stations of rail transit and, according to the model, allocates the passenger flow to each path. Experimental results show that the accuracy of real-time traffic flow prediction by this algorithm can reach 94.98%, which is about 9% higher than other methods. This algorithm can effectively optimize the route planning of urban rail transit network. This verifies the effectiveness of the route planning optimization algorithm proposed in this paper. Using the algorithm in this paper for line planning can get good real time, rationality, and optimality.

1. Introduction

One of the most serious issues that has plagued cities all over the world, particularly large and medium-sized cities, is traffic congestion. In recent years, the scale of Chinese cities has grown, the urbanization process has accelerated, and urban economic development has progressed rapidly. The number and distance of people's trips have increased as the city has grown and their living standards have improved, and traffic flow has increased significantly [1]. The rationality of urban traffic network layout, the scientificity of line facility configuration, and the effectiveness of network line services are all factors in urban rail transit planning [2]. It is critical to the city's overall development, functional layout, land use, and urban form evolution. Transportation, as an important infrastructure for promoting the exchange of materials and information within urban agglomerations, is critical in providing channels for city internal development and interconnection [3]. Fast transportation has the potential to amplify the power of urban development and connect cities. Network route planning is a subset of overall urban planning that uses the overall urban planning as a guide and, at the same time, has some impact on the overall urban planning due to the characteristics of urban rail transit [4]. It is a comprehensive, long-term, and guiding macro planning that involves many specialties such as urban planning, traffic engineering, rail transit engineering, architectural engineering, and social economy. Furthermore, urban rail transit requires a significant financial investment and a lengthy construction period, all of which have a significant impact on the city's social and economic development, as well as land development and utilization. To do a good job on such a large system project, we need to do overall planning and reasonable arrangements, as well as scientific and reasonable rail transit planning, to lay a good foundation and set the stage for the follow-up work.

Due to the slow construction of rail transit and the lack of practical verification and summary, there have been some problems such as too simple planning content, strong planning color, and poor implementability. At the same time, due to the uncertain factors in the process of urban development, the early planning of some cities can no longer meet the needs of current urban development. Therefore, it is necessary to optimize the urban rail transit network and improve its performance and transportation service capacity. The concept of deep learning (DL) [5, 6] originates from the research of ANN (artificial neural network) [7] and is a new research direction of machine learning [8–10]. ANN is a mathematical model that imitates biological NN (neural network) for distributed parallel information processing [8]. In ANN, neurons connect and interact with each other to form NN. There are different ways of linking neurons in different NN types. The obtained deep network structure of DL contains a large number of neurons, which has more levels and depths than the simple NN structure, so it is intended to study more abstract data representations. The "learning" of DL mainly focuses on the abstract representation of data and finds the essential relationship between variables by constantly mining the internal structure of data. A good data representation can keep the information useful to the learning task, and at the same time, it can eliminate the influence of the change of factors unrelated to the learning task in the input data on the learning performance. DL has the advantages of high model accuracy and simple feature extraction, and it has excellent applications in speech recognition, natural language processing, image recognition, and other fields. In this paper, DL algorithm is applied to the optimization of urban rail transit network route planning, and its innovations are as follows:

(1) Based on the idea that urban rail transit plays a key role in urban traffic, this paper studies the line planning theory of urban rail transit network; based on the analysis of existing practice and research results at home and abroad, and combining theory with practice, this paper puts forward solutions to several common problems in the route planning of urban rail transit network. Based on this, DL theory is used to study the optimization of urban rail transit network, which provides some reference for the optimization of urban rail transit network.

(2) The disequilibrium coefficient of passenger flow distribution in the section is calculated. This paper analyzes the influencing factors of cross section passenger flow from the aspects of network line conditions, land use, passenger factors, and environmental conditions. Based on the calculated cross section passenger flow data, several cyclic DL prediction models with time series as input are established and the parameters are optimized. The verification results show that the algorithm has high prediction accuracy and high running efficiency and meets the requirements of accuracy and timeliness. It provides a brand-new perspective for the route planning algorithm of urban rail transit network.

The main structure of this article is as follows: the first chapter is the introduction. This chapter mainly expounds the research object, background, purpose, and significance of the paper, and summarizes the research methods and the structure of the paper. The second chapter introduces the related research literature of urban rail transit network route planning at home and abroad, and further leads to the research work and research methods of this paper. The third chapter is divided into two parts. Section 3.1 compares and analyzes the development status of rail transit and introduces the related contents of DL. Section 3.2 mainly discusses the optimization algorithm of urban rail transit network route planning based on DL. The fourth chapter is the experimental part. In this chapter, the optimization algorithm of urban rail transit network planning based on DL proposed in this paper is tested and compared with other algorithms. The performance of this algorithm is comprehensively analyzed from the experimental results. The fifth chapter is the summary and outlook. Firstly, it reviews and summarizes the research content of this paper, points out the deficiency and improvement space of the research content, and looks forward to the follow-up research.

2. Related Work

The construction of urban rail system is the basic facilities of a city. It is also a systematic project with large investment and long construction period. At the same time, urban rail transit, as an important part of urban public transport, has a very important impact on urban social economy and land development. Therefore, according to the future development of the city, how to plan a reasonable rail transit network line form, scale, and surrounding land development form has attracted more and more attention from government departments, research institutions, experts, and scholars.

Wang et al. calculated the line density of the rail transit network based on the population density of a city, judged the rationality of the construction scale of its network lines, classified the urban space and the layout of the rail transit network lines, and analyzed the corresponding relationship between the two [11]. Shang et al. studied the vulnerability of urban rail transit systems and the optimization of network resilience [12]. Based on the analysis of the reasonable scale of network lines and its influencing factors, Li et al. took the traffic demand and the service level of network lines as the main influencing factors of the reasonable scale of urban rail transit and carried out a reasonable scale calculation [13]. Ding et al. constructed the probability distribution function of subway passenger flow and analyzed a certain urban rail transit system as an example, showing that the station passenger flow is closely related to the development degree of the surrounding land, industry, commerce, and residence [14]. Xin et al. took the algebraic connectivity as the objective function and the construction cost as the constraint condition, established an optimization model of the urban rail transit network invulnerability, and used the improved particle swarm optimization algorithm to solve the model [15]. Based on the directed connection graph of factors affecting the scale of network lines, Hu et al. obtained the hierarchical structure of factors affecting network lines by establishing an accessibility matrix; the matrix is based on the hierarchical division of influencing factors, and the hierarchical structure of each influencing factor is obtained [16]. Li et al. believed that the overall urban passenger demand is jointly undertaken by the road traffic passenger system and the rail transit passenger system; based on this supply-demand balance principle, a reasonable scale of network lines was calculated [17]. Through in-depth research on the demand relationship of rail transit, Nie et al. came to the conclusion that rail transit demand is concentrated in urban passenger flow corridors [18]. Ding et al. took urban rail transit network construction as the research object and established an urban rail transit network optimization model [19]. The model takes the rationality and accessibility of rail transit lines as constraints and selects the minimum total travel time, the minimum total line length, and the minimum total number of transfers to establish a multiobjective function. Wang et al. believed that urban rail transit planning can be divided into three interrelated problems [20]. The first category is to study the design of rail transit network; the second category is to analyze and forecast rail transit demand; the third category is to evaluate and decide on urban transportation planning. Jeongwoo et al. studied the robustness optimization problem of urban rail transit network under uncertain demand [21]. The research proposes the concept of robustness of rail transit network under uncertain demand and establishes predictable and unpredictable models of uncertain demand.

This paper proposes an optimization algorithm for urban rail transit network route planning based on DL, and analyzes and discusses the design and implementation of the algorithm in detail, based on a thorough review of previous literature. The passenger flow is allocated to each train on each line based on the passengers' arrival and departure times, the cross section passenger flow in the statistical period is calculated, and the stability of its time series is examined in this paper. The historical data information of the corresponding date type is selected as the network's training data for different forecast periods, and the trained LSTM (long short-term memory neural network) model is used to make short-term forecasts of cross section passenger flow, with the forecasting accuracy calculated by each error index to test the model's validity. Experiments show that this algorithm is more feasible and effective than other algorithms, and that it can produce better predictions.

3. Methodology

3.1. DL and Urban Rail Transit Network Route Planning. The concept of DL comes from the study of ANN, and it is a new research direction of machine learning. ANN evolved from biological NN, and a neuron is a nerve cell. Artificial neuron is the most basic unit to process information by using NN. Theoretically, the more parameters a model has, the higher its complexity and capacity, and correspondingly it can complete more complex learning tasks. However, in general, complex models often fall into low training efficiency and are easily over-fitted, so it is difficult to be favored by researchers. Compared with the traditional NN or machine learning, DL is a relatively novel research method and research direction. The advantages of DL are high model accuracy and simple feature extraction [22]. Practice has proved that it has good effects in computer vision, natural language processing, and future trend prediction. In this paper, the DL theory is applied to urban rail transit network route planning, and an optimization algorithm of urban rail transit network route planning based on DL is proposed. The DL model increases the number of nonlinear hidden layers and transforms the original signal layer by layer to obtain new abstract features for subsequent learning tasks. DL, as a major breakthrough in realizing machine learning and accelerating human beings to the era of artificial intelligence, is based on the research in the field of NN. The obtained deep network structure of DL contains a large number of neurons, which has more levels and depths than the simple NN structure, so it is intended to study more abstract data representations. DL is also a multilevel and multistep learning process. In order to better simulate the neuron structure of human brain, more hidden layers are added, and the learned knowledge is transferred layer by layer to achieve the purpose of information stratification and systematic learning. The basic model framework of DL includes convolutional NN, stacked automatic coder, recursive NN, and deep belief network. The NN model is shown in Figure 1.

The urban population has exploded in recent years, and a large number of migrant workers have flooded into cities. Urban traffic faces severe situations and challenges due to frequent exchanges of people and materials. Road congestion, chaotic traffic order, frequent traffic accidents, and traffic environmental pollution are all serious issues in many cities. Because of its large capacity and high speed, rail transit has gradually become the development focus of transportation infrastructure in large cities in this environment. It has been instrumental in resolving traffic congestion in cities and promoting the efficient use of urban land. To fully exploit the leading role of urban rail transit in economic development, it is critical to optimize the existing urban rail transit network and build new lines in the modern environment [23]. Urban rail transit, which includes subways, light rail, monorails, trams, new traffic, and high-speed maglev trains, is referred to as rapid rail transit. Large transportation capacity, high speed, safety, reliability, and punctuality are all common characteristics. It has the ability to travel on wheels and rails on the ground, in the air, and underground. Because of these characteristics, urban rail transit has obvious advantages as a mode of urban transportation. It is especially advanced compared to other modes of public transportation when it comes to resolving traffic congestion in large and medium-sized cities, such as heavy passenger traffic during peak hours. With the rapid development of rail transit and the continuous expansion of rail network lines in recent years, urban rail transit network operation has become a new trend. Because the urban rail transit system serves as a mode of transportation, its transportation service function must be considered. At the same time, it has the nature of a network, and optimizing it solely from one perspective is not comprehensive. The basic types of rail transit usually include subway system, light rail system, suburban railway, monorail system, new transport system, tram, and automatic passenger rapid transit system.

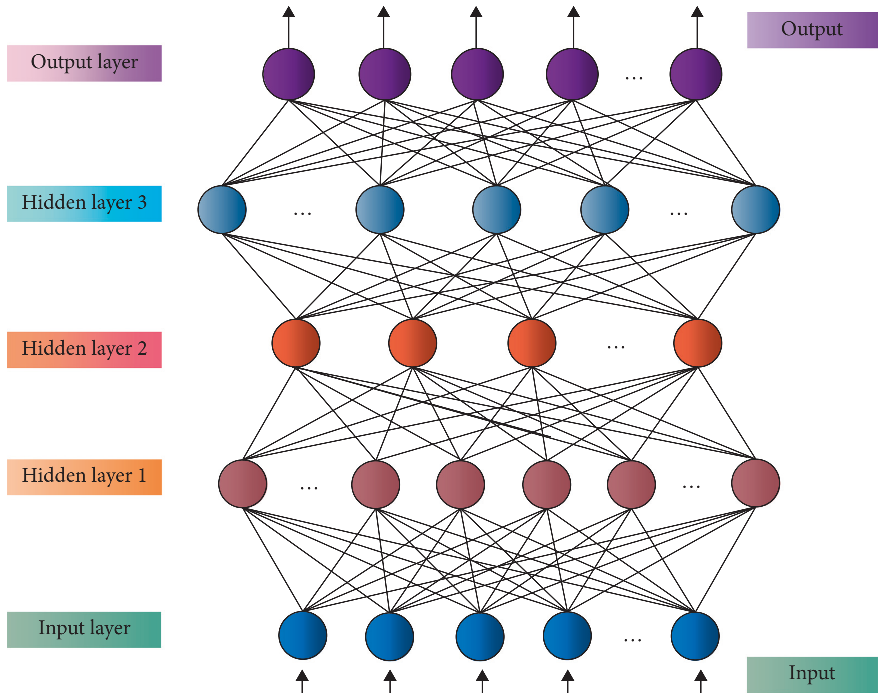

Figure 1: NN model.

In order to reasonably select the form of rail transit system under different objectives, the basic types of urban rail transit can be classified according to different standards.

The main objectives of urban rail transit planning include ① solving the contradiction between traffic demand and supply, ② achieving the goal of urban planning, and ③ meeting the needs of sustainable development. Rail transit can guide the development of urban structure, and its principle is to greatly improve the traffic supply and guide the high-intensity utilization of surrounding land. Urban rail transit with large capacity, high speed, and independent dedicated track has already met the conditions as the backbone transportation mode of public transportation system in big cities. The backbone system is to undertake a large proportion of urban passenger transport turnover [24]. It is generally difficult for a single rail transit line to meet this backbone requirement; this is mainly because of the limitations of its attracting range of passenger flow and route direction. Therefore, rail transit must form a network to play a key role. The research of network planning involves many specialties such as urban planning, traffic engineering, rail transit engineering, architectural engineering, and social economy. It is a comprehensive, long-term, and guiding macro planning. It emphasizes the unity of stability and flexibility. Stability is to plan that the overall layout of network lines should be stable in space, central city, and time; flexibility is the extension condition of planning. Under the condition of constantly changing urban conditions, there should be room for flexible changes in the outer urban areas in space and in the long term in time. In the planning of urban rail transit, the principles of functionality, rationality, economy, and sustainable development must be followed. There are actually three ways of urban rail transit lines: elevated, ground, and underground. They all have their advantages and disadvantages. In addition, the determination of standards such as curve and slope also needs to consider the specific conditions of the line. An important part of the route planning is the station planning and site selection, which needs to consider the station attraction, station form, station spacing, cost, and other aspects. The location of depot is also an important part of route planning. It requires the approach to the trunk line as much as possible and the necessary land conditions. Urban rail transit has a huge investment and a long construction period, which has a great influence on the social and economic development of the city, land development and utilization, etc. However, due to the uncertain factors in the process of urban development, the early planning of some cities can no longer meet the needs of current urban development. Therefore, it is necessary to optimize the urban rail transit network and improve its performance and transportation service capacity.

3.2. Optimization Algorithm of Urban Rail Transit Network Route Planning. Through DL-related content, this chapter focuses on the optimization algorithm for urban rail transit network route planning. The neuron model is the most fundamental unit in NN. According to the training data set, the NN learning process adjusts the connection weight between neurons as well as the threshold or bias of each functional neuron. NN can fit any nonlinear system, even if it only has one hidden layer. As a result, only one hidden layer is typically employed. After comparing and analyzing the fitting results of multiple hidden layers and a single hidden layer, it was discovered that the fitting results are not significantly different, so the reasonable scale of urban rail transit was calculated and analyzed using NN with three layers, including one hidden layer. However, as the prediction time step is increased, the influence of the previous time node on the current time node diminishes, and when information from a distant time node is needed in the model, the network model is unable to effectively reflect this connection; the learning ability is greatly weakened, the gradient disappears, and the model's prediction effect deteriorates. Therefore, LSTM is introduced in this paper. The LSTM structure and algorithm flowchart are shown in Figure 2.

In this paper, the SpaceL method is used to construct the urban rail transit network model. In the model, the nodes represent the urban rail transit stations and the connecting edges represent the interval routes. Transformation of rail transit network diagram into mathematical model is as follows:

$$G = (V, E). \tag{1}$$

Among them, V represents the set of nodes. If the rail transit includes n stations, there are

$$\begin{aligned} |V| &= \mathrm{nV} \\ &= (v_1, v_2, v_3, \ldots, v_n). \end{aligned} \tag{2}$$

E represents the set of edges. If the rail transit includes m section routes, there are

$$\begin{aligned} |E| &= \mathrm{mE} \\ &= (e_1, e_2, e_3, \ldots, e_m). \end{aligned} \tag{3}$$

In a subway network, a passenger travel path consists of stations and segments, and the base travel time for a path is equal to the inbound time, ride time, outbound time, and if transfers are involved, plus the sum of the transfer times. Let C_w^k denote the total time spent by most passengers traveling on the k th route between the traffic trip volume pair W, then

$$C_k^w = J_o + \sum_{i,j} T_{i,j}\delta_{ij,k}^w + \sum_i e_i^{l,m}\phi_{i,lm}^{w,k} + K_d, \tag{4}$$

where J_o represents the inbound time spent by passengers at the starting station on the route and K_d represents the exit time spent by passengers at the end station on the route. $\delta_{ij,k}^w$ and $\phi_{i,lm}^{w,k}$ are the relationship between the unit interval $[i, j]$, the transfer station i, and the traffic travel volume in the subway network to the path k between W.

Based on the idea of importance contribution matrix, this paper combines the structural holes and centrality features of the network to identify key sites. The K-kernel importance is used to describe the role of nodes in the network information dissemination, and the structural hole importance index and K-kernel importance index of adjacent nodes are used as the importance contribution values to reflect the local importance.

In the hidden layer of the LSTM model, the complexity of the hidden layer is increased due to the addition of three gate structures. Three different gate structures interact inside the hidden layer in a very specific way. The first structure is simpler and is often referred to as the forget gate. The input of the gate structure is the output of the hidden layer of the previous time node and the input of the hidden layer of the current node. The activation function of the gate structure is σ, and the output result is $f^{(t)}$, which is sent to the upper part to interact with the $C^{(t)}$ of the previous hidden layer. The forget gate structure can be expressed by the following formula:

$$C_k^w = J_o + \sum_{i,j} T_{i,j}\delta_{ij,k}^w + \sum_i e_i^{l,m}\phi_{i,lm}^{w,k} + K_d. \tag{5}$$

Among them, σ represents the activation function of the forget gate structure, which is the sigmoid function. W_f, U_f, and b_f represent the weight parameters and biases in the forget gate structure, respectively. The middle structure is called the input gate, and the input gate structure can be expressed as

$$\begin{aligned} i^{(t)} &= \sigma\left(W_i * h^{(t-1)} + U_i * x^{(t)} + b_i\right), \\ \widetilde{C^{(t)}} &= \tanh\left(W_c * h^{(t-1)} + U_c * x^{(t)} + b_c\right), \end{aligned} \tag{6}$$

where σ represents the activation function of the first part of the input gate. W_i, U_i, W_c, U_c, b_i, and b_c represent the weight parameters and biases of the corresponding parts, respectively. The last gate is called the output gate. The output gate structure can be expressed as

$$\begin{aligned} o^{(t)} &= \sigma\left(W_o * h^{(t-1)} + U_o * x^{(t)} + b_o\right), \\ h^{(t)} &= o^{(t)} * \tanh\left(C^{(t)}\right), \end{aligned} \tag{7}$$

where σ represents the activation function of the first part of the output gate. W_o, U_o, and b_o represent the weight parameters and bias of the output gate, respectively. The normalization formula of the indicator data is as follows:

$$y = \left(y_{\max} - y_{\min}\right) * \frac{\left(x - x_{\min}\right)}{\left(x_{\max} - x_{\min}\right)} + y_{\min}. \tag{8}$$

Among them, $y_{\min} = -1$ and $y_{\max} = 1$.

In this paper, a method for processing input real-number data using Gaussian distribution characteristics is presented, allowing the newly constructed deep belief network to process the experimental data effectively. Because each impact index has a different physical meaning and no uniform dimensional unit, it is difficult to get a satisfactory answer directly using the impact index as an input quantity, which will slow the network's convergence. This study applies dimensional processing to the data in order to make the indexes comparable. In general, due to the large range of collected data, it is generally required that the value of input data be between [−1, 1] in order to improve training speed and effectively avoid the saturation area of the sigmoid function. The DL feature extraction process can ignore the complex coupling relationship between urban rail transit vehicle equipment systems and the complex functional relationship between feature vectors, mine the data's internal structure, and find the essential relationship between variables. Robustness refers to the system's ability to provide alternate routes in the event of accidents or targeted attacks, and it is one of the key indicators used to assess the rail transit system's quality. The system's robustness is conducive to improving the urban rail transit system's reliability, service quality, and resilience, allowing it to fully exploit rail transit's

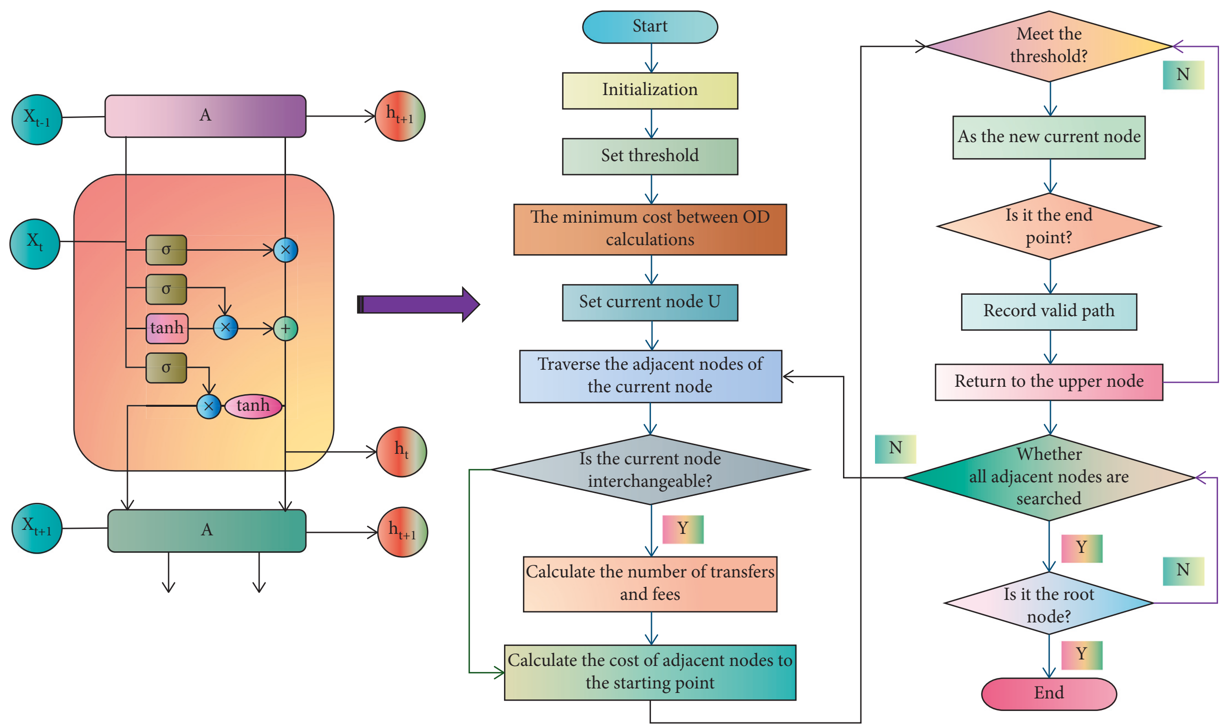

FIGURE 2: LSTM structure and algorithm flowchart.

obvious advantages. The LSTM model goes through the same training and optimization process as the NN model. To iteratively update all parameters in the model, it also uses a time-based back propagation algorithm and the gradient descent method. All of the parameters are based on partial derivatives of the loss function, which is the most important point. The network is trained and tested in a circular fashion in this paper, with the reasonable error range as the final error range. Finally, all of the remaining cities serve as training samples and models, with the trained models being used to research urban rail transit network route planning.

4. Result Analysis and Discussion

The model training platform is Windows 10, equipped with Intel 8-core CPU; memory is 32G. Python is chosen as the main programming language. TensorFlow framework in Keras not only has good usability and practicability, but also has flexibility and high efficiency, fast training speed, and flexible parameter change. It can provide corresponding operation support on multiple platforms. Therefore, this paper chooses TensorFlow in Keras as the back-end framework of DL model. After analysis and screening, 40 cities with developed urban rail transit were selected for analysis and research, and finally 12 representative cities were selected as samples for experiment. Then, the model parameters and targets are selected to be digitized. In order to get more accurate results and reasonable error range, 2 cities are selected as test samples from 12 cities, and the remaining cities are used as training samples. Run the program and record the error. Figure 3 shows the training results of the model.

In this study, the results obtained for the established predictive model are numerical data. Therefore, this chapter selects the representative MSE (mean squared error), RMSE (root mean square error), and MAE (mean absolute error) three indicators to test the algorithm, respectively. The calculation formulas of the three indicators are as follows:

$$\begin{aligned} \text{MSE} &= \frac{1}{n}\sum_{k=1}^{n}\left(y_k - y_k'\right)^2, \\ \text{RMSE} &= \sqrt{\frac{1}{n}\sum_{k=1}^{n}\left(\left|y_k - y_k'\right|\right)^2}, \\ \text{MAE} &= \frac{1}{n}\sum_{k=1}^{n}\left|y_k - y_k'\right|. \end{aligned} \tag{9}$$

Among them, n represents the number of predicted samples, y_k is the actual value, and y_k' is the model output value. The prediction accuracy evaluation methods of the three models are suitable for DL models. By comparing the evaluation indexes among different models, we can roughly understand the performance of the models. These three indexes are used to test different algorithms, and the results are shown in Table 1.

It can be seen from the data in the table that the errors of the optimization algorithm of urban rail transit network route planning in this paper are smaller than those of the comparison algorithm, and their values are at a low level. This shows the accuracy and reliability of this algorithm. Figure 4 shows the recall results of different

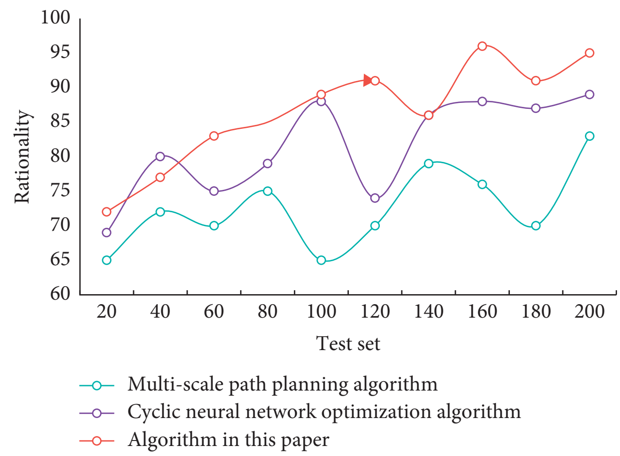

FIGURE 6: Comparison of rationality of planning with different methods.

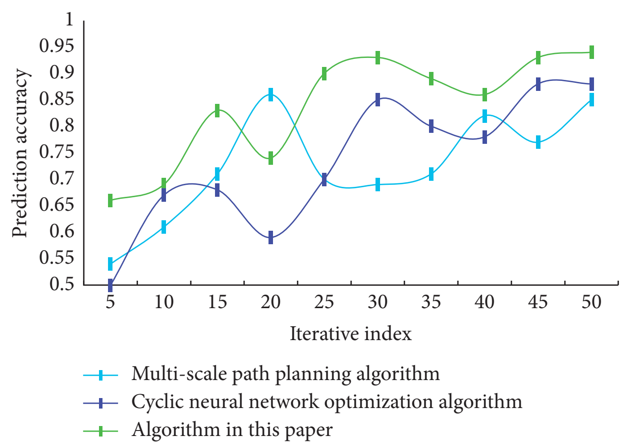

FIGURE 7: Accuracy of traffic flow prediction of different algorithms.

TABLE 2: Execution time of different algorithms.

Group	Starting point	Target point	Multiscale path planning algorithm	Cyclic neural network optimization algorithm	Algorithm in this paper
1	396	3678	894	136	81
2	579	3541	1103	94	46
3	863	2796	1039	87	51
4	827	3024	1004	98	58
5	978	4169	936	86	29

algorithms. Figure 5 shows the F1 values of different algorithms.

The existing saturation of rail transit of each sample is taken as the output target value of NN, and the training sample and the inspection sample should be representative. Through training and learning, the network adapts to the nonlinear mapping relationship between the input sample and the target value, and then it is used for simulation calculation. Test the rationality of using different algorithms for urban rail transit network route planning. The rationality comparison is shown in Figure 6.

The prediction results of several DL models are compared one by one according to the same evaluation index, among which the traditional time series prediction method and autoregressive summation average model are added to achieve the effect of horizontal comparison. The traffic flow prediction accuracy of different algorithms is shown in Figure 7.

According to the data in Figure 7, the accuracy rate of real-time traffic flow prediction by this algorithm can reach 94.98%, which is about 9% higher than other methods. The prediction results and accuracy prove the rationality and effectiveness of the proposed prediction method. This paper simulates the actual traffic conditions. Table 2 shows the comparison results of execution time of different algorithms.

It can be seen that under the same conditions, the execution time of the route planning optimization algorithm in this paper is short. This shows that the algorithm in this paper has higher efficiency and better performance.

Experiments in this chapter show that the accuracy rate of real-time traffic flow prediction by this algorithm can reach 94.98%, which is about 9% higher than other methods. This verifies the real time, rationality, and optimality of the proposed algorithm, which can reduce the management cost and obtain a higher input-output ratio. The algorithm proposed in this paper can achieve good results in the route planning of urban rail transit network.

5. Conclusions

Congestion is a major issue in today's major cities, and there are numerous solutions available. Construction of fast, large-capacity, safe, and environmentally friendly urban rail transit has almost become the default option for all major cities looking to alleviate traffic congestion. As a result, systematically analyzing and studying the functional positioning of urban rail transit network lines in the urban agglomeration regional rail transit system, integrating the regional rail transit system, and comprehensively planning and optimizing the network line layout in conjunction with the urban spatial structure and personnel travel characteristics are critical. It can effectively promote the formation of a regional high-speed comprehensive transportation system, ease people's travel, reduce traffic congestion, and lay a solid foundation for good urban traffic development. This paper proposes an optimization algorithm based on DL to address the low rationality and optimality of traditional urban rail transit network route planning. This paper describes the algorithm's design and implementation. The accuracy of this algorithm in predicting real-time traffic flow can reach 94.98 percent, which is about 9% higher than other methods, according to experimental results. This validates the proposed algorithm's real time, rationality, and optimality, lowering management costs and increasing the input-output ratio. The content of the urban rail transit mode is complex, involving a wide range of variables and numerous influencing factors. Despite the fact that this paper has made some progress in the theory and practice of urban rail transit network route planning, due to a lack of knowledge and time, there are still some issues that need to be addressed. We will expand the sample data set while appropriately deepening the model's depth, and we will determine the parameters in the model by distinguishing the samples during the week and at the weekend in the follow-up study in order to make the prediction model more applicable.

Academic Editor: Xin Ning

Face mask-wearing detection is of great significance for safety protection during the epidemic. Aiming at the problem of low detection accuracy due to the problems of occlusion, complex illumination, and density in mask-wearing detection, this paper proposes a neural network model based on the loss function and attention mechanism for mask-wearing detection in complex environments. Based on YOLOv5s, we first introduce an attention mechanism in the feature fusion process to improve feature utilization, study the effect of different attention mechanisms (CBAM, SE, and CA) on improving deep network models, and then explore the influence of different bounding box loss functions (GIoU, CIoU, and DIoU) on mask-wearing recognition. CIoU is used as the frame regression loss function to improve the positioning accuracy. By collecting 7,958 mask-wearing images and a large number of images of people without masks as a dataset and using YOLOv5s as the benchmark model, the mAP of the model proposed in the paper reached 90.96% on the validation set, which is significantly better than the traditional deep learning method. Mask-wearing detection is carried out in a real environment, and the experimental results of the proposed method can meet the daily detection requirements.

1. Introduction

The spread of COVID-19 endangers public safety, and its known transmission routes mainly include droplet transmission and close contact. Therefore, wearing masks has become the main means of preventing the spread of the virus [1, 2]. The traditional methods of inspecting mask-wearing are mostly manual inspections, which not only consume manpower and material resources and are inefficient but also cause certain difficulties in personnel management, which is more likely to cause crowds to gather and increase the risk of virus spread.

Mask-wearing detection technology is one of the key prevention means supervised by epidemic prevention departments, and the stability and robustness of mask detection algorithms are particularly important. Mask-wearing detection is developed based on face detection and target classification. Compared with simple face detection, mask-wearing detection needs to address many problems, such as different lighting, side faces, occlusion, and density. However, solving these problems and improving mask-wearing detection accuracy are of great significance [3, 4].

With the development of deep learning technology, mask-wearing detection technology based on deep learning has been widely used [5, 6]. However, due to the influence of a complex environment, the existing algorithms have the problems of low accuracy and slow detection speed, which cannot achieve real-time detection. To this end, based on the YOLOv5 model, this paper introduces an attention mechanism to selectively enhance the fused features, highlight important features, reduce the impact of redundant features, and use the CIoU loss function as a new bounding regression loss function to make the regression of the target model more documented and the positioning more accurate. The main contributions of the paper are as follows:

(1) Study the effect of different attention mechanisms (CBAM, SE, and CA) on improving the deep network model.

(2) Explore the impact of different bounding box loss functions (GIoU, CIoU, and DIoU) on mask-wearing recognition.

The rest of the content is arranged as follows: Section 2 introduces the work related to mask-wearing detection. Section 3 focuses on describing the framework and implementation details of the mask-wearing detection model. Section 4 verifies the performance of the proposed method through experimental tests and finally gives a summary and outlook.

2. Related Works

Mask-wearing detection is an object detection task that determines the location and category of each object in the image. Mask-wearing detection methods based on deep learning are divided into two categories. One is a two-stage target detection model based on region extraction, such as RCNN (regions convolutional neural networks) [7], Fast R-CNN [8], Faster R- CNN [9], R-FCN [10], Cascade R-CNN [11], and DeRPN [12], which divide the target detection into two steps: feature extraction and feature classification. The other is to obtain the classification results directly based on the regression method, which can realize real-time detection in terms of detection speed, but it is slightly insufficient in detection accuracy, such as SSD (single shot multibox detector) [13], YOLO (you only look once) [14, 15] series, RetinaNet [16], and RefineDet [17]. Recently, researchers have proposed various mask-wearing detection technologies based on the above methods. Fan and Jiang [18] proposed a high-performance single-stage mask-wearing detector named RetinaFaceMask, which includes a new dataset, a contextual attention module, and transfer learning. Jignesh Chowdary et al. [19] proposed a transfer learning model to automatically detect mask-wearing, which was performed by fine-tuning the pretrained InceptionV3 model. Rahman et al. [20] proposed a system to limit the growth of COVID-19 by using deep learning models and cameras to discover people who are not wearing masks in urban networks. Loey et al. [21] proposed a hybrid model based on deep learning and classical machine learning, including two parts: the first part uses ResNet50 for feature extraction, and the second part uses SVM and ensemble algorithms for classification. Ren and Liu [22] designed a YOLOv3-based convolutional neural network named Face_mask Net.

Attention mechanisms have achieved great success in various computer vision tasks [23]. The purpose of introducing an attention mechanism is to select key information from many redundant pieces of information to submit the detection ability of the network. Attention-based models include four stages in the field of computer vision: combining deep neural networks with attention mechanisms, representative methods include RAM [24]; in explicit prediction of discriminative input features, representative methods include STN [24, 25] and DCN [26]; to implicitly and adaptively predict potential key features, representative methods are SENet [27], CBAM [28], and CA [29]; attention methods are related to the self-attention mechanism, and the representative methods are nonlocal [30] and ViT [31]. Attention mechanisms are also divided into channel attention, spatial attention, temporal attention, branch attention, and multiple class mixing methods.

Bounding box regression is a mainstream technique in object detection that uses a rectangular bounding box to predict the location of the target object in the image, aiming to refine the predicted bounding box location. Bounding box regression adopts the overlapping area between the predicted bounding box and the ground-truth bounding box as the loss function, which is called the IoU-based loss function. Deep learning optimization suffers when the predicted and ground-truth bounding boxes do not intersect. GIoU [32] is an improvement on IoU. While maintaining the advantages of IoU, it also addresses other non-overlapping regions, reflecting the degree of overlap between the two to a certain extent. DIoU [33] considers the overlapping area and the center point distance. When the target frame wraps the prediction frame, it directly measures the distance between the two frames, so the convergence is faster. Based on DIoU, CIoU uses the aspect ratio of the prediction box and the target box as an impact factor. Alpha-IoU [34] can significantly outperform existing IoU-based losses and is more robust to small datasets and noise. Aiming at the problem of dense targets in mask recognition, Zhang et al. [35] proposed to learn the IoU-Aware classification score and design a new loss function named Varfocal Loss to propose a new bounding box feature representation method for prediction and boundary refinement. At the same time, real-time mask-wearing detection [36, 37] and transfer learning methods [38–40] have been widely studied. For example, Mahmoud et al. [36] proposed a real-time feature extraction module based on deep convolutional neural network. Xu [37] proposed a lightweight YOLOv5 model and used alpha-CIoU as the loss function. Mercaldo and Santone [38] proposed a transfer learning method that uses the MobileNetV2 model to identify illegal mask-wearing behaviors in videos. Su et al. [39] proposed a mask-wearing recognition method that integrates transfer learning and Efcient-Yolov3, using EfcientNet as the backbone network and CIoU as the loss function.

3. Methodology

3.1. Improved YOLOv5. YOLOv5 is a representative of a single-stage detection model, which has the advantages of fast speed and high accuracy. Compared with YOLOv4, the model has fewer parameters, simple operation, and easier transplantation to the mobile terminal. It was proposed by Ultralytics in May, 2020. There are four network models, namely, YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x. Among them, YOLOv5s has the smallest network depth and feature map width, and the other three models are continuously deepened and widened based on YOLOv5s.

Based on YOLOv5s, this paper adds the CBAM attention mechanism in the feature fusion process to improve feature utilization and uses CIoU as the bounding loss function to improve the positioning accuracy. The model structure is shown in Figure 1. The improved model is the same as the traditional YOLOv5s, including four parts: input, backbone, neck, and prediction:

(1) The input includes an adaptive anchor box and an adaptive image scaling.

(2) The backbone includes the focus module and the CSP module. The slicing operation in the focus module reduces the number of computations and improves the speed while realizing downsampling. The CSP module is beneficial for improving the network learning ability and reducing the memory cost. Two structures, CSP1 and CSP2, are designed in YOLOv5s. The CSP1 structure and the CSP2 structure are applied to the backbone and neck networks, respectively, to further speed up the inference speed of the network model.

(3) The core of the neck adopts FPN and PAN structures. The FPN and PAN structures realize the fusion and complementation of high-level features and low-level features. FPN is top-down and uses upsampling process to transfer and fuse the new type to obtain the predicted feature map. The PAN adopts a bottom-up feature pyramid. In this paper, CBAM is introduced into FPN, and the fused feature map is sent to CBAM to reduce the influence of redundant features after fusion.

(4) The prediction includes the bounding box loss function and nonmaximum suppression (NMS). In this paper, CIoU is used as the loss function to locate the target box more accurately. In the target detection prediction result processing stage, the optimal target frame is obtained by using the weighted NMS operation for screening numerous target frames.

3.2. Attention Mechanism. The convolutional block attention module (CBAM) is a lightweight convolutional attention module that combines channel and spatial attention mechanism modules. CBAM includes two submodules, the channel attention module (CAM) and the partial attention module (SAM), which perform channel and spatial attention, respectively. This not only saves parameters and computing power but also ensures that it can be integrated into the existing network architecture as a plug-and-play module. CAM is an adjustment to the structure of the SE module. Based on the SE module, a global maximum pooling operation is added to the CAM. CAM compresses the feature map into a one-dimensional vector in the spatial dimension, uses global average pooling and global maximum pooling to aggregate the feature information of the spatial map, and performs an element-by-element sum operation on the results by sharing the fully connected layer. The structure setting of the double pooling operation can make the extracted high-level features richer and provide more detailed information. SAM performs the concatenating operation on the result of the CAM operation based on the channel and performs single-channel dimensionality reduction through convolution. Similar to CAM, SAM adopts a double pooling operation. CBAM is similar to the SE module. The module structure mostly uses a 1×1 convolution to operate and completes the information extraction of the feature map through the entire channel dimension of the SAM, as shown in Figure 2.

Since the CBAM model adds a global maximum pooling operation to the CAM, it can make up for the information lost by the global average pooling to a certain extent. In addition, the generated 2D spatial attention map is encoded using a convolutional layer with a kernel size of 7, and a larger kernel is good for preserving important spatial regions. The YOLOv5s network with CBAM added can not only classify and identify the target more accurately but also locate the target more accurately.

3.3. Complete-IoU. The loss function of the target detection task consists of two parts: classification loss and bounding box regression loss. The most commonly used bounding box regression loss is IoU and its improved algorithm. The full name of the IoU algorithm is the intersection and union ratio, which is obtained by calculating the ratio of the intersection and union of the predicted box and ground-truth box, that is, $\mathrm{IoU}(A,B) = (A \cap B)/(A \cap B)$, where A is the predicted box and B is the ground-truth box. IoU can be used as the distance; then, $\mathrm{Loss}_{\mathrm{IoU}} = 1 - \mathrm{IoU}$. The advantage of IoU is that it can reflect the detection effect between the predicted box and the ground-truth box. IoU has two disadvantages: when the prediction bounding box and the ground-truth bounding box do not intersect and $\mathrm{IoU}(A,B) = 0$, the distance between A and B cannot be reflected. At this time, the loss function is not steerable and IoU loss cannot optimize the situation where the two bounding boxes do not intersect. Assuming that the sizes of the prediction bounding box and the ground-truth bounding box are determined, as long as the intersection value of the two boxes is determined and their IoU values are the same, the IoU value cannot reflect how the two boxes intersect. To this end, the paper adopts the CIoU loss function, and its formula is as follows:

$$\begin{aligned}
\mathrm{IoU} &= \mathrm{IoU} - \left(\frac{p^2\left(b, b^{gt}\right)}{c^2} + \alpha v\right),\\
\mathrm{Loss} &= 1 - \mathrm{IoU} + \left(\frac{p^2\left(b, b^{gt}\right)}{c^2} + \alpha v\right),\\
v &= \frac{4}{\pi^2}\left(\arctan\frac{w^{gt}}{\pi^{gt}} - \arctan\frac{w^2}{h}\right),\\
\alpha &= \frac{v}{(1 - \mathrm{IoU}) + v},
\end{aligned} \tag{1}$$

where b and b^{gt} represent the center points of prediction box B and ground-truth box B^{gt}, respectively, c represents the square of the diagonal length of the minimum bounding box C, p represents the calculation of the Euclidean distance between the two center points, α is the weight parameter, and v is used to measure the similarity of the aspect ratio. In addition, it can be seen that the CIoU loss function not only

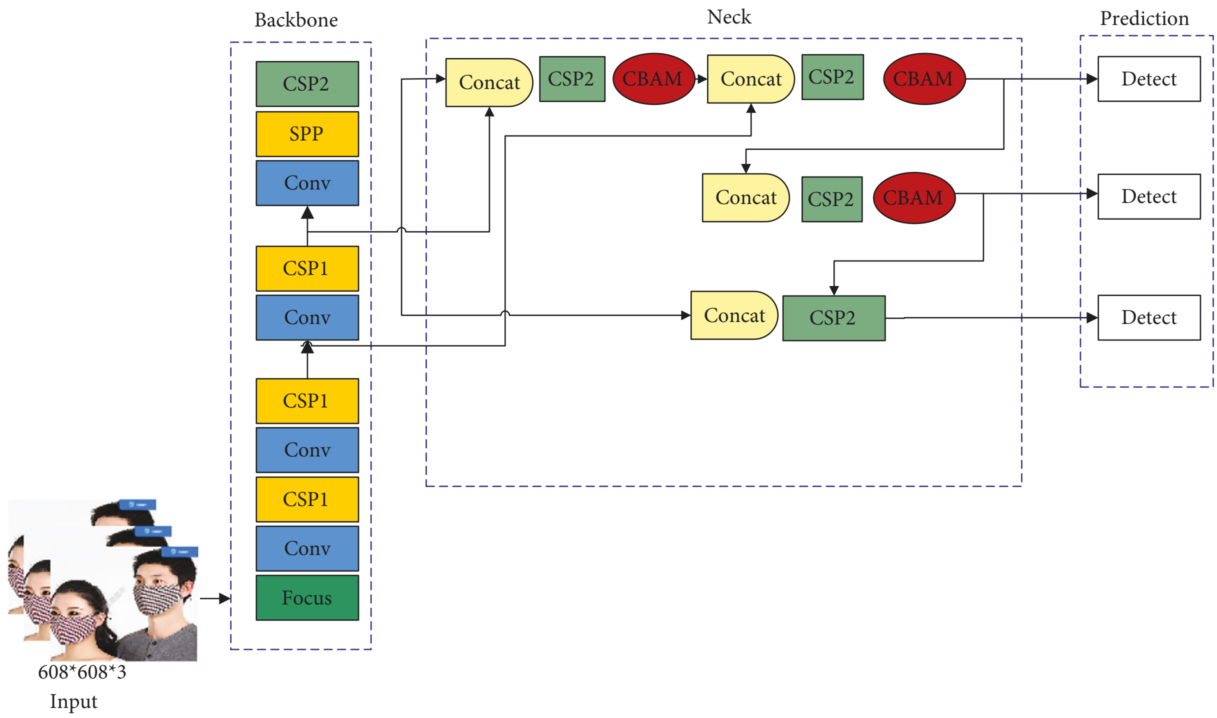

Figure 1: The proposed model network structure.

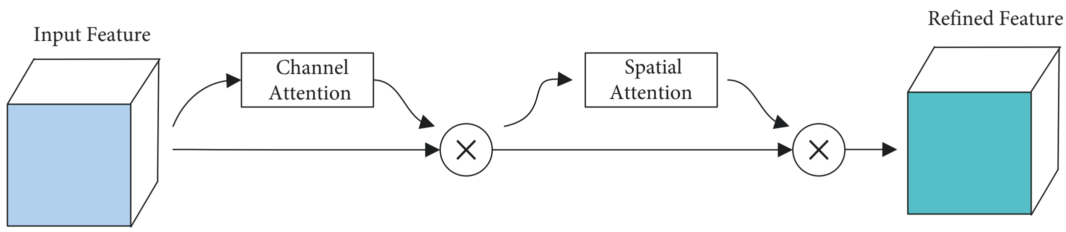

Figure 2: Convolutional block attention module.

considers the overlapping area of the predicted frame and the real frame but also considers the distance between the center points and the aspect ratio of the two. Therefore, in the mask-wearing detection environment, the performance is better than other loss functions.

4. Experimental Results

4.1. Experimental Data and Environment. The paper collects 7,958 pictures of people wearing masks and not wearing masks in the network and real scenes as a dataset, including 7,158 training sets and 800 test sets. The ratio of the training set and test set is 9 : 1, and 0 and 1 are used to label the two categories. The sample images are shown in Figure 3.

The experimental environment of this paper was completed on the Ubuntu18.04 operating system. The GPU model is an NVIDIA GeForce RTX3060 12G, and the software environment is CUDA11 and PyTorch 1.7.

4.2. Evaluation Standard. In this paper, the precision rate, recall rate, average precision (AP), and mean average precision (mAP@0.5) are used as model accuracy evaluation indicators, where AP represents the area under the PR curve and mAP@0.5 represents the average precision (AP) of all categories when IoU is set to 0.5. The specific formula is as follows:

$$\begin{aligned} \text{precision} &= \frac{\text{TP}}{(\text{TP}+\text{FP})}, \\ \text{recall} &= \frac{\text{TP}}{(\text{TP}+\text{FN})}, \\ \text{AP} &= \int_0^1 PdR, \\ \text{mAP} &= \frac{\sum_{i=1}^{N} AP_i}{N}, \end{aligned} \tag{2}$$

where TP is the number of correctly classified bounding boxes that are predicted and the bounding box coordinates that are correct, FN is the number of all unpredicted bounding boxes, and FP is the number of predicted bounding boxes that are misclassified or whose bounding box coordinates that are not up to the standard.

Figure 3: Sample images from the dataset.

4.3. Experimental Results. In the training phase of the YOLOv5s model, the initial parameter batchSize is set to 8 and 8 images are randomly selected for training each time. The epoch is set to 450 rounds, and the rect is true. By setting the same parameters, different loss functions are used to train the network. When the model is trained to 300 epochs, the model begins to converge. After 450 epochs, each model takes the optimal result.

4.3.1. Comparison of Attention Mechanisms. To verify the performance of the CBAM, this paper uses SE, CBAM, and CA to conduct comparative experiments. Among them, SE attention is channel attention, to solve the loss problem caused by the different weights occupied by different channels of the feature map in the process of neural network feature extraction. CBAM attention is additional spatial attention based on SE attention. The feature of CA is that the channel attention is divided into two different directions, horizontal and vertical, so that the information of the position and spatial direction of the input feature image can be fused, which can make the model more accurately locate the detection target.

By adding three attention mechanisms of SE, CBAM, and CA to different positions of the YOLOv5 network model (such as backbone network and neck network), the paper found that the performance of the same attention in different positions is different. Table 1 presents the optimal results of different attention mechanisms, where CA is the worst and CBAM performs the best, which can improve mAP by 0.52% compared to the normal model without increasing the network complexity. Figure 4 shows the comparison experiment curves based on the CBAM and the traditional network. It can be seen in the figure that adding the CBAM has a certain improvement effect.

4.3.2. Comparison of Loss Functions. To verify the detection performance of the CIoU loss function, the paper uses IoU, GIoU, DIoU, alpha-IoU [34], and Varifocal [35] for comparative experiments. Among them, alpha-IoU (aIoU for short) is a unified exponentiation of existing losses based on IoU for accurate bbox regression and object detection. In this paper, the alpha-IoU is improved based on CIoU and the alpha is set to 2 and 3 for experimental comparison. When alpha = 1, it corresponds to the original CIoU loss function. Varifocal is a new loss function for training dense object detectors.

Table 1: The performance of different attention mechanisms.

Model	Precision (%)	Recall (%)	mAP@0.5 (%)
YOLOv5s + SE	95.00	84.03	89.70
YOLOv5s + CBAM	94.78	85.56	90.95
YOLOv5s + CA	95.15	76.91	82.51

Table 2 presents the detection results of different loss functions. As can be seen from Table 2, CIoU is better than DIoU, GIoU, and aIoU and slightly lower than Varifocal. Figure 5 represents the precision, recall, and mAP curves for different algorithms. When alpha = 3, the recall curve of aIoU-3 has obvious advantages. In addition, Figure 6 shows the detection result pictures based on Varifocal and CIoU. Although Varifocal achieves slightly better mAP, there will be obvious false positives in the case of the side face. Overall, the CIoU loss function is better.

To further verify the effectiveness of the method proposed in the paper, Table 3 also gives the traditional two-stage algorithm Faster R-CNN and the one-stage algorithm YOLOv3 as comparative experiments and uses mAP, precision, and recall to evaluate and compare each mainstream algorithm. Table 3 shows that the comprehensive performance of the network model proposed in the paper is the best; its mAP is 1.18% higher than that of Faster R-CNN and 4.85% higher than that of the YOLOv3 network model structure. After adding the CBAM to the backbone network, the performance of the network model is further improved and the final mAP reaches 90.96%.

Pictures of people wearing masks and pictures of people without masks in real scenes are collected, and the YOLOv5s + CIoU and YOLOv5s + CIoU + CBAM network models are used to evaluate the collected pictures. The

YOLOv5s + CIoU	93.69	84.90	90.43
YOLOv5s + CBAM + CIoU	94.68	85.63	90.96

detection results in the real environment are shown in Figure 7. As can be seen from the figure, the two face targets on the left are occluded. The above picture does not use the CBAM attention mechanism, resulting in missed detection, while the following picture can be applied to face detection under occlusion. From the above experimental results, YOLOv5s has occlusion and missed detection in the real environment. In contrast, the model proposed in this paper performs relatively well, especially for small target detection, which can achieve relatively accurate detection, but there is still missing detection in the shadow area. With the addition of the CBAM, the performance of the network model can be enhanced, corresponding with the expected experimental results.

5. Conclusion

Aiming at the occlusion and density problems of mask-wearing detection, this paper proposes a mask-wearing detection model based on an attention mechanism and loss function and carries out experimental tests based on different attention mechanisms and loss functions. Taking YOLOv5s as the basic framework, the experimental results show that the CBAM is significantly better than the other two attention mechanisms. Experimental tests on different loss functions show that the CIoU loss function is slightly better than the other three loss functions. The experimental results tested in the real environment show that the proposed model is robust to small targets and occlusion. Future work will further study the new network model to improve the accuracy of mask detection.

Retracted: Optimization of Vocal Singing Training Methods Using Intelligent Big Data Technology

Computational Intelligence and Neuroscience

Received 26 September 2023; Accepted 26 September 2023; Published 27 September 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

The development of art education and information technology has led to the importance of computer technology and multimedia technology in the development of students' independent inquiry and research skills. In the context of "Internet+," new modes of teaching phonics have emerged, reconfiguring the spatial and temporal relationship of phonics education. The use of Internet resources is not only a simple collection and sharing of educational resources, but also a new way of teaching voice, which has the magic charm of becoming one of the resources for the majority of voice enthusiasts. However, in practice, there are very few assistive software suitable for music classroom teaching. It is important to research and implement teaching aids suitable for music classroom teaching. Based on intelligent big data technology to optimize the phonetic training methods, the teaching methods are more specific, scientific, and diverse, and improve the self-learning ability and learning interest of Chinese phonetic learners. The experimental results show that the weight of the phonetic teaching optimization process is 0.154 higher than the weight before processing, which is expressed as the value of the control reliability fuzzy quantifier in this test. In other words, the reliability is "absolutely reliable." Therefore, this study is expected to promote the modernization and scientific process of Chinese vocal education and propose a new way of thinking for Chinese vocal education.

1. Introduction

With the rapid development of the economy, music education in the Internet era is gradually developing in the direction of intelligence and networking [1]. Being in the new media environment is like being in a "university without walls." New media has brought great convenience and development to modern education [2]. The biggest difference between vocal education and other education is that the vocal teaching method is relatively abstract with the focus on performance, and it is an art form that resonates directly with the subject matter [3], which can be concretized, visualized, and informed if intelligent big data technology is applied to the vocal teaching method [4]. A set of basic information management, student music assignment management, music practice management, online classroom management, and information notification management is built by making full use of web technology and combining the characteristics of music majors [5]. The integrated educational platform of student big data platform can develop students' potential more effectively, promote students to acquire learning skills, and improve learning efficiency [6].

Computer technology is increasingly infiltrating the field of education [7], thanks to its advantages of speed, efficiency, convenience, and wide connectivity. The development of society is dependent on "Internet+," which allows us to innovate boldly [8]. It has enabled closer integration between industries for the benefit of society, increased people's convenience, and accelerated China's economic development [9]. Existing teaching methods have a number of flaws, including single teaching methods, a lack of teaching resources, and dull content, all of which are undergoing qualitative changes as computers are introduced [10]. In the future development of education and teaching, digitalization and informatization will become an unavoidable trend [11]. Vocal music is a highly technical and practical professional field [12]. It is both a science and an art. Learning by relying solely on theoretical knowledge and book materials is extremely difficult [13]. Correct vocal conditions, long and continuous hard training, and the singer's skills are all important factors in the vocal and singing process of vocal singing.

The use of intelligent big data technology to optimize vocal songs is undeniably of practical significance when traditional vocal music education is combined with information technology. In the traditional teaching process, live vocal music teaching solves the problems of uneven teacher distribution, timely teacher-student interaction during the teaching process, and passive student feedback after class [14, 15]. The following are the paper's unique features. (1) Using intelligent big data technology, an in-depth study and research on the teaching mode of vocal singing training are conducted, highlighting the benefits and drawbacks of the teaching mode and teaching form of vocal singing training. It also gives more room for future training methods to be improved. (2) This paper can analyze all of the students in a group specified by the teacher, such as several classes or a specific college, using a rule-based expert system, so that this system can better serve for teaching. (3) The purpose of this paper is to provide a systematic and comprehensive discussion and summary of vocal music teaching in the new media environment, including its uncertainty reasoning and optimization process.

2. Related Work

2.1. Vocal Music Training Method. In recent years, with the education goal of cultivating well-rounded and high-quality talents in the new era of China, music teaching, as an important part of quality education, has received the attention and love of many students. Whether for the love of the profession or for future employment, the number of students choosing music majors is increasing year by year, so colleges and universities have also taken this opportunity to expand their professional enrollment. With the help of the Internet platform and advantageous resources, a variety of innovative models such as massive open online courses, cell phone APPs, and WeChat have also emerged in vocal music teaching, which has laid a certain foundation for the development and research of vocal music teaching.

Medeiros et al. introduced the concept of e-learning support systems, the idea of which has been used until today. Under the influence of this idea, many similar e-learning service systems have been developed by foreign educational institutions and software manufacturers in the past two decades [16]. E-Learning support systems were proposed by Baker and Cohen et al., and their ideas have been used until today. Under the influence of this idea, many similar e-learning service systems have been developed by foreign educational institutions and software manufacturers one after another. The basic design model is to fully utilize computer multimedia technology to deliver knowledge to learners through video and audio [17]. Xiong et al. argue that the creation and development of the online classroom are based on the Internet. This Internet breaks the limitations of the traditional time and space processes, allowing learners to leave home and no longer be restricted by geography and time [18]. Li proposed three centers that represent "progressive education" in the traditional educational center of Herbart: the center of the teacher, the center of the classroom, the center of systematic book knowledge, the center of the child, the center of activities, and the center of personal direct marketing [19]. Chi argues that the emergence of online classrooms means that the walls of traditional campuses will be broken down and the traditional function of sharing quality educational resources will become inevitable [20].

After the informationization of music teaching resources, with the help of computer technology and the Internet, teaching resources are rapidly spread in the network, which will make it more convenient for students to obtain music teaching resources and knowledge, and learning will no longer be affected by geography and time.

2.2. Intelligent Big Data Technology. With the increasing number of students in colleges and universities, the teacher-student ratio has increased substantially compared to the past. In the limited teaching time, teachers pay more attention to the teaching of vocal expertise and some singing skills, making vocal teaching more theoretical. Big data technology is an emerging edge discipline developed on the basis of the interpenetration of computer science, cybernetics, information theory, neurophysiology, psychology, philosophy, linguistics, and other disciplines.

Yang proposed the Online Education Platform System, a representative online education platform that actively uses e-books and textbooks and has more than 100 million registered users [21]. Rosenzweig et al. describe the "Internet + education" model and propose that the "Internet + education" model should evolve into the "Internet education" model [22]. Simones and Lima concluded that although online voice teaching has many advantages over traditional voice teaching, it does not replace traditional voice in terms of the specificity of vocal music. Voice instruction is a teaching method. Sun pointed out that the education industry is facing the challenges of the "Internet+" era and the responsibility system of education informatization construction, and it is necessary to establish a "big database" in colleges and universities [23]. Sun pointed out that the education industry is facing the challenges of the "Internet+" era and the accountability of education informatization construction, and it is necessary to establish a "big database" for team analysis in universities [24]. "The concept of educational system proposed by Sturtevant can provide tools that allow even nontechnical general teachers to easily create online courses and secure websites for courses, homepages, student management, and learning process tracking functions" [25].

Therefore, through intelligent big data technology, learners can complete real-time playback of online learning resources within limited bandwidth without having to completely download courseware and learning materials. Learners can independently select a certain segment of learning content, and learning is more actionable and convenient.

3. Optimization of Vocal Singing Training Method Based on Intelligent Big Data Technology

3.1. Big Data Technology Optimizes Vocal Training and Establishes Expert System. The combination of big data technology and music has existed for quite a long time, the development of digital sound processing and software programs for music has made great progress, and the combination of big data technology and music education has produced numerous research results [26]. Vocal teaching can be divided into two parts: vocal practice and song singing, and vocal practice is the basis of song singing, so it is very important to practice vocal practice [27]. With the help of multimedia and the development of emotional robots and deep learning, the efficiency of learning and practicing is greatly improved and a good training cycle will be formed, as shown in Figure 1.

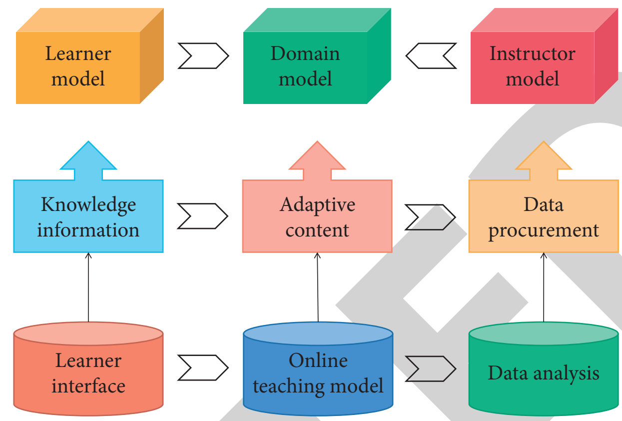

Figure 1: Interactive learning loop diagram.

To begin with, the teacher's explanation of vocal exercises in the traditional vocal teaching mode is very abstract. Only the student's own understanding and comprehension can cause him or her to feel it. Students can intuitively feel the application and changes of the diaphragm, throat, mouth, tongue, teeth, and other organs and grasp their rules by showing 3D animations of concepts such as "breathing" and "resonance" in the process of introducing modern information technology into vocal teaching. The content of vocal teaching for acting training is usually chosen by the teacher, who uses models to sing and explain the work, so catering to the acceptance of all students will inevitably be difficult. The best student in the current class is the teacher, because he or she is the one who knows the most. The following formula calculates the difference between the current average student level and the corresponding teacher level for each subject:

$$\text{Difference} - \text{Mean}_{j,}i = r_i\left(X_{j,k\text{best},i} - \text{TF} \times M_{j,i}\right). \tag{1}$$

$X_{j,k\text{best},i}$ is teacher's level in subject j.
r_i is random number from 0 to 1.
TF is teaching factor.
TF is randomly determined as 2 or 3 by the following formula:

$$\text{TF} = \text{round}\left[2 + \text{rand}(0, 1)\right]. \tag{2}$$

Therefore, to build an expert system, the development process follows the same steps and principles of software engineering as any other large software development process. The development toward emotional robotics and deep learning [28] with the help of multimedia significantly increases the efficiency of learning and practice. The process of the student phase is to adjust the learning by analyzing the differences between the two students. The stage process is shown in the following equation:

$$X'_{j,P_i} = \begin{cases} X'_{j,P_i} + r_i\left(X'_{j,P_i} - X'_{j,Q_i}\right), & f\left(X'_{j,P_i}\right) < f\left(X'_{j,Q_i}\right), \\ X'_{j,P_i} + r_i\left(X'_{j,Q_i} - X'_{j,P_i}\right), & f\left(X'_{j,Q_i}\right) < f\left(X'_{j,P_i}\right). \end{cases} \tag{3}$$

Therefore, the learning phase is modified in conjunction with realistic situations to enhance population diversity and improve the development of algorithms. The modalities are as follows:

$$X_{\text{new}i} = X_i + \text{Rand}\left(T_k - T_i\right). \tag{4}$$

k is k iteration.
X_i is individual.
Rand is random digit.

The instruction is divided into beginner, intermediate, and advanced levels, and students with vocal fundamentals can choose intermediate and advanced levels for their studies [29]. A detailed investigation and careful analysis of user requirements are performed, followed by the development of a unified design specification by designers, domain experts, and knowledge engineers based on the application problem to be solved, specifying the design goals, including the type and scope of the problem itself, and the people involved in the development process. That is, the value of TF decreases linearly as the iterations proceed. The improved teaching factor TF is as follows:

$$\text{TF} = \text{TF}_{\max} - \left(\frac{\text{TF}_{\max} - \text{TF}_{\min}}{\text{iter}_{\max}}\right)\text{iter} \tag{5}$$

$\text{TF}_{\max}, \text{TF}_{\min}$ are maximum and minimum values of teaching factors.
$\text{iter}_{\max}$ is maximum iterative algebra.
iter is current iterative algebra.

As a general performing arts discipline, the online vocal classroom is divided into a learner management module, a course education module, and a learning activity module. The online collaborative learning process based on the cloud course platform integrating social media is shown in Figure 2.

Second, by incorporating modern information technology into vocal learning, students can create their own vocal accompaniment using fun software, making their vocal practice more rich and interesting, and by creating their own accompaniment, they can strengthen their inadequate practice and comprehensively improve their vocal level. Under current technical conditions, consult a variety of domestic and international materials to collect, summarize, and organize domain knowledge, select appropriate knowledge acquisition methods, such as manual knowledge acquisition, semi-automatic knowledge acquisition, and

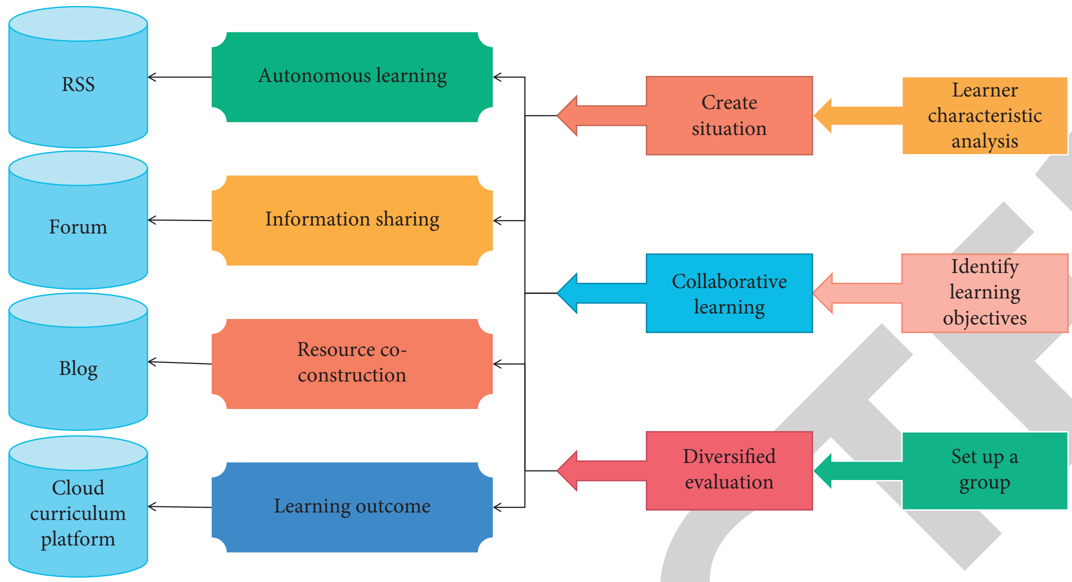

Figure 2: Design of teaching activities based on network collaborative learning.

automatic knowledge acquisition, and then conceptualize them.

Finally, modern information technology can effectively assist students in recording knowledge points and appropriate practice methods in the classroom, allowing them to practice correctly outside of class time and increasing learning continuity. To align with the characteristics of the problem to be solved, knowledge engineers must collect and reorganize formal knowledge, including the separation of knowledge and fact bases, knowledge representation, implementation of reasoning mechanisms, and human-computer interaction. Based on a thorough understanding of information users' needs, organize digital and web-based information and provide retrieval and relevant links. The most cutting-edge knowledge is delivered to those who need it most, ensuring that information resources are widely disseminated and resources are shared quickly and efficiently. Teachers can share their production results and exchange teaching methods and means via the campus network, which not only improves the quality of teaching but also creates opportunities for new "blood" to enter the teaching circle.

3.2. Optimizing Vocal Music Singing with Intelligent Big Data Technology. In traditional vocal music teaching, heuristic teaching mode is often used, which only abstractly introduces the feelings of daily life into vocal singing and allows students to imagine and comprehend the emotions and singing techniques of the songs by themselves [30]. Moreover, with the adoption of digital technology, there is no need to purchase expensive music equipment or to perform routine maintenance tasks. Educators only need basic computer operation skills and basic music knowledge to perform the most basic teaching tasks. The flowchart of the sight-singing and ear training is shown in Figure 3.

First, students can experience the songs directly through multimedia. Music learners access the learning portfolio by logging into the client, which is generally a learning platform, and then present the learning results to the teacher through human-computer interaction. For example, the traditional teaching model of "Morning in Miaoling" with flowery singing is just imagining the text.

Through the means of information technology, the content of the song can be produced, and the birds in the picture can jump to the rhythm. Students can not only hear the song, but also see the song directly and understand their emotions so they can sing with more enthusiasm. The users of the music teaching system include teachers, students, and system administrators. User information management is the basis of system management, including maintenance, query, and statistics of user information. During the teaching phase, individual students are updated by

$$X_{\text{new}} = X_{\text{old}} + \text{Difference} - \text{Mean}_i. \tag{6}$$

X_{old} is individual before update.
X_{new} is updated individual.

Secondly, through the application of modern information technology, students can use DV to film their singing process, then watch it afterward to find out the deficiencies, and then correct and improve their singing. The core algorithm model of the interactive music intelligence system uses big data technology algorithm. User queries are done by entering user keywords or combining multiple conditions, for any point x on the interval $[a, b]$; let its reverse point be x^*, the general reverse point be $\overline{x}$, the probability function of any point on the interval to the optimal solution be $P(\cdot)$, and the distance function be $d(\cdot)$, then the following conclusion holds

$$P(d(\overline{x})) < d(x) > \frac{1}{2}. \tag{7}$$

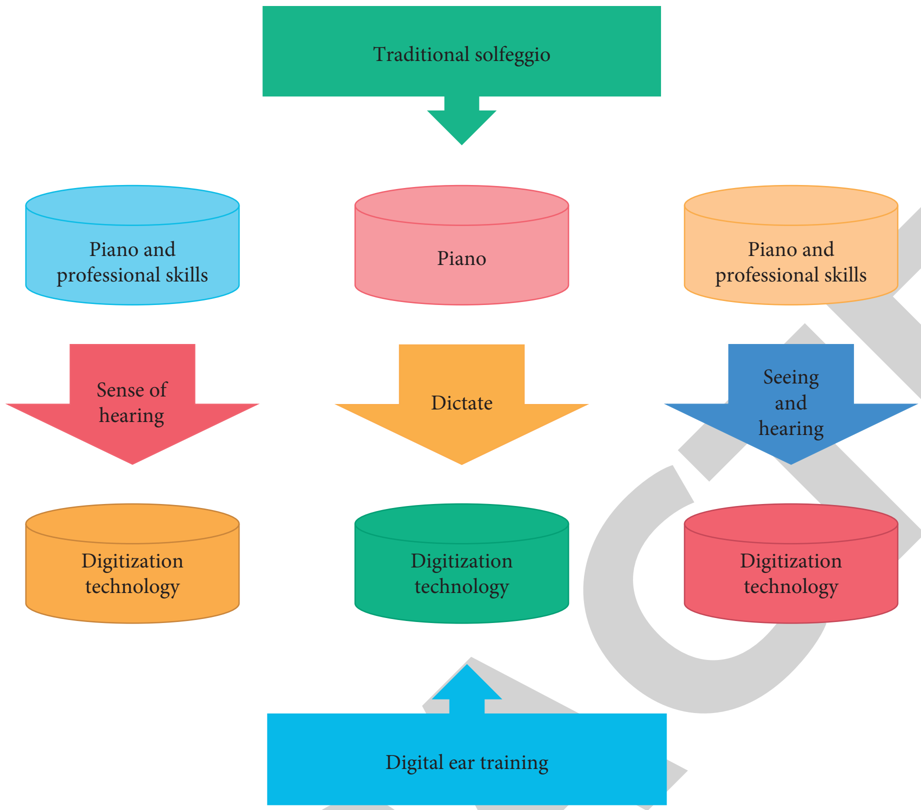

FIGURE 3: Flowchart of solfeggio.

When the teacher sings the training, they can choose from a number of templates for students with different voice conditions or different singing problems, explaining the key points and difficulties of the class in a variety of ways. The students watching the training can then choose their own optimal solution among these solutions to apply and improve the effectiveness of the lesson. Suppose that in the k th iteration, for some individual student $X_i = (x_1, x_2, \ldots, x_D)$, such that M_k is the average score of all students and T_k is the teacher, then

$$M_k = \frac{1}{NP}\left(\sum_{i=1}^{NP} X_{i,1}, \sum_{i=1}^{NP} X_{i,2}, \ldots, \sum_{i=1}^{NP} X_{i,D}\right),$$
$$T_k = \min\{f(X_i) \mid i = 1, 2, \ldots, NP\}. \tag{8}$$

Finally, we can teach remotely by means of the Internet, which not only saves teaching costs, but also teaches vocal music to a wider range of students. In order to improve the evaluation of the course itself, the review of the singing training evaluation should be conducted by experts, including educational experts, technologists, psychologists, and vocal teaching experts, in addition to the source network. A matrix of size $\max - \text{iter} \times D$ and a vector of $1 \times \max - \text{iter}$ are to be created to store the optimal individual and the optimal fitness values in each generation, respectively. The final space complexity is obtained as

$$S(D) = O((\max - iter + 2 \times NP) \times D). \tag{9}$$

That is, the basic maintenance of user information includes user name, user number, user address, etc. This basic information is the basis of the system, and the details of users can be viewed at any time throughout the system. The maintenance of user information includes add, modify, and delete operations. When a new user needs to be included in the charge, the user administrator needs to enter the user's details. This is a teaching method that uses Internet technology to solve the space limitation by teaching online instantly. When D takes a large enough value, the effect of lower powers on the time complexity is small and can be neglected, then the time complexity of the basic TLBO can be obtained from the above analysis as

$$T(D) = O(\max - \text{iter} \times 2 \times NP \times D). \tag{10}$$

D is dimension.

$\max - \text{iter}$ is iterations.

NP is population size.

The premise of this teaching method is to establish a voice or video chat room through the Internet, and then inform and advertise the chat room ID and the arrangement of video vocal teaching, so that people can learn and communicate online at the agreed time. By inheriting the UserControl class, developers can develop various controls according to their needs, and after creation, they can also be compiled into DLL files for other WPF programs to use.

4. Application and Analysis of Big Data Technology in the Optimization of Vocal Singing Training

4.1. Uncertainty Reasoning Analysis. In the actual development process of expert systems, the problem solving of expert systems is generally not as rigorous and accurate as that of mathematics and physics and other disciplines. Therefore, the knowledge of domain experts and the information we have to deal with are often uncertain and inaccurate.

First, uncertainty and ignorance are distinguished by introducing a trust function, which satisfies the axiom that is weaker than the probability function. Thus, the probability function is a subset of the trust factor. We specify the travel path and remove the average error and low-pass filter or low-precision approximation of the encoded trajectory curve to extract the smooth path curve. The results are shown in Figure 4.

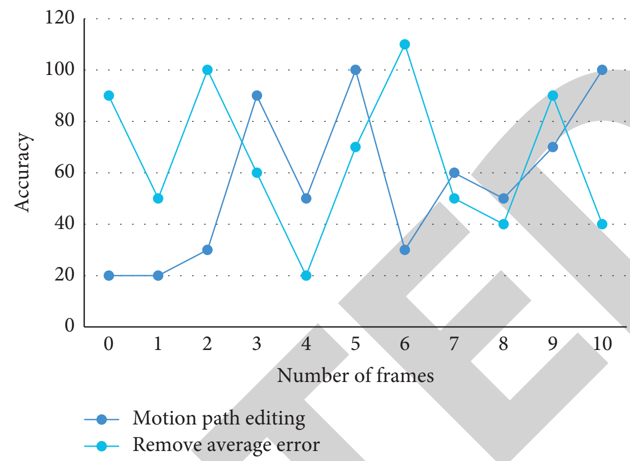

Figure 4: Results of editing motion path and removing average error.

In the control mode of vocal performance or training, students' live participation is added to achieve the basic interaction between computer and music training and performer-human-computer interaction. Through digital technology and multimedia means, animated effects of chest breathing, abdominal breathing, and combined chest and abdominal breathing are created to show the muscle groups in each movement in the working section. It gives the learner an immersive feeling from which he can see why chest and abdominal breathing are not suitable for singing. The multimedia depicts the fuzzy rule count. By learning samples, we try to make the least number of rules to learn and the most important. As the core of digital technology, the computer can be controlled by the teacher. For example, the vocal teacher can control the playing time of the computer music through the pedal, so that the feedback can be used to adjust the teaching at any time, so that the students are really the main focus, using "digital technology" for students and teaching. For the convenience of teachers, some fuzzy quantifiers and quantitative expressions were chosen to represent the confidence level, as shown in Table 1, taking into account the experience of experts in the field.

Table 1: Numerical representation of confidence fuzzy quantifiers.

Fuzzy quantifier	Absolutely credible	Strong credibility	Weak credibility	Untrustworthy
Numerical value	1	0.557	0.429	0.186

Second, possibility theory represents uncertainty in terms of likelihood, which is calculated by introducing an affiliation function. Cubase 5 software, developed by Steinberg, was used for the analysis and study. This software not only performs the necessary recording and production functions, but also allows editing the recordings. Another device in this software is a spectrum analyzer, which allows detailed analysis of the singer's spectrum and derives patterns. When targeting a series of larger data, the first m of the music data are used as initial training, which leads to the construction of an RBF model of students learning music knowledge, which is continuously evaluated through the designed software platform until a perfect model is finally constructed. Allowing the possibilities of interaction in computer music to be deeper, making this interaction more organic and giving the computer more room to play, for example, allowing the computer to "hear" the singer's real-time vocals or voice while deciding on its own what to feed back. A comparison was made between the performance of the vocal teaching system and the use of computer memory. Figures 5 and 6 compare the CPU and memory usage of the system before and after loading.

Finally, the adequacy and necessity measures are defined as probability ratios, and domain experts are only required to provide probability ratios rather than precise probability estimates. Professional software, on the other hand, can split the singer's voice and accompaniment into two tracks. Following the performance, the tutor can provide a detailed breakdown of what went wrong and improve interactive teaching. The algorithm concept is incorporated into the platform's design, and the algorithm is fully demonstrated while writing the code and implemented in the platform's functions to effectively match the interactive learning mode. By judging the accuracy of the singer's pitch, tone quality, volume, timbre, and vocal language during the singing or vocalization process, the computer determines what, what, how, and how to improve the feedback information. Learners can edit a set of orchestral or band accompaniment tapes to become familiar with the role of each instrument and the combination of accompaniment and voice once they are familiar with the song.

4.2. Analysis on the Process of Vocal Music Teaching Optimization. For vocal music teaching, there are certain differences from other teaching. Only very short classroom teaching necessarily requires a strong instantaneous memory, and for some students with weak memories, classroom teaching time becomes insufficient. Such a network means

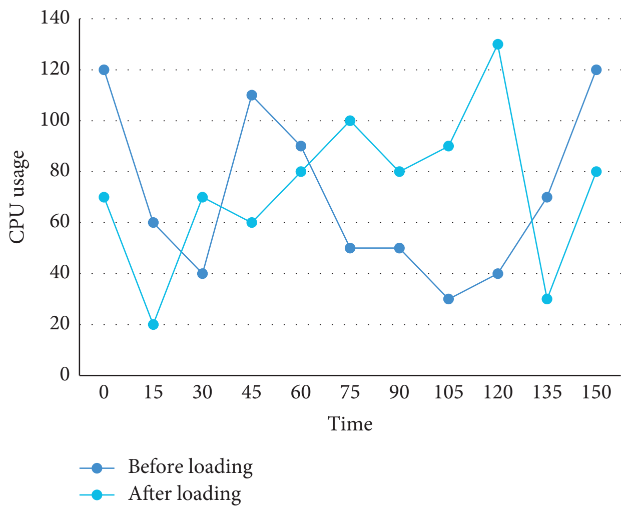

Figure 5: CPU usage comparison.

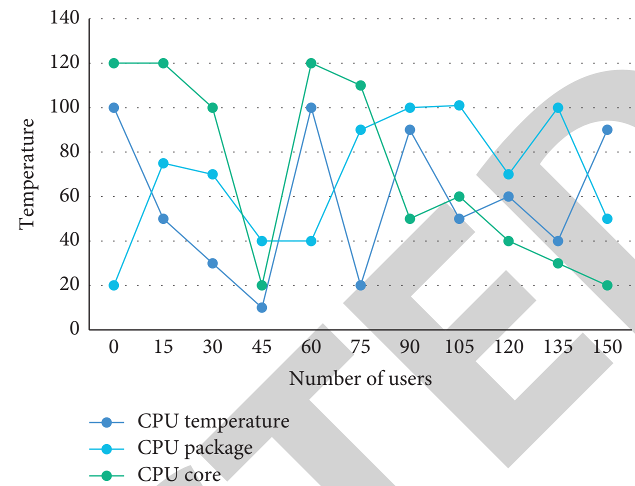

Figure 7: Curve changes after the number of users increases.

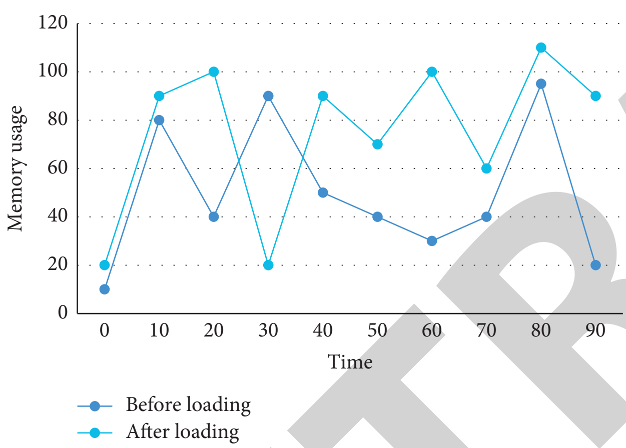

Figure 6: Comparison of memory usage.

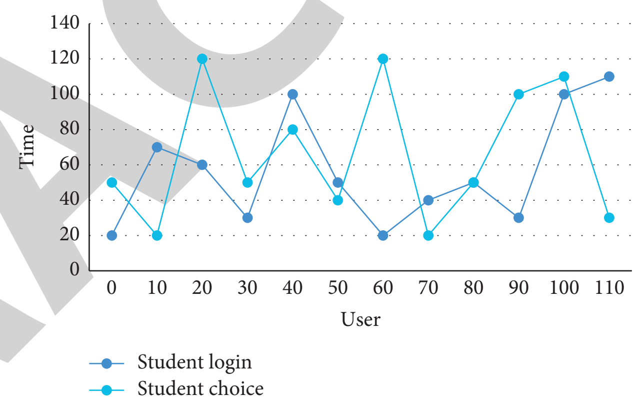

Figure 8: Curve of response time.

can solve the spatial constraint of the heterogeneous location of vocal learners and vocal teachers, and also allow learners to independently choose their favorite or interested teachers or teaching resources. Therefore, the optimization process of vocal music teaching is as follows.

First, teachers organize exams according to their respective teaching contents, teaching objectives, students' levels and usual exams, log into the system, add exams, select exam topics, receive exam papers, and take exams. The database links between the expert application system and other systems are relatively poor, resource sharing is not fully reflected, unified management is not convenient, and mutual access between users is restricted. All these factors limit the information exchange between expert systems. Therefore, with more and more users of the vocal teaching system, some computer-related hardware indicators such as CPU temperature, CPU package, CPU core difference, and other variables are shown in Figure 7.

However, through intelligent big data technology devices, such as MP4, MD, and some other classical teaching can do "eternal." On the one hand, after the class, students can listen to what the teacher teaches. On the other hand, teachers can listen to students' classroom recordings to find out some problems of students and develop some targeted measures to solve these problems in the next teaching activities.

Secondly, students choose an exercise mode to practice, and after the diagnostic exercises are completed, the system will analyze the students' exercises according to the exercises. Figure 8 shows accurately the average response time when different users access the music education information system.

MIDI and ZIPI are the main protocols used in devices to accomplish computer music technology interaction. Therefore, to make a qualitative change in the traditional expert system, the application system of the expert system must first of all have a strong network interconnection function. To achieve network interconnection between expert systems, it is necessary to solve the technical problems of the following kinds of interfaces: the interface between the system and various relational databases, multimedia information processing interfaces, full-text database interfaces, etc. It is a new protocol standard for data exchange between digital musical instruments proposed to overcome many

Table 2: Comparison of weight vectors before and after optimization of vocal music teaching.

Weight vector	μ_1	μ_2	μ_3	μ_4
Preweighting	0.556	0.257	0.461	0.672
After weighting	0.672	0.443	0.572	0.875
Differential value	0.116	0.186	0.111	0.203

shortcomings such as slow transmission rate and one-way transmission of MIDI. Its transmission rate is nine times that of MIDI, and there is no maximum bandwidth limit in order to adapt to the rapid development of computer technology. In addition, the network media has a huge amount of information, rich information content, and shorter information metabolism cycle, which can enable people to grasp the latest vocal theory knowledge in time and meet their learning needs. The credibility vector is the credibility of the rules in the knowledge base, and the weight vector is the weight vector given by experts. The comparison results of the weight vectors before and after the vocal music teaching optimization process are shown in Table 2.

According to the comparison of the ‘s weight vectors before and after the optimal treatment of vocal music, the weight of the optimal treatment of vocal music increased by 0.154 compared to that before the treatment. Therefore, in this test, the value of the fuzzy term of relative credibility was used; i.e., the credibility was “absolute credibility.”

Finally, a basic evaluation was given after each exercise to encourage students to practice on their own and to pique their interest in learning. This can be done without a tutor at home, at school, anywhere, and at any time. All that is required is that you record the entire process of the tutor’s singing using digital multimedia technology, and then record yourself singing and compare the two using the software to see where you went too far in terms of amplitude. The focus on the humanistic aspects of computer music, particularly the interaction of curriculum, vocal training, vocal performance, or lesson production with computer characteristics, can help to establish new computer music aesthetic principles. After all, music intelligence systems are closely linked to teachers, students, and teaching resources, so the corresponding services are slightly different.

5. Conclusions

Informationization has already pervaded people’s lives, and the information-based classroom will pervade future college classrooms and the general public’s learning life. To further improve the shortcomings of traditional vocal teaching methods, existing vocal teaching methods should be combined with digital vocal teaching methods. If multimedia and the Internet are solely used for informational purposes, they will inevitably be phased out over time. Modern information technology, in combination with multimedia and online education, has the potential to significantly improve the quality and efficiency of vocal education, as well as promote vocal singing. Its technical advantages can provide voice learners with a new method of learning vocal art, which has a broad application space and application prospects in the field of vocal education, by optimizing voice training methods based on intelligent big data technology. It completes the basic evaluation of the knowledge points learned by college music teachers and realizes the comprehensive evaluation of a single lesson using a combination of generative and framing knowledge expressions and uncertain reasoning techniques. Vocal music education should not only keep up with the evolution of the information society, but also provide a variety of information services to information users and continue to innovate. The advancement of modern information technology is the general trend, and vocal music must keep up with the times and develop and progress more comprehensively. The combination of big data technology and vocal music education has not only accelerated the diversification of music education, but also improved traditional vocal music education.

Academic Editor: Xin Ning

In this paper, melody and harmony are regarded as the task of machine learning, and a piano arranger timbre recognition system based on AI (Artificial Intelligence) is constructed by training a series of samples. The short-time Fourier transform spectrum analysis method is used to extract the piano timbre characteristic matrix, and the electronic synthesis of timbre recognition is improved by extracting the envelope function. Using the traditional multilabel classification method and KNN (K-nearest neighbor) algorithm, a combined algorithm of these two algorithms is proposed. The experimental results show that the detection rate increases from 61.3% to 70.2% after using the combined classification algorithm. The correct rate also increased from 40.3% to 48.9%, and the detection rate increased to 74.6% when the K value was set to 6. The experimental results show that, compared with the traditional classification algorithm, this algorithm has a certain improvement in recognition rate. Using this system to recognize the timbre of piano arrangement has a high recognition accuracy, which is worthy of further popularization and application.

1. Introduction

The art of music is vast and profound; for a true pianist or piano educator, touching the tip of the iceberg of piano music works is insufficient; they must also broaden their horizons to include all aspects of music art. It is obvious that you can hear the sounds of various instruments when playing the digital recording of the piano concerto. People may not be able to correctly identify the names of some instruments, but they should be able to recognize their general categories, such as stringed or wind instruments. The loss of information such as bells, melodies, and ringtones will have a significant impact on the accuracy of music recovery results, resulting in low recovery efficiency. The development of contemporary electronic music has been aided by the rise of AI (Artificial Intelligence) technology [1], and the technology's application fields are constantly expanding. The use of AI technology to solve problems like timbre recognition and feature extraction in music arrangers has gotten a lot of attention.

The exploration and research in the field of music have developed rapidly with the progress of computer science. Nowadays, the digital music creation mode has completely changed the traditional music industry and greatly improved the quality and production efficiency of music works. Patil and Elhilali recognized music as a series of music fragments, analyzed their music styles, and then established a statistical model in the existing music database to predict the style classification of other music [2]. Aucouturier and Pachet defined the emotional attribute value as an emotional plane and proposed a fusion algorithm, considering that a piece of music may have multiple emotions with interval changes [3]. Kailash et al. introduced the recognition principle of machine auditory system and applied the heuristic processing method to the sound signal, which can preliminarily understand the sound signal [4]. Chen and Guo put forward a timbre model based on piano pronunciation waveform, which uses the spectrum characteristics and amplitude envelope characteristics of timbre to construct piano timbre model [5]. Wu et al. introduced a timbre model based on trapezoidal wave. The model is divided into two parts: vibration submodel and inclusion submodel. Time, asymmetry, trapezoidal degree, and three angles are defined as timbre parameters for timbre synthesis [6]. A series of research works have been made on multipart piano music, and a machine hearing system has been developed, which can recognize multipart piano music. In the research process of machine hearing, the frequency spectrum analysis of musical instrument timbre signal has always been a research hotspot, which requires the selection of frequency spectrum feature extraction technology. Different technical application fields and analysis results are different.

The AI-based piano arranger timbre recognition system separates harmonic signals at the edge of music, transmits timbre, analyzes timbre signal continuity, and implements the system design, but the system's performance is poor. It is demonstrated that timbre is a type of sound feature that includes frequency spectrum and time based on psychological judgments of music timbre, analysis of physical characteristics of sound, and research of machine learning methods. To fully comprehend the true meaning of timbre, it is necessary to fully comprehend the number and significance of characteristic parameters that affect timbre. As a result, to design a piano arrangement timbre recognition system based on AI, this paper uses the Fourier analysis method. The use of computer technology in the field of music, as well as the use of computer technology in the field of music, will provide mankind with new musical experiences.

The innovation of this paper is summarized as follows:

(1) In this paper, taking piano music signal recognition and synthesis as an example, the characteristics of piano music signals are recognized and analyzed by mathematical methods, and the extracted characteristics of piano music signals are digitized to realize piano timbre recognition and simulation.

(2) Using the multilabel classification method [7, 8] and KNN algorithm, a combined algorithm of these two algorithms, namely, ML_KNN classification algorithm, is proposed. The experimental results show that the recognition rate of the classification algorithm based on ML_KNN is higher than that based on multilabel decision tree.

The following is a list of the sections of this article: The first section discusses the research's background and significance before moving on to the paper's main work. The second section focuses on the related timbre recognition techniques used in piano arrangements. The third section outlines the research's specific methods and methods of implementation. The superiority and feasibility of this research model are confirmed in the fourth section. The summary of the full text is found in the fifth section.

2. Related Work

2.1. Timbre Feature Recognition Method. Musical instrument timbre recognition is an important research trend of machine hearing. However, from the academic point of view of machine hearing, the difficulty of musical instrument timbre recognition is roughly equal to that of speech recognition. However, scholars who study musical instrument recognition need to be proficient in both music and computer, so the research population is small, and the progress of musical instrument timbre recognition is slower than that of speech recognition, with few achievements and few references.

Mitrovic et al. adopted KNN (K-nearest neighbor) method and Gaussian mixture model to realize automatic classification of musical instrument features. The experimental results show that the highest recognition rate of 14 musical instruments is 90% [9]. Peretz et al. extracted a series of musical sound features that can be perceived by human auditory system from the musical sounds of 27 musical instruments and applied these features to the classification of musical instruments. Finally, the recognition rate of musical instrument perception difference reached 71%, and the system developed by them had good stability in dealing with reverberation and noise syllables [10]. The music composition system developed by Han et al. allows people without music skills to intervene in its composition system to create music, and the generated melody can reach 16 bars in length [11].

Xing et al. pointed out that when using genetic algorithm to solve melody harmony, we will encounter the problem of harmony search space in irrelevant local optimal area [12]. Omar et al. put forward a graph [13] of arranging very interesting harmony for a given melody based on the training data. This graph model may be better than the hidden Markov model in obtaining the root sound movement showing global correlation. Wang et al. think that the timbre space of musical instruments includes five dimensions, and besides the characteristic dimensions of time domain and frequency domain, it also includes the dimension of time-frequency combination [14].

2.2. Research Status of Multilabel Classification. A natural scene can contain multiple target objects. For example, the scene can be described with multiple class labels. They usually use multiple labels to train samples to solve problems. However, this method is not suitable for music database, because each instrument can play different notes, and some of them can express different timbres by using different playing skills.

Xiang et al. discussed the emotion classification in music clips, which involved six kinds of emotion classification labels and a small number of timbre feature values. Emotion is a higher level of information, which can be further obtained from pitch, volume, rhythm, and timbre [15]. Mancia and Janssen used the trained neural network to recognize and classify 166 groups of music samples and achieved good classification results [16]. Cerri et al. proposed a pitch-independent instrument recognition system [17]. Further extracting features including basic frequency, spectrum, time domain, and modulation and solving their respective multivariate normal distributions, the recognition rate of the final instrument family reaches 90%, and the recognition rate of a single instrument reaches 80%. Sering et al. proposed several methods for high-order statistical modeling of musical sound signals and evaluated them in the environment of multimedia sound retrieval [18]. Ju et al. made it possible to separate two or more musical instruments by using single channel speech separation method through Gaussian modeling [19].

The multilabel emotion classification method based on dictionary is to extract the emotion keywords from the text on the basis of emotion dictionary database, so as to classify the text. Yong et al. designed a chat system based on text and embedded conversation messenger emotion estimation. This system is based on an emotional content evaluation module that evaluates text chat messages, extracts related emotions from the text through keywords, and then evaluates the text emotions through syntactic features, speech synthesis, and related emotional gestures [20]. Yan et al. put forward an interdisciplinary approach to study the structure of emotion and society, analyzed the influence of society on cognition and emotional interaction, examined how emotions are stimulated and expressed in society, and studied how society affects the processing and regulation of emotions [21].

3. Methodology

3.1. Piano Arrangement Timbre Recognition

3.1.1. Piano Spectrum Analysis. Timbre is the basis of identifying musical instruments, and it is the characteristic information that distinguishes musical instruments from other musical instruments. The sound of an instrument consists of fundamental tone and overtone. It is the tone with the lowest pitch frequency, and those that are not pitch are collectively called overtones. The human auditory system can tell which musical instrument the sound comes from, because the high-frequency harmonic components of musical instruments are different, and the harmonic proportions of different musical instruments are also different. The definition of timbre is too subjective to lead to automatic classification of music. Therefore, the main work of this paper is to parameterize the timbre features in detail for automatic recognition and classification.

Piano arrangers must play the parts of multiple people at the same time, which necessitates exceptional performance skills. The piano arranger represents the combination of conductor and orchestra, and the orchestra is made up of multipart staff. It is necessary to use both hands to play the condensed version of the previous parts. The band's concert editing is moderately difficult and plays a major and minor role in the overall work; the reduction of band accompaniment is relatively simple. Because the accompaniment part usually does not have a lot of "scenes," it is usually only used to fill in the gaps in the solo and highlight the band's characteristics.

Even if the strength, position, and striking method are all the same for piano strings, the volume is not always the same. Through simple music training, humans can tell the difference between musical instrument timbres. Humans can quickly distinguish piano tones from the sounds of a variety of musical instruments as well as background noise. To achieve musical instrument timbre recognition by listening machine, we must first understand the mathematical principle of sound waves and then determine the differences between musical instrument timbres in mathematical expression and then use these differences to quickly identify and distinguish musical instrument timbres. The projection function is used to represent the low-dimensional features of the spectrum after the rank reduction:

$$y_t = \left[r_t, \tilde{x}_t^T v_1, \tilde{x}_t^T v_2, \ldots, \tilde{x}_t^T v_k\right], \tag{1}$$

where $r_t, \tilde{x}_t^T, v_1, \ldots, v_k$ is calculated by the spectrum basis function.

The resonance frequency of different instrument resonators is different, and the shape of resonance peak in frequency spectrum is also different. Not only is resonance peak the decisive factor of sound quality, but also it reflects the physical characteristics of the resonant cavity. Cepstrum coefficient is a method to express resonance peak.

The cepstrum coefficient containing the signal quantity $y(n)$ is defined as F, and F represents discrete Fourier transform.

$$c(n) = F^{-1}\{\log |F\{y(n)\}\}. \tag{2}$$

The analysis of MFCC (Mel frequency cepstrum coefficient) is based on human auditory mechanism; that is, the spectrum of speech is analyzed according to the results of human auditory experiments, in the hope of obtaining good speech characteristics [17]. The delineation of the frequency domain of human subjective perception is not linear, and there is the following formula:

$$F_{mel} = 1125 \log \left(1 + \frac{f}{700}\right)_V, \tag{3}$$

where F_{mel} is the perceived frequency in Mel; f is the actual frequency in Hz.

The process of extracting MFCC features includes the following steps:

(1) Input the audio signal to be processed.

(2) Select the window length N to preemphasize, frame, and window the input audio signal.

(3) The processed audio segments of each frame are subjected to FFT (fast Fourier transform) to obtain the corresponding frequency spectrum.

(4) Mel cepstrum is obtained according to formula (3).

(5) Take the logarithm of Mel frequency cepstrum and do inverse Fourier transform (get Mel frequency cepstrum coefficient MFCC), and the 2nd–13th coefficients after discrete cosine transform are MFCC coefficients.

The lowest frequency of the piano is 28.5 Hz, so it can be seen that all the sound bands of the piano remain in the Fourier transform analysis area. Based on the auditory nervous system, human ears can fully perceive the music spectrum and feel the timbre of piano, so the choice of spectrum structure analysis is actually a simulation of human auditory nervous system. Based on Matlab software, according to the principle of Fourier transform, the FFT function program is written, and the spectrum analysis diagram of single tone is obtained. It shows that there are multiple octave overtones and octave vibrations in the piano, and the uniqueness of the piano and the rich characteristics of piano timbre are expounded.

3.1.2. Extraction of Timbre Matrix. Strings are the piano's basic sound source. The player presses the keys to cause the hammer to strike the strings, causing the strings to vibrate and producing the original sound, which then causes the resonance system to resonate. Some researchers discovered that some functional waveforms resemble those found on the piano. Sinc, Gaussian, and Cauchy functions are examples of specific functions that can be selected. The frequency domain waveform of piano tones can also be approximated using these specific functions, according to the researchers. Choose a suitable piano accompaniment type metastructure from the existing library, and configure the piano accompaniment spectrum for the new melody using the modes of melody segments, the root of chords, and various permutation functions provided in the selected piano accompaniment type metastructure.

In order to improve the high-frequency resolution of music signal and analyze the whole spectrum of the whole frequency band, a processing method is proposed, which usually uses a first-order digital filter for preemphasis before signal extraction. The transfer function of this filter is expressed as

$$H(z) = 1 - \alpha z^{-1}. \tag{4}$$

In the above formula, α is the preemphasis factor, which is generally taken as a decimal close to 1. In this paper, it is taken as 0.95. Preemphasis process transforms the signal as follows:

$$x(n) = x(n+1) - \alpha x(n). \tag{5}$$

The data obtained from the above formula is the preemphasized data, where $x(n)$ is the original audio signal.

In the calculation of short-time autocorrelation function detection method, multiple multiplications lead to a large amount of calculation, while the average amplitude difference method with long and short time uses a simpler difference form, which avoids multiple multiplications and achieves a performance similar to autocorrelation function.

The short-time average amplitude difference function $F_n(k)$ of the audio signal $s(m)$ is defined as follows:

$$F_n(k) = \sum_{m=0}^{N-k-1} \left| S_n(m+k) - S_n(m) \right|. \tag{6}$$

In the above formula, N represents the window length added by the audio signal $s(m)$; $S_n(m)$ is defined as follows:

$$S_n(m) = s(m) w(n-m). \tag{7}$$

The process of estimating pitch frequency by short-time average amplitude difference function detection method includes the five following steps:

(1) Input the audio signal to be processed.

(2) The input audio signal is preprocessed by windowing, framing, and endpoint detection, so that the audio signal of each frame becomes a short-term stable signal.

(3) Calculate the short-term average amplitude difference function of each frame signal, and get the valley value of the pitch period position.

(4) The obtained valley value estimates the pitch period and calculates the inverse of the pitch period to obtain the pitch frequency.

Because the weighted Cauchy function waveform is close to the piano waveform and can describe the fundamental frequency and frequency doubling analysis, and the simulation effect is similar to the actual timbre, the fifth frequency doubling method is selected to simulate and extract the piano timbre. Assume that the discrete Fourier transform of the discrete event signal $x(m)$, namely, $X(i\lambda)$, can be expressed as

$$X_j(i\lambda) = T_j(i\lambda) * P_j(i\lambda),$$
$$T_j(i\lambda) = \begin{cases} B_j \dfrac{b_j}{b_j^2 + \left(\lambda - \lambda_j\right)^2}, & \lambda_j - b_j \le \lambda \le \lambda_j + b_j, \\ B_j \dfrac{2}{\left|\lambda - \lambda_j\right|}, & \text{Other.} \end{cases} \tag{8}$$

In the above formula, λ_j represents the fundamental frequency or frequency multiplication of j sound; B_j represents amplitude; b_j stands for adjusting the waveform width around λ_j; P_j stands for sine and cosine function, which accurately simulates playing timbre, intensity, and pitch to realize computer performance.

The basic idea of KNN (K-Nearest Neighbor) is as follows: according to the traditional vector space model, the text content is formalized as a weighted feature vector in the feature space. For a test text, calculate its similarity with each text in the training sample set, find out K most similar texts, and judge the category of the test text according to the weighted distance. According to the feature words, a test text vector is formed. Calculate the text similarity between the test text and each text in the training set, and the calculation formula is

$$\mathrm{Sim}\left(d_i, d_j\right) = \frac{\sum_{k=1}^{M} W_{ik} \times W_{jk}}{\sqrt{\sum_{k=1}^{M} W_{ik}^2} \sqrt{\sum_{k=1}^{M} W_{jk}^2}}, \tag{9}$$

where d_i is the feature vector of the test text and dj is the center vector of class j; M is the dimension of the feature vector; W_k is the k-th dimension of the vector.

In the k neighbors of the test text, calculate the weight of each class in turn, and the calculation formula is as follows:

$$P\left(X, C_j\right) = \begin{cases} 1, & \sum\limits_{d_i \in KNN} \mathrm{Sim}\left(x, d_i\right) y\left(d_i, C_j\right) - b \geq 0, \\ 0, & \text{Other}, \end{cases} \tag{10}$$

where x is the feature vector of the test text; $Sim\,(x, d_i)$ is the similarity calculation formula; b is the threshold, which needs to be optimized; and the value of $y\,(d_i, C_j)$ is 1 or 0. If d_i belongs to C_j, the function value is 1; otherwise, it is 0.

In this chapter, KNN algorithm is improved. By introducing multilabel classification, an extended KNN algorithm, namely, ML_KNN (multilabel k-nearest neighbor) classification algorithm, is proposed to further improve the efficiency of classification matching. ML_KNN algorithm is the realization of this paper based on ML_KNN classification. The algorithm is as follows:

(1) Divide the audio file of chord music into divided frames with index window of 1 s.

(2) 12 MPEG eigenvalues and 72 new time domain eigenvalues are extracted.

(3) N tags with the highest confidence are selected as candidate tags for the current frame, and other tags with low confidence are discarded.

(4) After all the individual frames in the index window are classified, the average confidence of each candidate instrument tag is calculated, and if the average confidence is greater than the optimal threshold parameter, the candidate tag is retained. Otherwise, it will be discarded.

To sum up, the flow chart of piano arrangement timbre recognition is shown in Figure 1.

Using self-developed amplitude feature extraction code, the relationship between amplitude and time of sine wave, piano, flute, and guitar music is analyzed, and the envelope function of different instruments is determined to be different. With a good envelope function, we can simulate the sound intensity and amplitude characteristics of wind instruments and stringed instruments and even the subtle differences between percussion instruments and plucked instruments.

3.2. System Implementation. The sound library generation module, which includes the piano arrangement sound recognition system, is the system's core module. This module generates the piano sound library in the audio system using the audio synthesis model and recognizes the timbre of the piano arrangement using the audio data provided by the sound acquisition module and the timbre parameters provided by the man-machine interaction module. Different timbre parameters can be used to generate different piano timbres. A computer-based sound library generation module is used to realize the piano arrangement timbre recognition system in the application experiment for this document's sound library generation. The system is modular in design and has a high degree of versatility, with modules such as audio file reading and writing, audio information analysis, timbre parameter acquisition, and timbre and simulation performance. The general architecture of piano arrangement pitch recognition system is shown in Figure 2.

In piano simulation function module, piano can play different types of music and opera scores, which is widely used and can act as a band, so piano is the best choice for playing musical instruments. Piano timbre editing function module can record timbre editing in various ways in detail; in particular, the music timbre editing with wide range is difficult, but timbre editing is very critical. The acquisition module edits and acquires the timbre parameters through the man-machine interface. The timbre synthesis module is used for synthesizing timbre files, supporting batch synthesis of various timbres, and displaying the synthesis progress in real time. The simulation performance module is used to assess the simulation performance of timbre or music.

The unique piano timbre obtained from the recording is determined by the vibration equation of the strings, and the amplitude energy changes from strong to weak, so it cannot be processed twice. On the other hand, the monophonic amplitude of electronic synthetic piano is stable, and the loudness does not change. In the postprocessing, envelope function can be added to control the change of amplitude, so as to reproduce the difference between hitting strength and delaying pedal and make music more emotional. Here, the pitch variable in the metastructure of the piano accompaniment sound mode can be determined. If some notes in the metastructure are imitated, their pitch is related to the pitch of the original melody being imitated.

4. Experiment and Results

We can build a data prediction model by machine learning algorithm and automatically identify the emotional features of music by computer. From the dataset of 400 pieces of music, we selected the feature data of 300 pieces of music as the training set (80% of the data as the training set and 20% as the test set) and the feature data of the other 100 pieces of music as the test set. When using ML_KNN, the training set is cross-validated, so as to obtain the optimal values of the parameters in the model. Finally, we tested the model, and the specific results of model comparison are shown in Figures 3 and 4.

The average correlation coefficient (CC) for the test set is 45.36 percent. The test set's MSE (mean squared error) is 0.038. It can be seen that the ML_KNN algorithm performs better in terms of musical emotional cognition. However, recognition rates for three emotions, Modest, Dream, and Graceful, are all very low in the test set, indicating that more research is needed. Correlation is a general method that is independent of the stream because it is done in the audio domain. This eliminates the tedious task of parsing the text's outline. This function can clearly reflect the intensity change

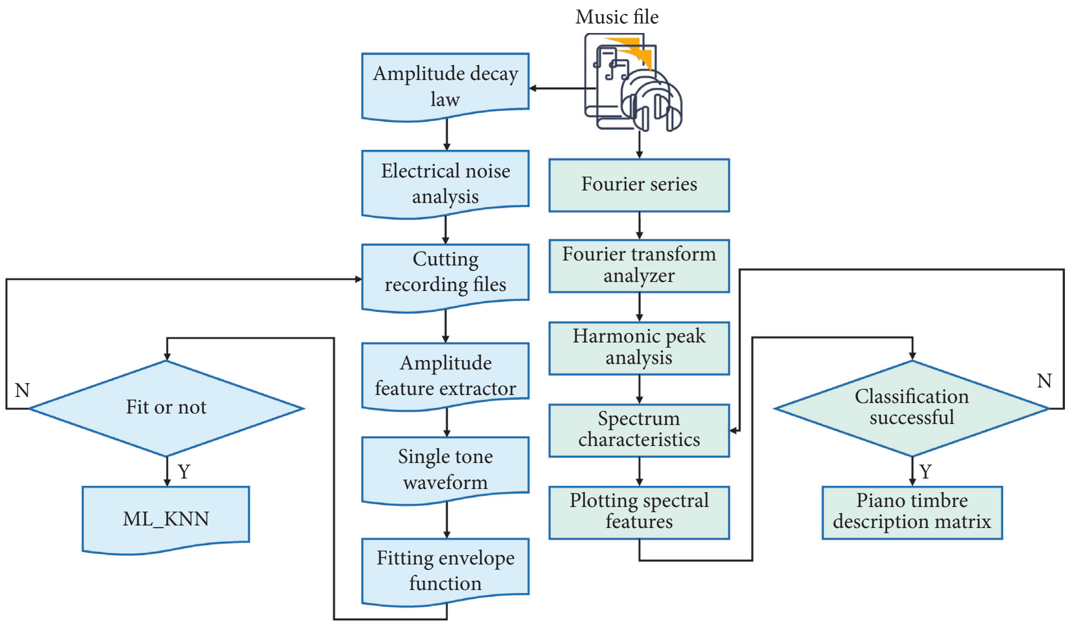

Figure 1: Flow chart of piano arrangement timbre recognition.

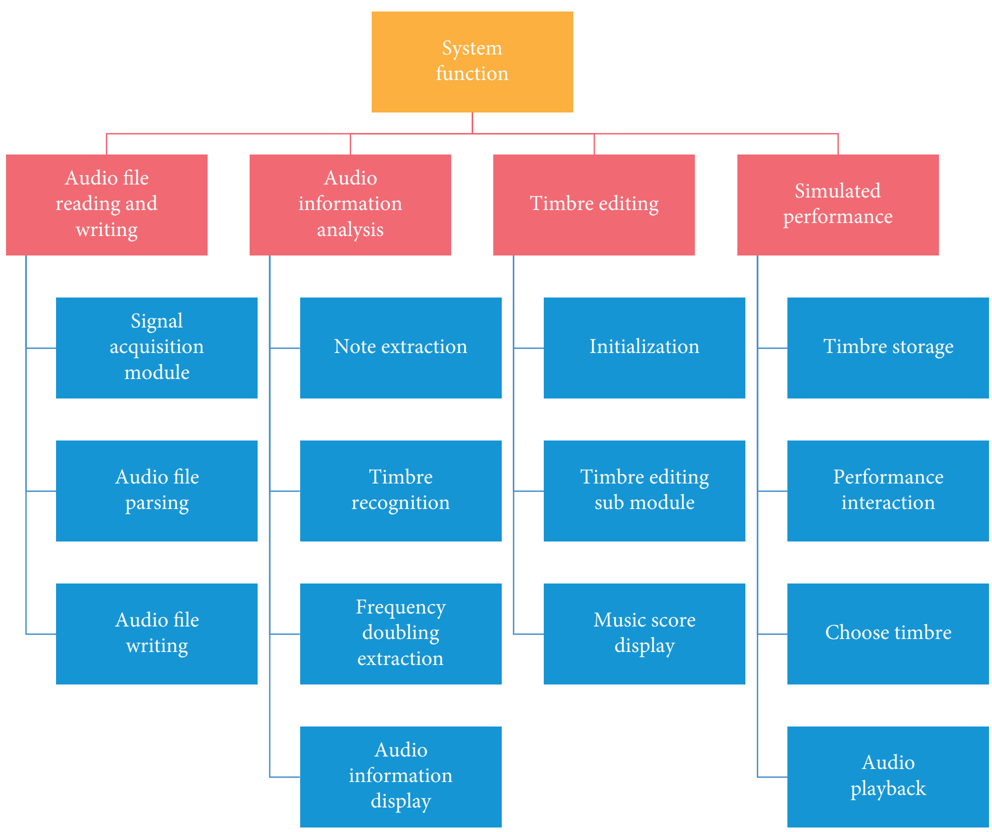

Figure 2: Overall architecture of piano arrangement timbre recognition system.

of sound at different times during the arrangement process. It is possible to ensure that the pitch synthesis process of a piano arrangement is essentially consistent with the changing trend of tone using the envelope function extraction. This function is performed while removing some unwanted noise. This method can be used in practice indefinitely. If the processing is done in a professional lab with a well-configured computer cluster, it can achieve extremely high efficiency while saving time and money.

The frequency composition and proportion of synthetic timbre and real timbre are different (the proportion of harmonic amplitude coefficient is also different), so the two

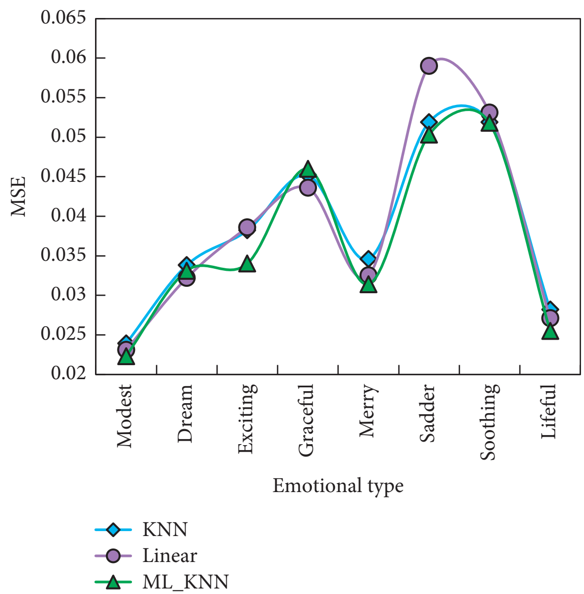

Figure 3: MSE test results of music emotion cognitive model.

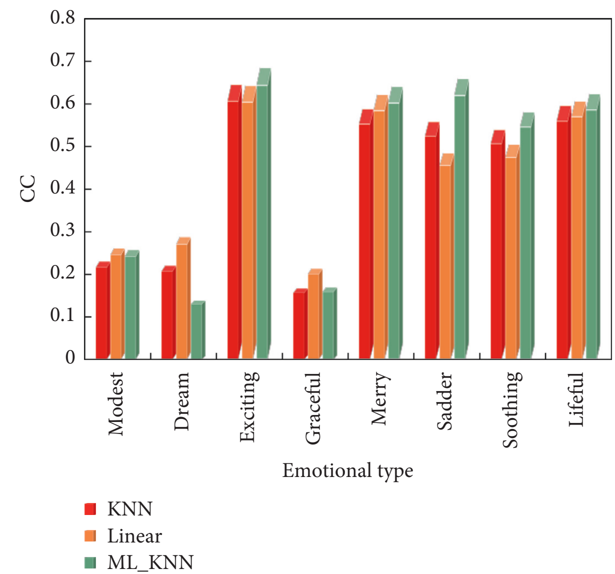

Figure 4: CC test results of music emotion cognitive model.

timbres are different in theory, which is proved by listening timbre. Compared with the positions surrounded by squares in Figure 4, although the synthesized timbre is very smooth in time domain, there are many burrs in frequency domain, and the timbre shows great noise. Therefore, their frequency domain characteristics are quite different. The single-tone datasets of musical instruments are classified, and the timbre expression spectrum is compared and analyzed based on the harmony structure proposed in this paper, so as to find the characteristics that can best reflect the timbre of musical instruments. Split the mono dataset of the instrument into five different datasets. The classification results based on different timbre features in different musical instrument monophonic datasets are shown in Table 1 and Figure 5. In the experiment, KNN is used as the classifier, the training set is 4/5 of the experimental data, and the test set is 1/5 of the experimental data.

It can be seen that the recognition rate of dataset 1 is generally high, because the timbre features of dataset 1 are all within a certain range, and the recognition of a single instrument is to find the specific corresponding point within this range. Regardless of the type of function set on which MFCC is based, the timbre expression spectrum of this paper performs well. According to the timbre expression spectrum function, the recognition rate of dataset 1 reaches 91.5%. According to MFCC function, the recognition rate of dataset 2 is 95.2%, that of dataset 3 is 78.4%, that of dataset 4 is 94.1%, and that of dataset 5 is 92.6%, which is the best result.

Extracting the same combination features of timbre and based on four supervised pattern recognition algorithms, KNN, Naive Bayes, Decision Tree, and ML_KNN, the classification and recognition experiments of single tones of musical instruments are carried out, respectively. The results are shown in Table 2 and Figure 6.

As can be seen, ML_KNN has the highest recognition rate across all datasets, so ML_KNN is chosen as the classifier for musical instrument classification and recognition in this paper. In addition, KNN is second only to ML_KNN in terms of classification and recognition of musical instruments. The performance of a detuned mode oscillator is better than that of a critical mode oscillator in various networks, which can be attributed to the clamping phenomenon mentioned earlier. The process of hijacking between local oscillator groups in the network to better track the time can be thought of as the rhythm change of a piece of music. The oscillator will show similar frequencies in the local area where strong resonance occurs. Average field networks have higher evaluation indices than other networks, but they also have a higher standard deviation. This demonstrates that the results of each round in the cross-validation process vary widely.

We conclude from our timbre analysis that all frequency components in the frequency domain interact to form a rich piano timbre and that synthesis of piano timbre cannot rely solely on overtone frequency components. The ratio of the vibration frequencies of the two pitches that make up the intervals determines the harmony of intervals, which is a characteristic that reflects the basic properties of intervals. Concordant intervals sound good and blend together, whereas dissonant intervals sound rougher and do not blend together. The Fourier transform algorithm is used to calculate the frequency, amplitude, and phase of various sine wave signals by accumulation [18]. Different playing skills of many musical instruments can produce different timbres. MFCC is extracted from these single-frame musical instrument sounds by describing the standard equation. The frame size is 130 ms, and the overlapping size of two adjacent frames is 80 ms, which reduces the information loss caused by window function. The hop count of the frame is 45 ms. The classifier is trained on these feature databases. Figure 7 shows the comparison results of ring estimation based on multilabel classifier.

It can be concluded that, after introducing ML_KNN classification algorithm, the label Decision Tree classification

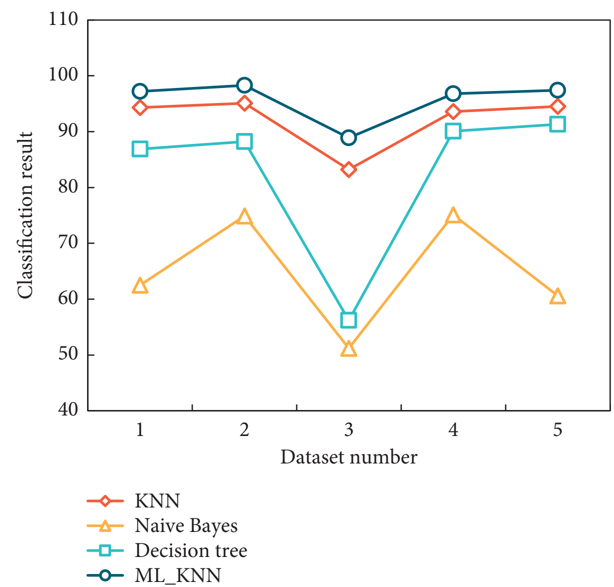

Figure 6: Classification and recognition results of musical instrument tones.

Table 2: Classification and recognition results of musical instrument tones based on different classifiers.

Dataset number	KNN	Naive Bayes	Decision Tree	ML_KNN
1	94.3	62.5	86.9	97.2
2	95.1	74.9	88.2	98.3
3	83.2	51.2	56.2	88.9
4	93.6	75.1	90.1	96.8
5	94.5	60.6	91.3	97.4

algorithm with more prediction effects is obviously improved. After using ML_KNN classification algorithm, the detection rate is increased from 61.3% to 70.2%. The correct rate also increased from 40.3% to 48.9%. When the k value was set to 6, the detection rate increased to 74.6%, but the correct rate decreased to 41.2%. The conclusion of this experiment is that ML_KNN classification algorithm has better recognition effect than Decision Tree classification algorithm.

In the process of learning and studying music scores, pianists will naturally find a lot of music knowledge to supplement, such as musical instrument materials, pronunciation principles, staff of various transposed musical instruments, orchestration methods, and performance methods. To shorten the spectrum of vocal music, we need to know the pronunciation methods. No matter what note it is, the same attenuation rate is used, but, through the judgment

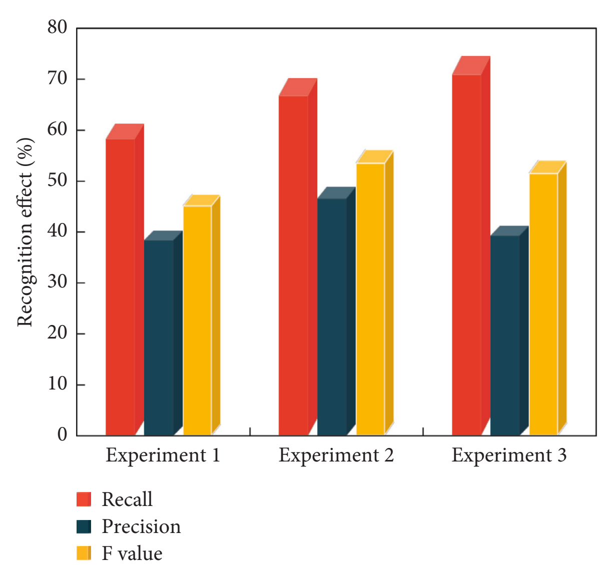

Figure 7: Comparison results of timbre estimation of multilabel classifiers.

of human ears, it can be found that the noise is reduced but not eliminated, so the music played is not very effective, and it is not musical with fluctuations. The combination of piano timbre characteristic matrix and sound intensity envelope curve can effectively distinguish the timbre differences of different songs, that is, identify the timbre of piano arrangement.

5. Conclusions

To sum up, this paper designs an AI-based piano arranger timbre recognition system based on Fourier analysis. Through short-time Fourier frequency shift spectrum analysis, the ringing characteristic matrix can be extracted. Get a tone shift envelope curve. The piano timbre can be clearly identified by the timbre characteristic matrix and transposition envelope curve. ML_KNN classification algorithm is applied to timbre recognition of chord music. The experimental results show that ML_KNN classification algorithm can improve the accuracy of chord music timbre recognition. After using ML_KNN classification algorithm, the detection rate increased from 61.3% to 70.2%. The correct rate also increased from 40.3% to 48.9%, and the detection rate increased to 74.6% when the k value was set to 6. The experimental results show that the timbre recognition system designed in this paper can synthesize clear piano music and has good timbre recognition performance, which is worthy of wide application.

In order to improve the effect of e-sports training, this paper combines the intelligent gesture recognition technology to construct an e-sports training system and judges the training effect of players through the recognition of players' gestures. Moreover, this paper studies the commonly used feature extraction algorithms and proposes an improved SLC-Harris feature extraction algorithm, and the feasibility of this algorithm is verified by the experimental results on the EUROC data set. In addition, this paper uses the KLT optical flow algorithm to track the extracted feature points and calculates the pure visual pose through epipolar geometry, triangulation, and PnP algorithms. The experimental research results show that the electronic economic training system based on intelligent gesture recognition proposed in this paper has certain effects.

1. Introduction

The reason why e-sports can become a sports competition is that it is closely related to the progress of society, the development of science and technology, and the spiritual and cultural needs of the people. Although there are countless people who enjoy this high-tech intellectual sports event, in fact, public opinion instills the harmful opinion of e-sports in people intentionally or unintentionally. Some media reported extensively that some students were addicted to games and could not extricate themselves, wasting their youth and studies, which made e-sports become "electronic heroin" that everyone shouted. The huge pressure of public opinion makes e-sports face severe survival pressure, and it is difficult for enterprises to enter this market justifiably. Moreover, athletes can only be called "players," and their treatment cannot be compared with that of ordinary athletes. At the same time, the majority of fans can only engage in e-sports secretly. In addition, in the face of huge pressure from public opinion, it is difficult for the government to guide and supervise confidently, and sometimes, it has to prohibit escrow. The ban on television broadcasting of e-sports competitions can be described as a huge obstacle to the normal development of the current social discrimination against the e-sports sports industry.

Generally speaking, the development of e-sports is not yet mature, and the development of e-sports is still in its infancy [1], which is manifested in many aspects: the public recognition is not enough, there are few related large-scale events, there is no professional-scale operation, there is less research in this area, and so on [2]. Especially on college campuses, although students have more time for self-discipline than before, the school does not pay enough attention to e-sports, and there is no relatively formal organization and management of participants, which has led to many human resources problems waste [3].

In order to cater to the trend of e-sports development, vigorously develop e-sports business, improve the overall level of e-sports, and enable e-sports activities to develop well in colleges and universities, the current primary task is to deepen the characteristics of students participating in e-sports activities [4]. Among them, the analysis and research on the current situation, development trend, and participation significance of e-sports in colleges and universities are particularly important in order to discover the problems existing in the development of campus e-sports and put forward reasonable suggestions for the development [5].

As emerging sports, e-sports are mainly participated by the younger generation, which has the characteristics of younger and younger age. E-sports can exercise people's thinking ability, psychological pressure resistance, unity and cooperation, hand-eye coordination, and so on. It can also make the younger generation have the awareness of abiding by the rules in the process of participating in e-sports [6]; trained participants have a fair and open, never admit defeat, pursue a stronger competitive spirit, and have a positive impact on the lives of participants. Many colleges and universities have successively opened related majors in e-sports. Although e-sports is popular in the world, the related research and guiding theories on how to cultivate e-sports talents are rare [7].

Different scholars have different views on the attributes and characteristics of e-sports. Literature [8] proposed that "e-sports include three basic characteristics: one is electronics, the other is competitive sports, and the third is a confrontation between people. At the same time, e-sports sports are divided into virtualized e-sports sports and fictionalized sports." Literature [9] pointed out that "the most fundamental characteristics of video games that distinguish them from other artificial games are: virtual environment, absence of the body and artificial intelligence," emphasizing the main position of electronic communication technology in e-sports. Scholar Yang Fang believes that "e-sports should return to the essence of games, and games to competitive sports are based on the evolution trend of play-game-competitive sports" and based on the development process of traditional competitive sports, puts forward a plan for the development of e-sports. Jia Peng and Yao Jiaxin believe that e-sports has great characteristics: the diversity of functional structure requirements, the full expansion of self-awareness, the complexity of sports information pattern recognition, the agility of information processing efficiency, and the accuracy of intuitive thinking and decision-making. Sex analyzes and clarifies the various attributes of e-sports from many aspects [10].

The discussion on the attributes of e-sports is still going on. Based on the current research, it can be determined that the two essential attributes of e-sports are electronic interaction and confrontational competition. Without electronic interaction, it becomes traditional competitive sports; it becomes a video game, so the two are interdependent and indispensable. With the development of electronic interaction technology, various forms of e-sports have emerged [11].

Event services are mainly engaged in e-sports referees, coaches, club operation and management, game commentary, data and tactical analysis, and so on. Practitioners need to have data analysis capabilities, management capabilities, and commentary capabilities. The production and broadcast of the event include content production and external dissemination, mainly involving the design of live content and promotion plans, venue layout, equipment debugging, video data collection, postprocessing, background data analysis, and so on. The practitioners should have journalism, communication, broadcasting, TV technology, and other related professional abilities [12].

Since the e-sports industry is an emerging industry, most employees are not from e-sports majors and have not received a complete and systematic e-sports theoretical education, but nearly 90% of the employees believe that the e-sports industry needs prejob training [13]. Judging from the current situation of the development of the entire industry, it is undoubtedly the most attractive option to work for game manufacturers, but it is difficult for game manufacturers to absorb more human resources without major business adjustments. Therefore, the need to train practitioners in support organizations around e-sports events becomes more obvious [14]. For example, training content production capabilities (reporters, screenwriters, copywriters, and anchors) requires a professional background in journalism and communication; training event support capabilities (coaches, data analysts, nutritionists, and brokers) requires sports and information technology. Professional background: training public relations, marketing capabilities (products, business, brand marketing, and media), requires a professional background in marketing and management [15].

E-sports self-media is still a media, and you must have the ability to report news, or you can dig deep into a vertical field, such as specializing in video commentary of games, specializing in game clearance strategies, specializing in sharing game skills, and so on. After all, hot spots can bring traffic. WeMedia is a personalized media with social attributes; it communicates with users; and it has its own distinct character orientation [16]. To be a self-media, you should also have strong analytical skills and be able to interpret a topic or special event from a unique or professional perspective. Current e-sports professional ability training pathways.

1.1. Current E-Sports Professional Ability Training Pathways. Most training institutions in society position themselves as training professional players but basically lack training resources. Training institutions do not have coaches, data analysts, or club managers, and it is difficult for the trained people to find a suitable position in the e-sports circle. Rather than cultivating professional skills, it is better to make money from e-sports hot spots. Money has no intention or inability to contribute to the development of the e-sports industry [17].

At present, the main e-sports talents are cultivated by e-sports companies and e-sports clubs. The club mainly trains professional players, coaches, and data analysts in order to achieve better results in the league. Game companies train referees, game developers, commentators, and other related talents to ensure the healthy development of the e-sports industry [18]. An analysis of the revenue structure of the e-sports industry can help us see the e-sports industry more transparently. The truly profitable institutions are still game manufacturers, which continuously create market value through development and operation. In the context of the continuous development and popularization of the video game industry, competition has become a starting point for expanding influence and creating new commercial value. The comprehensive development of competitive value is inseparable from the promotion of surrounding formats, and new jobs such as video, live broadcast, and commentary emerge in an endless stream [19].

This paper combines the intelligent gesture recognition technology to construct an e-sports training system and uses the player's gesture recognition to judge the player's training effect to improve the e-sports training effect.

2. Intelligent Gesture Recognition

2.1. Gesture Intelligent Positioning. The structural framework of the gesture autonomous localization algorithm is shown in Figure 1.

Monocular visual-inertial odometry uses a pure camera in the front end for motion estimation. The algorithm firstly extracts the features of the image information collected by the camera, then uses the optical flow method to track the feature points, and finally uses PnP (Perspective-n-Point) to perform motion estimation on the tracked feature points. Then, the algorithm eliminates the mismatched point pairs through random sampling consistency (RANSAC) and uses nonlinear optimization to optimize the pose. The front-end process is shown in Figure 2.

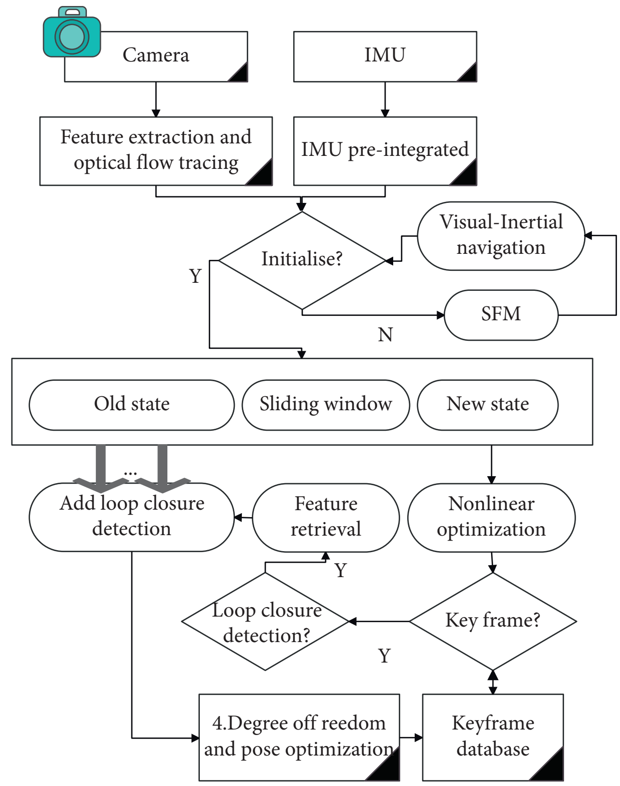

Figure 1: Gesture positioning algorithm structural framework.

2.2. SLC-Harris Feature Extraction. The feature is the digital expression of the object in the image, and the image can be quantitatively analyzed by extracting the feature. Commonly used feature extraction methods mainly include SIFT algorithm, SURF algorithm, and ORB algorithm.

The traditional Harris algorithm calculates the angular responsivity as shown below. It is mainly based on the weighted summation of the squared and multiplied gradients of all pixels in the window.

$$R = |C| - k \times (\text{trace}(C))^2. \tag{1}$$

Among them, there are

$$|C| = \lambda_1 \times \lambda_2, \tag{2}$$

$$\text{trace}(C) = \lambda_1 + \lambda_2. \tag{3}$$

In formula (1), k is a constant ranging from 0.04 to 0.06, and both λ_1 and λ_2 in formula (2) represent eigenvalues.

For a grayscale image, the value of any point (x, y) in the integral image ii (x, y) refers to the sum of all grayscale values from the upper left corner of the image to the area where this point is located, as shown in Figure 3.

The calculation formula of pixels in the rectangular window is as follows:

$$ii(x, y) = \sum_{x' \le x, y' \le y} I(x', y'). \tag{4}$$

The most complex calculation in the Harris algorithm is the calculation of diagonal responsivity. The original calculation method causes the calculation overlap between each pixel in the integration window, resulting in high computational complexity. For this, the gradient values in g_x^2, g_y^2 and $g_x g_y$ are used to integrate the image to speed up the calculation of the angular responsivity. The calculation formula is as follows:

$$\begin{aligned} ii_{xx}(x, y) &= \sum_{x' \le x, y' \le y} g_x^2(x', y'), \\ ii_{yy}(x, y) &= \sum_{x' \le x, y' \le y} g_y^2(x', y'), \\ ii_{xy}(x, y) &= \sum_{x' \le x, y' \le y} g_x(x', y') g_y(x', y'). \end{aligned} \tag{5}$$

Efficient nonmaximum suppression (E-NMS) is used to efficiently extract unique feature locations for each corner region, and the region thresholds are compared using image patches instead of pixels. The principle is shown in Figure 4.

2.3. KLT Optical Flow Tracking. After the key points are extracted, the optical flow method is used to calculate the minimum photometric error by establishing an error model. This method does not need to calculate descriptors or feature point matching, which will greatly save the amount of calculation.

The basic idea of LK optical flow is to assume that the optical flow in the local neighborhood of a pixel is invariant, and based on this assumption, construct a least-squares problem about the optical flow of the neighborhood pixels.

First, it is assumed that the light intensity of the pixel in each frame of the image is constant. According to this, for the pixel located at (x, y) at time t, moving to $(x + dx, y + dy)$ at time $t + dt$, there are

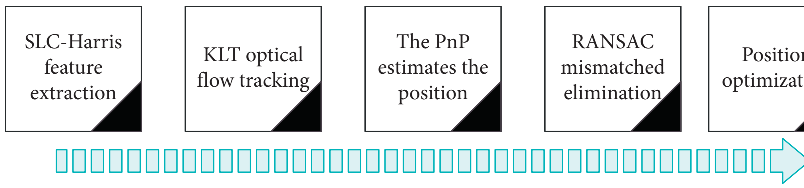

FIGURE 2: Front-end flowchart.

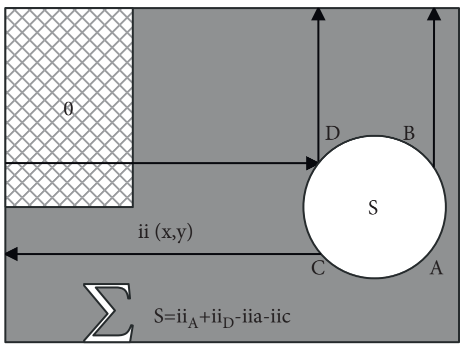

FIGURE 3: Rectangular window pixel calculation.

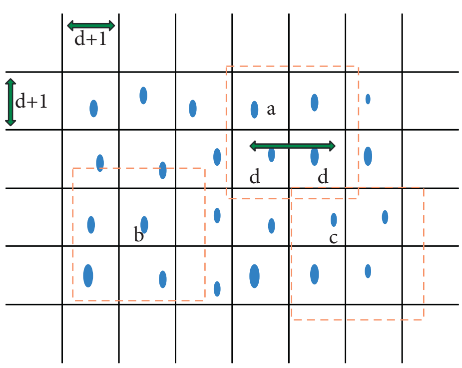

FIGURE 4: Efficient nonmaximum suppression.

$$I(x, y, t) = I(x + dx\ , y + dy\ , t + dt). \tag{6}$$

Then, according to another basic assumption of LK optical flow, the displacement of pixels in adjacent images is small; the Taylor expansion of formula (6) is

$$I(x + dx\ , y + dy\ , t + dt) \approx I(x, y, t) + \frac{\partial I}{\partial x}dx + \frac{\partial I}{\partial y}dy + \frac{\partial I}{\partial t}dt. \tag{7}$$

Combining the above formulas and dividing by dt into both sides of the formula, we get:

$$\frac{\partial I}{\partial x}\frac{\mathrm{d}x}{\mathrm{d}t} + \frac{\partial I}{\partial y}\frac{\mathrm{d}y}{\mathrm{d}t} = -\frac{\partial I}{\partial t}, \tag{8}$$

where $\mathrm{d}x/\mathrm{d}t$ represents the motion speed of the pixel on the x-axis, $\mathrm{d}y/\mathrm{d}t$ represents the motion speed of the pixel on the y-axis, and the two speeds are recorded as u and v, respectively. At the same time, $\partial I/\partial x$ represents the gradient value of the image in the x-axis direction at the pixel point; $\partial I/\partial y$ represents the gradient value in the y-axis direction at the pixel point; and $\partial I/\partial t$ represents the derivative value of the image in the t direction, which are denoted as I_x, I_y, and I_t, respectively. Therefore, formula (8) can be written in matrix form as follows:

$$\begin{bmatrix} I_x & I_y \end{bmatrix}\begin{bmatrix} u \\ v \end{bmatrix} = -I_t. \tag{9}$$

Finally, according to the third basic assumption of the LK optical flow method, adjacent pixels in the same image plane have similar motion; a $w \times w$ size window is defined. According to the same motion of all pixels in the window, w^2 formulas can be listed; the overdetermined formulas can be constructed; and the motion parameters of the center point can be obtained by the least square method. Accordingly, its formula can be expressed as follows:

$$\begin{pmatrix} \sum I_x I_x & \sum I_x I_y \\ \sum I_x I_y & \sum I_y I_y \end{pmatrix}\begin{pmatrix} u \\ v \end{pmatrix} = -\begin{pmatrix} \sum I_x I_t \\ \sum I_y I_t \end{pmatrix}. \tag{10}$$

Each image frame is downsampled by pyramid layering, and multilevel pyramids are established.

$$\begin{aligned} I^L(x, y) = {} & \frac{1}{4}I^{L-1}(2x, 2y) + \frac{1}{8}\begin{pmatrix} I^{L-1}(2x-1, 2y) + I^{L-1}(2x+1, 2y) \\ +I^{L-1}(2x, 2y-1) + I^{L-1}(2x, 2y+1) \end{pmatrix} \\ & + \frac{1}{16}\begin{pmatrix} I^{L-1}(2x+1, 2y+1) + I^{L-1}(2x+1, 2y+1)+ \\ I^{L-1}(2x+1, 2y+1) + I^{L-1}(2x+1, 2y+1) \end{pmatrix}, \end{aligned} \tag{11}$$

where L represents the Lth layer image.

The algorithm calculates the value of the bottom layer from top to bottom according to the Gaussian pyramid and calculates the pixel value near the edge of the image based on the following formulas:

$$\begin{aligned} I^{L-1}(-1, y) &\approx I^{L-1}(-1, y), \\ I^{L-1}(x, -1) &\approx I^{L-1}(x, 0), \\ I^{L-1}\left(n_x^{L-1}, y\right) &\approx I^{L-1}\left(n_x^{L-1} - 1, y\right), \\ I^{L-1}\left(x, n_y^{L-1}\right) &\approx I^{L-1}\left(x, n_y^{L-1} - 1\right), \\ I^{L-1}\left(n_x^{L-1}, n_y^{L-1}\right) &\approx I^{L-1}\left(n_x^{L-1} - 1, n_y^{L-1} - 1\right). \end{aligned} \tag{12}$$

The camera motion pose is estimated using SFM in the vision front end. For a monocular camera, the camera pose can be estimated by the geometric relationship between two points in different locations in real space and their projected points on their respective imaging planes. As shown in Figure 5, P is any point in the three-dimensional space, and its coordinates are $[X, Y, Z]^T$; O_1 and O_2 are the optical centers of the two camera positions. p_1 and p_2 are the projection points of point P on the imaging plane I_1 and the imaging plane I_2, respectively. According to the pixel positions of the two matched point pairs p_1 and p_2, the essential matrix E and the fundamental matrix F can be obtained.

According to the camera imaging model, we assume that K is the camera internal parameter matrix, and R and t represent the rotation matrix and translation vector from plane I_1 to plane I_2, and the following formula can be obtained:

$$s_1 p_1 = KP, s_2 p_2 = K(RP + t). \tag{13}$$

Homogeneous coordinate transformation and normalization between 2D and 3D, we can get

$$x_1 = K^{-1} p_1, x_2 = K^{-1} p_2, \tag{14}$$

where x_1 and x_2 represent the coordinates of pixels p_1 and p_2 in the normalized plane, respectively. The algorithm combines formuls (13) and (14) and multiplies by $x_2^T t^\wedge$ to obtain the essential matrix E and the fundamental matrix F, which can be sorted out as follows:

$$\begin{aligned} p_2^T K^{-T} t^\wedge R K^{-1} p_1 = 0, \\ E = t^\wedge R, F = K^{-T} E K^{-1}, \end{aligned} \tag{15}$$

where $t^\wedge$ represents the antisymmetric matrix.

When there are more than eight sets of point pairs such as p_1 and p_2, the eight-point method can be used to construct a linear formula system for the simplified formula, and then the unique solution of R and t can be obtained.

$$x_2^T E x_1 = p_2^T F p_1 = 0. \tag{16}$$

When the monocular camera recovers the pose through the epipolar geometric relationship, the obtained translation is the normalized value, which has no practical significance.

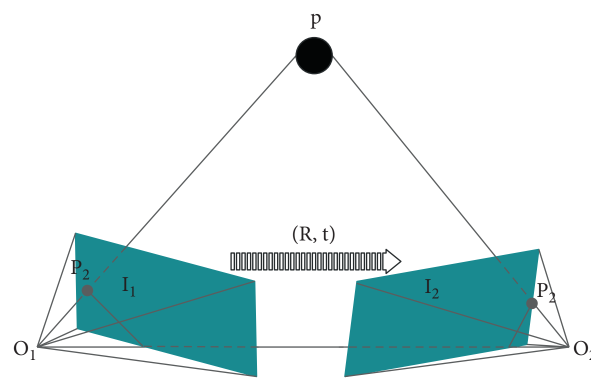

Figure 5: Epipolar geometric constraints.

In order to obtain the depth information on feature points, triangulation needs to be introduced. We assume that s_1 and s_2 represent the depth of the two feature points; we can get

$$s_2 x_2 = s_1 R x_1 + t. \tag{17}$$

The feature point depth values $x_2^\wedge$ and $x_1\wedge$ can be obtained by left-multiplying formula (17) by s_1 or s_2, respectively, as follows:

$$\begin{aligned} s_1 x_2^\wedge R x_1 + x_2^\wedge t = 0, \\ s_2 x_1^\wedge R x_2 - x_1^\wedge t = 0. \end{aligned} \tag{18}$$

When the positions of multiple points in space are known, the camera pose can be estimated by the PnP algorithm. Common PnP algorithms include P3P, DLT, and BA optimization. Among them, the P3P algorithm is the most common method. The algorithm needs to know at least three points and their projection points on the camera imaging plane. Then, the camera pose can be estimated by solving the relationship between point pairs according to the similar triangle principle and the cosine theorem. A schematic diagram of the P3P relationship is shown in Figure 6.

The coordinate system convention is as follows: the world coordinate system is represented by $(\cdot)^w$, and $(\cdot)^b$ and $(\cdot)^c$ represent the IMU coordinate system and the camera coordinate system, respectively. The relationship between the coordinate systems is shown in Figure 7. $(.)^v$ represents the visual reference frame in the sliding window, which is independent of the IMU measurement and can represent any frame in the visual structure. $(.)_b^w$ represents the transformation from the IMU coordinate system to the world coordinate system; b_k represents the IMU frame of the kth image; $(\cdot)_c^v$ represents the transformation from the camera coordinate system to the visual reference system; and c_k represents the camera frame of the kth image. $\widehat{(\cdot)}$ represents the measured value and parameter estimation value of the sensor; $\overline{(\cdot)}$ represents the latest scale parameter of the sliding window; and the rotation can be represented by the rotation matrix $\mathbf{R}$ and the quaternion $\mathbf{q}$. $\mathbf{g}^w = [0, 0, g]^T$ represents the gravity vector in the world coordinate system, and g^v represents the gravity vector in the visual reference coordinate system.

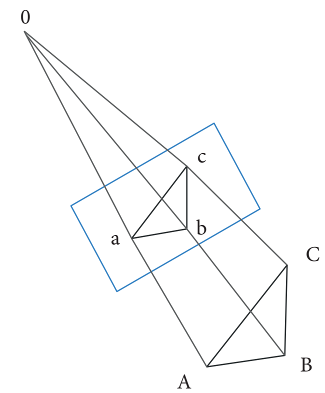

Figure 6: Schematic diagram of P3P relationship.

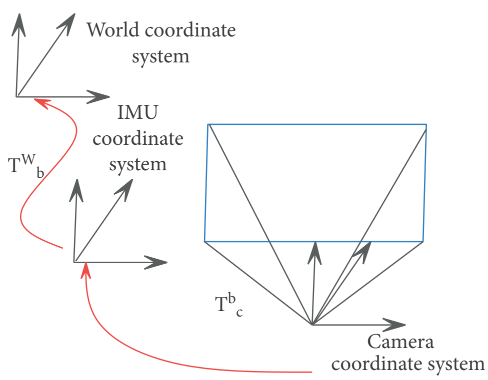

Figure 7: Coordinate conversion relationship.

2.4. IMU Preintegration. The sampling frequency of the camera used in this paper is 20 Hz, and the sampling frequency of the IMU is 200 Hz. It can be seen that the frequency of the IMU is much higher than that of the image. In order to avoid the repeated integration phenomenon caused by the frequency change of the visual frame optimization state caused by the high sampling rate of the IMU, a pre-integration technique is used for all IMU sampling data between two image key frames. Furthermore, inertial measurements between adjacent image key frames are aggregated into a relative motion constraint through a pre-integration technique. The principle of preintegration is shown in Figure 8.

In Figure 8, from top to bottom are the time scale line, the number of image frames generated, the number of image key frames generated, the number of IMU samples, and the IMU preintegration value.

The measurement error of the system is mainly affected by bias random walk b and white noise η, and other errors such as the Markov process are ignored. Then, the measurement model of the accelerometer and gyroscope in the IMU can be expressed by the following formula:

$$\hat{\omega}^b = \omega^b(t) + b_\omega + \eta_\omega \frac{1}{2},$$
$$\hat{a}^b = q_b^{w^T}\left(a^w - \mathbf{g}^w\right) + b_a + \eta_a, \tag{19}$$

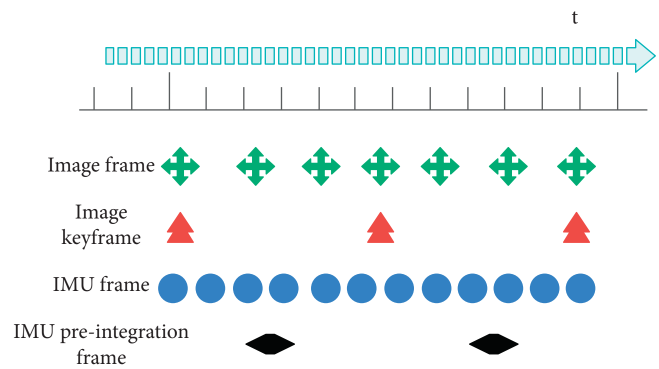

Figure 8: Principle of preintegration.

where $\hat{\omega}^b, \hat{a}^b(t), \omega^b(t)$, and $a^w(t)$ represent the measured value and real value of angular velocity and acceleration, respectively; $b_\omega, b_a, \eta_\omega$, and η_a represent the random walk noise and measurement white noise of angular velocity and acceleration, respectively; and $q_b^{w^T}$ is the rotation matrix transformed from the world coordinate system to the IMU coordinate system.

White noise obeys a Gaussian distribution, that is, $\eta_a \sim N(0, \sigma_a^2), \eta_\omega \sim N(0, \sigma_\omega^2)$. The derivative of random walk noise also obeys the Gaussian distribution, that is, $\eta_{b_a} \sim N(0, \sigma_{b_a}^2), \eta_{b_\omega} \sim N(0, \sigma_{b_\omega}^2)$.

The differential kinematic formulas for P, V, Q (representing the position, velocity, and rotation expressed in quaternions, respectively) versus time can be written as follows:

$$\dot{p}_{b_t}^w = v_t^w,$$
$$\dot{v}_t^w = a_t^w,$$
$$\dot{q}_{b_t}^w = q_{b_t}^w \otimes \begin{bmatrix} 0 \\ \frac{1}{2}\omega^{b_t} \end{bmatrix}, \tag{20}$$

where $\otimes$ represents quaternion multiplication.

Through the above derivative relationship, the position, velocity, and rotation at time $k+1$ can be obtained from the position, velocity, and rotation at time k and by integrating the measured values of the IMU over time Δt_k. The continuous integration formula for PVQ is as follows:

$$p_{b_{k+1}}^w = p_{b_k}^w + v_{b_k}^w \Delta t_k + \iint_{t\in[k,k+1]} \left[R_t^w\left(\hat{a}_t - b_{a_t}\right) - g^w\right] dt^2,$$
$$v_{b_{k+1}}^w = v_{b_k}^w + \int_{t\in[k,k+1]} \left[R_t^w\left(\hat{a}_t - b_{a_t}\right) - g^w\right] dt,$$
$$q_{b_{k+1}}^w = q_{b_k}^w \otimes \int_{t\in[k,k+1]1/2} \Omega\left(\hat{\omega}_t - b_{w_t}\right) q_t^{b_k} dt, \tag{21}$$

where $\hat{a}_t$ and $\hat{\omega}_t$ represent the acceleration and angular velocity measured in the IMU coordinate system, respectively. Δt_k represents the time difference from the kth frame to the $k+1$ frame. R_t^w represents the rotation matrix from the world coordinate system to the IMU coordinate system. Because the measured $\hat{a}_t$ and $\hat{\omega}_t$ belong to the IMU coordinate system, in order to transform the IMU measured value to the world coordinate system, the rotation matrix needs to be left-multiplied. $\Omega(\omega)$ means quaternion right multiplication; ω_x means antisymmetric matrix in quaternion multiplication (ω means the imaginary part value of quaternion). We assume that the quaternion is $q = [\,x \;\; y \;\; z \;\; s\,] = [\,\omega \;\; s\,]$; then we have

$$\begin{aligned}\Omega(\omega) &= \begin{bmatrix} -\omega_\times & \omega \\ -\omega^T & 0 \end{bmatrix},\\ \omega_\times &= \begin{bmatrix} 0 & \omega_z & \omega_y \\ \omega_z & 0 & -\omega_x \\ -\omega_y & \omega_x & 0 \end{bmatrix}.\end{aligned} \tag{22}$$

By observing the continuous integral formula of PVQ, it can be seen that the current state is recursively obtained from the state of the previous time, and the estimated value is constantly changing. This will cause the IMU measurements to be repropagated, causing the velocity and rotation to be reintegrated after each nonlinear optimization iteration, resulting in a higher computational cost. Therefore, the optimization variables are separated from the IMU preintegration terms of the two key frames, and the rotation matrix $R_w^{b_k}$ of the world coordinate system to the IMU coordinate system can be obtained by simultaneously left-multiplying the left and right sides of the continuous integration formula of PVQ:

$$\begin{aligned}R_w^{b_k} p_{b_{k+1}}^w &= R_w^{b_k}\left(p_{b_k}^w + v_{b_k}^w \Delta t_k - \frac{1}{2} g^w \Delta t_k^2\right) + \alpha_{b_{k+1}}^{b_k},\\ R_w^{b_k} v_{b_{k+1}}^w &= R_w^{b_k}\left(v_{b_k}^w - g^w\right) + \beta_{b_{k+1}}^{b_k},\\ q_w^{b_k} \otimes q_{b_{k+1}}^w &= \gamma_{b_{k+1}}^{b_k}.\end{aligned} \tag{23}$$

The image frames b_k and b_{k+1} of two consecutive moments are given, and the linear acceleration and angular velocity are preintegrated in the local coordinate system b_k to obtain

$$\begin{aligned}\alpha_{b_{k+1}}^{b_k} &= \int\int_{t\in[k,k+1]} R_t^{b_k}\left(\hat{a}_t - b_{a_t}\right) \mathrm{d}t^2,\\ \beta_{b_{k+1}}^{b_k} &= \int_{t\in[k,k+1]} \left[R_t^{b_k}\left(\hat{a}_t - b_{a_t}\right)\right] \mathrm{d}t,\\ \gamma_{b_{k+1}}^{b_k} &= \int_{t\in[k,k+1]2} (1/2)\Omega\left(\hat{\omega}_t - b_{\omega_t}\right)\gamma_t^{b_k} \mathrm{d}t,\end{aligned} \tag{24}$$

where $\alpha_{b_{k+1}}^{b_k}, \beta_{b_{k+1}}^{b_k}, \gamma_{b_{k+1}}^{b_k}$ represent the relative pose, velocity, and rotation constraints, respectively, and are also the relative motion of b_{k+1} to b_k. It can be seen that they are only related to $\hat{a}_t$ and $\hat{\omega}_t$ in b_k and b_{k+1}, and they have nothing to do with the initial position and velocity of coordinate system b_k.

Therefore, the preintegration formula is rediscussed, in terms of $\alpha_{b_{k+1}}^{b_k}$; it is related to $\hat{a}_t$ and $\hat{\omega}_t$ of the IMU; and $\hat{a}_t$ and $\hat{\omega}_t$ are also variables that need to be optimized. When the bias change is small, $\alpha_{b_{k+1}}^{b_k}, \beta_{b_{k+1}}^{b_k}, \gamma_{b_{k+1}}^{b_k}$ are adjusted according to their first-order approximations to the bias.

$$\begin{aligned}\alpha_{b_{k+1}}^{b_k} &\approx \hat{\alpha}_{b_{k+1}}^{b_k} + J_{b_a}^{\alpha}\delta b_a + J_{b_\omega}^{\alpha}\delta b_\omega,\\ \beta_{b_{k+1}}^{b_k} &\approx \hat{\beta}_{b_{k+1}}^{b_k} + J_{b_a}^{\beta}\delta b_a + J_{b_\omega}^{\beta}\delta b_\omega,\\ \gamma_{b_{k+1}}^{b_k} &\approx \gamma_{b_{k+1}}^{b_k} \otimes \begin{bmatrix} 0 \\ \\ \dfrac{1}{2}J_{b_a}^{\gamma}\delta b_\omega \end{bmatrix},\end{aligned} \tag{25}$$

where $J_{b_a}^{\alpha}$ and $J_{b_\omega}^{\alpha}$ are the block matrices in $J_{b_{k+1}}^{\alpha}$ and $J_{b_a}^{\beta}$ and $J_{b_\omega}^{\beta}$ are the block matrices in $J_{b_{k+1}}^{\beta}$.

There are errors in the integral values of the IMU at different times, and the errors at time t are mainly related to the measured values of $\alpha_t^{b_k}, \beta_t^{b_k}, \theta_t^{b_k}, b_{a_t}$, and b_{ω_t} at time t. The following definition is given to represent the error vector:

$$\delta z_t^{b_k} = \begin{bmatrix} \delta\alpha_t^{b_k} \\ \delta\beta_t^{b_k} \\ \delta\theta_t^{b_k} \\ \delta b_{a_t} \\ \delta b_{\omega_t} \end{bmatrix}. \tag{26}$$

The derivation is based on the derivative of the error term kinetic formula. First, two concepts are introduced: true and nominal, where true represents the real measurement value containing noise and nominal represents the theoretical value without noise, and δ represents the measurement error; there are

$$\begin{aligned}\delta\dot{\alpha} &= \dot{\alpha}_{\text{true}} - \dot{\alpha}_{\text{nominal}},\\ \delta\dot{\beta} &= \dot{\beta}_{\text{true}} - \dot{\beta}_{\text{nominal}}.\end{aligned} \tag{27}$$

Among them, there are:

$$\begin{aligned}\dot{\beta}_{\text{true}} &= R_t^{b_k}\left[\hat{a}_t - \eta_a - b_{a_t} - \delta b_{a_t} - \left[\hat{a}_t - b_{a_t\times}\delta\theta\right],\right.\\ \dot{\beta}_{\text{nominal}} &= R_t^{b_k}\left(\hat{a}_t - b_{a_t}\right).\end{aligned} \tag{28}$$

Combining the above formulas, we can obtain

$$\delta\dot{\beta} = -R_t^{b_k}\hat{a}_t - b_{a_t\times}\delta\theta - R_t^{b_k}\delta b_{a_t} - R_t^{b_k}\eta_a. \tag{29}$$

The derivation of $\delta\dot{\theta}$ is as follows, and according to the formula in the literature, it can be known that

$$q_{\text{true}} = q_{\text{nominal}} \otimes \delta q. \tag{30}$$

In this paper, according to the noise model and bias, we can get

$$\delta\dot{\theta} \approx -\hat{\omega}_t - b_{\omega_t\times}\delta\theta - \eta_\omega - \delta b_{\omega_t}. \tag{31}$$

In summary, the derivative of the IMU measurement error term at time t can be as follows:

$$\begin{bmatrix} \delta\dot{\alpha}_t^{b_k} \\ \delta\dot{\beta}_t^{b_k} \\ \delta\dot{\theta}_t^{b_k} \\ \delta\dot{b}_{a_t} \\ \delta\dot{b}_{\omega_t} \end{bmatrix} = \begin{bmatrix} 0 & I & 0 & 0 & 0 \\ 0 & 0 & -R_t^{b_k}\widehat{a}_t - b_{a_t\times} & -R_t^{b_k} & 0 \\ 0 & 0 & -\widehat{\omega}_t - b_{\omega_t\times} & 0 & -I \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \delta\alpha_t^{b_k} \\ \delta\beta_t^{b_k} \\ \delta\theta_t^{b_k} \\ \delta b_{a_t} \\ \delta b_{\omega_t} \end{bmatrix} + c \begin{bmatrix} \eta_a \\ \eta_\omega \\ \eta_{b_a} \\ \eta_{b_\omega} \end{bmatrix}. \tag{32}$$

We set $F_t = \begin{bmatrix} 0 & I & 0 & 0 & 0 \\ 0 & 0 & -R_t^{b_k}\widehat{a}_t - b_{a_t\times} & -R_t^{b_k} & 0 \\ 0 & 0 & -\widehat{\omega}_t - b_{\omega_t\times} & 0 & -I \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}, G_t = \begin{bmatrix} 0 & 0 & 0 & 0 \\ -R_t^{b_k} & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \end{bmatrix}$. The above formula can be simplified to

$$\delta\dot{z}_t^{b_k} = F_t \delta z_t^{b_k} + G_t n_t. \tag{33}$$

According to the definition of the derivative, the prediction formula of the mean is as follows:

$$\begin{aligned} \delta\dot{z}_t^{b_k} &= \lim_{\delta_t \longrightarrow 0} \frac{\delta z_{t+\delta t}^{b_k} - \delta z_t^{b_k}}{\delta_t}, \\ \delta z_{t+\delta_t}^{b_k} &= (1 + F_t\delta_t)\delta z_t^{b_k} + (G_t\delta_t)n_t. \end{aligned} \tag{34}$$

According to the error value at the current moment, the mean and covariance at the next moment can be predicted. The prediction formula for covariance is as follows:

$$P_{t+\delta t}^{b_k} = (1 + F_t\delta_t)P_t^{b_k}(1 + F_t)^T + (G_t\delta_t)Q(G_t\delta_t)^T, \tag{35}$$

where $P_t^{b_k}$ represents the initial value of the iteration and its value is zero and Q represents the diagonal covariance matrix of the noise term as follows:

According to formula (35), the iterative formula of the error term Jacobian can be obtained as follows:

$$J_{t+\delta t} = (1 + F_t)J_t, \tag{36}$$

where the iterative initial value of the Jacobian matrix J_t is I.

2.5. Sliding Window Initialization. When the camera extrinsic parameter matrix $(\overline{p}_{b_k}^{v}, \overline{p}_{c_k}^{v})$ is known, the pose obtained by the initialization of the monocular camera is transformed from the visual coordinate system to the IMU coordinate system to obtain the following formula:

$$\begin{aligned} q_{b_k}^{v} &= q_{c_k}^{v} \otimes q_b^{v}, \\ s\overline{p}_{b_k}^{v} + q_{c_k}^{v} p_b^{c} &= s\overline{p}_{c_k}^{v}, \end{aligned} \tag{37}$$

where s is the translation factor obtained by visual initialization, which has no real information.

The pure visual initialization method lacks absolute scale information. Therefore, the value estimated by the visual SFM is aligned with the IMU after preintegration to estimate the true scale. Visual-inertial alignment initialization is mainly to solve the following problems, including the initialization of gyroscope bias, the initialization of velocity, gravitational acceleration, and scale.

The first is to initialize the gyroscope. The gyroscope bias can be obtained from two consecutive key frames with known orientations, considering two consecutive frames b_k and b_{k+1} in the sliding window, and q_{bk}^{v} and $q_{b_{k+1}}^{v}$ represent the rotations obtained from the pure visual sliding window optimization, respectively. Linearize the IMU preintegration term for the gyroscope bias and minimize the following function:

$$\min_{\delta b_w} \sum_{k \in \mathscr{B}} \left\| q_{b_{k+1}}^{v-1} \otimes q_{b_k}^{v} \otimes \gamma_{b_{k+1}}^{b_k} \right\|^2. \tag{38}$$

Among them, there are:

$$\gamma_{b_{k+1}}^{b_k} \approx \widehat{\gamma}_{b_{k+1}}^{b_k} \otimes \begin{bmatrix} J_{b_w}^{\gamma} & 1 \\ & \delta b_w \end{bmatrix}. \tag{39}$$

In formula (42), $\mathscr{B}$ represents all the frames in the window, and the product of the two quaternions indicates that the camera rotates from the kth frame to the $k+1$th frame, and the gyroscope rotates from the $k+1$th frame to the kth frame, and the optimized objective function is

$$q_{b_{k+1}}^{v-1} \otimes q_{b_k}^{v} \otimes \gamma_{b_{k+1}}^{b_k} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}. \tag{40}$$

The algorithm takes $\widehat{\gamma}$ into the formula and multiplies the inverse moment ordering of the relative constraints obtained from the preintegration to the left on both sides of formula (40) and obtains by Cholesky decomposition (multiplying the transpose of $J_{b_w}^{\gamma}$ on both sides of the formula):

$$J_{b_w}^{\gamma T} J_{b_w}^{\gamma} \delta b_w = 2J_{b_w}^{\gamma T} 2\left(\widehat{\gamma}_{b_{k+1}}^{b_k-1} \otimes q_{b_k}^{v} \otimes q_{b_{k+1}}^{v-1}\right)_{vec}. \tag{41}$$

In this way, the initial calibration value of the gyroscope bias b_w can be estimated, and then the IMU preintegration terms $\widehat{\alpha}_{b_{k+1}}^{b_k}, \widehat{\beta}_{b_{k+1}}^{b_k}, \widehat{\gamma}_{b_{k+1}}^{b_k}$ are corrected with the new gyroscope bias.

The second is the initialization of velocity, gravitational acceleration, and scale. The initialized state vector is as follows:

$$\chi_I = \left[v_{b_0}^{v}, v_{b_1}^{v}, \ldots v_{b_n}^{v}, \mathbf{g}^{v}, s\right], \tag{42}$$

where the state vector $v_{b_k}^{v}$ represents the speed of the visual coordinate system of the kth frame image, $\mathbf{g}^{v}$ represents the gravity vector in the visual coordinate system, and s is the estimated scale parameter. To sum up, the dimension of χ_I is $3(n+1)+3+1$. The constraint relationship between the scale parameter and the speed of the visual SFM is as follows:

$$\widehat{z}_{b_{k+1}}^{b_k} = \begin{bmatrix} \widehat{\alpha}_{b_{k+1}}^{b_k} \\ \\ \widehat{\beta}_{b_{k+1}}^{b_k} \end{bmatrix} = \mathbf{H}_{b_{k+1}}^{b_k}\chi_I + \mathbf{n}_{b_{k+1}}^{b_k} \approx ,$$

$$\begin{bmatrix} -q_v^{b_k}\Delta t_k & 0 & \frac{1}{2}q_v^{b_k}\Delta t^2 & q_v^{b_k}\left(\overline{p}_{b_{k+1}}^v - \overline{p}_{b_k}^v\right) \\ \\ -q_v^{b_k} & q_v^{b_k} & q_v^{b_k}\Delta t_k & 0 \end{bmatrix} \begin{bmatrix} v_{b_k}^v \\ v_{v_{k+1}}^{g^v} \\ g^v \end{bmatrix}, \tag{43}$$

where $q_{b_k}^V, q_{b_k}^V, q_{b_k}^V$ are all obtained from visual SFM. $q_V^{b_k}$ and $q_{b_k}^V$ are mutually inverse matrices. The following linear least squares problem is constructed to complete the initialization of velocity, gravitational acceleration, and scale:

$$\min_{\chi_I} \sum_{k\in\mathcal{B}} \left\| \widehat{z}_{b_{k+1}}^{b_k} - \mathbf{H}_{b_{k+1}}^{b_k}\chi_I \right\|^2. \tag{44}$$

2.6. Monocular Visual Inertial Coupling Nonlinear Optimization. When coupling the visual constraint value and the IMU constraint value, the data of the inertial sensor should be introduced first, and the constraint value of the IMU on the state should be added to the optimized state vector. Then, nonlinear optimization is performed within a sliding window, and all state vectors of the sliding window are as follows:

$$\begin{aligned} \chi &= \left[\mathbf{x}_0, \mathbf{x}_1, \ldots \mathbf{x}_n, \mathbf{x}_c^b, \lambda_0, \lambda_1, \ldots \lambda_m\right], \\ \mathbf{x}_k &= \left[\mathbf{p}_{b_k}^w, \mathbf{v}_{b_k}^w, \mathbf{q}_{b_k}^w, \mathbf{b}_a, \mathbf{b}_g\right], k\epsilon[0,n], \\ \mathbf{x}_c^b &= \left[\mathbf{p}_c^b, \mathbf{q}_c^b\right], \end{aligned} \tag{45}$$

where $\mathbf{x}_k$ represents the state of the IMU when the kth image is captured. There are $n+1$ states in the sliding window, and each state contains the position, velocity, and rotation in the world coordinate system, and the IMU offsets in the IMU coordinate system. λ_m represents the inverse depth information of the mth 3D point, and $\mathbf{x}_c^b$ represents the external parameter from the camera to the IMU. The objective function is

$$\begin{aligned} \min_\chi \Bigg\{ &\left\| r_p - \mathbf{H}_p\chi \right\|^2 + \sum_{k\in\mathcal{B}} \left\| r_{\mathcal{B}}\left(\widehat{\mathbf{z}}_{b_{k+1}}^{b_k}, \chi\right) \right\|_{\mathbf{P}_{b_{k+1}}^{b_k}}^2 \\ &+ \sum_{(l,j)\acute{o}C} \rho\left(\left\| r_C\left(\widehat{z}_l^{c_j}\right) \right\|_{\mathbf{P}_l}^2 c_j \right) \Bigg\}, \end{aligned} \tag{46}$$

where $\mathbf{H}_p$ is the Huber norm, which is defined as follows:

$$\rho(s) = \begin{cases} 1, s \geq 1, \\ 2\sqrt{s} - 1, s < 1. \end{cases} \tag{47}$$

In formula (52), $\|\cdot\|_P$ represents the Mahalanobis distance weighted by the covariance matrix $\mathbf{P}$, and $\{r_p, \mathbf{H}_p\}$, $r_B(\widehat{z}_{b_{k+1}}^{b_k}, X)$, and $r_C(\widehat{z}_l^c, X)$ represent the marginalized prior information, the IMU measurement residual, and the visual reprojection error, respectively. $\mathcal{B}$ is the set of all IMU measurement frames, and $\mathcal{C}$ is the set of visual features in the sliding window.

According to the Gauss–Newton method, the incremental method can be used to calculate the minimum value of the Gaussian objective function, as follows:

$$\begin{aligned} &\min_{\delta X} \left\| r_{\mathcal{B}}\left(\widehat{\mathbf{z}}_{b_{k+1}}^{b_k}, \chi + \Delta X\right) \right\|_{\mathbf{P}_{b_{k+1}}^{b_k}}^2 \\ &= \min_{\delta X} \left\| r_{\mathcal{B}}\left(\widehat{\mathbf{z}}_{b_{k+1}}^{b_k}, \chi\right) + J_{b_{k+1}}^{b_k}\Delta X \right\|_{\mathbf{P}_{b_{k+1}}^{b_k}}^2, \end{aligned} \tag{48}$$

where $J_{b_{k+1}}^{b_k}$ is the Jacobian matrix of the error term $r_{\mathcal{B}}$ with respect to all state vectors χ.

The algorithm differentiates the above formula from ΔX and then sets its derivative to 0, and the formula for the increment ΔX can be calculated as follows:

$$J_{b_{k+1}}^{b_k T} P_{b_{k+1}}^{b_k -1} J_{b_{k+1}}^{b_k} \Delta X = -J_{b_{k+1}}^{b_k T} P_{b_{k+1}}^{b_k -1} J_{b_{k+1}}^{b_k} r_{\mathcal{B}}. \tag{49}$$

The overall incremental equation of the objective function is as follows:

$$\begin{aligned} &\left(\mathbf{H}_p + \sum J_{b_{k+1}}^{b_k T} P_{b_{k+1}}^{b_k -1} J_{b_{k+1}}^{b_k} + \sum J_l^{c_j^T} P_l^{c_j -1} J_l^{c_j}\right)\Delta X \\ &= b_p + \sum J_{b_{k+1}}^{b_k T} P_{b_{k+1}}^{b_k -1} r_{\mathcal{B}} + \sum J_l^{C_j^T} P_l^{C_j^{-1}} r_C, \end{aligned} \tag{50}$$

where $P_{b_{k+1}}^{b_k}$ represents the covariance of the IMU preintegrated noise term and $P_l^{C_j}$ represents the visually observed noise covariance. When the noise covariance $P_{b_{k+1}}^{b_k}$ of the IMU is larger, the inverse of $P_{b_{k+1}}^{b_k}$, that is, its information matrix is smaller, which means that the IMU observations are not as reliable as the visual observations. Formula (50) can be simplified to

$$\left(\Lambda_p + \Lambda_B + \Lambda_C\right)\Delta X = b_p + b_B + b_C, \tag{51}$$

where Λ_p, Λ_B, and Λ_C represent the Hessian matrix. Using the perturbation method to calculate, we can get

$$\begin{aligned} J &= \frac{\partial r}{\partial X} \\ &= \lim_{\delta X \longrightarrow 0} \frac{r(X \oplus \delta X) - r(X)}{\delta X}, \end{aligned} \tag{52}$$

where δX represents the small disturbance of the state vector instead of the incremental ΔX, $\oplus$ represents the disturbance of the state vector.

The continuous preintegration formula is derived in the IMU preintegration, and the IMU residuals are as follows:

$$r_{\mathscr{B}}\left(\widehat{z}_{b_{k+1}}^{b_k}, \chi\right) = \begin{bmatrix} \delta\alpha_{b_{k+1}}^{b_k} \\ \delta\beta_{b_{k+1}}^{b_k} \\ \delta\theta_{b_{k+1}}^{b_k} \\ \delta b_a \\ \delta b_g \end{bmatrix} = \begin{bmatrix} R_w^{b_k}\left(p_{b_{k+1}}^w - p_{b_k}^w - v_{b_k}^w \Delta t_k + \frac{1}{2} g^w \Delta t_k^2\right) - \alpha_{b_{k+1}}^{b_k} \\ R_w^{b_k}\left(v_{b_{k+1}}^w \Delta t_k - v_{b_k}^w \Delta t_k + g^w \Delta t_k\right) - \beta_{b_{k+1}}^{b_k} \\ 2\left[\gamma_{b_{k+1}}^{b_k} \otimes q_{b_k}^w \otimes q_{b_{k+1}}^w\right]_{xyz} \\ b_{a_{b_{k+1}}} - b_{a_{b_k}} \\ b_{\omega_{b_{k+1}}} - b_{\omega_{b_k}} \end{bmatrix}. \tag{53}$$

According to the above formula, it can be seen that the optimization variables of the IMU residual mainly include the position, rotation, speed, and inertia bias at the i and j times:

$$\begin{gathered} \left[p_{b_k}^w, q_{b_k}^w\right], \left[v_{b_k}^w, b_{a_k}, b_{\omega_k}\right], \\ \left[p_{b_{k+1}}^w, q_{b_{k+1}}^w\right], \left[v_{b_{k+1}}^w, b_{a_{k+1}}, b_{\omega_{k+1}}\right]. \end{gathered} \tag{54}$$

To calculate the Jacobian matrix, perturbation is added to each optimization variable to obtain

$$\begin{gathered} \left[\delta p_{b_k}^w, \delta\theta_{b_k}^w\right], \left[\delta v_{b_k}^w, \delta b_{a_k}, \delta b_{\omega_k}\right], \\ \left[\delta p_{b_{k+1}}^w, \delta\theta_{b_{k+1}}^w\right], \left[\delta v_{b_{k+1}}^w, \delta b_{a_{k+1}}, \delta b_{\omega_{k+1}}\right]. \end{gathered} \tag{55}$$

Taking the partial derivatives for the above disturbance variables, respectively, we can get

$$\begin{aligned} J[0]^{15\times 7} &= \left[\frac{\partial r_B}{\delta p_{b_k}^w}, \frac{\partial r_B}{\delta\theta_{b_k}^w}\right], \\ J[1]^{15\times 7} &= \left[\frac{\partial r_B}{\delta v_{b_k}^w}, \frac{\partial r_B}{\delta b_{a_k}}, \frac{\partial r_B}{\delta b_{\omega_k}}\right], \\ J[2]^{15\times 7} &= \left[\frac{\partial r_B}{\delta p_{b_{k+1}}^w}, \frac{\partial r_B}{\delta\theta_{b_{k+1}}^w}\right], \\ J[3]^{15\times 7} &= \left[\frac{\partial r_B}{\delta v_{b_{k+1}}^W}, \frac{\partial r_B}{\delta b_{a_{k+1}}}, \frac{\partial r_B}{\delta b_{\omega_{k+1}}}\right]. \end{aligned} \tag{56}$$

The visual residual is a reprojection error, which represents the difference between the estimated value and the observed value of the feature point in the normalized camera coordinate system. The small receiver camera used in this paper belongs to the fisheye camera model and belongs to the fisheye with a large viewing angle, so its projection on the unit sphere needs to be considered, as shown in Figure 9.

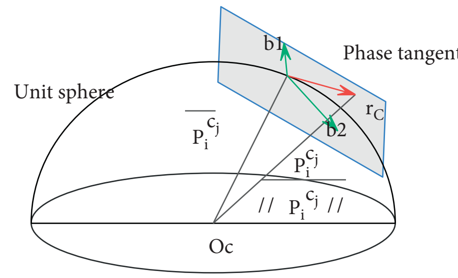

Figure 9: Unit spherical projection model.

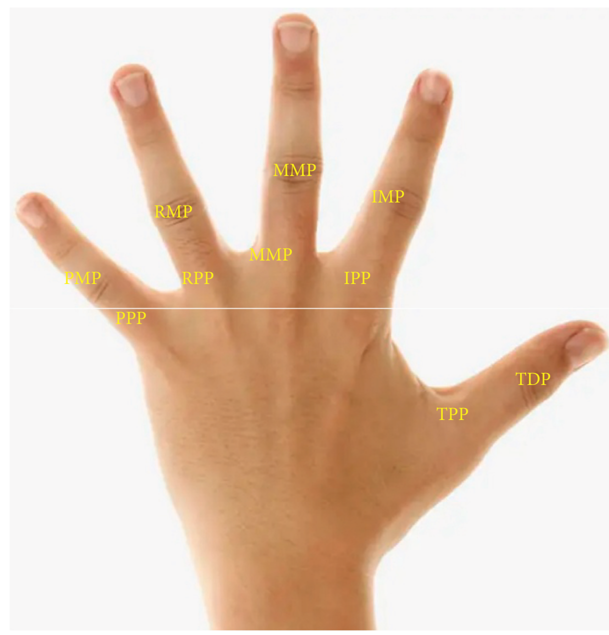

Figure 10: Demarcation boundaries of hand movements.

Through the unit spherical projection model illustrated in the figure above, the value of the visual residual is decomposed into two directions. The final visual residual model looks like this:

$$\begin{aligned} r_c\left(\widehat{z}_l^{c_j}, \chi\right) &= \left[b_1, b_2\right]^T \cdot \left(\widehat{p}_l^{c_j} - \frac{p_l^{c_j}}{\left\|p_l^{c_j}\right\|}\right), \\ \widehat{p}_l^{c_j} &= \pi_c^{-1}\left(\begin{bmatrix} \widehat{u}_l^{c_j} \\ \widehat{v}_l^{c_j} \end{bmatrix}\right), \\ p_l^{c_j} &= R_c^b\left\{R_w^{b_j}\left[R_{b_i}^w\left(R_c^b \frac{1}{\lambda_l} \overline{P}_l^{c_i} + p_c^b\right) + p_{b_i}^w - p_{b_j}^w\right] - p_c^b\right\}, \end{aligned} \tag{57}$$

where $\widehat{\overline{p}}_l^{c_j}$ and $p_l^{c_j}$ represent the estimated and observed coordinates of the landmark point 1 in the j-th frame image under the normalized camera coordinate system,

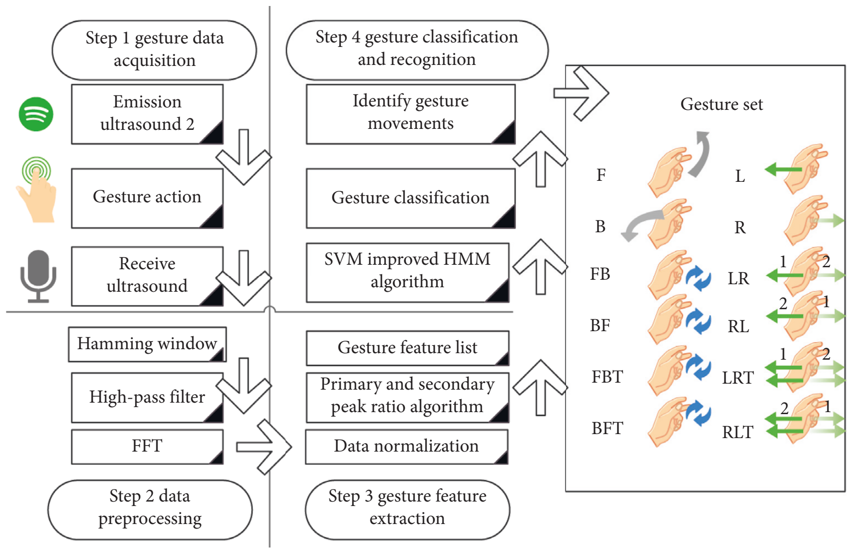

Figure 11: Overall system framework.

9	88.050	21	91.253	33	89.507
10	87.621	22	86.770	34	88.130
11	88.498	23	86.843	35	91.326
12	86.304	24	90.614	36	86.846

Table 2: The application effect of the method proposed in this paper in the e-sports training system.

Number	Training effect	Number	Training effect	Number	Training effect
1	82.685	13	82.234	25	79.365
2	80.315	14	78.537	26	81.356
3	79.700	15	81.913	27	78.790
4	78.179	16	82.938	28	79.700
5	82.942	17	78.167	29	78.194
6	80.821	18	78.250	30	78.253
7	81.176	19	81.512	31	80.133
8	78.183	20	80.076	32	82.668
9	82.636	21	81.925	33	83.747
10	81.613	22	82.857	34	82.354
11	80.514	23	82.951	35	78.416
12	80.913	24	79.066	36	83.128

respectively. The optimization variables of the visual residual are as follows:

$$\left[p_{b_i}^{w}, q_{b_i}^{w}\right], \left[p_{b_j}^{w}, q_{b_j}^{w}\right], \left[p_c^{b}, q_c^{b}\right], \lambda_l, \tag{58}$$

where λ_l represents the inverse depth value when the landmark point 1 is first observed by the j-th image. The inverse depth is used as the optimization variable because the inverse depth satisfies the Gaussian distribution, and it can reduce the parameter variables in the actual optimization process. According to the above formula, by adding disturbance to each optimization variable, the following Jacobian is obtained:

$$J[0]^{3\times 7} = \left[\frac{\partial r_C}{\partial p_{b_i}^{w}}, \frac{\partial r_C}{\partial q_{b_i}^{w}}\right],$$

$$J[1]^{3\times 7} = \left[\frac{\partial r_C}{\partial p_{b_j}^{w}}, \frac{\partial r_C}{\partial q_{b_j}^{w}}\right], \tag{59}$$

$$J[2]^{3\times 7} = \left[\frac{\partial r_C}{\partial p_{c}^{b}}, \frac{\partial r_C}{\partial q_{c}^{b}}\right],$$

$$J[3]^{3\times 1} = \frac{\partial r_C}{\partial \lambda_l}. \tag{60}$$

3. E-Sports Training System Based on Intelligent Gesture Recognition

This paper combines the finger joints and the sensor in the data glove to demarcate the movement of the finger joints. This paper mainly considers the distal phalanx of the thumb (TDP) and the proximal joint proximal phalanx of the thumb (TPP) of the thumb as shown in Figure 10 and the changes in the intermediate joints middle phalanges (MP) and proximal phalanges (PP) of the remaining four fingers.

This paper combines the algorithm part of the second part to construct the e-sports training system, and the overall framework of the system is shown in Figure 11.

The simulation of the system proposed in this paper is carried out through the MATLAB platform, and the gesture recognition effect of the system and the application effect in the e-sports training system are evaluated, and the obtained results are shown in Tables 1 and 2.

It can be seen from the above research that the electronic economic training system based on intelligent gesture recognition proposed in this paper has certain effects.

4. Conclusion

As emerging sports, e-sports are mainly participated by the younger generation, which has the characteristics of younger and younger age. E-sports can exercise people's thinking ability, psychological pressure resistance, unity and cooperation, hand-eye coordination, and so on. Moreover, in the process of participating in e-sports, it can also make the younger generation have the awareness of abiding by the rules, cultivate the participants to have a fair and open, never admit defeat, pursue a stronger competitive spirit, and have a positive impact on the participants' lives. This paper combines the intelligent gesture recognition technology and the construction of the performance e-sports training system and judges the training effect of the players through the player gesture recognition. The research shows that the electronic economic training system based on intelligent gesture recognition proposed in this paper has certain effects.

Academic Editor: Xin Ning

In the daily inspection task of the expressway, accuracy and speed are the two most important indexes to reflect the detection efficiency of nondeformation diseases of asphalt pavement. To achieve model compression, accelerated detection, and accurate identification under multiscale conditions, a lightweight algorithm (PDNet) based on improved YOLOv5 is proposed. The algorithm is improved based on the network structure of YOLOv5, and the improved network structure is called YOLO-W. Firstly, a novel cross-layer weighted cascade aggregation network (W-PAN) is proposed to replace the original YOLOv5 network. Secondly, more economical GhostC3 and ShuffleConv modules are designed to replace C3 and Conv modules in the original network model. In terms of parameter setting, CIoU is selected as the loss function of the model, and the K-Means ++ algorithm is used for anchor box clustering. Before the model training, the confrontation generation network (GAN) and Poisson migration fusion algorithm (Poisson) are used for data enhancement and the negative sample training (NST) method is used to improve the robustness of the model. Finally, Softer-NMS is used to remove the prediction box in the prediction stage. Seven common asphalt pavement disease data sets (FAFU-PD) are constructed at the same time. Compared with the original YOLOv5 algorithm, PDNet improves the scores of FAFU-PD data sets on F1-score by 10 percentage points and FPS by 77.5%.

1. Introduction

Asphalt pavements on expressways are damaged by natural disasters, such as prolonged exposure to sunlight, rain erosion, and natural weathering. And the durability of asphalt pavement will also be reduced due to factors such as pavement materials, traffic flow, construction quality, and postmaintenance levels. If these damaged roads cannot be discovered and maintained in time, the service life of the expressway will be shortened, which may induce traffic accidents [1].

At present, the detection of highway asphalt pavement diseases is mainly based on manual methods. This method has some disadvantages. For example, the detection takes a long time and requires more manpower and material resources, and the detection will cause congestion on the highway, and the safety of the detection personnel is difficult to be guaranteed. At the same time, some human factors interfere with the test results. With the continuous increase of highway mileage, manual detection methods are difficult to meet the detection requirements of large-scale highways and cannot meet the needs of highway development [2].

To further improve the service life of highways and use an accurate and efficient detection method to replace the traditional manual detection method, some researchers have conducted research on the automatic detection of pavement diseases based on visual technology, which includes image processing, machine learning, and deep learning. Image processing research includes threshold segmentation, edge detection, and regional growth. The threshold segmentation method is mainly to set the appropriate pixel threshold in the image and separate the disease from the background by using the pixel difference between the crack and the surrounding background. The edge detection method mainly realizes the edge detection through various edge detection operators. These edge detection operators include Sobel operator [3], Prewitt operator [4], and Canny operator [5]. The region growing method mainly displays the specific information inside the disease through pixel integration.

Compared with the traditional manual detection method, the image processing method has been greatly improved, but this method is easily disturbed by external factors such as road background and sunlight, the types of road diseases are complex and diverse, and the image processing method is difficult to detect various types of complex diseases [6].

In recent years, machine learning and deep learning have developed rapidly, especially in industrial applications. It has become possible to use machine learning or deep learning to build a model for pavement disease detection. Machine learning methods mainly include wavelet transform, support vector machine, and random forest methods. Among the deep learning methods, convolutional neural networks (CNNs) have made great progress in semantic segmentation and target detection tasks. From the current development status of the target detection field, the target detection methods based on deep learning are mainly divided into one-stage method and two-stage method. The two-stage method mainly includes R-CNN [7], fast-RCNN [8], and faster-RCNN [9]. The advantages of these algorithms are high recognition accuracy, but they also have the disadvantage of slow speed, so it is not suitable for engineering applications. To solve this shortcoming of the two-stage method, the researchers proposed the algorithm framework of the one-stage method. The representative works include SSD [10], YOLO series, and anchor-based RetinaNet [11], Adaptive Sample Selection (ATSS) [12], Fully Convolutional One-Stage Object Detection (FCOS) [13], and Anchor-Free Based RepPoints [14].

At present, whether it is based on traditional image processing methods or methods based on machine learning and deep learning, there are still some problems in the detection of asphalt pavement diseases: (1) based on traditional image processing methods, in terms of recognition speed, the effect is poor, and it is difficult to deal with complex engineering tasks. (2) The cost of network training and prediction using machine learning and deep learning methods is too high, and the use of feature extraction will make the network lose real-time performance and cannot meet industrial needs. (3) The engineering application scenarios are complex, and there are various types of diseases, and it is difficult to guarantee the accuracy and recall rate of disease identification. Figures 1(a) and 1(b) are schematic diagrams of the redundancy of the target frame; Figures 1(c) and 1(d) show that the model incorrectly identifies negative samples as positive samples; Figures 1(e) and 1(f) show a schematic diagram of inaccurate prediction of anchor boxes; Figures 1(g) and 1(h) show the situation that the model does not extract disease features in place. (4) There is a lack of large data sets for various types of diseases.

To meet the real-time performance and improve the accuracy and recall rate of target recognition, this study proposes a real-time, lightweight, and higher-precision target detection algorithm (PDNet) based on YOLOv5. In Section 2, this article mainly introduces the domestic and foreign research status of nondeformation disease detection of asphalt pavement, and Section 3 introduces the research methods used in this article. Section 3.1 introduces the overall architecture of the YOLO-W network proposed in this article; Section 3.2 introduces the cross-layer weighted cascade aggregation network (W-PAN); Section 3.3 introduces the improved GhostC3 module; Section 3.4 introduces the improved ShuffleConv module; Section 3.5 is mainly about the settings of network model parameters, including loss function and anchor frame settings, respectively; Section 3.6 introduces a data set of seven diseases including transverse cracks, longitudinal cracks, and repair strips collected from one province and four cities (FAFU-PD); Section 3.7 introduces a negative sample algorithm (NST) for the problem of model misidentification, which can effectively improve the recognition accuracy of the model; Section 3.8 uses an adversarial generative network (GAN) to generate a larger number of samples; Section 3.9 uses the Poisson transfer fusion algorithm, which is transplanted based on GAN to generate disease-free pictures to generate new disease samples; Section 3.10 introduces the Softer-NMS algorithm. It solves the problem that there are many false detections of diseases in dense scenes and the positioning of the prediction frame with high default confidence of NMS is not very accurate. Section 4 is the experimental part, Section 4.1 introduces the data and experimental environment used in this experiment, and Section 4.2 is the ablation experiment for each method proposed in Section 3. Section 5 analyzes the methods proposed in this article and describes the advantages of each method. Section 6 summarizes this article.

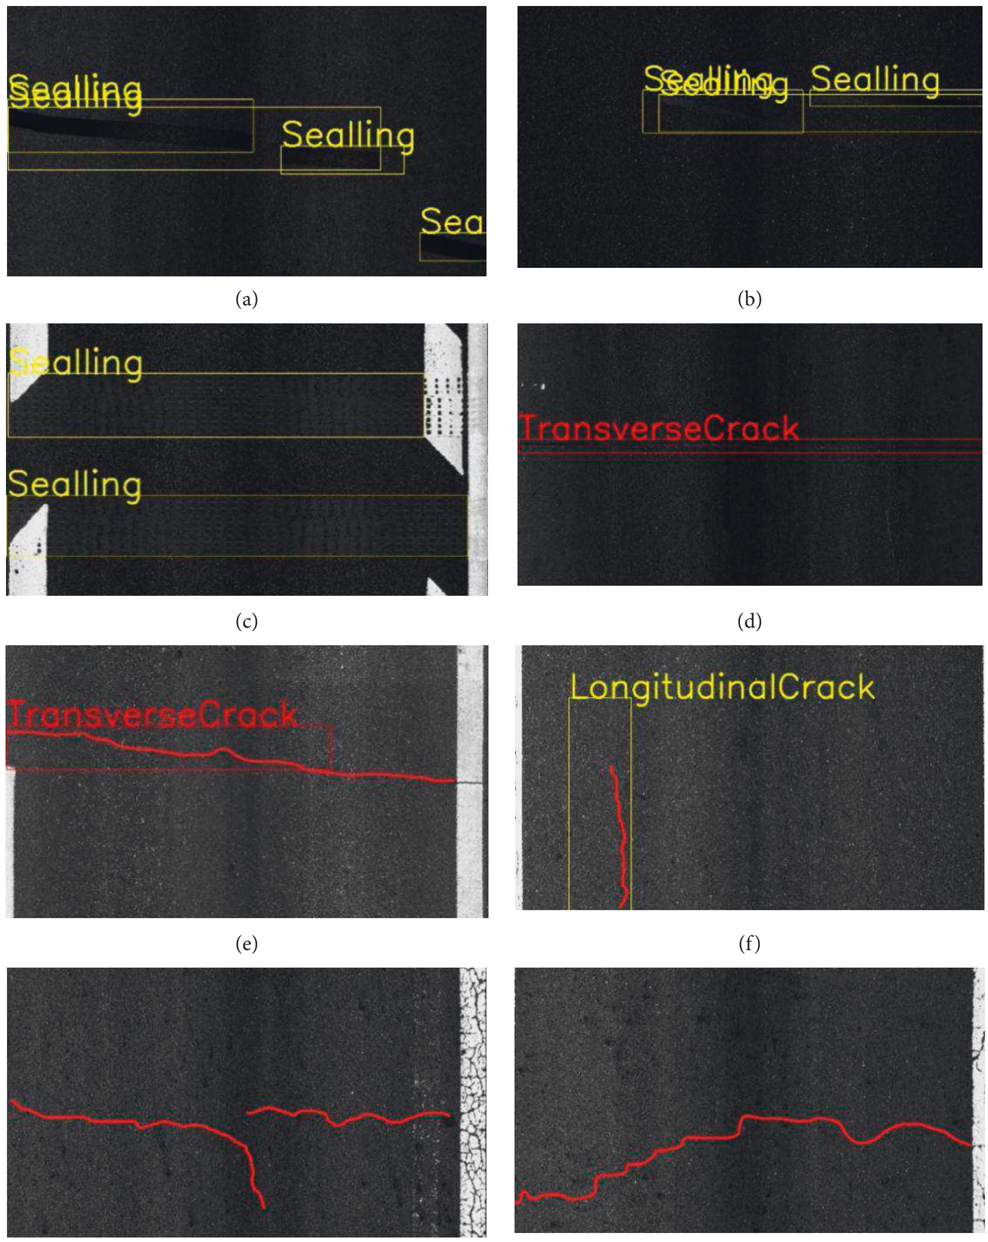
The main contributions of this article are as follows:

(1) It proposes an improved target detection network YOLO-W. First, to prevent the loss of shallow target features, a cross-layer cascaded weighted fusion structure is added to the PANet structure to transfer detailed information to the deep network, and a cross-layer weighted cascaded path aggregation network (W-PAN) is proposed to obtain richer semantic information, deepen the depth of the pyramid, correspondingly increase the detection layer of the head part, and perform detection at four scales, so that the laying interval of anchor boxes is more reasonable; finally, it reduces the feature loss caused by the upsampling process, which improves the upsampling method.

(2) Lightweight network: the GhostC3 module is used to replace the original C3 module, and the ShuffleConv module is used to replace part of the Conv module, which alleviates the problem of computational occupancy in the process of feature channel fusion and enhances the expressiveness of features.

(3) uses the K-Means ++ algorithm to redesign the size of the prior box and match it to the corresponding feature layer.

(4) The negative sample training method (NSTM) is adopted to improve the detection accuracy without



(a) (b) (c) (d) (e) (f) (g) (h)

Figure 1: Misrecognition or inaccurate recognition of deep learning models in engineering application scenarios: (a, b) target detection frame redundancy, (c, d) background is misidentified, (e, f) the target frame recognition is inaccurate, and (g, h) the disease characteristics are not obvious, and the detection is missed.

reducing the detection speed and reduce the false detection rate.

(5) uses an adversarial generative network (GAN) to generate diseases with a small number of samples.

(6) uses the Poisson transfer fusion algorithm to transfer the color of the sample generation disease to make it better match the sample and add the generated sample to the training set and the validation set.

(7) constructs 7000 data sets (FAFU-PD) including one province, four cities, and seven diseases.

2. Related Studies

2.1. Pavement Damage Detection Method Based on Image Processing and Machine Learning. In the early days, most of the pavement disease detection methods based on image processing [15–17] were based on threshold segmentation, because, in images with cracks and other diseases, the pixel values of cracks and diseases are darker than the surrounding background, and threshold segmentation is used. The contours of diseases such as cracks can be well extracted. Early researchers proposed crack detection algorithms based

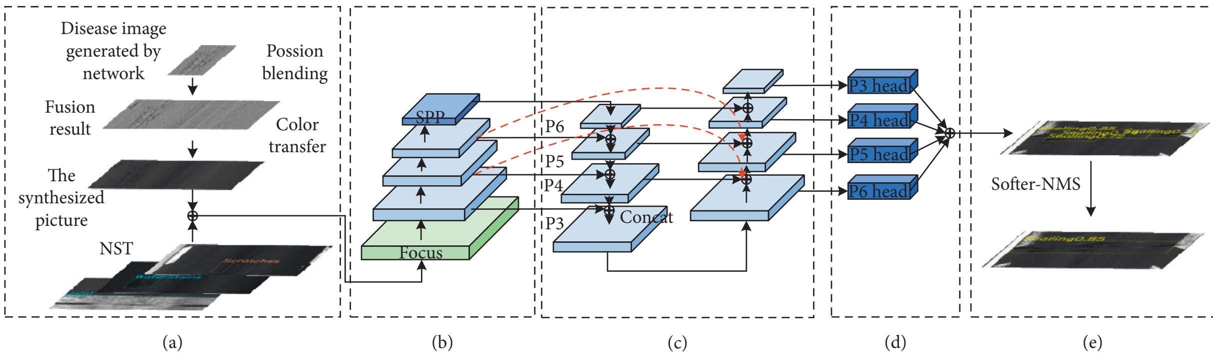


FIGURE 2: PDNet overall network framework. (a) Preprocessing side, (b) backbones, (c) necks, (d) heads, and (e) nondeformation disease detection of asphalt pavement.

on threshold segmentation from different perspectives. Oliveira and Correia [18] proposed a new framework for automatic crack detection and classification. This framework preprocesses the generated images using morphological filters to reduce pixel intensity variations. Then, dynamic thresholding was applied to identify dark pixels in the image, and a second dynamic threshold was applied to the resulting matrix of entropy blocks, which was used as a basis for identifying image blocks containing cracked pixels. Ayenu-Prah and Attoh-Okine used BEMD and Sobel edge operators for pavement crack detection. Multiple images were filtered by BEMD to remove noise, and the residual image was analyzed by Sobel edge operator [19]. Yan et al. introduced morphology into crack detection of high-grade highway pavement and proposed a new image processing method. This method reconstructs the median filter algorithm to enhance the pavement grayscale image and combines the morphological gradient operator and the morphological closure operator to extract crack edges and fill crack gaps [20]. Wei et al. proposed a pavement crack detection algorithm based on Beamlet transform [21]. Wavelet transform is also one of the common methods for pavement crack detection [22–24]. However, the above methods are very susceptible to noise interference, and it is difficult to obtain accurate detection results. Nguyen et al. proposed a new method that considers both brightness and connectivity in the segmentation step for crack detection in road surface images. Features computed along each free path can detect cracks in any form and any direction [25]. Amhaz et al. proposed a new algorithm for automatic crack detection from 2D road surface images. This algorithm, which relies on the localization of the smallest path in each image, has been intensively validated on synthetic and real images, and it provides very stable and accurate results in a variety of situations in a completely unsupervised manner [26]. Ai et al. proposed a new method to automatically detect pixel-level pavement cracks using multiscale neighborhood information and pixel intensities. Using the pixel intensity information, a probabilistic generative model (PGM) based method was developed to calculate the crack presence probability for each pixel [27]. Shi et al. introduced random structure forests to generate high-performance crack detectors that can identify arbitrarily complex cracks [28]. However, these traditional methods rely heavily on postprocessing and require a large amount of computation, which is not conducive to engineering applications.

2.2. Pavement Damage Detection Method Based on Deep Learning. In recent years, the application of deep learning methods in the field of target detection has become more and more extensive, including the identification of nondeformable diseases of asphalt pavement. Neural networks such as CNN and R-CNN have played an important role in the field of target detection. Cha et al. proposed a vision-based approach that uses a deep architecture of convolutional neural networks (CNNs) to detect cracks without computing defect features. Since CNN can learn image features automatically, the proposed method can extract features without IPT conjugation [29]. Zhang et al. used CNN convolutional neural network for image preclassification [30]. Yang et al. implemented a novel deep learning technique called a fully convolutional network (FCN) to solve the pixel-level crack identification problem [31]. Chen and Jahanshahi proposed a deep learning framework based on convolutional neural network (CNN) and a naive Bayesian data fusion scheme called NB-CNN for analyzing a single video frame for crack detection and proposed a new data fusion scheme is proposed to aggregate information to improve the overall performance and robustness of the system [32]. Park et al. proposed a CNN-based deep learning model, patch-CNN, which consists of segmentation and classification modules for crack detection [33]. Zou et al. proposed an end-to-end trainable deep convolutional neural network (DeepCrack) for automatic crack detection by learning high-level features represented by cracks [34]. These deep learning-based methods can improve the accuracy of disease identification to a certain extent, but they cannot achieve both recognition speed and accuracy and lose speed while improving the accuracy of disease identification.

3. Methodology

Figure 2 shows the overall network structure of the algorithm (PDNet) shown in this article. In the preprocessing stage, a generative adversarial network (GAN) is used to generate a small number of disease types, and then the Poisson color transfer algorithm is used to generate the generated diseases. The image is fused with the background to obtain new disease samples. Secondly, all negative samples that are prone to misidentification are labeled (NST). After processing, all training and validation sets are sent to the training network (YOLO-W). At the prediction end, the Softer-NMS algorithm is used to remove redundant boxes to obtain the final recognition result.

3.1. The Overall Architecture of the YOLO-W Network. YOLO-W is a high-performance target detection network based on YOLOv5. It adopts a cross-layer weighted cascaded path aggregation network (W-PAN) to improve the accuracy of model recognition and lightweight modules GhostC3 and ShuffleConv to reduce the complexity of the network. The network structure of YOLO-W is shown in Table 1. The changes in the backbone and neck parts of YOLO-W compared with the original YOLOv5 network model are shown in Figures 3 and 4.

Among them, "from" represents the output layer corresponding to this layer module, and "−1" represents the previous layer. "Add" represents the cross-layer weighted addition module in W-PAN, and "GhostC3" and "ShuffleConv" represent the GhostC3 module and ShuffleConv module used in YOLO-W, respectively.

3.2. Cross-Layer Weighted Cascade Aggregation Network (W-PAN). The shallow network of deep learning focuses on detailed information, such as edge features. Based on obtaining simple features, it can help the network return to the target boundary more accurately; the deep network focuses on extracting high-level semantic information and can extract more complex features, which can help the network detect the target accurately. The FPN structure uses shallow features to distinguish simple objects and deep features to distinguish complex objects, aiming to obtain more robust detection results. The FPN structure of YOLOv5 is based on PAN, which creates a bottom-up path enhancement, accelerates the flow of underlying information, and can well integrate semantic information at all levels. To further enhance the model's attention to shallow semantics, fully integrate the semantic information extracted by each layer of the FPN, and enhance the network's ability of returning to the target boundary, this study improves the FPN of YOLOv5, called W-PAN, and the specific improvement points are as follows:

(1) Add cross-layer weighted connections between input and output nodes of the same size [35]. The cross-layer cascade structure can effectively integrate the shallow details, edges, contours, and other information into the deep network and can fuse the shallow details of the target with almost no increase in the amount of calculation so that the network can be more sensitive to the target boundary. The regression is more accurate, and the intersection ratio

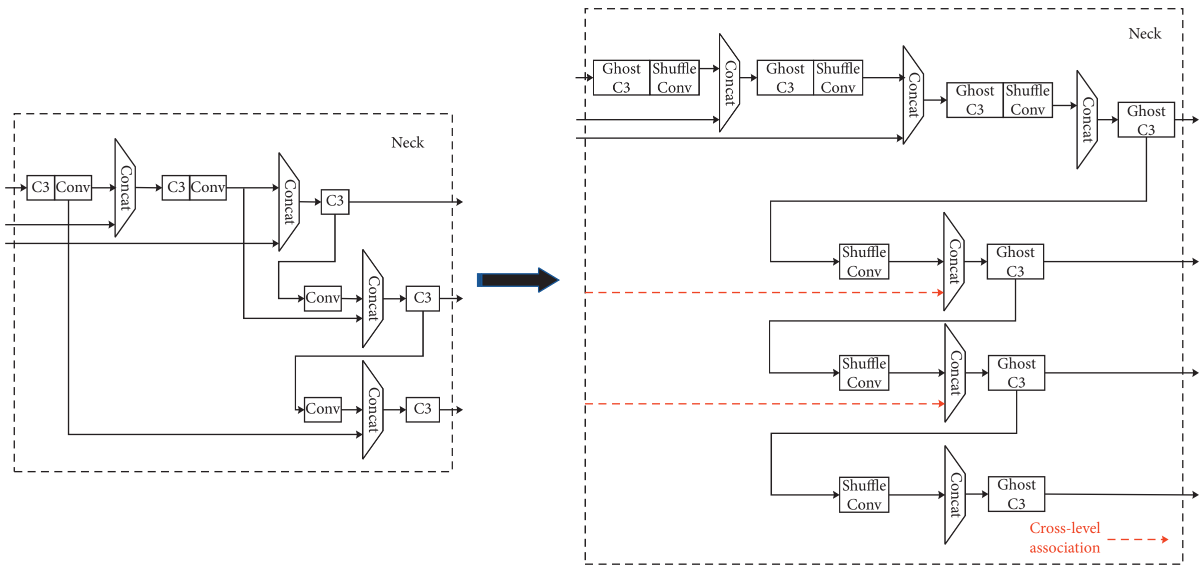

FIGURE 4: The improved neck module.

between the predicted frame and the real frame is effectively improved. At the same time, considering that the integration of shallow features will have a certain impact on deep semantic information when using cross-level concatenation, a learnable method is adopted for fusion. The two fusion methods used in this study are given as follows: in the process of feature fusion, since the information flow of the top and bottom nodes is fast and the number of convolutions experienced is small, the loss of detailed information is not much. There is complexity of the small model, so the concat operation is directly used to perform feature fusion by channel. The process is shown in Figure 5. F represents the feature map, w represents the width of the feature map, h represents the height of the feature map, and c represents the number of channels of the feature map.

For nodes in other layers, the concat operation is used for feature fusion on adjacent paths, and the weighted add operation with learnable weights is used for feature fusion on nonadjacent paths. The add operation can not only reduce the amount of calculation but also reduce the amount of invalid shallow information. Fusion calculation is shown in the following formula:

$$\mathrm{OUT} = \sum_i \frac{\mu_i \cdot x_i}{\varepsilon + \sum_j \mu_j}, \tag{1}$$

where x_i represents each feature map to be fused; ? is the weight coefficient of the feature map, which can be updated through learning. The initial weight coefficient is set to 1, indicating that the two layers of feature maps are fused equally; ε is a very small number ($\leq 10^{-3}$) which can effectively prevent numerical instability. Normalizing the weights between 0 and 1 increases the speed of training while preventing unstable training. According to formula (1), the feature fusion method for an intermediate layer is shown in Figure 6.

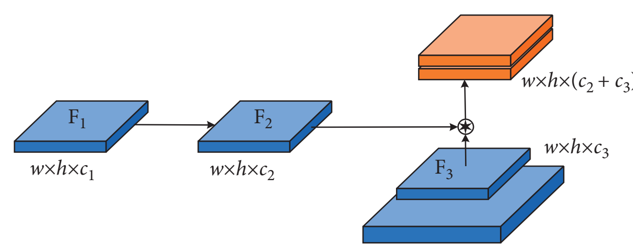

FIGURE 5: Schematic diagram of general feature fusion.

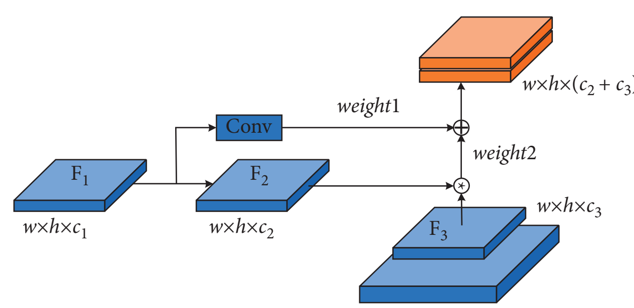

FIGURE 6: Schematic diagram of the cross-layer connection.

In Figures 5 and 6, given the input feature map $F_1 \in \mathbb{R}^{w\times h\times c_1}$ of a certain layer, the top-down path corresponds to the layer's feature map $F_2 \in \mathbb{R}^{w\times h\times c_2}$, and the bottom-up path corresponds to the layer's feature map $F_3 \in \mathbb{R}^{w\times h\times c_3}$, " $*$ " indicates the concat operation, "+" indicates the add operation, and weight1 and weight2 are the weight values of the feature map fusion on the two paths, respectively. It can be seen from the two figures that the feature fusion of the top and bottom output nodes adopts the concat operation, while the feature fusion of the

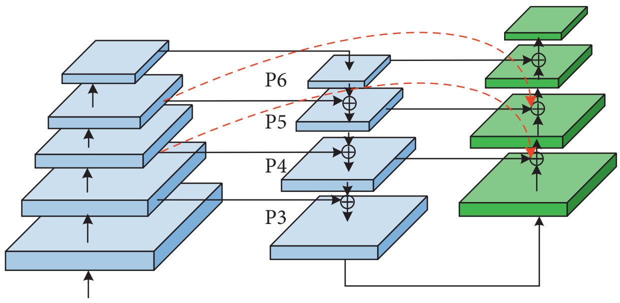

Figure 7: FPN structure used in this article (W-FPN).

middle layer nodes first undergoes the concat operation and then performs weighted add with the channel-aligned input layer operation. The final feature map obtained at the output node is a composite feature map containing details, edges, and high-level semantic information. For ease of understanding, taking the middle layer P4 as an example, the calculation of the output on each path is shown in the following formulas:

Table 2: Comparison of YOLOv5s effects before and after deepening the pyramid.

Module	Parameters	GFLOPs	F1-score (%)
PAN	7114785	16.5	81.34
W-PAN-Deep	12395500	16.7	84.39

$$P4^{td} = \mathrm{Concat}\left(P4^{in}, \mathrm{Resize}\left(Conv\left(P5^{in}\right)\right)\right), \tag{2}$$

$$P4^{out} = \frac{\mu_1 \cdot \mathrm{Concat}\left(P4^{td}, \mathrm{Resize}\left(Conv\left(P3^{out}\right)\right)\right) + \mu_2 \cdot P3^{out}}{\varepsilon + \mu_1 + \mu_2}, \tag{3}$$

where Pk^{in} represents the input of the kth layer, Pk^{td} represents the output of the kth layer intermediate node in the top-down path, and Pk^{out} represents the output of the kth layer output node in the bottom-up path.

(2) Increase the depth of the feature pyramid upwards. The high-level perception field of FPN is large, and the semantic information contained is more advanced, which can increase the learning ability of the network and further improve the detection accuracy. The FPN of YOLOv5 is 3 layers. Based on improvement 1, this study deepens it to 4 layers, which can make full use of the proposed cross-layer cascade structure. In addition, to match the depth of FPN, this study adds the detection layers of the detect part, named tiny, small, medium, and large, respectively, performs target detection on the feature maps output by P3, P4, P5, and P6 in turn, and increases the detection. The laying interval of anchor boxes after the layer becomes more reasonable, and the stability of training and the convergence speed and accuracy of the model will be effectively improved. Based on the improvement points 1 and 2, the simplified version of the FPN structure used in this article is shown in Figure 7.

The red dotted line in Figure 7 is the cross-layer cascading. It can be seen from the figure that the cross-layer weighted fusion is only used for the two middle layers P4 and P5. For the top layer P6 and the bottom layer P3, there is no much loss due to information flow. Considering the operating efficiency of the model, this study directly splices the two feature maps by channel. To objectively give the impact of deepening the pyramid on the network, Table 2 shows the comparison of the effect of YOLOv5s before and after deepening the pyramid, where W-PAN-Deep represents the PAN module after deepening the pyramid.

The comparison of the effect of YOLOv5s before and after deepening the pyramid shows that, after deepening the pyramid, although the F1-score of the model has been greatly improved, the large increase in the number of parameters makes loading the network need more video memory, which not only increases the hardware requirements for model training but also affects the speed at which the model runs. To solve such a problem, this study introduces the Ghost series of modules to lighten the network, to a certain extent, to make up for the negative impact of the increased network complexity after deepening the pyramid.

(3) Improve the YOLOv5 upsampling method. YOLOv5 uses the nearest neighbor interpolation method for upsampling. This method uses a single reference point pixel value for estimation. Although the speed is fast and the overhead is small, the upsampling process will cause serious feature loss and reduce the detection accuracy of small targets. The bilinear interpolation method uses four points to estimate the interpolation, and the obtained feature map is more delicate and the loss of details is less. Therefore, this study changed the upsampling method to the bilinear interpolation method, and the complexity of the two is only a constant level gap, relatively to the improvement in accuracy; the computational overhead is acceptable. Table 3 shows the experimental accuracy comparison of YOLOv5s using PAN structure and two W-PAN structures; W-PAN

Table 3: Comparison of the effects of W-PAN-Deep and PAN under YOLOv5s.

Module	F1-score (%)
PAN	81.34
W-PAN-Deep	84.39
W-PAN	85.77

indicates that the FPN structure proposed in this study is completely used.

It can be seen from the table that the F1-score index of using W-PAN is improved by 5.16% compared with that of PAN and the F1-score index of W-PAN-Deep, which deepens the pyramid, is improved by 1.6%, which proves that the cross-level cascade structure can further improve the regression accuracy of the network to the boundary. In general, the W-PAN structure makes the fusion of semantic information at all levels of the network more reasonable and sufficient. The introduction of W-PAN has greatly improved the accuracy of the network, especially the accuracy of high intersection and is higher than the required accuracy, which proves that the network from The W-PAN structure incorporates more effective feature information, which can better return the bounding box of the target and fit the industrial target detection task of high cross-comparison.

3.3. Improved GhostBottleneckCSP. GhostNet proposes an innovative module Ghost, which generates more feature maps with fewer parameters and computations [36]. The implementation of Ghost is divided into 2 parts, one is ordinary convolution, and the other is a linear operation with fewer parameters and computations. First, a part of the feature map is obtained through limited ordinary convolution, and then the obtained feature map is linearly operated to generate more feature maps, and finally the two sets of feature maps are spliced in the specified dimension. The operating principle of Ghost is shown in Figure 8.

The operation of the ordinary convolution layer is shown in

$$Y = X * f + b. \tag{4}$$

The Ghost module containing block contains a small number of convolutions, a population identity map, and $m \times (s-1)$ linear operations. First, generate a small number of feature maps through general convolution; then perform cheap linear operations on the feature maps obtained in the first step to generate Ghost feature maps. Finally, the two sets of feature maps are spliced by channel to generate enough feature maps to match the given number of output channels.

For an input $X \in \mathbb{R}^{W\times H\times C}$, the output $Y \in \mathbb{R}^{W'\times H'\times n}$ of a general convolution can be denoted by $Y = X \cdot f + b$, the $f \in \mathbb{R}^{k\times k\times C\times n}$ represents $C\times n$ convolution operations with a kernel size of $k\times k$, and b represents the bias term. W and H represent the width and height of the input feature map, respectively. W' and H' represent the width and height of the output feature map, respectively. C refers to the number of input channels. The FLOPs of a general convolution can be denoted by $W'\cdot H'\cdot n\cdot k\cdot k\cdot C$. Ghost convolution adopts the step-by-step strategy, and the calculation method is shown in

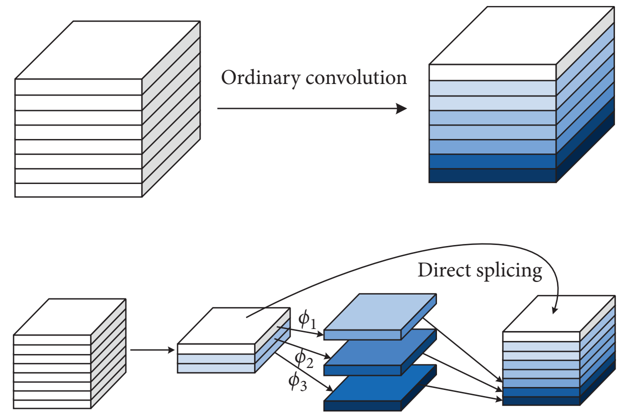

Figure 8: Comparison of Ghost convolution and general convolution.

$$Y' = X \cdot f', \tag{5}$$

$$Y_{ij} = \Phi_{ij}\cdot Y_i', i \in [1, m], \quad j \in [1, s]. \tag{6}$$

In a small number of convolution results, $Y \in \mathbb{R}^{W'\times H'\times m}$ represent the m feature maps ($m \ll n$) generated by the general convolution $f' \in \mathbb{R}^{k\times k\times C\times m}$ on the input X; then the m feature maps are linearly operated one by one, and each feature map generates s feature maps, and a total of $n = m\times s$ feature maps are generated. Feature map Φ_{ij} represents the ith linear operation on the jth feature map Y_i' generated in the first step of convolution; $\Phi_{i,s}$ represents a direct feature identity map. To ensure the efficiency and practicability of CPU or GPU, set the size of the convolution kernel of each linear operation to be $d\times d$; then the speed ratio of general convolution and Ghost convolution can be calculated by

$$\begin{aligned}
RATE_s &= \frac{W'\cdot H'\cdot n\cdot k\cdot k\cdot C}{W'\cdot H'\cdot m\cdot k\cdot k\cdot C + W'\cdot H'\cdot (n-m)\cdot d\cdot d\cdot C}\\
&= \frac{W'\cdot H'\cdot n\cdot k\cdot k\cdot C}{W'\cdot H'\cdot (n/s)\cdot k\cdot k\cdot C + W'\cdot H'\cdot (s-1)\cdot (n/s)\cdot d\cdot d\cdot}\\
&= \frac{k\cdot k\cdot C}{(1/s)\cdot k\cdot k\cdot C + ((s-1)/s)\cdot d\cdot d}\\
&\approx \frac{s\cdot C}{s + C - 1}\\
&\approx s.
\end{aligned} \tag{7}$$

Here, $k\times k$ and $d\times d$ have the same size, and $s \ll C$. From the simplification results, the calculation amount of general convolution is roughly s times that of Ghost convolution. Similarly, the number of parameters can be calculated as s times. Ghost convolution is a lighter and faster module. Based on this, this study designs GhostBottleneck

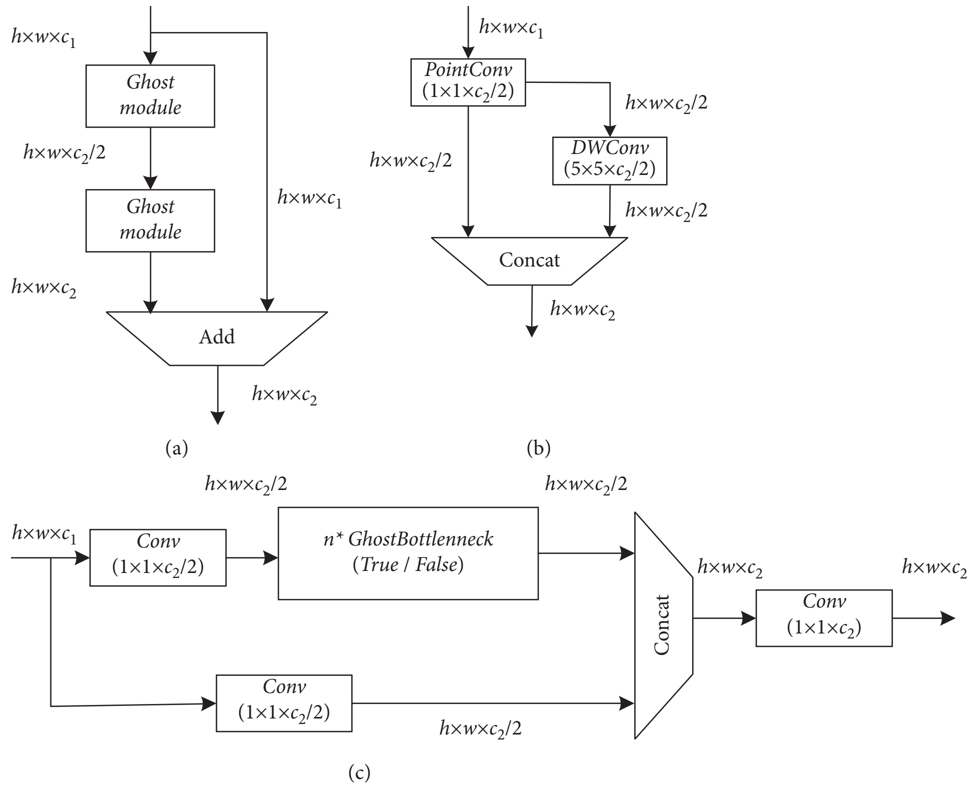

Figure 9: (a) Ghost module, (b) GhostBottleneck, and (c) GhostBottleneckCSP.

and GhostBottleneckCSP modules based on the Ghost module. The specific structure is shown in Figure 9.

C_1 and C_2 in Figure 9 refer to the number of channels of input and output characteristic graphs, respectively. In this article, the 1×1 ordinary convolution shown in Figure 9(a) is used to reduce the number of channels to 1/2 of the number of output channels, and then a depthwise convolution with a size of 5×5 is performed according to the obtained feature map. Finally, the two sets of features are spliced together. The first Ghost module in Figure 9(b) first reduces the number of output channels to 1/2 of the number of target output channels, and then the second Ghost module restores the number of channels to the number of target output channels and transmits the number of channels together with the residual. The incoming input feature maps are added point by point for feature fusion. As shown in Figure 9(c), use GhostBottleneck to replace all bottleneck modules in YOLOv5 and form a new GhostBottleneckCSP with the C3 module. The original bottleneck consists of 1×1 and 3×3 standard convolutions. The new structure replaces the original bottleneck. There are more 3×3 standard convolutions in the model, which reduces the amount of computation and compresses the model.

3.4. ShuffleConv. Most of the current excellent lightweight networks use group convolution or deep separable convolution to reduce the amount of computation generated by convolution operations. However, to achieve feature fusion between channels, the 1×1 convolution used in these

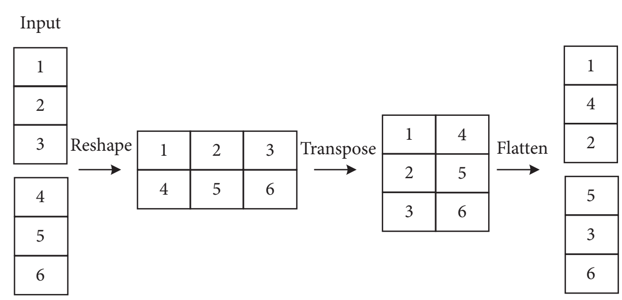

Figure 10: Experimental process of mixed washing in channels.

networks takes up more computation throughout the process. To alleviate this problem, ShuffleNet [37] proposed the concept of channel mixing. After group convolution, the use of channel blending can realize the flow of information between groups and enhance the expression ability of features in a more economical way. Channel mixing can be achieved by conventional tensor operations, as shown in Figure 10.

The number in Figure 10 is the number of the input channels. The channel is extended to two dimensions using the reshape operation, and the extended two dimensions are replaced by transpose. Through this operation, the information between the group convolution channels can be fused without increasing the amount of computation. Finally, the flatten operation restores the two dimensions to the original initial dimension and completes the channel washing. Based on the above principle, it can be considered that a point-by-point convolution can be replaced by a 1×1 group convolution and a channel mixing operation combination. Compared with the standard convolution, the parameter number and calculation amount of the group convolution are greatly reduced, and the group convolution has a similar regular effect, which can reduce the probability of overfitting. For these advantages, this article improves the ordinary convolution operation in 6 Conv modules of 3×3 and 2 Conv modules of 1×1 in YOLOv5. The original ordinary convolution is replaced by group convolution and channel mixing module, which can theoretically realize further compression of the model.

3.5. Parameter Setting

3.5.1. Loss Function. In the prediction of YOLOv5, Generalized IoU (GIoU) [38] is used as the loss function of BBox, and weighted nonmaximum suppression (NMS) is used. The loss function is shown in

$$L_{GIoU} = 1 - IoU + \frac{C - \left(B \cup B^{gt}\right)}{C}, \quad (8)$$

$$IoU = \frac{A \cap B}{A \cup B}. \quad (9)$$

However, when the prediction box is in the ground-truth box and the size of the prediction box is the same, the relative position of the prediction box and the ground-truth box cannot be distinguished.

Therefore, this article uses Complete IoU (CIoU) [39] to replace GIoU. Based on considering GIoU loss, CIoU loss considers the consistency of BBox overlapping area, center distance, and BBox aspect ratio. It can better predict the target. The definition of the loss function of GIoU is shown in

$$R_{CIoU} = \frac{\rho^2\left(b, b^{gt}\right)}{c^2} + \alpha\nu, \quad (10)$$

$$\nu = \frac{4}{\pi^2}\left(\arctan\frac{w^{gt}}{h^{gt}} - \arctan\frac{w}{h}\right)^2, \quad (11)$$

$$L_{CIoU} = 1 - IoU + R_{CIoU}, \quad (12)$$

where $\rho^2\,(b, b^{gt})$ represents the Euclidean distance between the prediction box and the target box and c^2 represents the diagonal distance of the minimum enclosing rectangle. w^{gt}/h^{gt} and w/h represent the width-to-height ratios of the target box and the prediction box, respectively. The trade-off parameter is defined as α, which is a parameter greater than 0. The definition of trade-off parameters is shown in

$$\alpha = \frac{\nu}{(1 - IoU) + \nu}. \quad (13)$$

3.5.2. K-Means ++ Clustering Anchor Frame. YOLOv5 conducts K-Means clustering on the COCO data set of general target detection and obtains the initial prior anchor frame. However, there are many types of targets in the

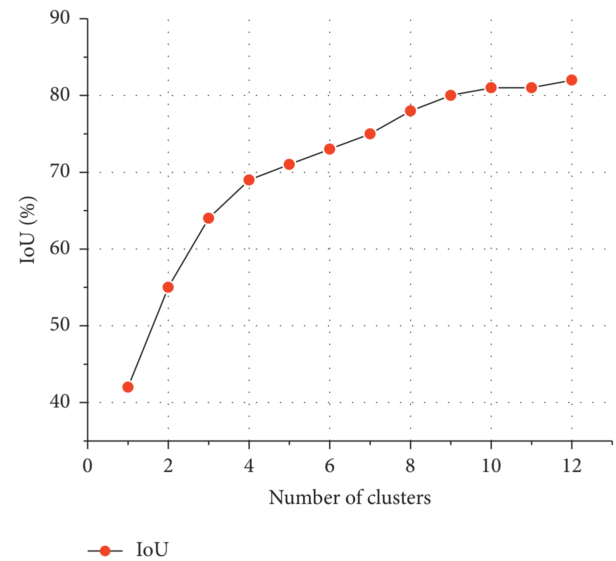

Figure 11: Number of centers of different clusters and average intersection-sum ratio.

COCO data set, which can reach more than 80 categories, and the types of pavement diseases in this article are 6 categories, which cannot meet the needs of actual disease detection. Therefore, it is necessary to redesign the size of the prior anchor frame. In this article, the K-Means ++ clustering algorithm is used to cluster the annotated target boundary anchor frames in the disease data many times, and different numbers and sizes of prior frames are generated as much as possible to increase the matching degree between the prior box and the actual target box, to further improve the detection accuracy. In the clustering process, the average intersection corresponding to the number of centers of different clusters is shown in Figure 11.

It can be seen from Figure 11 that when the number of prior frames is from 0 to 9, IoU shows a rapid upward trend, but when the number of prior frames is from 9 to 12, the growth rate of IoU slows down. In order to balance the detection accuracy and rate, nine prior anchor frames are finally selected, and the sizes of the anchor frames after clustering are, respectively, [54.2 99.2], [32.7 634.1], [604.1 354.2], [194.9 300.1], [251.2 95.9], [39.4 258.0], [47.1 427.7], [239.2 611.0], and [574.1 109.9]. The clustering center effect is shown in Figure 12.

3.6. FAFU-PD Data Set. Training a deep learning model with high accuracy and strong generalization ability needs to rely on large-scale and high-quality data sets, but many specific problems do not have a rich variety of public data sets, so it is particularly important to obtain high-definition pavement disease images. At present, the existing pavement disease data sets are collected by cameras installed in the cab or on the roof. In the actual highway inspection task, the image data collected in this way cannot well determine the pile number of the collection sites. There are two sources of road disease image data in this article: one is the road disease data provided by Fujian Highway Datong Detection Co., Ltd.,

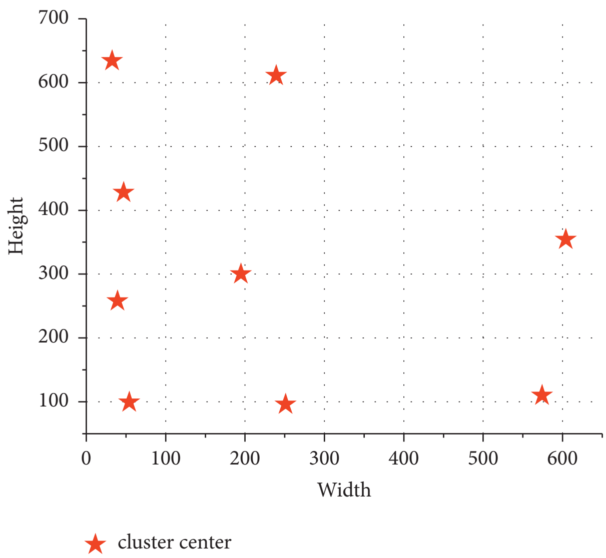

Figure 12: Cluster center effect diagram.

Figure 13: DHDV multifunctional detection vehicle.

and the other is the road disease data collected by the Digital Highway Data Vehicle (DHDV). As shown in Figure 13, the DHDV multifunction detection vehicle is jointly developed by Oklahoma State University, Arkansas University, and WAYLINK Company. The detection vehicle can collect road data at the speed of 100 km/h, and the acquisition range can cover a 4 m lane width. The accuracy of surface texture data collected in the vertical direction can reach 0.3 mm, and the accuracy of data in the longitudinal direction can reach 1 mm. The PaveVision3D sensor equipped on DHDV carries the latest imaging technology, which can obtain 2D and 3D laser imaging data from the road through two separate left and right sensors. Customized optical filters and high-power line laser projection systems enable DHDV to maintain consistency in image quality both during the day and night. DHDV collected part of the two-dimensional laser asphalt pavement nondeformation disease images as shown in Figure 14.

3.7. NST Algorithm. When detecting targets according to the characteristics of the object, the objects with similar characteristics are often classified as a class. Asphalt pavement disease is the target that we need to detect. In the actual detection process, it often conflicts with some other background targets. For example, the detection of crack diseases is often affected by the induction coil under the road, the lane scratch, and the pavement spray. The disease detection of patch type is often affected by pavement construction expansion joints, road markings, and indicator arrows. When the disease of patch type is detected, it is often affected by water stain, oil stain, and rutting. Particularly, when continuous water stain and oil stain occur on the pavement, the probability of false detection will be greatly improved. Figure 15 shows the partial misdetection of the model.

To solve the hidden dangers brought by negative samples to road inspection, this article proposes a new negative sample training method. When training and labeling the target object, it is used as data for a series of backgrounds such as induction coils, water stains, and oil stains. The centralized negative sample labels, that is, the negative samples such as induction coils, water stains, and oil stains, are labeled. During the training process of the data set, the model will simultaneously label the positive samples (horizontal seam, vertical seam, patch, patch, etc.) and negative sample labels (induction coils, water and oil stains, etc.) for detection, and these negative sample labels can be excluded from the final detection results.

The advantages of this negative sample training method can be analyzed from the theory of information entropy. Information entropy is often used as a quantitative index of the information content of a system, which can be further used as the objective of system equation optimization or the criterion of parameter selection. The definition of information entropy is shown in

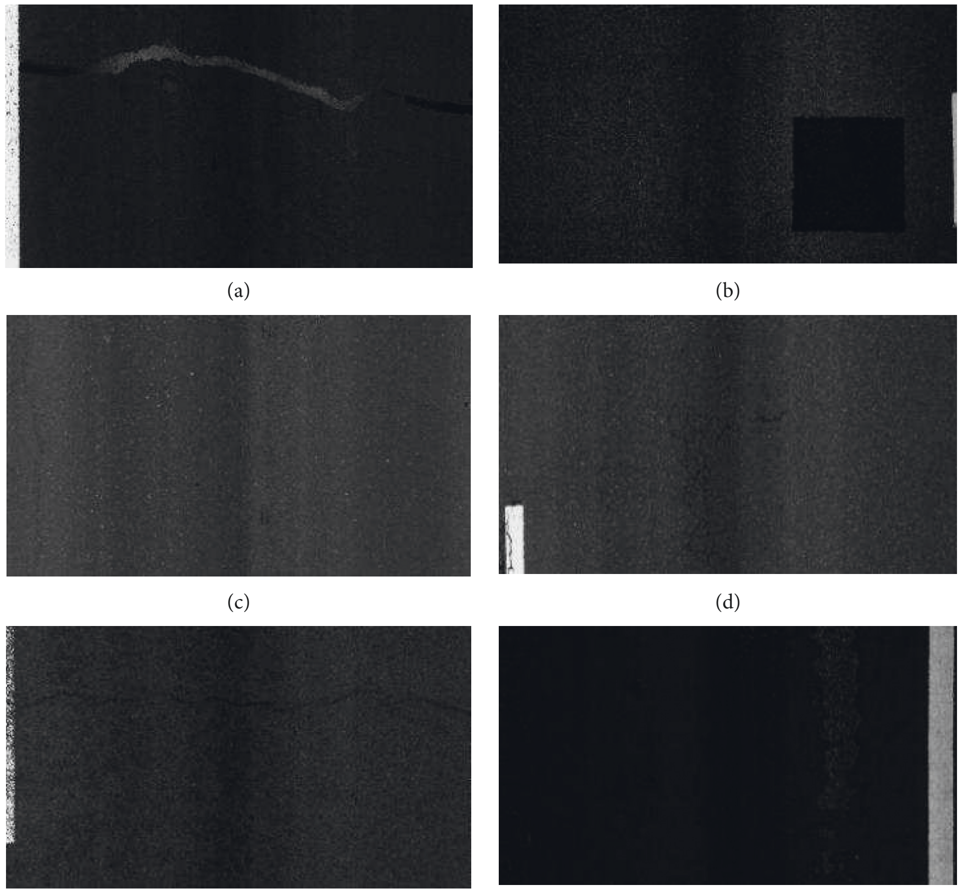
$$H(X) = -\sum_{i=1}^{n} p_i \log p_i, \tag{14}$$

where p_i represents the probability that the *ith* symbol appears in the information source. H stands for information entropy.

After applying the NST method, positive sample (disease) tags and negative sample (background) tags may appear in the XML file generated by the detection. According to the principle of YOLOv5 and formula (14), the information entropy of the data set with and without negative sample labels can be obtained. From the principle of the neural network, it can be known that when the size of the image sent to the detection is different, it will affect the final recognition effect. We found that when the size of the image is 896, the number of false detections is converted into probability, before and after adding negative samples. The information entropy is 0.07405 and 0.07809, respectively; obviously, the gain is increased by 5.17%.

The negative samples and their labels of the NST method are shown in Figure 16.

3.8. Generative Adversarial Network Data Augmentation Algorithms. A generative adversarial network (GAN) is a game model based on adversarial generation proposed by



(a) (b) (c) (d) (e) (f)

Figure 14: Two-dimensional laser asphalt pavement nondeformation disease image. (a) Repair-strip, (b) patch, (c) longitudinal crack, (d) crack, (e) transverse crack, and (f) loose.

Creswell et al. [40]. The GAN framework includes a generator network (G) and discriminator network (D). G and D confront each other through their respective strategies and reuse each other's strategies to adjust their strategies in time [41].

In our collected highway asphalt pavement disease data, the number of cracks, loose, and other diseases is small. To reduce the impact of unbalanced data types, we choose the GAN data enhancement algorithm to expand the amount of data on cracks, loose, and other diseases.

The basic framework of the GAN network used in this article is shown in Figure 17. The noise is fused into the original image to generate data. The generated data are input to G and the feature information of the pit is extracted. The fitting data are generated to deceive D, and D is used to identify the authenticity of the output data and feedback to the generated network to train the model.

Ratliff et al. [42] proposed Wasserstein distance to replace JS divergence (Jensen-Shannon divergence, JS), that is, Wasserstein generated adversarial network (WGAN) to improve the mode collapse problem of GAN. WGAN still has the problem of gradient explosion and gradient disappearance caused by gradient clipping. Therefore, Hsu et al. [43] proposed WGAN-GP with gradient penalty term. In this study, WGAN-GP with better data generation performance was used to generate pit data. The G and D of WGAN-GP were set to five layers of convolutional neural networks, and the number of layers was 1~5. G is composed of transposed convolution (ConvTrans2d), batch norm (BN), and ReLu and Tanh activation functions. D is composed of convolution (Conv2d), instance norm (IN), and LeakyRelu activation functions. The detailed parameter settings of the network are shown in Table 4. In the table, K (kernel size, K) represents the size of the convolution kernel, N_out (number of out, N_out) represents the number of convolution kernels, and S (stride, S) represents the step size.

3.9. Poisson Migration Fusion Algorithm. In this study, the groove image generated by WGAN-GP is inserted into the disease-free road image to generate new training data. Firstly, the Poisson algorithm is used to output the fused image [44], and then the synthesized image is output by the color migration algorithm [45]. When integrating the image, the image should be integrated as real as possible. When synthesizing the image, the natural effect of the original data set should be maintained. Therefore, the color migration is added based on the Poisson fusion, which is called the

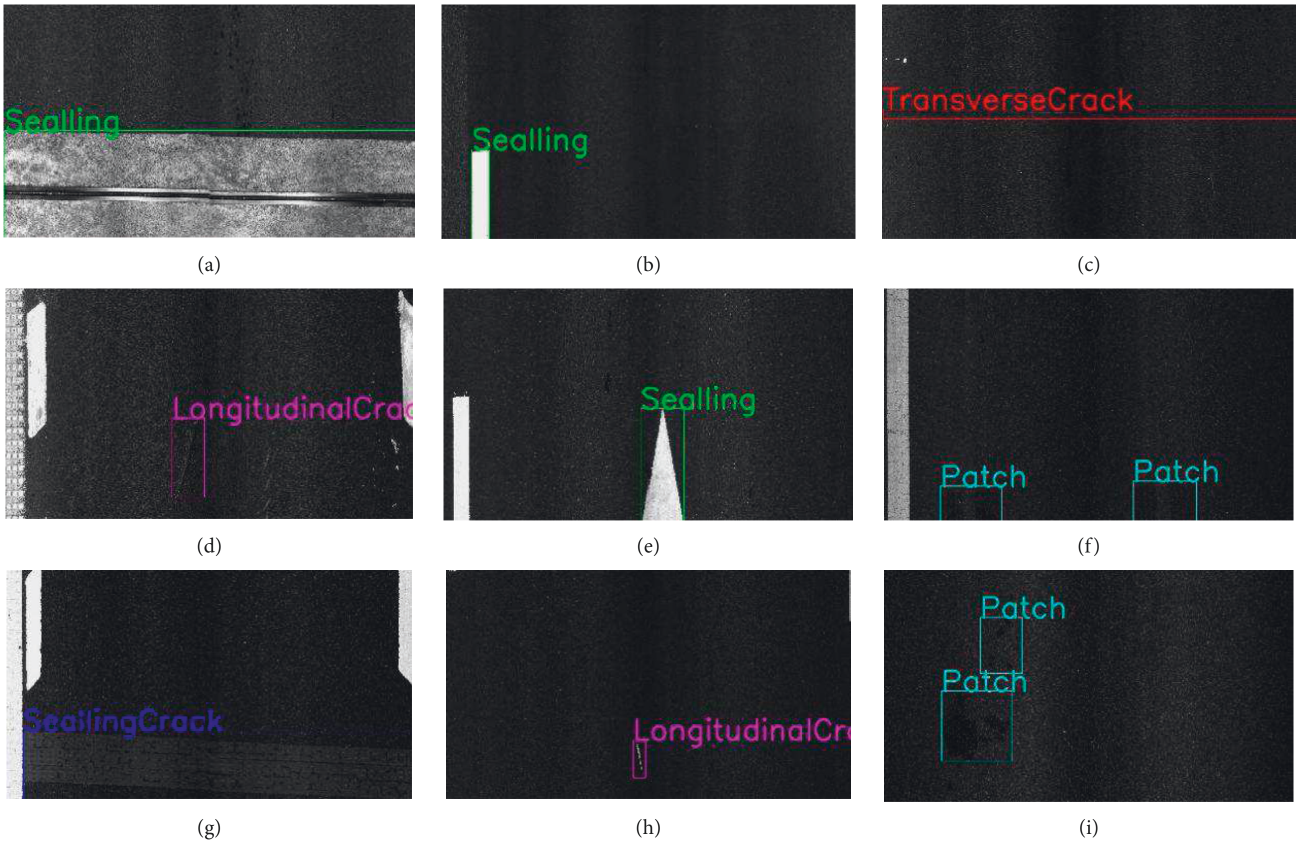


Figure 15: Misdetection. (a) Misidentification of joints as a patch, (b) misidentification of lane markings as a patch, (c) misidentification of induction coils as transverse cracks, (d) misidentification of pavement scratches as longitudinal cracks, (e) misidentification of lane indicator arrows as patch, (f) misidentification of rut imprints as a patch, (g) misidentification of deceleration belts as patch, (h) misidentification of pavement splits as longitudinal cracks, and (i) misidentification of water stains as a patch.

Poisson migration fusion. As an image fusion method, the Poisson algorithm can better integrate the source image into the target image. In this study, the reference code of Poisson fusion implementation is shown in the literature. The color transfer algorithm can ensure that the target image and the reference image have the same pixel mean and variance in the color space. In this study, the color transfer implementation code is shown in the literature. In the Poisson algorithm, the pixel value of the unknown region is calculated by the Poisson equation, and the calculation method is shown in

$$\left\{\begin{array}{l} \min\limits_{f} \iint_{\omega} |\nabla f - v|^2 \\ f|\partial_{\omega} = f^{*}|\partial_{\omega}. \end{array}\right\}. \tag{15}$$

Type: ω for the target image; ∇ is a gradient operator; v is the gradient region in the image; f is the unknown function of the target image; f^{*} is the known function of the source image; ∂_{ω} is the boundary between the source image and the target image.

In the color transfer algorithm, the best matching pixel of the target image is found according to the color component of the reference image. The calculation method is shown in

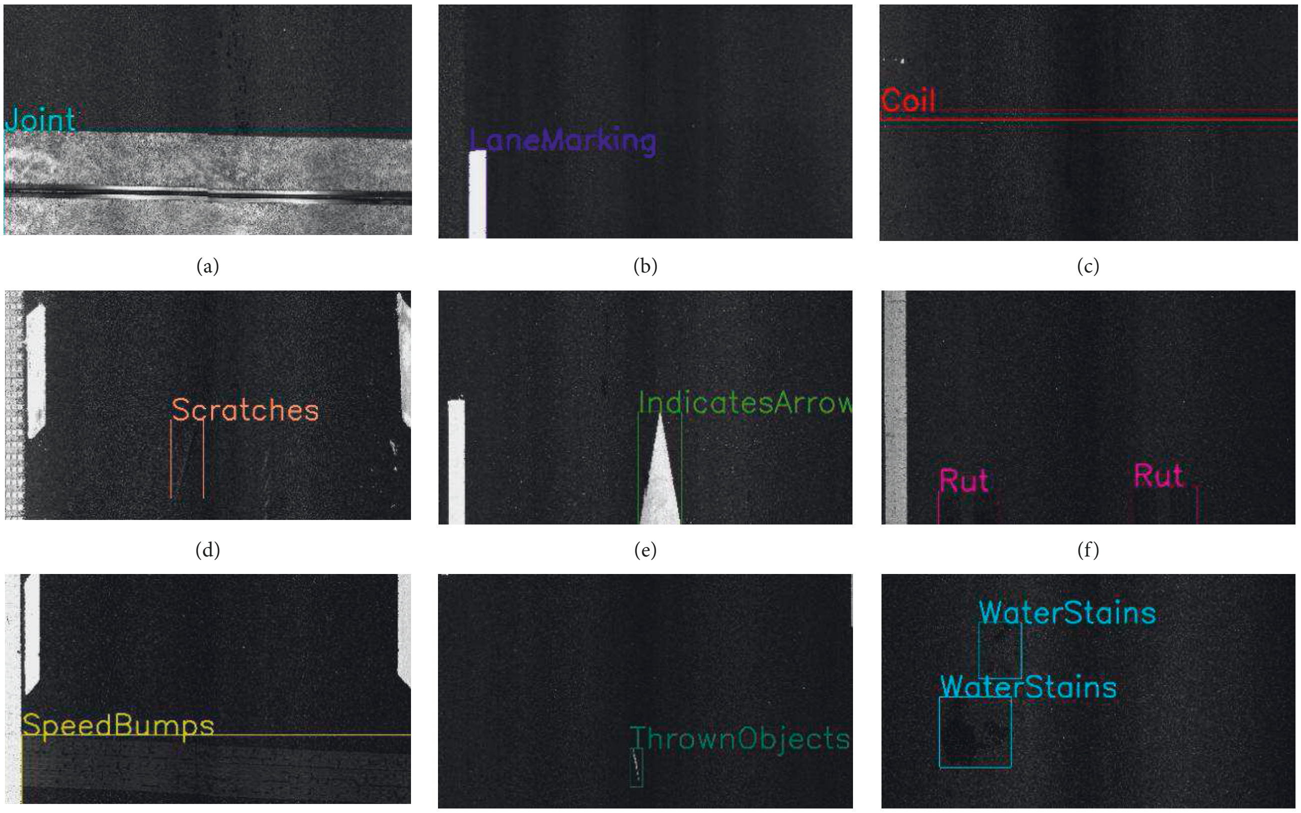
$$T_{i,j} = \left|d_i - d_j\right| + \left|\sigma_i - \sigma_j\right| + \left|f_i - f_j\right|, \tag{16}$$

where i and j are pixels of two images, respectively; d_i and d_j are the distance between pixels and clustering points; σ_i and σ_j are spatial dynamic selection coefficients of images; f_i and f_j are the average brightness of two images. The schematic diagram of the Poisson migration fusion algorithm is shown in Figure 18.

3.10. Softer-NMS. Softer-NMS for final result processing nonmaximum suppression (NMS) is mainly used for postprocessing of target detection model output based on deep learning, to remove redundant detection boxes and obtain correct detection results. But through the analysis we can find that NMS has the following defects:

(a) There are more missed detections in dense scenarios: when there is partial overlap between two targets nearer, there is a greater likelihood of missed detections for targets with less confidence.

(b) The NMS default box with higher confidence scores is more accurate, and this condition is not always valid because classification and regression tasks are not directly related. High confidence border boxes are not always more reliable than low confidence border boxes.



(a) (b) (c) (d) (e) (f) (g) (h) (i)

Figure 16: Negative sample labels. (a) Expansion joints (joint), (b) road markings (laneMarking), (c) induction coils (coil), (d) lane scratches (scratches), (e) lane indication arrows (indicatesArrow), (f) rut, (g) speedBumps, (h) thrownObjects, and (i) waterStains.

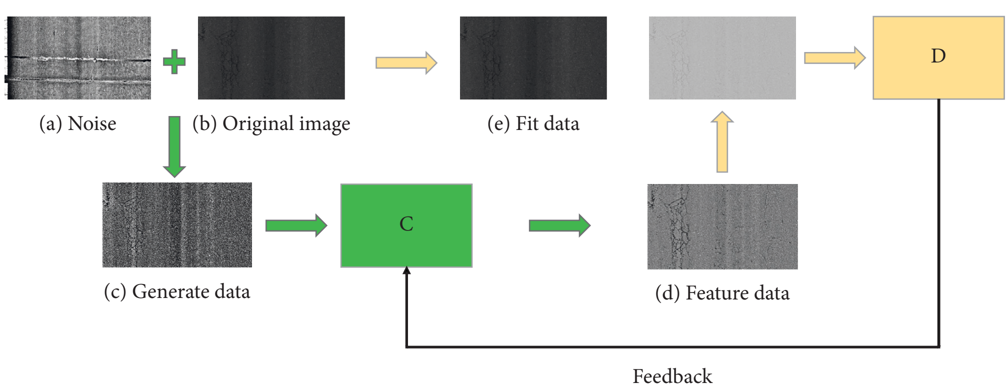


Figure 17: Generating the basic framework of an adversarial network (GAN).

(c) The labeling of ground truth may not be reliable.

Aiming at the first problem of NMS, Soft-NMS designs the degree function of confidence score decline according to the size of IoU and has achieved certain results. But for the other two problems the classification confidence score is not strongly correlated with the IoU of the box, so a new method is needed to measure the location confidence of the box. Based on this, Softer-NMS puts forward two ideas, respectively, to build the confidence of IoU to model how much grasp that the current frame and GT are coincident; a method is proposed to combine multiple frames according

Table 4: WGAN-GP network detailed parameter table.

to the IoU confidence to optimize the final generated frame. For IoU confidence, Softer-NMS uses Gaussian functions to model the prediction box. The calculation method is shown in

$$P_\theta(x) = \frac{1}{2\pi\sigma^2} e^{-(x-x_e)^2/2\sigma^2}. \tag{17}$$

Using delta distribution to model GT frame, the calculation method is shown in

$$P_D(x) = \delta\left(x - x_g\right). \tag{18}$$

In formulas (17) and (18), $P_\theta(x)$ represents the Gaussian probability distribution of the predicted bounding box, $P_D(x)$ represents the delta probability distribution of the predicted bounding box, x represents the value of the actual bounding box, σ represents the standard deviation, x_e represents the prediction box after offset, and the output x_g represents the GT box.

Softer-NMS method can effectively avoid missed detection in complex asphalt pavement disease processing scenarios, to improve the recall rate and meet the needs of engineering tasks.

4. Experiments

4.1. Data and Experimental Environment. The experiment in this article requires good hardware configuration and GPU acceleration. The running environment of the experiment is shown in Table 5. The data set used in this article is from the subgrade and pavement safety detection platform of the Digital Fujian Intelligent Transportation Technology Internet of Things Laboratory of Fujian Agriculture and Forestry University and Fujian Expressway Datong Detection Company. This data set selects 7,000 training set images and 1750 test set images, respectively. To increase the robustness of the training model, the data set adds background images that do not contain diseases and adds background labels such as road markings, indicator arrows, and bridge joints. All label categories are shown in Table 6.

4.2. Ablation Experiment

4.2.1. Evaluating Indicator. The automatic identification of highway asphalt pavement diseases belongs to the category of target detection. At present, the commonly used indexes to evaluate the training performance and robustness of the model are precision (P), recall (R), and mean average precision (mAP).

The target detection and evaluation index is applied to the test of highway asphalt pavement diseases, and two kinds of results images can be obtained, including images with diseases and images without diseases. True-positive (TP), false-positive (FP), true-negative (TN), and false-negative (FN) are important indicators to describe the accuracy of the model. The specific formulas of the above metrics are shown in

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} = \frac{\text{TP}}{\text{all detections}}, \tag{19}$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} = \frac{\text{TP}}{\text{all ground truths}}, \tag{20}$$

$$\text{AP} = \int_0^1 P\,\mathrm{d}R, \tag{21}$$

$$\text{mAP} = \frac{\sum_{i=1}^{N} \text{AP}_i}{N}. \tag{22}$$

TP, FP, and FN refer to correct check box, wrong check box, and missing check box, respectively. AP value is the area of the P-R curve, and N represents the total number of detection categories; this article is 10. mAP @ 0.5 refers to the average AP of all categories when IoU is set to 0.5. mAP @ 0.5 :

Table 6: All label categories in the data set.

Disease	Label	Nondisease	Label
Transverse crack	TransverseCrack	Deck expansion joint	Joint
Longitudinal crack	LongitudinalCrack	Road marking	LaneMarking
Alligator crack	AlligatorCrack	Induction coil	Coil
Repair-strips	Sealing	Scratch	Scratches
Repair block	Patch	Guide finger	IndicatesArrow
Loose	Loose	Rut	Rut
Repair seam	SealingCrack	Deceleration strip	SpeedBumps
		Sprinkler	ThrownObjects
		Water stain	WaterStains

0.95 refers to the average mAP on different IoU thresholds. The IoU value ranges from 0.5 to 0.95, and the step length is 0.05. The average detection processing time includes network self-inference time and NMS processing time.

F1-score is a measure of classification problems. Some machine learning competitions for multiclassification problems often use F1-score as the final evaluation method. It is the harmonic average of precision rate and recall rate, with a maximum of 1 and a minimum of 0. Based on this, this article selects F1-score as the final model evaluation criteria. The calculation method of the F1-score is shown in

$$F_1 = 2 \times \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}}. \tag{23}$$

4.2.2. Selection of Detection Image Size. In the process of image recognition, the larger the size of the image, the higher the clarity, the higher the recognition accuracy, and the slower the speed. The image with a small size is exactly the opposite. Therefore, how to balance the relationship between speed and accuracy is a very critical factor for us to select the image size. The variation trend of F1-score and FPS with the size of the detected image is shown in Figure 19. The black curve in the figure represents the change of the F1-score with the size of the detected image. The red curve represents the change of FPS with image size. It can be seen from the figure that the F1-score increases rapidly with the increase in image size. When the detection size exceeds 896, the curve becomes smooth. At the same time, the detection speed decreases with the increase of detection size. Considering this comprehensively, 896 is selected as the size of image detection, and 1024 is selected as the reference standard.

4.2.3. Network Structure Ablation Experiment. In this section, the performance change caused by the change in network structure is gradually verified by ablation experiments. Four experiments are conducted for the target detection model of YOLOv5. Four networks, YOLOv5, YOLOv5-WPAN, YOLOv5-WPAN-Ghost, and YOLOv5-WPAN-Ghost-Shuffle (YOLO-W), are trained, respectively, in the four experiments. The network name can correspond to the structure described above one by one. Figure 20 shows the precision curve of the four networks when the input image size is 896, and Figure 21 shows the recall curve of the four networks when the input image size is 896. The

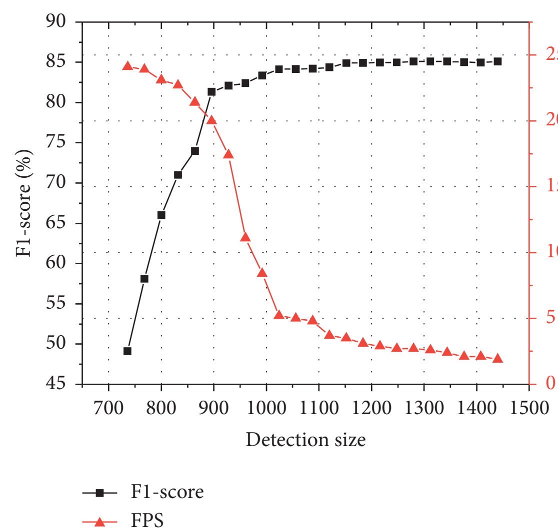

Figure 19: F1-score and FPS versus image size.

brightness of the curve increases in turn, respectively, representing YOLOv5, YOLOv5-W-PAN, YOLOv5-WPAN-Ghost, and YOLOv5-WPAN-Ghost-Shuffle (YOLO-W). In Figure 20, the accuracy of YOLOv5-WPAN-Ghost-Shuffle has an obvious loss, and the fluctuation is more intense. Fortunately, in the late training period, the difference between the accuracy of the model and YOLOv5 is lower than that in the early stage. The cause of fluctuations found during later debugging is related to batch-size settings.

As can be seen from Table 7, when the image size is 896, the calculation amount and parameters of the YOLOv5 network model with W-PAN structure are increased by 1.2% and 27.9%, respectively, and the F1-score is increased by 5.2%. After adding GhostBottleneck, the computation and parameters of the model are reduced to 53.3% and 65.3% of the original YOLOv5 network, respectively. The F1-score is increased by 7.5%, the model size is reduced by 37.8%, and the speed is increased by 5.9% with GPU.

After the standard convolution is replaced by ShuffleConv, the number of model parameters and the amount of calculation are further reduced to 29.5% and 29.3%, the F1-score is increased by 0.6%, and the model size is reduced by 29.9%. The result that the speed is not improved in the case of GPU is also expected. On the GPU platform with sufficient computing power, although the group convolution reduces the amount of computation and parameters, due to

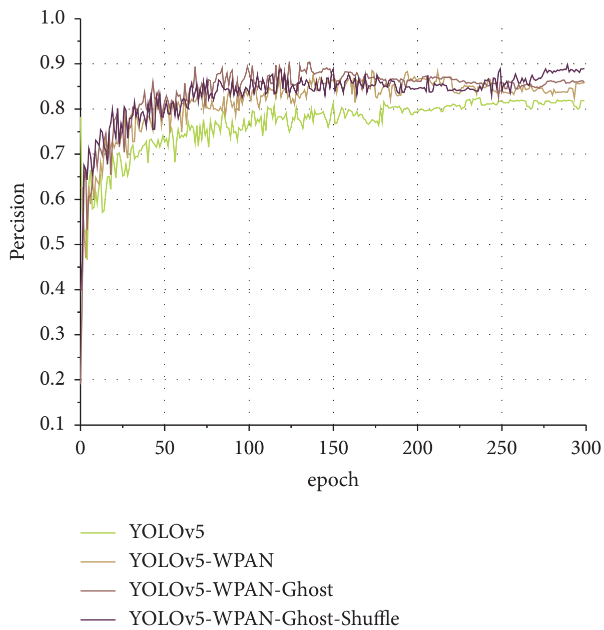

Figure 20: Schematic diagram of the precision change curve.

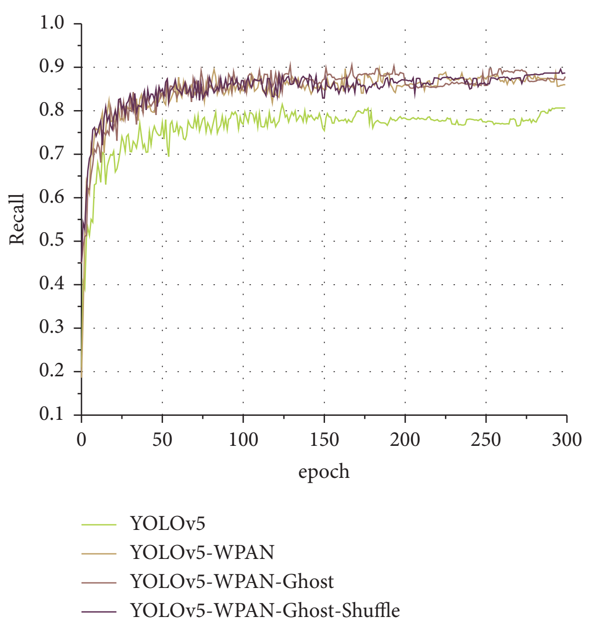

Figure 21: Recall change curve diagram.

the limitation of memory exchange speed, the bottleneck of ShuffleConv is not the computational strength, so this module has little effect on the GPU environment. In addition, YOLOv5-WPAN-Ghost-Shuffle improves F1-score compared with YOLOv5-WPAN-Ghost, which proves the regularization effect of group convolution to some extent.

To further verify the efficiency of the proposed modules and networks, it is compared with similar lightweight networks YOLOv3-tiny and YOLOv4-tiny. It can be seen from Table 7 that the proposed network model has absolute advantages over YOLOv3-tiny and YOLOv4-tiny. The model size was only 59.0% and 44.7% of the above models, but the F1-score exceeded YOLOv3-tiny and YOLOv4-tiny by 13.6% and 10.6%. Therefore, the proposed model is reasonable and economical in engineering applications.

Secondly, by adding YOLOv3-tiny-Ghost-Shuffle, YOLOv3-tiny, YOLOv4-tiny-Ghost-Shuffle, and YOLOv4-tiny into two groups of comparative experiments, the optimization versatility of GhostBottleneck and ShuffleConv modules on other networks is proved. Compared with YOLOv3-tiny, YOLOv3-tiny-Ghost-Shuffle reduces the computation and parameter by 81.4% and 92.8%, respectively. The model size was compressed by 91.6% and the F1-score was increased by 1.4%. Compared with YOLOv4-tiny, YOLOv4-tiny-Ghost-Shuffle reduced the calculation amount and the number of parameters by 58.5% and 64.4%, respectively, reduced the model size by 58.5%, and increased the F1-score by 1.2%.

4.2.4. GAN Ablation Experiment. In this section, we verify the performance change of the network model caused by the confrontational generation network (GAN) through ablation experiments. Three experiments are carried out for the YOLOv5 network model. The three experiments train YOLOv5, YOLOv5 + GAN + Poisson, and YOLO-W + GAN + Poisson networks, respectively. The experimental results are shown in Table 8. Taking the input image size of 896 as an example, YOLOv5 + GAN + Poisson is 2.54% higher than YOLOv5 in F1-score, and YOLO-W + GAN + Poisson is 9.13% higher than YOLOv5. Experiments show that the performance of the model can be effectively improved by adding a small number of diseases generated by the confrontation generation network (GAN) in the data set.

4.2.5. NST Ablation Experiment. In this section, the data sets with and without nondisease labels are used for training, and the performance of each model in the NST ablation experiment is shown in Table 9. Taking the input image size of 896 as an example, YOLOv5+NST is 3.55% higher than YOLOv5 in F1-score, YOLOv5+GAN +Poisson+NST is 2.32% higher than YOLOv5+GAN+Poisson, and YOLO-W+GAN+-Poisson+NST is 2% higher than YOLO-W+GAN+Poisson. Experiments show that the NST algorithm can effectively improve the performance of the model.

5. Analysis

To further verify the efficiency of the PDNet network architecture proposed in this article, the MMDetection tool is used to compare it with other classical networks on the FAFU-PD data set (including negative samples and generating disease data). These classical networks include a single-stage target detection network and a two-stage target detection network. The comparison results of different network performances are shown in Table 10.

The results show that this article improves the detection accuracy and speed of nondeformation diseases of asphalt pavement by improving the model network architecture

Table 7: Performance comparison of models in network structure ablation experiment.

Size	Model	Parameters	GFLOPS	Speed-GPU	Weight	F1-score (%)
896	YOLOv5	7114785	16.5	1.7	14.2	81.34

design, parameter setting, and preprocessing algorithm. Combining our model with different processing techniques and using this as a comparison, our PDNet is essentially a YOLOv5-based nondeformable disease detection algorithm for asphalt pavements with additions such as Generative Adversarial Networks (GAN), Poisson transfer fusion algorithm, and negative sample algorithm (NST). The performance of the model is inseparable from the technology it adds. In the following, we will analyze the advantages of various processing techniques and how they work.

The W-PAN structure makes the fusion of semantic information at al levels of the network more reasonable and sufficient. The introduction of W-PAN has greatly improved the accuracy of the network, especially the accuracy of high-intersection which is higher than required. However, during its introduction also the parameter amount and calculation amount of the model are increased.

The addition of the Ghost module and Shuffle module reduces the computational complexity and parameter volume of the model and compresses the model.

Adversarial generative network (GAN) and Poisson transfer fusion algorithm generate disease types with a small number of samples, which solves the imbalance of training samples to a certain extent and improves the performance of the model without reducing the speed of the model.

The NST algorithm also improves the score without reducing the speed, because in the nondisease samples we

Table 11: Performance parameters of each model in the actual test section.

Model	896		1024	
	Speed (FPS)	F1-score (%)	Speed (FPS)	F1-score (%)
YOLOv5	20.0	81.34	5.2	84.13
YOLO-W	33.5	88.49	16.0	89.32
YOLO-W + GAN + Poisson	35.5	89.51	16.1	90.74
YOLO-W + GAN + Poisson + NST(PDNet)	35.5	91.34	16.7	92.38

increase the information entropy and increase the amount of useful information for disease detection.

In addition, the performance of the model is also affected by some parameter settings. For some parameters, some minor adjustments may cause the performance of the model to oscillate, such as the setting of the anchor box, the size of the detection image, and the number of detection layers.

Table 11 visually shows some performance differences of different types of models in the actual road test. From the YOLOv5 model to PDNet, the F1-score with detection sizes of 896 and 1024 is increased by 10.0% and 8.25% respectively; the speed of the model is increased by 15.5% FPS and 11.5 FPS to meet the needs of industrial applications.

6. Conclusion

In this study, based on the YOLOv5 target detection model, a real-time and high robustness detection network-PDNet for nondeformable diseases of asphalt pavement was realized. It realized the rapid and accurate detection of nondeformable diseases of asphalt pavement in the actual road detection process. When the image detection size was 896, the F1-score of 91.34 and the speed of 35.5 FPS were obtained on the Jetson nanoplatform. This algorithm will provide data support for the realization of highway daily maintenance. At the same time, the proposed W-PAN, GAN, Poisson, NST, and other technologies provide a reference for the specific application of artificial neural network optimization methods in edge computing equipment.

Each Chinese region has its own ancient opera, which is a treasure of folk culture and a living fossil for studying the historical origins of a local culture. It has significant academic value and historical significance at the national and local levels, whether from the perspective of promoting and disseminating national culture or from the perspective of protecting the world's intangible cultural heritage. Based on this practical significance, this paper conducts a study using the particle swarm algorithm to manage the marketing archives of drama intangible cultural heritage. The article employs the PSO algorithm to test the particle swarm optimization algorithm's convergence and conditions. The effectiveness of the algorithm is analysed in the Sphere function, Rosenbrock function, Griewanks function, and Rastrigin noncont function, and then the algorithm is compared, including the calculation speed comparison between the algorithm in this paper and the three optimal fitness functions. The experimental results show that the PSO algorithm has the highest four items in the statistics of the Schwefel function experimental results. About 45.0379 is the best value and 70.5878 is the maximum precision. The optimal average value is 6.1524, while the average value is 56.15245. In comparison to the QPSO and PSO algorithms, the algorithm in this paper has a faster convergence speed and better search accuracy. The topic of the intersection of the disciplines of drama, intangible cultural heritage marketing, and archive management using the particle swarm algorithm is well-developed.

1. Introduction

Intangible cultural heritage is the precious cultural wealth of mankind. It is the embodiment and memory of national cultural traditions. It can promote the inheritance of traditional culture and the protection of cultural diversity. Nowadays, more and more people organically combine the protection of intangible cultural heritage with tourism development, attracting the emerging elements of intangible cultural heritage into tourism activities, which has become an important way for intangible cultural heritage to meet the needs and development of modern society. Various forms of folk performances, including folk activities and performing arts, are constantly being updated and gradually integrated into this cultural heritage with great potential for development. As intangible cultural heritage, its scope has a definition, including poetry, mythology, etc. However, it is not limited to this category. In addition, there are many kinds of folk performing arts, such as epics and stories. Even rituals passed down from generation to generation by ordinary people and practices related to traditional folk knowledge and cultural sites are included. For example, the electronic file information management module includes four business modules of file maintenance, review, query, and statistics.

In recent years, China is committed to the protection of intangible cultural heritage, and many experts and scholars have carried out research on this aspect. Hammou I considered that intangible heritage is increasingly featured in the planning of several agencies that aim to raise awareness among countries about safeguarding their cultural diversity and to help them develop programmes so as to protect and preserve this type of heritage. However, there was a lack of information when he solved this problem [1]. Zhang and Lee explored the dialectical relationship between authenticity and alienation in intangible cultural heritage (ICH) tourism research based on assessing the role of cultural values in Chinese tourism. His research has certain implications for tourism marketing, aiming to understand the authenticity of the supply side of intangible cultural heritage tourism. However, his research data is not processed by mixed methods, and there may be data errors [2]. Zhang et al. proposed a tourist-based authenticity model to address this problem, where the authenticity of heritage sporting events contains both "cool" and "hot" factors. Using Naadam as an example, the model examined these factors and their impact on tourist satisfaction and loyalty. About 700 questionnaires were distributed in six locations from eastern to western Inner Mongolia, China. His research showed that there are two separate factors for coldness and heatness. Both factors of cold authenticity directly affect thermal authenticity and satisfaction [3]. Veghe explored the links between cultural heritage, marketing and local community sustainability based on secondary data on engagement, perceived importance, access and stewardship. He argued that despite the increasing recognition and expansion of capitalization, the use of tangible and intangible cultural heritage as assets that may benefit local communities remains limited. However, his research did not involve the different geographical conditions at home and abroad, and has geographical limitations [4]. Although the research content is sufficient, the research on intangible cultural heritage is still limited by geographical and human resources, which makes people in the era of big data and algorithms cannot help considering: Is it possible to manage the intangible cultural heritage archives using the ideas of the intersection of disciplines?

Particle swarm optimization is a hot research topic recently, and people have tried to use this algorithm to study many aspects. Jain et al. reviewed the research progress of particle swarm optimization algorithm (PSO) from 1995 to 2017. He discussed the progress, improvement, and application of particle swarm optimization algorithm. He divided PSOs into nine categories according to different aspects. However, his research did not hybridize PSO technology with other evolutionary technologies, which did not have theoretical breadth [5]. Tang and Guan took time delay as an additional parameter and gave parameter estimates for chaotic systems with time delays. The parameter estimation problem is transformed into an optimization problem, which finds an optimal parameter combination, that is, minimizes the objective function [6]. Chen proposed a multiple attribute decision-making (MADM) method based on interval-valued intuitionistic fuzzy-weighted geometric mean (IIFWGA) operator, interval-valued intuitionistic fuzzy-valued precision function (IVIFV), and particle swarm optimization (PSO) techniques. Among them, the attribute weight and the evaluation value of the alternatives relative to the attribute are denoted by IVIFV. But his research did not generate optimal weights for attributes, which has limitations [7]. Gong Y J first developed a new framework to organically combine PSO with another "learning" optimization technique, leading to the generalized paradigm of "PSO learning". He also proposed a new *L-PSO algorithm, called genetic learning PSO (GL-PSO), using genetic evolution techniques to generate promising samples for particle swarm optimization (PSO) algorithms. But his study did not perform mechanical parallel stacking [8]. In the research of these scholars, it is inevitable to encounter the limitations of particle swarm optimization. The algorithm is very easy to "premature," and the population diversity is lacking in the late iteration, which makes it easy to fall into the local optimum situation. This is very unfavorable for the analysis of the problem.

Since its inception, the PSO algorithm has attracted the attention of many researchers due to its few parameters, simple operation, and easy implementation. In a very short period of time, a large number of research findings have emerged. Due to some flaws in the PSO algorithm, relevant scholars have made a number of enhancements, which are primarily focused on the following three aspects: (1) improvements to the PSO algorithm, such as inertia factor and parameter selection; (2) integrating PSO with other optimization algorithms to improve; and (3) optimising the PSO algorithm's network topology. The PSO algorithm has been improved in recent years. Adding the weight w, for example, can achieve the goal of balancing particle local search and overall search ability, which can improve the PSO algorithm's performance. Another example is the dynamic inertia weight change strategy, which uses two attractor and repulsion processes to optimise particle evolution and speed up the algorithm's convergence. It accelerates population convergence and effectively prevents particles from settling in local best-fit solutions. The goal of the article is to improve the algorithm's shortcomings and apply it to the creation of drama intangible cultural heritage archives.

2. Particle Swarm Optimization and Intangible Cultural Heritage Deconstruction Methods

2.1. Swarm Intelligence Overview. In recent years, team intelligence has received extensive attention in many fields [9, 10]. In nature, although many biological individuals are simple and without intelligence, the behavior of groups is often very complex [11]. This natural phenomenon has aroused great interest of biologists and computer scientists at home and abroad [12]. In recent years, with the rise of biomimicry and research, scientists have begun to study social organisms, such as ants, schools of fish, and flocks of birds, so as to solve practical problems, and swarm intelligence algorithms were born. The swarm intelligence algorithm is a stochastic optimization algorithm that solves practical problems by simulating the intelligent characteristics of certain swarm behaviors in nature [13]. The main characteristics of swarm intelligence include the followings: 1. simplicity; 2. distribution; 3. robustness; 4. wide applicability. Adaptability means that the algorithm proposed in this paper can not only solve the problem of numerical optimization, but also solve the problem of the distribution of discrete variables. It can be a single set of data or a combination of many discrete variables. The initial flowchart is shown in Figure 1:

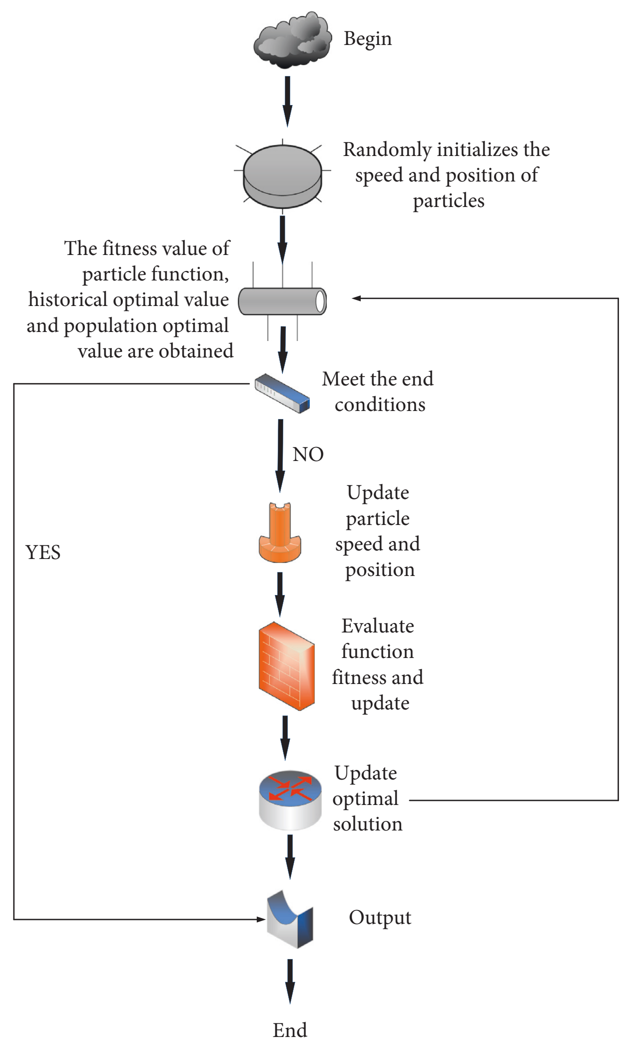

Figure 1: Initial PSO flowchart.

2.2. Explanation of Correlation between the Coordinated Development of Intangible Cultural Heritage and Ecotourism. Since the end of the last century, China's intangible cultural heritage has been dying. The main reasons include two aspects: (1) Many traditional intangible cultural heritage heirs are getting old, and young people are reluctant to learn, resulting in the inheritance of intangible cultural heritage culture. (2) With economic construction and development, many intangible cultural heritage sites have been demolished, resulting in fewer places for cultural heritage. Different from nature tourism, ecotourism is characterized in that it has certain functions of ecological environment education and protection of local characteristic culture [14], which can help tourists and local communities to establish awareness of natural and humanistic environmental protection. It makes tourists have a certain sense of responsibility for the environment and reduce the adverse impact on the environment of ecotourism areas [15], making tourists consciously maintain the stable state of the ecosystem and local culture. The employees of the scenic spot need to take the sustainable development of the scenic spot as the working principle, strengthen the awareness and habits of saving and protection in their work, and infect tourists with practical actions [16], as well as use the cultural heritage of intangible cultural heritage to attract tourists. Intangible culture is closely related and inseparable from traditional Confucianism in the inheritance of thousands of years. It can be said that intangible cultural heritage is a carrier of Confucianism.

Coordination refers to the phenomenon in which two (or more) systems or system factors influence each other through different interactions [17]. This is a benign relationship between multiple systems or elements. "Development" refers to the process in which the system itself or system elements change from small to large, from simple to complex, from low to high, and from disorder to order [18]. "Coordinated development" seems to be based on a virtuous circle, in which the system or system factors develop from low to high, from simple to complex, and from disorder to order. It emphasizes the comprehensive integrated development of multiple systems or systemic factors under the constraints and regulations of "coordination," seeking global optimization, structural optimization, and joint development based on overall improvement [19]. The degree of coordinated development includes the system or element coordination system (that is, collaborative planning) and the level of development of both [20].

Initiative refers to the principle that the initiative stipulates that collectors of intangible cultural heritage archives must have or cultivate a high sense of responsibility to improve their own enthusiasm and initiative, and have a spirit of loyalty.

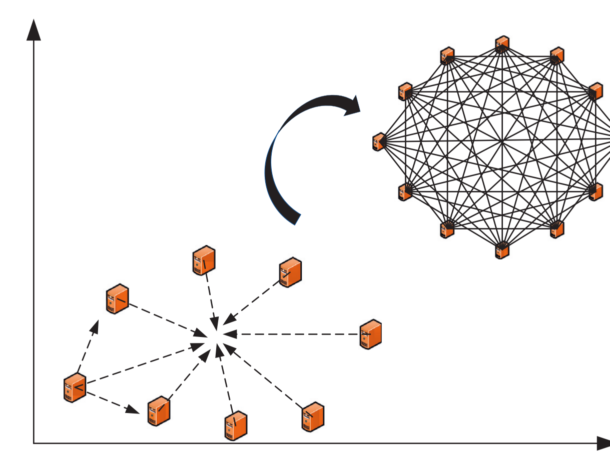

Figure 2: PSO algorithm principle and ER network structure diagram.

2.3. Particle Swarm Optimization Algorithm. Particle swarm optimization is a random search algorithm. Its evolution equation is a discrete dynamic system equation. By analyzing the state change of the dynamic system, the necessary and sufficient conditions for the algorithm to converge are determined, which provides a theoretical basis for the

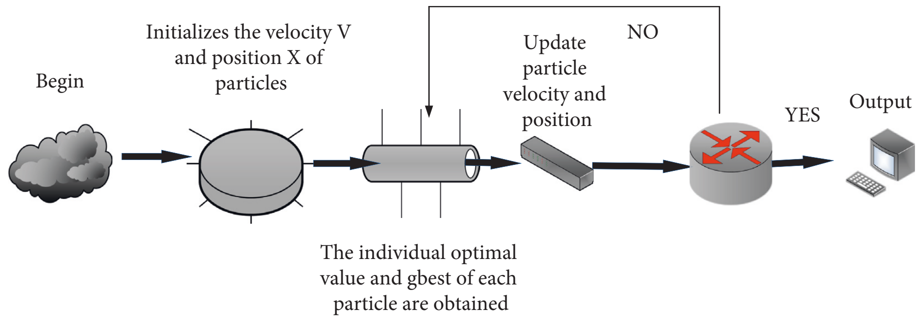

Figure 3: Running process of the standard particle swarm algorithm.

improvement of the algorithm. The PSO optimization algorithm was originally inspired by the life patterns of flocks of birds and fish. In nature, in the process of foraging, birds sometimes need to forage in groups. Sometimes they also need to forage in groups. In each search, there is always a bird with a strong ability to detect the location of the food, so it will transmit information between the flocks and then guide the flock to the food source. The principle of the PSO algorithm and the structure of the ER network are shown in Figure 2:

Information fusion is an information processing process that automatically analyzes and integrates multisource information through certain rules to achieve prediction, reasoning, and decision-making tasks. Through the above research, the operation process of the standard particle swarm algorithm can be given, as shown in Figure 3.

In order to verify the convergence and conditions of the particle swarm optimization algorithm, the evolution equation of the standard particle swarm optimization algorithm is used for analysis, as shown in the following formulas:

$$V_{\mathrm{id}}(t+1) = \omega V_{\mathrm{id}}(t) + c_1 r_1 \left(\mathrm{pbest}_{\mathrm{id}} - x_{\mathrm{id}}(t)\right) + c_2 r_2 \left(\mathrm{gbest}_d - x_{\mathrm{id}}(t)\right), \quad (1)$$

$$x_{\mathrm{id}}(t+1) = x_{\mathrm{id}}(t) + v_{\mathrm{id}}(t+1). \quad (2)$$

First, the d in the evolution equation is removed, and the particle swarm optimization problem is formulated as a one-dimensional optimization problem, namely as formulas (3) and (4):

$$V_i(t+1) = \omega V_i(t) + c_1 r_1 \left(\mathrm{pbest}_i - x_i(t)\right) + c_2 r_2 \left(\mathrm{gbest} - x_i(t)\right), \quad (3)$$

$$x_i(t+1) = x_i(t) + v_i(t+1). \quad (4)$$

In the form of a matrix vector, formula (5) can be obtained as follows:

$$\begin{bmatrix} V_i(t+1) \\ x_i(t+1) \end{bmatrix} = P \begin{bmatrix} V_i(t) \\ x_i(t) \end{bmatrix} + Q \begin{bmatrix} p_i \\ p_s \end{bmatrix}. \quad (5)$$

Among them, there is formula (6) as follows:

$$P = \begin{bmatrix} \omega & -\omega \\ \omega & 1-\phi \end{bmatrix}, \quad Q = \begin{bmatrix} \phi_1 & \phi_2 \\ \phi_1 & \phi_2 \end{bmatrix}. \quad (6)$$

Formula (5) is a discrete-time linear system of equations. Therefore, a sufficient and necessary condition for the algorithm to converge is that the modulus of the eigenvalues of P is less than 1 as follows:

$$f(\lambda) = \lambda E - P = \begin{bmatrix} \lambda - \omega & -\omega \\ \omega & \lambda - (1-\phi) \end{bmatrix}. \quad (7)$$

It can be simplified as follows:

$$\lambda^2 + (\varphi - 1 - \omega)\lambda - \omega = 0. \quad (8)$$

The eigenvalues of P can be obtained as follows:

$$\lambda = \frac{\varphi - 1 - \omega \pm (\varphi - 1 - \omega)^2}{2} = 0. \quad (9)$$

For the convenience of discussion, if the modulus of the eigenvalue is less than 1, formula (10) can be obtained as follows:

$$-2 < \omega + 1 - \phi + (\varphi - 1 - \omega)^2 - 4\omega < 2. \quad (10)$$

In order to test the effectiveness of the algorithm, several functions are selected for comparison.

(1) Sphere function

$$f(x) = \sum_{i=1}^{n} x_i^2. \quad (11)$$

(2) Rosenbrock function

$$f(x) = \sum_{i=1}^{n-1}\left(100\left(x_i^2 - x_{i+1}^2\right)^2 + \left(x_i - 1\right)^2\right). \quad (12)$$

(3) Griewanks function

$$f(x) = \sum_{i=1}^{n} \frac{x_i^2}{4000} - \cos\frac{x_i}{i} + 1. \quad (13)$$

(4) Rastrigin_noncont function

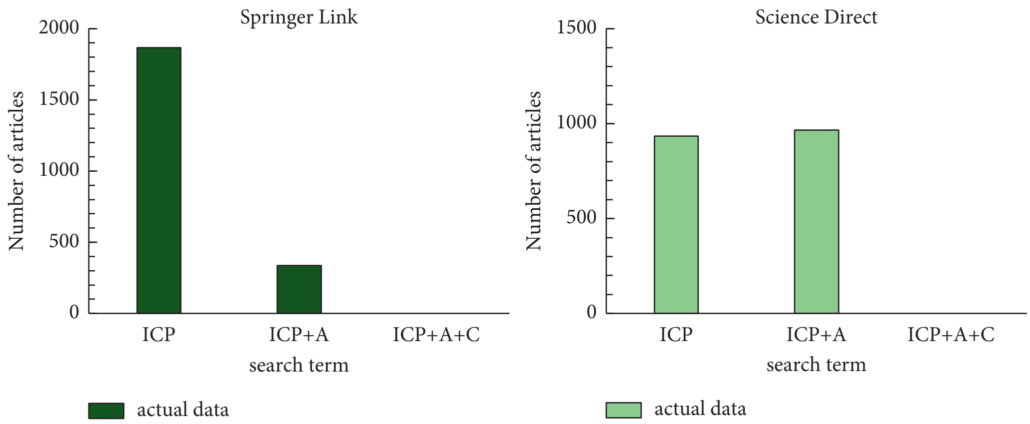

Figure 4: Springer link and science direct literature search results.

$$f(x) = \sum_{i=1}^{n} \left(z_i^2 - 10 \cos(2\pi z_1) + 10 \right),$$
$$z_1 = \begin{cases} x_1 & x_1 < 1/2, \\ \text{round}(2x_i), & x_1 \geq 1/2 \\ 2, & \end{cases} \tag{14}$$

In order to change such limitations, generalized transition distributions and acceptance criteria can be used, which can greatly reduce the problem of lack of diversity. In summary, the speed update formula proposed in this paper is as follows:

$$\begin{aligned} V_{\text{id}}(t+1) = {} & \omega V_{\text{id}}(t) + c_1 r_1 \left(\text{Pbest}_{\text{id}} - x_{\text{id}}(t) \right) \\ & + c_2 r_2 0.7 \times \left(p_b - X_{\text{id}}(t) \right) 0.2 \times \left(p_m - x_{\text{id}}(t) \right) \\ & + 0.1 \times \left(p_w - x_{\text{id}}(t) \right), \end{aligned} \tag{15}$$

$$x_{\text{id}}(t+1) = x_{\text{id}}(t) + V_{\text{id}}(t+1). \tag{16}$$

3. Experiment on the Archives' Management System of Drama Intangible Cultural Heritage

3.1. Data of Intangible Cultural Heritage Archives. At present, the full-text electronic journals provided by Springer link include a total of 439 academic journals. The journals published by Science Direct are recognized as high-quality academic journals in the world, such as the well-known Science journals. Most of them are core journals and are included in many famous secondary literature databases in the world. A data survey was carried out on the research results of foreign cultural heritage archives. ICP stands for "intangible cultural heitage protection." $\text{ICP} + A$ means "intangible cultural heitage protection + archives," and $\text{ICP} + A + \text{C}$ represents "intangible cultural heitage protection + archives + classification." The result is shown in Figure 4.

As can be seen from Figure 4, there are more documents on intangible cultural heritage archives in Springer Link, but there are no documents on intangible cultural heritage protection + archives + classification in the two libraries.

The CNKI journal database was used to search the full-text database of master and doctoral dissertations in China. The results are shown in Table 1.

3.2. Distribution Characteristics of Drama Intangible Cultural Heritage in a Province. When studying the distribution of intangible cultural heritage in a province, statistics were made on the regional distribution of national and provincial intangible cultural heritage in the province, which are expressed from A to U according to the ranking of prefecture-level cities in the province, as shown in Figure 5.

It can be seen from Figure 5 that the total amount of intangible cultural heritage in the province is relatively large, but the regional distribution is uneven. There is a positive correlation between the number of national intangible cultural heritage and the regional distribution.

Since the culture of the province is the cultural basis for the survival of traditional drama, the intangible cultural heritage of the province mainly focuses on drama. From 2015 to 2021, the development of tourism to the province due to intangible cultural heritage such as drama is shown in Figure 6.

As can be seen from Figure 6, the province's year-on-year growth rate of intangible cultural heritage tourism revenue has changed from 27.4% to 29.8%, and the proportion of its contribution to the country's tourism has also increased from 9.38% in 2015 to 10.88% in 2021. It shows that the protection of intangible cultural heritage can promote the development of tourism in this area.

A survey was conducted on tourists and ordinary citizens on the intangible cultural heritage of drama. The results are shown in Figure 7.

For plays unique to the province, 17 had seen some, 146 had heard of it but had not seen it, and 19 had not heard of it. It shows that the popularity of the drama is average. About 94% of people have not seen it, while only 6% of people have seen it. Therefore, the drama should be brought into the life of the masses, so that more people have the opportunity to enjoy the drama.

3.3. Simulation Test Results of the Intangible Cultural Heritage Archives' Management System. In order to show the performance of different algorithms more intuitively, PSO, DRWS-PSO, and ST-PSO were compared and the three algorithms were run independently for 50 times. The maximum, minimum, average, and average time for each algorithm were derived, as shown in Table 2.

According to Table 2, it can be seen that for the four functions used for testing, the improved ST-PSO algorithm takes less time, which is more efficient than the traditional

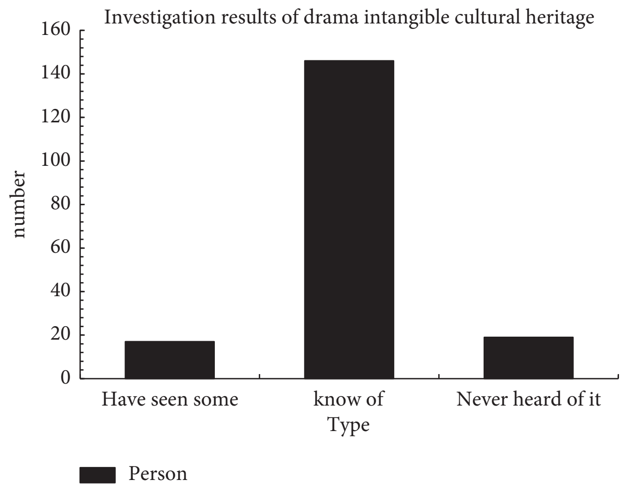

Figure 7: Results of the investigation on the intangible cultural heritage of drama.

Table 2: Function test results.

Test function	Algorithm	Max	Min	Average	Average time
$F1$	PSO	18.6564	21.1245	43.0168	0.98
	DRSW-PSO	17.1547	14.6653	20.1518	0.99
	ST-PSO	16.4155	12.1544	13.2201	0.88
	PSO	14.1524	11.1545	10.1576	1.15
$F2$	DRSW-PSO	24.4587	21.2545	22.1547	1.04
	ST-PSO	34.4154	29.2584	32.4557	1.00
	PSO	18.9694	8.7015	8.4852	1.29
$F3$	DRSW-PSO	19.6673	4.8814	4.3343	1.21
	ST-PSO	18.8685	1.0015	1.1205	1.05
	PSO	615.5458	598.5245	606.2218	1.13
$F4$	DRSW-PSO	374.2545	361.5245	368.7541	1.33
	ST-PSO	330.1545	298.5247	311.2435	0.85

PSO and DRSW-PSO. In addition, since the ST-PSO algorithm refers to the scale-free network as the domain structure of particles, the experimental results confirm that its algorithm performance is significantly better than that of PSO and DRSW-PSO.

The best solution and worst value of each algorithm and the average and standard deviation of the optimal fitness function are listed below.

Rosenbrock functions are generally nonconvex functions for testing optimal algorithms, which is also called the banana function. The statistics of the experimental results of the Rosenbrock function are shown in Table 3.

In the experimental results of Rosenbrock function, the optimal value of the PSO algorithm is the highest. The worst value is the lowest. The optimal fitness is moderate, which are 44.7568, 237.248, and 26.4578, respectively.

The statistics of the experimental results of the Griewank function are shown in Table 4.

Table 3: Statistics of experimental results of the Rosenbrock function.

	Best	Worst	Average	Stdev
PSO	44.7568	237.2487	62.4154	26.4578
DRSW-PSO	44.5247	111.4154	48.4558	9.3457
ST-PSO	32.1547	148.1545	56.4789	36.5847

Table 4: Statistics of experimental results of Griewank function.

	Best	Worst	Average	Stdev
PSO	0.0916	4.9451	1.3215	1.0145
DRSW-PSO	0.0223	-1.1147	0.2558	0.1685
ST-PSO	0.0578	0.4935	0.1998	0.05457

Table 5: Statistics of experimental results of Schwefel function.

	Best	Worst	Average	Stdev
PSO	45.0379	70.5878	56.15245	6.1524
DRSW-PSO	16.2457	39.2458	24.2415	4.2459
ST-PSO	23.2458	39.2456	30.5487	4.1558

In the statistics of the experimental results of the Griewank function, the average value of the PSO algorithm is the highest, and the optimal fitness is extremely high. The results are 1.3215 and 1.0145, respectively.

The statistics of the experimental results of the Schwefel function are shown in Table 5.

In the statistics of the experimental results of the Schwefel function, the four items of the PSO algorithm are the highest. The optimal value is 45.0379. The maximum accuracy is 70.5878. The average value is 56.15245, and the optimal average value is 6.1524. Therefore, in general, APSO algorithm has faster convergence speed and better search accuracy than QPSO algorithm and PSO algorithm.

In order to test the scheduling performance of the improved particle swarm algorithm, the following compares the completion time of the Chebyshev dynamic chaotic perturbation particle swarm optimization algorithm with adaptive inertia weight and traditional particle swarm optimization algorithm, round-robin scheduling algorithm (RR), and Max-Min algorithm. When the tasks are 20 and 50, the comparison results are shown in Figure 8.

Compared with the traditional particle swarm optimization algorithm, the traditional chaotic perturbation particle swarm optimization algorithm, and the chaotic perturbation particle swarm optimization algorithm, the improved particle swarm optimization algorithm converges faster in the repeated initial stage. However, in the later stage of algorithm repetition, the improved algorithm has better convergence effect, which is more stable. It has a shorter total completion time, which obviously meets the needs of users.

In order to expand the task volume, the algorithms are compared when the tasks are 200 and 500. The comparison results are shown in Figure 9.

It can be seen from Figure 9 that the Chebyshev chaos perturbation particle swarm optimization (Chevbyshev-FAPSO) with adaptive inertia weight has better scheduling

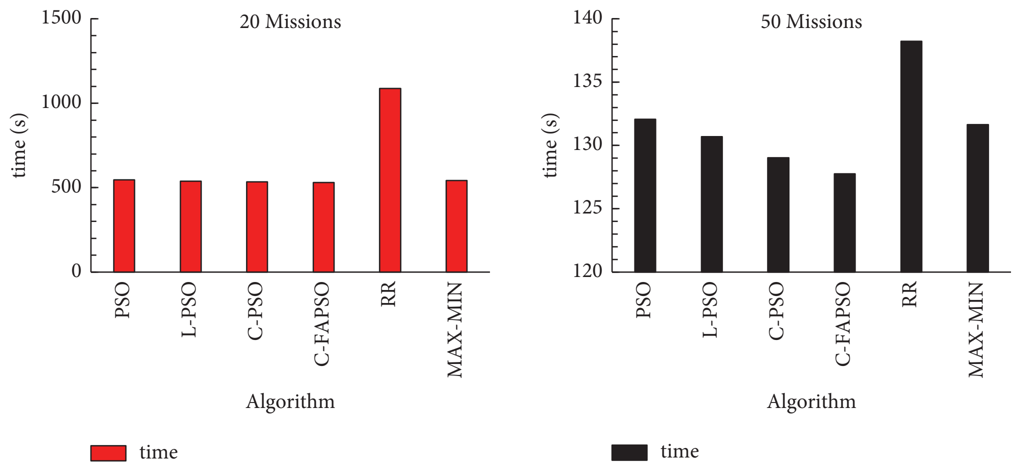

Figure 8: Time spent when there are 20 and 50 tasks.

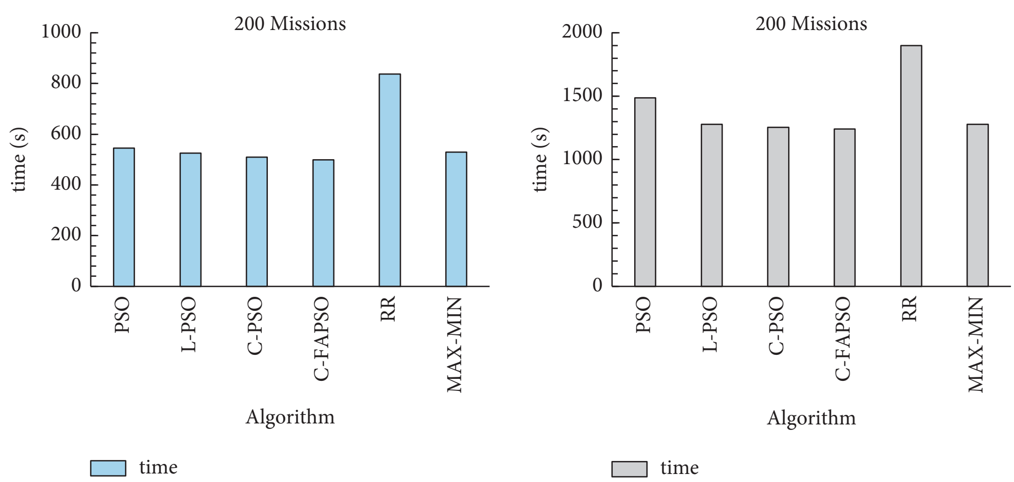

Figure 9: Time spent when there are 200 and 500 tasks.

results, and the improved particle swarm optimization takes the shortest time to complete the same tasks.

4. Particle Swarm Algorithm and File Management

4.1. Agent Modeling and Chaos Mapping. Agent often refers to a person who has the ability to recognize and practice in the objective world. For machines, it is an intelligent body with autonomous perception, judgment, reasoning, and decision-making. From the perspective of knowledge, the Agent is defined as an agent who has experience knowledge and can use knowledge to solve problems. The characteristics of Agent determine that the system it builds is nondeterministic, because the autonomy of Agent will make the system also have autonomy. Such a system is difficult to accurately predict, evaluate, and make decisions. Similarly, the behavior and state of the Agent system are random in design, and it is difficult to determine. Although the behavior of each Agent can be standardized, the system will only show the randomness of the state when it is running. Therefore, the unpredictability of the behavior of the traditional Agent model is a problem that needs to be solved.

Although the Agent method has inherent defects, it is necessary to expand and enhance the interactive semantic representation ability of Agent. The cyber-physical system (CPS) can provide this function to make up for the defect of the Agent system. CPS includes system engineering such as environment perception, embedded computing, network communication, and network control, so that the Agent system has the functions of autonomous perception, communication interaction, judgment, reasoning and decision-making, remote cooperation, and autonomy. Such a CPS-Agent system can accurately predict, evaluate, and make decisions based on the perception of itself, the environment and other agents, which can also solve the real-time dynamic randomness problem of the system.

Chaos covers almost every branch of the natural and social sciences. It has its own unique characteristics. The phenomenon of chaos seems to be random, but it has its inherent delicate structure, instead of intricate and disorganized chaos, which is a variable that fluctuates in the interval [0, 1]. In recent decades, gratifying results have been achieved in the study of chaos theory. Approximation methods and numerical integration methods of nonlinear differential equations have enabled people to fully and thoroughly understand, understand and apply the chaos.

The chaotic variable is ergodic, that is, it can search every state of the space without repetition. The randomness of a chaotic variable means that the turbid variable is as cluttered as a random variable. Chaotic variable is very sensitive to the initial conditions, and a small change in the initial value will cause a huge change in the later movement, which may lead to a large discrepancy. Due to these characteristics, the turbidity-based search technology is more advantageous.

4.2. File Management. In recent years, network management and automated document management have quietly become research directions in related fields. Meanwhile, good progress has been made in management level and innovation in theory and practice. For example, developed countries in Europe and the United States, Australia, and other advanced regions have integrated the research methods of network information document management into the national development planning process, and management tools have also changed. That is, they have their own management plans for the company in the country, from loose management to complex unified centralized management. These changes fully demonstrate that network information management has become an inevitable trend in the development of document management. The development of these documents also affects the management of our country.

Because in the original database table, it is often necessary to input file information, and the file information statistics need to generate monthly loan information. Therefore, multiple queries are required to statistic file information. Eventually monthly files are created and stored in statistic view. In countries such as Europe and the United States, it has been proposed to manage documents and documents through a network management framework. At the same time, it will also combine e-government for effective document and archive management. More than 90% of important official documents will no longer be stored on printed materials and computers. In other words, the information management of network file records has become an effective means of government management. Australia also put forward the strategic idea of network file management, aiming to transform traditional management into a more effective network management tool.

4.3. RFID Technology. With the rapid development of electronic technology, electronic file management system came into being. It not only improves the efficiency of work, but also backs up the original paper archives to ensure the safety of the archives. However, electronic files are not suitable for storing all data, and large enterprises and companies have a large number of files, so it is impossible to completely convert all files into electronic storage in a short period of time. Therefore, the management method of physical archives is still irreplaceable. It is very urgent to develop a set of archives management system that can meet the current needs.

RFID (Radio Frequency Identification) technology is a new technology that was born at the end of the last century and has developed rapidly in recent years, which is one of the key technologies of the Internet of Things. RFID technology uses radio-frequency antennas to communicate to achieve the purpose of exchanging data and identifying targets, and integrates signal transmission, automatic identification, radar, and other technologies. It has the characteristics of strong storage capacity, high security, and outstanding antipollution ability, and has been maturely used in various fields of society. RFID systems can be classified according to energy supply mode, operating frequency, and working mode.

China's RFID technology started relatively late, with a lack of core technology, especially in RFID UHF is still in its infancy. In addition, China's RFID technology standards are not unified. The products produced by various manufacturers are quite different, and they are not compatible with each other, which greatly limits the development of RFID technology. But in recent years, China's RFID technology has also made great progress. Among them, the automatic identification system of railway vehicle number (ATIS) is the earliest system using RFID technology in China. Using ATIS can accurately collect the running status data of locomotives and vehicles, such as vehicle number, vehicle number, status, location, and departure time, and can track vehicle movements in real time. At present, China has issued a total of 1.4 billion second-generation ID cards, realizing the large-scale application of RFID technology, and it has also been widely used in mobile payment, public transportation, commodity tracking and anticounterfeiting, and medical and health fields.

4.4. Backup and Storage of Intangible Cultural Heritage Archives. Sudden and highly destructive events such as fires, earthquakes, and environmental hazards often seriously threaten the security of archives and affect the order of archives work. The daily management of intangible cultural heritage archives includes the formulation of emergency plans. Through drills and training, the staff's emergency rescue ability can be improved in multiple ways. When emergencies occur, emergency protection techniques can be widely used and effective rescue work can be carried out in time, which can not only prevent the slow response, insufficient rescue, and ineffective response caused by insufficient preparation, but also reduce or even avoid the damage of intangible cultural heritage archives. These emergency measures cannot guarantee that the precious intangible cultural heritage will be avoided from the danger of extinction, so the backup and preservation of the intangible cultural heritage archives should also be implemented. The backup storage of intangible cultural heritage archives mainly includes the implementation of off-site backup storage, and heterogeneous backup storage. The off-site backup strategy of archives refers to making real-time available safe copies of intangible cultural heritage archives in another place. Off-site backup storage can minimize the losses caused by unexpected events, but the disadvantage is that the capital demand is too large. Therefore, off-site backup storage is mainly aimed at particularly important intangible cultural heritage files, for example, microforms of precious paper intangible cultural heritage files, files of traditional skills that are on the verge of being lost, etc.

In addition to off-site backup files, intangible cultural heritage files should also implement heterogeneous backup of intangible cultural heritage files. Heterogeneous backup is to realize the backup of different file forms, and use materials of different textures to store the intangible cultural heritage information, for example, the use of optical discs, magnetic disks, or other materials of different textures for backup, in order to achieve the purpose of backup. Compared with the disadvantage of large demand for storage funds for off-site backup, the cost of heterogeneous backup is low and the difficulty of storage is small. After the heterogeneous backup, the intangible cultural heritage archives have multiple copies, which is helpful for the long-term preservation of the intangible cultural heritage archives.

In addition, there is a cloud backup of intangible cultural heritage files. Cloud backup has the advantages of high storage capacity, high utilization rate, high security performance, and low cost. Cloud backup is mainly suitable for intangible cultural heritage electronic files with high frequency of use and large access volume. It can not only ensure the security of archive data, but also realize automatic management and backup for users of intangible cultural heritage archives, which can be fully used in the utilization of intangible cultural heritage archives.

5. Conclusions

The treasure of human society is intangible cultural heritage. It carries a nation's history and culture, as well as the nation's cohesion and centrifugal force, which is vital. Intangible cultural heritage has become increasingly marginalised in modern society as our country's economy has developed rapidly. When the feedback algorithm interacts with a human, the process becomes more complicated, and the accuracy of the feedback algorithm is severely limited. The optimization of particle swarm optimization is critical in order to achieve breakthroughs in both retrieval efficiency and accuracy. The topic of using algorithms to manage the archives of the intangible cultural heritage of drama is relatively new at a time when ideas about the intersection of disciplines are gaining traction. It has been tried by a small number of people, and research on it is scarce. The particle swarm algorithm and file management are examined from this practical perspective in this article. Backup storage, intangible cultural heritage file management, RFID, and other contents are among the features introduced. The particle swarm algorithm has been integrated into the marketing archives management of drama intangible cultural heritage, and the research has been completed to a high standard. When the task volume is 20, 50, or 200, 500, the article compares adaptive inertia weight algorithms, and the experimental results are excellent. For future research and development of this academic hotspot, researchers can try to generalise more intangible cultural heritage archives. The protection of intangible cultural heritage can also be done by individuals.

Academic Editor: Xin Ning

Information-based instruction is the most important and recently altered sort of instruction. Numerous changes in educational techniques have emerged from the ongoing growth of science and technology. Teachers must also grasp and enhance their capacity to educate with information on a regular basis. The goal of this research is to look at how to use the TPACK model and computational intelligence to build and explain a model for evaluating English normal students' informatization teaching skills. To measure information-based teaching competence, this research recommends using the Technical Pedagogical Content Knowledge model and Few-Shot Learning technology. As a result, this paper covers the principles and related algorithms of both, as well as constructing and assessing the case design and analysis of the information-based teaching ability evaluation model. According to the experimental data, the average CK of normal students' subject material knowledge is 3.522, which is the highest among the seven dimensions. The subject content is well-understood by ordinary students. When compared with teaching abilities, the competence level is low, and the performance of the integration of technology and teaching content needs to be improved.

1. Introduction

The rapid advancement of information technology has altered the way we work, learn, and play, and this is true in education as well. Education faces significant hurdles in today's quickly evolving digital culture. To raise the level of teacher education, a scientific and effective evaluation plan for teachers' information teaching competence is required. The TPACK framework is a knowledge system that combines technology into topic teaching in the classroom. Teachers actively select appropriate technical tools based on the actual teaching situation. It is the process of bringing individual topic expertise to teaching practice, with a focus on the importance of incorporating technology into the classroom.

It examines concerns linked to the cultivation of ordinary students' information teaching capacity using the TPACK model. This can provide a specific theory for nurturing ordinary students' information teaching ability, as well as a deeper understanding of teachers' information teaching ability from the theoretical standpoint of TPACK. TPACK opens up a new study field for the effective integration of information technology and curriculum, as well as theoretical direction for teachers on how to teach in a technological context more effectively. It is a novel idea to improve teacher professional development, and it is the knowledge base for teachers to effectively carry out instruction when the technology of the information age has invaded education.

The innovation of this paper is (1) through the combination of the TPACK model and information teaching, this paper introduces the theory and related methods of TPACK and computational intelligence in detail, as well as artificial neural network and genetic algorithm. (2) Based on a comprehensive review of the importance of information technology teaching ability, this paper proposes an index system for evaluating teachers' information technology teaching skills. And this paper uses the TPACK theoretical model to determine the structural relationship between the index system and teaching ability. Through weight calculation, it is concluded that the teaching ability level of normal students is relatively high, but the ability related to technology is relatively low, and the ability to integrate technology and subject content is not strong.

2. Related Work

With the development of information technology and the continuous advancement of educational informatization, TPACK has become an important standard for measuring teachers' teaching ability in the information age. The main purpose of Gomez-Trigueros I M is to evaluate the realization of spatial and digital competence through the intervention of the TPACK teaching model in the classrooms of primary school teachers at the University of Alicante. However, he did not take into account the influence of other factors [1]. Salas-Rueda RA analyzed the impact of the TPACK model in the design of predicate logic instructional units, taking into account the use of Raptor software, YouTube videos, and the social network Facebook. However, the number of samples in his experiments is small [2]. Almenara J C aimed to assess knowledge based on the TPACK (Technical, Pedagogical, and Content Knowledge) model and he used quantitative, descriptive, and relational methods. The conclusions he drew underscore the need for a kind of teacher training that is based not only on the technical aspects but also on the pedagogical and content aspects in an integrated approach. However, his views are not supported by a large amount of objective evidence [3]. D Mourlam used a mixed methods approach to attempt to describe teacher development experiences based on TPACK and adult learning theories directed by teacher developers. The findings suggest that teachers find the ongoing nature of the development experience valuable and value the support of teacher developers in achieving their goals. The survey results also showed an increase in TPACK for both teachers and teacher education candidates participating in the program. However, his experiments are one-sided [4]. Miguel-Revilla D analyzed the practical utility of the TPACK model and the effectiveness of a pedagogical intervention for social studies secondary education prospective teachers in a university setting over a two-year period. Finally, his experimental results can lead to the conclusion that the pedagogical and conceptual orientation of the teaching program has shown positive effects, demonstrating that the effectiveness of an integrated approach that can adapt to the specificities and challenges of social studies education. However, he ignored the interference of realistic factors [5]. Eutsler L explored how the use of TPACK's pedagogical knowledge structure and steps to release responsibility framework can help senior teachers design instruction to read and write using the iPad. His analysis revealed that teacher-controlled teaching methods attract the attention of experienced teachers to lesson plans. The pedagogical approach "teacher as facilitator" increases user confidence and exploration. Problem-based teaching methods help target individualized students. However, his analysis is not universal [6]. Stefani S aimed to describe the use of a Problem-Based Learning (PBL) model based on Theology, Teaching and Content Knowledge (TPACK) to improve the integrated topic learning process in V SDN 07 Pandam Gadang. The findings suggest that a Problem-Based Learning (PBL) model based on Technology, Pedagogical, and Content Knowledge (TPACK) can improve the integrated topic learning process in the elementary classroom. However, his model is not very feasible [7]. Starting from a theoretical framework, Bustamante C described the development of joint displays in mixed methods research case studies. However, the method he describes is somewhat monolithic [8].

3. TPACK and Computational Intelligence Methods

3.1. TPACK

3.1.1. Connotation of TPACK. TPACK is a new concept emerging in the process of teacher specialization, and it is a comprehensive science and technology of knowledge teaching. It was originally called PACK but was changed to TPACK for ease of memory and pronunciation. TPACK provides a new way of thinking. Once it is proposed, it has attracted great attention of educational scientists at home and abroad. TPACK is a new requirement for teachers' computer skills.

If teachers can effectively integrate technology into their professional knowledge structure in a modern educational environment and complete teaching efficiently, it will also become an important criterion for measuring teachers' teaching ability in the information age.

3.1.2. TPACK Structure. The use of instructional technology in educational contexts has become synonymous with technology integration. To help measure and guide teachers' use of educational technology, a variety of educational technology models and frameworks have been established. Many educational technology specialists believe that topic knowledge has an impact on how technology is used in the classroom. There are substantial contrasts, for example, between technology in science curriculum, successful curriculum integration, and effective technology and curriculum integration in social sciences. A new theory integrating pedagogical knowledge, subject knowledge, and technical knowledge (PK, CK, and TK) is shown in Figure 1.

This theoretical framework is called Technical Educational Content Knowledge (TPCK or TPACK) and expands its definition on the basis of the PCK knowledge structure, adding an element of technical support. The structural framework of TPACK consists of seven components, namely, TK, CK, PK, TPK, PCK, TCK, and TPACK.

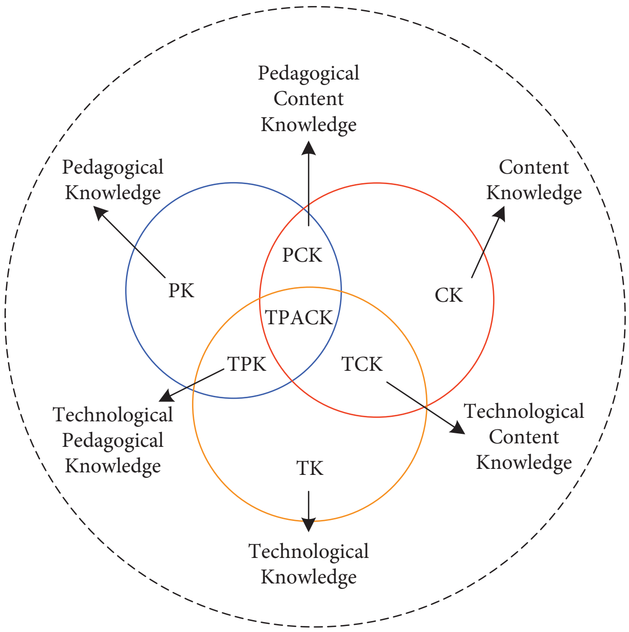

Figure 1: TPACK framework.

(1) *TK (Technological Knowledge).* Technical knowledge such as the use of blogs and various mobile devices, computers, projectors, and laboratory equipment is used in teaching. Office software such as PPT and word in teaching design is the necessary technical knowledge for teachers.

(2) *PK (Pedagogical Knowledge).* It is general pedagogical knowledge. General teaching strategies include teaching of theorems, concepts, definitions, and arrangement of teaching links such as the design of lesson plans. It is the basic teaching method that teachers must master.

(3) *CK (Content Knowledge).*It is subject knowledge required to be taught to students in various disciplines, such as laws, definitions, concepts, and formula theorems in science teaching. Students mastering these subject knowledge is the main goal of teaching but also the knowledge background that teachers must have.

(4) *TCK (Technological Content Knowledge).* It is disciplinary knowledge that integrates technology. Technical knowledge is used to help present a particular subject knowledge, but this composite knowledge is independent of pedagogical knowledge. For example, in the teaching of functions in mathematics courses, using technology to show the changing trend of functions can be considered as TCK.

(5) *TPK (Technological Pedagogical Knowledge).* It is pedagogical knowledge that integrates technology. The process of using technology to help teaching in the teaching of various disciplines is a combination of technology and pedagogical knowledge. This integrated pedagogical knowledge is not so much specific to the teaching of a specific subject as it is applicable to all subject pedagogical knowledge. The classroom discussion teaching is used in the Internet environment, that is, the learning environment supported by the computer (CSCL teaching environment).

(6) *PCK (Pedagogical Content Knowledge).* It is subject teaching method knowledge. This knowledge is intended to enable students to experience a complete teaching experience so that they can understand and master the knowledge of the subject.

(7) *TPACK (Technological Pedagogical Content Knowledge).* There is a debate on the definition of TPACK. One is that TPACK is an extension of PCK; that is, the element of technology is added to Schulman's PCK theory. The other is that it is a cross combination of three basic elements (TK, CK, and PK), TPACK is to strengthen students in learning a certain subject, such as using Google Earth in geography teaching to help students explore and learn El Niño phenomenon. It is a fusion of technology and pedagogical knowledge of subject knowledge, designed to allow students to experience a certain learning process and better understand the content that needs to be mastered.

3.2. Computational Intelligence Technology. Computational intelligence methods [9, 10] are inspired by biological evolutionary mechanisms and some natural phenomena, and many new solutions to complex optimization problems are widely used in various fields of problems, concerns, and applications due to their high optimization performance and less requirement for specific information. Computational intelligence methods include neural network [11, 12], fuzzy control, genetic algorithm, immune computing, and swarm intelligence.

3.2.1. Artificial Neural Network. The artificial neural network [13, 14] is based on the physiological research results of brain tissue, simulates some mechanisms and mechanisms of the brain, starts from the basic functions of neurons, and gradually forms a network from simple to complex. Its organization simulates the interaction of biological nervous systems with real-world objects. It simulates parallel processing on a large scale, has strong robustness and fault tolerance, and has strong self-learning ability. The first one is about the most basic and primitive model in the neuron synapse model: the binary threshold unit (Binarythresholdunit), the famous M-P model, as shown in Figure 2.

In Figure 2, θ represents the threshold when neurons are excited, and the M-P model reflects the structural and functional characteristics of biological neurons to a certain extent. Its mathematical description is as follows:

$$\begin{cases} \sum_{i=1}^{a} E_i - \theta \geq 0, & \text{and} \sum_{j=0}^{b} I_i = 0, Y = 1, \\ \text{other}, & \text{Y} = 0. \end{cases} \tag{1}$$

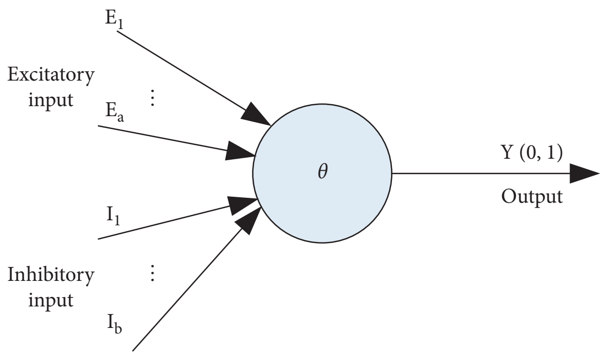

Figure 2: M-P model.

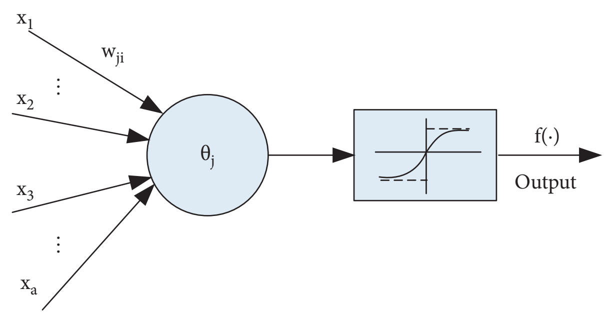

Figure 3: Neuron structure model.

With proper setting of neuron thresholds and combination weights, the model can approximate any binary function and can complete any finite logical function. The basic idea is that when two neurons are excited or inhibited at the same time, the connection strength between them increases. It is mathematically expressed as follows:

$$\begin{cases} \sum_{k=1}^{a} x_i^{(k)} x_j^{(k)}, & i \neq j, \\ 0, & i = j. \end{cases} \tag{2}$$

The meaning of this learning rule is that the adjustment of the connection weight is proportional to the product of the activity states of the two neurons, and the connection weight is symmetric. The connection weight of a neuron to itself is zero, which is still used in various neural network models.

A typical single artificial neuron model is shown in Figure 3.

The neuron input-output relationship is as follows:

$$\begin{aligned} y_j &= f\left(\sum_{i=1}^{a} w_{ji} x_i - \theta_j\right) \\ &= f\left(\sum_{a=1}^{a} w_{ji} x_i\right), \\ \mathrm{inx}_0 &= \theta_j, \\ w_0 &= -1. \end{aligned} \tag{3}$$

In the formula, the threshold is θ_j, the link weight coefficient is w_{ji}, and f(·) is the output transformation function, also known as the excitation function and the transfer function.

The more commonly used transfer functions are as follows:

(1) *Symbol Function*. As shown in Figure 4(a),

$$y = f(\varphi) = \begin{cases} 1, & \varphi \geq 0, \\ 0, & \varphi < 0. \end{cases} \tag{4}$$

(2) *Piecewise Linear Function*. As shown in Figure 4(b),

$$y = f(\varphi) = \begin{cases} 1, & \varphi \geq \alpha, \\ \vartheta, & 0 \leq \varphi < \alpha, \\ 0, & \varphi < 0. \end{cases} \tag{5}$$

(3) *Sigmoid Function*. As shown in Figure 4(c),

$$f(\varphi) = \frac{1}{1 + e^{-\varphi}}. \tag{6}$$

(4) *Hyperbolic Tangent Function*. As shown in Figure 4(d),

$$f(\varphi) = \frac{1 - e^{-\varphi}}{1 + e^{-\varphi}}. \tag{7}$$

Commonly used neural network learning algorithms are as follows:

(1) Error Correction Learning. $y_k(t)$ is the actual output of neuron k at time t when $x_k(t)$ is input, and $y_{k\,d}(t)$ is the expected output, and then the error signal is as follows:

$$e_k(t) = y_{k\,d}(t) - y_k(t). \tag{8}$$

The ultimate goal of error correction learning is to minimize a specific objective function $e_k(t)$, so that the actual output of each output unit on the network approximates the expected output in a statistical sense. The most commonly used objective functions are as follows:

$$\lambda(t) = \frac{1}{2} \sum_k e_k^2(t). \tag{9}$$

Calculate the minimum value of λ(t) for the weight w as follows:

$$\Delta w_{kj} = \sigma e_k(t) x_j(t). \tag{10}$$

In the formula, the learning step size is σ.

(2) Hebb Learning. "When neurons at both ends of a synapse are activated (activated and inhibited) at the same time, the strength of the connection should be strengthened, otherwise it should be weakened" is a summary of Hebb's learning rule. The mathematical expression is as follows:

$$\Delta w_{kj}(t) = F\big(y_k(t), x_j(t)\big). \tag{11}$$

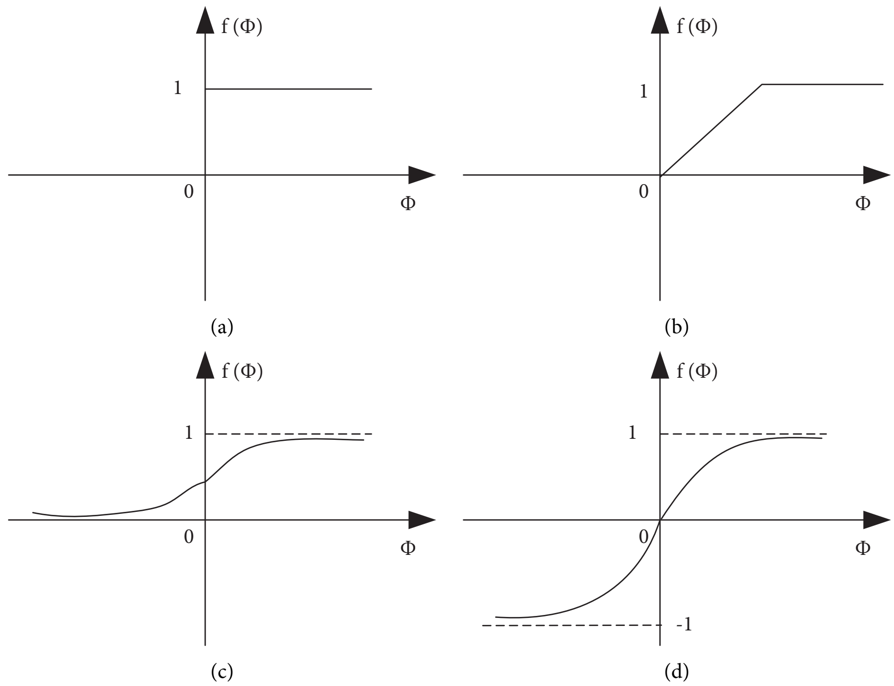

Figure 4: Neuron state transition function.

Among them, the states of neurons at both ends of w_{kj} are $y_k(t)$ and $x_k(t)$, and the most common cases are as follows:

$$\Delta w_{kj} = \sigma y_k(t) x_j(t). \tag{12}$$

Since Δw_{kj} is proportional to the correlation between $y_k(t)$ and $x_j(t)$, it is sometimes called the correlation learning rule.

(3) Competitive Learning. In the competitive learning process, each network output unit competes with each other and finally only one strongest unit is activated, as shown in Figure 5. The most common case is inhibitory lateral phase connections between output neurons. So, in the initial output unit, if one unit is stronger, it will win and overwhelm the others, and in the end, only this stronger unit will be active.

The most commonly used competitive learning rules can be written as follows:

$$\Delta w_{kj} = \begin{cases} \sigma\left(x_i - w_{ji}\right), & \text{Ifneuron}\, j\,\text{competestowin}, \\ 0, & \text{Ifneuron}\, j\,\text{failstocompete}. \end{cases} \tag{13}$$

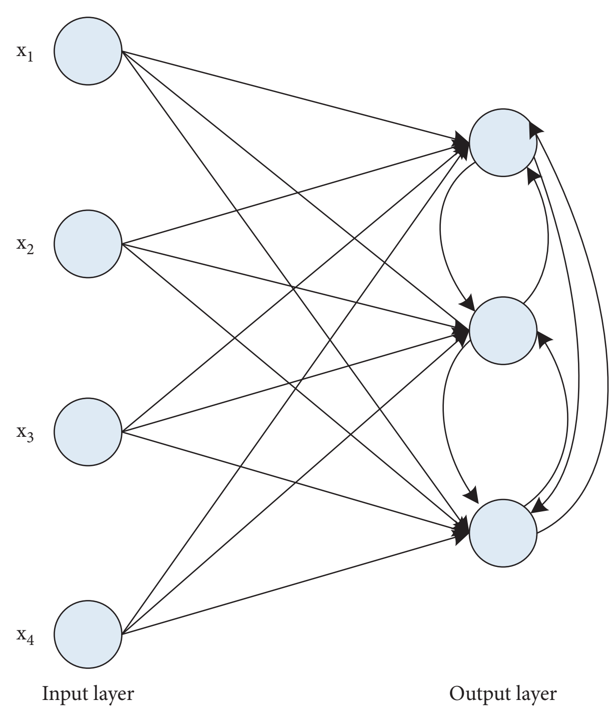

Figure 5: Competitive learning network with lateral inhibitory connections.

3.2.2. Genetic Algorithm. Genetic algorithm is an optimization method that simulates natural selection and genetic mechanisms, simulating the phenomena of reproduction, hybridization, and mutation in natural selection and natural genetic processes. When solving a problem using a genetic algorithm, each possible solution to the problem is encoded as a "chromosome," that is, an individual and thousands of individuals form a group (all possible solutions). At the beginning of a genetic algorithm, some individuals (i.e., initial solutions) are always randomly generated. Each individual is evaluated against a predetermined objective function, which gives a fitness value. Based on this fitness value, it selects individuals to replicate in the next generation. The selection operation embodies the principle of "survival of the fittest," where "good" individuals are selected for replication and "bad" individuals are eliminated. Then, the selected individuals are recombined through crossover and mutation operators to generate a new generation. Because this group of new individuals inherits some excellent characters of the previous generation, their performance is better than that of the previous generation, which gradually evolves towards a better solution. Therefore, the genetic algorithm can be regarded as a process of gradual evolution of a group composed of feasible solutions. The basic process of the genetic algorithm is shown in Figure 6.

The execution process of the genetic algorithm contains many random operations, so it is necessary to analyze its mathematical mechanism. A schema is a collection of strings that take the same characters at certain positions. Extract the following symbols as follows:

P: a certain mode

f_i: fitness of the i-th string (solution)

$\overline{f}(t)$: the average fitness of the t-th generation population

$\overline{f}(P,t)$: the average fitness of pattern P in the t-th generation population

$n_i(P,t+1)$: the expected value of the number of offspring produced by the solution i of the P mode of the t generation in the $t+1$ generation

$n(P,t)$: the number of solutions belonging to pattern P in the t-th generation

$\varphi(P)$: the definition distance of P

$O(P)$: the order of P

Consider first the outcome of the selection. In the standard genetic algorithm, the selection criteria are based on the principle of proportionality; therefore, through the action of the ith selector, the expected value of the number of people who will continue to exist in the next generation is $n(f_i/\sum f)$ and then

$$\overline{f}(P,t)=\frac{1}{n(P,t)}\sum f_i. \tag{14}$$

Then,

$$n(P,t+1)=n(P,t)\cdot\overline{f}\,\frac{(P,t)}{f(t)}. \tag{15}$$

The formula shows that the role of the selection operator will increase (decrease) the ability of a pattern that is above (below) average in its applicability across generations, improving quality.

This plan can obviously be maintained in the next generation if there is no intersection or if the intersection point is beyond the character positions specified on the left and right ends of Figure 6. Therefore, the probability R_s that the P mode will continue to exist in the next generation should satisfy

$$R_s\geq 1-R_c\cdot\frac{\varphi(P)}{(L-1)}. \tag{16}$$

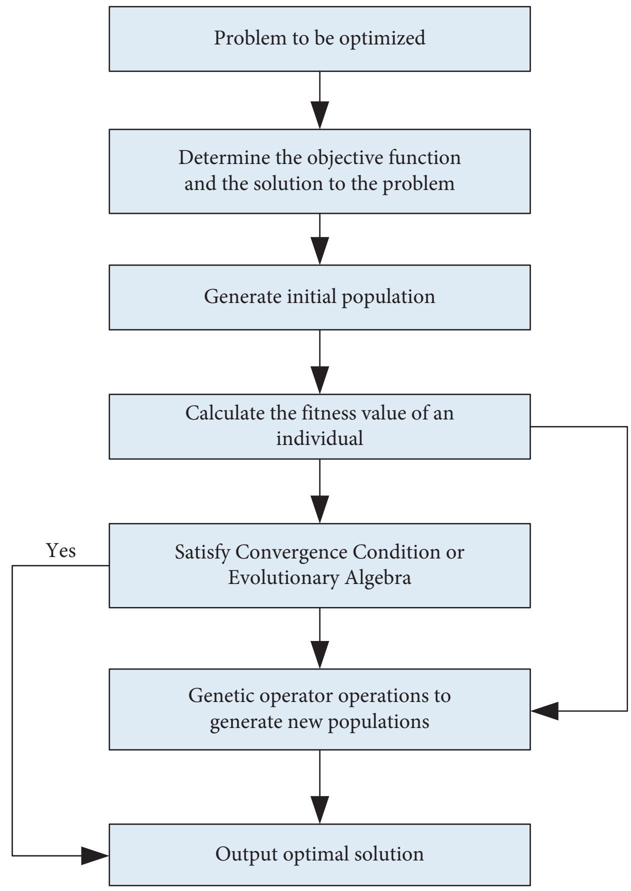

Figure 6: Basic flow chart of the simple genetic algorithm.

Taking into account the effects of selection and crossover, there are

$$n(P,t+1)\geq n(P,t)\cdot\overline{f}(P,t)\cdot\left[1-R_c\cdot\frac{\varphi(P)}{(L-1)/\overline{f}(t)}\right. \tag{17}$$

Finally, because R_m represents the probability of the mutation operator acting, the constant probability is $1-R_m$.

$$\left(1-R_m\right)^{O(P)}\approx 1-R_m\cdot O(P). \tag{18}$$

The probability of unreserved is about $O(P)\cdot R_m$. Therefore, considering the functions of selection, crossover, and mutation operators, we end up with

$$n(P,t+1)\geq n(P,t)\cdot\overline{f}(P,t)\cdot\frac{\left[1-R_c\cdot\varphi(P)/L-1\cdot R_m\right]}{\overline{f}(t)}. \tag{19}$$

This result is the so-called model theorem. If only the influence of the selection operator is considered, the amount of solution contained in the standard solution increases or decreases with the passage of generations, which is related to the average suitability of the standard solution. Specifically, if $\overline{f}(P,t)=f(t)(1+c)$, $c>0$ is a constant and then

$$n(P,t)=n(P,t-1)(1+c)=n(P,O)(1+c)^t. \tag{20}$$

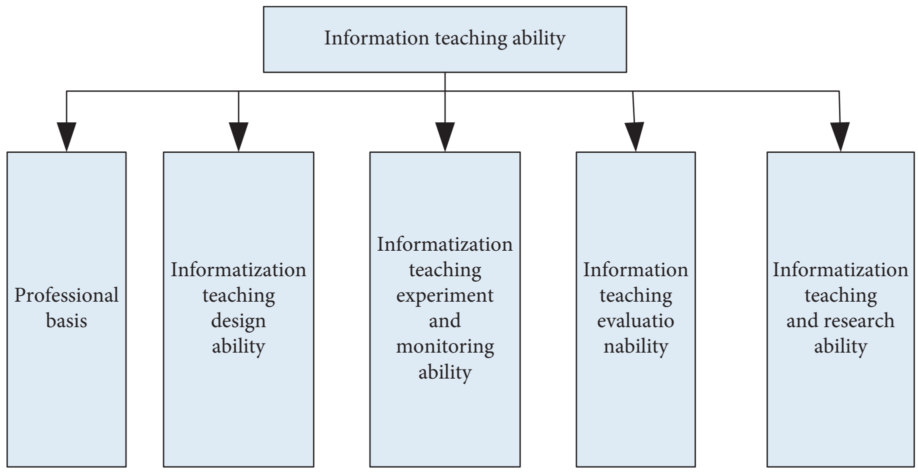

Figure 7: Theoretical framework of the first-level index of informatization teaching ability.

That is, functions with high average fitness grow exponentially in their ability to compete with other functions. However, high average conditions alone are not enough to guarantee high growth rates. When considering other impacts in detail, the definition of an operating model that requires good quality should be smaller in length and shorter in scope. High average suitability modes, low resolutions, and low order distances enable exponential growth in the number of solutions contained in generation after generation of group transmissions, which is the essence of the model theorem [15].

3.3. Information-Based Teaching Ability. "Competence" is the subjective condition that people need to solve problems, complete specific tasks, and be competent. Informatization teaching ability refers to the ability of teachers to rationalize and optimize the teaching process under the condition of providing sufficient information to use information technology and information resources. It is a reflection of the comprehensive quality of teachers combining various technologies and resources to carry out practical teaching. It is a composite of various abilities that teachers have in the integration of information technology and curriculum, and it points to the level of teaching practice, the application of technology, and the ability to integrate [16, 17].

In this study, the training object of information-based teaching ability is normal students. In view of the fact that normal students are in the survival stage of teachers' professional development, they mainly focus on whether they can stand on the podium and how to complete a class but do not really pay attention to students. In addition, the main task of normal students is to learn the theoretical knowledge related to the professional development of teachers and to imitate the theoretical knowledge learned into practice; in this process, there are fewer opportunities to actually contact students. During the four-year study process, the normal students in most normal colleges and universities in China are limited by various conditions, and the contact time with students ranges from 2 to 4 months.

The research on information-based teaching ability emerges along with the research on teachers' ability, which is the product of the information age. Awareness of technology integration, subject teaching methods, and knowledge are important ways to improve teachers' information teaching ability and teaching ability. Teachers' computer skills are the ability to implement TPACK. In other words, teachers' informatization teaching ability is their ability to integrate technology, classroom pedagogy, and subject content knowledge. Figure 7 shows the content related to the first-level indicators of information-based teaching ability.

Informatization teaching ability and educational technology ability are included, and the relationship between information literacy and information technology ability is a cross relationship, with the same part and different parts [18]. The relationship between the four is shown in Figure 8.

4. Experiment and Analysis on the Evaluation Model of Normal Students' Informatization Teaching Ability

4.1. Investigation and Analysis of TPACK Level of English Normal Students. The scale is a common tool for measuring the level of TPACK. In order to ensure the scientificity and validity of the scale, the accuracy of the data, and the objectivity of the results, the questionnaire was tested in this study. The test subjects were English normal students from normal universities, a total of 100 people, and 100 questionnaires were distributed, all of which were valid questionnaires.

The questionnaire is divided into two parts, one part is the TPACK level survey scale for normal students and the other part includes 7 basic information questions and 2 open-ended questions. In order to test the scientificity and accuracy of the questionnaire design, the author uses SPSS19 software to test the reliability and validity of the scale, so as to make the questionnaire more reasonable and effective. Reliability refers to the stability, reliability, and consistency of the results presented by the measurement tools. The higher the reliability is, the more stable and reliable the

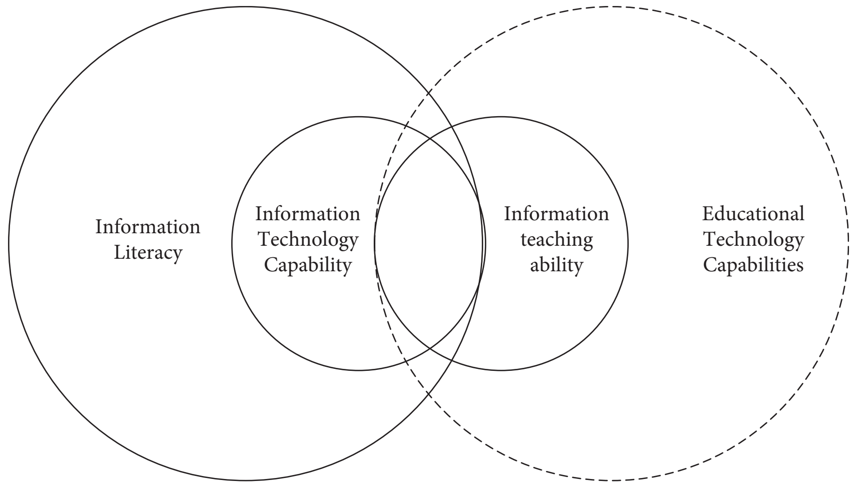

Figure 8: The relationship between information teaching ability and related concepts.

Table 1: Questionnaire reliability analysis table.

Dimension	Number of items	Cronbach's alpha coefficient	Cronbach's alpha coefficients based on standardized terms
PK	7	0.89	0.89
CK	4	0.81	0.81
TK	8	0.81	0.81
TPK	6	0.88	0.88
PCK	5	0.72	0.72
TCK	4	0.81	0.82
TPACK	6	0.88	0.88
Overall	40	0.95	0.95

Table 2: KMO and Bartlett sphericity test.

Kaiser–Meyer–Olkin measure of sampling adequacy		0.819
	Sig.	0.000
Bartlett's sphericity test	Approximate chi-square	1633.041
	df	526

measurement results are. If the a coefficient of the questionnaire is between [0.7, 0.8], it means that the reliability of the questionnaire is high, and the a coefficient between [0.8~0.9) means that the reliability of the questionnaire is very high. A coefficient above 0.9 indicates that the reliability of the entire questionnaire is very high.

The internal consistency of each part of the TPACK scale was tested by Cronbach's alpha using SPSS19 software, and the results are shown in Table 1.

It can be seen from the reliability analysis of the questionnaire in Table 1 that, in each dimension of the scale, except for the PCK dimension, the reliability of the remaining dimensions is above 0.8. It can be seen that the internal consistency of the scale is relatively satisfactory, and the overall reliability is high, which can be used for research.

Validity testing usually includes two parts, content validity and construct validity, which are tested after many discussions and revisions. Therefore, it ensures the scientific nature of the questionnaire content validity test to a certain extent. In the structural validity test of the scale, factor analysis is usually used to verify it according to the KMO decision criteria. The value of KMO is between 0 and 1. The larger the KMO value, the more common factors among the variables in the questionnaire and the more suitable for factor analysis. When the KMO is less than 0.5, it means that it is not suitable for factor analysis, and when the KMO is greater than 0.8, it means that the quantity is expressed to a good degree [19].

The construct validity of the TPACK scale was tested using SPSS19 software, and the results are shown in Tables 2 and 3.

It can be seen from the reliability analysis of the questionnaire in Table 2 that the KMO values of each category of the scale are all above 0.70. The overall KMO was 0.819, which was greater than 0.8 in the Kaiser decision criterion, the chi-square value of Bartlett's sphericity test was 1633.041, the degree of freedom P was 528, and the Sig. was 0.000, reaching a significant level ($P < 0.05$). Based on the data analysis [20], the scale has common factors in the overall correlation table. According to its construct validity analysis, the correlation factors among different dimensions of the questionnaire and the correlation between dimensions, the coefficients reached a significant level, indicating that the scale has high construct validity. Overall, the TPACK

TPACK	0.678	0.539**	0.534**	0.789**	0.677**	0.721**	1	
Overall	0.720**	0.768**	0.732**	0.880**	0.824**	0.821**	0.884**	1

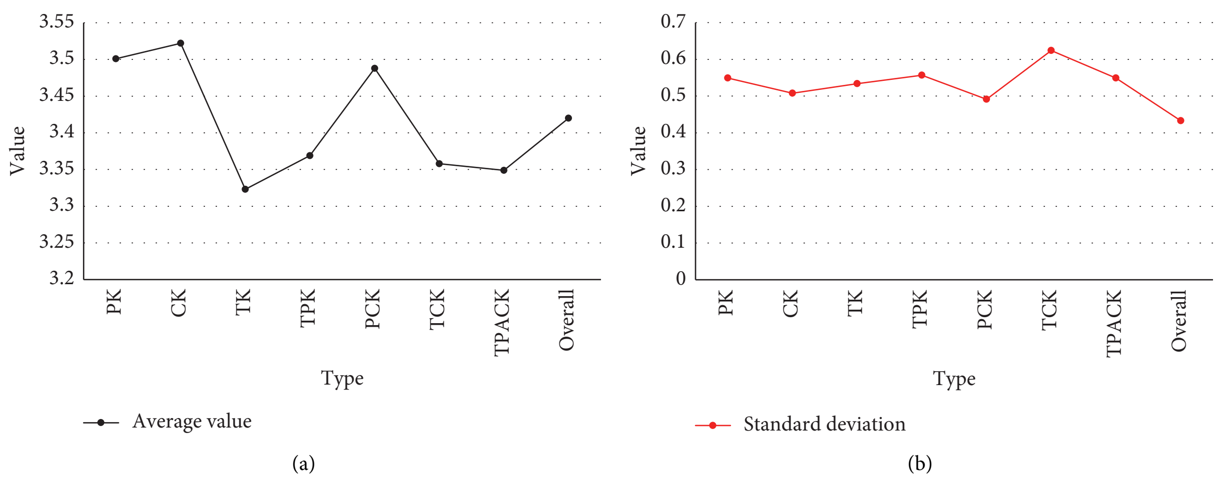

Figure 9: Descriptive analysis of each dimension of TPACK.

Normal Student Research Scale has high reliability and validity.

In order to investigate the overall level of TPACK of normal students, English normal students from normal universities were selected as the research objects. In order to reflect the overall situation of TPACK, this paper selects a total of 100 normal students in different stages from freshman to junior year and distributes 100 questionnaires, all of which are valid questionnaires. In order to understand the overall level of TPACK of normal students, this paper uses SPSS19 software to analyze the mean and standard deviation of the survey results by dimension, as shown in Figure 9.

It can be seen from Figure 9 that the average value of each TPACK dimension of normal students is $M = 3.420$, which is between "average" and "good," which is a medium level. Second, there are differences between the dimensions of TPACK for normal students. The seven dimensions present different levels, and they are sorted to obtain TK < TPACK < TCK < TPK < PCK < PK < CK. The highest among the seven dimensions is knowledge of course content, with an average CK of 3.522, indicating that normal students have higher knowledge of subject content than other dimensions. The average values of the three dimensions of PCK's subject pedagogy knowledge, PK's pedagogical knowledge, and CK's subject content knowledge are also higher. It shows that normal students have high self-confidence in subject content knowledge and pedagogical knowledge.

4.2. Scenario Application Ability of Informatization Teaching. According to the research results of the TPACK structure model and the specific meaning of the indicators for evaluating information teaching ability, Figure 10 shows the structure model of the evaluation index of normal students' informatization teaching ability.

In terms of the quantitative relationship between the evaluation indicators of informatization teaching ability, the path coefficients in the model are $\rho 1 \sim \rho 6$. They represent the influence weights of the three second-level indicators of the basic ability of informatization teaching on the three second-level indicators of the integration and application ability of informatization teaching. Among them, $\rho 1$ and $\rho 2$ are the influence weights of technology-related capabilities on the ability to integrate technology and teaching and the ability to integrate technology and subject content, respectively. $\rho 3$ and $\rho 4$ are the influence weights of teaching-related ability on integration of technology and teaching ability and subject teaching ability, respectively. $\rho 5$ and $\rho 6$ are the influence weights of subject-related ability on subject teaching ability and ability to integrate technology and subject content, respectively. The path coefficients $\rho 7 \sim \rho 9$, respectively, represent the influence weights of the three secondary indicators of the integrated application ability of informatization teaching on the situational application ability of informatization teaching. Among them, $\rho 7$ is the influence weight of integrating technology and teaching ability on the subject teaching ability integrating technology. $\rho 8$ is the influence

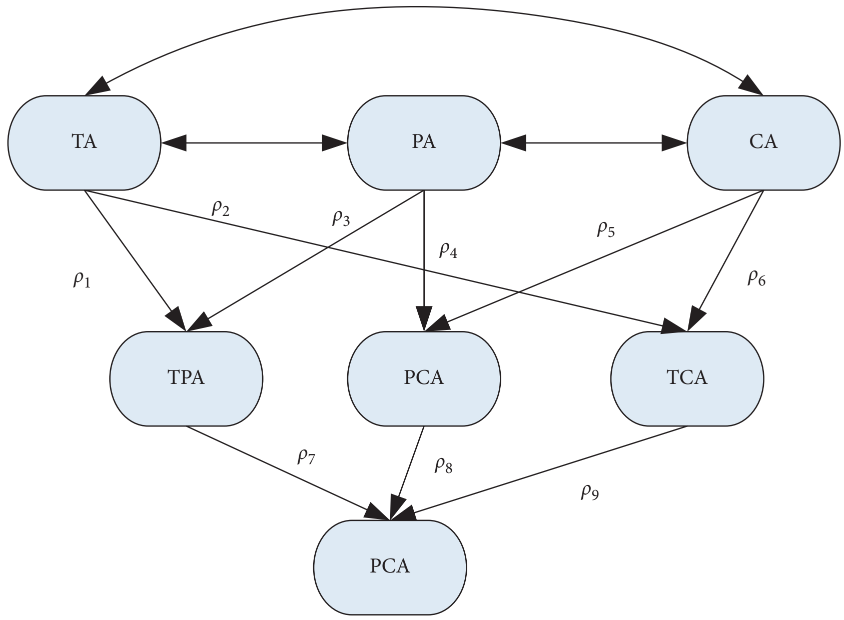

Figure 10: The structure model of the evaluation index of information teaching ability.

Table 4: Weights of evaluation indicators of information-based teaching ability.

First-level indicator	Index weight	Secondary indicators	Index weight
Basic ability of informatization teaching	$\rho_{TA} + \rho_{PA} + \rho_{CA}/\rho_{\mathrm{SUM}}$	TA PA CA	$\rho_{TA} = \rho_1 \times \rho_7 + \rho_2 \times \rho_9$ $\rho_{PA} = \rho_3 \times \rho_7 + \rho_4 \times \rho_8$ $\rho_{CA} = \rho_5 \times \rho_8 + \rho_6 \times \rho_9$
Informatization teaching integration application ability	$\rho_{TCA} + \rho_{PCA} + \rho_{TCA}/\rho_{\mathrm{SUM}}$	TPA PCA TCA	$\rho_{TPA} = \rho_7$ $\rho_{PCA} = \rho_8$ $\rho_{TCA} = \rho_9$
Informatization teaching situation application ability	$\rho_{\mathrm{TPCA}}/\rho_{\mathrm{SUM}}$	TPACK	$\rho_{\mathrm{TPCA}}/\rho_{\mathrm{SUM}} = 1.00$

weight of subject teaching ability on subject teaching ability integrating technology. $\rho 9$ is the influence weight of integrating technology and subject content ability on the subject teaching ability integrating technology.

Regarding the calculation of the weight, the ability to apply the IT teaching status has the most important influence on the teacher's informatization teaching ability. The weight of the secondary indicator integrated technology subject teaching ability is defined in 1.00. The weight should be calculated according to the index influence path coefficient reflected in the teaching ability rating index structure model. Based on this information, the influence path coefficient of this paper on the subject teaching ability of integrated technology is shown in Table 4.

4.3. Evaluation Model of Informatization Teaching Ability. In order to verify the validity of the teacher's structured information evaluation model and calculate the weight evaluation of each index, this study carried out an empirical research on the evaluation of information-based teaching ability. The seven subindicators should be measured proportionally, and the measurement data should be modeled through a path analysis model to determine the weight of each indicator. The empirical research results show that the actual measurement data are in good agreement with the structural model of the evaluation index of information teaching ability. This also shows that the model can more accurately evaluate the informatization teaching ability of normal students. According to the weight model of indicators at all levels, among the three first-level indicators, the ability to apply educational information context is crucial. The ability to integrate and apply information teaching is secondary, and the basic skills of informatics teaching are the least important. Among all secondary indicators, the target teaching ability index of integrated technology has the largest weight, the integrated technology and teaching ability index has the second weight, and the ability index related to subject teaching has the lowest weight. Figures 11 and 12 are the descriptive statistical analysis results of each index level and the overall level of informatization teaching ability.

After completing the three-year teacher training course, the general level of information teaching ability of normal students is relatively high. Among the three first-level indicators, the ability to implement the state of informatization teaching is the highest, the completion and application index of computer teaching is at the middle level, and the basic skills index of computer teaching [21] is at the middle level.

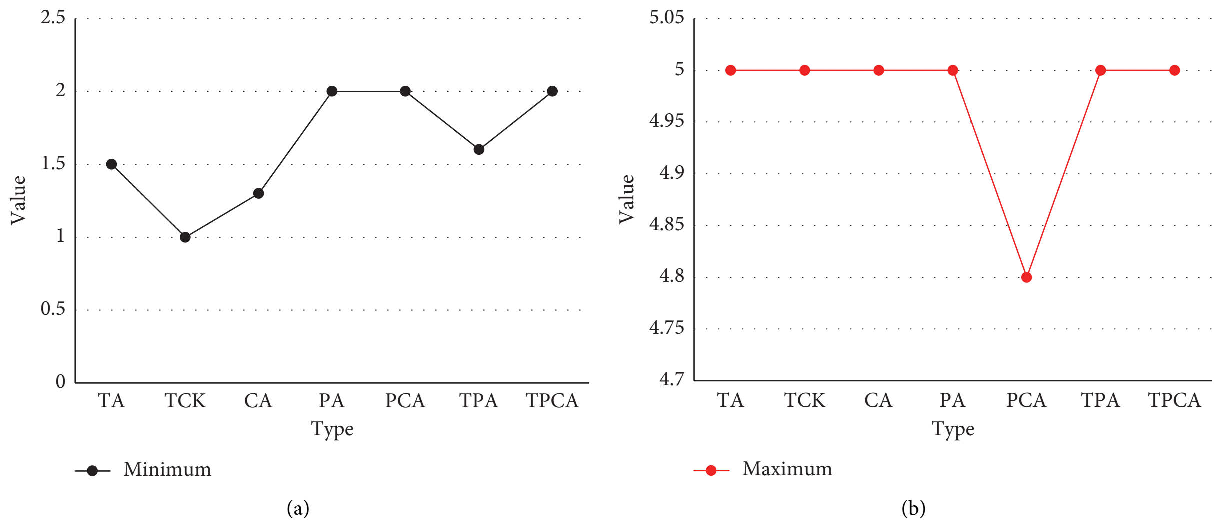

Figure 11: The minimum value and maximum value of the evaluation index of information teaching ability.

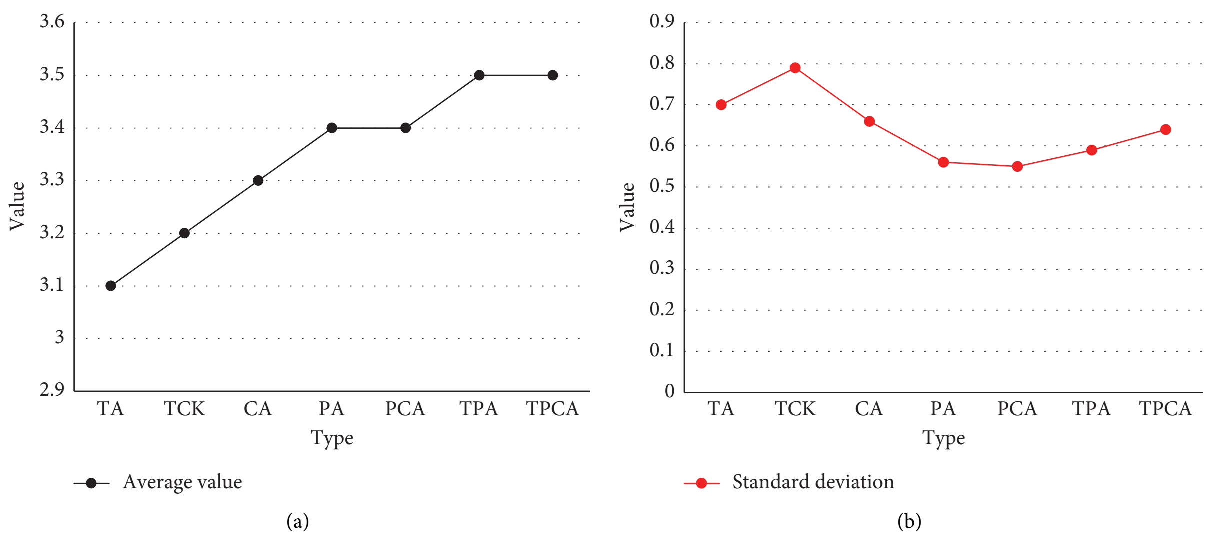

Figure 12: Mean and standard deviation of the evaluation indicators of information-based teaching ability.

Among the seven secondary evaluation indicators, the skill index related to technology is the lowest, and the skill index of teaching objects related to technology is the highest [22]. Among the three secondary indicators of ability to complete and implement computer-based instruction, the level of ability to integrate technology and subject content was lower than the other two indicators. Among the three secondary indexes of basic computer teaching ability, the level of technology-related ability indexes is lower than the other two indexes.

To sum up, normal students have high information teaching ability, which to a certain extent reflects that general education has achieved remarkable results in cultivating teachers' information teaching ability. The measurement results show that normal students have high teaching ability and can well integrate technology, teaching methods, and content to form good teaching decisions. Compared with teaching ability, normal students have relatively low technology-related abilities, and their ability to integrate technology and disciplinary content is poor. In the future, the proportion of courses related to technology integration in different subject courses should be increased to promote the comprehensive development of normal students' information teaching ability, thereby improving the level of educational development.

5. Discussion

First of all, through the study of relevant knowledge points of literature works, this paper initially masters the relevant basic knowledge and analyzes how to conduct research on the evaluation of the information-based teaching ability of medical-oriented English normal students based on the TPACK model and computational intelligence. This paper expounds TPACK and informatization teaching ability, focuses on the method of computational intelligence, and analyzes the evaluation of informatization teaching ability based on TPACK and computational intelligence through experiments. And this paper constructs the evaluation model of information teaching ability. This paper also focuses on artificial neural network and genetic algorithm, and artificial neural network is an artificial neural network created according to the physiological structure and information processing process of the brain, imitating human intelligence. The genetic algorithm is more suitable for large scale, large population, complex environment, and unclear problem structure [23, 24].

Through experimental analysis, this paper shows that normal students have high informatization information teaching ability and teaching ability and can well integrate technology, teaching methods, and content to form good teaching decisions. Compared with teaching ability, normal students have lower skill levels and lower performance in integrating technology and teaching content.

6. Conclusion

Computer science is an inevitable trend of future development, and computer science teaching is an important part of future education development. The final foothold of the evaluation index system of teachers' informatization teaching ability is still practice. This research also hopes to update the teaching concept ideologically and improve teachers' understanding of the development of information-based teaching. Teachers should actively use multimedia technology to assist teaching, optimize the teaching process, fundamentally change the traditional teaching structure and teaching methods, and achieve the goal of quality education in the new era. Although the traditional exam-oriented education is strong, the development of science and technology is rapid. With the popularization of computer teaching methods, teachers' computer teaching ability has been continuously improved. With the implementation of the quality education policy, the overall quality of national education will surely rise to a higher level.

This study discovers a certain complementary relationship between different algorithms after conducting a comprehensive and in-depth analysis of proposal algorithms. This study proposes a big data music individualization proposal method based on big data analysis, which integrates user behaviour, behaviour context, user information, and music work information, based on traditional music proposal methods; improves the collaborative filtering proposal algorithm based on user behaviour; and calculates the semantic similarity between lyrics, as well as the song co-occurrence similarity based on the user's music download history. Because the lyrics represent the thoughts and feelings that the song wishes to convey to the listeners, the proposal module is completed, and the music proposal system is realized, by combining the two different similar information, using the improved algorithm and the Hadoop distributed framework. The music similarity and label similarity are combined to alleviate the problem of cold start and data sparseness, and a mixed similarity calculation formula is proposed to calculate the similarity between music. The accuracy similarity of the big data music proposal model proposed in this study is improved by about 20% through experimental comparison when compared with the collaborative filtering model and the hybrid model. It reflects the efficiency, scalability, and stability of the music proposal system as well as the ability to meet users' individual music needs.

1. Introduction

With the development of network technology, the music recommendation system has also developed rapidly, and online music platforms have become the first choice for people to listen to music. However, the music recommendation system also faces some problems, such as data storage confusion, low computational efficiency, cold start, and data sparsity caused by the large scale of data [1]. Aiming at the above problems, this study designs and implements a music recommendation system. Firstly, two channels of offline data transmission and real-time data transmission are designed to collect and transmit data. A music data warehouse is built to process and store the data in layers. Then the data are preprocessed to facilitate the calculation of the recommendation model [2]. Secondly, based on the improved algorithm, combined with the Hadoop distributed framework, the proposal module is completed, and the music proposal system is realized. Finally, after the functional test and nonfunctional test, it reflects the efficiency, scalability, and stability of the music recommendation system, which can meet the individualization music needs of users.

The core algorithm of the personalized music recommendation system developed in this article is the semantic-enhanced big data technology. Experiments show that when recommending unpopular music, the big data recommendation algorithm proposed in this article is more effective than pure content-based and collaboration-based recommendation methods. In order to meet the needs of the current huge user group to recommend massive music, the current mainstream big data distributed computing platform is used in the development of this system. Through a comprehensive and in-depth analysis of the two types of recommendation algorithms, it is found that there is a certain complementary relationship between the two types of algorithms. Therefore, this study proposes a semantic-enhanced big data technology [3] that combines content-based recommendation algorithms and collaborative filtering recommendation algorithms. The algorithm first analyzes the semantic information implied in the lyrics and calculates the semantic similarity between song lyrics, and then calculates the co-occurrence similarity of songs based on the user's music download history. Because the lyrics represent the thoughts and feelings that a song wants to convey to the listeners, this recommendation algorithm can improve the shortcomings of big data technology by combining these two different similar information [4]. The research object of this study is lyric songs. In the following, music and song refer to a song with lyrics.

Through the mapping relationship between interest degree and time, the algorithm introduces the influence of time decay factor when calculating the item rating matrix through historical behaviour, so as to obtain a more accurate recommendation result [5]. In the face of the cold start problem, a hybrid recommendation mode based on tags and collaborative filtering is adopted. When the system is first deployed and the number of users and rating items is less than a certain threshold, the songs are matched by the initial preference tag when the user registers, whereas when the number of users is sufficient, the improved collaborative filtering algorithm is used for music recommendation. The user's operations are monitored and recorded in real time, and the user's personalized recommendation list will be updated accordingly. The system should be developed by investigating the needs of users, referring to the current excellent music recommendation system, designing each functional module of the system, developing a good user interface, and aiming to design an accurate and easy-to-use system of personalized music recommendation [6].

The innovation of this study are as follows: the proposal algorithm combined with user behaviour analysis realizes the proposal according to a series of user behaviour records. The model, according to the complexity and diversity of user interests, learns the influence of different attributes on user interests.

The rest of the article is organized as follows: Section 2 introduces related big data technology concepts. Section 3 applies big data technology to the individualization music model. Section 4 applies big data technology [7] to the individualization music model. Based on the proposed big data proposal model, collaborative filtering model, and hybrid model, the section makes recommendations. Section 5 summarizes the entire article.

2. Related Works

Common recommendation methods have a number of flaws, including the inability to improve recommendation effects, migrate with changes in users' hobbies, mine users' potential hobbies, and make accurate recommendations based on users' hobbies. However, with the rapid development of big data and artificial intelligence [7, 8], traditional recommendation methods can now be improved. To meet users' daily needs, we can combine the benefits and drawbacks of traditional recommendation methods with new elements, as well as learn from each other. As a result of the new circumstance, the music recommendation system should also keep up with the pace of change. It is critical at this time to design and implement a comprehensive music recommendation system that is both accurate and easy to use. It is critical to create a music recommendation system that provides a better user experience.

Wang et al. implemented a user-based collaborative filtering algorithm on the cloud computing platform Hadoop, which solved the scalability problem of the collaborative filtering algorithm [9]. Yuqiao et al. used a collaborative filtering proposal algorithm to use user preference data to predict products that new users may like [10]. Hu et al. introduced matrix factorization techniques applied in recommendation systems and analyzed the impact of each matrix factorization technique on recommendation systems [11]. Tong et al. studied a hybrid proposal algorithm based on collaborative filtering and used the dimensionality reduction method of singular value decomposition to find the most similar items and users in item clusters and user clusters, which effectively improved collaboration [12]. Zhang et al. proposed a collaborative filtering proposal algorithm based on the social network. Based on the traditional matrix factorization model, the user preferences of social networks were integrated to obtain a trust feature matrix, which reduced the impact of data sparsity [13]. Liang et al. proposed a new deep learning model to utilize image content for content proposal in social networks. W. Cai et al. [7] applied the k-means clustering algorithm to a traditional content-based proposal and proposed a new proposal algorithm [14]. Chen et al. proposed the field of music proposal. The previous collaborative proposal can no longer meet the requirements of the audience. The essence of music proposal has become the proposal of listening experience. The article describes the solutions to the current music proposal problem in academia and industry: playlist generation, contextual proposal, and music production proposal [15]. Huang et al. proposed research on the robustness of recommender systems, including classifying the types of proposal model attacks, computing the impact of research attacks, and recommending replacement plans [16]. Jiang et al. reviewed and summarized the principles and challenges of recommender systems used in online music and looked forward to some future techniques that might be used to improve music proposal results [17]. Zhang et al. believed that traditional proposal systems try to help users find related items, but this is not enough. Proposals need to give more appropriate results based on the time and location of the user at that time, that is, considering the scene recommended [18]. Bauer and Schedl first extracted acoustic features from the audio inquiries and used the content-based collaborative filtering proposal method to complete music proposal. Domestic scholars' research on music individualization proposal has also formed a series of scientific research results [19]. Su et al. used spectrogram analysis to obtain the characteristic data matrix of musical works and calculated the similarity between stored music and query data to achieve Top-N proposal [20]. Zhang et al. studied the multi-domain recommender systems, because traditional recommender systems only consider items in the same field, while cross-field recommender systems support operations on items in different fields, making the recommender system more accurate [21]. Feng used the method of bibliographical analysis to complete the proposal algorithm from different perspectives by using differential strategies and analyzed various descriptions of music-related documents to obtain its regularity to complete the proposal [22].

In this era of excess data, there are various connections between data, and it is obviously unrealistic to rely on humans to distinguish. However, with the rise of big data technology, various tools for data processing have made it possible for us to discover the internal connection of data. This is a significant breakthrough by mining potential connections between data and serving recommender systems. Data can be analyzed from multiple perspectives, such as user behaviour context, scene atmosphere, time perception, etc., to improve the accuracy of the proposal system from multiple perspectives.

3. Concepts Related to Individualization Proposal Technology Based on Big Data Analysis Technology

Data acquisition is the basic premise of processing. With the rapid development of the Internet, Internet of Things, and cloud computing, they have become important channels for obtaining data. Especially with the rapid development of smart mobile terminals, a large amount of data is generated every day, among which mobile phones and mobile terminals are representative.

The main functions of data integration are data extraction, cleaning, and storage. The data collected during the data acquisition stage are typically large in scale and diverse in nature. Data extraction's main goal is to convert complex data types into unified or easy-to-understand data structures. The amount of data collected is usually large, but the amount of valid data is not. Many of the data may be of little or no use in specific application scenarios, and even more data may contain incorrect information. Data cleaning ensures data quality, while data storage serves as a platform for data processing. The core of the processing process and the process of extracting useful information from big data is data analysis. The only way to get useful information is to use the right method. After the user's historical data, such as search terms, have been used, it is saved in the database and never used again. Big data typically contain some basic data, and valuable information can be mined by expanding these data. Parts of the data have less value than the overall value, so different data sets are reorganized for analysis to achieve a relatively high total value. Sometimes useful information can be found in error data, such as spell-checking during searches. The Internet can be used to obtain very public data, and the majority of them are obtained by advanced enterprises and research institutions both at home and abroad. These open data can be used by researchers to conduct research and create more value. The user is presented with the processed results during data interpretation. In contrast to data analysis, which requires professional knowledge, the results of data processing are displayed to ordinary users who do not necessarily understand the technology of data analysis. As a result, how to clearly display the results to ordinary users is a critical issue, which is usually accomplished through the use of graphics, charts, or tabular methods.

As shown in Figure 1, user 1 purchases three items A, B, and D, and user 3 purchases items B and D. By analyzing the purchase behaviour of users, it can be found that the similarity between user 1 and user 3 is relatively high. Among them, user 1 has purchased item A, so it can be inferred that user 3 is very inclined to purchase item A, so it is recommended to user 3.

The concept of big data technology has been deeply influenced at the interaction level. This chapter will combine the theory of interaction to expound the interaction in music. Audience research has become an increasingly important part of social media research. When the real interpersonal communication is more and more carried out in the virtual network, the social activities between people will also change more or less, which are shown in Figure 2.

The algorithm is divided into three steps: the first is item representation, in which we must extract the item's content features to represent the item; the second is song recommendation, in which we can use the song's tags as well as the singer's tag and other features; and the third is item recommendation, in which we must extract the item's content features to represent the item. We can use the user's historical behaviour to describe the user's item feature preference for feature learning. This type of preference can be expressed in music recommendations based on the user's song behaviour data. Finally, a recommendation sequence is generated, and through similarity comparison, a set of items with the highest similarity is generated for the user. Data on the user's online behaviour are collected and stored. User online behaviour refers to a user's new behaviour, such as listening to new songs, dancing to new songs, collecting albums, saving the data in the appropriate database, and classifying the information in the database. Users can sort their preferences, and they can check their listening records at any time. When a user contacts the system and registers as a new user, the user can display the music he likes and hide the music he does not like based on his personal preferences, and the user can change the information set by himself at any time. The music recommendation system can recommend songs that the user is interested in and prevent songs that the user does not like from appearing in his music playlist based on the user's music preference information.

4. Design of Music Proposal Model Based on Big Data Analysis

4.1. User Preferences Similarity Calculation Based on Big Data Analysis. The similarity formula is used at the heart of massive data technology to calculate project similarity, and

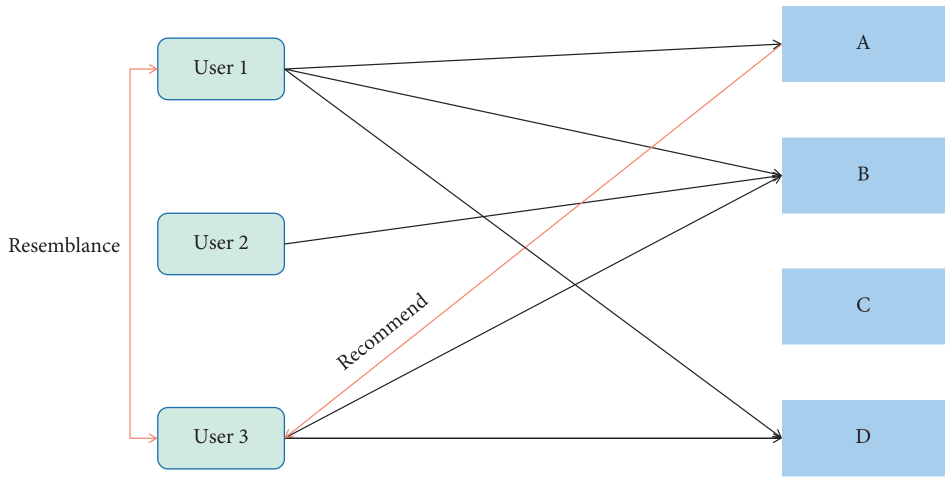

Figure 1: Proposal process based on big data technology.

the similarity that can be selected for different projects is also different. Massive data technology, in comparison to collaborative filtering and mixed model algorithms, can learn the influence weights of different attributes and the interaction between attributes on user interests. Big data technology, for example, can learn not only the impact of a single attribute on user interest, but also the impact of any combination of attributes. Using the example of user age, gender, and time, big data technology can determine the impact of these three attributes alone on user interest as well as the impact of any two or even three attributes combined on user interest. This is classic modelling. Algorithms are incapable of accomplishing this. This study takes into account the impact of modelling and the amount of computation, but only considers the impact of a single attribute and any two attributes on user interest.

The user information is represented as $X(x) = \{x1, x2, \ldots, xz, y\}$ after processing, where y is the user's preference value for the item expressed by this behaviour, and xi is the value of the i feature of the user's current behaviour. The method of big data technology is to use user data to pass learning to obtain a prediction function $f(x)$. It represents different interest models of users, and the calculation formula is as follows:

$$f(X) = w_0 + \sum_{i=1}^{n} w_i x_i + \sum_{i=1}^{n} \sum_{j=i+1}^{n} v_{ij} x_i x_j, \tag{1}$$

where w_0 is the global parameter deviation, x_i is the value of the i attribute of the user's current behaviour, the meaning of the $w_i x_i$ part is the contribution of the attribute x_i to the user's interest, and $v_{ij} w_i x_j$ represents the effect of the attributes x_i and x_j on the user's interest.

The data set is to learn the function $f(x)$ by using big data technology on the data in the data set. The purpose of the test set is to test the learning effect of the function $f(x)$. The following formula defines the loss function L of the big data technology:

$$L = \sum_{i=1}^{N} \operatorname{loss}(f(X), Y) = \sum_{i=1}^{N} (\hat{y}(x_i) - y_i)^2. \tag{2}$$

In the pursuit of minimizing the loss function, it is necessary to prevent the occurrence of overfitting. The regularization term in this article introduces the parameter vector formula (3), which is the calculation of the optimization problem of big data technology.

$$L = \arg\min \sum_{i=1}^{N} (\hat{y}(x_i) - y_i)^2. \tag{3}$$

The above formula represents all the model parameters of big data technology, that is, the specific influence weights of attributes on user interests. There are two related functions $g(x)$ and $h(x)$ for any parameter of $f(x)$, as shown in the following formula:

$$\hat{y}(x) = g(x) + h(x). \tag{4}$$

When $w_0 = 0$,

$$\hat{y}(X) = \sum_{i=1}^{n} w_i x_i + \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} \left(v_i^T v_j\right) x_i x_j + w_0. \tag{5}$$

When $w_0 = 1, 2, \ldots, n$, as shown in (5),

$$\hat{y}(x) = w_0 + \sum_{i=1}^{n} w_i x_i + \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} \left(\sum v_{ls} v_{js}\right) x_i x_j. \tag{6}$$

Only one parameter is optimized in each calculation process, and the iterations are performed round by round. Music can usually have a variety of tag information, which can be analyzed and described from different dimensions. The more tags, the better the representation of items. Each piece of music has a different label, and the more common labels between two pieces of music, the more similar they are. The calculation formula for defining the similarity of labels is as follows:

$$\mathrm{sim}_{tah(u,v)} = \frac{I_u \cap I_v}{I_u \cup I_v}. \tag{7}$$

The tag-based proposal algorithm can still recommend music in the absence of user ratings and alleviate the problem of cold start to a certain extent. Although the tag-

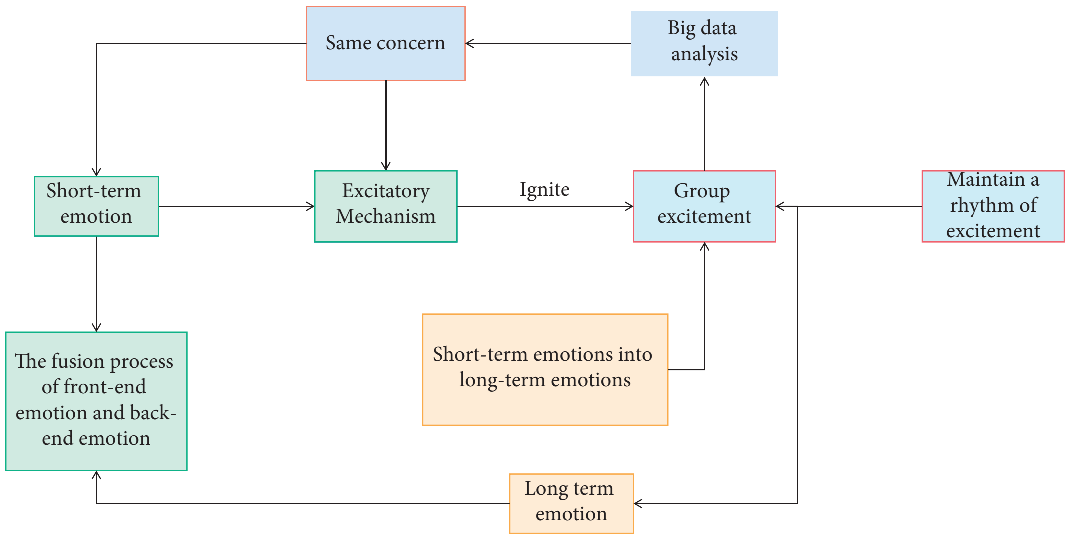

FIGURE 2: The interactive ritual chain linked to emotion in music.

based proposal algorithm does not require the user's score record, only the tag of the music itself is needed. Combining the tag-based proposal algorithm with other proposal algorithms can improve the proposal effect.

4.2. Music Score Clustering Algorithm. Each user has his own scale when scoring the music. For a very favorite item, conservative-type users rate lower than positive-type users. From a mathematical point of view, different users have different mean and variance of ratings. Therefore, in order to have a unified standard for user preferences, it is necessary to normalize user ratings. In the method based on the clustering algorithm, the principle is to subtract the average of the user's score from the user's score on the music, which is shown in the following formula:

$$h(r_{ui}) = r_{ui} - \overline{r}_u. \tag{8}$$

Bringing formula (8) into formula (9), we can get the predicted user u score for the new music i as

$$r_{ui} = \overline{r}_u + \frac{\sum_{v\in N_i(u)} w_{uv}\left(r_{vi} - \overline{r}_v\right)}{\sum_{v\in N_i(u)} \left|w_{uv}\right| \sum} \tag{9}$$

The special feature of big data technology is that normalization takes into account the variance of user ratings. For user-based methods, the definitions are shown in the following expression:

$$h(r_{ui}) = \frac{r_{ui} - \overline{r}_u}{\sigma_u}. \tag{10}$$

Bringing this formula into formula (9), the user's rating of the new music can be predicted, which is shown in the following formula:

$$\widehat{r}_{ui} = \overline{r}_u + \sigma_i \frac{\sum_{j\in N_i(i)} \left(w_{ij}\left(r_{vj} - \overline{r}_j\right)/\sigma_j\right)}{\sum_{j\in N_i(u)} \left|w_{uv}\right|}. \tag{11}$$

4.3. Individualization Proposal Model Based on Big Data Technology. The main component of the recommendation module is the recommendation model, which is the heart of the recommendation system. As a result, the user experience is directly related to a good recommendation model. After analyzing and summarizing a variety of common recommendation models, it was discovered that each model has distinct advantages and disadvantages in terms of generating an accurate user recommendation list. This system uses a hybrid recommendation system that relies heavily on the use of tags and collaborative filtering. When the number of users or the number of user-rated items is insufficient, a tag-based recommendation model is used. This is primarily used to address the collaborative filtering recommendation problem—problem with cold start. The improved collaborative filtering algorithm is enabled when the number of users and user rating items is sufficient. Time considerations are introduced into traditional collaborative filtering because users' interests may change over time. Figure 3 depicts the recommendation process for accurate recommendations.

The core idea behind the big data-based recommendation algorithm is to use audio features to describe a piece of audio data, and then use those features to calculate similarity with other audios. It analyses the feature information of the tracks, traverses the music database, and recommends tracks based on a user's listening time, number of clicks, collection, and download behaviour. The music recommendation system's data content primarily consists of user data, music data, and user-system interaction behaviour data. Basic information about the user is contained in user data. Music data contain various details about music and can be used to extract interesting features, making it an important data source for recommender systems. The user's interaction with music is included in user behaviour data, and the recommendation system can be used to mine the user's potential information. The purpose of data processing technology is to clean, process, and transform the system's data so that the algorithm layer can obtain clean and effective data, thereby

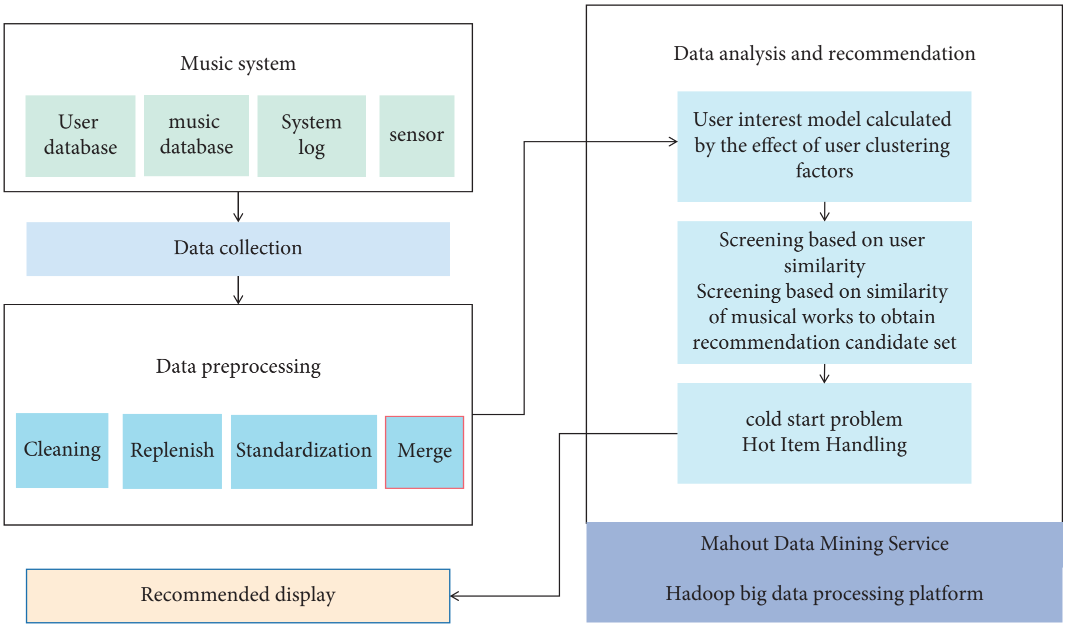

FIGURE 3: Big data music individualization proposal process.

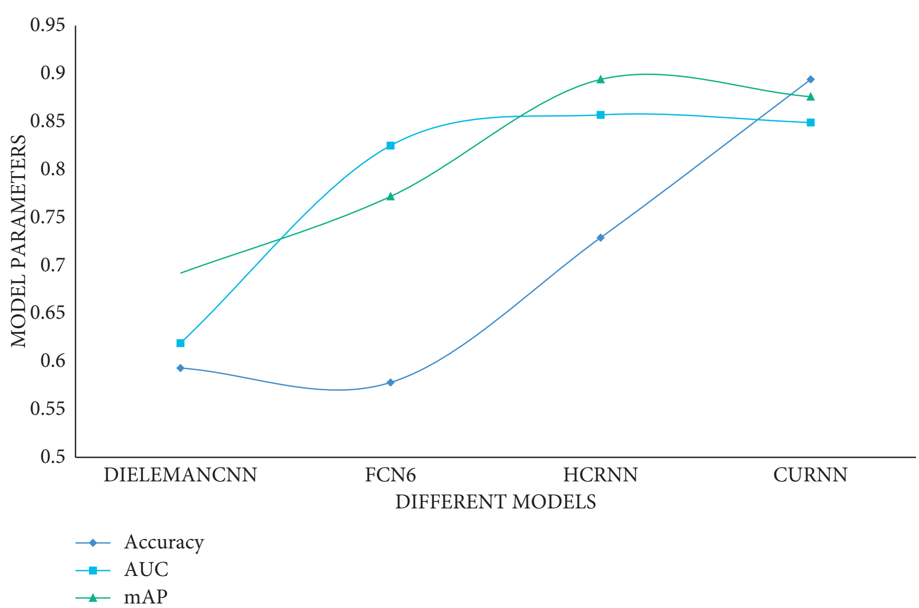

FIGURE 4: Comparison of different model experiments.

improving the recommendation system's performance. The validity of the behaviour data directly affects whether the recommendation result can meet the user's needs because the user's historical behaviour information reflects the user's preferences at different times. The background log information will record each user's behaviour, such as clicking on music, commenting on music, and sharing music, and the stored content format will be in the form of a dictionary. Finally, a data format that is beneficial to the calculation of the recommendation algorithm can be obtained after systematic processing. The information gathered will be processed. Missing data, data noise, and data duplication may occur during the data collection and transmission process, affecting subsequent model training and resulting in low model robustness. As a result, the information must be processed. There may be many data attributes when analyzing and processing data, but some are irrelevant and some are relevant, so it is necessary to select the most relevant features for processing to improve the model's robustness. The accuracy of a recommendation is insufficient. The diversity of recommendation results is critical with the growing number of Internet services and changing user needs. If users listen to ancient songs for a long time, for example, our recommendation list should include some variety based on personalization and precision, such as sad songs that are not very similar to ancient styles. The recommendation is

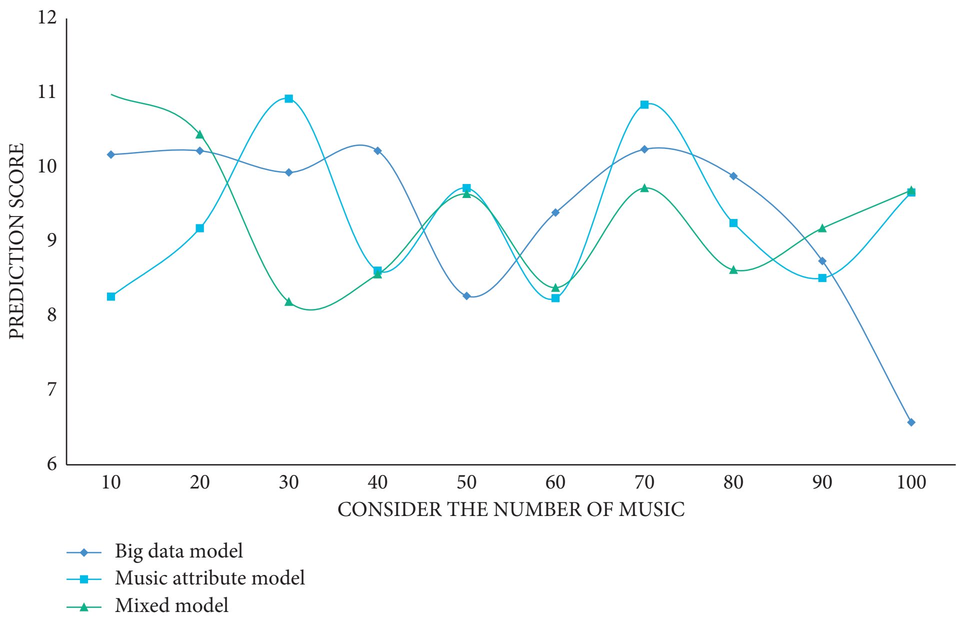

Figure 5: Comparison experiment of L value of different models.

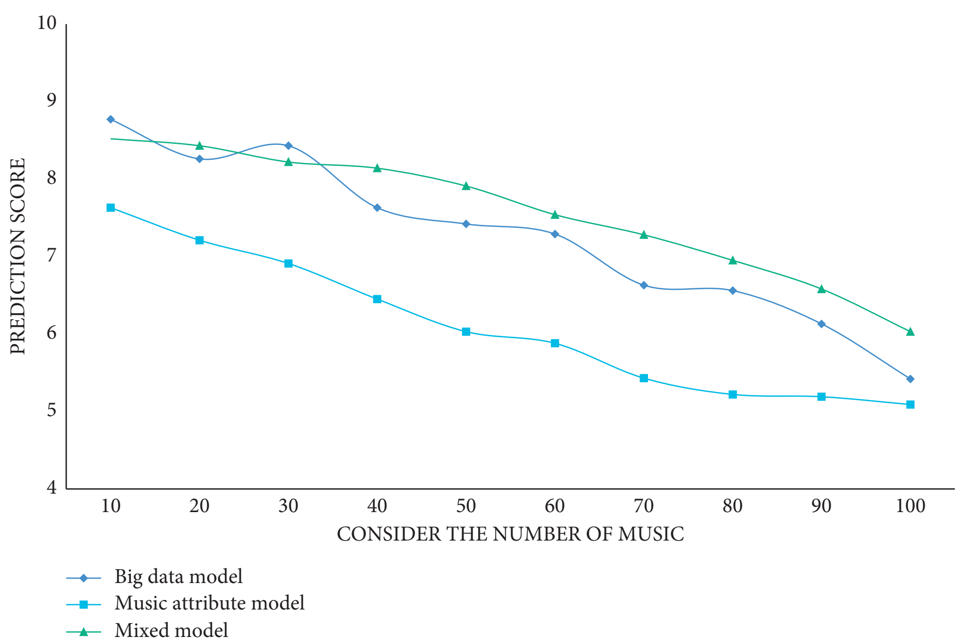

Figure 6: Comparison experiment of R value of different models.

successful if the user clicks. The recommendation results differ depending on each user's unique historical behaviour data. The system can update the recommendation in real time based on short-term data and long-term data, allowing the user to experience the system's personalization. The recommender system learns from the user's past behaviour and improves its personalization and accuracy over time.

The higher the big data recommendation model's evaluation value, the more interested in music the user is; the big data recommendation model is generated into the nearest neighbour set, which is the user's big data recommendation model set that is similar to the user's interest. Two user big data recommendation models are regarded as two vectors in the vector space using the method of vector space similarity calculation, and the similarity between them is measured by calculating the cosine value of the angle between the two vectors in the big data recommendation model. Finally, the big data recommendation model's recommendation set is generated. The user's evaluation value of the song is predicted based on the similarity between neighbour users and the user as well as the neighbour users' evaluation value of the song. Then, using the big data recommendation model, the first few songs with the highest ratings are measured, and the recommendation results are

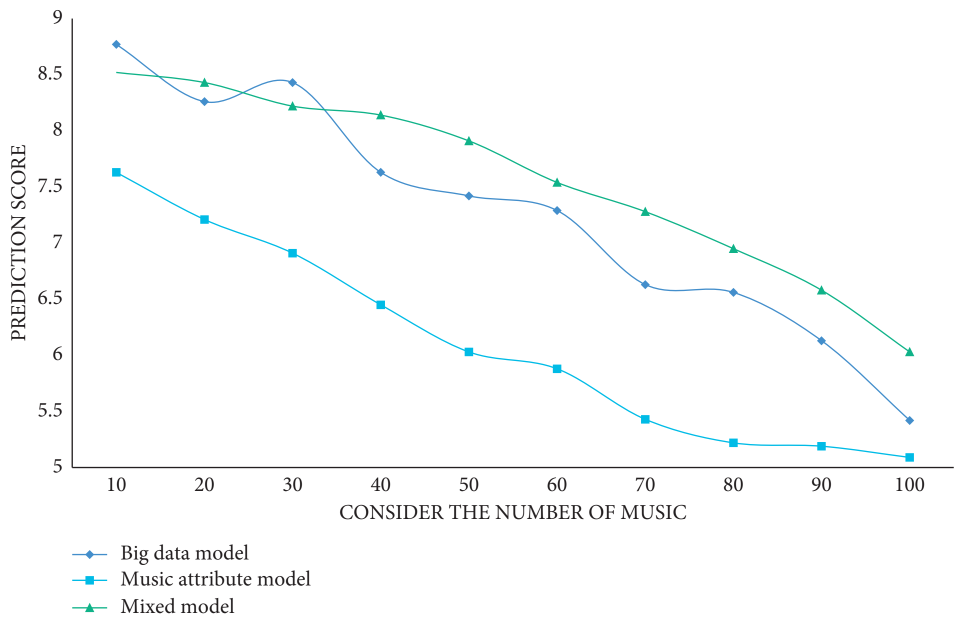

Figure 7: Comparison experiment of G values of different models.

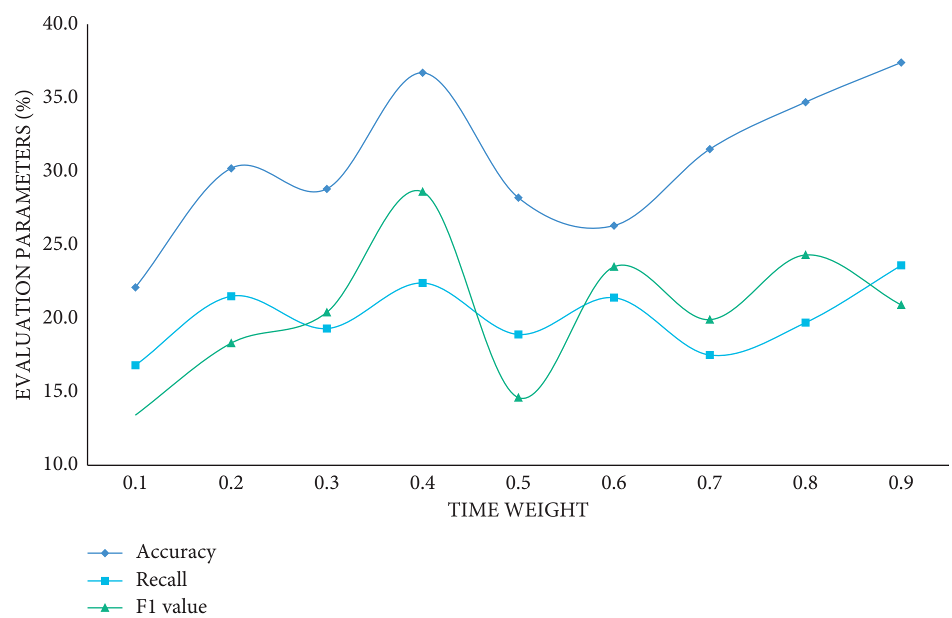

Figure 8: Improved big data proposal model.

fed to the model's first few users. To begin, their features are extracted to generate the user interest model of the big data recommendation model based on the music resources downloaded, searched, and rated within a certain period of time according to the big data recommendation model, and then different big data recommendation models are generated from the ringtone resources in the ringtone library. The content recommendation set is made up of music and user interest models with similar attribute values; second, the big data recommendation model predicts the user's predicted score for some songs and finds the nearest neighbour based on the users with similar interests. The big data recommendation model's recommendation set is recommended; third, the content recommendation set in the recommendation set and the music sorted by the nearest neighbour big data recommendation model are scored according to the weight, and the big data recommendation model with the highest score is chosen as the final recommendation item to be recommended to the user.

5. Experiments on Proposal Models Based on Big Data

The individualization music proposal model of big data technology proposed in this study introduces the GRU network after the XCNN network, which has long-term

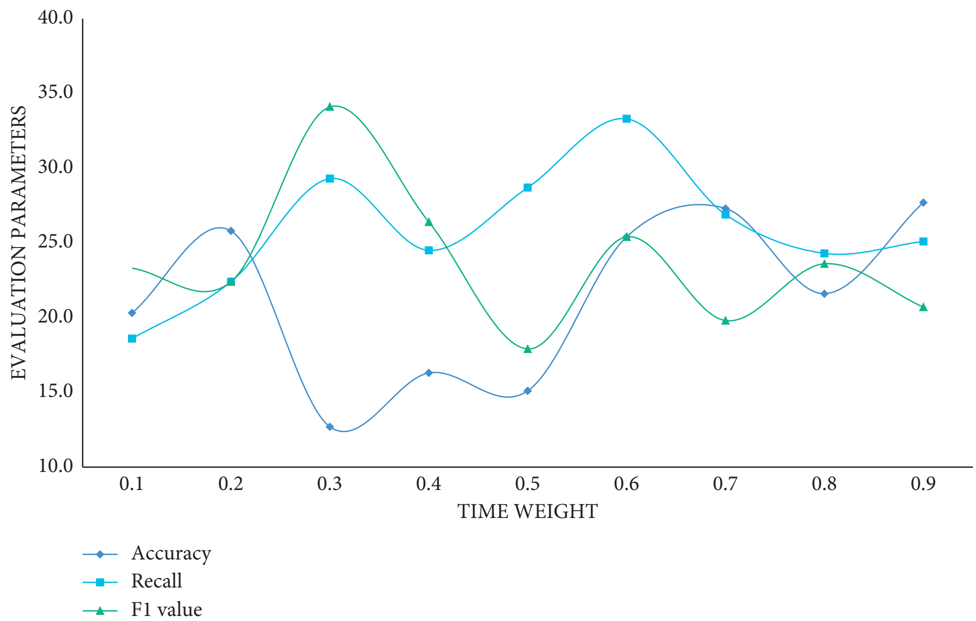

Figure 9: Improved collaborative filtering proposal model.

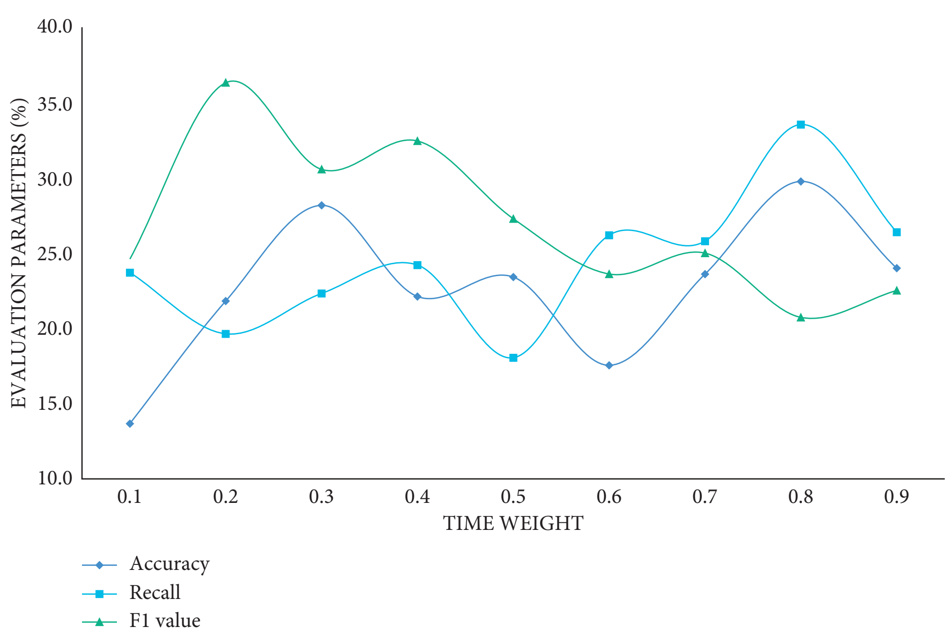

Figure 10: Improved hybrid proposal model.

memory ability and can extract the feature relationship between pre- and post-sequence images. In order to verify the music classification effect of the CURNN model in this study, the experimental results are compared with music classification methods such as HCRNN, FCN6, and DielemanCNN, and the accuracy, AUC, and mean average accuracy mAP of each method are calculated. The results are shown in Figure 4.

It can be seen from the experimental data that CURNN has higher accuracy, AUC, and mean average accuracy rate mAP than the other three models due to the addition of a big data proposal model. The closer the accuracy, AUC, and mAP values are to 1, the better the classification effect is, so the classification effect of the model CURNN proposed in this study is much higher than that of DielemanCNN and FCN6 that only use their own data. Compared with the HCRNN model that also uses the RNN network, CURNN is still ahead. For the three music proposal models proposed in this article, the user's score is predicted on the collection of songs; the predicted scores of 10 to 100 songs are randomly selected; and the L, R, and G values are calculated. The experimental results are shown in Figures 5–7.

As the number of predicted scores increases, the parameter scores decrease continuously. According to the experimental results, the prediction scores of the prediction results of the big data proposal model are higher than those of the other two models, and it has a better proposal effect. The user's behaviour is temporal, so time weights should be introduced into the user prediction scoring formula. Different time weights have different effects, thus affecting the final proposal result. This study sets the time weight value of 0.1 to 0.9 for comparative experiments. In this section, the experimental results will be displayed and analyzed, and the evaluation indicators will be precision rate, recall rate, and $F1$ score. The specific experimental results are shown in Figures 8–10.

The relationship between the time weight coefficient, precision rate, recall rate, and $F1$ is neither positive nor negative, as can be seen. Precision, recall, and $F1$ scores increase steadily as the time weight increases, and when the time weight reaches 0.4, the three indicators' scores tend to be flat. To summarize, the proposed big data music proposal model is about 20% more accurate than the collaborative filtering model and the hybrid model when the time weight is 0.4. And the big data-based proposal algorithm is clearly superior to the single similarity proposal algorithm.

6. Conclusions

Traditional proposal methods frequently limit themselves to user behaviour data while ignoring background data and other issues. This study investigates a data collection method that combines system logs, system databases, network interfaces, and sensors; collects data from multiple sources; and prepares a complete data set for individualization proposals, in conjunction with the big data collection method. Following the completion of data collection, this study uses the appropriate standardization processing methods to perform data standardization work in the preprocessing according to the various types of data collected. We start with two aspects in the proposal candidate set screening stage. On the one hand, it seeks out similar users' favorite music, and on the other, it uses clustering to find music that is similar to the user's favorite music. Starting with two aspects, it ensures that the candidate set is personalized, as well as fully covering the user's interests and improving the quality of the final proposal results. Massive music works and users cause a slew of issues for recommender systems. This study solves the problem of cold start and hot item processing by increasing proposal probability and decreasing item weight, which not only improves the coverage of the proposal system but also ensures the accuracy of the proposal, thus alleviating these issues. The ability of the system to process data is also important in the big data environment. Using the Hadoop big data processing framework, this study improves the system's processing ability. To begin, the recommender system's functional and nonfunctional requirements are analyzed, and various designs required for system implementation are completed. A working environment is created in which a music individualization proposal system can be implemented. Finally, testing is used to confirm the system's feasibility and effectiveness. To mine user preferences and complete the recommendation process, this study primarily uses user data, music work data, user behaviour data, and behaviour context data. However, there is a lot of data that can be added to the recommendation process calculation. Tag data are typically used by users to mark their feelings and experiences with musical works, allowing tags to link users to musical works. These data should be the focus of future research.

In recent years, with the rapid development of emerging Internet of Things technology and short-range wireless communication technology, smart healthcare monitoring network technology has become a research hotspot. It provides convenience for people and enhances the development of people's own healthcare awareness. This paper aims to study how to make its application in the field of smart healthcare education more applicable through the use of related technologies in the Internet of Things era and few-shot learning. For this reason, this paper proposes to optimize and improve the new sensor technology and the algorithm of few-shot learning, and to adjust some parameters as a whole. At the same time, related experiments and analysis are designed for the improved algorithm to study and understand its performance. The experimental results in this paper show that the improved algorithm improves its application effect by 36.9% and is relatively more applicable than the unimproved algorithm.

1. Introduction

Intelligent medical care is a new medical service sharing system that combines computer technology, communication network technology, and modern medical technology. Smart healthcare is designed to serve as a link between patients and hospital specialists, allowing patients to seek advice from specialists in distant hospitals at any time and from any location, and to receive effective treatment and healthcare, as well as other medical services, based on recommendations. It achieves "zero distance" consultation between specific medical costs and time, and patients and hospital experts and medical personnel, and improves medical resource efficiency and distribution rationality.

Intelligent medical monitoring can continuously send human physiological parameter information to a medical monitoring center in a remote hospital for analysis and diagnosis by experts or medical personnel using medical sensors and communication networks. As a result, hospital experts and medical personnel can quickly obtain the patient's testing results, record historical data, and describe reasonable and correct diagnoses and treatment options. In the hospital's database center, the function of long-term tracking of the patient's physical condition can also be realized. The demand for remote medical monitoring is increasing, and the market prospect is broad, thanks to the rise of network applications of medical supplies and the gradual improvement of people's own health awareness.

The novelty of this paper is that it adjusts the classification of the algorithm and other related parameters based on research and understanding of new sensor technology in the emerging Internet of Things era, combined with algorithm optimization for few-shot learning. It makes the improved algorithm's application effect in the actual field of education more applicable, and it can play its role more effectively.

2. Related Work

With the rapid development of Internet-related technologies, people have a wide range of applications for decorrelation. As one of the main extensions of the Internet of Things technology, sensor technology has never been interrupted. Mokhtari et al. proposed a new body recognition sensor that can effectively distinguish multiple residents in a home environment to detect their height as a unique biometric. The sensor includes three sensing/communication modules: a pyroelectric infrared (PIR) occupancy, an ultrasonic array, and a Bluetooth Low Energy (BLE) communication module. The PIR occupancy module is used to detect the moving direction, while the ultrasonic array module is used to detect the height of the moving residents [1]. Shimada proposes that, with the application of magnetic fields and magnetically responsive fluids such as magnetic composite fluids (MCFs) as fillers, the effect of electrolytic polymerization on NR-latex such as plastic-type polymer solutions is enhanced. The current new MCF rubber vulcanization method is efficient enough to be widely used in tactile sensors in robotics and engineering applications [2]. Miao et al. believe that new sensor technologies such as near-infrared spectroscopy, chemical imaging, electronic nose, and electronic tongue play an important role in the quality evaluation of traditional Chinese medicine and have prospects and opportunities for future research [3]. Ebrahimi and Mardani propose a new, simple, and inexpensive sensor to detect multipoint contact of a typical robotic wheel. The new sensor enables wheeled robots to scan surfaces and find stability margins during real-time motion without the need for cameras or laser sensors. In addition, it enhances the real-time solution capability of dynamic equations [4]. Chaiendoo et al. proposed a selective colorimetric method for the detection of formaldehyde (FA) based on polymethacrylic acid-(PMAA-) templated silver nanoclusters (AgNCs). In the presence of AgNCs (AgNCs@Tollens), chemical dosimeters are easily fabricated by forming Tollens reagents. Compared with other aldehyde-containing compounds, the proposed method exhibits excellent selectivity for FA [5]. Kuchlyan et al. proposed that Mercury ions pose a great threat to humans due to their high toxicity in living systems. Therefore, its detection at the nanometer level is of current interest. Rhodamine derivatives are one of the rarest examples of Hg2+ fluorescent chemosensors, in which the phthalic acid moiety showing antibacterial activity is responsible for specific binding [6]. Wu and Yan believe that adaptive immune cells are usually not equipped with pattern recognition receptors. In immunity, they revealed an “innate-like” cytosolic DNA sensing mechanism of KU complexes in senescent CD4+ T cells, which exacerbates senescence-related autoimmunity [7]. The new sensor-based wearable technology proposed by Monje et al. is gradually revolutionizing PD care by objectively measuring these manifestations and improving PD diagnosis and treatment monitoring. However, their use in clinical practice remains limited, probably due to the lack of external validation and standards for their continued use at home [8]. The abovementioned articles are very comprehensive for the introduction of related new sensors, and the structure of the sensor and its specific design principles are clearly expressed. However, there is no experimental verification for the application of the sensor in related fields, and there is a lack of research on the reliability of the sensor.

3. Application Method of Few-Shot Learning in Smart Health

3.1. Smart Healthcare System. The smart healthcare system [9] is to monitor the basic parameters of the human body’s important physiological parameters such as human body temperature, pulse, and blood pressure. These parameters can reflect a basic health condition of the human body, so the system chooses to monitor the parameters of the human body’s body temperature, pulse, blood pressure, and blood oxygen. The most important part of the system is to transmit the collected data. Data transmission is generally divided into two forms: wired transmission and wireless transmission. The cost of wired transmission is high, the wiring is cumbersome, and the scalability is not very good. When new equipment is added, rewiring may be required, and the disturbed lines may cause psychological pressure on the ward [10]. The wireless transmission method is relatively simple in terms of placement, because it does not require cables, so the cost is relatively low, and the adaptability and scalability are good. It does not require rewiring, and because there are no complicated wires, the instrument is easy to carry and move. This system is designed to be able to monitor their own health at home, requiring the instrument to be portable, simple to operate, simple and easy to install, and easy to expand [11]. According to the above comparison of wired transmission and wireless transmission, the wireless transmission mode is selected. It replaces the cables used in the traditional monitoring system, which not only facilitates the movement of the ward but also reduces the trouble and psychological pressure caused by the disturbed wires.

The system is mainly composed of three parts: parameter acquisition and transmission system, client monitoring software system, database management system. The parameter acquisition and transmission system is composed of parameter acquisition sensors, Zigbee acquisition nodes, and coordinators, which are responsible for acquiring the health parameters of the monitored person, such as pulse, blood pressure, body temperature, and other parameter data [12]. Each acquisition node transmits the collected data to the coordinator through the wireless network, and the coordinator processes the data and sends it to the PC serial port through RS232. The client monitoring software system displays and stores the data received by the serial port. At the same time, the client also has the functions of video consultation and health parameter historical data and abnormal data query, which constitute the diagnosis and treatment subsystem. The client also provides doctor data and electronic medical records, which constitute the data query subsystem. The database management system mainly stores and performs simple data processing, deletion, addition, and query of user information and parameter data [13]. The block diagram of the system structure is shown in Figure 1.

3.1.1. Selection of Wireless Transmission Methods. In recent years, with the rapid development of technology and network, especially the rapid development of the Internet industry, the popularity of portable electronic products such as

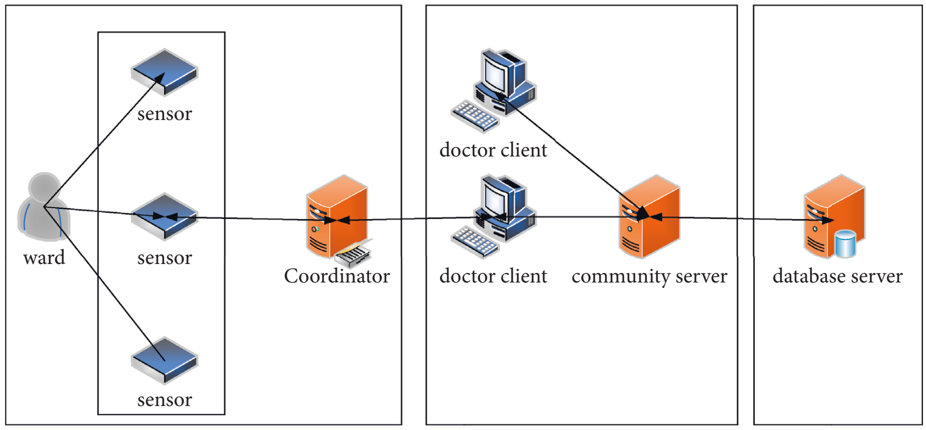

Figure 1: System structure block diagram.

mobile phones and laptop computers has been quite high. People's requirements for network communication are gradually increasing, and wired communication can no longer meet people's mobile needs. They hope to obtain mobile, convenient, and short-distance wireless networks to provide services for these mobile electronic products [14]. The current more common centralized short-range wireless communication technology is shown in Figure 2.

Figure 2: Common centralized short-distance communication methods.

3.1.2. Selection of Network Topology. At present, Zigbee mainly supports star, tree, and mesh network topologies, which constitute three network structures of star network, tree network, and mesh network [15]. The schematic diagram of the star network topology is shown in Figure 3.

The star network belongs to the slave-master-slave structure, and each wireless network node realizes the network connection through the coordinator. Communication between nodes can only be done through the coordinator. There is no direct communication between nodes, only through the coordinator, which belongs to the point-to-point communication mode [16]. When an FFD is activated, it will automatically form a network and become the main coordinator of the entire Zigbee network. Only one master coordinator is allowed in each Zigbee star network structure, which means that each star network is independent. The uniqueness of the network is ensured by selecting a PAN identifier. After selecting the PAN identifier, the master coordinator will allow the FFD or RFD to join the network. In addition, when multiple wireless nodes transmit data messages to the coordinator at the same time, it is easy to cause network congestion, resulting in data loss or transmission failure. However, it is still widely used due to its advantages of simple structure, flexible layout, and convenient management. The star network structure is suitable for occasions with a small range and few terminal devices [17]. The tree network topology is different. The schematic diagram of the tree network topology is shown in Figure 4.

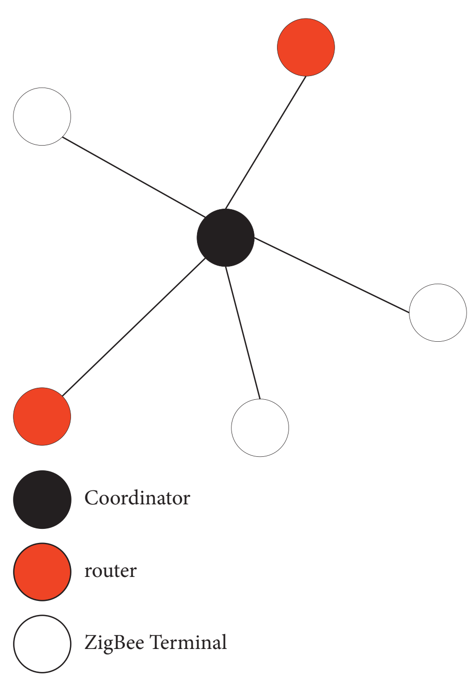

Figure 3: Star network topology.

In a tree-shaped network topology, the communication between nodes can only be carried out along the path of the tree; that is, each node can only communicate with its parent and child nodes. If two nodes have the same parent node, the data will be transmitted from one node to the parent node during data transmission, and then from the parent node to

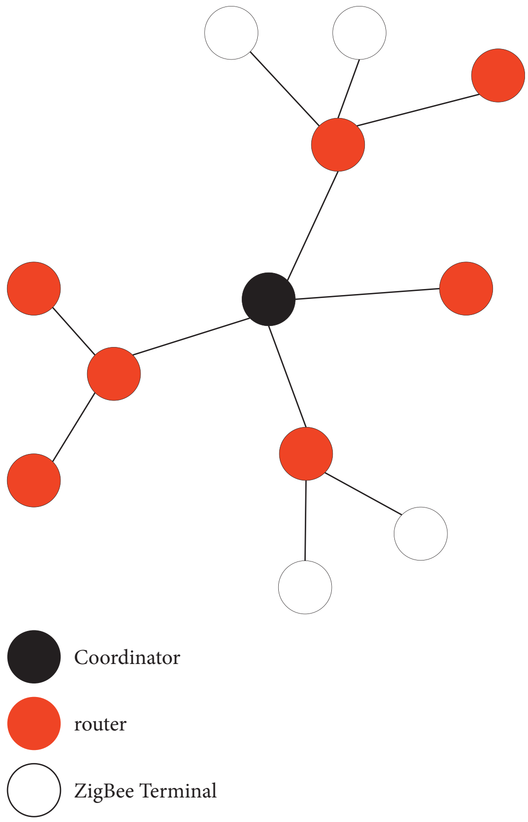

Figure 4: Tree network.

another node [18]. If two nodes have different parents, the information will be passed up the tree path. When it is passed to the nearest ancestor node, it finds the parent node of the target node along the path and then continues to pass down to the final target node.

A mesh network is more flexible than a tree network. Similar to the tree network structure, it also includes a coordinator, multiple routers, and multiple terminal nodes, but the connection method is different [19]. The schematic diagram of the mesh network topology is shown in Figure 5.

Most of the nodes in the mesh structure are FFDs with complete functional characteristics. Each FFD node can communicate directly; it can not only send and receive information but also automatically forward the information to other nodes in the network. FFD has the function of rerouting. When a node in the network fails, the nearby nodes will automatically replace the faulty node and continue to transmit information according to the principle of optimal path. The "multihop" mechanism is adopted when the mesh network transmits data, which greatly increases the reliability of the system, increases the security in the process of data transmission, and reduces the delay of data transmission. The mesh network structure is relatively complex, has self-organization and self-healing ability, and can adapt to extremely complex environments [20]. It is suitable for a wide range of applications with complex environments.

3.2. Few-Shot Improved Algorithm. Since the introduction of linear discriminant analysis, a lot of supervised learning has been developed in the past few decades to improve the few-shot problem. Representative ones include subspace selection based on geometric mean, local sensitive discriminant analysis, and edge analysis [21]. GMSS uses the general mean definition to replace the arithmetic mean in LDA, so it can get more robust results than LDA. LSDA and MFA are classical manifold learning algorithms, and both have their own solutions to the SSS problem. The PAF framework can better sort out the essential differences of this kind of manifold learning. Although the local geometric information preservation and how to extract discriminative information are fully discussed in current algorithms, the hyperparameter selection problem that exists in most manifold supervised dimensionality reduction is rarely addressed.

Based on the findings, this paper proposes a new essential manifold estimation method based on the RPDA algorithm and ensemble learning that preserves the ensemble manifold's ordering information. This method investigates the problem of supervised learning from two perspectives. To begin, the objective function is optimized on the block based on the RPDA algorithm; that is, the preservation of the ordering information of the same samples is emphasized on the local block formed by the sample, in order to achieve the goal of obtaining the sample's original distribution information, while maximizing sample edge distance between classes in order to retain discriminative information. Second, a new objective function with essential manifold estimation is defined based on the previous step, and the essential manifold of the data is approximated by finding the optimal linear combination of registration matrices, avoiding the hyperparameter selection problem in the traditional manifold supervised learning algorithm.

The ranking information of the samples within the class is available for classification. Inspired by the LE algorithm, we define the intraclass ordering information on a local block as

$$R(y_i) = \sum_{j=1}^{k_1} \left\| y_i - y_{i^j} \right\|^2 (w_i)_j. \tag{1}$$

Here the weight factor $(w_i)_j$ is defined as

$$(w_i)_j = \begin{cases} \exp\left(\dfrac{-\left\|x_i - x_{i^j}\right\|^2}{t}\right), & \text{if } x_{i^j} \in N_{k_1}(x_i); \\ 0, & \text{otherwise.} \end{cases} \tag{2}$$

According to the PAF framework, we can deduce the formula as follows:

$$\begin{aligned} R(y_i) &= tr\left\{ \begin{bmatrix} (y_i - y_{i^1})^T \\ \vdots \\ (y_i - y_{i^j})^T \end{bmatrix} \operatorname{diag}(w_i) \left[y_i - y_{i^1}, \ldots, y_i - y_{i^j} \right] \right\}, \\ &= tr\left(Y_{R(i)} L_{R(i)} Y_{R(i)}^T \right). \end{aligned} \tag{3}$$

Here,

$$L_{R(i)} = \begin{bmatrix} -e_{k_1}^T \\ I_{k_1} \end{bmatrix} \operatorname{diag}(w_i) \left[-e_{k_1} \quad I_{k_1} \right]. \tag{4}$$

For popular supervised learning, discriminative information plays a crucial role. As far as the EMRP algorithm is concerned, we consider the purpose of extracting discriminative information by maximizing the distance sum of y_i and its k_2 interclass samples, namely,

$$D(y_i) = \sum_{p=1}^{k_2} \left\| y_i - y_{i_p} \right\|^2 (v_i)_j. \tag{5}$$

The definition of the weight factor $(v_i)_j$ here considers the factor of removing the interclass ranking information, namely,

$$(v_i)_j = \begin{cases} 1, & \text{if } x_{ij} \in N_{k_1}(x_i); \\ 0, & \text{otherwisel.} \end{cases} \tag{6}$$

Under the framework of PAF, we can further derive (5):

$$\begin{aligned} D(y_i) &= tr\left\{ \begin{bmatrix} \left(y_i - y_{i_1}\right)^T \\ \vdots \\ \left(y_i - y_{i_p}\right)^T \end{bmatrix} \operatorname{diag}(v_i) \left[y_i - y_{i_1}, \ldots, y_i - y_{i_p} \right] \right\}, \\ &= tr\left(Y_{D(i)} L_{D(i)} Y_{D(i)}^T\right). \end{aligned} \tag{7}$$

Here,

$$L_{D(i)} = \begin{bmatrix} -e_{k_2}^T \\ I_{k_2} \end{bmatrix} \operatorname{diag}(v_i) \left[-e_{k_2} \quad I_{k_2} \right]. \tag{8}$$

Therefore, we can get the optimization objective function on the local block:

$$\arg\min_{y_i} \left(\sum_{j=1}^{k_1} \left\| y_i - y_{ij} \right\|^2 (w_i)_j - \gamma \sum_{p=1}^{k_2} \left\| y_i - y_{i_p} \right\|^2 (v_i)_j \right). \tag{9}$$

Here, $\gamma \in [0,1]$ is the balance parameter used to synthesize the contributions of intraclass samples and interclass samples on the local patch. By defining an indexed collection,

$$F_i = \left\{ i, i^1, i^2, \ldots, i^{k_1}, i_1, i_2, \ldots, i_{k_2} \right\}. \tag{10}$$

And we derive (9):

$$\begin{aligned} &\arg\min_{y_i} \sum_{j=1}^{k_1} \left\| y_i - y_{i_j} \right\|^2 (w_i)_j - \gamma \sum_{p=1}^{k_2} \left\| y_i - y_{i_j} \right\|^2 (v_i)_j, \\ &= \arg\min_{y_i} tr\left\{ Y_i \begin{bmatrix} -e_{k_1+k_2}^T \\ I_{k_1+k_2} \end{bmatrix} \operatorname{diag}(w_i) \left[-e_{k_1+k_2} \quad I_{k_1+k_2} \right] Y_i^T \right\}. \end{aligned} \tag{11}$$

Here, $tr(\ )$ is the matrix trace operator:

$$e_{k_1+k_2} = [1, \ldots, 1]^T \in R^{k_1+k_2}. \tag{12}$$

According to the PAF framework, we further define the registration matrix:

$$L_i = \begin{bmatrix} -e_{k_1+k_2}^T \\ I_{k_1+k_2} \end{bmatrix} \operatorname{diag}(w_i) \left[-e_{k_1+k_2} \quad I_{k_1+k_2} \right]. \tag{13}$$

Formula (11) can be simplified to

$$\arg\min_{Y_i} tr\left(Y_i L_i Y_i^T\right). \tag{14}$$

We define the selection matrix:

$$(S_i)_{pq} = \begin{cases} 1, & \text{If } p = F_i\{q\}; \\ 0, & \text{else.} \end{cases} \tag{15}$$

Here,

$$\text{where } S_i \in R^{N \times (k_1+k_2+1)}. \tag{16}$$

Subsequently, we can unify all local blocks on a consistent coordinate system. The specific operation method is as follows: first, coordinate Y_i comes from the global coordinate system, and its coordinate expression can be given by the following formula:

$$Y = U^T X = \left[y_1, y_2, \ldots y_N \right] \in R^{d \times N}. \tag{17}$$

That is,

$$Y_i = Y S_i. \tag{18}$$

Therefore, the optimization objective function 14 on the local block can be written as

$$\arg\min_{Y} tr\left(Y S_i L_i S_i^T Y^T\right). \tag{19}$$

Secondly, by accumulating the optimization objective function 19 defined on the local block formed by N samples, we can obtain the global registration objective function, which has the following form:

$$\begin{aligned} &\arg\min_{Y} \sum_{i=1}^{N} tr\left(Y S_i L_i S_i^T Y^T\right), \\ &= \arg\min_{Y} tr\left(Y L Y^T\right). \end{aligned} \tag{20}$$

However, different hyperparameters correspond to manifolds with different geometric information, which will seriously affect the final recognition accuracy. Therefore, an automatic manifold estimation method is valuable for solving this problem.

3.3. Wireless Sensor Networks. WSN is a network application system composed of multiple intelligent nodes centrally arranged in a monitoring area, and a multihop self-organized network system formed by wireless communication. It is widely used in facility security, environmental monitoring, industrial applications, traffic control, etc. Therefore, WSN

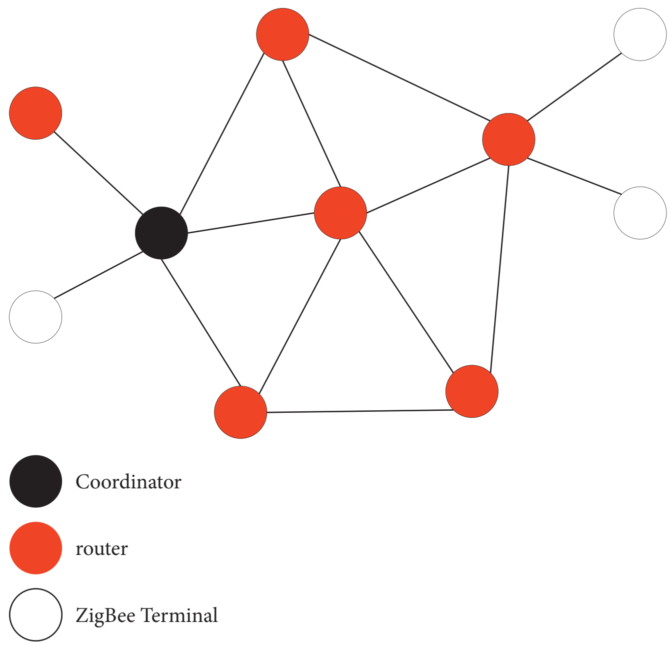

FIGURE 5: Network structure.

can be said to combine the world of logical information with the world of objective physics, changing the interaction between humans and nature. The wireless sensor network structure is shown in Figure 6.

A sensor network system usually includes sensor nodes, sink nodes, and management nodes. A large number of sensor nodes are randomly deployed in the detection area to form a network in a self-organizing manner. It transmits the detected data to the sink node through multihop relay and finally reaches the management node through the Internet or satellite. The measured data is sent to the sink node and finally reaches the management node through the Internet or satellite. The user configures and manages the sensor network through the management node, publishes detection tasks, and collects detection data.

4. Algorithm Module Implementation Experiment

4.1. Heart Sound Signal Recognition Experiment

Production Mechanism. The vibrations of the heart valves and great vessels under the impact of blood flow pass through the cardiothoracic conduction system to the chest wall to form heart sounds that can be received by a stethoscope. The wavelet transform method is used for denoising, and then the envelope algorithm is used to extract the peaks. It defines the feature vector and then uses the multiclass support vector machine decision tree (SVM-DT) for pattern recognition to distinguish the type of signal; in order to measure the predictive performance of the classifier for unknown samples, it needs to be tested, and the number in the test set is increased to 50, and $p = 2$ is also set. The test results are shown in Table 1.

It can be seen from the above table that the algorithm has good prediction ability for unknown samples while maintaining high training accuracy. Through this method, we have established a correct and relatively complete heart sound recognition algorithm, which can reduce the uncertainty of signal recognition and identify the type of signal accurately and effectively.

4.2. Breath Sound Signal Recognition Experiment. There are usually two types of breath sounds: normal breath sounds and additional sounds. The breath sound energy of normal and bronchitis patients are mainly concentrated in the inspiratory phase and less in the expiratory phase; the opposite was true in asthmatic patients. Therefore, we need to study the expiratory phase and the inspiratory phase separately, so that the characteristics of the breath sound signal are more obvious.

Input the sample feature vector group of unknown breath sound type after feature extraction to the learned network, and the output is the classification result as shown in Table 2.

4.3. Pulse Signal Recognition Experiment. Firstly, the most primitive sampling sequence is used to discretize the pulse signal, and the signal is decomposed twice by the wavelet transform of the discrete sequence; thresholding and secondary reconstruction of the high-frequency coefficients of the signal to obtain the signal after noise removal; normalizing the denoised signal, extracting the signal envelope, and then defining the eigenvectors; finally using the cluster analysis method for pattern recognition.

The pulse data obtained by the final screening were analyzed by using the classical statistical dynamic K-means

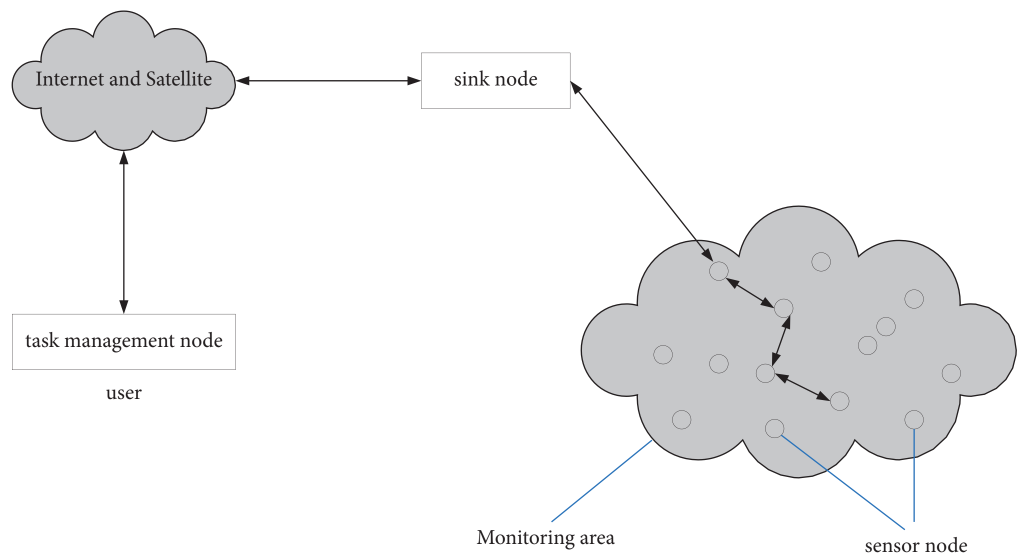

Figure 6: Wireless sensor network architecture.

Table 1: Calculation results of the classifier during testing.

Heart sound type	Training set		Test set	
	Number of misclassified samples	Accurate %	Number of misclassified samples	Accurate %
X	0	100	0	100
Y	2	95.2	1	96.7%
Z	1	96.4	0	100
Total	3	97.4	1	96.5%

Table 2: Classification results.

Type	Number of test samples	Normal	Asthma	Tracheitis	Recognition rate	Average value
Normal	25	23	1	1	92%	
Asthma	25	0	22	3	88%	92%
Tracheitis	25	1	0	24	96%	
Total	75	24	23	28		

Table 3: Class centers.

Cluster center	Vascular compliance coefficient	Peripheral resistance coefficient	Aortic valve function coefficient	Cardiac ejection function	Heart rate
First kind	1.61	1.4	0.07	4.6	0.5
Second kind	1.4	1.25	0.05	4.3	0.8
Third kind	1.22	1.01	0.03	3.8	1.2

cluster analysis function. When $K = 3$, the class centers of the cluster analysis results are shown in Table 3.

Passing N groups of test samples through the test of the training network, the error we get has reached the expected result. This algorithm has a concise idea and fast clustering speed. However, there are still some problems, such as the inappropriate selection of initial agglomeration points, which has a great influence on the clustering results and still needs to be improved.

4.4. Fusion Algorithm Experiment. Through the above algorithms, we identify and classify the signals collected by each sensor. In this section, we can obtain the final probability distribution value by calculating each classification result of each sensor and the correlation coefficient in each sensor. *Fusion Idea*. The probability distribution value of each sensor target type obtained by the weighted average method (or template method) is fused through the DS evidence theory, which can reduce the uncertainty of the signal and obtain the user's physical condition more accurately, as shown in Table 4.

After getting the probability distribution values corresponding to the sensors, we need to fuse these probability distribution values. When the intersection proposition is an empty set, the decision result can be obtained through evidence fusion. The fusion process is shown in Table 5.

Table 4: Probability assignment values.

	O_1	O_2	O_3	O_4
m_1	0.321	0.1928	0.0913	0.3949
m_2	0.4101	0.234	0.2465	0.1094
m_3	0.51	0.1143	0.0056	0.3701

Table 5: Fusion process.

$m_1(u) = 0.3949$	$m(o_1) = 0.1619$	$m(o_2)$ 0.0924	$m(o_3)$ 0.0973	$m(u)$ 0.0432
$m_1(o_3)$ 0.0913	$m(\phi)$ 0.0374	$m(\phi)$ 0.0021	$m(o_3)$ 0.0225	$m(o_3)$ 0.01
$m_1(o_2)$ 0.1928	$m(\phi)$ 0.0791	$m(o_2)$ 0.0451	$m(\phi)$ 0.0475	$m(o_2)$ 0.021
$m_1(o_1)$ 0.321	$m(o_1)$ 0.1316	$m(\phi)$ 0.0751	$m(\phi)$ 0.0791	$m(o_1)$ 0.0351
	$m_2(o_1)$ 0.4101	$m_2(o_1)$ 0.2340	$m_2(o_3)$ 0.2465	$m_2(u)$ 0.1094

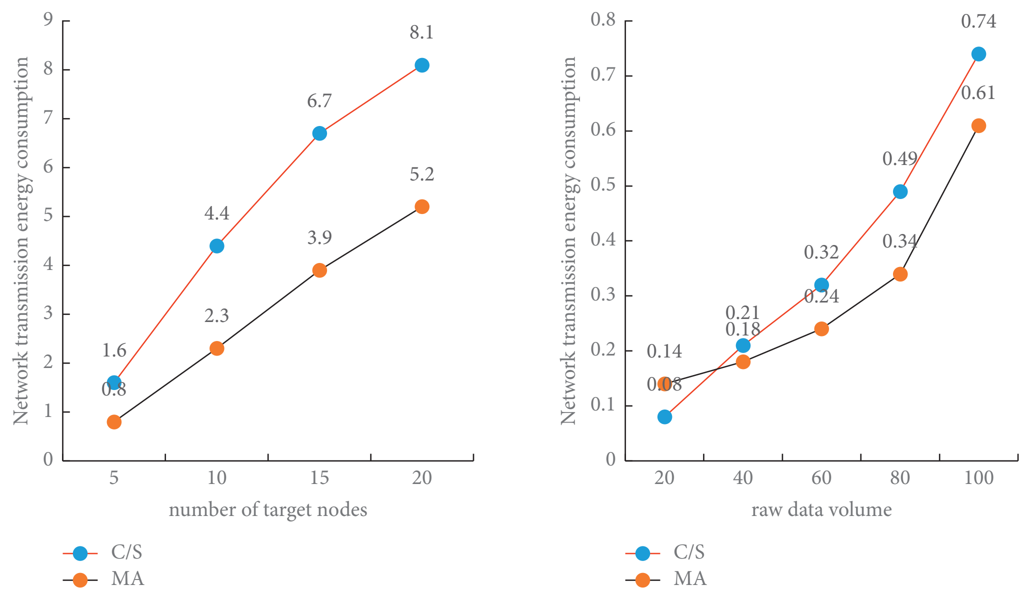

Figure 7: The relationship between the number of target nodes and the amount of raw data, transmission energy consumption, and network energy consumption.

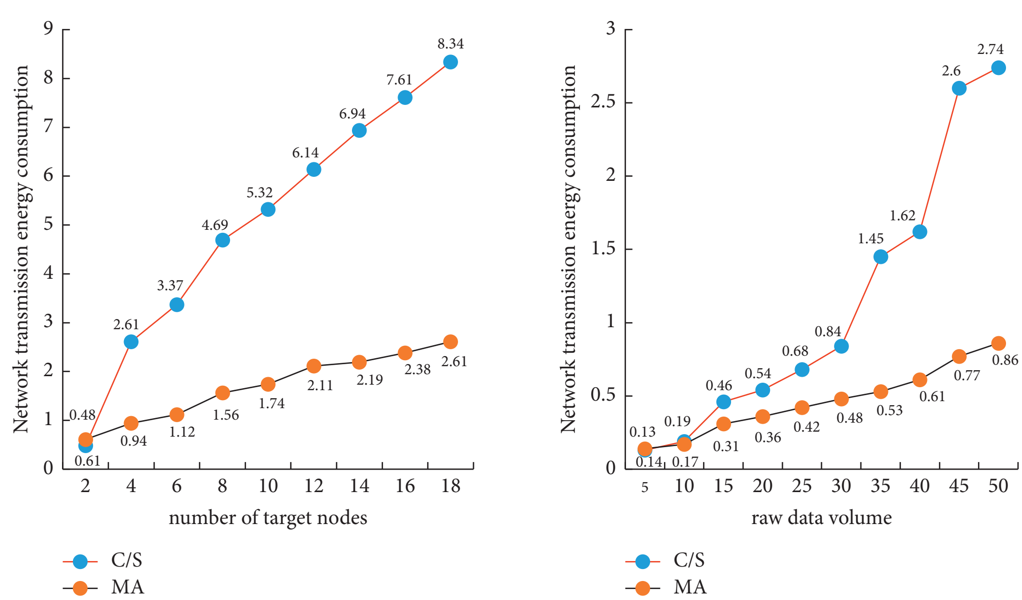

Figure 8: Simulation results between the target node and the original data volume and transmission energy consumption.

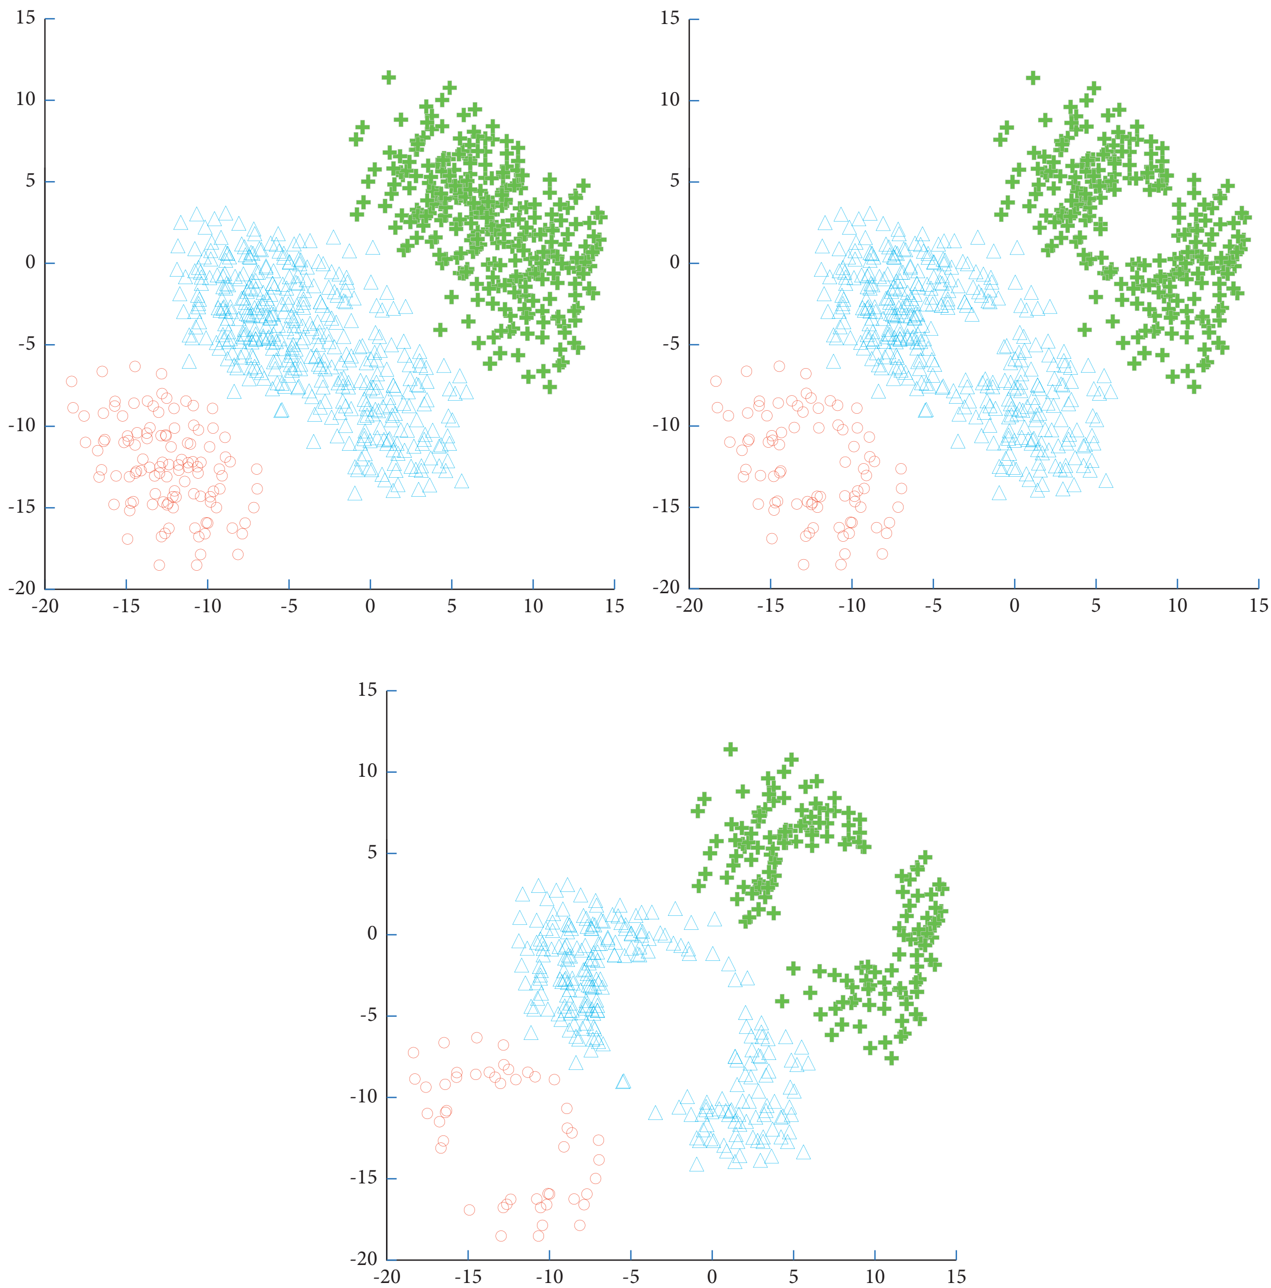

Figure 9: The subset of data selected by the SE algorithm during the iterative process.

It can be seen from the above experimental data that the fusion algorithm can significantly reduce the uncertainty and obtain a more accurate physical condition of the patient.

5. Multisensor Model Analysis

5.1. Model Analysis. This section will quantitatively analyze the difference between mobile agent-based wireless sensor network applications and traditional Client/Server model sensor network applications, focusing on the data transmission model and network energy consumption.

The modules that consume energy in the sensor node include sensor module, processor module and communication module. Since most of the energy consumption of sensor nodes is in the wireless communication module, the energy consumption of the wireless communication module is approximately 30 times the total energy consumption of the sensor module and the processor module. Therefore, the energy consumption of the sensor module and the processor module can be ignored in the energy analysis of the sensor node, and only the energy consumption of the communication module can be considered. In the Client/Server mode and the mobile agent mode, respectively, Figure 7 shows the comparison of the number of target nodes and network energy consumption, as well as the comparison of the original data volume and

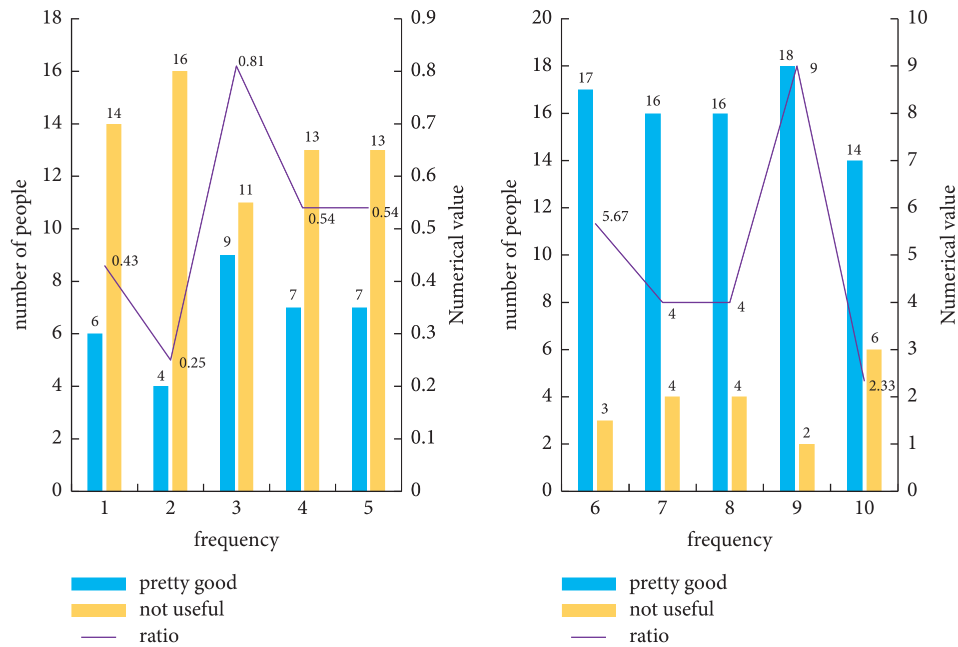

Figure 10: Effect evaluation of few-shot learning algorithm before and after improvement.

network energy consumption. The number of target nodes in the network has little effect on the energy consumption of the sensor network using the mobile agent mode, as can be seen on the left side of the figure; however, when the number of target nodes is small, the mobile agent mode may consume more energy. The right side of the figure shows that the mobile agent mode saves more energy than the traditional Client/Server mode as the amount of raw network data grows; however, when the amount of raw data grows small, the mobile proxy mode consumes more energy.

At the same time, OMNet is used to simulate the relationship between energy consumption in Client/Server mode and mobile agent mode. Suppose there are 600 nodes irregularly distributed in an area of 300 meters × 300 meters, and the code length of the mobile agent itself is 50 bytes. *kr* is related to the original data volume, the default value is 2 bytes, and the default original data volume of the node is 10 bytes. The specific results are shown in Figure 8: the left side of Figure 8 is the change diagram of network energy consumption during the process of increasing the number of target nodes from 2 to 18.

It can be seen from Figure 8 that the network energy consumption of Client/Server mode and mobile agent mode increases with the increase of the number of target nodes, but the mobile agent mode consumes less energy. Moreover, the growth rate of energy consumption in Client/Server mode is higher than that in mobile agent mode, which is consistent with the above theoretical analysis. The right side of Figure 8 is a simulation diagram of data transmission volume and network energy consumption. The right side of Figure 8 shows that as the amount of raw data increases, the energy consumption of both modes increases. With the increase of the amount of raw data, the energy consumption based on the Client/Server mode increases significantly and exceeds that of the proxy mode, which is also consistent with the above theoretical analysis. When the length of the original data itself is very small compared to the length of the mobile agent code, the Client/Server model has less energy consumption.

5.2. Parameter Analysis. In this experiment, a set of two-dimensional datasets is artificially generated, which consists of 1500 instances and contains 3 categories. The dataset shown in Figure 9 shows the instance selection results of the SE algorithm under different reduction rate conditions, which is helpful to observe the SE algorithm process.

In order to further understand the influence of parameters on the performance (accuracy and speed) of SE algorithm, this experiment conducted an in-depth analysis of SE on artificial datasets and Newsgroup datasets.

The SVM classification surface is obviously shifted because a large number of support vectors are accidently deleted. When dealing with multiclassification problems, this type of geometric algorithm must be transformed into multiple binary classification problems for processing: positive classes are considered positive, while negative classes are considered negative. As a result, edge instances in the positive class must be identified with the help of the negative class. It will be very difficult to identify edge instances if the distribution of negative classes surrounds the distribution of positive classes. Furthermore, CNN and KMSVM only retain a small portion of the support vectors, whereas NNSVM only eliminates a few samples that overlap each other.

5.3. Application Effect Analysis. In order to better understand the effect of the improved few-shot learning algorithm on the promotion of the new sensor technology in the current Internet of Things era before and after the improvement, this paper designs 10 different experiments, numbered 1–10. The first five experiments are to improve the application effect of the previous algorithm on the new sensor technology on smart healthcare, and the last five experiments are the application effect of the improved algorithm on the new sensor technology on smart healthcare. To ensure that the five experiments are the same except for the sample learning algorithm, other irrelevant variables are the same, and other irrelevant variables are controlled. Statistical experimental data are shown in Figure 10.

From Figure 10 above, we can see that the ratios of good and bad applications considered before the improvement are 0.43, 0.25, 0.81, 0.54, and 0.54, respectively, and the overall ratio is low; after the improvement, the ratios of good and bad applications were considered to be 5.67, 4, 4, 9, and 2.33. The overall ratio is much higher than that before the improvement, and the effect is increased by 36.9%, which can be better applied to the field of smart healthcare education.

6. Conclusions

This paper mainly uses the new wireless sensor technology and few-shot learning in the Internet of Things era to explore its application in the field of education. First of all, this paper proposes to improve the algorithm of few-shot learning. By redefining the classification method of the algorithm, the algorithm is optimized. At the same time, it designs relevant experiments to adjust some parameters and conducts data analysis and comparison in the analysis part. From the conclusions of the analysis part, it is not difficult to see that the optimized algorithm has been greatly improved in performance and practical application effect and can be better applied to the application of new sensors in the field of education.

China is a large rare earth country that has pushed for related rare earth research, development, and application in the global development and progress of rare earths. The rare earth resource reserve strategy must be implemented by China due to the situation of rare earth resources at home and abroad, national security, and the need to strengthen the right to speak in the international market. This article builds the rare earth mineral resources reserve system and model from the perspective of regional development and uses the improved SURF algorithm to solve the problems of inaccurate mine location, mine location deviation, dislocation, overlap, and other issues, resulting in more accurate mineral resources reserve management data. The results show that the maximum relative error between the parallel profile method and the traditional method is 2.6%, which meets the requirement for mineral reserve calculation accuracy and can be used to calculate reserves. China's peak ionic rare earth output will be 46,797.06 tonnes in 2024, and then, it will decline at a 4% annual rate thereafter. This demonstrates how a graded reserve and orderly promotion can improve the workflow and efficiency of the rare earth mineral resources reserve.

1. Introduction

China has the world's richest proven rare earth reserves, and the variety, quality, output, and export of rare earths frequently rank first in the world [1, 2], making it critical to the global rare earth supply. China is a large rare earth country that has pushed for related rare earth research, development, and use in the global development and progress of rare earths. However, environmental damage, backward technology, low technological content of products, excessive export, low price, indiscriminate mining and excavation, and other serious issues plague China's development and utilization of rare earth resources.

Modeling of reserves: A steady supply of resources is critical whether it is for national economic security or national defence security. To begin with, a country's economic development is heavily reliant on resources, particularly strategic resources, and the economy's long-term viability cannot be separated from a reliable supply of resources. In modern industry [3], high-tech, and national defence technology, rare earth is an essential strategic mineral resource. Pan et al. believed that there have been many studies on the catalytic and surface performance of alkali metal, alkaline earth metal, and other metal oxides, but rare earth oxides have received relatively little attention [4]. Krishnamurthy presented and explained the geochemical characteristics, classification, and distribution of rare earth elements in sedimentary rocks [5]. Xiao investigated the effect of rare earth elements on the compressive ductility of ferromagnetic shape memory alloys and found that rare Earth elements can significantly improve the material's compressive ductility [6]. According to Ilyas et al., the output of foreign rare earths will increase significantly due to the restart of rare earth projects in countries other than China and the expansion of related rare earth enterprises [7]. Rare earth is a crucial component of modern weapons and equipment. To ensure national sovereignty and protect against foreign invasion, rare earth must be preserved. As a result, we can only ensure domestic demand for a sustainable supply of rare earth and national defence security by reserving rare earth and other strategic resources and increasing the degree of protection of rare earth resources.

The research on the optimal allocation of rare earth resources is conducive to solving the problems existing in the development and utilization of rare earth resources, improving the economic and social benefits of rare earth resources development, contributing to the healthy and sustainable development of rare earth industry, and having important practical significance for the optimization of regional development economic layout structure and the implementation of national rare earth strategy [8]. At the same time, the research on this topic also has reference significance for the research of other important mineral resources optimal allocation.

The main innovations of this article are as follows:

(1) The reserve system of rare earth mineral resources oriented to regional development has been constructed, and the quantitative evaluation standards of some indexes have been established, which not only helps to improve the scientificity and accuracy of index evaluation but also provides a reference for the research of other resources' optimal allocation.

(2) Aiming at the characteristics of a large matching area and high precision of mine spatial location, the SURF algorithm is improved in the order of feature point extraction, pixel optimization in the feature extraction stage, and image segmentation in the feature extraction process.

(3) The clustering results of geochemical sampling points by K-means have a corresponding relationship with the stratigraphic lithology distribution in the corresponding sampling areas, and clustering can achieve good geological results. Graded reserve and sequential advance can clarify the workflow and improve the work efficiency of rare earth mineral resources reserve.

The section structure of this study is as follows: Section 1 introduces the research background and significance and then introduces the main work of this article. Section 2 mainly introduces the related research status of rare earth mineral resources. Section 3 puts forward the specific methods and implementation of this research. Section 4 verifies the superiority and feasibility of this research model. Section 5 is the summary and prospect of the full text.

2. Related Work

2.1. Research on Rare Earth Resources. Rare earth is of great strategic value. With its abundant rare earth resources and cheap production cost, China has achieved the first output, the first application, and the first export in the world rare earth resources. Nassani et al. pointed out that the current supply cost of rare earths is too low, and the supply of rare earths far exceeds the demand, which is an important reason for the low price of rare earths [9]. Li and Peng pointed out that there are some problems in China's rare earth industry, such as waste of resources, environmental pollution, unreasonable product structure, lagging development of end products, and imperfect quota management. They put forward some measures to promote the development of China's rare earth industry, such as strengthening the source control of rare earth, strengthening the research of rare earth application theory, and perfecting quota management [10].

Raharjo et al. think that the government should strengthen the management and protection of rare earth resources, actively guide enterprises to develop into high-end application industries, and increase the economic added value of industries, so as to promote the sustainable development of rare earth industry and improve its competitiveness in the international market [11]. Gromov et al. focused on the storage and exploitation status of rare earth resources. On the basis of the research on the whole rare earth resources, they found that there were some problems in the rare earth industry, such as serious resource waste, severe environmental pollution, and chaotic industry supervision, and put forward some measures to improve the utilization efficiency of rare earth resources and turn the advantages of rare earth resources into economic advantages [12]. Diether et al. thought that the upstream and downstream enterprises of rare earth industry are all self-interested, and the main bodies in the industry chain are in their own way, and there is no sufficient information communication between them, ignoring the government's policy guidance, which leads to the low comprehensive performance of the rare earth industry chain [13]. Zhai et al. studied the important role of rare earth in iron and steel production and pointed out that rare earth elements can improve the shape and distribution of inclusions, refine grains, and then significantly improve the impact toughness, tensile strength, and oxidation resistance of products [14].

2.2. Research on Optimal Allocation of Resources. Optimal allocation of resources is the core topic of economic research, which can be summarized as static allocation and dynamic allocation of resources in terms of methodology. Norregaard et al. studied the optimal utilization of exhaustible resources by a mathematical model and pointed out that if the social value of nonrenewable resources is to be maximized, the price growth rate of the resources should be equal to the discount rate [15]. Chen et al. have made a long-term and in-depth study on the optimal depletion path and capital accumulation of nonrenewable resources [16]. Fu et al. thought that the mining industry is facing many severe sustainability challenges and studied and constructed the indicator system framework of sustainable development of the mining industry, which includes economic, environmental, social, and comprehensive indicators [17]. Liu et al. deeply studied the physical and chemical properties of rare earth elements and discussed the related applications of rare earth elements in catalytic materials, permanent magnet materials, hydrogen storage materials, luminescent materials, and agriculture [18].

Wang et al. systematically summarized the utilization status and broad prospects of rare earth elements in tricolor fluorescent lamps, electroluminescent materials, and fluorescent materials for medical devices. At the same time, they also pointed out that there was still a big gap between the application level of rare earth elements in China and some foreign countries [19]. Shibuya et al. elaborated the process and polishing mechanism of polishing powder, focused on the application fields of polishing powder, and looked forward to the future application of products [20]. Liu et al. thought that the total amount of nonrenewable mineral resources in the crust is a fixed value, but the economically recoverable reserves change dynamically with time. Liu et al. discussed how to use the market mechanism to optimize the allocation of mineral resources under the market economy [21].

3. Research Method

3.1. Rare Earth Mineral Resources Reserve System. The crust is rich in rare earth elements, but they are scattered. As a result, although rare earth elements have vast absolute reserves, there are currently few rare earth minerals that can be used in industrial production, and they are also unevenly distributed around the globe. Whether it is Japan, the European Union, or other major rare earth consumer countries, or the United States, Russia, India, Australia, and other major rare earth producers and consumers, they have recognized the strategic position and importance of rare earth mines, formulated relevant laws and regulations, established a rare earth resource strategy that is appropriate for their own economic development, and made arrangements and arrangements for the production and consumption of rare earths. Many countries' practises in this area have significant reference significance for China's rare earth development and are worthy of in-depth study and enlightenment by relevant Chinese departments and experts in order to improve China's rare earth resource strategy.

Because a large portion of the areas where rare earth resources are reserved are rare earth mining provinces, these areas with rare earth industry as the pillar and local rare earth resources as the main source of fiscal revenue, once the reserve of rare earth resources is implemented, it will reduce the income from resource development in rare earth resources reserve areas, causing local economic backwardness. As a result, it is important to understand how central interests and local interests can be reconciled, taking into account the stark contradiction between rare earth resources and mineral reserves and local development, and ensuring that local economic interests are not jeopardized and social development is stable, which is also a major impediment to China's implementation of strategic rare earth resource reserves.

The research results of optimal allocation and protection zoning of rare earth resources serve the practice of mineral resources planning, which determines the practicability of the research method. It is the working principle of this study to adopt the principle research method that the optimal allocation of empirical rare earth resources should strictly implement the access conditions of technology and environmental protection. China is rich in rare earth resources, and there are great differences in rare earth ore reserves, types, grades, and industrial basic conditions for regional development in different regions. These differences determine the differences in the initial conditions for developing rare earth resources and developing economy in different regions. The analysis and research of these differences can make a scientific evaluation of the resource elements for developing different regions.

The development and utilization of rare earth resources, as well as their optimal allocation and other activities, must be carried out not only in accordance with the characteristics of the resources, the level of regional industrial development, and other factors but also in accordance with a number of constraints. The resource development and utilization constraint index is a negative factor. The greater the impact on resource development, utilization, and allocation, the stronger the constraint. The smooth development of rare earth resources is directly linked to the degree of water security and water cost. The cost of land use in the early stages of resource development, which primarily affects mining areas that have not yet begun construction or large-scale expansion, is known as land resource constraint. The cost of developing rare earth resources or destroying other resources is known as other resource constraints. The cost constraint becomes more severe as the cost rises. The index hierarchy of the evaluation index system is shown in Figure 1.

The geographic location, geometric shape, and reserve information of mineral resources are the key points of mineral resources management [4]. Three-dimensional geological models established by mining software are mainly divided into three categories: exploration engineering database, geological entity model, and reserve block model. Then, based on the standards, the coordination of modeling and design of geological survey and mining is realized, and a unified process and standardized model data are formed. Through the execution management of geological survey production, the sequential and real-time geological survey data can be realized so as to realize the three-dimensional dynamic management of mineral resources reserves. The construction framework is shown in Figure 2.

The digital standard provides the foundation for managing rare earth mineral resources digitally. Mine geological survey digital standards include technological standards, production and operation standards, data standards, and geological survey knowledge base, which involve geological modeling and model updating, reserves estimation and statistics, and actual measurement modeling and statistics. The fine management of the entire process of mineral resources by mines and mining groups can be realized, and the dynamic integrated management of geological exploration reserves, production reserve, mineral production consumption, and resource reserve can be realized by systematically guiding the planning management of mine geological exploration and mining production.

The digitized and informationized technological process of geology, survey, and mining underpins the collaborative platform for geological survey and mining. It can streamline and standardize 3D digital modeling and design by allowing real-time data sharing and collaborative operation on the same platform and environment. Change the traditional technical mode, lowering labour intensity and production costs while increasing technician productivity and quality.

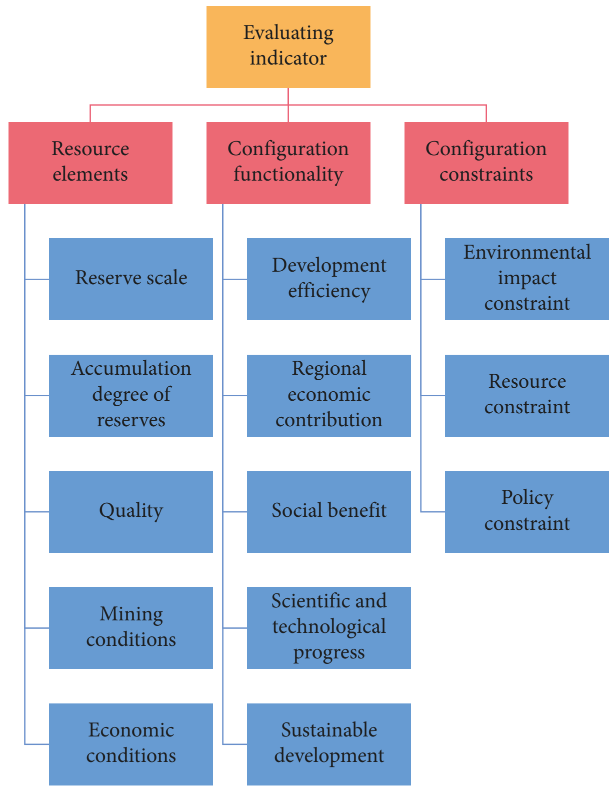

Figure 1: Index hierarchy chart of the evaluation index system.

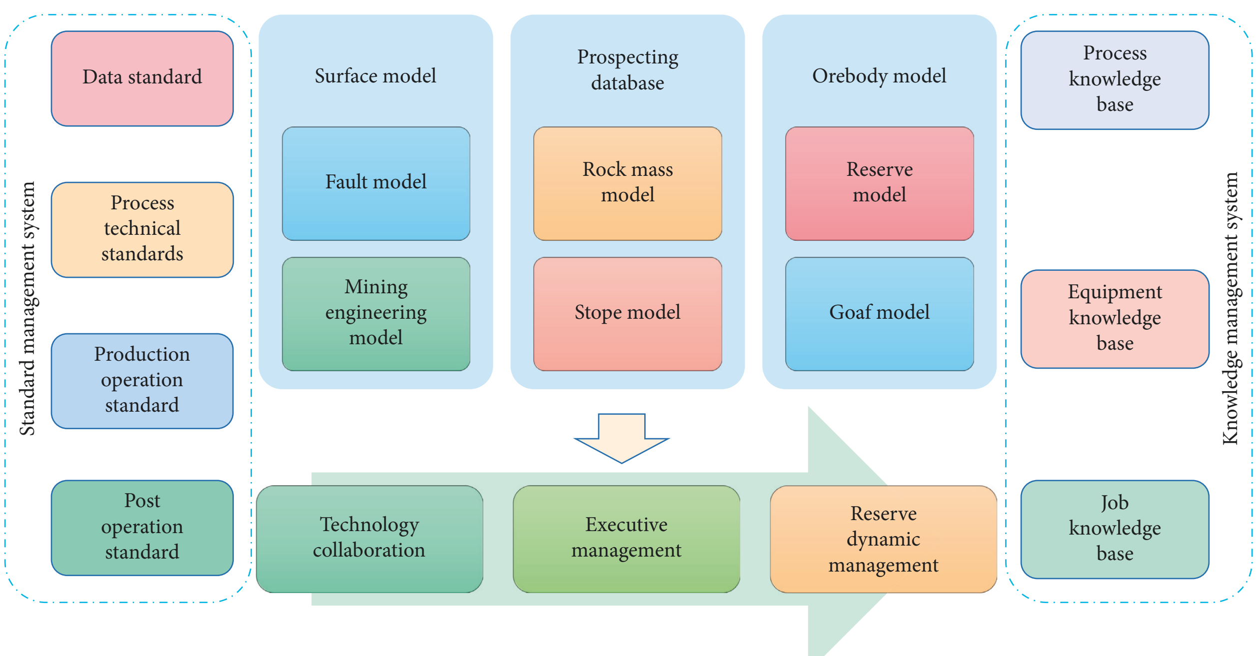

Figure 2: Construction framework of dynamic management of rare earth reserves.

3.2. Classification of Reserve Levels. There are basically two forms of mineral resources reserves in the world: mineral products reserves and mineral resources strategic base reserves. Comparatively speaking, the reserve cost of mineral resources strategic base is low, and the reserve is safe. The disadvantage is that it takes a long period to use, and it has a weak ability to reflect short-term supply interruption and price changes. The reserve cost of mineral products is high and the operation and management are complicated, but its advantage is that it can be put into the market quickly to ensure timely supply.

Mineral resources are strategic base reserves, the object of reserves is the areas that contain or may contain important strategic minerals, and in fact, the reserves are proved reserves or unexplored resources. The operation of other metal mineral resources reserves and the management of mineral resources can also refer to the practice of oil to establish product reserves. It should be noted that it is necessary to select the reserve of mineral resources strategic base, raw material type or product type reserve, or both in combination with specific minerals.

A strategic reserve is the reserve of mineral land to prevent the shortage of resources caused by unexpected events or uncertain factors and ensure the sustainable supply of the mineral resources in China. In order to improve the reliability of T value, the average value of historical survey data of several discovered resource sites is used to express it.

$$T = t_{\text{generalsurvey}} + t_{\text{siftthrough}} + t_{\text{explore}}. \tag{1}$$

Then the reserve scale model of strategic reserve can be established as shown in the following formula:

$$R_1 = \sum_{i=1}^{n} \frac{C_i^1}{\alpha}, \tag{2}$$

where R_1 is the scale of strategic reserve; C_i^1 is the domestic consumption in i year after the reserve starts; α is the comprehensive utilization rate of resources, which is the product of mining recovery rate and mineral processing recovery rate.

Advantage reserve is to prevent the worldwide resource shortage caused by unexpected events or uncertain factors and to ensure the sustainability of the advantage of mineral resources in advantage strategy. It must be emphasized that the reserve can meet the consumption of this mineral in foreign T time, which is not the same as having to meet foreign demand but only as a strategic bargaining chip of the country when resources are in short supply. Therefore, the scale model of the advantageous reserve can be established, as shown in the following formula:

$$R_2 = \sum_{i=1}^{n} \frac{C_i^2}{\alpha}, \tag{3}$$

where R_2 is the advantageous reserve scale; C_i^2 is the consumption of this mineral product in the world except China in i year after the reserve starts; α is the comprehensive utilization rate of resources.

When calculating the volume of ore bodies in blocks, a reasonable calculation formula should be selected according to the geometric shape and relative area ratio of ore bodies in two adjacent sections, and there are usually the following situations.

When the shapes of two adjacent sections are similar and the relative area difference between them is less than 40%, the block volume is calculated by the trapezoidal formula:

$$V = \frac{1}{2} l (S_1 + S_2). \tag{4}$$

When the shapes of two adjacent sections are similar, but the relative difference of their areas is greater than or equal to 40%, the section cone formula is used to calculate the block volume:

$$V = \frac{1}{3} l (S_1 + S_2 + \sqrt{S_1 S_2}). \tag{5}$$

In the above formulas, V is the ore body volume of the block, m^3; l is the distance between two sections, m; $S_1 S_2$ is the area of the ore body on the block in two adjacent sections, m^2.

The ore reserves of ore blocks are equal to the volume of ore blocks multiplied by the average weight of ore, which is calculated by the following formula:

$$Q = VD, \tag{6}$$

where Q is the ore reserve of ore block, t; V is the ore body volume of ore block, m^3; D is the average ore weight of the ore block, and t/m^3. D is replaced with the arithmetic average of the weights of two sections.

3.3. Establishment of the Mathematical Model of Reserve Scale. Rare earth resource reserves cannot be sustained without significant reserve fund investment. The reserve fund is a hybrid of a national reserve fund and a private reserve fund, comprising both the government-backed reserve fund and a large number of privately raised funds. Despite the fact that the gap between China's economic development and that of developed countries around the world is gradually closing, the conditions for rare earth resource reserves are currently met. The author believes that adopting independent legislation for rare earth resource reserves is more appropriate and that China's reserve legislation system will continue to improve as the reserve system is implemented and the economy develops.

SURF (Speeded-Up Robust Features) is a "high robustness" and "high stability" local image feature point detection and matching algorithm, which has few requirements and conditions for image matching. SURF algorithm has been widely used in military reconnaissance, traffic management, face recognition, target detection and tracking, image matching, and many other fields [10].

Assuming a point $p(i, j)$ of an image $f(x, y)$, on the scale σ, the Hessian matrix $H(x, \sigma)$ of this image is defined as follows:

$$H(x, \sigma) = \begin{bmatrix} L_{XX}(X, \sigma) & L_{XY}(X, \sigma) \\ L_{XY}(X, \sigma) & L_{YY}(X, \sigma) \end{bmatrix}. \tag{7}$$

Among them, L_{XX} is the convolution of the second derivative of the Gaussian template and image $f(x, y)$ at point $p(i, j)$. When the local value of the Hessian determinant is the largest, we think that the value we seek is the feature point of the image, and its L_{XX}, L_{YY} is the same.

When SURF calculates the feature point information of the image, a 3D template is used. According to the preset Hessian matrix threshold H, when $h > H$, the points that are larger than the response values of 26 adjacent points are selected as the interest points [12]. Finally, the position of the feature points is accurately determined by interpolation. Figure 3 shows the interpolation diagram.

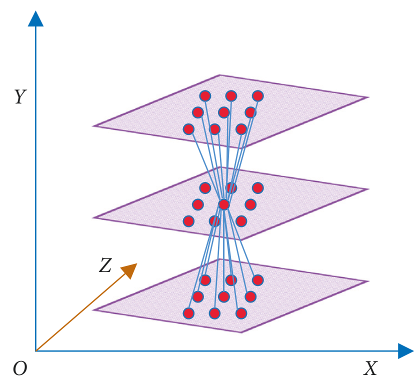

Figure 3: Construct scale space map.

However, the traditional SURF algorithm still has its shortcomings, especially when the algorithm calculates the main direction of feature vectors, it has certain limitations. For example, some images have higher exposure, while others have lower exposure. Therefore, in view of the characteristics and shortcomings of the traditional SURF algorithm in the geoscience field, this article optimizes and improves the matching of mine DEM (digital elevation model).

In this matching work, the edge of the image is protected by using the advantages of the bilateral filter. At the same time, the filter filters out a large amount of image noise, which avoids the result of matching failure caused by multisource and multitemporal imaging methods. The following is the mathematical expression of the bilateral filtering method:

$$H_{BL}(I_x) = \frac{1}{W_X} \sum_{y \in s} G\sigma_d(\|x-y\|) G\sigma_\gamma(I_x - I_y) I_y. \quad (8)$$

Among them,

$$W_X = \sum_{y \in s} G\sigma_d(\|x-y\|) G\sigma_\gamma(I_x - I_y). \quad (9)$$

K-means is a commonly used partition-based clustering method [22], which is used to group samples according to the similarity between sample attribute values. *K*-means is regarded as an unsupervised classification method. The basic idea is to divide the data set into K classes, and the samples in each class are very similar, but the samples in different classes are very different.

In each iteration of the algorithm, each sample is assigned to the class represented by the nearest centroid. The distance is expressed by the square of Euclidean distance, so the distance from sample i to centroid j is as follows:

$$d_{ij} = \|X_i - C_j\|^2 = \sum_{q=1}^{Q} (X_{qi} - C_{qi})^2, \quad (10)$$

where X_i is the vector composed of attribute values of sample i, C_j is the centroid vector of class j, Q is the number of attributes, X_{qi} is the q attribute value of the i th sample, and C_{qi} is the q attribute value of the centroid of class j.

For each sample, calculate its distance from each centroid. The record is assigned to the class whose centroid is closest to the record. In this process, a sample may be transferred from one class to another.

Taking geochemical sampling points as data objects, geochemical elements of sampling points as attributes, and element analysis results as attribute values, K-means is used for clustering analysis. Get the category characteristics of each sample and the average value and standard deviation of each category. The purpose of cluster analysis is to study the distribution characteristics and laws of regional geochemical elements and find meaningful resource targets.

When $K = 7$, the correlation analysis is carried out on the data of one area, and the correlation coefficients among 25 groups of element samples are obtained. After $r < 0.3$, the elements are connected with each other, and no research is done. Generate the correlation analysis linear graph, as shown in Figure 4.

There is a certain gap in the correlation results due to the difference in the five correlation data of k as 7,8,9,10, and 11. We take the correlation analysis results that have the same majority; that is, La is related to Pr, Nd is related to Pm, Eu is related to Gd, Tb, and Er is related to Y.

4. Result Analysis

Taking a rare earth mine as an example, this article introduces how to use the parallel section method to estimate resource reserves in DIMINE software. DIMINE software can calculate the mine reserves and then calculate the mine metal quantity according to the average grade of each block. In this article, the calculation data of four blocks are selected and calculated by the traditional reserve estimation method and the parallel section method, respectively. The calculation results are given in Table 1. The calculation results of the two methods are analyzed and compared, and the comparison results are given in Table 2.

The results of the calculations show that the maximum relative error between the parallel section method and the traditional method is 2.6 percent, which meets the requirements for mineral reserve calculation accuracy and can be used to calculate reserves. This demonstrates that the parallel section method can be used to estimate mine reserves. This method improves not only the working efficiency of reserves estimation but also the visual analysis degree of reserves estimation to some extent.

Based on the output data of ionic rare earths, we choose the annual data with a good linear relationship and use the linear trial and error method to calculate and predict the future output of mixed rare earths. The forecast results show that the peak output of ionic rare earths in China will appear in 2024, with a peak output of 46,797.06 tons, and then it will decrease at an average annual rate of 4% (Figure 5).

Rare earth is the general name of a group of elements, including La, Ce, Pr, and Nd, which mostly occur in the form of rare earth oxides. Due to the differences in the electronic layer structure and physical and chemical properties of each element atom, the application fields of different elements are also different. From the forecast results, the oxides of each element show different growth trends and peak output (Figure 6).

Table 2: Comparative analysis of block reserves calculation.

Block	Traditional method	Parallel section method	Contrast (%)
A1-21	8736.21	8512.71	2.6
A2-22	5886.01	6003.87	2
A3-23	996.27	1022.41	2.6
A4-24	7896.62	8201.93	3.9

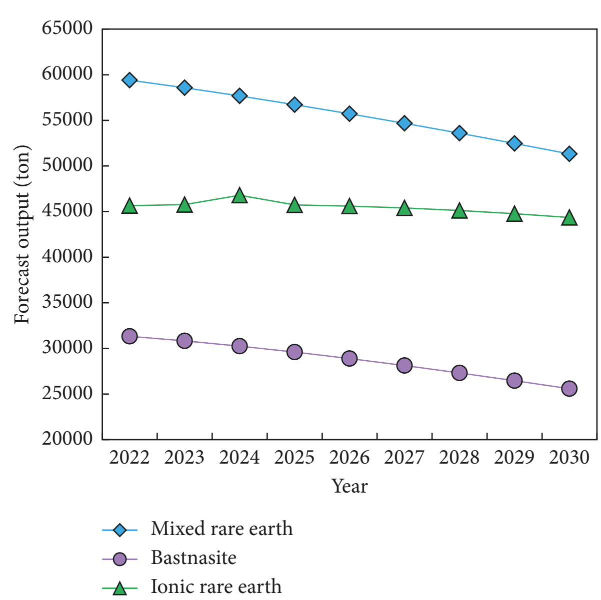

Figure 5: Prediction of rare earth ore yield.

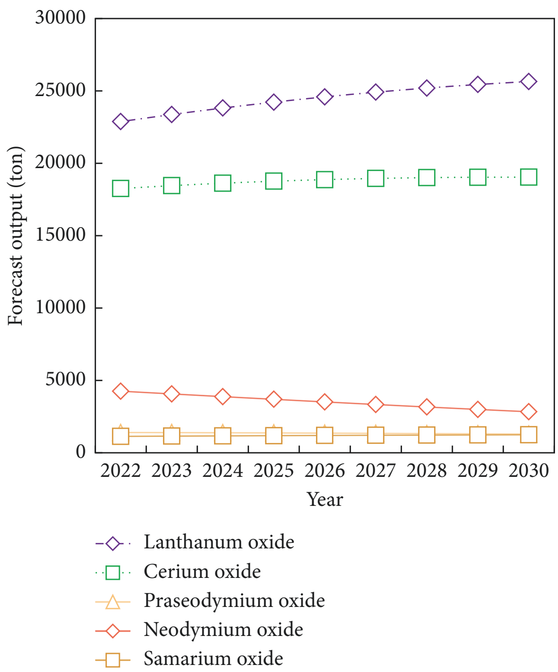

Figure 6: Output prediction of each element oxide.

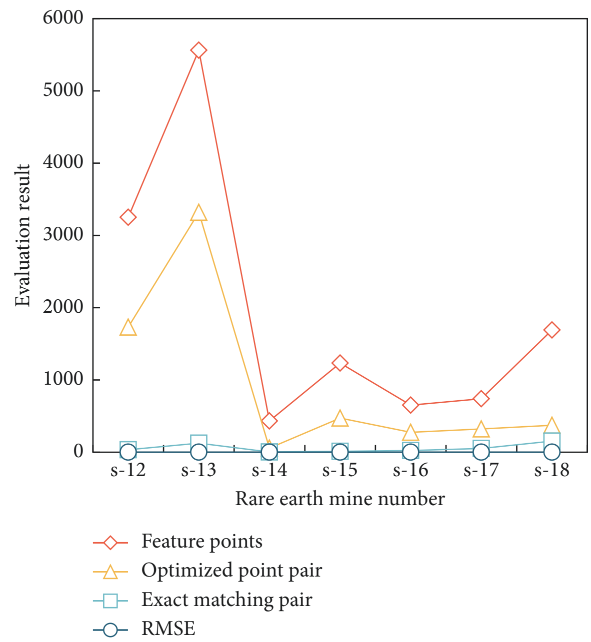

Figure 7: Verification result of the mine positioning effect.

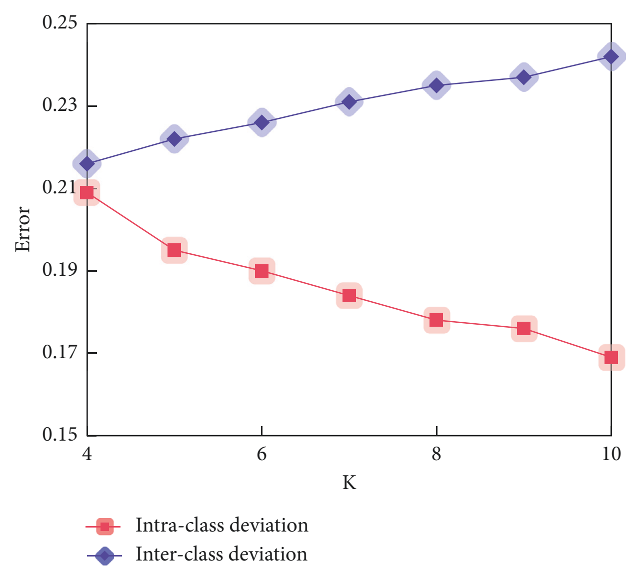

Figure 8: Class deviation comparison.

Mixed rare earth and bastnaesite output has reached or will soon reach a peak, owing to the fact that the minerals containing light rare earth are primarily mixed rare earth and bastnaesite, whereas ionic rare earth output is steadily increasing. It is because only ion adsorption minerals and xenotime contain heavy rare earths, and they are mostly concentrated in southern China. As a result, the world's heavy rare earths (such as terbium, erbium, dysprosium, and yttrium) are primarily supplied by ion adsorption rare earth mines in southern China, and this pattern cannot be significantly improved in a short period of time, and China retains its monopoly advantage.

In order to verify the practicability of the SURF algorithm in mine spatial location determination, this article designed a verification test to verify the robustness of the algorithm. We used several rare earth mines as experimental objects and carried out matching experiments from different angles. The verification results of the mine positioning effect are shown in Figure 7.

As can be seen from Figure 7, only one of the seven different types of mines selected from the database under different geological conditions failed to identify their spatial positions, and the other six mines could identify the feature points to be matched with high accuracy. We began to study when k took 3, and the research value below 3 was not significant. The value of K determines how many sampling points (data objects) we classify. The purpose of choosing different K values is to analyze the stability and reliability of clustering results. The quality report generated by $K = 4 \sim 10$ is shown in Figures 8–10.

The red background area in the class similarity report indicates that the similarities between classes are very close, the yellow background area indicates that the similarities between classes are not far or near, and the green background area indicates that the similarities between classes are far. The clustering segmentation is considered strict when most or all of the background colours are green, and the clustering effect is excellent because there is sufficient separation between classes. The absence of a red background indicates that the clustering result is satisfactory. When K is greater than 10, although the intraclass deviation is small, the interclass deviation is large. However, the red and yellow background increased, while the green background decreased. It shows that the clustering effect begins to decline. Therefore, in this topic, we only study the K-means clustering analysis with K from 4 to 9. The clustering effect is better according to the summary of the quality report generated by clustering. It

conforms to the basic idea of clustering: make the similarity of samples within the class as large as possible and the similarity of samples between classes as small as possible.

5. Conclusion

Due to their unique physical and chemical properties, rare earths are widely used in national economic development, national defence, and military construction. This article analyzes the current situation and existing problems of rare earth resources development and utilization in China and constructs a rare earth mineral resources reserve system based on research on the construction of rare earth mineral resources reserve system and model based on regional development. The reserves of rare earth mineral resources are divided into different levels of mineral reserves, including strategic reserves, dominant reserves, and controlled reserves, according to different levels of strategic objectives, and corresponding mathematical models of reserves scale are established for strategic reserves and dominant reserves. The maximum relative error between the parallel profile method and the traditional method is 2.6 percent, which meets the precision requirement of mineral reserve calculations and can be used to calculate reserves. China's peak ionic rare earth output will be 46,797.06 tonnes in 2024, and then, it will decline at a 4% annual rate thereafter. The stratigraphic lithology distribution in the corresponding sampling areas has a corresponding relationship with the K-means clustering results of geochemical sampling points. Clustering has the potential to improve geological effect and geochemical exploration efficiency.

Multisource information mining systems and related business intelligence technology are currently a hot topic of research. However, the current commercial applications and applications are not ideal in terms of application. Because there is still much work to be done before decision support, it is best to transition to them only financially. This paper examines the multisource part of the information used in mining and introduces research hotspots in the fields of accounting informatization, the development status of intelligent financial analysis software, the research and application status of data warehouse, data mining, and decision support systems. This paper examines the specific composition and content of a financial information system using information mining to lay a solid foundation. Financial intelligent analysis, financial intelligent monitoring, financial intelligent decision-making, and financial intelligent early warning are the four parts of the financial intelligent system. It then examined the structure and processing of the financial intelligence system and proposed a financial intelligence system operation strategy. Financial intelligence low-risk integrated implementation strategies and ideal financial intelligence models, according to the current state of research and practical applications. According to the findings, the overall discrimination accuracy of the financial information system based on mining multisource information features is up to 95%, which is 42% higher than the traditional model. The development and use of financial information benefit from the realization and exploration of the financial intelligence system model.

1. Introduction

Industrialization, processization, and decision-making are the three stages of the development of an information system. Financial records can neither fully reflect the work level and needs of modern network technology and enterprise records nor they fully cover their important content, due to the rapid development of network information technology. Communication will consider not only the use of information technology but also its financial impact on the company. It differs from traditional records and computer people who are only interested in technology or dealing with a specific machine component. A financial decision support system (FDSS) is a computer-assisted decision-making process that assists industry –decision makers in obtaining relevant data. Small-scale processing and financial management models, for example, have a relatively poor financial status in terms of economic management. Intelligent financial systems are popularizing China's accounting information system at the same time. The system's benefit is that it can display and provide information about business efficiency. ERP business management software also has a business intelligence application. From a difficult decision to a scientific one, the decision-making process has evolved. Financial information, sales information, purchasing information, and production information are all covered by business intelligence, which brings financial business information to the world of financial software. Financial information includes the ability to identify short-term solutions to complex problems, the ability to test the impact of various strategies, the ability to test new ideas and insights, good management skills, low costs, and the ability to make objective and important decisions. The audit and execution of financial information will become the focus of financial statement auditing and execution under the guidance of this system.

As an important branch of data analysis in the computer field, machine learning mainly analyzes data, mines potential laws, and uses laws to predict unknown samples, that is, to discover and count useful information, knowledge, and even wisdom from data. As an interdisciplinary field, machine learning mainly includes ensemble learning, semi-supervised learning, transfer learning, and rule learning. Among them, rule learning, as a research method of knowledge discovery in the field of machine learning, mines hidden patterns or rules with practical significance from data. For classification problems, rule learning is often used to make judgments about the class labels of unknown samples. Classification-oriented rule learning methods have been widely used in various practical application fields. For example, in the structural information prediction of biological proteins, the function of protein structure can be predicted by using rule learning. In judging the type of mechanical failure, it is possible to determine what kind of failure the machine has by learning the rules. This paper uses the method of multisource information mining features to design and implement the construction of financial function system.

First, research the inevitable development process required to support future computing, financial intelligence, with specific and long-term goals in mind, such as creating a platform for account computing and business intelligence, as well as ample space for follow-up. Second, it is through the promotion and implementation of intelligent financial analysis systems, such as cabin management, electronic reporting, and clear tables, which is exactly what is required for statistics and is also a key factor for accountants that education will gradually transform. Third, from the standpoint of businesses, research ideas guide the employment transformation of financial practitioners while also using computers to collaborate, so that financial practitioners can lead financial practitioners into the information age.

2. Related Work

In the construction and realization of the financial intelligence system, many experts at home and abroad have done the research. Zhang W believed that the intelligent financial system can improve the utilization rate of data, improve the work efficiency of financial personnel, and increase the security of financial processing services. The system can help managers make important financial decisions, financial budgets, etc. [1]. *D* Aikman et al. provided a framework for assessing the accumulation of vulnerabilities in the financial system. They collected 46 indicators of financial and balance sheet health, covering valuation pressures, nonfinancial borrowing, and measures of financial sector health [2]. Prochniak M et al.'s study aimed to analyze the impact of the development and stabilization of the financial sector on economic growth based on quantitative methods that yield robust results. It is tested that the relationship between the development of the financial sector and economic growth is nonlinear [3]. Polzin F et al. believed that diversification makes financial systems more resilient. Furthermore, the transition to a more sustainable energy system presents diverse financial investment needs [4].

However, the traditional financial system construction is not perfect, and there are many shortcomings, so in the experiment, the paper uses the method of multisource information feature mining to construct the functional financial system. Han *Z* et al. proposed a method to identify key assembly structures in assembly models from the perspective of assembly topology and multisource properties. The assembly model is based on complex network representation, and a two-level evaluation model is proposed to evaluate the importance of assembly parts [5]. *X* Gao et al. believed that the Dempster–Shafer theory has inestimable value in dealing with uncertainties in the field of multisource information fusion, but how to fuse highly conflicting information is still an open question [6]. Wu B et al.'s research proposed a multisource information fusion method combining cloud model, support vector machine, and evidence-based reasoning. In the data processing stage, various information sources are trained through different models to analyze financial value at risk [7]. Wu Y et al. believed that the multisource information fusion model consists of three heterogeneous meta-learning machines, namely, neural network, support vector machine, and random forest, and the final metaspectrum can be obtained by executing the final decision method [8]. However, the above data have not been recognized by the public because the experimental process is not rigorous enough.

3. Multisource Data Mining Source Ensemble Learning Method

In reality, many application fields [9, 10] are faced with multisource data sources, and the structure information of data sources is inconsistent; that is, data sources are divided into two categories: labeled data sources and unlabeled data sources. Therefore, it is difficult to traditionally integrate multiple data sources directly into a single data source for learning. Based on this, the research makes full use of the label information of the labeled data source and the internal structure information of the unlabeled data source, proposes two label propagation methods to make the unlabeled data source have class labels, and then constructs an ensemble learning method of multiple data sources. The experimental results showed that compared with the two traditional classification algorithms [11], the multiheterogeneous data source ensemble learning method based on label propagation has higher classification accuracy, better robustness, and stronger scalability. In addition, when the number of unlabeled data sources is large, the local consistent label propagation method is better than the global consistent label propagation method.

Multisource data source ensemble learning is essentially a multiclassifier system in which subclassifiers are trained by local data sources. Figure 1 shows the integrated learning framework of multisource data sources. The main ideas are given as multiple data sources; based on label propagation to

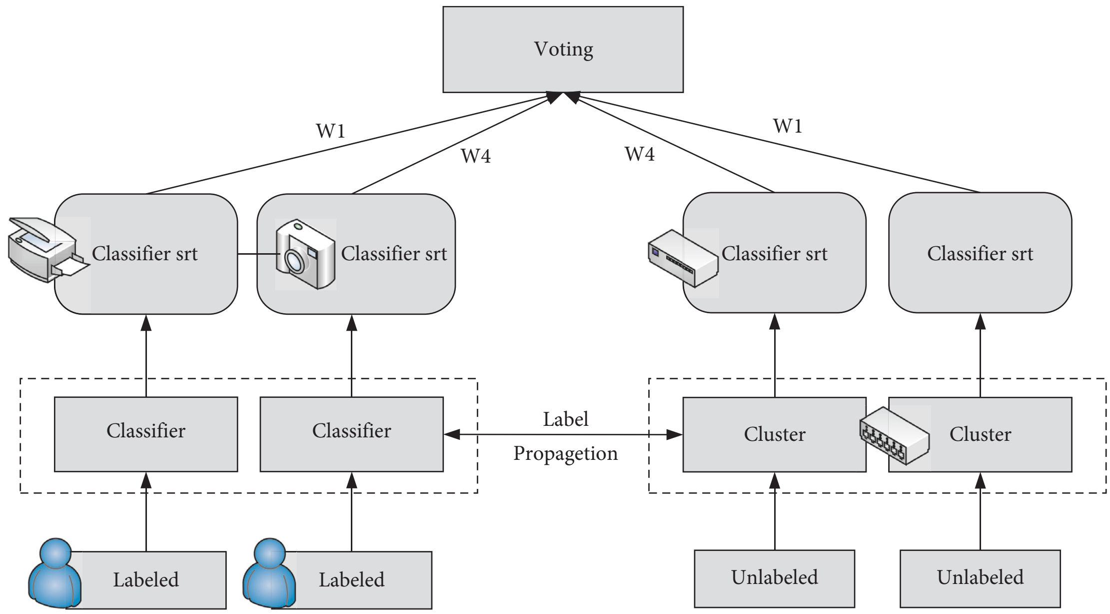

Figure 1: An ensemble learning framework for multisource data sources.

make unlabeled data sources have labels, a base classifier is obtained by training each local data source, and the result pair distribution of the multibase classifier is fused, which tests the classification results of samples in different data sources as the final prediction results. Based on the ensemble learning framework for obtaining multisource data sources, the following will introduce the two label propagation methods of global consistency and local consistency in detail and point out that these two label propagation methods are mutually replaceable.

The research provides a multisource information system composed of multiple data sources. First, the sampling range is computed at each local data source to obtain a set of local decision rules [12]. Second, the rules are constrained by certain local decision-making standards; local decision-making standards that do not meet the minimum coverage are removed, and selection is made according to the minimum coverage. Third, the votes for each rule are counted in all local decision documents, and some rules for candidate decision voting include the global coverage and global average coverage of candidate decision rules [13]. Finally, the decision rules that do not meet the world average are excluded from the decision-making rules set by the high-voted candidates, and all the decision-making rules that get high votes are combined. The specific algorithm flow is shown in Figure 2.

3.1. Using Weights to Synthesize Decision Rules. Given a multisource decision information system, neighborhood granulation is used to extract decision rules from each local data source, and these decision rules are, respectively, forwarded to the corresponding knowledge base. Meanwhile, the decision rules in the knowledge base are called local decision rules. Finally, all local decision rules are synthesized to solve the global decision rules [14]. In order to synthesize global decision rules from multiple knowledge bases, the weight of each data source is obtained by learning, and the weight is used to infer the neighborhood size of each global decision rule. Figure 3 presents the framework of a multisource decision rule synthesis model [15]. The traditional multidata source learning algorithm concentrates the data from all data sources into a unified data source for processing, which will lead to problems such as large data volume, data privacy leakage, and high transmission cost. Compared with traditional methods, the method using the weight synthesis model can effectively avoid these problems, thus providing a new feasible technique for multi-information source knowledge discovery [16].

3.2. Integration Model. Different data sources can provide descriptive information from different perspectives of the sample set, so the integrated learning model can be built directly on the multisource information system. To build an ensemble model on multiple heterogeneous data sources, on the basis of label propagation through global consistency or local consistency, all data sources describing the training sample set have class labels [17]. Among them, Figure 4 shows the label propagation algorithm based on global consensus.

3.3. Dataset and Its Statistics. This study introduces two real-world datasets used to evaluate recommendation performance, including their preprocessing and simple statistics on the datasets. Then, the evaluation metrics and evaluation protocol of recommendation performance are given. It is evaluated on two datasets: Epinions and Ciao [18]. Users can rate items, trust relationships can be established between users, and users can express their opinions on products and write review texts. First, it needs to eliminate stop words, and then, select the first $L = 8000$ words by word frequency as

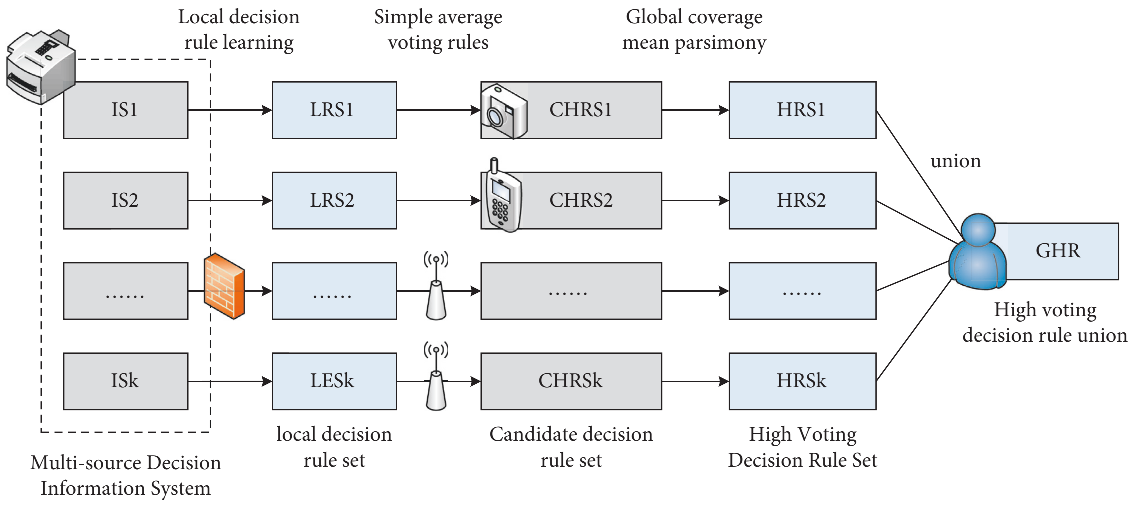

Figure 2: The mining process of high-voting decision rules in multisource information systems.

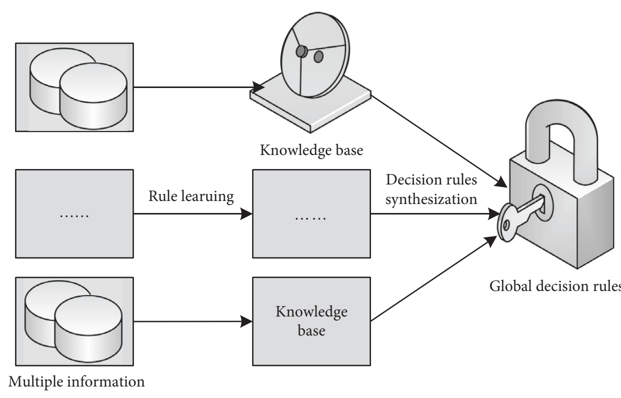

Figure 3: Decision rule synthesis model in multisource information system.

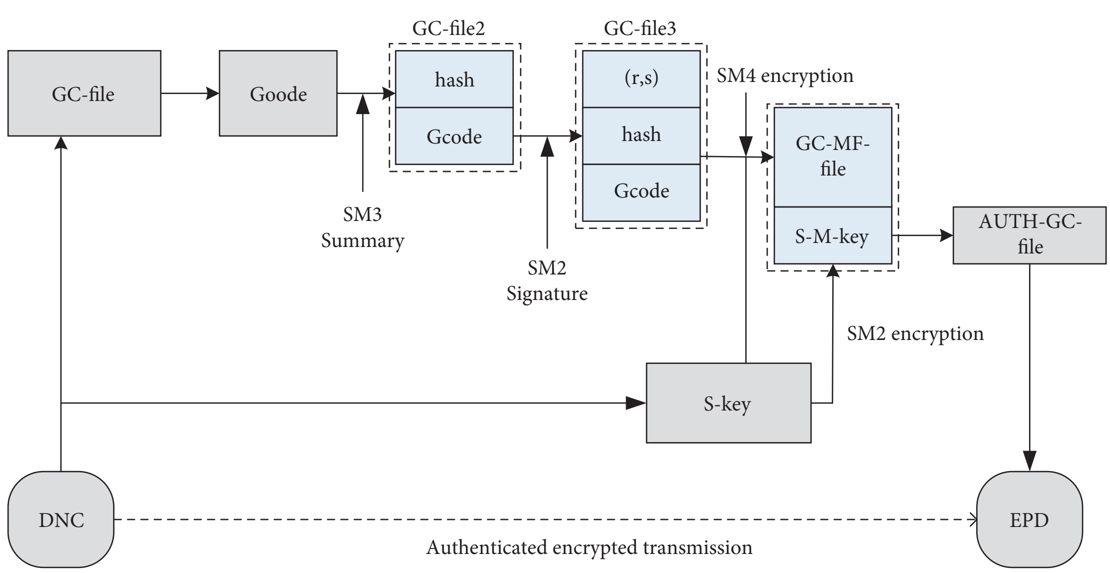

Figure 4: ELMG algorithm framework.

vocabulary. To reduce noise and errors, it keeps only users who clicked on at least 4 items and deletes those users with only 1 or 2 points [19]. The item index in the rating matrix corresponds to the document index of the document matrix in the review repository, that is, combining all user reviews of an item into the total reviews of an item [20]. The final statistics are shown in Table 1.

It can be found that the scores on both datasets are very sparse, and the average length of documents on the Epinions dataset is very short. The average number of comment words contained in each item on the Ciao dataset is 42 times that of Epinions, and Ciao's social relationship density is 12 times that of Epinions. Therefore, the additional data sources are included in the Ciao dataset; information reviews and social information are richer and of higher quality, and they can be expected to have a greater impact on the final recommendation performance. This observation is consistent with previously obtained quantitative assessments. A more compact use of scoring information and social information, that is, capturing social influence with a neighbor graph structure through trust values, can improve the RMSE prediction performance on both datasets. For example, compared to the LOCABAL model, the eSMF model has a relative RMSE performance improvement of 1.18%, 0.89%, and 0.72% when the Epinions training set accounts for 20%, 50%, and 70%, respectively, as shown in Figure 5.

3.4. Evaluating the Multisource Information Fusion Model. Mean: this method uses the mean of the scores in the entire training set to predict, which is the term μ in the formula. This method is the best constant prediction under the RMSE metric [21]:

$$\widehat{R}_{u,i} = \mu + b_u + b_i + P_u^T Q_i. \tag{1}$$

In this method, PMF decomposes the scoring matrix to learn user and item feature vectors, as shown in the formula. It is a representative method of hidden factor collaborative filtering, which only utilizes the scoring data source:

$$\min_{P,Q} \sum_{Ru,i\neq 0} \left(R_{u,i} - \widehat{R}_{u,i}\right)^2 + \lambda\left(\|P\|_F^2 + \|Q\|_F^2\right). \tag{2}$$

The LOCABAL method is based on matrix factorization, exploiting both social local and global context, as shown in Equations 3–6. It is a representative method of the social matrix decomposition method, which only utilizes the scoring data source and social information:

$$\min_{P,Q,H} \sum_{Ru,i=0} \left(R_{u,i} - \widehat{R}_{u,i}\right), \tag{3}$$

$$\lambda_{rel} \sum_{T_{u,u\neq 0}} \left(S_{u,v} - P_u^T H P_v\right)^2 + \lambda_{\text{norm}} \Omega(\Theta). \tag{4}$$

HFT hidden topics are learned from reviews, as shown in the formula. It is a representative method of the topic matrix factorization method, which only utilizes the scoring data source and comment text information. The RMSE comparison results are shown in Table 2.

$$\min_{P,Q,\Phi} \sum_{Ru,i\neq 0} \left(R_{u,i} - \widehat{R}_{u,i}\right)^2, \tag{5}$$

$$\lambda_{rev} \sum_{d-1}^{N} \sum_{n\in Nd} \left(\log \theta_{zd,n} + \log \varphi_{zd,n,wd,n}\right). \tag{6}$$

The data have shown that eliminating all auxiliary data sources MR3/content/social from the fusion model MR3 results in a 7.99% decrease in the overall relative RMSE, and the study wanted to know how the additional data sources helped the MR3 model improve its predictive performance. The problem can be examined from the richness of review data and social information. Figure 6 shows the prediction performance of MR3 and its S components.

For the first time, this paper proposes the MR3 fusion model, which can use multiple recommendation data sources at the same time. Unlike other fusion models, both components used are tried and true techniques. Simultaneously, an efficient extended social recommendation model, eSMR, is obtained, and the efficiency of the two proposed models has been verified on two large-scale datasets, indicating that recommendation performance can be improved further by using the neighbor graph structure and adding additional data sources. We will discuss how to extend the fusion model MR3, which mines implicit feedback information from scoring data sources, in order to delve deeper into the limited recommendation data sources. The fusion model and the extended fusion model both mine implicit feedback, and their model parameter learning processes are similar. Figure 7 shows the multisource information mining performance prediction.

3.5. Evaluation and Selection Methods of Information Source Quality. Multi-information sources refer to providing description information from multiple perspectives for the same sample set. First of all, it is pointed out that importance and redundancy are two important factors for evaluating the quality of information sources. Among them, the degree of importance represents the contribution of one information source to the classification, and the degree of redundancy represents the degree of overlap of the available information in different information sources. Second, a metric is devised using mutual-neighborhood information to assess quality and select information sources with the highest importance and least redundancy. Experimental results show that the metric is useful for finding a range of task-relevant information sources and outperforms many commonly used methods. Given a random variable, the entropy of A is defined as follows:

$$H(A) = -\sum_{i=1}^{n} p(a_i)\log(a_i), \tag{7}$$

$$H(A,B) = -\sum_{i=1}^{n}\sum_{j=1}^{m} p\left(a_i,b_j\right)\log\, p\left(a_i,b_j\right), \tag{8}$$

Table 1: Dataset statistics.

Statistics	Epinions	Ciao	Notes
User number	49454	7340	56794
Number of items	74154	22472	96626
Ratings/comments	790940	183947	974914

Social density	0.00018	0.0021	N/A
Average number of words per item	30.3	1284.9	N/A
Average number of relationships per user	8.78	15.38	N/A

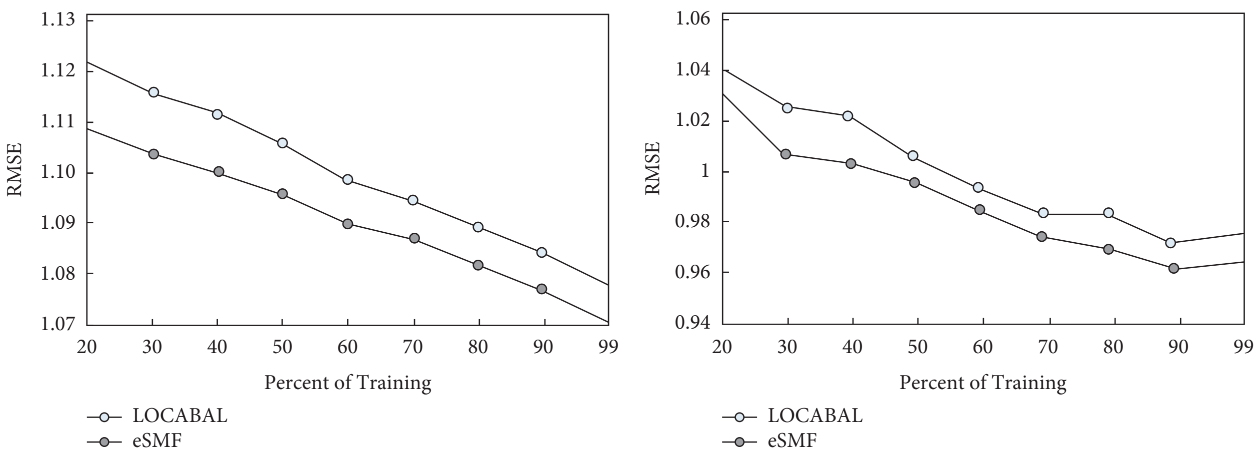

Figure 5: Comparison of the eSMF model with a standard social matrix decomposition model LOCABAL.

Table 2: RMSE comparison of fusion model MR3 and different methods.

Datasets	Training (%)	Methods				
		Mean	PMF	HFT	LOCABAL	MR3
Epinions	20	1.2265	1.2001	1.1857	1.1222	1.1051
	50	1.2239	1.1604	1.1323	1.1055	1.0809
	80	1.2225	1.1502	1.0960	1.0892	1.0648
	90	1.2187	1.1484	1.0867	1.0840	1.0634
Ciao	20	1.1095	1.0877	1.0439	1.0287	1.0142
	50	1.0964	1.0536	1.0379	0.9930	0.9740
	80	1.0899	1.0418	0.9958	0.9709	0.9521
	90	1.0841	1.0391	0.9644	0.9587	0.9451
Average						

$$H(A|B) = H(A,B) - H(B) = -\sum_{i=1}^{n}\sum_{i=1}^{m} p\left(a_i,b_j\right)\log\, p\left(a_i \mid b_j\right). \tag{9}$$

Given A and B, the mutual information between A and B is

$$MI(A;B) = -\sum_{i=1}^{n}\sum_{j=1}^{m} p\left(a_i,b_j\right)\log\frac{p\left(a_i \mid b_j\right)}{p\left(b_j\right)}. \tag{10}$$

To describe the numerical or discrete feature set F, the neighborhood of sample x on f is defined as f(x), so the uncertainty of the example in this field is defined as follows:

$$NH_{xi}^{\delta} = -\log\frac{\left\|\delta_f\left(x_i\right)\right\|}{n}, \tag{11}$$

$$NH^{\delta}(f) = -\frac{1}{n}\sum_{i=1}^{n}\log\frac{\left\|\delta_f\left(x_i\right)\right\|}{n}. \tag{12}$$

Suppose r and f are two self-feature sets. The conditional neighborhood entropy of r with respect to f can be defined as follows:

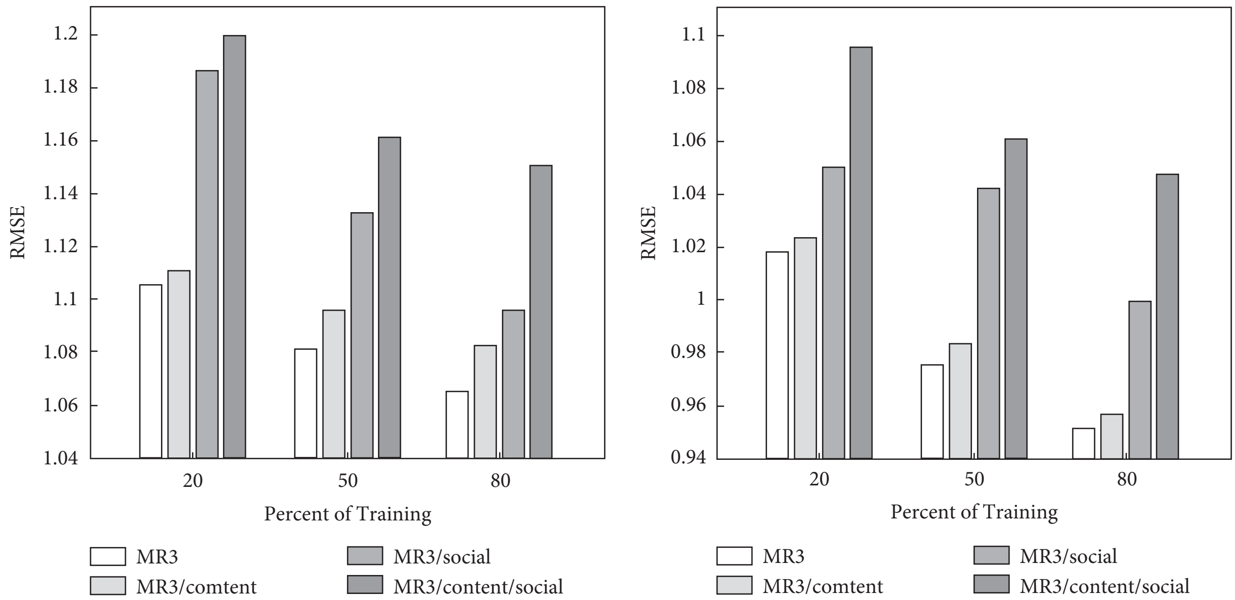

Figure 6: Prediction performance of fusion model MR3 and its S components.

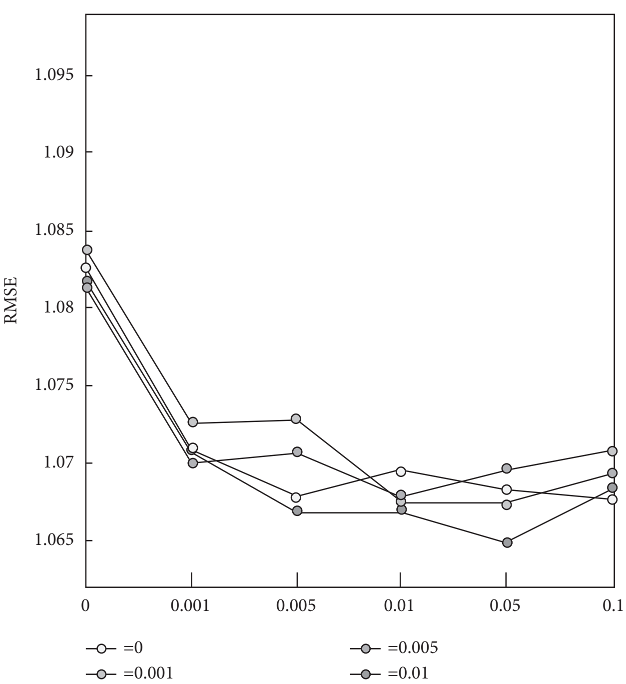

Figure 7: Prediction performance of fusion model MR3.

$$NH^{\delta}(r,f) = -\frac{1}{n}\sum_{i=1}^{n}\log\frac{\left\|\delta_{f\cup r}(x_i)\right\|}{n}, \tag{13}$$

$$NH^{\delta}(r,c) = -\frac{1}{n}\sum_{i=1}^{n}\log\frac{\left\|\delta_{r\cup c}(x_i)\right\|}{n}, \tag{14}$$

$$NH^{\delta}(r\mid f) = -\frac{1}{n}\sum_{i=1}^{n}\log\frac{\left\|\delta_{r\cup f}(x_i)\right\|}{\left\|\delta_{f}(x_i)\right\|}, \tag{15}$$

$$NMI^{\delta}(r;f) = -\frac{1}{n}\sum_{i=1}^{n}\log\frac{\left\|\delta_{r}(x_i)\right\|\bullet\left\|\delta_{f}(x_i)\right\|}{n\left\|\delta_{r\cup f}(x_i)\right\|}. \tag{16}$$

In the process of information source selection in a multisource environment, a set of information sources with the greatest contribution to the classification is selected first. Usually, the selection process of information sources is based on the magnitude of importance. Therefore, the formula for selecting according to the importance of the information source is

$$SU(f_1;f_2) = 2\left[\frac{MI(f_1;f_2)}{H(f_1)+H(f_2)}\right], \tag{17}$$

$$NSU^{\delta}(f_1;f_2) = 2\left[\frac{NMI^{\delta}(f_1;f_2)}{H^{\delta}(f_1)+H^{\delta}(f_2)}\right], \tag{18}$$

$$TSU^{\delta}(F;c) = \frac{nNSU^{\delta}_{cf}}{\sqrt{n+n(n-1)NSU^{\delta}_{ff}}}, \tag{19}$$

$$\max\ D(S,c),\ D = \frac{1}{|S|}\sum_{si,\notin S} TSU^{\delta}(s_i;c). \tag{20}$$

In addition, ten-fold cross-validation method and ensemble learning based on majority voting are used to verify the classification ability of the proposed algorithm; that is, for each dataset, one hundred information sources are generated ten times, and ensemble learning is performed based on multiple information sources each time to obtain classification accuracy. Then, the average of the ten running results is used as the final classification accuracy. In addition, the threshold of the neighborhood is set to 0.01 and the class label of each information source is consistent with the class label of the original dataset, as shown in Table 3.

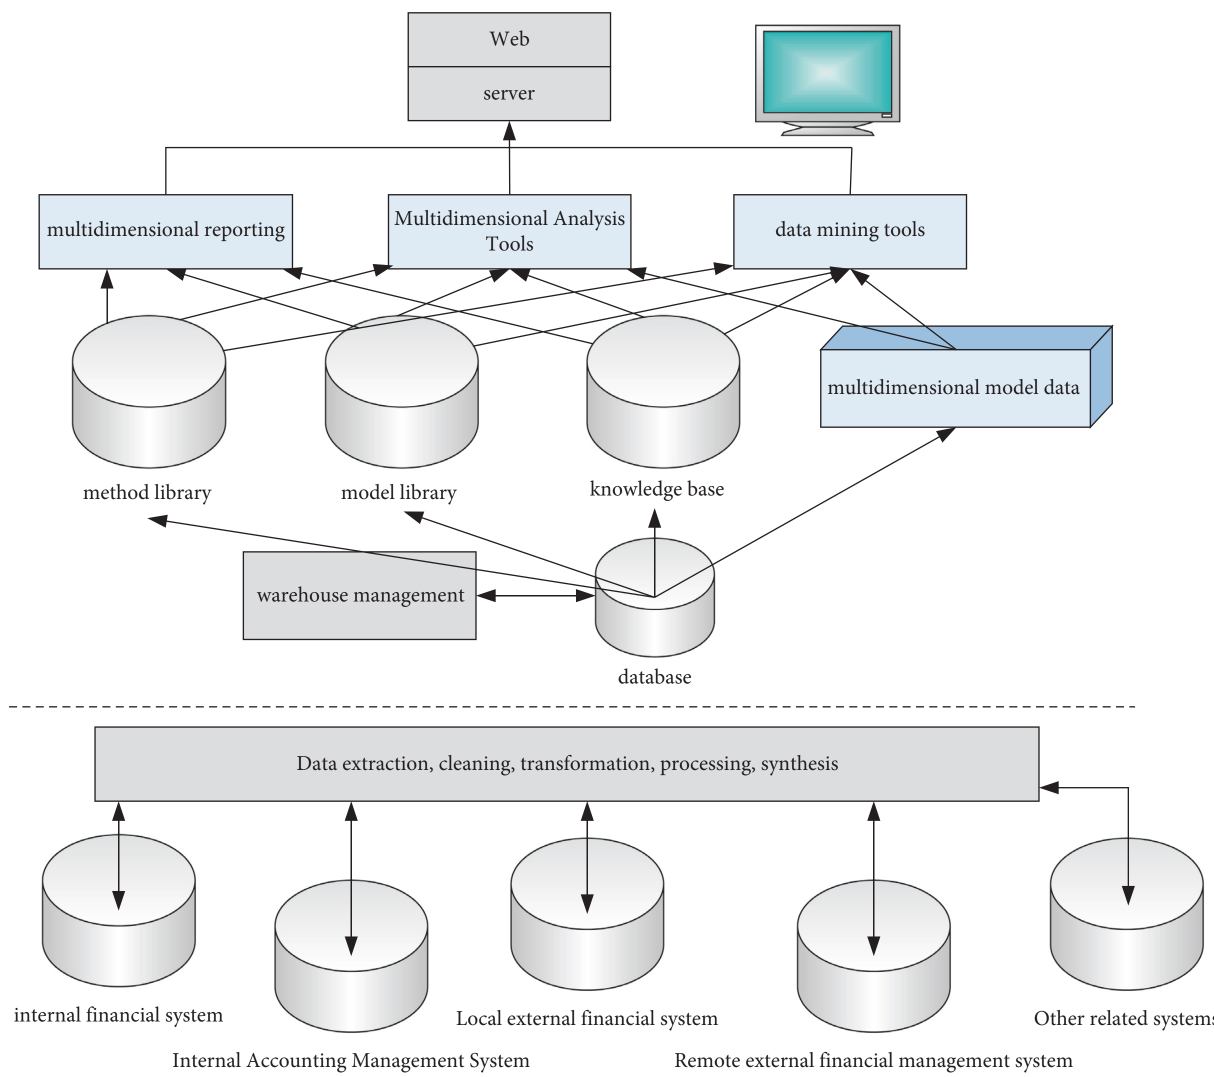

Figure 8: Financial intelligence system.

4. Financial Intelligence System Architecture and Implementation Strategy

The overall architecture of the financial intelligence system is divided into three layers, the data acquisition layer, the data organization storage organization layer, and the data analysis display layer, as shown in Figure 8.

Data are extracted from the original business processing system by the data acquisition layer. Internal financial system, internal accounting management system, local external financial system, remote external financial system, and so on are all included. The financial data are loaded into the data warehouse, and the material data are prepared for the construction of the next analysis model, thanks to data extraction, cleaning, conversion processing, and comprehensive improvement. The data organization and storage layer, which includes the data warehouse, is a platform for organizing and storing data retrieved from the data source after ETL. ETL tools are used to extract, clean, update, process, and synthesize source data to create a comprehensive statistical element library. The data layer of each granularity is an enterprise-level global data repository established according to the needs of subject analysis, and it includes detailed level, light integration level, medium level, and high level integration. Because the data warehouse is different from a traditional database, its management is also different. The data warehouse serves as the foundation for the method base, model base, knowledge base, and multidimensional analysis model base. The method library provides data mining and data analysis method guidance. Concrete models are available in the model library. The knowledge base converts data and information into knowledge by processing the results of data mining and data analysis. The purpose of the multidimensional analysis model library is to keep a hierarchical analysis model of commonly used dimensions and to answer complex analysis questions quickly. Multidimensional reporting, multidimensional analysis, and data mining tools, as well as interactive imaging and data drilling technology, are used in the data analysis display layer. All tasks such as reporting, analysis, and charting can be done quickly and easily in a relaxed environment, enhancing the data volume and providing truly informative data.

4.1. Advantages of Low-Risk Financial Intelligence Implementation Strategies. ERP is a "top-level project," and the financial intelligence mainly used for decision support for senior managers is data engineering. The support of senior managers is directly related to the success or failure of implementation. The traditional financial intelligence implementation strategy has long battle lines, and the establishment of data warehouses is difficult. The main reason is that data warehouses are subject-oriented, and managers have an insufficient understanding of requirements. In addition, today's social environment changes very fast, so the themes often change, which makes it very difficult to implement and extend the front line, and a lot of resources are invested but no effect can be seen. If the data cannot see the effect, it will not support the implementation of the project, and the lack of data to support the project will make it more difficult to implement and even directly lead to the failure of the project implementation. The adoption of low-risk financial intelligence strategies can allow managers to see the visual display and analysis of data for decision support through some simplified processes from time to time and constantly communicate with managers to understand their needs in the process. Through the continuous promotion of the low-risk implementation strategy, the managers' understanding of the entire system has been continuously improved, and the requirements put forward on this basis are more targeted and reasonable. In this way, the confidence in the implementation of financial intelligence will be enhanced, the support of data will be obtained, and the probability of successful project implementation will be greatly improved.

In the implementation of the financial intelligence system, the business personnel should be the protagonists compared with the technical personnel. The business personnel should make detailed analysis on the macro demands put forward by the decision makers, and the technical personnel should provide the platform and technical support for the business personnel. In the low-risk financial intelligence implementation strategy, through simple training of business personnel, they can turn data into information, visualize and interactively display it, improve business insight, and discover knowledge from information. Table 4 is the data structure of the voucher and detailed table.

4.2. Low-Risk Financial Intelligence Implementation Strategy Practice. From the above analysis, it can be seen that using ExcelCrystal and EasyTable tools, we can realize data warehouse, data mining, OLAP, interactive data, visualization data analysis, and other functions. From the perspective of business personnel, these two programs do not require programming or coding. After self-study or simple training, they can create excellent interactive visualizations according to their own business. Excel is a common data analysis software used by any enterprise. As long as you have a little understanding of the business, it is a boon for those who simplify the business. The training bit can master the skills of data mining and analysis. Therefore, at this stage, management decisions can be fully supported by implementing a low-risk financial intelligence strategy. Here is an example of data drilling in a sales report, showing how to achieve low-risk financial intelligence through the combination of Excel and Crystal Xcelsius. Sales data are generally the basis for the analysis and evaluation of business performance, but sales data are generally very large, with many dimensions, and there are many levels under each dimension. Faced with a large amount of complex data, in the past, when managers needed data, they needed to filter and summarize these large amounts of data to obtain the required data of the corresponding dimensions and levels. However, when the demand changes and other information is needed, these large and complex data must be filtered and summarized to obtain data of other dimensions and levels. These tasks will be repeated every time the requirements change, and different reports will be provided. The timeliness and accuracy of the reports are very low, which seriously affects the decision-making. And EXCEL's pivot table summarizes all the data into a pivot table and then sets multiple page fields such as year, region, product category, price, and channel to realize the multidimensional display of data, as shown in Table 5.

Due to the flexibility of the pivot table, each field can be dragged and placed at the desired position, and many data can be constructed into multidimensional tables to display all the data, and then filter out the required data. It can be seen that the more page fields are set, the more data can be stored. Not only page fields but also row fields and column fields can be added to increase the dimension of data. And it is also very flexible in the processing of time, which can be aggregated by month, quarter, year, and even by hour, minute, and second. In this way, when the management requirements change, the required data can be found by

Table 4: Data for the voucher schedule.

Serial number	Field name	Illustrate	Type	Length
1	I-id	Unique ID when entering	Int	4
2	I period	0 refers to the initial transaction detailed account, 21 refers to the preliminary bank account to be checked, 20 refers to the balance before adjustment of the bank account, and 1 refers to the voucher and details	Tinyint	1
3	Csign		Varchar	8
4	I signseq	According to the assignment by the system, it can be null at the beginning of the period	Int	4
5	Ino-id	The voucher number is assigned by the system and can be null at the beginning of the period	Smalint	2
6	Inid	Assigned by the system, it is 1 at the beginning of the period	Smalint	2
7	Dbill-date	Amendments to a limited range of dates available	Datetime	8

	Season 4	235					

simply dragging and dropping, and the information needed for decision-making can be obtained quickly and accurately. In addition, a chart analysis model with analysis and graphic display functions can also be drawn, as shown in Figure 9.

Product sales revenue is the key monitoring of enterprises. In this model, the line chart on the right can easily monitor the actual sales and planned sales amount of each product each month and the forecasted sales for future months based on that. The difference between actual and planned is visualized by the scale on the left. The scale at the bottom left shows the sales contribution of each product in the form of a pointer. In the upper right bar area, you can monitor the cumulative actual sales, planned cumulative sales, and corresponding variances for each product. Figure 10 is a comparison of financial system performance between traditional financial statistics and multisource information feature mining.

5. Discussion

In this model, there are not only two variables of sales volume and adjustment volume but also intuitive understanding of the value of income. The model uses a structure diagram to illustrate the relationship between several factors that affect profitability. For example, by setting the variable cost sliders, change the different factors that affect changes in value, total cost, and final revenue. The revenue growth model uses a transition line with advance notice. If the profit is positive, the growth line will appear green, and if the profit is negative, the loss line will appear red, creating a red flag and attracting the attention of decision makers. In the transaction progress process, there is an initial alert table that visually determines the gap between current transaction volume and downtime and provides a way to adjust the gap. Also, for

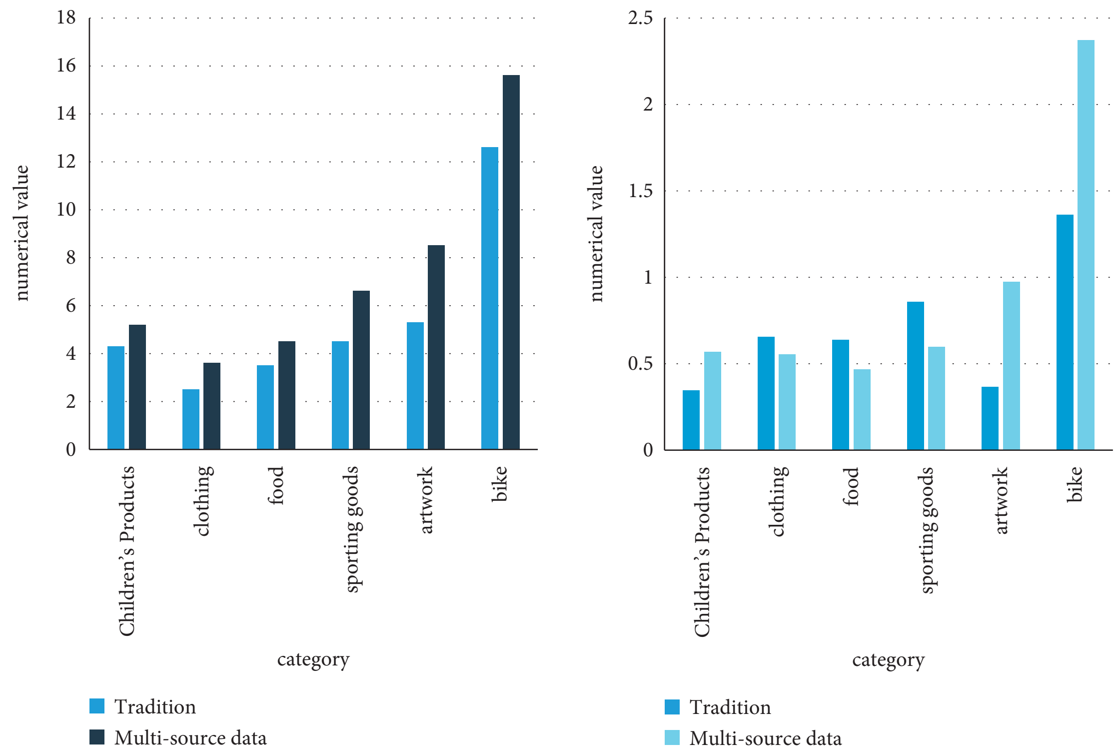

Figure 9: Graphical presentation model of sales data.

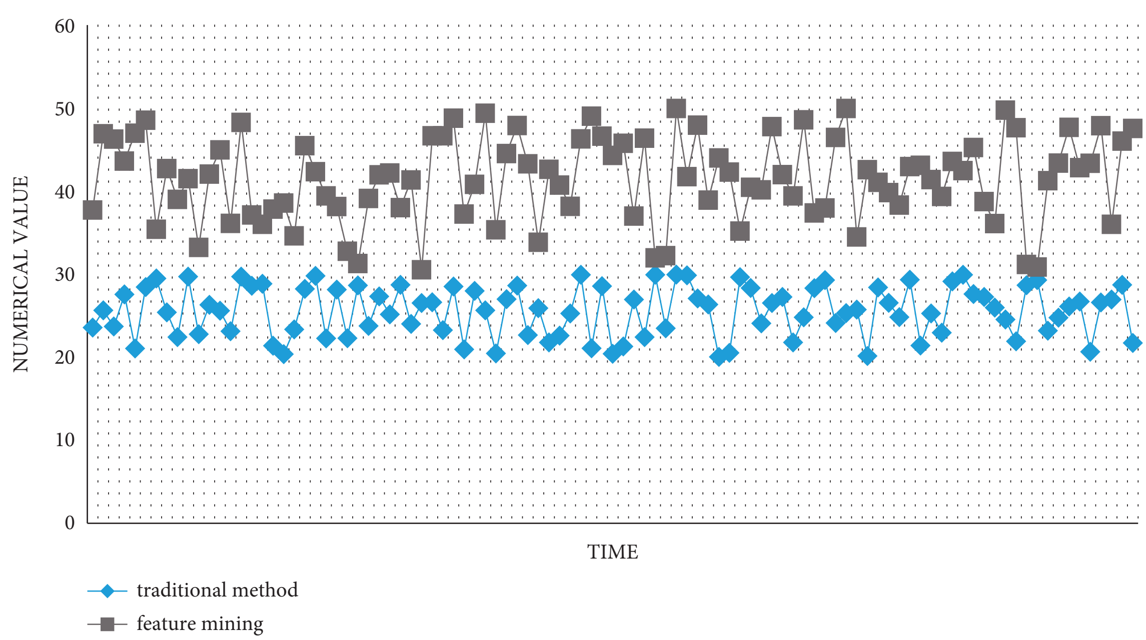

Figure 10: Product sales revenue monitoring.

breakeven, you can change unit prices, fixed or variable prices, change breakeven sales, etc.

Furthermore, the model includes an operational risk dashboard that allows decision makers to see the impact of various factors on profits in their current state. When the selected factors move in an unfavorable direction in the current state, operational risk is defined as the percentage impact on profits. To select the influencing factors, click the "factor selection" button and then choose the single most important influencing factor. Check "unit price" to see the impact of unit price changes on profit; if the sales volume is unstable, check "sales" to see the impact of sales volume changes on profit, etc., that is, single factor analysis. It can also be chosen multiple important factors, such as unstable product prices and unstable raw material supply prices; simply check "unit price" and "material" to see how these two factors interact to affect profits, which is known as multifactor analysis. The business subinsurance is displayed as a dashboard, and an early warning system is used to visually see the impact of the selected factors on profit in the current state. There are also scheme buttons in this model for saving, loading, and deleting schemes, allowing users to save their results after adjusting all of the variables, as well as view and delete them after loading.

6. Conclusion

Financial data are primarily used for business management decision-making, and Chinese SMEs are limited in their use and promotion of financial data due to a variety of factors including capital and technology. Financial intelligence solutions that are both cost-effective and simple to use are in high demand. On the basis of research on some of the financial intelligence products currently used by large domestic enterprises, this paper examines the basic theories of business intelligence and financial intelligence, as well as the construction of financial intelligence in small- and medium-sized enterprises. The following are the main aspects of this paper's research findings: propose a low-risk enterprise financial intelligence strategy and locate the enterprise financial information system model construction. This is the conclusion reached after examining existing technical abilities and previous knowledge, as well as the characteristics of EXCEL and Xcelsius. An example of financial intelligence analysis, an example of financial intelligence monitoring, an example of financial intelligence decision-making, and an example of financial intelligence early warning are all established on the basis of the actual combat financial system. These examples enable businesses to assess the feasibility of the proposed financial intelligence application scheme. The use of multisource information feature mining and VBA technology in EXCEL in the technical realization is the most notable feature of this paper's research results. Their use among Chinese financial personnel is rapidly spreading due to their outstanding performance. Because the design and construction of a financial intelligence system is a very complex project, only a few parts that are closely related to the research of this topic are included in this paper, as well as some issues that have not been discussed, due to time, materials, and the author's own ability. This paper only provides a broad classification of financial intelligence systems and attempts to implement some common models. It is also necessary to conduct extensive research on the specific models of each component, which is a continuous improvement process. In the realization of financial intelligence, this paper mainly not only considers adopting low-risk financial intelligence implementation strategies but also needs to do in-depth research on ideal and comprehensive implementation strategies. This research focuses on financial intelligence, but after the research and application of financial intelligence are fully mature, it is necessary to study the transition to business intelligence and even decision support on this basis.

This paper proposes corresponding teaching methods and instructional modes based on predecessors' research on mathematics instructional mode and the current state of mathematics teaching. In addition, this paper constructs a teaching evaluation model based on DL algorithm based on an in-depth study of DL-related theories in order to accurately and scientifically analyze the problems that exist in mathematics teaching. This paper constructs an instructional quality evaluation index system based on rationality and fairness, and uses the BPNN evaluation model to train and study a set of instructional quality data. Finally, the experimental results show that this system has a high level of stability, with a 96.37 percent stability rate and a 95.42 percent evaluation accuracy rate. The results of this paper's evaluation of the mathematical instructional quality model are objective and reasonable. It can accurately assess instructional quality while also assessing problems in the teaching process based on the instructional quality scores and making reasonable recommendations for teaching improvement based on the weak links in the teaching process. It has the potential to provide a workable system for assessing instructional quality.

1. Introduction

The modernization of education necessitates the improvement of instructional quality [1]. Many teachers use the boring lecturing classroom mode in the traditional mathematics classroom, resulting in a serious and boring classroom atmosphere. Students are effectively shackled as a result of this, and their ability to learn in class suffers as a result. We can optimize the mathematics instructional mode to change the above teaching phenomenon. Mathematics instructional mode optimization can effectively deepen students' understanding of mathematics. Teachers should constantly optimize the mathematical model based on students' learning situations and cognitive characteristics in order for students to comprehend and master the theoretical knowledge and content of mathematics from multiple angles and dimensions during actual teaching. The new curriculum reform emphasizes establishing students' dominance in classroom instruction. This necessitates teachers completely altering the traditional model and establishing a new teacher-student relationship. In general, the optimization of a mathematical model entails the following components: language category optimization, language syntax optimization, and language logic optimization. The optimization of classroom instructional mode and the construction of effective mathematics classrooms are of great teaching and practical importance in today's environment.

The scientificity, rationality, and timeliness of instructional quality evaluation play a key role in the optimization of instructional mode. However, the limitations of the traditional instructional quality evaluation method itself make it controversial. Therefore, it is of practical significance to establish a scientific and reasonable instructional quality evaluation model to evaluate mathematics instructional quality. Deep learning (DL) [2–4] is an extension of the research field of machine learning [5–7] and an effective way to realize artificial intelligence. Due to the rapid development of DL, NN (neural network) [2, 8] in DL has also been well developed, and its effect has been well verified in many network models. NN is a complex calculation method to simulate the neuron and neuron connection structure of human brain. NN technology is mainly based on the workflow of human nerves and uses human nerves to process related contents for calculation. BPNN (back-propagation neural network) is a three-layer feedforward hierarchical network composed of input layer, hidden layer, and output layer. Its learning process consists of two processes: forward propagation of information and backward propagation of errors. BPNN has the advantages of strong generalization and fault tolerance, but it also has some shortcomings. Genetic algorithm is an algorithm that refers to and simulates biological genetic mechanism and natural selection. Its basic idea is to simulate the evolution process of population. After three genetic operations, selection, crossover, and mutation, the population is constantly updated, and the excellent degree of the population is constantly enhanced, approaching the global optimal solution. Aiming at the shortcomings of BPNN, genetic algorithm can be used to improve it. This paper mainly studies the optimization model of mathematics instructional mode based on DL algorithm, and its innovation lies in: (1) this paper improves the existing evaluation index system and constructs a new instructional quality evaluation index system based on rationality and fairness. To train and study the instructional quality data, the BPNN evaluation model is used. After demonstration, the instructional quality evaluation index system in this paper is scientific, objective, and reasonable. (2) This paper improves the problem that extracting principal components from the correlation coefficient matrix of indexes cannot reflect the difference information of the variation degree of each index by introducing the basic principle of principal component analysis. Because BPNN is highly dependent on its initial weights and thresholds, a genetic algorithm is used to optimize BPNN's initial weights and thresholds in order to improve the prediction accuracy and convergence speed of instructional quality evaluation results. The experiment shows that this system can be used as a benchmark for evaluating instructional quality and making decisions.

2. Related Work

Based on the content of the instructional quality evaluation index system, Sergis et al. constructed a convolutional neural network instructional quality evaluation model based on the convolutional neural network learning expert instructional quality evaluation samples [9]. Maulana et al. mainly considered different disciplines and majors, set up different evaluation index projects, and established different evaluation index systems. And we use the powerful functions of the MATLAB toolbox to establish a BP neural network, train the network, test the network, and finally analyze the experimental results [10]. Choi and Kim et al. pointed out that under the current background, more and more emphasis is placed on strengthening the interaction between teachers and students, and the main form of interaction is the "dialogue" in the classroom. And we summarize the effective instructional mode of mathematics around "dialogue" [11, 12]. Starting from a brief analysis of the optimization of classroom instructional mode, Petraki E analyzed the main points of constructing an effective mathematics classroom after expounding the problems existing in today's mathematics classroom [13]. Onozawa M uses a deep learning algorithm to design an instructional quality evaluation system, which intelligently evaluates the instructional quality and puts forward rationalization suggestions [14]. Aiming at the problems existing in the quality evaluation of NC bilingual teaching courses, Liu et al. tried to use the analytic hierarchy process to carry out exploratory analysis, thus providing a scientific case basis for the evaluation of bilingual course instructional quality [15]. Northrup et al. believed that improving the pertinence of homework is one of the core contents of constructing an effective mathematics classroom. While intensifying in-class training in mathematics and improving the effectiveness of feedback correction, we must pay attention to the efficiency of mathematics after-school homework training [16, 17]. Ottmar et al. expounded the design idea and implementation method of neural network for instructional quality evaluation, introduced and analyzed the traditional instructional quality evaluation method, and trained and tested the designed neural network for instructional quality evaluation [18].

This paper proposes corresponding teaching methods and instructional modes based on predecessors' research on mathematics instructional mode and the current state of mathematics teaching. Furthermore, this paper constructs a teaching evaluation model based on DL algorithm based on an in-depth study of DL-related theories. The optimization of the mathematics instructional mode is carried out based on the evaluation of the teaching evaluation model. In this paper, a rich basic dataset of teaching evaluation has been formed through the evaluation of teaching experts, teachers' peers, and students. The normalization formula is used to process the input samples. Furthermore, because BPNN is so reliant on its initial weights and thresholds, this paper employs a genetic algorithm to optimize BPNN's initial weights and thresholds and reduce the time it takes for BPNN to find the weights and thresholds that satisfy the training termination conditions, in order to improve NN's instructional quality evaluation results' prediction accuracy and convergence speed.

3. Methodology

3.1. Optimizing Classroom Instructional Mode and Constructing Efficient Mathematics Classroom. Math textbooks for each stage are also designed according to students' knowledge base, cognitive level, and thinking ability, as there are high expectations for mathematics students' thinking ability. However, many teachers adopt the tedious lecture-based classroom mode during the actual teaching process, resulting in a serious and monotonous classroom environment [19]. We can improve the mathematics instructional mode to change the above-mentioned teaching phenomenon. Students' understanding of mathematics can be effectively deepened by optimizing mathematics instructional mode [20]. The term "dialogue" is used in class to describe how teachers and students communicate. The amount of "dialogue" and its effect on the classroom atmosphere and instructional quality are both directly determined by the amount of "dialogue." An effective dialogue instructional mode can help students break free from the constraints of their thinking, causing them to think and express more actively, and thus promoting the development of independent thinking abilities. Because mathematical models are all expressed in mathematical languages, they must be transformed using different mathematical languages. In order to successfully transform mathematical languages, students must master a variety of mathematical languages, including geometric language, algebraic language, and symbolic language. Therefore, in mathematics teaching, teachers should pay attention to the training of students' mutual conversion between different languages when changing "numbers" into "shapes" through the equivalent exchange of mathematical model languages. Besides, the guiding ideology of optimizing classroom instructional mode also includes the corresponding concept of "efficient classroom." The main contents of this concept include teaching preparation, teaching process, training and testing, after-class counseling, teaching evaluation, and other aspects of different courses. Therefore, on this basis, the optimization of classroom instructional mode can be better applied.

First of all, in order to realize the correct and efficient conversion between mathematical languages, teachers must help students establish a correct mathematical language structure. Usually, mathematical models are based on mathematical concepts, which are connected by verbs. The main reasons for their complexity are the order relationship, hierarchical relationship, and logical relationship in the structure of mathematical models. Therefore, in order to correctly grasp the mathematical model, it is necessary to correctly sort out the structural relationship between mathematical concepts to ensure the correct transformation of mathematical model. Furthermore, teachers must teach students how to ask questions in class; that is, the questions posed must be of sufficient inquiry value, conform to classroom teaching content, and have a clear purpose. Students will have a better understanding of the meaning of asking questions as a result of the increased teaching time, and they will be able to grasp the points that are appropriate for asking questions more accurately and master effective questioning methods, resulting in a better awareness of questions. This not only is beneficial for creating a productive classroom but also allows students to improve their mathematical inquiry learning abilities. At the same time, the most important thing is to cultivate students' interest in mathematics. Students' interest in mathematics learning is influenced not only by the number of mathematical concepts and formulas taught in class by mathematics teachers but also by the number of classic questions explained and analyzed in exercise classes, as well as other factors. Mathematics teachers must not only have good mathematics knowledge, teaching skills, and teaching process to improve students' interest in mathematics learning; they must also have better mathematics teaching methods, mathematics teaching emotions, mathematics teaching attitudes, and mathematics teaching values.

Teachers should master the effective teaching method of question situation and avoid the traditional acceptance method of asking questions. We should not only attach importance to the results but also to the whole process of students' participation in classroom interaction. The effective construction of mathematics classroom needs the effective support of corresponding points. This is mainly reflected in the effective preparation before class, the reasonable improvement of classroom teaching efficiency, the emphasis on promoting students' cooperative learning, and the pertinence of homework after class. In classroom teaching, teachers can realize the simplification of mathematical problems by flexibly changing mathematical thinking patterns. Through the rational application of the above strategies, students can successfully realize the transformation between mathematical models. This method can get better results in the application of trigonometric function, geometry, and complex number knowledge. In the process of inquiry learning, teachers do not instill knowledge stiffly, but let students actively participate in knowledge exploration, and naturally digest and absorb knowledge in the process of exploration. Therefore, it can promote the effective improvement of mathematics classroom instructional quality and cultivate students' interest in mathematics invisibly. At the same time, the effective cooperative learning among students can play a very good role in promoting the creation and optimization of teaching links. The exploration of effective mathematics instructional mode cannot be separated from the joint efforts of students and teachers. Finally, in order to promote the continuous improvement of classroom instructional quality, teachers should also organize students to carry out classroom teaching and evaluation of learning situation, so as to better find problems and put forward improvement measures. For some good places, it is necessary to keep them.

3.2. Application of DL Algorithm in Instructional Quality Evaluation. It is an extension of the research field of machine learning and an effective way to realize artificial intelligence [21]. As a new technology, DL has opened up a new way for pattern recognition [22], nonlinear classification [23], artificial intelligence, and other research with its basic characteristics such as nonlinear mapping, learning classification, and real-time optimization. It involves biology, electronics, computer, mathematics, physics, and other disciplines, and has a wide application prospect. Due to the rapid development of DL, NN in the field of DL has also been well developed, and its effect has been well verified in many network models. NN is a complex calculation method to simulate the neuron and neuron connection structure of human brain. NN technology is mainly based on the workflow of human nerves and uses human nerves to process related contents for calculation. Because of the parallelism of NN, it is very effective for solving combinatorial optimization problems. From the point of view of automatic control, NN can be regarded as a high-dimensional nonlinear dynamic system. Neurons are the processing units in this system. This system has many inputs and many outputs, and we regard its input-output relationship as a mapping from input to output. Therefore, it is reasonable to apply NN to the design of instructional quality model. The three-layer BPNN model is shown in Figure 1.

BPNN is an iterative algorithm consisting of two processes: forward propagation of input vector and backward propagation of error. The algorithm is divided into two stages: ① forward propagation of input vector. ② Back-propagation of error. BPNN has the following advantages: ① BPNN is suitable for solving problems with complex internal mechanisms. ② It can process information in parallel. ③ It can abstract the relevant laws from the samples. ④ It has a strong self-learning function. ⑤ For the input samples in BPNN, there may be errors with large errors. But BPNN still has some limitations. For example, it is easy to fall into the local optimum, the recognition accuracy is easily affected, there is no fixed basis for setting network parameters, there is a tendency to forget the old samples when learning new ones during training, and the generalization ability is poor. Based on DL algorithm, this paper constructs an instructional quality evaluation model. For an instructional quality evaluation system, it can be regarded as a mapping from input to output. NN's self-learning ability, that is, the plasticity of mapping, enables it to simulate the required mapping relationship through training, thus replacing domain experts to automatically evaluate the evaluation object.

3.3. Construction of the Teaching Evaluation Model Based on DL. Instructional quality evaluation system is an evaluation of teachers' phased teaching effect, which provides favorable analysis basis for mastering teachers' teaching ability and improving instructional quality. When evaluating the instructional quality, we should adhere to an objective, fair, and rational attitude. We should not speculate subjectively or mix personal feelings, and we should be ideological, scientific, and feasible. The establishment of a reasonable model of teacher's teaching evaluation system can not only enable teachers to revise and improve the teaching plan according to the teaching effect in time but also help the school to understand the implementation of teachers' teaching tasks and make macro-control. More importantly, a perfect evaluation system is of great significance to the establishment of a teaching evaluation model for teachers in colleges and universities. The instructional quality evaluation system based on DL algorithm is designed based on B/S mode. The advantages of designing the instructional quality evaluation system based on B/S mode are as follows: it is convenient for different types of users to operate, the online evaluation can be completed in a short time, and the system maintenance is convenient. Client, application unit, and database are three important components of the system. According to the experience of this article, we try to use an implicit layer first. The DL-based instructional quality evaluation model and algorithm flow are shown in Figure 2.

The samples used in data analysis frequently contain a large number of variables, and adding more variables increases the complexity of the analysis problem. The information contained in these principal components should be required to be independent of one another in order for them to not overlap. The main goal of principal component analysis (PCA) is to reduce the dimensions of variables and simplify problems by retaining the most important information from the original variables, making it easier to understand the main contradictions when studying complex problems. The function of DL is to learn the inherent law and representation level of sample data. The BPNN model in the DL algorithm is used to evaluate instructional quality when designing the instructional quality evaluation system. The evaluation method is a nonlinear problem because there are many uncertain and complex factors in the evaluation process. BPNN has demonstrated its unique advantages in solving such problems by having a strong adaptive learning ability that can approximate any function. The steps of BPNN learning rules are as follows: the output of the i neuron in the hidden layer is as follows:

$$a1_i = f1\left(\sum_{j=1}^{r} wl_{ij}p_j + b1_i\right), \quad i = 1, 2, 3, \ldots, s1. \tag{1}$$

The output of the kth neuron in the output layer is as follows:

$$a2_k = f2\left(\sum_{i=1}^{s1} w2_{ki}a1_i + b2_i\right), \quad k = 1, 2, 3, \ldots, s2. \tag{2}$$

We define the error function as follows:

$$E(W, B) = \frac{1}{2}\sum_{k=1}^{s2}\left(t_k - a2_k\right)^2. \tag{3}$$

We assume that the evaluation indicators of the evaluation system are N, the result grades are M, and the classification of the total indicators is divided into L categories; the evaluation scores of each indicator can be used as the input of the scoring comprehensive network, which is expressed as follows:

$$X = \left[x_{11} < x_{1j} < x_{1m} < x_{i1} < x_{ij} < x_{im} < x_{n1} < x_{nj} < x_{nm}\right]^T. \tag{4}$$

The rating coefficient of the evaluation result is taken as the output of the scoring comprehensive network, which is expressed as follows:

$$K = \left[k_1 k_2 < k_j < k_m\right]^T. \tag{5}$$

The importance coefficient of each index is connected by the synaptic weight matrix, which is expressed as follows:

$$W = \left[W_1 W_2 < W_j < W_m\right]^T. \tag{6}$$

In this paper, roulette is adopted. First, the fitness value of a certain generation of individuals, namely, BPNN weight and threshold, is calculated. Then, we calculate the proportion of the fitness value in the total fitness value, that is, the probability of the individual being selected in the

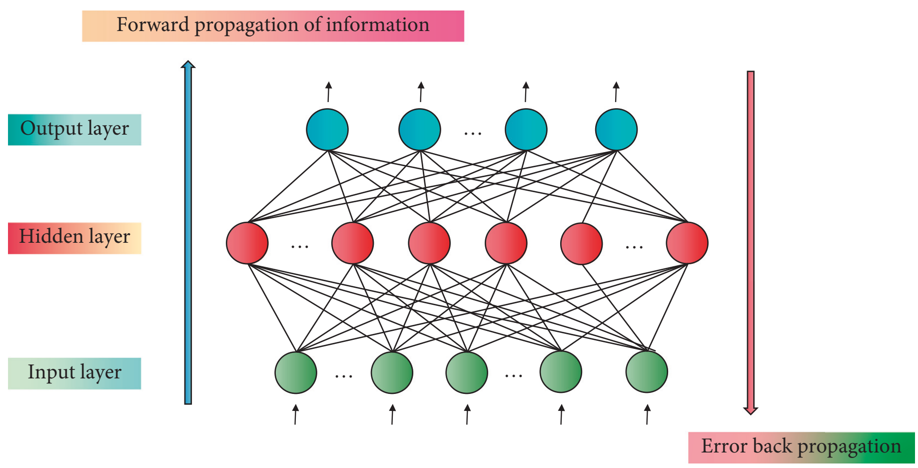

FIGURE 1: Three-layer BPNN model.

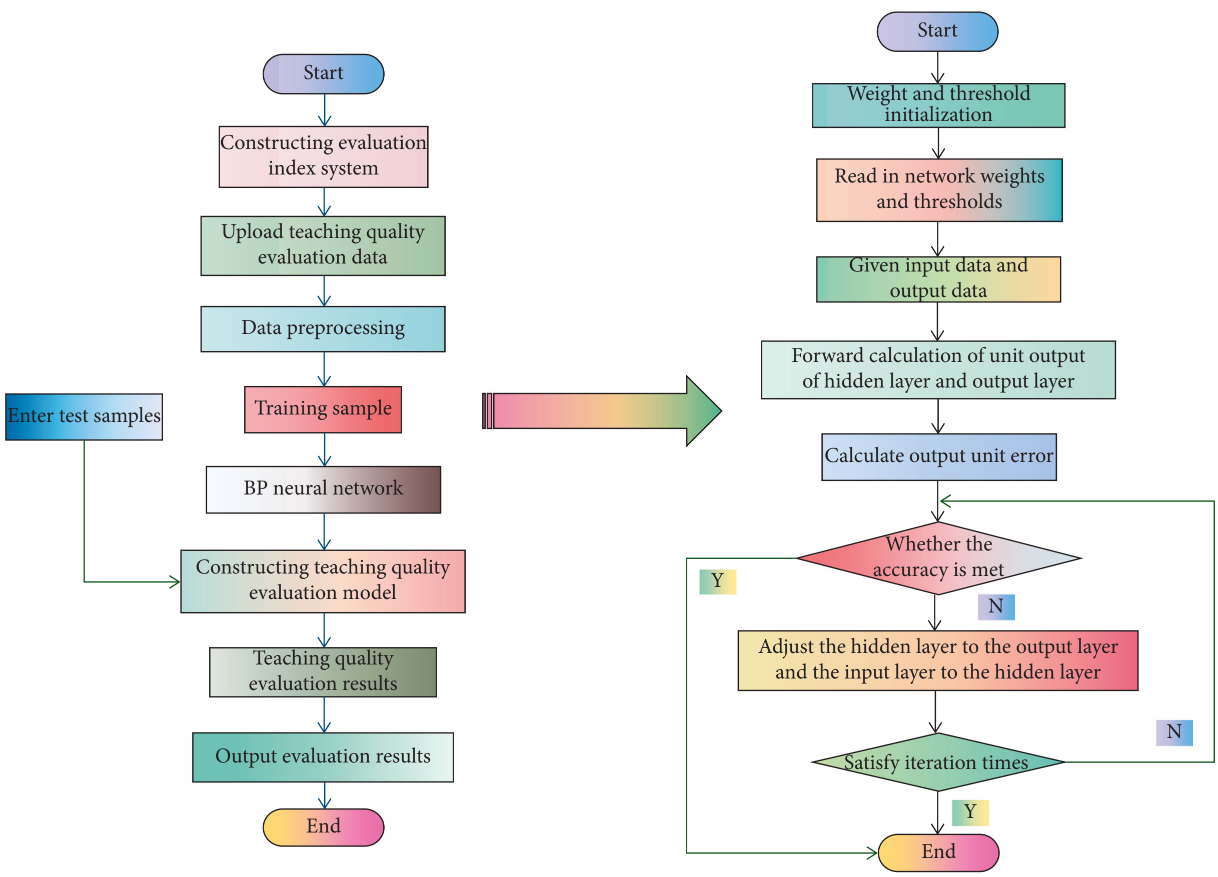

FIGURE 2: DL-based instructional quality evaluation model and algorithm flow.

selection process. The calculation of the selection probability is shown in the following formula:

$$z(a_j) = \frac{f(a_j)}{\sum_{j=1}^{d} f(a_j)}. \quad (7)$$

Among them, a_j represents an individual in the group, $z(a_j)$ is the probability that a_j is selected, $f(a_j)$ is the fitness value of individual a_j, and d is the population size. After calculating the probability of each individual being selected, it is necessary to determine whether the selected individual can continue to be inherited to the next generation of individuals according to the size of the cumulative probability. The calculation formula is as shown below.

$$q(a_k) = \sum_{j=1}^{k} z(a_j). \quad (8)$$

Among them, $q(a_k)$ is the cumulative probability of individual a_k, and then, a new population of the next generation is obtained through genetic manipulation, the fitness value is judged, and the above steps are repeated until the population is stable. The action function of each neuron is taken as a linear function:

$$F(S_j) = S_j. \tag{9}$$

The output of the node at this point is as follows:

$$K_j = S_j = W_j^T X. \tag{10}$$

In this paper, the average method is used for dimensionless processing, which can extract more original information with less principal components, thus reducing the workload and making the solution to the problem more perfect, more accurate, and more comprehensive. Valuable data such as instructional quality evaluation index data, evaluation subject, and object data are stored in the database. The evaluation is divided into two aspects: index scoring and grading and classification. Therefore, two networks can be used for processing, and one network can store and memorize the importance coefficients of each index and synthesize the scores, which is called comprehensive network. The other one classifies the index scores linearly or nonlinearly, so as to obtain the final evaluation result of the total index, which is called classification network. In the process of evaluating the instructional quality, certain principles should be followed. Evaluation principle plays a key role in ensuring the validity and reliability of evaluation results, and is the basic requirement of evaluation work. The evaluation index system of instructional quality designed in this paper follows the following basic principles: ① the principle of comprehensiveness, ② principle of directionality. ③ scientific principle, ④ principle of measurability, ⑤ principle of encouragement and improvement, ⑥ principle of objectivity, ⑦ principle of subjectivity, and ⑧ principle of consistency. In this paper, the teaching process, teaching environment, teaching teachers, and instructional quality monitoring are the first-level indicators of the instructional quality evaluation index system. There are several secondary indicators under the primary indicators. The evaluation index system of instructional quality constructed in this paper is shown in Table 1.

After the establishment of the evaluation index system, it is more scientific to set the corresponding weights of the index system. In the process of setting weights, we can first establish the weights set by experts' evaluation indicators and build a BPNN model learning network through the powerful function of MATLAB toolbox according to the weights of experts' indicators. Then, we input the weights set by experts and adjust the weights of indicators set by experts through network training according to the functions of BPNN model. The final error is minimized, and the weight is relatively more reasonable. The user management unit of the system is divided into two aspects: system login and security management. Different types of users log in to the instructional quality evaluation system according to different unit entrances, and users perform operations in their respective permission pages. Considering the security of user information, users are divided into five types: teaching supervisor, audit administrator, administrator, teacher, and student.

4. Result Analysis and Discussion

The instructional quality evaluation system designed based on DL algorithm in this paper contains a large amount of data, so there are certain requirements for the running hardware and software environment. In order to ensure the efficient operation of the system, the test environment in this paper is set as follows: the CPU is 2.4 GHz, the memory size is 8 GB, the computer hard disk is 1 T, and the system is Windows. In this paper, the number of nodes in the input layer, hidden layer, and output layer is $16 \times 4 \times 1$, respectively; the learning rate is 0.8; and the function of each node adopts the Sigmoid function. After testing, the convergence curve of the algorithm is obtained as shown in Figure 3.

The commonly used mean square error and accuracy rate are selected as the indexes to test the performance of this algorithm. These two indexes are used in different algorithms for testing and comparison. The mean square error of different algorithms is shown in Figure 4. The accuracy of different algorithms is shown in Figure 5.

The results show that this algorithm can not only speed up the convergence of the network but also improve the evaluation accuracy of the model. Its performance is better than that of the comparison model. Taking ten math classes in the second grade of a school as examples, the quality of math teaching was evaluated, respectively. The evaluation results of mathematics instructional quality are shown in Table 2.

The above statistics of mathematics instructional quality evaluation in different classes show that this system can identify the highest score, lowest score, and average score of instructional quality evaluation in different classes. It provides different types of data for comprehensive analysis of mathematics instructional quality. Figure 6 shows the stability test results of different systems.

It can be seen from Figure 6 that the stability of this system is high. Moreover, the analysis and suggestion function of the instructional quality evaluation system designed in this paper reflects the degree of intelligence of the system, shares the workload of manually evaluating teachers' teaching effect, and improves the operational efficiency of instructional quality evaluation. Through training, quantifiable classification criteria or experts' experience information that is not easy to quantify is stored in the nonlinear network, and the instructional quality evaluation NN is measured with new experimental data. Comparison between different system evaluation results and expert evaluation results is shown in Figure 7.

It can be seen from Figure 7 that, compared with other systems, the evaluation network constructed in this paper can give results consistent with expert evaluation. This shows that this method has certain accuracy and reliability. The experimental results show that the stability of this system is high, reaching 96.37%, and the evaluation accuracy rate can

algorithm has the advantage of being able to analyze the existing problems in teaching and put forward suggestions for improving instructional quality.

5. Conclusions

With the continuous improvement of teaching levels and the rapid development of classroom instructional mode, the optimization of mathematics classroom instructional mode has become increasingly important in the process of instructional mode innovation. Mathematical instructional mode optimization has a distinct value and function. Teachers must update their teaching concepts, adopt various teaching strategies to promote the development of students' mathematical thinking, and develop students' thinking flexibility and creativity through the training of various mathematical exercises in order to continually optimize mathematics instructional mode and construct more efficient classroom teaching. Simultaneously, mathematics teachers should have a thorough understanding of how to optimize classroom teaching content in order to effectively improve the overall level of mathematics teaching through practice. The current state of mathematics instructional mode is examined in this paper, as well as the implementation strategy for mathematics classroom teaching optimization. Furthermore, the instructional quality evaluation system is based on the DL algorithm. This paper's system has a high level of intelligence. It can accurately assess instructional quality while also assessing problems in the teaching process based on the instructional quality scores and making reasonable suggestions for teaching improvement based on the weak links in the teaching process. The experimental results show that the system's stability is high, with a 96.37 percent stability rate and a 95.42 percent evaluation accuracy rate. This system has a high level of reliability and practical utility, and it can be used to develop a feasible scheme for evaluating instructional quality. The analysis and suggestion function of the instructional quality evaluation system proposed in this paper reflects the system's intelligence, reduces the workload of manually evaluating teachers' teaching effectiveness, and improves the operational efficiency of instructional quality evaluation. However, due to my limited knowledge and time, there are still some flaws in this paper's instructional quality evaluation system. The next step will be to discuss how to improve the system's efficiency without sacrificing accuracy.

The establishment of enterprise target inventory is directly related to the forecast of drug sales volume. Accurate sales forecasting can help businesses not only set accurate target inventory but also avoid inventory backlogs and shortages. In this paper, NN technology is used to forecast sales and is optimized using the PSO algorithm, resulting in the creation of a drug sale forecast model. The model optimizes the weights and thresholds of NN using the improved PSO optimization algorithm and predicts the periodic components based on time correlation characteristics, effectively describing the trend growth and seasonal fluctuations of sales forecast data. Furthermore, the model in this paper has been creatively improved according to the needs of practical application, which has improved the shortcomings of traditional NN, such as long training time, slow convergence speed, and ease to fall into local minima, to improve performance and quality, and has received positive results in application. The experimental results show that this model has a prediction accuracy of 96.14 percent, which is 12.78 percent higher than the traditional BP model. The optimized model can be used to forecast drug sales in a practical and feasible way.

1. Introduction

With the intensification of market competition, users of information systems are no longer satisfied with the fact that computers are only used for daily affairs, and they urgently need information that supports the decision-making process [1]. At the same time, in today's market, the market environment that enterprises face is so complicated and changeable as understanding the course, carrying out work actively and effectively, and making decisions are problems that an enterprise must solve [2]. The sales link, which connects suppliers, sellers, and consumers, is an important link in enterprise planning. The most important part of the sales process is sales forecasting, and most commodity circulation industries' supply chains have inventory and sales problems due to a lack of appropriate sales forecasting methods. The sales forecast is modeled using a set of highly complicated nonlinear systems that are manually defined [3]. One of the most important aspects of a company's sales plan, as we all know, is sales forecasting. It is inseparable from the planning of the future development direction, regardless of how large the company is or how complicated the sales staff is. However, because the future sales situation will inevitably and to a large extent influence the development direction, the sales forecast is almost an important pending event for enterprise managers and decision-makers related to the survival of enterprises. At present, many enterprises are still using traditional sales forecasting methods. Although the traditional sales forecasting method is widely used and the effect is good, it is difficult to deal with the complicated nonlinear relationship and various complicated influencing factors. Therefore, we need a new method [4]. Based on this, this paper will forecast and analyze the historical sales data of the sales department of the pharmaceutical group through PSONN (particle swarm optimization neural network) and provide some references for decision-makers in purchasing, selling, and storing drugs.

With the development of computer science, more and more researchers began to explore the use of artificial intelligence forecasting methods for medium and long-term load forecasting. At present, the most commonly used forecasting methods mainly include time series analysis, linear regression, nonlinear regression, grey forecasting, input-output forecasting, Markov forecasting, and ANN (Artificial neural network) [5–7] forecasting. Among several commonly used forecasting methods, the ANN forecasting method has attracted much attention in recent years. BPNN (backpropagation neural network) is a kind of commonly used ANN, which is used to train multilayer forward NN (neural network). BPNN contains the best part of NN theory, with a simple structure and strong plasticity. It adopts a Sigmoid type transfer function, and its learning mode is a multilayer feedforward network with minimum mean square error. There have been a lot of research studies on NN prediction [8, 9], but simply using NN to predict can no longer meet the real-time needs, and in the increasingly complex environment, more and more methods are needed to improve NN research. In this paper, the learning theory of PSOBPNN (particle swarm optimization backpropagation neural network) is used to establish an algorithm to predict the drug sales in the next year, and an optimization method is proposed for drug production, thus forming an effective drug production decision model. The innovations of this paper are as follows:

① This paper analyzes the difficulties in forecasting the sales volume of multivariety drugs in enterprises, the difficulties in the application of existing forecasting methods, and the advantages of the model in dealing with the problems and difficulties. To solve these problems, a BPNN learning algorithm is put forward. On this basis, PSOBPNN is used to forecast the sales data.

② In this paper, the PSO optimization algorithm is used to globally search the weights and thresholds of BPNN, and the optimized BPNN is used to establish a prediction model to predict the drug sales index. This model improves the shortcomings of traditional NN, such as long training time, slow convergence speed, ease to fall into a local minimum, and makes it have superior performance quality, and it has received good results in application.

2. Related Work

Prediction analysis is the process of speculating and predicting unknown future events based on known past and present events, as well as providing qualitative and quantitative descriptions of some uncertain factors and unknown events that may occur during the course of the predicted events. In general, an enterprise's sales forecast is the process of using past sales volume, sales amount, profit, and other indicators in the system to calculate future demand indicators using an algorithm mining model. Currently, a large number of academics are researching enterprise sales forecasting. The related literature of sales forecasting theory at home and abroad is discussed in this chapter, as are the benefits and drawbacks of various methods, as well as the research methods and ideas of this paper.

Arinaminpathy et al. proposed a method to build a data warehouse based on historical drug sales data and established a drug sales forecast model [10]. The improved NN by Yucesan et al. made self-calibration with reference to the prediction of synchronous time series and used a genetic algorithm to achieve self-optimization through calibration, simplifying the network structure [11]. Lian et al. took the preliminary prediction results as the input of the improved BPNN, then trained and predicted on this basis, and constructed a combined prediction model based on the improved BPNN [12]. Aiming at the characteristics of a company's drug sales, inventory, and the main problems in the sales process, Duan et al. proposed a hierarchical clustering model for multivariety drug sales forecast to predict the company's drug sales [13]. Russo et al. proposed a combinatorial optimization grey ANN model for seasonal load forecasting. The trend is predicted with a grey model; the seasonality is predicted with NN; finally, the optimal combination is carried out [14]. Aiming at some of the problems of BPNN, Curtis et al. added a momentum term to improve learning efficiency and avoid local minima [15]. Shibata et al. proposed a model for time series forecasting based on the discounted least-squares idea, and the discount is reflected in the constructed error function [16]. The discounted least squares error function biases the NN learning towards more recent observations and contemporaneous observations, while also taking into account long-term trends in the time series. Urquhart proposed an improved extreme learning machine algorithm combining batch processing and successive iterations and applied it in medium and long-term forecasting [17]. This method can improve the recognition performance of ANN in extension ability by continuously updating the training sample set. Ali and Pinar proposed two prediction models based on information fusion: one is a fusion model based on the weighted average of multiple models; the other is a fusion model that uses the advantages of various algorithms to complement each other [18]. Hassani et al. proposed an improved sales forecasting algorithm based on NN [19]. Stormi et al. studied the research on sales forecasting of the model combining NN, genetic algorithm, and PSO (particle swarm optimization) algorithm in intelligent algorithms [20].

Based on the previous research results on drug sales forecast, this paper puts forward a new research perspective and method. Because NN can approximate a nonlinear function with arbitrary precision, it can well establish the functional mapping relationship between sales volume and its various influencing factors. In this paper, using PSONN, a prediction model is constructed. A drug sales forecasting algorithm based on chaotic PSONN is proposed to improve the PSO algorithm. Inert particles tend to appear in the later stage of optimization and converge to the local optimal point prematurely. The simulation results show that the prediction effect of this model is better than that of the traditional NN model. The model and research method established in this paper are practical and effective, which not only simplifies the network structure and improves the convergence speed but also improves the prediction accuracy.

3. Methodology

3.1. NN Algorithm and Sales Forecast. ANN processor has the natural characteristics of storing and applying empirical knowledge, which is similar to that of the human brain. ANN is mainly trained by two learning algorithms, namely, the guided learning algorithm and nonguided learning algorithm. Among them, the representative BPNN is a multilayer feedforward network with hidden layers, which is a kind of error back propagation [21]. BPNN is a very effective intelligent forecasting method. Generally, BPNN is a multilayer feedforward NN, and its transfer function usually adopts the Sigmoid function. This algorithm consists of the forward transmission of information and the backward propagation of error. Its basic principle is to constantly revise the weights and thresholds of nodes at all levels in the network until the output of the network reaches the target output value, and it has good generalization ability. BPNN uses the error between the output response of the network to the learning signal and the expectation as the tutor signal and adjusts the network connection strength. Through repeated adjustments, the error is minimized, thus completing the learning process.

The learning process of BPNN is divided into two stages: ① input the known learning samples and calculate the output of each neuron backward from the first layer of the network through the set network structure and the weights and thresholds of the previous iteration; ② modify the weights and thresholds, calculate the influence of each weight and threshold on the total error from the last layer forward, and modify the weights and thresholds accordingly. Each neuron of NN can calculate and process independently according to the received information and then transmit the output results to other neurons for parallel processing. In the training process, as long as the input patterns are provided to NN, NN can automatically adapt to the connection weights, so that similar features can group the input patterns together. The sales forecast is an important part of the enterprise decision support system. The sales forecast is to take the purchase and sale of commodities in the market as the main object, to foresee and speculate on the changes in various purchase and sale activities, prices, and competitive conditions of commodities, and to take advantage of the situation and results. For the current sales industry, it is very important to forecast the sales of commodities [22], but the difficult problem is how to forecast the sales quickly and efficiently, but it is not easy. Traditional sales forecasting methods are mainly divided into qualitative sales forecasting methods and quantitative sales forecasting methods. In recent years, the quantitative sales forecasting method is widely used because of its objectivity and high interpretability [23]. In fact, the sales forecast of products can be regarded as a process of searching for "knowledge." It is mainly a process of fitting the forecast model and outputting the forecast results of sales through visual software based on the data information of related commodity sales in the past and converting the original and superficial information into the relevant "knowledge" we want. Since sales forecast is to forecast the future data demand by using the characteristics of historical data, it is an effective method to divide the data into historical data and future data at different time points and then to forecast the future data by exploring the characteristics of historical data. The conventional method has some limitations in nonlinear prediction. Recently, ANN has attracted people's attention. At present, many scholars use ANN to build sales forecast models. However, the traditional BPNN has some shortcomings, so it needs to be improved. The process of using PSOBPNN in this paper is shown in Figure 1.

The network parameters and size are related to the properties of NN used for prediction. The number of neurons, the number of hidden layers, and the connection mode are all part of the network structure. The training process for a given structure consists of adjusting the parameters to obtain an approximate basic relation. The root mean square error is used to define the error, and the training process can be thought of as an optimization problem. PSO is a population-based optimization method in which the population is referred to as a particle swarm and the individual is referred to as a particle. Its basic concept is based on the simulation of seabird predation behavior, such as that of seagulls. PSO outperforms traditional random methods in terms of simplicity, ease of implementation, global optimization ability, and computing speed [24]. The position of the particle in the basic PSO algorithm represents the potential solution of the optimized problem in the search space. The optimized function determines the fitness value of each particle, and each particle has a speed that determines its flying direction and distance. Particles search the solution space by following the current best particle. Each particle state is a possible solution to the optimization problem and a fitness value determined by the objective function to be optimized in the algorithm's search space. PSO has a number of advantages, including ease of implementation, a small number of parameters to adjust, quick convergence, and low computational requirements. It has been widely used and has been proven to be an effective method for solving many global optimization problems.

3.2. Construction of Drug Sales Forecast Model of PSONN. Sales forecasting is a highly complex nonlinear system, and the modeling of sales forecasting needs the guidance of many theories, including mathematical statistics theory, artificial intelligence theory, economic theory, and nonlinear dynamics theory. In this section, PSONN is used to build a drug sales forecasting model. In this method, the weights and thresholds of BPNN are trained by PSO, the hidden rules can be automatically extracted from massive data by NN, and the advantages of global search and fast convergence of PSO are integrated to predict the economic indicators. The process of drug sales forecast based on PSONN is shown in Figure 2.

All of the weights of connections between neurons are encoded as real vectors, which are used to represent individuals in the population. The original steps of the algorithm are used to generate groups of these vectors at random and iterate them. The mean square deviation of all NN-generated

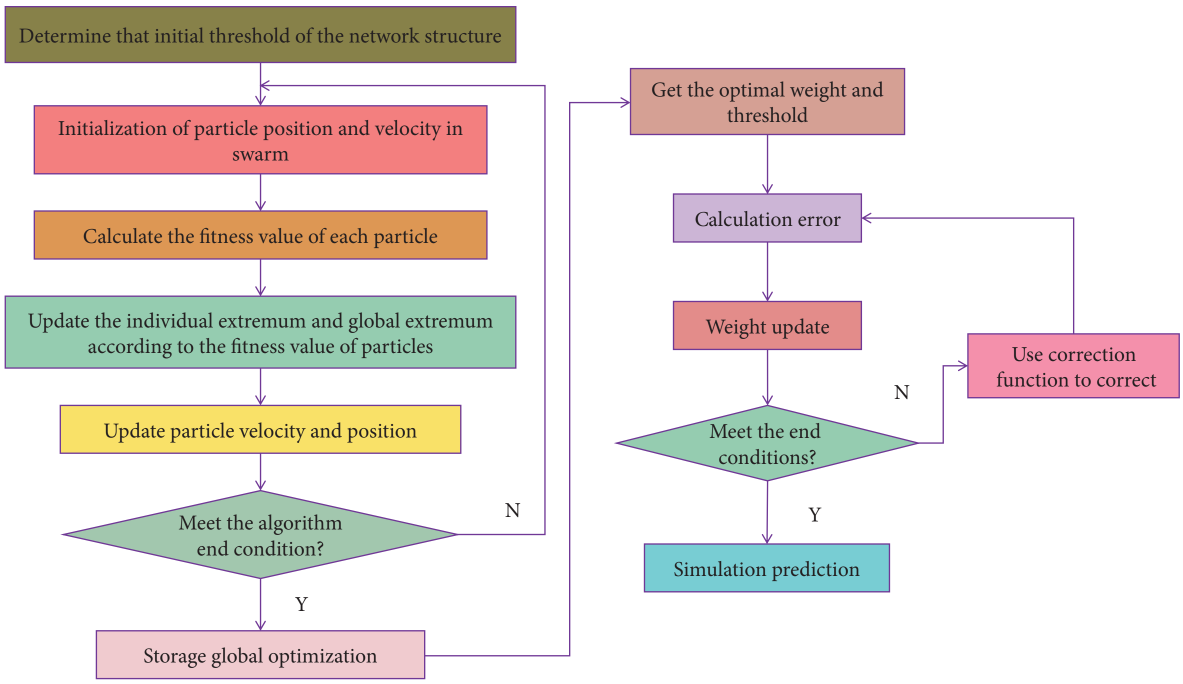

Figure 1: Flow chart of BPNN.

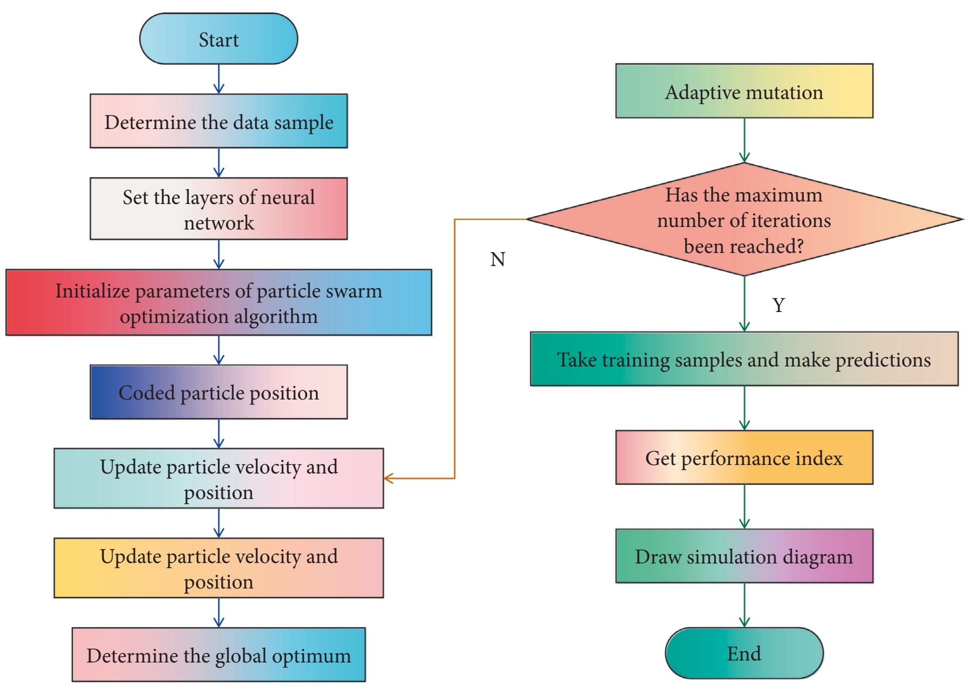

Figure 2: Flow chart of drug sales forecast based on PSONN.

samples is calculated after the newly generated individual vectors in the iteration are reduced to NN weights. The training process is stopped if it is less than the system-specified error; otherwise, it is continued until the maximum number of iterations is reached. The error information is returned according to the original route during the backward propagation process, and the weights and thresholds of NN are corrected according to the learning rules. The forward propagation process is then performed, and the two processes are repeated until the actual training output of all training samples falls within a certain error range when compared to the expected output.

The emphasis of BPNN is network error and weight adjustment. When the network output is not equal to the expected output, there is an output error E, which is defined as follows:

$$E = \frac{1}{2}(d-o)^2 = \frac{1}{2}\sum_{k=1}^{l}(d_k - o_k)^2. \quad (1)$$

Expand the above error definition to the hidden layer as follows:

$$\begin{aligned} E &= \frac{1}{2}\sum_{k=1}^{l}\left[d_k - f(\mathrm{net}_k)\right]^2 \\ &= \frac{1}{2}\sum_{k=1}^{l}\left[d_k - f\left(\sum_{j=0}^{m} w_{jk} y_i\right)\right]^2. \end{aligned} \quad (2)$$

Expand further to the input layer as follows:

$$\begin{aligned} E &= \frac{1}{2}\sum_{k=1}^{l}\left[d_k - f\left(\sum_{j=0}^{m} w_{jk} y_i\right)\right]^2 \\ &= \frac{1}{2}\sum_{k=1}^{l}\left\{d_k - f\left[\sum_{j=0}^{m} w_{jk} f\left(\sum_{i=0}^{n} v_{ij} x_i\right)\right]^2\right\}. \end{aligned} \quad (3)$$

It can be seen from the above formula that the network input error is a function of the weights w_{jk} and v_{ij} of each layer, so the weights can change the error E.

In this paper, we first consider setting up only one hidden layer. When the number of hidden nodes in a hidden layer is too large to improve the network performance, we only consider adding another hidden layer. We determine the predetermined error requirements, the maximum allowed iteration steps, the search range, the maximum speed, and the number of particles according to the network scale. In order to avoid the phenomenon of weight oscillation and slow convergence in the learning process, it is necessary to consider the influence of the previous weight change on the current weight change and add the momentum factor.

Given the original data sequence with variable $x^{(0)}$,

$$x^{(0)} = \left[x^{(0)}(1), x^{(0)}(2), \ldots, x^{(0)}(n)\right]. \quad (4)$$

Generate a first-order cumulative generation sequence as follows:

$$x^{(1)} = \left[x^{(1)}(1), x^{(1)}(2), \ldots, x^{(1)}(n)\right]. \quad (5)$$

Among them,

$$x^{(1)}(k) = \sum_{i=1}^{k} x^{(0)}(i). \quad (6)$$

Since the sequence $x^{(1)}(k)$ has an exponential growth law and the solution of the first-order differential equation is exactly the solution of the exponential growth form, it can be considered that the $x^{(1)}$ sequence satisfies

$$\frac{\mathrm{d}x^{(1)}}{\mathrm{d}t} + ax^{(1)} = u. \quad (7)$$

In the formula, α and u are parameters and u is called the control term. The solution to this differential equation is

$$x^{(1)}(k+1) = \left[x^{(0)}(1) - \frac{\widehat{u}}{\widehat{\alpha}}\right]e^{-\widehat{\alpha}k} + \frac{\widehat{u}}{\widehat{\alpha}}, \quad (8)$$

where $\widehat{\alpha}$ and $\widehat{u}$ are approximate solutions of equation (7).

When learning BPNN, the initial value of its weight is very important. If the initial value is too large or too small, it will affect the learning speed, which is a complicated process of parameter system optimization. In this paper, the weights are coded by real numbers, the initial weights are set to random numbers, each particle represents the initial distribution of weights of NN, and the maximum speed limit of particles is set. We set the number of neurons in the input layer, hidden layer, and output layer of the NN. The connection weights w_{ij} and w_j to be optimized, the scaling factor a_j, and the translation factor b_j are taken as the position vector of each particle, which is

$$\mathrm{present}(m) = \left[w_{ij}, w_j, a_j, b_j\right]. \quad (9)$$

Among them, m is the number of particle swarms. We calculate the initial fitness value as follows:

$$F = \sum_{i=1}^{n}\left|y_i - h_i\right|. \quad (10)$$

We update the record that each particle has searched for the best position so far and the global search for the best position. The fitness function is the absolute sum of the prediction errors of the NN. n is the total number of network output nodes, y_i is the predicted output of the i th node, and DD is the expected output of the h_i th node. In this section, PSO is introduced, and by using its good algorithm convergence, the problem can converge to the global optimal solution or suboptimal solution with high probability, which solves the local convergence problem of BPNN itself. At the same time, the weights and thresholds of BPNN can be optimized, and the accuracy of BPNN in economic index prediction can be improved.

4. Result Analysis and Discussion

This section will introduce the data testing scheme and design process of the PSONN prediction model in detail. It will also test the model through actual data sets and compare it with other commonly used and similar models. The experimental results are discussed and analyzed. In this paper, Matlab software is used for simulation and prediction. Firstly, we design the structure and parameters of the network. The parameters to be determined in this paper are the number of nodes in the input layer and output layer of the network, the number of hidden layers, the number of nodes in hidden layers, the initial weights, etc. We set the number of nodes in the middle layer to 25, the hidden layer of the model to 30, and the weight learning rate to 0.2. The number of neurons in the input layer is 10, and the number of neurons in the output layer is 1. When the number of hidden neurons is 16, the model has the best prediction effect. We initialize the parameters of the PSO algorithm, with iteration times of 200 and a population number of 30. We take the sales data of a pharmaceutical company in 2019 as the original test data. The data are classified into training sample data and test data. Three terms of "sales time," "commodity number," and "sales quantity" are extracted from the test data, and the original sales details data are preliminarily screened and then summarized. The results are shown in Table 1.

In this paper, the original data are normalized, that is, the input and output data are uniformly limited to [0, 1] or [−1,1] by a certain linear transformation. The normalization process makes the drug sequences with different units and dimensions mapped into the [0,1] interval, which eliminates the influence of different dimensions on the input data and speeds up the training speed of NN and its related algorithms. The PSONN model is tested by using the preprocessed drug sales series. A simple mutation operator is added to reinitialize the particles with a certain probability, and the optimization is carried out by cyclic iteration until the maximum number of iterations is reached, and the optimal individual fitness value is recorded. The variation process of the optimal individual fitness value in the optimization process based on the adjusted inertia weight PSONN is shown in Figure 3.

From Figure 3, it can be seen that the PSO algorithm has a strong optimization ability, and the optimization of the algorithm is faster at the initial stage of iteration. Through the construction and testing of the model proposed in this paper, the AdaBoost-BP model and AdaBoost-ELM model, the prediction accuracy of each drug, the average accuracy of all drugs, and the total running time of the three models are obtained. Figure 4 shows the comparison of prediction accuracy of different models. Figure 5 shows the running time comparison of different models.

As can be seen from Figure 4, the sales forecasting accuracy of this model is higher than that of the other two models, and it is at a high level. The prediction accuracy of this model can reach 96.14%, which is about 12.78% higher than that of the traditional BP model. From the analysis of Figure 5, it can be seen that the running time of this model is short and its efficiency is high. Therefore, the sales forecasting method based on PSONN proposed in this paper has certain superior performance and has certain reliability and practicability.

The connection weights and thresholds are fixed in the prediction knowledge base. At this time, the whole NN is a time series prediction model, and the performance of the model is tested by test samples. The prediction error defined in this paper is the difference between the predicted value and the actual value. Figure 6 shows the error comparison of different models.

It can be seen that, on the whole, the error rate of this model is at a low level, indicating that the accuracy of this method is high. Table 2 shows the specific situation of the corresponding predicted performance indicators.

It can be seen from the data in the table that the overall trend between the predicted value and the actual value is consistent, which indicates that it is feasible to forecast the drug sales based on PSONN. The simulation diagram of drug sales forecast based on PSONN and traditional BPNN is shown in Figure 7.

Table 1: Summary of original sales details data.

Sales time	Commodity number	Sales volumes
2019-01	23769	758
2019-02	13875	544
2019-03	36974	721
2019-04	25897	473
2019-05	23521	130
2019-06	13267	167
2019-07	53679	871
2019-08	89732	165
2019-09	13078	746
2019-10	75890	752
2019-11	18970	546
2019-12	57698	655

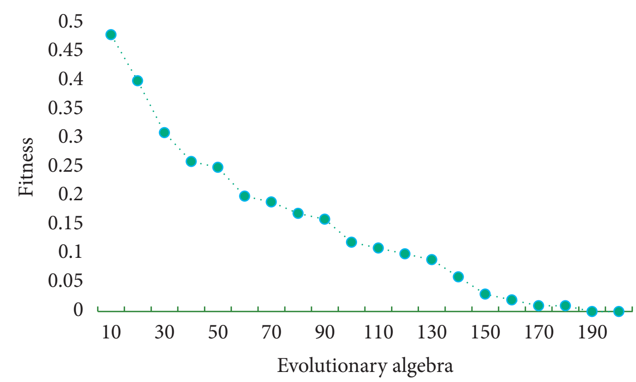

Figure 3: PSO process of adjusting inertia weight.

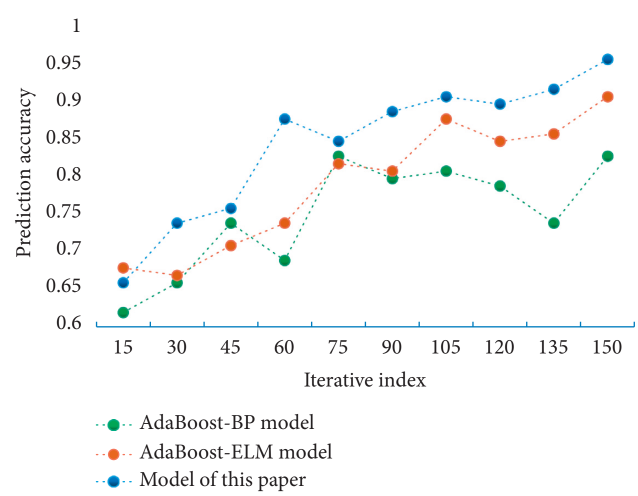

Figure 4: Comparison of prediction accuracy of different models.

It can be seen from the prediction chart that the predicted value based on PSONN is closer to the actual value, and its prediction effect is better than that of traditional BPNN. It shows that the improved algorithm is better than the traditional prediction model. A large number of experimental results in this chapter show that the NN sales forecasting model optimized by PSO can achieve 96.14% forecasting accuracy, which is about 12.78% higher than the

traditional BP model. Using PSO instead of the traditional training method of gradient descent of NN improves the dilemma that NN easily falls into the minimum value, improves the convergence speed, and makes the model have a certain superior performance.

5. Conclusions

The sales link, which connects suppliers, sellers, and consumers, is an important link in enterprise management. The most important part of the sales process is sales forecasting, and most commodity circulation industries' supply chains have inventory and sales problems due to a lack of appropriate sales forecasting methods. ANN has some advantages in dealing with nonlinear problems because it can cluster and learn from a large amount of historical data and then find some rules of behavior changes. As a result, the BPNN model is chosen as the basic forecasting model for drug sales forecasting, as it is the most widely used among the NN models. PSO is used to overcome the drawbacks of traditional NN, such as long training times, slow convergence speeds, and the ease with which it falls into local minima, resulting in improved performance. Experiments show that the PSO-optimized NN sales forecasting model can achieve a forecasting accuracy of 96.14 percent, which is about 12.78 percent higher than the traditional BP model. This model addresses traditional NN's flaws, such as long training times, slow convergence speeds, and a proclivity to fall into local minima, among others, and improves performance quality, yielding positive results in practice. The research shows that the forecasting method presented in this paper has a better forecasting effect on drug sales forecasting and that using the optimized model presented in this paper to forecast drug sales is practical and feasible. It is a good starting point for creating a prediction model for other problems. Although this model's prediction accuracy and run time have clearly improved, it still has some limitations. PSONN and particle swarm improvement have randomness, which makes prediction stability poor. In addition, the model comparison does not include the testing of some algorithms related to sales forecasting in this paper. I hope that the optimization algorithm will be further investigated in future work and research and that the algorithm's stability will be improved, resulting in a more perfect and reasonable model.

Monitoring and guiding instructional management require student performance evaluation. Traditional evaluation and analysis methods based on absolute scores, on the other hand, have certain flaws and are unable to fully reflect the information contained in student performance, thus limiting the impact of student performance evaluation on teaching and learning management. Data mining is regarded as the backbone technology for future information processing, and it introduces a new concept to the way humans use data. Schools must analyse and evaluate the performance of students in the same grade level and secondary school in a timely and staged manner. Clustering is a type of data mining that uses similarity rules to classify sample data into groups with a high degree of similarity. To address the difficulties caused by the wide variation in course difficulty in student performance evaluation, a method based on the *K*-means clustering algorithm is proposed. The *K*-means algorithm and the improved K-means algorithm with student information are investigated. The test results showed that the *K*-means clustering algorithm, the improved algorithm in this paper, and the fast global mean clustering algorithm all cluster the same randomly generated data set with noisy points, but the clustering time of the algorithm in this paper is only 0.04, which has obvious advantages. As a result, the clustering algorithm-based higher education management and student performance evaluation mechanism provides some insights for future research on student learning patterns. It is hoped that instructional administrators will gain a better understanding of students' learning characteristics so that they can better guide their teaching.

1. Introduction

Humans have greatly improved their ability to collect, process, organise, and produce information using information technology as the world moves toward an information society [1]. This has resulted in the creation of tens of thousands of databases of various types, all of which play an important role in scientific research, technology development, production management, market expansion, business operations, government offices, and other areas [2, 3]. Schools now have a variety of systems and databases that collect a large amount of data on the student achievement. Staff can only obtain a small amount of information through simple statistics of Excel tools due to a lack of relevant mining knowledge and technology, and the information hidden in these large amounts of data cannot be applied [4]. The globalised information reserve is expanding, and the amount of information available to people is expanding as well [5]. However, people's thirst for knowledge grows as they learn how to quickly find the information they need from such a vast amount of data [6].

However, there are some issues with evaluating teaching quality in universities in general. Traditional teaching quality evaluation methods have a number of flaws, and the results obtained are not scientific or accurate enough [7]. Various systems and databases are used by universities to collect large amounts of data [8]. Through a series of scientific and systematic evaluations, the primary goal of evaluation is to encourage universities to optimise their own resources, improve efficiency, improve academic research and talent training quality, and realise the social functions of universities [9]. Higher education management is a critical aspect of higher education operations, as it is linked to the quality and efficiency of the institution [10]. Data structure can be classified without prior classification using the cluster analysis method, revealing the inherent differences and connections of objective things [11]. Massive data analysis can provide useful guidelines for business management, project development, Internet finance, and efficient scientific research, allowing data resources to be fully utilised [12].

There are several clustering methods available, the most basic of which is partitioned clustering [13, 14]. Partitioned clustering tries to divide a data set into disjoint subsets in order to find the best clustering criteria. Researchers have divided clustering analysis into four categories to address these specific practical issues: partition-based methods, hierarchical methods, density-based methods, and grid-based methods [15]. Clustering algorithms are an important step in the modernization of education, which promotes the cultivation of innovative talents and improves the quality of all people. It completes the digital network automation of educational teaching management, campus life management, and other activities, encourages the growth of the educational information industry and the effective use of educational big data, and gradually develops an innovative educational management model that adapts to the needs of social informatization. Among them, the K-means algorithm is a traditional clustering algorithm based on division that performs clustering through continuous iteration. When the algorithm reaches the end condition, the iterative process is completed and the clustering results are output. The following are the paper's unique features. (1) In this study, data mining technology [16] is used to analyse students' academic performance data using fuzzy clustering, and "teaching" and "learning" are organically combined. (2) We can identify a number of undesirable phenomena in teaching activities, judge whether the teaching methods are reasonable, consider whether existing teaching theories can support classroom teaching, and assist in the development of teaching theories by evaluating classroom teaching quality. (3) Analyzing higher education management and student performance evaluation mechanisms using clustering algorithms. Data mining techniques can be used to describe and classify data, predict future behaviors and trends, and solve the time-consuming problem of traditional data analysis.

2. Related Work

2.1. Higher Education Management and Student Achievement Evaluation. Exams and teaching are inextricably linked in school education, and exam results are crucial in determining how well the students learn. Colleges and universities frequently use the average or total score as the grade standard when evaluating the general qualifications of students. This evaluation method is simple and easy to use in real-world teaching feedback, but it ignores the singularity and one-sidedness of the evaluation results caused by the test paper difficulty. As a result, we should investigate the current state of academic achievement evaluation in China's secondary schools, use data mining technology to investigate models and methods suitable for secondary school academic achievement analysis and comprehensive evaluation, and infuse new thinking into secondary school education quality comprehensive evaluation reform.

Omar's academic achievement evaluation should pay special attention to the process evaluation, which is a dynamic evaluation. It should not only be the evaluation of learning achievement, but should include learning attitude, behavior, and habit in the evaluation system. Li et al. judged from three aspects of evaluation view, evaluation method, and evaluation process, and proposed the evaluation model of two-way evaluation subject, comprehensive evaluation method, and multi-way evaluation perspective [17]. Goh et al.'s school uses test scores to evaluate students in a single way, which causes valuable data resources of wasting. It is recommended to use better models and software to analyse the scores [18]. Omolewa et al. analysed evaluation activities in terms of pedagogical elements and constructed a new evaluation model in terms of objectives, form, and content [19]. Wiechetek and Pastuszak argue that the evaluation of students' academic performance should tend to be diversified, focusing not only on their creativity, but also on their behavioral habits and values [20].

Through the comprehensive evaluation of students' academic performance, we can identify the gaps between students and classes, and then recognize the differences between the level of discipline teachers' teaching and classroom management of classroom teachers, so as to guide the next stage of discipline teaching and classroom management more effectively. In addition, through the analysis and comparison of various types of students' performance, corresponding improvement suggestions are given, which provide a theoretical basis for students' performance evaluation, personalized development and teachers' differentiated teaching.

2.2. Clustering Algorithm. Evaluation is an important tool for assessing and monitoring educational quality, as well as guiding teachers' teaching practices and encouraging students to pursue learning. Traditional performance analysis methods, on the other hand, are unable to objectively and accurately reflect the relative distribution of students' performance and the classification of their learning situation. It can only perform statistical analysis on the scores and knowledge points on candidates' test papers, and it cannot mine and analyse large amounts of data from the remote examination system well. If we are to make full use of the vast amount of data accumulated in the past and dig them out, we must first understand the characteristics of students' learning. We can analyse these academic performance data in depth as school administrators, classroom teachers, and subject teachers, discarding the "criticism" brought on by traditional performance ranking and exploring the data's value in providing powerful support for the implementation of the education strategy of "teaching according to students' abilities"

Davenport constructed a variable precision rough set model based on relational algorithms and performed a preliminary analysis of student performance [21]. Anoopkumar and Rahman et al. proposed a nonparametric clustering method for categorical attribute data, which became the K-modes-CGC algorithm, similar to the traditional K-means algorithm for

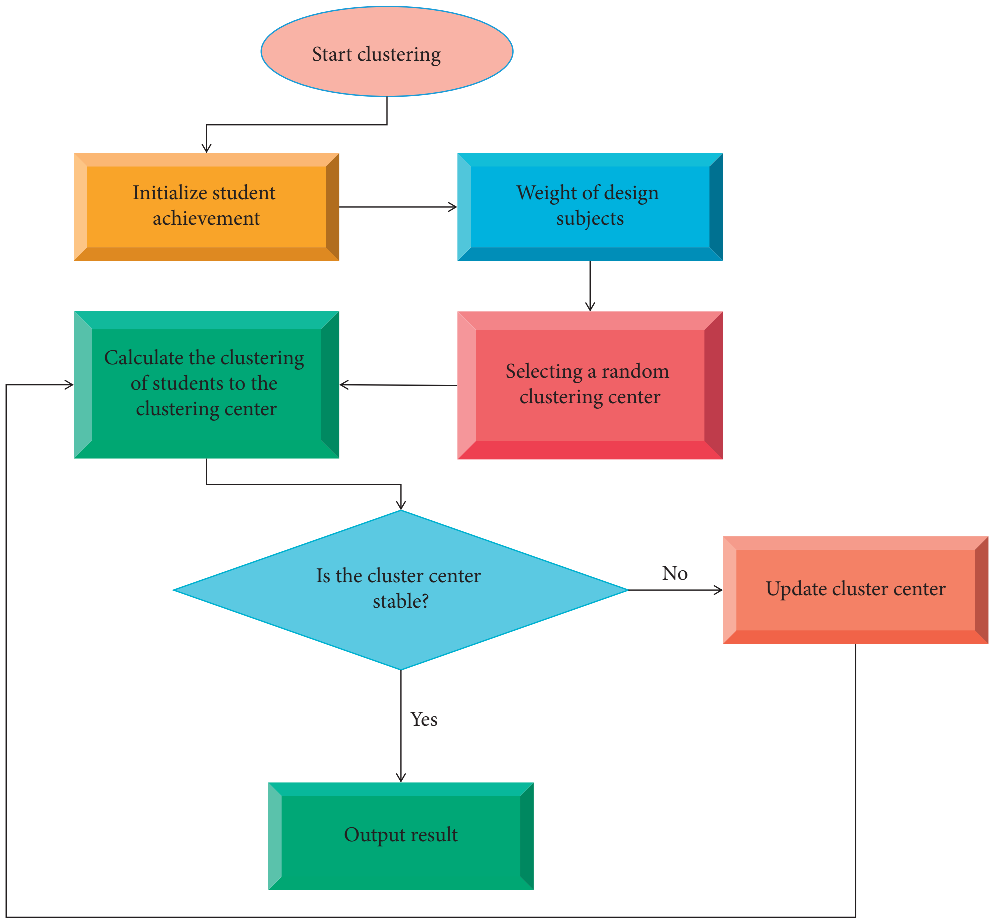

Figure 1: K-means algorithm studies the process of students' achievement.

numerical data [22]. Mayureshwar et al. used data mining techniques for distance learning in educational systems. In a distance personalized learning system, resources can be allocated for the individual learning needs of the students [23]. The Weka tool built by Belan Velasco et al. integrates various data mining algorithms into an interactive interface, which includes a variety of data preprocessing, categorization, degradation, regression, clustering, correlation rules, and optimization [24].

The process of teaching informatization has produced a vast volume of educational data, and these valid records are a reliable support for us to carry out the next stage of data mining. Clustering to several classes or clusters of data objects enables high similarity among objects in the identical clusters, but with significant differences among objects in various clusters. Through aggregation, one can identify dense and sparse regions, and discover global distribution patterns and interesting relationships among data attributes.

3. Thoughts on Higher Education Management and Student Achievement Evaluation Based on Clustering Algorithm

3.1. Performance Evaluation Scheme Based on Clustering Algorithm. Student performance evaluation is a kind of educational evaluation, a key link and important element of teaching and instructional management, and the most important source of information for teaching quality evaluation. Clustering analysis, as an exploratory analysis method, is widely used in pattern recognition [25, 26], computer vision [27, 28], data mining, and other fields. Its purpose is to divide a physical or abstract set of objects into several subsets based on the principle of similarity, and analyse the intrinsic connections, patterns, and characteristics of data objects within each subset. The sum of data corresponding to each clustering element is calculated by dividing the data of each element by the sum of data of this element, i.e.,

$$x'_{ij} = \frac{x_{ij}}{\sum_{i=1}^{m} x_{ij}}, \ (i = 1, 2, \ldots, m; \ j = 1, 2, \ldots, n). \tag{1}$$

Scientific evaluation of students' learning performance can help teachers and parents to grasp students' learning, and teachers and parents can make corresponding adjustments to the teaching and supervision of students' learning based on the evaluation results. The flowchart of studying student performance with K-means algorithm is shown in Figure 1.

The first step is data collection. In order to ensure the completeness and accuracy of the data, the original data sources must be well selected and organised. The original data source is input and with the participation of experts, it is decided which attribute features to use to describe the nature

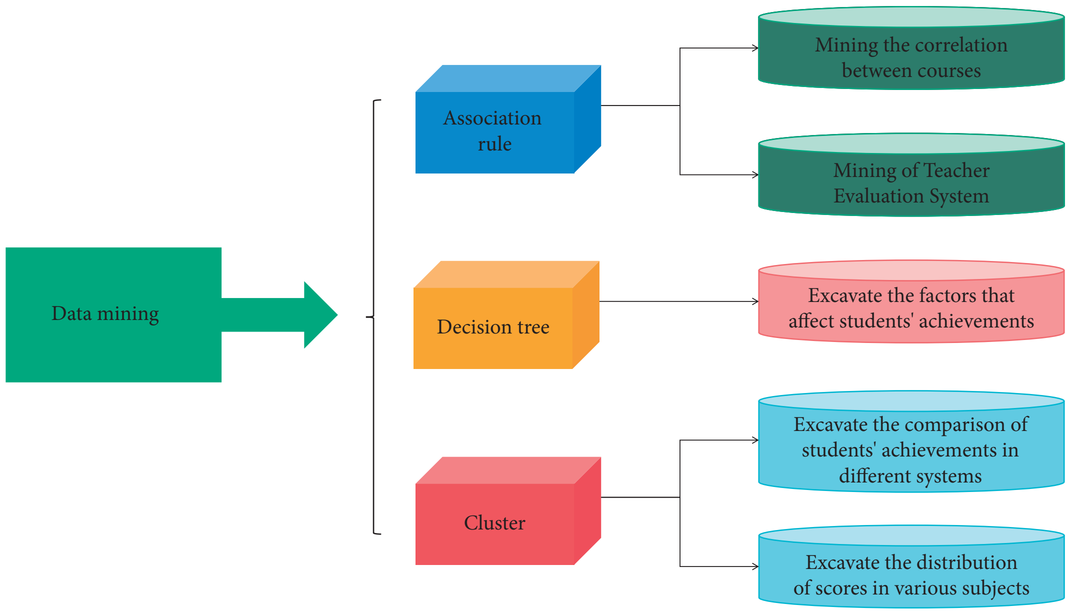

Figure 2: Data mining process.

and structure of the data source. Feature extraction outputs a matrix where each row represents a sample and each column represents a feature index variable. The new data obtained by this normalization has a maximum value of 1 for each element and all other values are less than 2. Therefore, the normalization is poor, i.e.,

$$x_{ij} = \frac{x_{ij} - \min(x_{ij})}{\max(x_{ij}) - \min(x_{ij})}, \; (i = 1, 2, \ldots, m; \; j = 1, 2, \ldots, n). \tag{2}$$

The representative data among them are extracted, and these extracted data are what are normally called sample data in data-related work [29]. Each data object is considered as a point in the d dimensional space, and then a certain distance is used to represent the similarity between the data objects. Data objects that are closer are similar in nature, while data objects that are farther away are very different. This is a phase of great workload and time. The data mining process is shown in Figure 2.

Next is data preprocessing, through the four steps of data review, data cleaning, data conversion, and data verification, the data is preprocessed to resolve data conflicts and data inconsistencies, and finally form student reports. The most commonly used clustering standard function, the error sum of squares, is applicable to all sample distributions with dense samples and small differences in sample size:

$$J_c = \sum_{j=1}^{c} \sum_{k=1}^{n_j} \left\| x_k - m_j \right\|_2. \tag{3}$$

The quality of data mining results will be adversely affected if the data input to the database has anomalous data, irrelevant fields, or even conflicting fields, improper data coding methods, and other anomalies [30, 31]. The sample matrix extracted in the first step is input to the clustering, and the individual sample is imagined as a point in the feature variable. The mean squared deviation is generally used as the standard measure function and is defined as follows:

$$E = \sum_{i=1}^{k} \sum_{p e C_i} \left| p - m_i \right|_2. \tag{4}$$

Since there are many indexes in the raw data, each index may have different dimensions and orders of magnitude. If the calculation is done directly using the raw data, it is likely that a large number of indexes will directly affect the clustering results. By definition, those data that are not suitable for training and learning are extracted from the sample data and excluded from the system. It should be noted that these data that need to be cleaned up generally refer to incomplete data. To accommodate the introduction of fuzzy partitioning [32, 33], the affiliation matrix allows the elements to have values between 0 and 1. However, using the normalization rules, the sum of the affiliations of the data set is always equal to 1:

$$\sum_{i=1}^{c} u_{ij} = 1, \forall j = 1, \ldots, n. \tag{5}$$

Finally, after performing the clustering algorithm to determine the mining task, the K-means clustering algorithm is written in matlab to implement the processing of the student achievement analysis. If the form of data used for mining does not match the characteristics of mining and they are necessary, in the face of this situation, what needs to be done is data conversion, conversion of display formats or coding formats, etc. After obtaining the clustering spectrum map in the second step, the expert can select the appropriate threshold value according to the particular applied situation. The data requires "sorting" and "filtering" to prevent

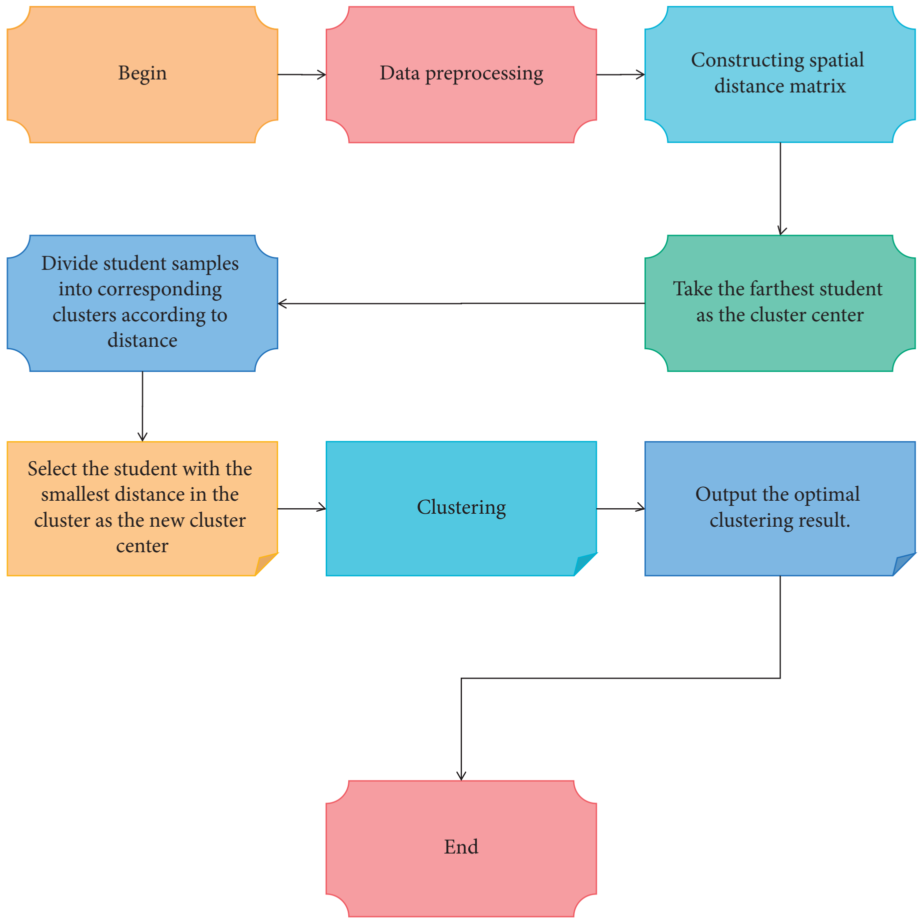

Figure 3: Clustering process of higher education management.

anomalies in the input data, which can enhance the effectiveness of data mining and the accuracy of mining results. When two vectors are similar in direction, the cosine of the angle is larger, and vice versa, it is smaller. When two vectors are parallel, the cosine of the angle is 1, and when the vectors are orthogonal, the cosine of the angle is 0.

3.2. Higher Education Management Method Based on Clustering Algorithm. As far as the school is concerned, the school needs data mining technology so that it can see the differences with other universities and enhance its competitiveness. It also needs a detailed and comprehensive understanding of its students' characteristics to improve their academic performance and practical skills, which in turn improves its teaching quality. The whole clustering higher education management process is divided into three parts: data preprocessing, multiple clustering result comparison, and optimal clustering result output, as shown in Figure 3.

First, you can tap into students' learning patterns, divide them into different groups, designate reasonable learning plans based on guidance, understand the characteristics of students in the groups, and strive for effective learning strategies. In the evaluation of student achievement, each class is an achievement group. Different classes divide each achievement group accordingly, corresponding to the central scores given to the different achievement groups. These center scores are one of the reference criteria for the classification of student achievement. We call the distance between two class centers the inter-class distance. If C_i is the clustered sample, define the class centers of C_i as follows:

$$\overline{x_i} = \frac{1}{n_i} \sum_{x \subset C_i} x, \tag{6}$$

n_i is the number of points in the ith cluster.

In practical problem analysis, different fuzzy similarity matrix construction methods may lead to different clustering results. It is necessary to decide the best fuzzy similarity matrix construction method based on the comparison results of the nature of the problem.

Next are class management, developing lesson plans, prescheduling, group class selection, managing scheduling, managing student attendance, and open control of teaching services. The total objective of evaluating teachers' teaching is divided into different secondary objectives, such as teaching attitude and teaching ability. Each secondary objective is then decomposed into several influencing factors, thus forming a hierarchical structure model. Standardized data can be processed by the following methods:

$$r_{ij} = \left\{ \begin{matrix} 1, & i = 1 \\ \frac{1}{m}\sum_{k=1}^{m} x_{ik} \cdot x_{jk}, & i \neq j \end{matrix} \right\} M = \max\left(\sum_{k=1}^{m} x_{ik}, x_{jk}\right). \tag{7}$$

The mined information is provided to teaching decision makers to adjust teaching strategies, further guide teaching efforts and improve student performance. Use the distance formula to calculate the distance between data objects; then select the k data objects with the first and last connection and the largest distance product from the distance matrix as the initial clustering centroid set. The distances between other data in the data set and the k centroids are also calculated, and the data are classified into the classes to which the nearest data belong by comparative filtering. When the absolute value of the data is compared with the specified threshold, the soft threshold noise is removed because the part less than or equal to the threshold is zero, and the part greater than or equal to the threshold is the difference from the specified threshold. The formula is as follows:

$$\omega\lambda = \begin{cases} [\mathrm{sign}(\omega)](|\omega| - \lambda), & |\lambda| \geq \lambda, \\ 0, & |\omega| < \lambda, \end{cases} \tag{8}$$

Then, exploratory factor analysis was used to explore the dimensions of each index system level and the loadings of each factor, remove unreasonable entries, determine the formal scale, and examine the correlation coefficients between the factors of the scale. Called X of the whole c fuzzy division space. If it contains degenerate division, then it is called degenerate c fuzzy division space. Let

$$V = i\frac{\sum_{j=1}^{n}\left(u_{ij}\right)^{m} x_j}{\sum_{j=1}^{n}\left(u_{ij}\right)^{m}}. \tag{9}$$

Finally, maintain the basic data needed to manage the academic affairs system, such as faculty information, major setting information, classroom information, teacher information, and textbook information. But if the result of mining is not what mining wants or the knowledge obtained is not meaningful, then it is necessary to go back to the previous stage in the process of data mining. In iterative optimization, the similarity metric can be changed and a new criterion function can be selected if necessary. Therefore, before selecting a new criterion function, the data needs to be preprocessed and transformed to be suitable for mining. Assume a certain mixed data $X(k)$, consisting of m dimensional observed signal vectors.

$$\mathrm{x}(k) = \left[x_1(k), x_2(k), \ldots, x_m(k)\right]^T. \tag{10}$$

Based on the distance between each cluster's mean and the remaining objects, the most similar cluster is assigned. Following that, each cluster's data matrix is computed. The data matrix is often referred to as a modal matrix because its rows and columns have different meanings, whereas the dissimilarity matrix's rows and columns represent the same entities, so it is referred to as a unimodal matrix. Self-reflexivity, symmetry, and transferability must be satisfied to determine whether a fuzzy relation satisfies the equivalence relation. The relation matrix is self-reflexive when all elements of the main diagonal are 1. The symmetry of a relation matrix can be demonstrated by showing it to be a symmetric matrix. Adjust the data set after calculating the centroid values of the new symmetric matrix. We consider that we have obtained the final data clustering result if the clustering centers between the new and old classes do not change or remain within a small range.

4. Analysis of the Clustering Algorithm in the Higher Education Management and Student Performance Evaluation Mechanism

4.1. Analysis of K-Means Clustering Algorithm. The K-means clustering algorithm is used to deal with data clustering problems. Due to its simplicity and early introduction, the algorithm has a wide impact in scientific and industrial applications. The K-Means algorithm allows us to understand the learning situation of a course by analyzing the students' comprehensive examination results. According to the characteristics of this course, combined with the students' own existence, it is possible to make a reasonable and scientific evaluation of the students' learning effectiveness, providing some guidance for teaching activities, and the final results will inspire the teachers' teaching methods. After clustering students' performance using the global central clustering algorithm, the results of $k = 2, 4, 6$ clustering were compared with CH indicators, and the relationship between the indicator values and the number of clusters is shown in Figure 4.

Firstly, k objects are arbitrarily selected from n data objects as the initial clustering centers. If the data is given in the form of a data matrix, the data matrix can be converted into a phase difference matrix. A new cluster center is calculated for each assigned cluster, and then the data assignment process continues. After several iterations, if the cluster centers no longer change, it means that all data objects are assigned to their clusters and the clustering criterion function converges; otherwise, the iterative process continues until convergence. Students are divided into two categories, excellent and deviant, and the number of clusters should be close to the number of clustering variables used. In this experiment, $k = 6$ was chosen. Several students' academic performance was randomly selected as the initial clustering centers through initial center of data analysis. The clustering results of the first class of students and the second class of students are shown in Figure 5.

Select an actual object that represents the cluster. Then, based on the similarity, each remaining object is clustered into the cluster where the most similar object is located. Based on the initial clustering of the set, the sample with the smallest distance and in the class is selected as the cluster center to generate a temporary set of cluster centers. A comparison of the distances between the scores of the students in the first category and the students in the second category to each cluster center is shown in Figure 6.

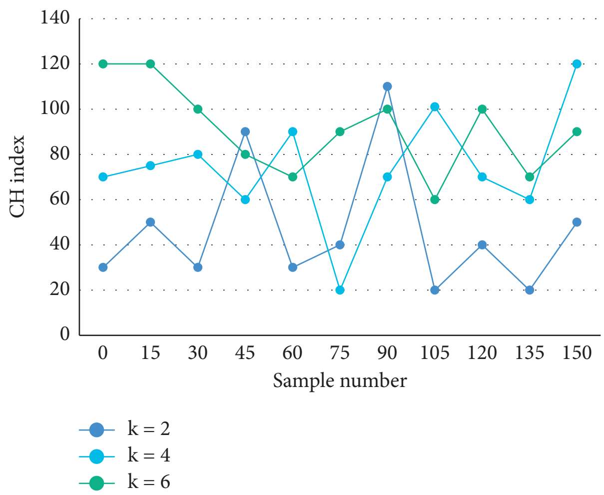

Figure 4: CH indicators of different k values.

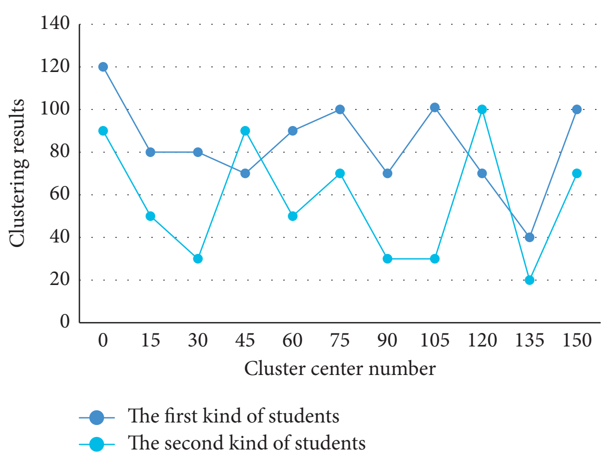

Figure 5: Comparison of clustering results between the first type of students and the second type of students.

Based on different classification patterns, the behavior of other data can be predicted. Obviously, the larger the value of interclass distance and criterion function, the better the separation of the various types of clustering results and therefore the higher the quality of clustering. Which distance calculation formula is used to measure the similarity between data objects needs to be chosen from the actual situation.

Next, the distance of each object to the center of each cluster is calculated and the object is assigned to the nearest cluster. Usually, clustering algorithms use the separation in characteristic space as a measurement to determine the similarity between the two samples. Suppose there is a data set containing n objects, and the data set is divided into k clusters by a division-based clustering method. With each sample as the center of the sphere and d as the radius, the number of samples that fall on the sphere is called the density of that point and is sorted by density. A batch of coalescing points is selected at first according to a certain method, and then the samples are allowed to coalesce to the

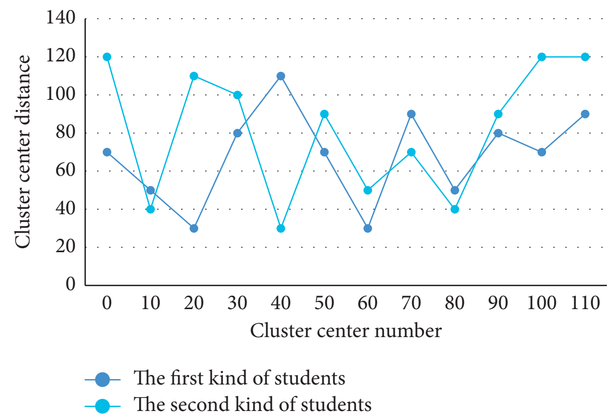

Figure 6: Comparison of the distance between the scores of the first class students and the second class students to each cluster center.

nearest coalescing point so that the points coalesce into classes to obtain the initial classification. There are many data preprocessing techniques that can be used to remove noise, and for those null values, we can also use some data normalization methods that can make the clustering algorithm more accurate. Then, according to the nearest distance principle, the unreasonable classification is corrected until the classification is reasonable, thus forming the final classification result.

Finally, the centers of the K clusters are recalculated after all objects have been specified. The method is implemented based on the principle of minimizing the sum of the differences between the corresponding reference points of all objects. Each sample is divided into corresponding clusters according to the minimum distance, and the iterative process of clustering centers is repeated until the clustering error sum-of-squares function converges and the clustering is completed. A characteristic of this algorithm is to adjust the distribution of all data points in each iteration, and then recalculate the clustering centers into the next iteration. If the positions of all data points are unchanged in a certain iteration and the corresponding clustering centers are unchanged, it indicates that the clustering criterion function has converged and the algorithm is finished.

4.2. Analysis of Improved K-Means Algorithm. Educational data mining takes a very vital function in the process of school education, and the huge and complex educational data brings difficulties to our work. How to utilise education data better for data mining and provide better support analysis for college decision making is another major problem we face. The traditional K-means algorithm can only be used when the mean value of the class is determined; the algorithm requires the user to give k in advance; this algorithm is not suitable for discovering clusters with non-convex shapes or clusters with large size differences. The improved K-means algorithm introduces a new measure of dissimilarity to deal with the classified objects. Instead, a simple matching pattern of phase dissimilarity measures is used and corrected using a frequency-based approach during clustering to minimize the value of

Table 1: Results of clustering.

	Good	Medium	Poor
Teaching ability	27.36	19.56	9.49
Teaching method	45.22	39.54	18.40
Content of courses	44.28	17.67	10.65
Teaching attitude	39.52	29.55	18.76
Number of samples	43	57	50
Percentage	29%	38%	33%

the clustering cost function. We collected 150 samples and conducted an experimental study of the data in these samples using the *K*-Means clustering algorithm. The number of clustering process was $k = 2$ and the results after clustering analysis are shown in Table 1.

First, we find a random representative object for each cluster, and determine the k clusters of n data objects. At present, academic examinations for secondary school students contain many subjects, and the results are basically presented in the form of "scores". The scores of each subject can be the same or different, usually 150 or 100 points. According to the distance axiom, four conditions of the distance axiom should be satisfied when defining the distance measure: self-similarity, minimum value, symmetry, and triangle inequality. If the distance between the attribute values calculated from the data samples is less than the set threshold, we consider these sample data as the same cluster and grouped into one category, otherwise, they are considered as different categories.

Secondly, if the quality of the obtained clusters can be improved by replacing a cluster representative, then the old cluster objects can be replaced by new ones and other objects will belong to each corresponding cluster according to their distances from these cluster representatives. Students have a well-defined interval for their exam results, with a minimum score of 0 and a maximum score of full. Each subject is measured in terms of scores within this range, and there are no cases of abnormally high or low data. The comparison of clustering time and sum of squared clustering errors using *K*-means clustering algorithm, fast global mean clustering algorithm, and the improved algorithm in this paper is shown in Table 2.

The *K*-means clustering algorithm, the fast global mean clustering algorithm, and the improved algorithm in this paper have the same clustering effect on randomly generated data sets with noisy points, but the clustering time of this algorithm is only 0.04, which has obvious advantages.

On the basis of the sample similarity measure, it is also necessary to determine the criterion function for evaluating the quality of the clustering results, so that the samples that really belong to the same class are aggregated into a type of subset and the samples of different classes are separated. The objects in the same cluster should be as close as possible, and the objects in different clusters should be "far away". After clustering, the similarity between data in the same cluster, i.e., the same class of data, is extremely high, while the similarity between data in different clusters is very low, i.e., the data in the clusters are very different. In order to show the superiority of *K*-means algorithm in time, the graphs of

Table 2: Comparison of clustering results of randomly generated data.

	E ($\times 10^3$)	T (s)
K-means clustering algorithm	0.567	1.23
Fast global mean clustering algorithm	0.674	0.12
Improved *K*-means clustering algorithm	0.749	0.04

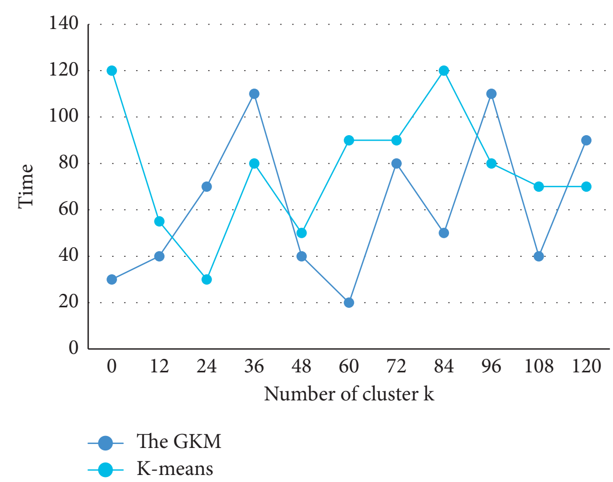

Figure 8: Running time of two algorithms when different categories are taken on Segmentation data set.

the GKM and *K*-means algorithm running time with increasing number of clusters on two sets of data are given in Figure 7 and 8.

Finally, the clustering quality is assessed using a cost function based on the distance between each object and its clustering representative, with the change in distance variance accumulated by replacing unsuitable representatives, which is the clustering criterion function's output. The mean of the data becomes a constant 0, the standard deviation is a constant 1, and the coefficient of variation does not exist after the translation standard deviation transformation, indicating that the data resolution is completely assimilated. The clustering criterion function can also be used to assess the clustering results' quality. The clustering process should be repeated if the clustering quality does not meet the requirements. Instead of considering the entire data set, a representative sample of the data is chosen, and then the centroids are chosen from the sample.

5. Conclusions

The rapid development of the Internet has provided excellent technical support for the growth of online education, allowing it to overcome the time and space constraints of the existing school education system and the teacher-led education model. Clustering is an unsupervised learning algorithm that can cluster data sets without using predefined classification rules, allowing it to mine hidden information in data and create relevant data models. In the trend of education informatization, the application of data mining technology to data analysis in the teaching field will undoubtedly have a very broad perspective. Academic performance evaluation is an important component of the comprehensive evaluation reform of education quality. The use of a clustering algorithm in student performance analysis compensates for the lack of traditional evaluation methods by comparing student performance differences horizontally. Clustering analysis has evolved into a tool that can be used not only for data processing but also for data analysis when combined with other algorithms. As a result, this paper proposes a mechanistic analysis of higher education management and student performance evaluation based on clustering algorithm to assess the quality of college classroom teaching from two perspectives: students' learning effects and teachers' teaching work, with the K-Means algorithm as the primary method. The theory and application of clustering are highlighted based on a summary of data mining theory. This research presents a set of scientific and reasonable management capability evaluation index systems for universities, which serves as a strong foundation for relevant departments to conduct university administration capability evaluations in the future and, as a result, contributes significantly to raising the standard of university administration.

With the popularity of the Internet and the advancement of information technology, more and more people are accepting the teaching and sharing of knowledge through the digitalization of information. The widespread adoption of 5G technology has pushed online learning even further into the mainstream. However, because online teaching does not have the drawback of being intuitive like classroom teaching, teachers' assessments of students' learning situations are less accurate. As a result, how to effectively evaluate students' academic performance in the context of 5G wireless network technology is a pressing issue that must be investigated. By processing these heterogeneous large-scale learning records and integrating multiple perspectives to analyze this learning record information to identify students' learning behaviors, this study proposes an integrated analysis algorithm based on artificial intelligence information technology. The possible learning outcomes of students are predicted based on their current learning situation, so teachers can provide auxiliary teaching strategies to students who may have learning difficulties based on the predicted information. The method proposed in this article uses information technology to predict students' grades, and the analysis shows that the method is very effective. In this article, different grades of classification methods are used to analyze and predict the whole students. All grade classification methods are effective in describing decision rules. No matter what grades classification method is used, the error rate of students' grades distribution is predicted to be below 40%.

1. Introduction

5G networks have significant advantages over traditional 3G and 4G communication networks, including high information transmission efficiency and relatively fast speeds. It is organically combined with big data, the Internet of Things, and other technologies, greatly promoting business needs and business model innovation in a variety of fields and providing strong support for society's intelligent development. Artificial intelligence is formed when computer technology and communication technology are combined in this way. Massive amounts of data are generated every second in the big data environment [1]. Artificial intelligence can greatly improve the speed and quality of data processing and be used to process large amounts of complex data, increasing data security. Artificial intelligence, when used extensively, not only improves the information processing capability of computer systems but also promotes their evolution toward intelligence and automation. Furthermore, it can completely ensure the system's stability. Massive amounts of data are generated every second in the big data environment. Artificial intelligence can greatly improve the speed and quality of data processing and be used to process large amounts of complex data to improve data security [2]. With the development of artificial intelligence and the arrival of the 5G communication era, in order to realize the effective management of massive network information, advanced artificial intelligence technology can be adopted, many scientific and reasonable solutions can be compiled, and an expert knowledge sharing system can be established to gradually improve the data analysis and processing effect. On the other hand, experts in the field of theory should effectively strengthen scientific research, summarize theoretical results, and fully reflect the advantages of artificial intelligence.

Based on artificial intelligence information technology, this article proposes an algorithm for predicting students' academic performance. The decision tree's input and output variables are determined by the algorithm using the student learning behavior factor data table [3]. Then, all samples are randomly divided into three datasets, which are used for training, testing, and validation, and the characteristics of students' learning behavior are analyzed accordingly, resulting in an algorithmic basis for predicting students' grades. Find the decision-making rules between students' various learning behavior attributes and learning outcomes for each course in the fifth and sixth semesters and explain the results. This study uses the same course in different semesters as the object of verification, and the data from the fifth, sixth, and seventh semesters as training data and test data, respectively, to verify the discovered decision rule. The training error rate and the test error rate are used as verification indicators to try to find the best prediction time point using different time units and to try to find the best grade classification method using various grade classification methods. The artificial intelligence-based decision tree for predicting students' academic performance analyses and discusses the students' learning situation and provides specific educational guidance based on the data analysis results [4].

This study examines the relationship between course attributes and decision rules under different courses, the relationship between different time points and decision rules under different time units, and the relationship between different grade classification methods and decision rules by processing these heterogeneous large-scale learning records, the relationship between each time point within the time unit and the high and low score prediction effect, the relationship between different grade classification methods and the high and low score prediction effect, and so on. Students' current learning circumstances predict their potential learning effect [5].

This article's chapter structure is as follows: this article extracts data from learning records, uses artificial intelligence technology to classify and analyze the data, and then provides teachers with information on the relationship between students' learning behavior and learning effectiveness, as well as the degree of correlation between the two. Teachers can predict various learning situations that may exist in current and future students based on their past learning behavior and provide learning assistance or adjust teaching strategies in real time.

The following are the article's unique features: the first chapter introduces related research on artificial intelligence information technology and teaching strategies; the second chapter examines current educational management needs in light of current educational development; the third chapter is based on artificial intelligence information technology. The fourth chapter uses intelligent information technology to quantitatively analyze the results and summarize the rules, and the fifth chapter is a summary of the entire text.

2. Related Work

The international empirical analysis of student achievement prediction has also developed from the original manual statistics to the joint statistics of artificial intelligence and information technology.

Combined with the current situation of information technology teaching in junior high schools, Kaptein MC built a junior high school information technology teaching model with the concept of flipped classroom teaching and proposes to improve learners' interest in information technology through independent learning or cooperative exploration among learners and cultivate students' ability in the learning process. In terms of research on learning motivation, creativity, and initiative [6], Zhou H tried to revise and perfect the new model in teaching practice through three rounds of action research. Through questionnaire survey and SOLO taxonomy, the impact of this model on the deep learning and learning ability of primary school students was analyzed [7]. After in-depth research, Luo X built a grade prediction model. By using this model, the characteristics of students can be predicted, and then the low-achieving students can be analyzed in a targeted manner [8]. Huang X collected students' learning information through questionnaires, studies students' learning behavior and then converted students' tacit knowledge into explicit information through the Apriori algorithm and cluster analysis, and this explicit information can be used as follow-up services so as to improve students' learning satisfaction [9]. Kirichenko A V et al. used a combination of a self-organizing competitive neural network (SOM) and BP neural network to establish a student achievement prediction model [10]. After intensive research, Cui L proposed a system that can predict student grades based on multiagent learning (MAFDS) behavior [11]. Jie H used two data mining methods, genetic algorithm and decision tree, to establish a model to find out the potential relationship between factors in student behavior data and use a decision tree for preliminary classification [12]. Zhang Z used three methods: support vector machine, logistic regression, and decision tree C5.0 to construct a low learning achievement risk classification model, and they used a 10-fold cross-validation method to verify the model and found that the method with the best prediction effect was support vector machine [13]]. Ting-Ting LU used a variety of data mining methods to integrate expert opinions and then used genetic algorithms to find the best combination solution to create an optimal integrated student achievement prediction model. The best prediction method is a neural network [14]. Liu Y's research found that the classification and prediction of students' grades is an important problem, and the commonly used classification methods often include the logistic regression model and Bayesian algorithm. Chen Y used the decision tree in data mining technology to classify the data mining application of predicting students' grades. The results show that the expected evaluation effect can be achieved by using the decision tree [16]. Zhang X pointed out that the use of support vector machines has achieved good prediction results in terms of student achievement, and studies have shown that the application of support vector machines in feature selection and prediction has achieved high classification accuracy [17].

In literature, it is generally emphasized that the application of innovation theory is used to reform teaching methods, but there are no articles that specifically propose methods and strategies for various management work in colleges and universities, such as teaching management, student management, campus culture construction, and enrollment work. Through the research on the application of data mining in student achievement prediction, it can be found that at present, most of the research on student achievement prediction is focused on students' examination results, but there is no research on how to effectively predict students' academic achievements under the new teaching method such as online education, and an in-depth study on the correlation between academic achievements and learning courses, learning time and learning patterns.

3. Education Management Needs Analysis

Most of the talents cultivated by higher education will become leaders and leaders of all walks of life and can be regarded as high-end talents in all walks of life. For this type of talent, in the actual leadership work, they need to put aside traditional and conservative old views and old ideas, so they need a more innovative spirit. As a cutting edge of the education industry, higher education should pay more attention to the cultivation of innovation ability and apply the innovation concept to daily education management. Since the concept of artificial intelligence information technology was put forward, more and more people began to realize the importance of innovation, and more and more people began to put it into practice [18]. Nowadays, the trend of educational development is no longer to align with scores, no longer to train high flyers of top universities, and no longer to blindly ask students how many scores they get in TOEFL and IELTS but to pay more attention to students' personal ability while valuing scores. Students with high test scores, low abilities, and a lack of innovative ability are already unpopular, and in today's information age, they will be questioned and eliminated. They are energetic, persistent, focused, imaginative, and adventurous; they have a strong ability to learn and explore themselves; they have broad and solid knowledge, a high professional level, good moral cultivation, and the ability to cooperate or coexist with others. True innovative talents with the aforementioned characteristics will become the most in-demand talents in today's society and Muhui's mainstay. Artificial intelligence information technology, on the surface, refers to making improvements to original educational concepts, educational methods, and educational methods in order to make them more current and effective. In essence, artificial intelligence information technology is used to break through the ingenious vertebrae of previous educational development through educational innovation, making education more grounded and in line with the needs of the times, rather than simply activating the classroom atmosphere and enriching the content of textbooks. In the new situation, education reform is focusing on improving students' innovative awareness and ability [19, 20].

Constructivist learning theory believes that learning is the process of students actively constructing internal mental representations in the process of interacting with the learning environment. Knowledge is not obtained through the teacher's teaching and transmission but is obtained by students in a certain situation, with the help of other means, using necessary learning materials and learning resources, and by means of meaning construction. Constructivism puts forward the viewpoint of situational cognition, emphasizes the situational nature of learning, knowledge, and wisdom and believes that knowledge cannot exist abstractly without being separated from the activity situation, and learning should be combined with situational social practice activities. These need to be arranged in a hierarchy from low level to high level, as shown in Figure 1.

The four needs at the bottom of the hierarchy are classified as missing needs, which are essential for individual survival and must be met to some extent [21]. When all of the missing needs are met, the individual will pursue the above three high-level needs, which are classified as growth needs and can improve the quality of the individual's life. According to Maslow's hierarchy of needs theory, everyone has a need for understanding, respect, and self-realization, and everyone has a desire and need to communicate. Even the most withdrawn, independent person, or the so-called poor students in the eyes of some teachers, hope to receive understanding, care, and assistance in their hearts. Students can benefit from rich learning resources, convenient interaction methods, and a humanized situation design in the information technology teaching environment, which can meet their communication, respect, knowledge, and aesthetic needs. Once these needs are met, students will have a positive attitude toward themselves and gain positive emotional experiences like satisfaction, happiness, and pride, which will aid in developing advanced social emotions like reason, beauty, and morality so that the students have a positive mental attitude [22].

4. Quantitative Evaluation of Teaching Based on Artificial Intelligence Information Technology

The ultimate goal of this article is to improve the level of school teaching management, make teaching management more convenient and fast in the future, digitize teaching evaluation information, and allow users of teaching evaluation to access the system from any location and time on the campus network without being limited by time and space. The purpose of reviewing the information you need is diversified, which can meet the current practical needs of various evaluation purposes. At the same time, focusing on the fundamental purpose of promoting the development of teachers, the main functions of the teaching management unit are transferred to the collection, processing, and transformation of digitalization, the realization of technical means, and the transformation of service methods [23].

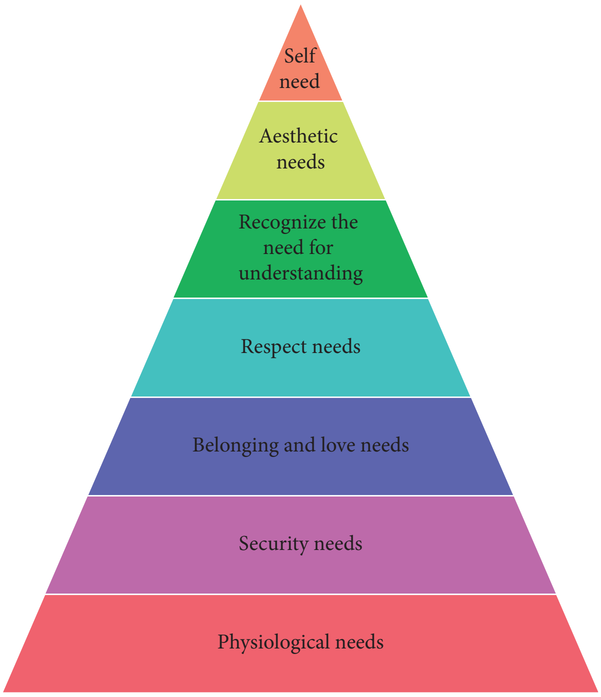

Figure 1: Need hierarchy theory diagram.

After an in-depth analysis of the problems, when the factors contained in the problems are divided into different levels, such as target level, criterion level, index level, scheme level, and measure level, the subordinate relationship of hierarchical structural factors of the levels is explained in the form of the block diagram. When a certain level contains many factors, the level can be further divided into several levels. Since it is quite difficult to directly use the definition to calculate the eigenroot and eigenvector of the matrix, after the paired comparison matrix is constructed, the sum-product method or the square root method can be used to approximate the maximum eigenroot and corresponding weight vector of the constructed paired comparison matrix. Using the sum-product method to calculate, the formula is shown in as follows:

$$a_{ij} = \frac{a_{ij}}{\sum_{k=1}^{n} a_{kj}} \, (i = 1, 2, \ldots, n). \tag{1}$$

For the judgment matrix normalized by column, sum it by row as shown in the following:

$$\overline{\omega}_i = \sum_{j=1}^{n} \overline{a}_{ij}. \tag{2}$$

Normalize the vector $\overline{\omega} = [\overline{\omega}_1, \overline{\omega}_2, \ldots, \overline{\omega}_n]^T$ as shown in the following:

$$\omega_i = \frac{\overline{\omega}_i}{\sum_{i=1}^{n} \overline{\omega}_i}. \tag{3}$$

In the actual evaluation, the evaluation experts can only roughly estimate the value of the element a_{ij} in the pairwise comparison matrix, which often leads to inconsistent logic errors. In this article, the difference between $\lambda_{\max}$ and n is used to test the consistency. First, calculate the maximum eigenvalue such as the following equation:

$$\lambda_{\max} = \sum_{i=1}^{n} \frac{(A\omega)_i}{n\omega_i}. \tag{4}$$

Calculate the consistency index as shown in the following equations:

$$CI = \frac{\lambda_{\max} - n}{n - 1}, \tag{5}$$

$$CR = \frac{CI}{RI}. \tag{6}$$

When $CR < 0.1$, the inconsistency scale of task A is within the allowable range. Otherwise, the evaluation expert needs to reestimate and adjust the value of the element a_{ij} in the pairwise comparison array until the consistency requirements are met. The average consistency principle is shown in Table 1.

After obtaining the relative weights between the indicators of the same layer, the absolute weights of the indicators at all levels can be calculated from the top to the bottom. Overall consistency is considered acceptable when $CR < 0.1$. Otherwise, it is necessary to adjust this paired comparison matrix until the consistency test of the total ranking of the hierarchy meets the requirements. In summary, the process of calculating the absolute weight can be obtained as shown in Figure 2.

Since the indicators have different unit dimensions, the indicators must be standardized, and all indicators are converted into indicators without units. There are positive indicators, reverse indicators, and moderate indicators in the indicator system, and the advantages and disadvantages of the indicators are not clear. Therefore, the method of fuzzy quantization, that is, fuzzy membership function, is used to carry out dimensionless processing of each indicator [24].

For the positive index, the semirising trapezoidal fuzzy membership function is used to quantify, and the processing of the positive index is shown in the following:

$$x_{ij} = \frac{x_{ij} - x_{\min}}{x_{\max} - x_{\min}}. \tag{7}$$

For the reverse index, the semidrop trapezoidal fuzzy membership function is used to quantify, and the reverse index processing is shown in the following:

$$x_{ij} = \frac{x_{\max} - x_{ij}}{x_{\max} - x_{\min}}. \tag{8}$$

For the moderate index, the semisublimation descending trapezoidal fuzzy membership function is used to quantify the moderate index processing, as shown in the following:

$$x_{ij} = \begin{cases} \dfrac{x_{ij} - x_{\min}}{x_{half} - x_{\min}}, & x_{ij} > x_{half}, \\ 1, x_{ij} = x_{half}, & \\ \dfrac{x_{ij} - x_{\min}}{x_{\max} - x_{half}}, & x_{ij} < x_{half}. \end{cases} \tag{9}$$

Table 1: Average consistency index.

N	1	2	3	4	5	6	6	7	8	9	11

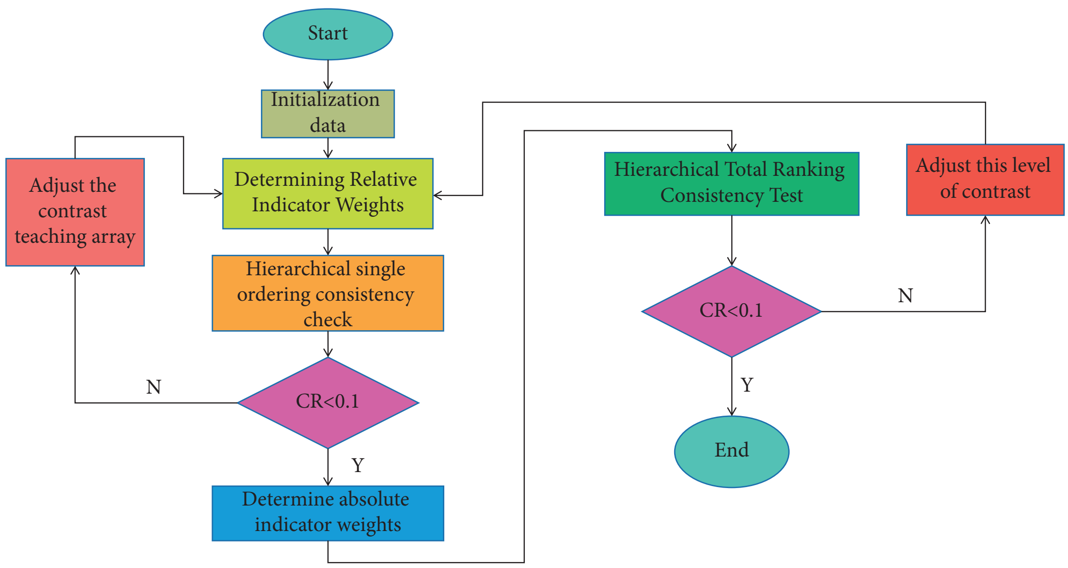

Figure 2: Flowchart of weight indicator.

The decision-making rules generated by artificial intelligence information technology analysis are for each course, and most of the analyzed data are historical data of the entire semester. For teachers, these decision-making rules are not directly helpful to the courses being taught, and they are based on the data of the whole semester. Whether these decision-making rules can be applied to the same courses in different semesters is indeed necessary to verify the accuracy of these decision-making rules in predicting the courses.

5. Data Analysis

5.1. Test Score Indicators. The median is the value of a point in the center to represent the central tendency of a set of data. The median is suitable not only for data with skewed distribution, irregular distribution, large difference between variable values, and unbounded at one or both ends but also for data with symmetrical distribution or unclear distribution. The arithmetic square root value of each variable value from the square of the mean deviation, also known as the square root of deviation from the mean. As an overall parameter, it is usually represented by a symbol, and the formula is shown as follows:

$$\sigma = \sqrt{\frac{\sum (X-u)^2}{N}}. \tag{10}$$

Evaluate the overall difficulty and discrimination of the test paper, and conduct difficulty analysis and discrimination analysis for each question. Through analysis, we can better understand the degree of difficulty and distinction of the test paper and evaluate the quality of the test paper as a whole. Evaluate the option ratio distribution of multiple-choice questions and design questions more scientifically. The test paper evaluation model validation process is shown in Figure 3.

Since the records of the log files are too scattered, they have no substantial meaning and help for teachers or students. Therefore, it is necessary to combine the basic data files of students and the data of the course database of the relationship between course information and students. After preprocessing and after the data are sorted and processed, a learning record database describing the learning behavior of each student in each course can be further established, which can be used as a reference for quickly querying the real-time learning status of students in each course in the future.

5.2. Data Analysis of Student Achievement Prediction. Analyzing the decision-making rules that link students' learning behaviors and learning outcomes in each course can help teachers and teaching assistants understand what learning behaviors students exhibit in this course and how they may affect academic performance. They can also observe the attribute value changes of related learning behaviors in subsequent lessons and provide assistance ahead of time. However, it is understandable to analyze these learning behaviors using only data from the entire semester; however, these decision rules can only describe students' learning behavior during the previous entire semester of the course, not at different time points, because the real learning behavior is not predictable. We can predict the possible learning effects of students based on their current learning

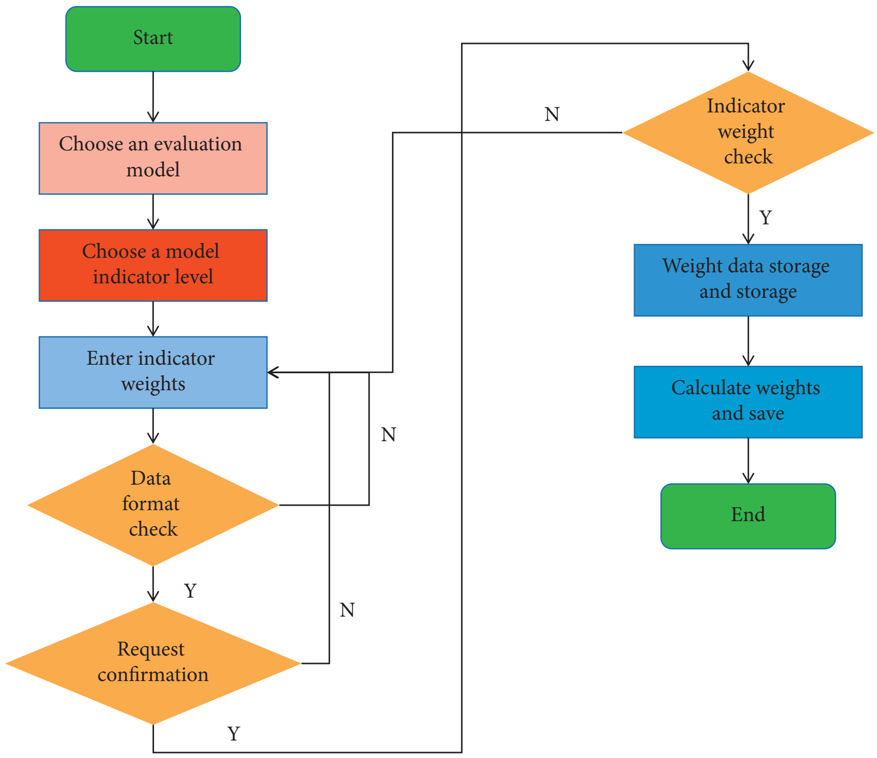

Figure 3: The flowchart of test paper evaluation model verification.

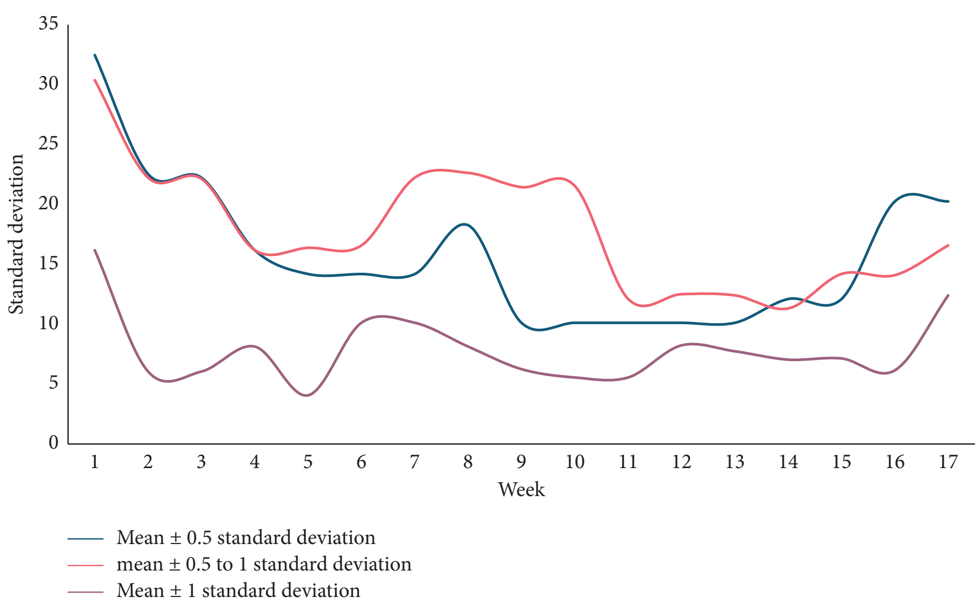

Figure 4: The standard deviation of the training error rate at each time point with 7 days as the time unit.

situation and give the purpose of auxiliary teaching in advance by observing these learning behaviors. This study uses the training error rate and the prediction error rate as comparison indicators for various analyses when validating the decision rules in order to verify the relationship between each time point and the decision rules. The goal of tracking the training error rate is to avoid having a high training error rate. The prediction error rate refers to the error rate of the decision rules trained in the sixth semester as the test data in the seventh semester. It can be used to ensure that decision rules are applied consistently across semesters. As a result, the focus of this section will be on observing the relationship between each time unit and the prediction error rate. It is primarily based on the cumulative amount of learning behavior attribute values at various time points; that is, the cumulative value of each frequency is calculated from the start of the school day to each time point, and by observing the relationship between changes in the cumulative amount

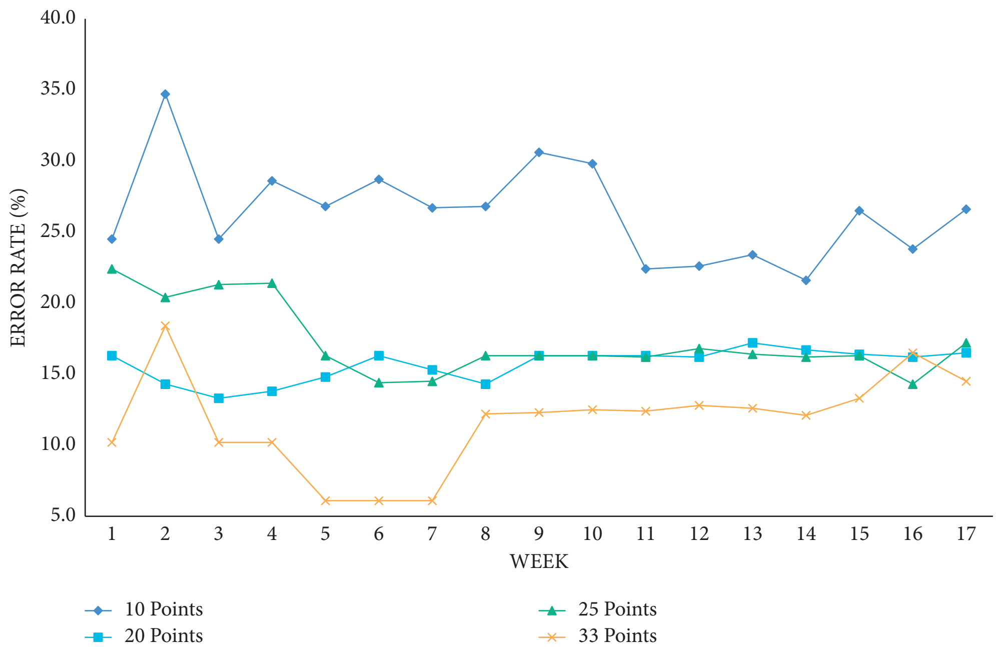

Figure 5: Training error rate at each time point with 7 days as the time unit.

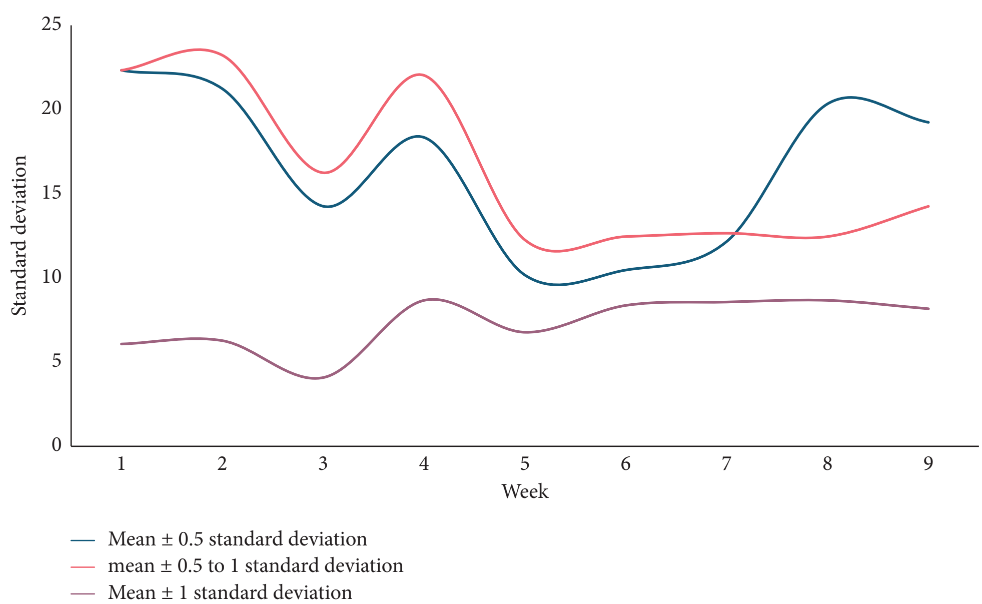

Figure 6: The standard deviation of the training error rate at each time point with fourteen days as the time unit.

of learning behavior variables at various times and the learning effect, to provide future decision tree analysis, by observing the relationship between attributes and the learning effect. The cut-off points for grades in this article are 10 points, 20 points, 25 points, and 33 points, and the time variables used in most previous studies are used as the observation dimensions of learning type analysis. In other words, whether the attributes in the decision rules are the same at all time points and whether it is possible to predict ahead of time which students will fall into the low-scoring group and have poor learning outcomes before the semester ends and provide remedial teaching or a related teaching strategy. Students' final semester grades in the course are used to assess learning outcomes.

This article first observes the changes and trends of the training error rate and prediction error rate at various time points under different time units such as seven days, fourteen days, and twenty-eight days. Finally, a conclusion is drawn by comparing the prediction effects of different time units. The training error rate at each time point with seven days as the time unit is shown in Figures 4 and 5.

Taking seven days as a time unit, the training error rate of various performance classification methods can be below 30%, and the average error rate of the mean ± 1 standard

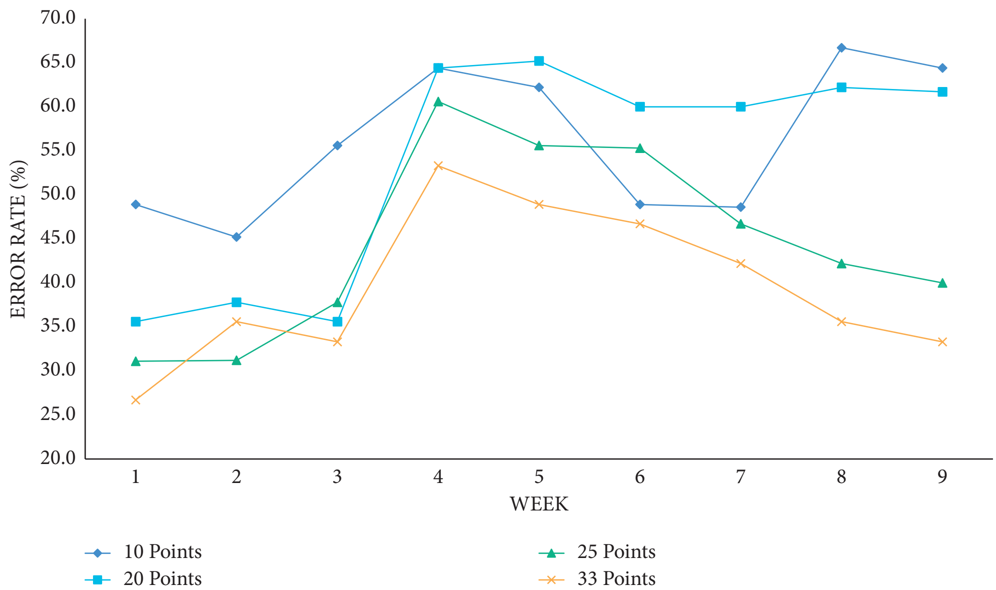

Figure 7: The training error rate at each time point with fourteen days as the time unit.

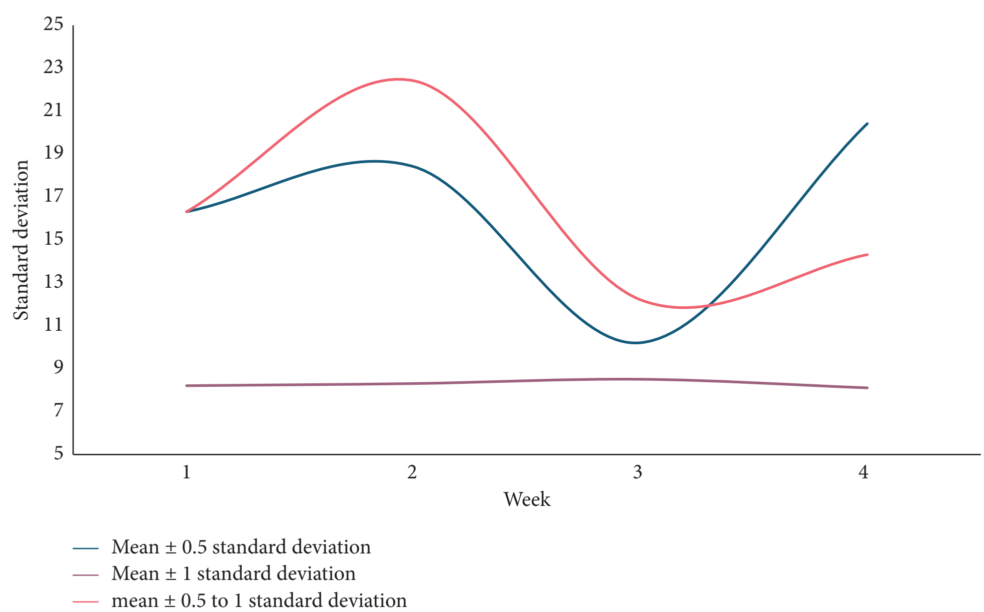

Figure 8: The standard deviation of the training error rate at each time point with twenty-eight days as the time unit.

deviation can be trained in the eighth to ninth weeks. The performance is lower if it falls below 15%, and each classification method can reduce the error rate over time and drop below 20% in the score range of 20, 25, and 33 points.

The training error rate at each time point with 14 days as the time unit is shown in Figures 6 and 7.

Figure 7 shows the prediction error rate at each time point under the time unit of fourteen days. Taking 14 days as the time unit, the prediction and practice error rates of various performance classification methods can be below 50%, and the average performance of the error rate with the mean ± 1 standard deviation is lower and the mean ± 1 standard deviation can drop to the error rate below 35% in weeks seven to eight. Among them, if compared with Figure 7, it can be seen that the two methods of mean ± 0.5 to 1 standard deviation and 20 points are the two methods, the prediction effect in the time unit of 14 days has become less obvious, so it is concluded. Therefore, as the time period increases, the effect of reducing the error rate will become less obvious, and the two are inversely proportional.

The training error rate at each time point with twenty-eight days as the time unit is shown in Figure 8 and Figure 9.

Figure 9 shows the training error rate at each time point under the time unit of twenty-eight days. Taking twenty-eight days as the time unit, the mean ± 1 standard deviation, and the difference between the mean ± 0.5 and 1 standard

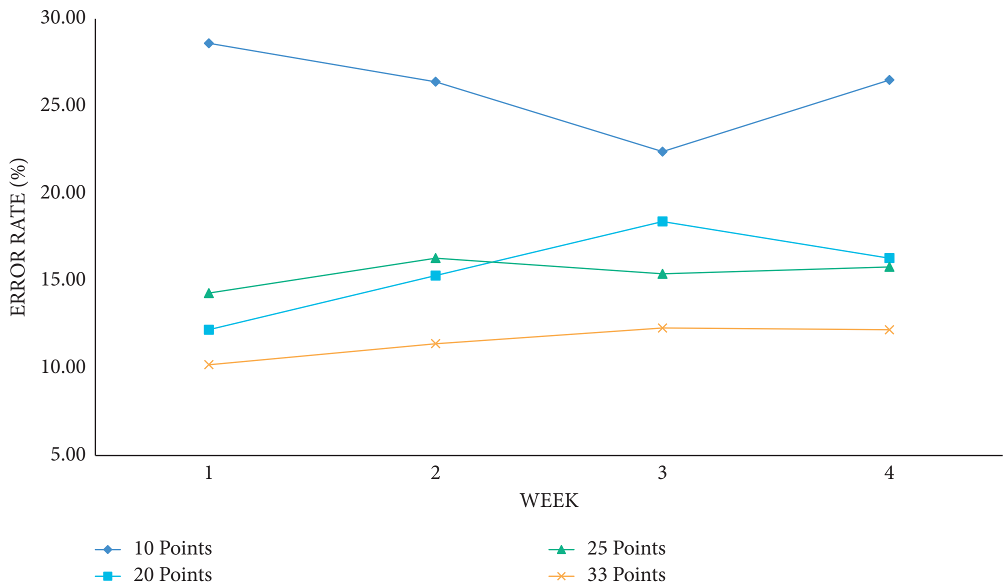

Figure 9: The training error rate at each time point with twenty-eight days as the time unit.

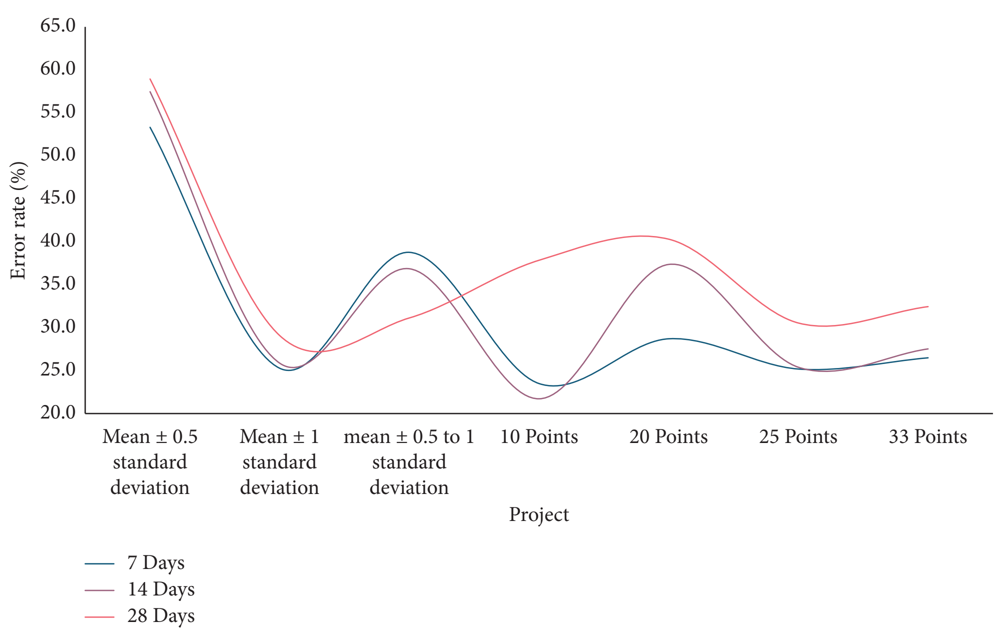

Figure 10: Prediction error rate at each time point in different time units.

deviation, the average performance for error rates is low, all below 40%. As mentioned earlier, the relationship between the accumulation over time and the decrease in error rate becomes less and less obvious, and the way of representing the time forecast in months is not ideal.

5.3. Prediction Error Rate Analysis of Different Grade Classification Methods. The decision-making rules of learning behavior and learning effect of various time units and different grades can be predicted for all students taking the course under different time units, but these decision-making rules are used regardless of the type of grades used. The accuracy of predicting a student's overall learning behavior and learning effect is not very good. Each time point under different time units will be used as the analysis point of observation and prediction in this subsection. The average training error rate in different time units for each time point: the prediction error rate at each time point under different time units is shown in Figure 10.

From Figure 10, an interesting phenomenon is found for the prediction error rates of high-segmentation groups at various time points in different time units; that is, from the perspective of seven days as a time unit, each classification method is the error rate at the beginning. The lowest is the lowest and then gradually increases. The effect of prediction in different time units is not very different. However, different classification methods of grades have a strong relationship with the effect of prediction for high-scoring groups. In this article, different grade classification methods are used to analyze and predict the whole students. All grade classification methods are effective in describing decision rules. No matter what grades classification method is used, the error rate of students' grades distribution is predicted to be below 40%. Other predictions are good, and it can be seen that in terms of average predictions, the results analyzed in this study can indeed effectively predict the distribution of academic performance.

To summarize, the longer the time unit, the less obvious the effect of lowering the error rate. High-scoring students' learning behavior, on the other hand, is more difficult to predict. The error rate starts out low and gradually rises. The effect of various grade classification methods on the prediction will then be examined. Whether it is seven days or seven months, the prediction effect is the same. Most grade classification methods can be significantly reduced after the eighth week, whether in terms of time units of 14 days or 28 days. This has more meaning for teachers because it means that the students' learning status and learning behavior can be observed in real time during the semester using the method used in this study, and which students may fall into the low-scoring group can be predicted in advance using the method used in this study. Students with low learning effectiveness are identified so that teachers or teaching assistants can provide immediate assistance in order to achieve targeted programme teaching.

6. Conclusions

The goal of this study is to develop an integrated analysis algorithm that will provide teachers with decision-making rules as auxiliary information for teaching, allowing them to instantly understand students' learning status during class and provide different teaching or assistance to students with different learning behaviors. It can help teachers and teaching assistants understand what kind of learning behavior students perform in the course, which may lead to a final academic performance of a high or low score, and can observe the attribute value changes of related learning behaviors when the same course is offered again, using intelligent information technology to analyze the decision-making rules between students' learning behavior and learning effectiveness in each course. This study uses the same course in different semesters as the verification object, and the data from two semesters as training and test data, respectively, and the training and test error rates in decision tree analysis as verification indicators to try to pass different levels of verification. It also tries out different grade classification methods to see which one is the best; the analysis objects are divided into three categories: overall students, high-scoring students, and low-scoring students. And in this way, you can examine the learning habits of various students and draw some useful conclusions. Learning records are analyzed through the time dimension using the classification analysis method in data mining, and individual course decision-making rules are generated to give teachers a better understanding of the possible relationship between students' learning behaviors and learning outcomes. This article presents a comprehensive analysis algorithm based on intelligent information technology, and the decision rules generated can predict students' learning behavior to a degree. Teachers and experts who can verify and provide feedback on these decision rules will help them become more widely used teaching aids. It can be used in conjunction with CAI to provide teachers with more information about relevant learning records.

Academic Editor: Xin Ning

The forecast of capital demand has the characteristics of uncertainty. There are known and unknown information about the capital demand for regional economic development. In fact, there are also some in between, that is, uncertain. Consumption is the ultimate goal of production and a key link in realizing a virtuous circle of economic development. This paper uses the GM (1, 1) model to compare the predicted value of the test area with the actual value in 5 years, and the loudness is as high as 90%. Under the guidance of the profit model, the regional economic capital demand has a decisive influence on the regional economic development. The predictive analysis model of capital needs is conducive to fully mobilizing the impact of infrastructure construction of all parties and is an important factor affecting economic development. The mathematical model proposed in this paper is helpful for deepening the research on the management of regional economic development and enriching the theoretical system of regional economic development.

1. Introduction

At present, grey system modeling methods are mainly used for grey prediction and decision-making, and have achieved good results. The construction of grey model, through the action of grey generation or sequence operator, weakens randomness, taps potential laws, and realizes a new leap in establishing continuous dynamic differential equations using discrete data sequences through the exchange of grey difference equations and grey differential equations. The grey prediction of the sequence formed by the system behavior characteristic index value is called sequence prediction [1, 2]. In the GM (1, 1) model, GM (1, 1) represents a first-order, one-variable differential equation prediction model, which is a first-order single-sequence linear dynamic model, which is mainly used for time series prediction. For the sequence of system behavior characteristic indicators, through different combinations and trade-offs, multiple derived sequences are formed, and a prediction model is established for it.

It is difficult to distinguish the quantitative relationship between factors and the primary and the secondary relationship between systems among many factors in the objective world due to lack of data, incomplete information, and uncertainty. The goal of grey correlation analysis is to figure out how closely factors in a system are related. The abovementioned freight volume and cargo turnover can both represent capital demand, but which one is more representative? A type of social and economic activity that leads to demand is capital demand. The correlation analysis with the two indicators, expressed in terms of income elasticity value, can determine which indicator is more representative [3, 4]. The main issues arise during the transition from one mode of regional economic development to another. These issues are most visible in the following areas: regional energy consumption is excessive, and the growth mode is extensive, which makes it difficult to adjust and optimize the industrial structure; in the process of rapid regional economic growth, environmental protection issues have not been prioritized, resulting in serious pollution; for a long time, the region's primary sources of income were investment and export. Consumption has been insufficient for a long time, and the development of investment and consumption is uncoordinated; the industrial structure is unreasonable, traditional industries remain dominant, the proportion of high-tech industries is low, there are issues of weak agricultural foundations, low industrial quality, and lagging development of service industries: urban and rural; the industrial structure is unreasonable, traditional industries remain dominant, the proportion of high-tech industries is low; there are problems of weak agricultural foundations, low industrial quality, and lagging development of unbalanced regional development, widening income gaps between residents; low investment in scientific and technological talents, education, and research and development, affecting labour quality improvement; insufficient independent innovation ability, serious lack of independent brands; overseas enterprises' investment difficulties, and so on [5].

The innovation of this paper is to combine the grey system theory method with the classical consumption demand theory and econometric method, conduct a comprehensive analysis of regional consumption demand and regional economic development capital demand, combine the income elasticity value and forecast income elasticity value, and make a comparison; it is concluded that the degree of acquaintance between the predicted value and the actual value is as high as 90%. The structure of this paper is as follows. Section 1 studies and summarizes the related research on regional economic development theory and grey system model. Section 2 briefly introduces the concept of grey system model and establishes a mathematical model based on grey system model. Section 3 puts forward the relationship between regional residents' income and regional economic development, introduces a certain region's consumption expenditure as a sample, and conducts model statistics. Section 4 predicts and compares sample values based on GM (1, 1) model. Section 5 summarizes the full text.

2. Related Work

With the development of human society, especially the development of industrial revolution and information technology, human's understanding of the connotation of infrastructure has experienced a process of continuous development of levels and scope. In the mid-19th century, Hong et al. put forward the idea of social indirect capital on the basis of summarizing earlier economists' arguments, pointing out that social indirect capital includes all those foundations such as electricity, transportation, or communication industry [6]. Nowak et al. based on uncertainty and rational expectations, put forward the theory of excessive sensitivity, and the theoretical framework of consumption under uncertainty has been initially established [7]. Liu et al. introduced uncertainty into consumption theory for the first time and proposed a random walk model to analyze the influence of uncertainty factors on consumption [8]. Zu et al. put forward a hypothesis theory, which holds that there are two different types of consumers in the economy who choose consumption in each period according to the life cycle hypothesis and decide consumption behavior according to current income [9]. Man and Chen simulated and verified the buffer stock model through the backward method and found that there is a very significant linear relationship between income uncertainty, persistent income, and wealth goals. Consumption structure is also an important aspect that reflects the level of residents' consumption demand [10]. René et al. believe that infrastructure includes two categories: one is core infrastructure, mainly referring to transportation and electricity, whose role is to increase the productivity of physical capital and land, and the other is human infrastructure, including healthcare and education [11]. Ma et al. put forward the idea of social indirect capital on the basis of summarizing the early economists' discussions, pointing out that social indirect capital includes all those basic industries such as electricity, transportation, or communication [12].

It is further pointed out that social indirect capital is divided into broad and narrow senses, and it is believed that in its broad sense, it includes everything from law, order and education, public health to transportation and communication, power, water supply, and agricultural indirect capital such as irrigation and drainage systems. Public service [13]: regarding the development scale of infrastructure, it mainly focuses on the relationship between total public capital expenditure and total output, the relationship between physical stock of infrastructure and total output, infrastructure, and sectoral output, and the difference between infrastructure and regional economic growth. Research: the general conclusion is that there is an obvious elastic coefficient between the total expenditure of infrastructure and the total output [14]. The "priority development theory" advocated by Chen et al. believes that in order to rapidly change the face of economic backwardness, a region must concentrate its energy, invest a large amount of money at one time, and give priority to the development of infrastructure [15]. Zeng and Luo used ELES and AIDS models to compare and analyze the consumption demand of regional residents [16]. Ho et al. studied the evolution mechanism, characteristics, and laws of regional residents' consumption behavior from multiple perspectives, and made an empirical analysis on the influencing factors of regional residents' consumption behavior by combining the western neoclassical consumption theory with the actual situation in China [17]]. Liu et al. proposed an extended linear expenditure system model that further considers income distribution, and preliminarily constructed a more explanatory rural residents' consumption demand function according to the actual situation of the region. The function theory research has injected new blood [18].

The research results of the above scholars have important reference and reference significance for promoting the theory of capital demand for regional economic development, based on the above literature. However, most consumer demand theory research uses more mature economic theories of the grey system model to conduct exploratory and confirmatory analysis of the actual situation in the region; however, due to data availability and authenticity limitations and some scholars' lack of data processing methods, the results are frequently unsatisfactory, resulting in weak convincing. Furthermore, related researchers share a common research perspective on regional economic consumption demand. Majority of academic research focuses on the structure of economic development capital demand, but there is a lack of in-depth and detailed research on consumption rate and the factors that influence consumption demand. At the same time, some scholars have glaring flaws in their sample data selection or analysis methods.

3. Concept and Model Establishment of Grey System

The data model established by using grey theory is not the original data sequence, but the data model generated by a series of processing. The GM (n, m) model is the basic model of the grey forecasting method, where n is the order of the differential equation, and m is the number of variables. The GM (1, 1) model is a grey model with a differential equation order of 1 and a variable unit digit of 1. It is the simplest grey prediction model.

The modeling steps of the GM (1, 1) prediction model are as follows:

Suppose the original data sequence is (1):

$$X^{(0)} = \left(x^{(0)}(1), x^{(0)}(2), \ldots, x^{(0)}(n)\right). \tag{1}$$

Due to the low regularity and large fluctuation of the original data, it will adversely affect the prediction results [19, 20]. Therefore, in the grey prediction, the data is usually processed by the cumulative generation, and the cumulative generation sequence is (2):

$$X^{(1)} = \left(x^{(1)}(1), x^{(1)}(2), \ldots, x^{(1)}(n)\right), \tag{2}$$

Where, $X^{(1)}(k) = \sum_{i=1}^{k} x^{(0)}(i)$, $k = 1, 2, \ldots, n$ is the number of original data.

Define the data sequence on the basis of the data sequence generated after the accumulation $Z^{(1)}$ as $X^{(1)}$. The next-to-neighbor mean generation sequence is

$$Z^{(1)} = \left(z^{(1)}(2), z^{(1)}(3), \ldots, z^{(1)}(n)\right), \tag{3}$$

where $z^{(1)} = 1/2\left(x^{(1)}(k) + x^{(1)}(k-1)\right), k = 2, 3, \ldots, n$ is the number of original data.

Then, define the basic form of GM (1, 1) as (4):

$$x^{(0)}(k) + az^{(1)}(k) = b. \tag{4}$$

The parameters in formula (4) are:a represents the coefficient of development, the parameter b represents the grey action.

Use the least squares estimation method to find (5)

$$[a, b]^T = \left(B^T B\right)^{-1} B^T Y. \tag{5}$$

Perform whitening (6):

$$\frac{dx^{(1)}}{dt} + ax^{(1)} = b. \tag{6}$$

Get the time response sequence (7):

$$\widehat{x}(k+1) = \left(x^0(1) - \frac{b}{a}\right)e^{-ak} + \frac{b}{a}, k = 1, 2 \ldots. \tag{7}$$

Although the GM (1, 1) model has made great improvements in prediction accuracy and data requirements than other prediction models, it is easy to cause errors when the original data rules are weak and there are abnormal or missing data. Therefore, this paper establishes an improved grey forecasting model.

Assuming the regional economic development fund demand as a system factor, the data sequence of relevant factors is (8):

$$X_i = \left(x_i(1), x_i(2), \ldots, x_i(n)\right) \quad, i = 1, 2, \ldots. \tag{8}$$

Finally, according to the system factors, the evaluation value of the correlation coefficient is obtained, that is, the required correlation degree (9):

$$r_{0i} = \frac{1}{n}\sum_{k=1}^{n} r_{0i}(k), \quad i = 1, 2, 3, \ldots. \tag{9}$$

The value of r_{0i} is between 0 and 1, and the larger the value, the higher the correlation between the modification factor and the feature sequence.

4. Construction of Forecasting System of Fund Demand for Regional Economic Development

4.1. Analysis on the Composition of Investment and Financing Mechanism of Regional Economic Infrastructure. The essence of the investment and financing mechanism for regional economic infrastructure projects is to promote competition through the reform of the investment and financing system, and to realize that the market-oriented investment and financing mechanism plays a fundamental role in the allocation of various resources for regional economic infrastructure projects [21].

This paper believes that the construction of a market-oriented investment and financing mechanism system for regional economic infrastructure projects should include three mechanisms: investment and financing external restraint mechanism, investment and financing subject interest coordination mechanism, and investment and financing operation mechanism, based on the logical structure of investment and financing operation of regional economic infrastructure projects. The external investment and financing mechanism is the external environment constraint mechanism for the operation of regional economic infrastructure investment and financing projects, and it is the existence condition and foundation of the regional economic infrastructure investment and financing mechanism. Policy mechanisms, institutional guarantee mechanisms, and payment mechanisms are all included. The investment and financing subjects' interest coordination mechanism is a game and is a coordination mechanism for the behavioral constraints of investment and financing subjects of regional economic infrastructure projects, as well as their own interests. In the process of investing in and financing regional economic infrastructure projects, the investment and financing operation mechanism is the financing demand, investment, and financing channel and method selection, and operation procedure mechanism. External mechanisms for investment in and financing of regional economic infrastructure projects, as well as a mechanism to coordinate the interests of investment and financing entities and an investment and financing operation mechanism, are required [22]. The investment and financing mechanism is shown in Figure 1.

4.2. The Relationship between Economic Development and Consumer Demand. The demand for funds for economic development is reflected not only in terms of quantity but also in terms of consumption structure. The absolute quantity of various consumer goods reflected in a certain form of measurement (physical form or value form, this paper uses value form) is referred to as consumption quantity; the proportion of various consumer goods in total consumption is referred to as consumption structure. The entire process of changes in the level of consumption demand is accompanied by changes in consumption quantity and structure. They are two aspects of consumption demand that are complementary to each other. The upgrading of the consumption structure often leads to the increase in consumption quantity, and the increase in consumption quantity in turn promotes the upgrading of the consumption structure, so that the level of consumption demand develops in a fast and positive direction. The general rule governing the evolution of residents' consumption structures is that when income levels are low, people's consumption expenditures go toward food, clothing, and other necessities. The proportion of consumption expenditures dedicated to development and enjoyment will skyrocket [23].

General principles of economics state that economic activity is the most efficient only when the private rate of return on an investment is close to or equal to the social rate of return. Therefore, the efficient economic development of regional consumer demand projects should also follow such a rule and strive to make various investment entities obtain their reasonable expected returns when investing in regional consumer demand. In the practice of economic development of regional consumer demand projects, the source of funds can include both domestic capital and international capital. The main bodies of domestic capital include governments, enterprises, financial institutions, residents, and non-profit institutions, while international capital includes governments, financial institutions, enterprises, and individuals of various countries. As the main body of economic development, the government focuses more on obtaining social benefits from the construction of regional consumer demand, while other economic development bodies are relatively more willing to obtain economic benefits. The combination of the two constitutes the total expected return of investment. When the actual income from the completion of the regional consumer demand project is close to the total expected income of each investment entity, it is a feasible investment behavior in theory. Financing portfolio structure, resulting in various financing models, is shown in Figure 2.

As shown in Figure 2, the size of the economic contribution (benefit) of the consumer demand infrastructure project is reflected in the degree of satisfaction that its output products bring to consumers. The monetary performance of this degree of satisfaction is the consumer, that is, including all stakeholders. Willingness to pay: under the condition of market economy, the willingness to pay price is the shadow price of the product, and the willingness to pay of consumers for the output of the project is the contribution of the project to the economy. Consumer willingness to pay can be further divided into two parts: actual consumer payment and consumer surplus. Consumer surplus is the balance of the currency that consumers are willing to pay more than the currency actually paid when purchasing a certain commodity.

Consumption demand refers to the various types of consumption materials consumed by residents in the process of consumption under certain social and economic conditions, which can be divided into two types: physical form and value form. Among them, the physical form is the most basic and primitive form of various types of consumption materials consumed in the consumption process represented by the physical quantity; and the value form is represented by currency in the consumption process and the types of consumption data, which are embodied in various living consumption expenditures in real economic life. By analyzing the value of various types of consumption data consumed by regional residents, the development level and changing trend of regional residents' consumption demand at different time periods are revealed. The consumption demand of various types of consumer goods of regional residents analyzed in this paper is expressed in the form of value.

4.3. Statistical Data Selection of Regional Residents' Consumption Demand. Since it is not easy to distinguish developmental and enjoyment expenditures, this article will facilitate the forecasting and calculation of regional economic development capital needs in the future. Referring to the consumption expenditure statistics of a certain place, the living consumption expenditures of residents in the modified area are divided into food, clothing, housing, household equipment, transportation and communication, and culture, education and entertainment, healthcare, and other goods and services. The specific statistics are shown in Tables 1 and 2.

5. Consumption Demand Forecast Based on GM (1, 1)

5.1. Model Parameter Estimates and Errors. From Table 1, it can be seen that the housing expenditure data in the eighth year is abnormal, which is not increased but decreased compared with the previous data. This abnormal data should be excluded when using the GM (1, 1) model for simulation. Taking the horizontal data in Table 1 as the original time series data, a GM (1, 1) model is established, respectively,

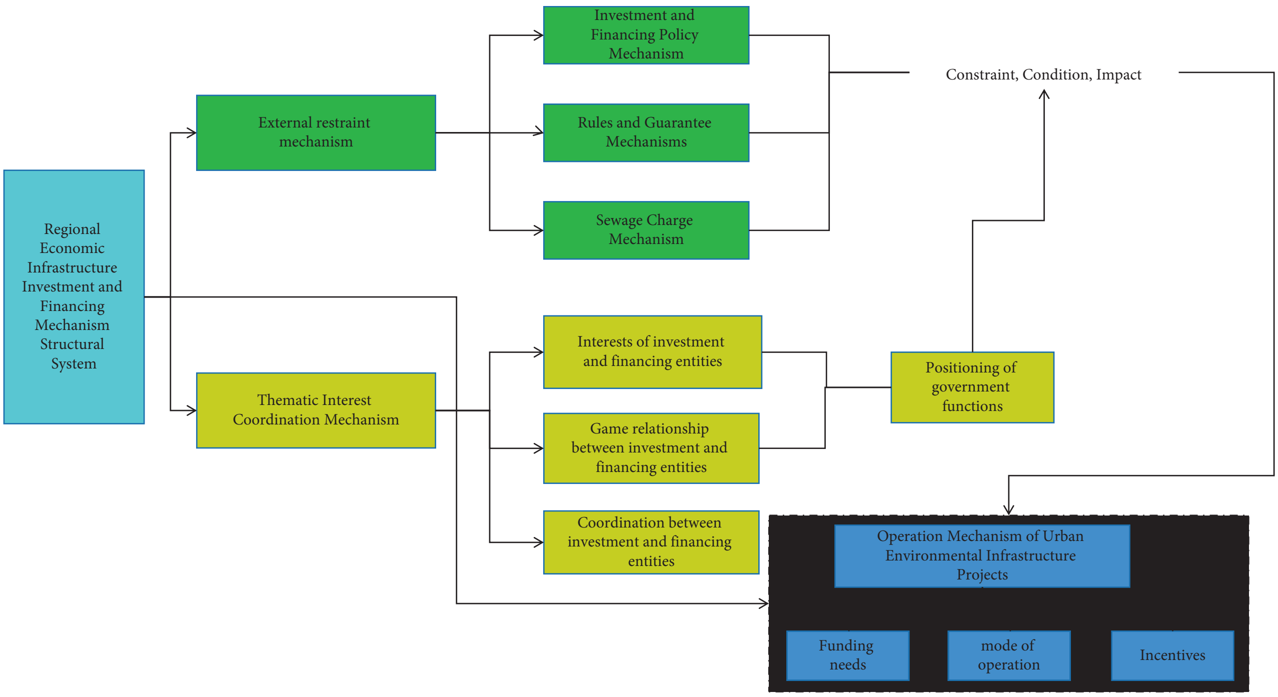

FIGURE 1: The structural system of regional economic infrastructure investment and financing mechanism.

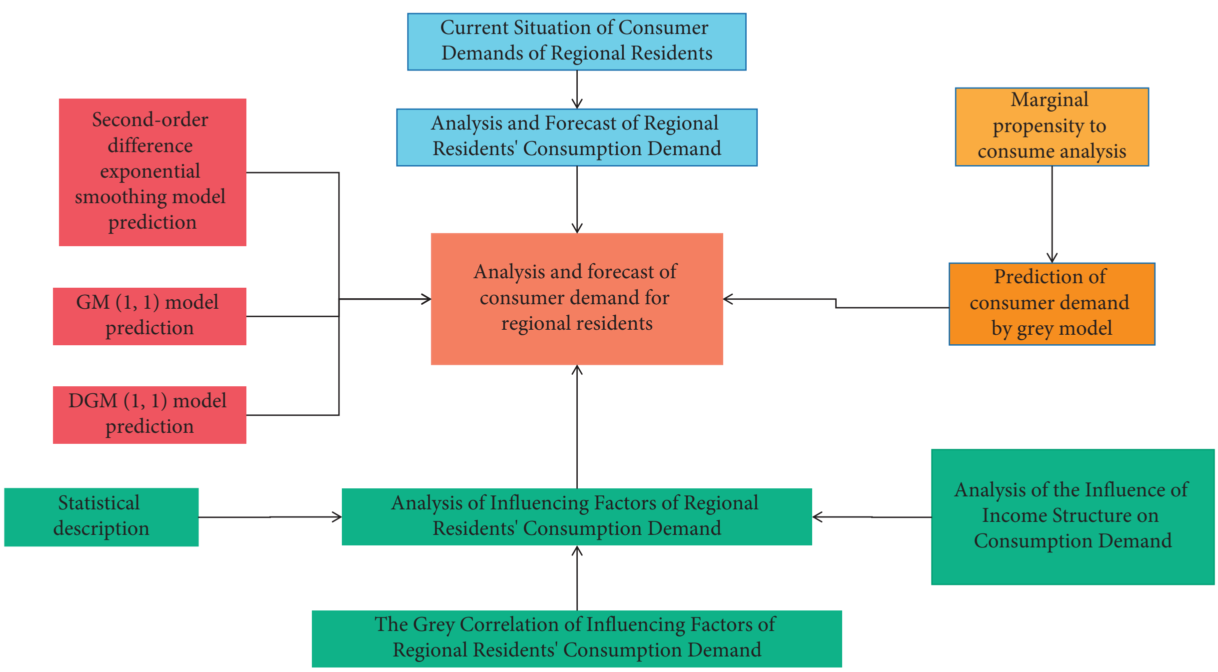

FIGURE 2: Investment and financing mechanism model of regional consumption demand and economic development.

and the average relative error of parameters a and b can be obtained as shown in Table 3 and Figure 3.

It can be seen from Figure 3 that the absolute value of the development coefficient a is less than 0.3, so GM (1, 1) can be used for medium- and long-term forecasting. The correlation degree and error are shown in Table 4 and Figure 4.

It can be seen from Figure 4 that the average relative error of other items except traffic communication is less than 5%, so the fitting accuracy is high. The average relative error of traffic communication is larger, reaching 7.245%, but it is within the acceptable range.

5.2. Model Based Parameter Estimation. The data required by the grey system model are the per capita net income of regional households, the total expenditure of living consumption, and the expenditure of its various components. From the data in Tables 1 and 3, the parameters b in Figure 3

Table 1: Average per capita net income and living consumption expenditure of residents in a certain region in 8 years (unit: yuan).

Project/year	1	2	3	4	5	6	7	8
Net income per capita ($A1$)	2236	2553	2871	3261	3852	4454	4807	5524

Communications (*A*7)	89	0.0875	202	0.1059
Culture, education and entertainment (*A*8)	103	0.0268	153	0.0181
Healthcare (*A*9)	56	0.0616	185	0.0836

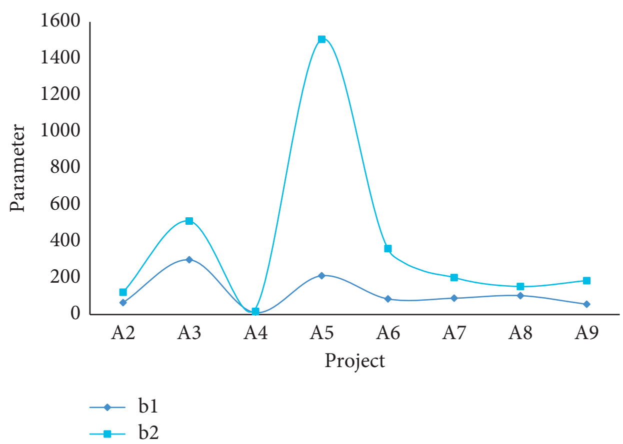

Figure 5: Comparison of parameter *b* samples and predictions.

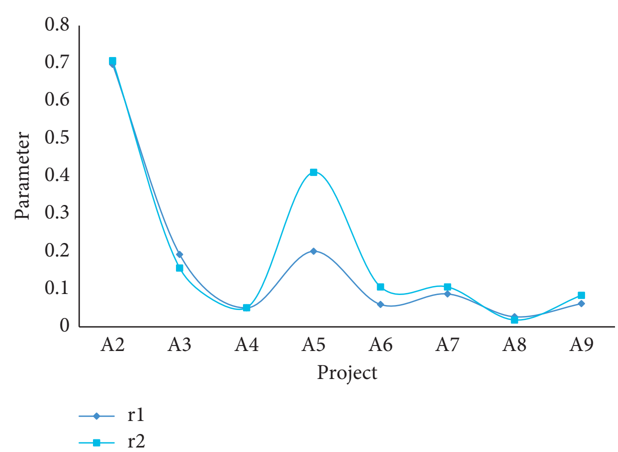

Figure 6: Comparison of parameter *r* samples and predictions.

are estimated by the least squares method in the mathematical model established above. The results are shown in Table 5, Figures 5 and 6.

It can be seen from the table that with the continuous improvement of income level, the consumption desire of regional residents has increased significantly. The marginal propensity to consume of regional residents' total living consumption expenditure increased from 0.6970 in the sample period to 0.7068 in the forecast period. This shows that regional residents will use 70.68% of the new net income for consumption; that is to say, for every RMB 1 increase in disposable income, regional residents will spend RMB 0.7068 for consumption. And the new net income is mainly used for food and housing consumption, which will help to improve the diet and living standards of regional households. It can also be seen from the table that the marginal propensity to consume of regional residents has grown the fastest, from 0.2007 in the sample period to 0.4103 in the forecast period, more than doubling. This shows that with the improvement of living standards, regional residents have a strong demand for the improvement of living conditions after the basic satisfaction of food and clothing. Followed by household equipment supplies and services, which increased from 0.0594 to 0.1059, an increase of 78.28%. This shows that the residents of the region are paying more attention to the improvement of basic living needs such as clothing, food, and housing, and at the same time, they are also pursuing more development-oriented and enjoyment-oriented consumption. Because durable household equipment such as washing machines, refrigerators, air conditioners, shower water heaters, mobile phones and color TVs, video cameras, home computers, and medium- and high-end musical instruments not only bring more enjoyment in life to the residents of the vast area, but also its own development has a great role in promoting. Therefore, the government should correctly guide the consumption of durable consumer goods by regional residents, continue to strengthen policies to strengthen and benefit farmers such as "home appliances to the countryside," and strive to improve the overall quality of regional residents while promoting domestic demand. In addition, the marginal propensity to consume for transportation, communication and healthcare also increased by varying degrees. Transportation and communication increased from 0.0875 to 0.1059, an increase of 21.03%; healthcare increased from 0.0616 to 0.0836, an increase of 35.71%. This shows that the regional residents' consumption demand for these two items has also increased. More travel, exchanges, and attention to physical health will enable them to develop their spirit and body well, and contribute to the construction of a new socialist region and lay the foundation for cultivating more new types of residents. However, the marginal propensity to consume of food and cultural, educational, and recreational goods and services has decreased by varying degrees. Food decreased from 0.1924 to 0.1563, a decrease of 18.76%; cultural, educational, and recreational goods and services decreased from 0.0268 to 0.0181, a

decrease of 32.46%. The downward trend in the marginal propensity to consume food items is expected. Because, at this stage, the food needs of regional residents have been basically met and will be gradually increased. Therefore, with the basic satisfaction of regional residents' food consumption needs, their desire for food consumption needs will decrease. This is consistent with the Law of Diminishing Marginal Utility stage 3 and is basically consistent with the current situation in the region. The marginal propensity to consume of cultural, educational, and recreational goods services is the lowest in both the sample period and the forecast period, and continues to decline. It can be seen that the current consumption of cultural, educational, and recreational articles and services by regional residents is still at a very low level and has a downward trend, which may be closely related to the consumption habits of regional residents who focus on food consumption and less on spiritual consumption.

5.3. Regional Economic Development and Income Elasticity Analysis. When the income changes by 1% and the price remains unchanged, the percentage of change in consumption demand is an important indicator of the capital demand for regional economic development. w_k is the income elasticity of item k consumer goods demand, as shown in (10) .

$$w_k = \frac{dV_k}{dY}\frac{Y}{V_k} = \frac{\beta_k Y}{V_k}. \tag{10}$$

From the data in the table below and according to formula (10), the income elasticity of various consumption demands of regional residents in each year of the sample period and the forecast period can be calculated as shown in Table 6, Figures 7 and 8.

The income elasticity of regional residents' total consumption demand during the sample period and the forecast period is greater than 1, with the exception of the seventh year, indicating that regional residents' overall consumption demand is growing faster than their income. The income elasticity of consumer demand for clothing, residence, household equipment supplies and services, transportation

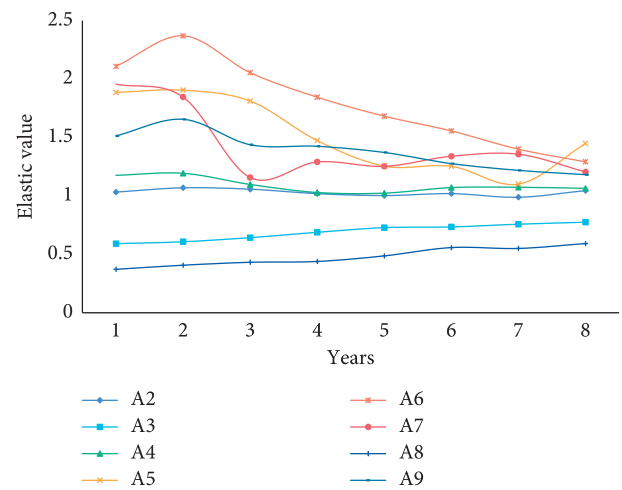

Figure 7: Income elasticity of regional residents during the sample period.

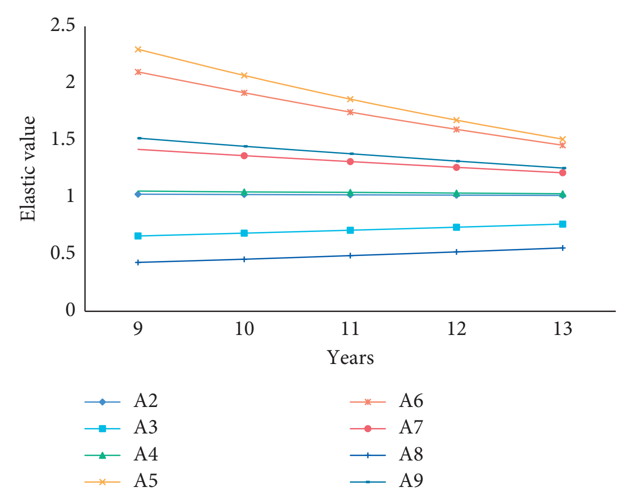

Figure 8: Income elasticity of regional residents during the forecast period.

and communication, and medical care is significantly greater than 1, indicating that regional residents' consumption demand for these types of goods and services is significantly

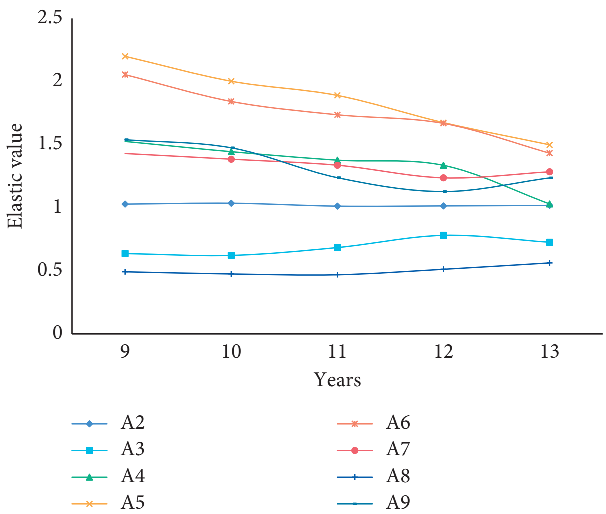

Figure 9: Income elasticity of residents in the sample area from 9 to 13 years.

higher than their income growth rate; the two items of household equipment, supplies, and services are significantly higher than the other items, indicating that regional residents' consumption demand for these types of goods and services is significantly higher than their income growth rate; and the two items of household equipment, supplies, and services are significantly higher. As a result, first, in the coming years, such consumer goods will become a powerful lever for leveraging consumer demand, contributing more to economic development. Second, the income elasticity of consumer demand for food and cultural, educational, and recreational goods and services are all less than 1, indicating that these two consumption demands are growing at a slower rate than residents' income; in particular, the income elasticity of consumer demand for cultural, educational, and recreational goods and services is much lower than 1. It demonstrates that regional residents' demand for such consumption is currently growing at a much slower rate than their income.

Based on this, we select the statistics of residents' consumption income and expenditure in the modified region from 9 to 13 years and compare it with the predicted elasticity value as shown in Figure 9.

No matter in the sample period or the forecast period, the income elasticity of consumer demand for each item whose income elasticity of consumption demand is greater than 1 shows a downward trend; at the same time, the income elasticity of consumption demand is less than 1 for food, cultural, educational, and recreational goods and services. However, the income elasticity of consumer demand shows a clear upward trend; thus, the total income elasticity of consumer demand tends to converge toward 1. The similarity between the predicted income elasticity value and the actual elastic growth value is 90%. With the development of the regional economy and the improvement of the living standards of the regional residents, the growth rate of capital demand will keep pace with the income growth.

This paper uses the grey relative correlation analysis method to analyze several main influencing factors that affect regional residents' economic development demand, based on the grey system model theory and the more representative economic development demand theory. The actual elasticity growth value is 90% similar to the predicted income elasticity value. Because it is difficult to find reasonable quantitative indicators for individual factors and data for some indicators is scarce, this paper analyses influencing factors such as regional residents' per capita net income, regional residents' economic development price index, urbanization rate, and per capita GDP. The findings show that each factor has a different impact on regional residents' economic development spending. Because per capita net income is the most important factor influencing economic development, this paper also examines the income structure of regional residents and the impact of various sources of income on economic development requirements. The findings show that net income from family businesses has the greatest impact on regional residents' economic development needs, followed by wage income, and property and transfer income. When regional residents' overall income growth is slow or difficult, improving the income structure can help to promote economic development.

6. Conclusions

Since some statistical data are difficult to obtain, this paper uses time series data instead of panel data when selecting sample points. Therefore, this study cannot reflect the economic development needs and development trends of regional residents of different income levels. In further research, we can consider selecting relevant panel data of regional residents at different income levels. For example, regional residents can be divided into low-income groups, middle-low-income groups, middle-income groups, middle-high-income groups, and high-income groups according to their income levels. Each of the five income levels are analyzed, and the economic development needs of different income levels of regional residents are specifically analyzed, and efforts are made to study the needs and future development trends of regional residents at different levels for different types of economic development in more detail.

This study designs and implements a digital English instructional resource management recommendation system based on collaborative filtering technology based on CF research and the construction of digital English instructional resources. This study designs the system with *B*/*S* structure combined with hierarchical design architecture, plans the overall design goal, architecture design, compilation structure, and key technologies, and designs and implements the system's core modules on the basis of fully analysing the functional and nonfunctional requirements of personalized educational resource recommendation system. Furthermore, the traditional CF has been improved to address scalability, data sparseness, and user cold start in the recommendation process. The evaluation results show that this algorithm has a recall rate of 96.37% and a system resource recommendation accuracy rate of 95.31%, both of which are higher than the traditional method's 6.37%. This algorithm can overcome the drawbacks of traditional algorithms, improve recommendation accuracy, and efficiently provide high-quality English teaching resources. Educators and students will be more likely to find high-quality digital English instructional resources if they use the instructional resource system proposed in this study.

1. Introduction

The use and development of digital technology have ushered in a technological revolution in the world of education. It has an impact on education, resulting in significant changes in educational and learning methods [1]. The result of the digitalization of teaching media is digital instructional resources. In the field of online education, particularly in the teaching environment, digital instructional resources have become indispensable. The information, digitalization, and networking era have posed a challenge to traditional college English instruction. The need for college English teaching reform is critical in order to adapt to the new situation and requirements [2]. The goal of digitalizing English knowledge is to divide it into manageable chunks, allowing students to customise, acquire, and organise the platform as they see fit. It is an English decomposition and matrix assembly process that assists students in establishing English logic and thinking as well as internalising English into habits by effectively connecting and bearing various knowledge such as society, life, major, and workplace [3]. People gradually realize that digital and multimedia network technology can be organically integrated with education and teaching. Digital technology provides technical support for delivering a variety of required scenarios that can vividly show phenomena and processes that are difficult to express in traditional teaching modes, as well as vividly express abstract content and guide learners to intuitively feel abstract language concepts [4]. In today's Internet age, the degree of educational informatization, the digitization of instructional resources, and the efficacy of their application have gradually become an important symbol for evaluating a country's or region's educational modernization process. With the advent of the Education 4.0 era, the creation and use of digital resources in English teaching will become more common [5]. Building and perfecting a digital college English instructional resource database can help college English teachers better accomplish their goals and develop English professionals who are well rounded in listening, speaking, reading, writing, and translation.

The acquisition range of college English instructional resources has greatly expanded in the information environment. It can now be extended to all of the world's instructional resources, not just those in schools and China. The abundance of instructional resources also encourages teaching mode innovation. The term "instructional resource bank" refers to a resource bank that can meet teaching requirements, has rich and diverse teaching content that adheres to specific requirements and norms, and is convenient for professors to impart knowledge and recipients to learn more effectively [6]. Digitalization of instructional resources in the information environment is easier to integrate than books, newspapers, and other written materials, which is beneficial to the role of resource allocation. Driven by reform power and teaching demand, all universities have set up their own instructional resource banks and network electronic resources to varying degrees after practice and development [7]. However, nowadays, the creation of digital resources frequently follows a centralised and unified management model, in which each university creates its own resource bank. As a result, each digital instructional resource bank and resource management system are relatively self-contained, and their resources are essentially closed off from one another, resulting in information barriers and islands [8]. The current research focus is on how to solve the problem of information isolation and personalized resource recommendation. Personalized recommendation services are now widely used in a variety of industries. Collaborative filtering technology is currently the most studied and widely used recommendation system, as well as a personalized recommendation system with high recommendation efficiency. Many mixed recommendation methods use collaborative filtering technology, according to research and analysis of the current personalized recommendation literature. In the recommendation process, CF (collaborative filtering) algorithm does not need to extract the content features of items and can make cross-domain recommendations, resulting in a high level of personalization and automation. This study focuses on the creation and implementation of CF-based digital English instructional resources. The following are some of its innovations:

① Based on the project characteristics of digital English instructional resources, this study designs a specific instructional resource recommendation process. When searching for the nearest neighbor of the target user, considering the relationship among users, resources, and resource attributes, the method of combining the similarity of rating with the similarity of preference of resource attributes is adopted, making full use of effective information to mine out more similar users, improving the recommendation quality of the system and solving the problem of data sparsity.

② According to the principle, advantages, and disadvantages of collaborative filtering recommendation algorithm in personalized recommendation technology, combined with learners' learning behavior characteristics, this study constructs a digital English instructional resource management recommendation model. In the construction of user model, the system extracts the features of users' personalized resource access to form an individual user model and clusters users with similar interests to form a group user model. Finally, an integrated user interest vector is formed to construct an integrated user model. This system provides a good solution for a personalized recommendation of digital English instructional resources.

This study is divided into five sections based on the research requirements: the first section is the introduction. This section explains the research's content, significance, methods, and definitions of related concepts and provides a quick overview of the study's structure. The second section is the literature review. This section summarises relevant literature from both domestic and international sources, as well as the study's research ideas and methods. The third section is methodology. This section explains the concept, types, and characteristics of English educational resources; this study examines the current state of English educational resource construction; a recommendation system for managing English instructional resources based on CF is developed, along with the implementation process. The fourth section conducts an experiment with the model developed in this study, analysing its performance and practical application impact. The fifth section is a summary and outlook. This section begins by summarising the research work of this study, explaining the findings, and then looking ahead to future research work and prospects.

2. Related Work

Network teaching relies heavily on the creation of digital instructional resources. Each website has formed a certain scale of instructional resources as a result of the establishment of various websites of instructional resources. However, how to find interesting information from a large number of instructional resources quickly and effectively remains a problem. Personalized recommendation services have a bright future in the information age, and they offer a fresh perspective on the instructional resource system. More platforms are introducing recommendation systems to provide personalized services to users, and many scholars and experts have devoted themselves to recommendation system research, with excellent results.

Li designed a flexible, reliable, high-performance personalized recommendation system architecture that can store and process petabytes of data and make real-time recommendations [9]. Osipov et al. proposed an intelligent online learning recommender system that can self-evolve while achieving self-adaptation to learners and an open network environment [10]. The information resources existing in the system are not fixed, and the learning resources on the network can be integrated into the system according to the interaction between users and the system. Kambanaros et al. analysed the user's browsing behavior and preference information by sampling and then presented the generated instructional resource recommendation list to the user, effectively realizing the sharing and recommendation of resources [11]. Davis studied the application of collaborative filtering technology in the personalized recommendation system of scientific literature and proposed two methods of collaborative recommendation [12]. One is a collaborative recommendation algorithm based on ontology concepts and user interests, and the other is a collaborative recommendation algorithm based on weighted association rules. Hafner pointed out that the existing network instructional resource system has not really applied the personalized recommendation technology and is only in the research stage. With the continuous enrichment of instructional resources, the need to realize personalized recommendation service of network instructional resource system is more and more urgent [13]. Shi and Yang proposed a method for real-time recommendation of current and subsequent learning materials based on learner interests and progress [14]. The method is implemented through three links: data and processing, mining neighbor learners, and recommendation of learning materials. Gee et al. proposed an online automatic recommendation system based on a hybrid filtering recommendation technique. The system combines content-based filtering and collaborative filtering to make recommendations based on the user's recent navigation history [15]. Yuan builds a user interest model by combining explicit tracking and implicit tracking of users [16]. Nielsen and Hoban applied web mining, association rule mining, and decision tree techniques to recommender systems to recommend suitable resources to users [17]. Arnaiz-González et al. studied the personalized resource recommendation service in the basic education resource network and proposed a personalized resource recommendation service model [18]. Aiming at the contradiction between the current ubiquitous mass instructional resources and the personalized needs of users, Barry proposed to introduce personalized recommendation technology into the network instructional resource system [19]. The system fully pays attention to the individual differences of learners and provides users with personalized services according to the learners' learning background and interests. For the sparsity problem of rating data, Cazden proposed that the dimensionality of item space can be reduced by using the singular value decomposition technique, thereby improving the sparsity of user rating data [20].

This study examines CF and related literature in the field of instructional resource construction, as well as personalized recommendation technology. A recommendation system for English instructional resource management based on CF is designed based on the foregoing. The algorithm chooses the user with the greatest distance as the initial clustering centre, divides users with similar resource attribute preferences into the same cluster through offline clustering, and searches the nearest neighbors in several clusters close to the target user, reducing the time and space cost of neighbor query. The flexible data processing ability of Spark and Hadoop technologies is realized in this study, and the discipline classification tree is constructed to form a better organisational resource model and user model of tagged data sources. The cold start problem is solved and the algorithm's accuracy is improved by using a hybrid recommendation algorithm based on content and collaborative filtering. The experiment demonstrates that the research presented in this study can aid in the creation and sharing of digital instructional resource databases and improve learners' learning efficiency.

3. Methodology

3.1. Digital English Instructional Resources. Digital instructional resources refer to all kinds of materials or systems that are processed digitally, support the effective operation of teaching, realize the teaching purpose, and can run on the computer or network environment [21]. It can reduce the macroworld, enlarge the microworld, turn the abstract into the concrete, turn the virtual into reality, and put history, future, and present into operation at the same time. It can fully arouse students' positive thinking in all senses. It can enable students to find and share digital knowledge and information resources through independent or creative ways, realize multilevel communication, evaluation, and exchange, and stimulate students' interest in learning. The design of digital instructional resources has two contents, one is the organisational design of instructional resources and the other is the description information design of instructional resources. In order to make the best use of digital English instructional resources, digital English instructional resources must be designed concisely, easy to understand, and operate. Some fashion elements can be added to the resource library to attract students. At the same time, it is necessary to fully consider the description of the resources themselves, that is, the design of descriptive information of instructional resources. Generally, it should include overall description, history and current situation description, metadata description, teaching characteristics description, ownership description, generic information description, and quality information description [22]. The particularity of digital English instructional resources lies in the following aspects: ① dealing with digitalization and realizing the quantification and standardization of information. ② Network transmission, clear information support points and links, and establishing an information chain. ③ Intelligent retrieval to meet the demand of customised information acquisition. ④ Multimedia presentation and realizing multilayer simultaneous stimulation such as audiovisual and speaking. ⑤ Hyperlinking of organisation, which realizes platform-type hyperlink of various information and resources and completes the knowledge structure. The digital college English instructional resource management model is shown in Figure 1.

The depth and breadth of college English textbooks and courseware are currently lacking [23]. Many teachers discover that the format of courseware solidifies over time. As a

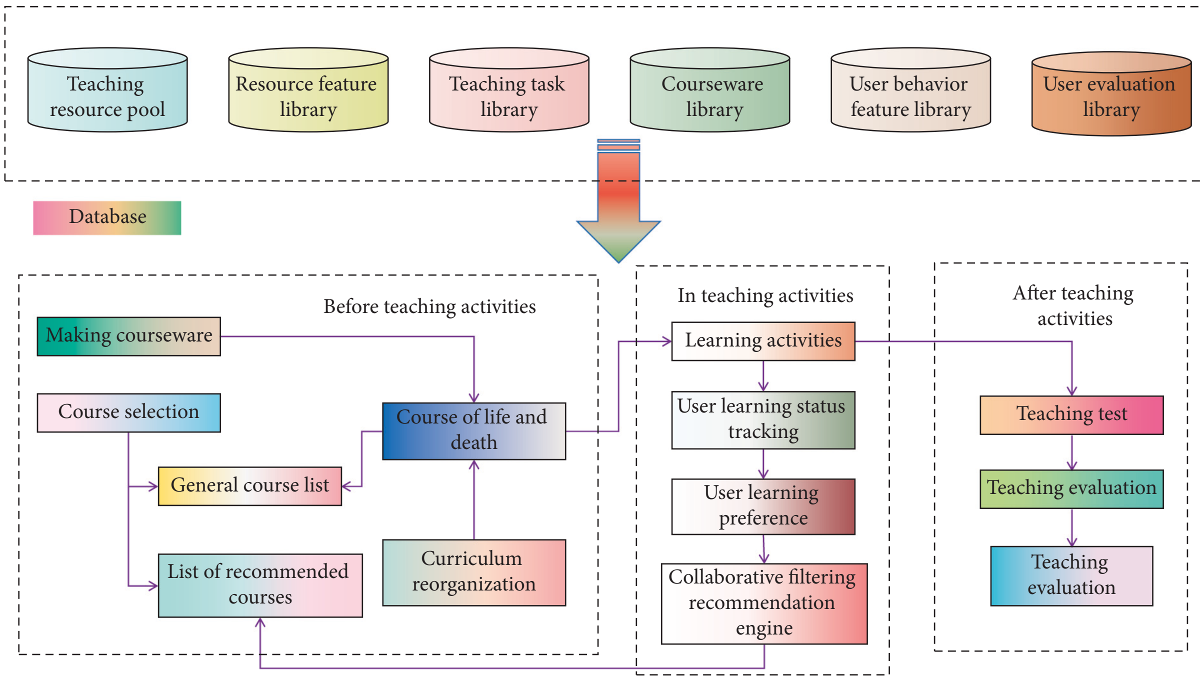

Figure 1: Digital college English instructional resource management model.

result, the digital English instructional resource database must use the existing or under-construction campus network to provide teachers with access to instructional resources and to aid in the teaching of students' English listening, speaking, reading, writing, and translation skills. Multimedia materials, teaching software, a network platform, and an integrated teaching system are just a few of the digital English instructional resources available. These digital resources can be organised by classifying knowledge points, teaching emphasis or difficulty, or knowledge and skill. It is important to note that the goal of digitalizing English knowledge is to divide it into manageable chunks so that students can customise, acquire, and organise the platform as they see fit. It is an English matrix assembly and linear decomposition process. It can assist students in developing English logic and thinking, as well as internalising English into habits, by effectively connecting and bearing various types of knowledge, such as society, life, major, and workplace. Learning resources in the network differ from traditional books and teaching materials due to the digitalization of learning objects. Traditional instructional resources are blocked and rigid due to the lack of digital media technology, making information sharing and transmission difficult. Learning objects that have been digitalized can help with the effective transmission of learning materials and resource sharing [24]. Digital instructional resources provide vivid and intuitive learning materials for students; through a large number of repeated information input, listening and speaking training becomes easy, thereby arousing the enthusiasm of students' classroom participation and promoting classroom interaction. It overcomes the passive situation of students in traditional classroom teaching and provides an effective guarantee for improving students' listening and speaking abilities. In the functional application of digital English instructional resources, teachers and students are more dependent on retrieval function and interactive function.

3.2. CF. This section mainly introduces the recommendation system and common collaborative filtering recommendation technology in detail. In the traditional system platform, the user browsing platform can only passively receive the information provided by the platform. Because of the different needs of each user, it cannot serve every user. With the development of educational informatization, the number of instructional resources on the Internet is also increasing [25]. Information technology has become increasingly difficult to help users find the resources they need. The personalized recommendation technology changes the system from a passive information provider to providing users with interesting information, which is more targeted than the traditional way. A personalized recommendation system can free users from massive information and greatly save the time and cost of finding commodities. At present, personalized service has become a new research hotspot in intelligent information processing and network technology. Personalized recommendation technology can analyse and predict users' behavior by collecting and analysing users' information, so as to better provide users with their corresponding services and achieve the purpose of personalized service. From the overall hierarchical structure, the recommendation system is mainly composed of three modules: ① *Input Function Module.* Its main function is to collect and update data and do some preprocessing work to improve data quality. ② *Recommendation Algorithm Module.* It is the core and part of the recommendation system, through which users will get the final recommendation result. ③ *Output*

Function Module. The results obtained by the recommendation algorithm module are displayed to users through this module.

The personalized recommendation algorithm is at the heart of the system, and it plays a critical role in recommendation quality. When selecting a personalized recommendation algorithm, it is necessary to weigh the benefits and drawbacks of various recommendation algorithms in light of the application field's unique characteristics in order to select the most appropriate recommendation algorithm for this application. A good recommendation algorithm can improve the performance of a recommendation service, find the information users require quickly and accurately, and increase resource utilisation and website service quality. User statistics-based recommendation, content-based recommendation, and collaborative filtering recommendation are the three types of personalized recommendation technology currently available. Users should be able to express their needs easily, and personalized recommendation systems should actively recommend resources to them. The system can adapt to changing user requirements over time. The advantage of a recommendation based on user statistics is that it does not rely on user behavior information, so there is no cold start problem. It can be used internally in a variety of fields because it is not dependent on the resource's information. In the field of information retrieval, content-based recommendation is proposed. Content-based recommendation is a recommendation method that was previously used with personalized recommendation technology. Content-based recommendations are based on the assumption that items that are similar in content to information items that the user was interested in previously will remain interesting to the user in the future. The basic idea behind content-based recommendation is to assess users' behaviors and needs based on the content they have access to. User interest files are used to describe each user's interests; a feature vector is created by extracting the features of each resource's information content; the recommendation system recommends resources based on similarity. This recommendation mechanism is more accurate than the statistical recommendation method of users because it can model the user's preference resources well.

The principle of collaborative filtering recommendation is to find the correlation between resources or between users according to their preferences for items or resources and then make recommendations based on these correlations. Collaborative filtering recommendation is mainly divided into user-based recommendation and project-based recommendation. The basic idea of collaborative filtering is very intuitive. In daily life, people often make some choices such as shopping, reading, and music according to the recommendations of friends and relatives. Collaborative filtering technology is to apply this idea to information recommendation and recommend a certain user based on other users' evaluation of certain information. Generally speaking, collaborative filtering needs to solve two problems: ① how to determine the user groups with similar interests and ② how to predict the resources or items that users are interested in. There are three basic starting points: ① users can be classified according to their interests, ② the user's rating information on the project includes the user's interest information, and ③ users' ratings of unevaluated items are similar to those of similar users. The structure of English instructional resource management recommendation system based on improved CF is shown in Figure 2.

Users must make an explicit subjective evaluation of the resources on the web page in order to score their preferences for resources. Implicit behavior, on the other hand, does not require users to make subjective judgments, and some website actions are recorded. We can combine display tracking with implicit tracking to better grasp the user's interest, using display tracking to obtain the static user's interest and implicit tracking to obtain the dynamic user's interest. The collaborative filtering recommendation algorithm makes recommendations to target users based on their closest neighbors' preferences. When determining the target users' nearest neighbors, it calculates the similarity between the target users and other users in the user group and then chooses the K users with the greatest similarity to form the target users' nearest neighbors. The collaborative filtering recommendation algorithm is based on the assumption that people have similar behaviors and will make similar decisions. The user's choice contains information about the user's interests. The algorithm calculates the similarity between users by analysing which items' users evaluate, generate the user set with the most similar interest to the current users, predict the current users' rating on the items by using the item ratings in this user set, and finally obtain the recommendation list and make recommendations. When CF recommends users, the main process is divided into three parts: constructing a scoring matrix, finding the nearest neighbors, and generating recommendations.

3.3. CF-Based Recommendation System for English Instructional Resources Management. The overall goal of the English instructional resource management recommendation system in this study is to realize the digital instructional resources that can be used by teachers and students in multicampus conveniently under the environment that conforms to the overall planning and design of the construction unit. The core of personalized network instructional resource system is recommendation module, which determines the performance of personalized network instructional resource system to a great extent. The key of recommendation module is to choose an appropriate personalized recommendation algorithm, which can effectively integrate with application fields, reduce possible problems, improve recommendation quality, and reduce the complexity of the system. The traditional recommendation of instructional resources focuses on the main body, while ignoring the interrelation between instructional resources. Aiming at the problems existing in CF and instructional resource recommendation, this study comprehensively considers the relationship between resources and the characteristic behavior information of users themselves to improve the algorithm. First, the learner's behavior and information are digitally modeled to form a model. Then,

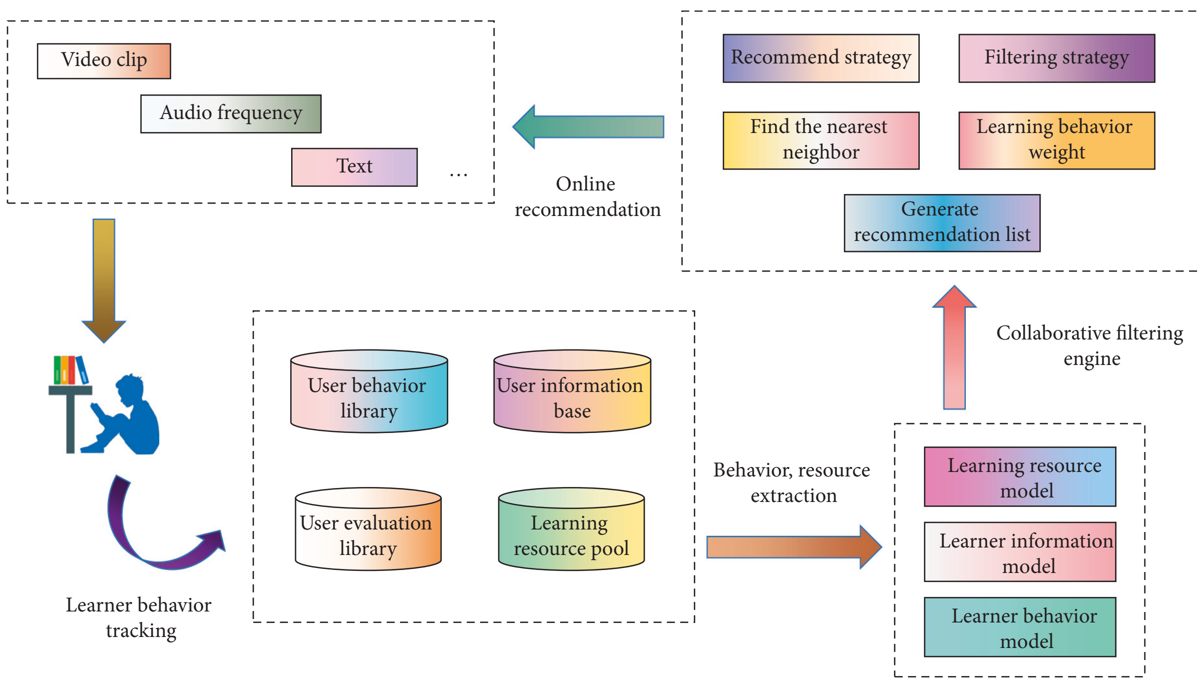

FIGURE 2: Improved structure of English instructional resource management recommendation system based on CF.

according to the current system situation, the filter strategy is selected, and the learner's behavior influencing factors are added to form the nearest neighbor set. Finally, online recommendation of learners in various media will be conducted, and the interaction between learners and the system will have an impact on the whole recommendation system, thus forming an organic whole repeatedly. In order to solve the cold start problem in recommendation system, that is, how new users recommend personalized resources to users without any interest preferences and associated friends, this study adopts content-based recommendation algorithm to solve this problem. In a recommendation system based on collaborative filtering technology, the input data can usually be expressed as a user-item evaluation matrix R with $m * n$, as follows:

$$R(m,n) = \begin{bmatrix} R_{1,1} & R_{1,2} & \dots & R_{1,n} \\ R_{2,1} & R_{2,2} & \dots & R_{2,n} \\ R_{3,1} & R_{3,2} & \dots & R_{3,n} \\ R_{m,1} & R_{m,2} & \dots & R_{m,n} \end{bmatrix}. \tag{1}$$

Among them, the rows represent users, with a total of m and the columns represent items, with a total of n. The value of R_{ij} represents the evaluation value of the item j by the user i, which is generally obtained by the user displaying the submission interest evaluation level. For two users i and j, the resource sets scored by the two users are as follows:

$$\begin{aligned} I_u &= \{i_c \mid i_c \in I \wedge r_{uc} \neq 0\}, \\ I_v &= \{i_c \mid i_c \in I \wedge r_{vc} \neq 0\}. \end{aligned} \tag{2}$$

The weight function can be expressed as follows:

$$f(u,v) = \frac{|I_u \cap I_v|^2}{|I_u| \times |I_v|}. \tag{3}$$

At the same time, the Pearson correlation coefficient modified by the weight function is shown in the following formula:

$$\mathrm{Sim}_p(u,v) = \frac{|I_u \cap I_v|^2}{|I_u| \times |I_v|} \frac{\sum_{i\in I_{UV}} (R_{ui} - \overline{R}_u)(R_{vi} - \overline{R}_v)}{\sqrt{\sum_{i\in I_{UV}} (R_{ui} - \overline{R}_u)^2} \sqrt{\sum_{i\in I_{UV}} (R_{vi} - \overline{R}_v)^2}}. \tag{4}$$

In the calculation of similarity, users' preferences for user resources can be used as a vector to calculate the similarity between users. The similarity is judged according to the distance between two vectors. The smaller the distance, the greater the similarity between them. Traditional CFs generally only recommend users according to the scoring matrix, but in the instructional resource system, the user scoring data are less than the resource scale, so the overall scoring data are sparse. Aiming at this problem, this study considers the attribute characteristics of resources. When a user generally gives a high rating to the resources with certain attributes, it can be considered that the user prefers such attributes. By comprehensively measuring user similarity through scoring similarity and resource attribute preference similarity, we can mine users' potential points of interest, increase data density, and alleviate data sparsity. By constructing a discipline classification tree as the basic structure of instructional resources classification and user tag data, the system labels users by using the professional direction selection and interest topics when users register or log in for the first time, and the skimming data come from the classification tree. User model updating is to improve the original model according to the explicit or implicit feedback from users. In this way, the model can be well matched with the latest preferences of users, thus improving the accuracy and recommendation quality of the model. The system information database is the data source of the whole digital collaborative system. In this model, we collect and record learners' learning behaviors and mine learners' learning behavior trajectories to establish learners' behavior models.

Items i and j can be viewed as vectors of two n dimensions. The similarity of two items is estimated by calculating the spatial angle of these two vectors. For the scoring matrix of $m * n$, the similarity calculation formula of item i and item j is as follows:

$$\mathrm{Sim}(i, j) = \cos(\vec{i}, \vec{j}) = \frac{\vec{i} \cdot \vec{j}}{|\vec{i}| \cdot |\vec{j}|}. \tag{5}$$

Among them, $\cdot$ represents the vector inner product. The predicted score of the target user u to the item j is as follows:

$$P_{u,j} = \frac{\sum_{j=1}^{k} \mathrm{Sim}(i, j) \times R_{u,j}}{\sum_{j=1}^{k} \mathrm{Sim}(i, j)}. \tag{6}$$

Among them, k represents the resource set most similar to item i in the nearest neighbor table, and $R_{u,j}$ represents the evaluation that user u has made on item j and the predicted evaluation value obtained by the content-based algorithm. Mainly combined with cross validation to achieve, the formula is as follows:

$$\mathrm{MAE} = \frac{\sum_{g^{\text{test}} \subset G^{\text{test}}} \left| g^{\text{test}}(\text{prediction}) - g^{\text{test}}(\text{authentic}) \right|}{\left| G^{\text{test}} \right|}. \tag{7}$$

Among them, $g^{\text{test}}(\text{authentic})$ is the real score, $g^{\text{test}}(\text{prediction})$ is the predicted score, and G^{test} is the entire set of user scores to be predicted. The system uses recall and precision to evaluate the performance of its personalized recommendation. The formula is as follows:

$$\text{Recall ratio} = \frac{\text{Recommended number of related resources}}{\text{Total number of related resources}} \times 100\%,$$
$$\text{Precision ratio} = \frac{\text{Recommended number of related resources}}{\text{Number of recommended resources}} \times 100\%. \tag{8}$$

The user-item scoring matrix is used in this study to express users' preferences for items, and it is used to implement collaborative filtering recommendation technology. Its advantage is that it is suitable for the representation and establishment of a specific group user model due to group users' interest bias. All users can benefit from the system's recommendation function, which allows both logged-in and non-logged-in users to recommend personalized results and non-logged-in users to capture their interests based on real-time page operations. Learners will rate their satisfaction with a course after completing it, and the data will be saved in the user evaluation database. The accuracy of collaborative filtering recommendations is affected by the detail of the user evaluation database. Users with similar resources have a high degree of similarity in this study. Users in the system are clustered based on scoring information and resource attribute information, and clustering technology is applied to collaborative filtering recommendation. Users who have similar resource attribute preferences are grouped together. Finding the nearest neighbor in several clusters near the target user reduces the space-time cost of neighbor search, alleviates some scalability and real-time issues, and improves recommendation efficiency and quality. The personalized network instructional resource system actively provides recommendation resources to users based on their registration information and behavior characteristics after the introduction of personalized recommendation technology, transforming users from passive browsers to active learners.

4. Result Analysis and Discussion

The comparison experiment of the model and algorithm, as well as the analysis of the results, is the main focus of this chapter. This study designs an evaluation experiment for the model and algorithm to quantitatively obtain the recommendation index of the recommendation model after the English instructional resource management recommendation system has been implemented. This will allow us to gain a better understanding of the recommendation model's benefits and drawbacks, as well as serve as a guide for optimising the model's parameters and further optimisation. The system has 100 users registered, and a database of 100 users' personality traits has been created. The instructional resource database has a scale of 200 and 50 interest groups. The top ten English instructional resources with the most similarity are chosen and made available to the appropriate users. The experiment data come from the user operation log in this system, which is used to train the homepage recommendation module. The system will call each module to calculate the recommendation degree of this instructional resource to the user and then save the recommendation degree and the user scoring characteristic value into the database, when the user browses the detailed page of instructional resources and scores the instructional resources. Table 1 lists the experimental setup.

The function of the instructional resource retrieval module is to receive users' retrieval requests. First, users express their query requirements as keywords or search expressions and input them into the system through the user interface. After the system receives the user's search words or search expressions, the traditional database management system will find out all qualified instructional resources from the instructional resource database according to the matching of the query fields, and form the search results. In the experiment, the sparse level of the data set is also considered, which is defined as the percentage of items in the user-item scoring matrix that are not scored. Figure 3 shows the subjective rating results of users on recommended resources of different recommendation systems.

Table 1: Experimental environment settings.

Category	Setup
Processor	Dikaryon
Internal storage	512
Hard disc	80 GB
Operating system	Windows
Development platform	MyEclipse
Program	Java
Database system	MySQL

It can be seen that the recommended results of English learning resources in this system are more in line with users' needs and preferences, so its score is higher. In addition, the evaluation algorithm, as a standard to measure the recommendation effect of recommendation system, plays a very important role. Therefore, the selection of evaluation algorithms and the characteristics of different evaluation algorithms need to be taken into account, so as to comprehensively evaluate the recommendation effect of a recommendation system. At the same time, it can compare with other recommendation systems comprehensively and get a comprehensive understanding of the recommendation effect of the recommendation system. Figure 4 shows the comparison of different algorithms when selecting different sparsity.

As can be seen from Figure 4, the improved CF is more accurate than other algorithms because it adds the user behavior weight calculation when the sparsity is small. In this experiment, the average absolute error and recall rate, which are the most widely used and intuitive statistical accuracy measurement methods, are used as evaluation criteria. During the experiment, the data set is divided into a training set and testing set. The algorithm works in the training set and predicts the items in the testing set through the data in the training set. The comparison algorithm used in this study is the classic user CF and project CF. The average absolute error results of different algorithms are shown in Figure 5. The recall results of different algorithms are shown in Figure 6.

The smaller the absolute error value, the higher the recommendation quality. The higher the recall rate of the algorithm, the better the performance of the algorithm. From the comparison results of the average absolute error and recall rate of the evaluation algorithm, it shows that the recommendation algorithm in this study is more accurate than the project CF and the user CF in recommending instructional resources. Table 2 lists the experimental results of filtering evaluation indexes.

Using the collected data set, under the condition of the same training set and testing set, the recommendation accuracy of different models is compared, and the nearest neighbor size is adjusted to make it produce the best effect in the recommendation process as much as possible. The recommended accuracy results of different models are shown in Figure 7.

The results show that the recommendation accuracy of this model is high. The average filtering accuracy of this system is slightly higher than that of the control

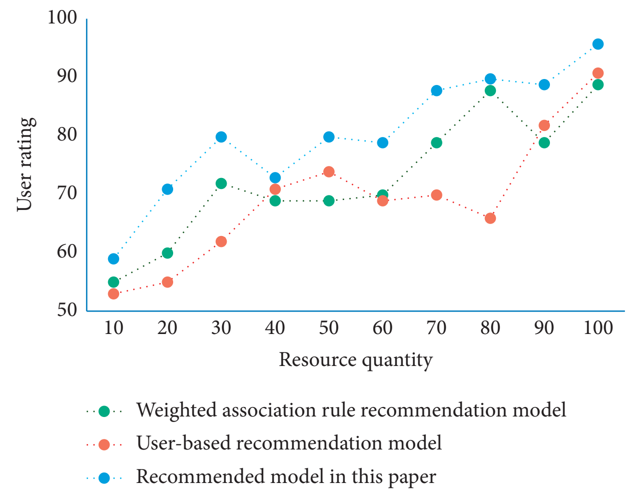

Figure 3: Comparison of users' subjective ratings.

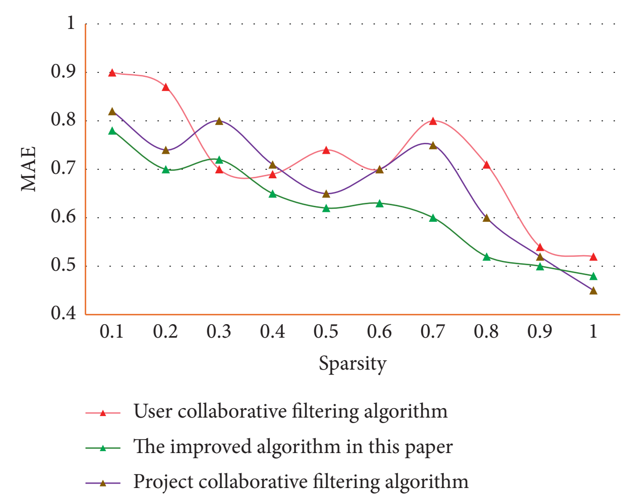

Figure 4: Comparison of algorithm results when selecting different sparsity.

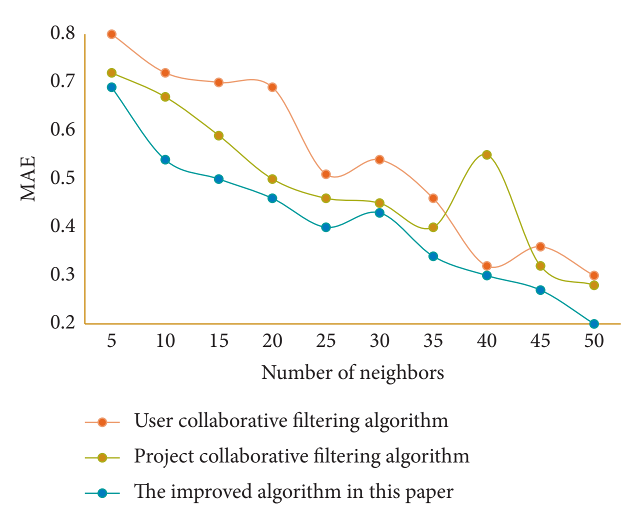

Figure 5: Average absolute error results of different algorithms.

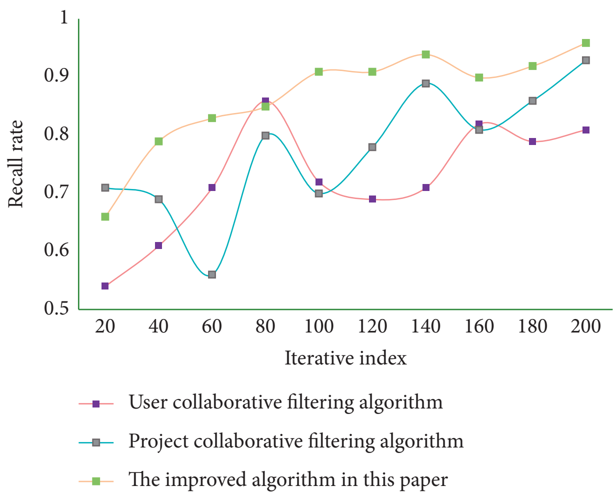

Figure 6: The recall results of different algorithms.

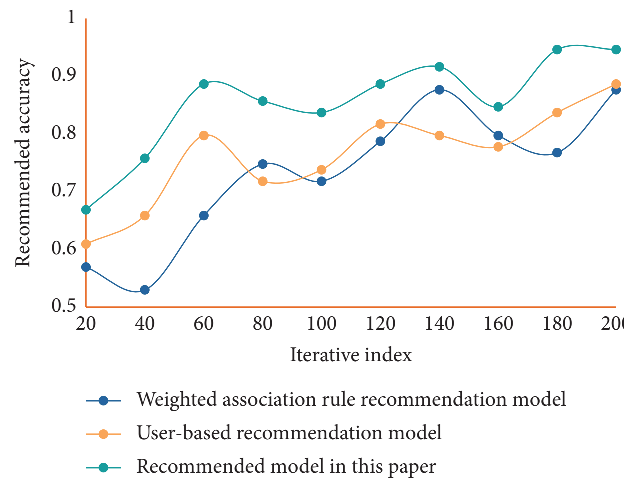

Figure 7: Recommended accuracy results of different models.

Table 2: Experimental results of evaluation index.

Model	Average precision rate (%)	Average recall rate (%)
Weighted association rule recommendation model	89.34	91.42
User-based recommendation model	84.12	86.37
Content-based recommendation model	82.36	85.24
Recommended model proposed in this study	95.36	96.17

experimental system. The main reason is that the former filters instructional resources according to the personalized characteristics of users, and the results are more targeted. Therefore, the model designed in this study, which has the learning function of users' personality characteristics and comprehensive filtering function, can effectively improve the recall and precision of personalized retrieval and personalized recommendation in English instructional resource service. Through the analysis of various experimental data, it can be seen that the English instructional resource management recommendation system constructed in this study is stable. The algorithm's recall rate can reach 96.37%, and the recommendation accuracy rate is as high as 95.31%, which is higher than the traditional method's 6.37%. The English instructional resource management recommendation system constructed in this study has good performance in all aspects and effectively improves the satisfaction of resource users. It can effectively provide high-quality resources for English teaching and can better satisfy users' experiences.

5. Conclusions

This study examines the use of personalized recommendation systems and digital English instructional resources, as well as the principle, recommendation process, and classification of collaborative filtering recommendation algorithms. This study has conducted extensive research on the topics of sparsity, cold start, and scalability of collaborative filtering recommendation algorithms, as well as proposed solutions. A CF-based English instructional resource management recommendation system is designed and implemented as a result of this. This study describes in detail the key technologies used in the system, presents the overall framework and functions of the digital English instructional resource system, and designs and implements a personalized recommendation module in the instructional resource system based on the learning habits and instructional resources of users. The system's advancement allows for better sharing and reuse of digital resources, as well as the discovery of instructional resources that learners may be interested in. The system's usability, ease of use, stability, and high real-time performance are demonstrated through the running test and performance analysis, and the system's convenient capacity expansion for many times in the future is also demonstrated. According to the research, this algorithm has a recall rate of 96.37% and a recommendation accuracy rate of 95.31%, which is higher than the traditional method's 6.37%. The English instructional resource management recommendation system developed in this study performs well in all areas and effectively increases resource users' satisfaction. It has the potential to effectively provide high-quality resources for English teaching while also improving user satisfaction. However, because the digital

English instructional resource system is a complex learning platform with time and technology constraints, there are still some issues in the system's research and development that need to be addressed. The balance between the real-time performance of the recommendation system and recommendation quality is the focus of the following work. Additional research into the characteristics of educational resources is necessary to expand the user interest model and instructional resource model.

Data Availability

With the evolvement, standards have changed, mobile Internet technology has also been upgraded, and it has also driven the development of smart objects mobile. With the continuous development of smart objects mobile, the bottleneck of small node size and low battery energy storage has not been solved in the end, which makes the research of wireless sensor network energy-saving technology become the focus, and the improvement of routing technology is an effective way to improve energy-saving technology. From the data transmission energy consumption of smart objects mobile, the routing algorithm of smart objects mobile is discussed and analyzed and the classical representative LEACH is the object of in-depth research. Routing algorithms can easily and reliably process network data and make the network work well and are widely used in highly secure military systems and smaller commercial networks. Aiming at these deficiencies, a corresponding improved algorithm is proposed, and it is tested through simulation and specific experiments to verify the correctness and the system's reliability. The SMPSO-BP algorithm converges when the number of iterations is about 600, which is earlier than the LEACH algorithm and the improved LEACH algorithm, so the SMPSO-BP algorithm is due to the other two algorithms. In the wireless sensor network routing energy consumption experiment, in addition, the SMPSO-BP algorithm uses less energy than the other two methods. Therefore, the energy-saving algorithm under the neural network data fusion mechanism is still feasible.

1. Introduction

The smart objects mobile is the main path of data transmission in the Internet of Things, along with the advancement of Internet, which is the main support for data transmission, and it is also the function that consumes the most energy in the wireless sensor network, which directly affects the overall performance of the entire network. As a new generation of communication technology integrating embedded computing, sensor, network, and wireless communication, wireless sensor network has been widely used in various fields. With information science's rapid growth, wireless sensors with the ability to obtain information from multiple technologies have been applied in various fields of intelligent data monitoring and are favored by various fields because of their low cost and multifunctionality.

The wireless sensor routing energy-saving algorithm aims at delaying the network service life under the premise that the node energy is exhausted and can undertake the network protection function. With the vigorous development of information technology, data transmission has become an indispensable part. The network routing is the carrier of data transmission, in order to improve the efficiency of data transmission and reduce energy consumption during the transmission process. According to the LEACH algorithm, the shortcomings of energy saving in wireless sensors are analyzed, and the redundancy of the original data collection by the sensor nodes is solved to boost downlink costs and decrease wireless carbon emissions using CNNs data space technology.

The combination of neural network and wireless sensor network is used to realize the data fusion in the network. First, the LEACH algorithm is a classic hierarchical routing algorithm used to stabilize the data transmission of wireless sensors, and then an improved LEACH algorithm is introduced on the basis of stable data transmission, and the improved LEACH algorithm is used to find the best path in the data transmission process. Finally, using the powerful platform complex utilization only fits the standards of co-operative sensing processes that are performed, improves the data transmission intelligence level of wireless sensors, reduces energy consumption, and prolongs service life.

2. Related Work

Wireless sensors have become one of the research hotspots because of their flexibility and high-precision monitoring capabilities. Dey et al. designed a home version of a wireless ECG monitoring system using Zigbee technology to monitor people's health at home, and the real-time monitoring system records, measures, and monitors ECG activity while maintaining consumer comfort [1]. Jamhour et al. proposed a new SDWSN control plane based on the Constrained Application Protocol to provide comprehensive specifications for the control plane, including the communication infrastructure, control plane protocols, and basic network functions in the controller [2]. Aarti and Anuj discovered the optimum path to transfer packet data from node to receiver, which includes communications systems, core router interfaces, and basic network activities in the computer. Aarti and Anuj considered the wide range of applications and delicate environments inside which WSNs are used, wherein transmission is as crucial as fuel economy, whereas the best route focused simulated annealing, simulated annealing, and efficient heuristic XGBoost have just been offered to increase delivery ratio [3]. These studies can analyze the relevant conditions of wireless sensors, but the research on sensor life and energy consumption needs to be improved.

With the increase of the number of distributed sensor nodes, researches on energy saving and consumption reduction of wireless sensors appear one after another. Song et al. used the Wasser procedure to execute data mining technique and conversation amongst sink nodes, guaranteeing that each node operates as a member node with quite an additional option, allowing the cable network nodes to spend energy more equitably [4]. Bhola et al. proposed LEACH, a modular technology that changes IoT devices with sensor nodes (CH), which analyzes and organizes data before sending it to the destination node to identify the best path [5]. In order to provide interesting solutions to problems related to agricultural resource optimization, decision support, and land monitoring, Khriji et al. proposed a localization-based RSSI algorithm to determine node locations and developed a low energy adaptive clustering approach adaptive neurofuzzy inference to minimize energy usage across all sink node [6]. In order to realize the efficient and optimal transmission of renewable energy power generation in the energy router, Guo et al. proposed a minimum loss routing algorithm based on the matchmaking tradeoff competition mechanism for the optimal selection of the existing ER transmission path [7]. Liu et al. proposed a Chaos Elite Eco-Evolutionary Algorithm (CENEA) for low-power clustering in EMWSNs for environmental monitoring. Results have shown that CENEA balances node energy and improves node energy usage efficiency, improves accuracy, and minimizes computation time [8]. The research on these energy-saving algorithms is instructive to a certain extent, but in some cases, the demonstration is not sufficient or accurate enough and can be further improved.

3. Energy-Saving Algorithm for Wireless Sensor Network Routing

3.1. LEACH Algorithm. The Scheme (LEACH) is a minimal flexible grouping routing mechanism that was the first to be published in sensor nodes [9]. The protocol is executed cyclically in units of rounds. Other ordinary nodes select the cluster head closest to themselves and join it to complete the establishment of the cluster; entering the stable data communication stage, the ordinary node transmits the collected data to the cluster head of the cluster where it belongs. After receiving the data, the cluster head completes the fusion operation and finally sends it directly to the sink node [10]. After a round of execution, waiting for a period of time, the network enters the next round of work cycle. The LEACH cluster routing algorithm mainly has two stages: the cluster establishment stage and the stable operation stage. The group building cycle primarily focuses on cluster setup, while the good performance of the proposed level mostly focuses on transmission, as shown in Figure 1. As one of the most classical routing algorithms, LEACH algorithm has some shortcomings, but its proposed hierarchical structure and round-robin mechanism have great reference value.

The LEACH algorithm is a hierarchical routing algorithm, and it is also the most classic one in hierarchical routing. Hierarchical routing algorithms have become a hot research direction of routing algorithms due to their high scalability, high energy utilization, and easy data fusion. The LEACH algorithm solves the stress problem by evenly dispersing the entire platform's electricity cost with each including to [11]. Hierarchical routing is shown in Figure 1. The algorithm randomly selects the cluster head and splits the cluster in a random cycle. This method of selecting cluster heads counterbalances the consumption of energy of nodes and improves the longevity of the network to some extent [12]. Energy saving, network lifetime, data fusion, and scalability are compared across three different topologies, as shown in Table 1.

As shown in Table 1, the Layered Routing algorithm outperforms the other two on all counts [13]. The sensor nodes perform real-time monitoring, information acquisition, and information processing functions on the monitoring object. The collected data is transmitted back to rendezvous junction, which processes the digital information and sends it to the user through the network, thus achieving the purpose of environmental monitoring, target tracking, and data collection [14]. Sensor nodes, sink nodes, and task management nodes form a wireless sensor network system. The traditional wireless sensor network structure is shown in Figure 2.

The routing computing capability of the node also needs to depend on the computing unit. The wireless communication module is composed of the network, MAC, and transceiver and mainly realizes the data communication

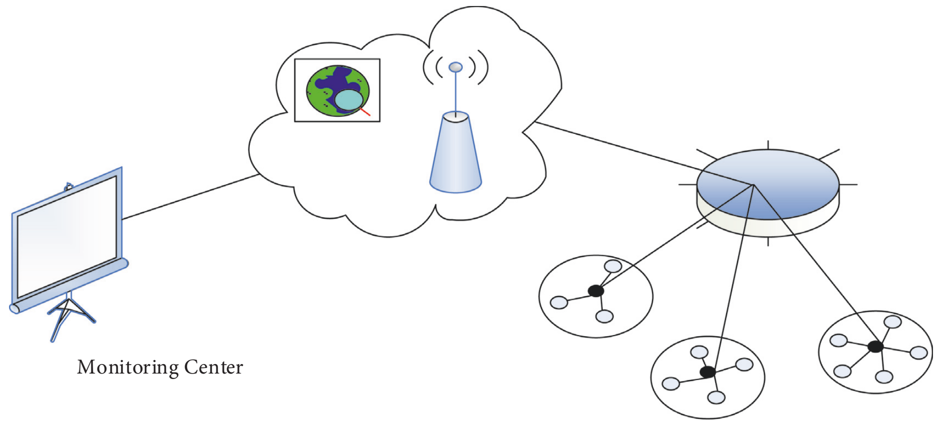

Figure 1: Hierarchical routing.

Table 1: Routing classification comparison.

Algorithm	SPIN	GAF	LEACH
Topology	Flat	Location	Level
Energy saving	Have	Have	Generally
Network life	Long	Long	Long
Data fusion	Have	None	Have
Extensibility	Generally	It is good	It is good

function: the power supply module supplies energy for the entire sensor node [15].

As can be seen from Figure 3, the power module is the most important module, and all other modules need the support of the power module. However, most power modules use batteries for energy supply, and the energy is limited, so an effective routing mechanism needs to be designed to lessen the power expenditure of the web and extend the lifespan of the web [5].

The advantages of trunking over flat roaming solutions in saving energy are reflected in the following points: the cluster member nodes simply send the data to the club leaders of the clusters after sensing such traffic. The upper layer backbone network consisting of club leader completes the long distance transmission of data to the sink nodes. The communications modalities can be turned off by the member nodes for the majority of the transmission time [16]. This working mode not only ensures the data communication in the entire network, but also greatly reduces the communication volume in the web and less power hungry. The nodes that constitute the wireless sensor network are usually deployed randomly, and closer to the point where the data gathered by the knots may be relatively resemblance. Meanwhile, the cluster topology is well expandable and applies to massive linear wireless transceiver systems. No matter what type of routing protocol is used, the purpose is to minimize the effort of energy overhead for data transmission and to extend the longevity of the system [17]. The running "round" of the LEACH algorithm is shown in Figure 4.

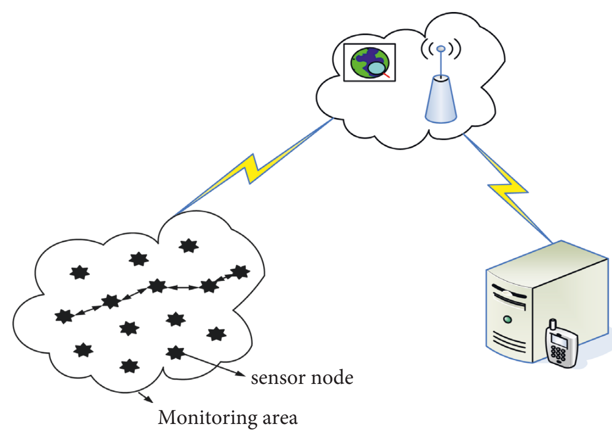

Figure 2: Wireless sensor network architecture.

In the initialization phase of wireless sensor network data transmission, each node generates a random value of [0, 1], and the node compares the random value generated by itself with the threshold. If the randomly selected value is less in value than the quota, which will be picked for container leaders. The formula is as follows:

$$T(i) = \begin{cases} \dfrac{z}{1 - z \times (r \times \operatorname{mod}(1/z))}, & i \in G, \\ 0, \quad \text{else.} \end{cases} \tag{1}$$

In WSN, the functions of sensor nodes are mainly to perceive, process, and transmit data. Since the power expenditure for performing data feeds is quite different from that of other functions, the energy consumption analysis of WSN only considers the communication power generation. The communication energy consumption of wireless sensor network increases with the increase of distance, so the data transmission route has a great influence on the energy consumption of the sensor. Correlation between communication distance Y meters and the energy consumption X bit generated by the generated data is expressed as the following formula:

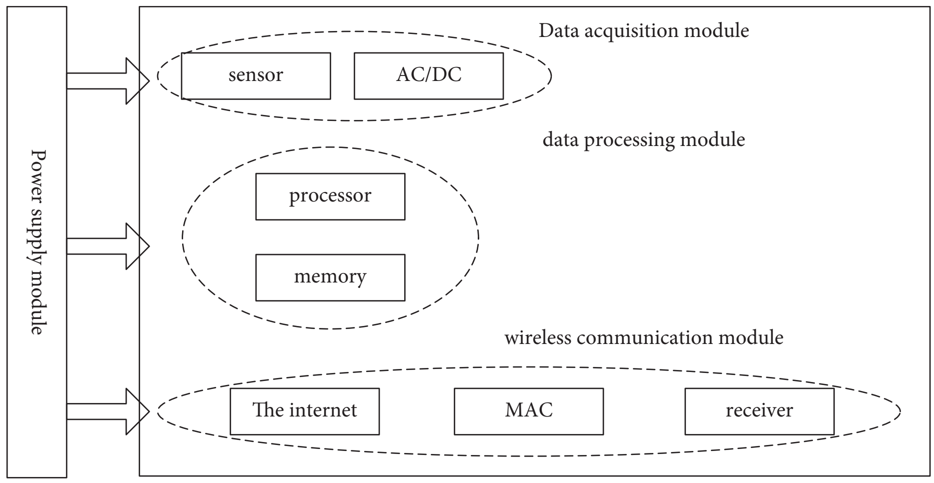

Figure 3: Sensor node block diagram.

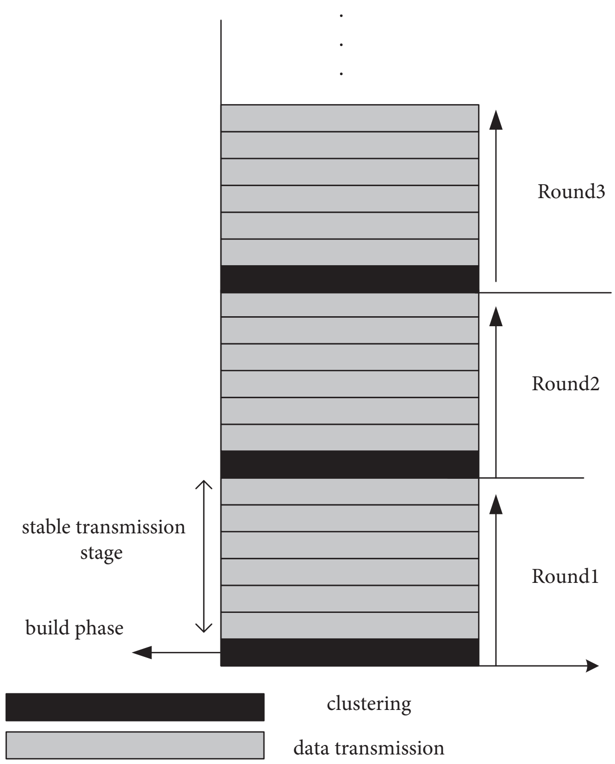

Figure 4: LEACH algorithm run cycle diagram.

$$Q_{ch}(X,Y)=\begin{cases} XQ_{\text{elec}}+X\varepsilon_{fs}Y^2, & Y\le D_{\text{threshold}},\\ XQ_{\text{elec}}+X\varepsilon_{ch}Y^4, & Y> D_{\text{threshold}},\end{cases} \tag{2}$$

$$y_{\text{threshold}}=\sqrt{\frac{\varepsilon_{fs}}{\varepsilon_{ch}}}, \tag{3}$$

$$Q_{RX}(X)=XQ_{\text{elec}}, \tag{4}$$

$$Q_{AG}(X)=XQ_{Ya}. \tag{5}$$

Here, Q_{Ya} represents the circuit loss energy of fusing unit-bit data [18]. Therefore, the transmission route has a great influence on the power generation speed of the sensor web, and it is very important for the wireless sensor network to design an efficient route to reduce the power expenditure of the web [19].

3.2. Improved LEACH Algorithm. The improved LEACH algorithm introduces the concept of temporary tuft leader head and final tuft leader in the first round of tuft head election. All temporary tuft leader located within the same cluster radius competes for the ultimate tuft leader, avoiding the phenomenon of multiple tuft leader within a tuft radius, and uniformizing the distribution of tuft leader [20]. Compared with the LEACH algorithm, the improved algorithm calculates the optimal number of cluster heads based on the energy characteristics of the base station, so that the cluster heads are distributed relatively uniformly in the node area. The energy threshold is judged during the rotation between the cluster heads within the cluster, and the energy consumption is effectively reduced through multihop transmission between the cluster heads to the base station.

Assuming that each node cluster is a circle with the tuft leader as the center, according to the network model of the algorithm, if the area of the node distribution area is m^2, the sum of knots is N, and the proportion of cluster heads is p, then there are N_p nodes in the network. If the clusters are to cover the entire node distribution area, the coverage radius of each cluster needs to be satisfied. R is also the shortest distance between cluster head nodes [21].

$$T=\frac{P}{\sqrt{Qn\pi}}, \tag{6}$$

$$Q_{ab}=Qn. \tag{7}$$

On average, there are (Q/Q_{ab}) nodes in each cluster in the network, including $Q/Q_{ab}-1$ cluster head and q member nodes [22]. The receiving node receives data, fuses data, and sends data. Let $N_{to\ \sin\ k}$ be the distance from the tuft leader to the flume knot, and then power expenditure of the tuft leader is

$$W_{ab} = k\left(\frac{Q}{Q_{ab}} - 1\right)W_{elec} + k\frac{Q}{Q_{ab}}W_{DA} + kW_{elec} + k\varepsilon_{mp}d^4_{tosink}. \tag{8}$$

During a single cluster in each round, the member knots in a single climate only need to transmit water to the leader of the climate. If Y_{totoch} is the distance from the member node to the leader of the climate, the power expenditure of the member node is

$$W_{cm} = kW_{elec} + k\varepsilon_{fs}Y^2_{\text{totoch}}. \tag{9}$$

It is assumed that the coverage area of each cluster is a swarm leader focused on a swarm with a root size of approximately of $R/\sqrt{Q_{ab}\pi}$. If the distribution density of nodes that are part of a fleet of node is $\partial(x, y)$, the expectation of the square of the distance from any member node in the circular cluster to the center of the circle is

$$W\left[Y^2_{\text{toch}}\right] = \iint\left(x^2 + y^2\right)\partial(x + y)YxYy, \tag{10}$$

$$W\left[Y^2_{\text{toch}}\right] = \iint r^2\partial(r, \theta)YrY\theta, \tag{11}$$

$$W\left[Y^2_{\text{toch}}\right] = \partial\int_0^{2\pi}\int_0^{\left(R/\sqrt{Q_{ch}\pi}\right)} r^3YrY\theta, \tag{12}$$

$$W\left[Y^2_{\text{toch}}\right] = \partial\frac{R^4}{2Q^2_{ch}\pi}. \tag{13}$$

If the nodes are evenly distributed throughout the network area, then

$$\partial = \frac{1}{\left(R^2/Q_{ch}\right)}, \tag{14}$$

$$W\left[Y^2_{\text{toch}}\right] = \frac{R^2}{2Q_{ch}\pi}, \tag{15}$$

$$W_{cm} = kW_{\text{elec}} + k\varepsilon_{fs}\frac{R^2}{2\pi Q_{ch}}. \tag{16}$$

Then, the power expenditure of a single cluster in each round is

$$W_{\text{cluster}} = W_{ch} + \left(\frac{Q}{Q_{ch}} - 1\right)W_{ch} \approx W_{ch} + \frac{Q}{Q_{ch}}kW_{cm}. \tag{17}$$

Then, the energy consumption of the whole network in each round is

$$W_{wsn} = Q_{ch}W_{\text{cluster}} = Q_{ch}\left(W_{ch} + \frac{Q}{Q_{ch}}W_{cm}\right), \tag{18}$$

$$W_{wsn} = k\left(2QW_{\text{elec}} + QW_{DA} + Q_{ch}\varepsilon_{mp}Y^4_{to\ \sin\ k} + \frac{\varepsilon_{fs}}{2\pi}\frac{QR^2}{Q_{ch}}\right). \tag{19}$$

In order to find out what value Q_{ch} takes, W_{wsn} is the smallest; let W_{wsn} take the first derivative of Q_{ch}, and let $(YW_{wsn}/YQ_{ch}) = 0$, and it can be obtained that

$$\varepsilon_{mp}Y^4_{to\ \sin\ k} = \frac{\varepsilon_{fs}}{2\pi}\frac{QR^2}{Q_{ch}}. \tag{20}$$

Then, the best amount of tuft leaders in terms of the number of tuft tips can be solved for

$$Q_{ch} = \frac{Q}{Y^2_{to\ \sin\ k}}\sqrt{\frac{Q\varepsilon_{fs}}{2\pi\varepsilon_{mp}}}. \tag{21}$$

It can be seen from the formula that the optimal number of tuft tips Q_{ch} is only related to parameters ε_{fs} and ε_{mp}, the size of the node distribution area R, the total number of nodes Q, and the distance $Y_{to\ \sin\ k}$ from the tuft tip to the sink node. The cluster heads generated by the LEACH random method cannot guarantee their uniform distribution. The information collected by these cluster heads has large redundancy, and the transmission of redundant data is a waste of the limited energy of nodes. Therefore, in the network initialization stage, the ideal quantity of pack leader in the web can be figured out according to the following formula parameters, and an appropriate number of cluster heads can be selected in the first round of cluster head election. In the cluster routing mechanism, the data collected by the member nodes are collected and merged by the cluster head before being forwarded, which reduces the data redundancy and reduces the traffic.

3.3. SMPSO-BP Data Fusion Algorithm. A neural web (NN), also known as an armed artificial network (ANN), is a process that simulates the thinking of the human brain through extensive interconnections. With the powerful error resilience and the ability of adaptive self-learning, self-organization, and self-adaptation, neural networks model sophisticated affine line mappings and can meet the processing demands of data fusion technology, which is especially suitable for sensor networks. Wireless sensor networks need to solve the problems of limited network energy supply, data transmission quality and network data transmission security in the process of mass data transmission, the ability of utilizing the system's signal manipulation function and auto-reasoning capabilities of neural net. Data fusion is realized, and the development of wireless sensor network application field is also promoted, so the emergence of artificial neural network data fusion technology is inevitable.

The basic idea of data fusion is to correlate and analyze the sensing data from multiple sensor nodes, filter invalid information, and extract feature information and combine it into a data packet of the same size with high accuracy. The reduction of data traffic means the reduction of the amount of data sent or received by sensor nodes, which can effectively extend the network life cycle. The total of packets are received at the sink node satisfactorily. Sink node is used as the basis for measuring the data traffic in the network. The comparison of this data can not only reflect the role of data fusion in wireless sensor network routing, but also reflect the difference in data volume control.

Neural network has the ability of parallel processing, distributed storage, and self-learning for a large amount of data, especially suitable for the stage where data needs to be processed at the same time and can solve the problem of inaccurate information processing. The main idea of the SMPSO algorithm is to mutate some particles whose fitness is too low in the early stage. The way is to update the position of the particle to be the average value of the position of the particle with the highest fitness value, thereby reducing the diversity of the population. Then, the particle calculation formula in the SMPSO algorithm is used to update each particle, and the optimal particle obtained after training is the optimal parameter output. Among them, the fitness value function $f(x)$ is the mean square error generated in the sample training, as shown in the following formula:

$$k(x) = \frac{1}{1 + (1/2n) \sum_{b=1}^{n} \left(y_b - t_b\right)}. \tag{22}$$

The standard deviation of the output sequence of the hidden layer node i is calculated according to the formula given below, and the correlation between the ith neuron node and the jth neuron node in the hidden layer is calculated.

$$f_t^2 = \sum_{b=1}^{n} \left(V_{ib} - \overline{V}_i\right)^2, \tag{23}$$

$$C_{ij} = \frac{\sum_{b=1}^{n} \left(V_{ib} V_{jb} - n\overline{V}_j \overline{V}_i\right)}{f_i f_j}. \tag{24}$$

Here, V_{ib} is the outcome value of the ith node of the hidden layer for sample p, and $\overline{V}_i$ is the average value of V_{ib}. If $C_{ij} > h_1, f_i > h_2, f_j > h_2$; delete neuron j and modify the connection weight w_{ei} and threshold θ_e of any neuron e in the next layer, as shown in the following formula:

$$w_{ei} = w_{ei} + aw_{ei}, \tag{25}$$

$$\theta_e = \theta_e + b\theta_e. \tag{26}$$

The wireless sensor network has limited energy, and the communication energy consumption is the main energy consumption of the network. The routing algorithm determines the stability of the entire network. The data fusion model based on BP neural web includes a BP web optimization algorithm based on optimized PSO, namely, the design of the SMPSO-BP algorithm, and it is used to implement the data merge course of the nodes in the wireless sensor web cluster.

4. Routing Test of Wireless Sensor Network Based on Neural Network

4.1. Test Parameter Settings. Before testing the relevant functions of the wireless sensor on the relevant algorithm, the preparation work should be done first, and the relevant parameters should be set:

(1) The sensor node does not move, and it will enter the state of death when its energy is exhausted.

(2) In the entire wireless sensor network, there is only one sink node, that is, the sink node, and this node has unlimited energy and computing power and does not need to consider energy supply and node death.

(3) Sensor nodes have unique IDs and can communicate with each other.

(4) The energy depletion model for text wireless transmission uses the WSN channel energy depletion model, and the node distance is set as the experimental approximate value of 90 m. The sensor knots are strategically located in the measurement area and have the same transmission range. The specific parameters are shown in Table 2.

4.2. Node Test Comparison of Related Algorithms. The convergence rate, which can be expressed by the average best fitness and the average number of iterations, is used to demonstrate the effect of the SMPSO-BP algorithm's search performance. The average number of iterations will be 100, based on previous experience and experimental testing conditions. Figure 5 shows the SMPSO-BP calculations for verification with the LEACH calculations and the improved LEACH calculations under the experimental parameter settings. We get the verification of the SMPSO-BP algorithm's convergence simulation results when the number of sensor nodes is 600, 700, and 800, respectively. The curve of the SMPSO-BP algorithm first reaches the level, as shown in the graph above, when the number of knots is 800, indicating that the individual particle swarm obtains the best fitness value first. The scenario with 700 points comes next, followed by the scenario with 600 points. As a result, the SMPSO-BP algorithm proposed in the paper can be applied not only to small-scale nets, but also to massive systems, with a relatively fast aggregation speed.

It is seen from Figure 5 that, by increasing the frequency of repeated generations, the fitness value is constantly approaching the optimal fitness value, and finally the average fitness value is close to 1, which is stable, and the curve converges. This shows that it is practicable to integrate and combine neural neck networks with SMPSO-BP algo for data fusion in radio signal systems. Further, the SMPSO-BP algorithm can arrive at the sweet fitness value much earlier compared to the improved LEACH method; that is, the optimal reading value of the BP neural network can be obtained faster. It can also be seen from the figure that the curve of the original LEACH algorithm without optimization is the slowest, which shows that the LEACH algorithm does have the problem of slow convergence. The other two algorithms with intelligent optimization have a significantly higher curve convergence rate than the LEACH algorithm. And the improved LEACH algorithm converges when the number of evolution iterations is about 700, while the SMPSO-BP algorithm converges, and when the total number of iterations is about 600, this suggests that the

Table 2: Experimental parameter value settings.

Parameter	Parameter value
The number of sensor nodes	1000
Node initial energy	0.8 J
Perceived data interval	0.5 s
Data transmission energy consumption	50 nJ/bit
Receive data energy consumption	35 nJ/bit

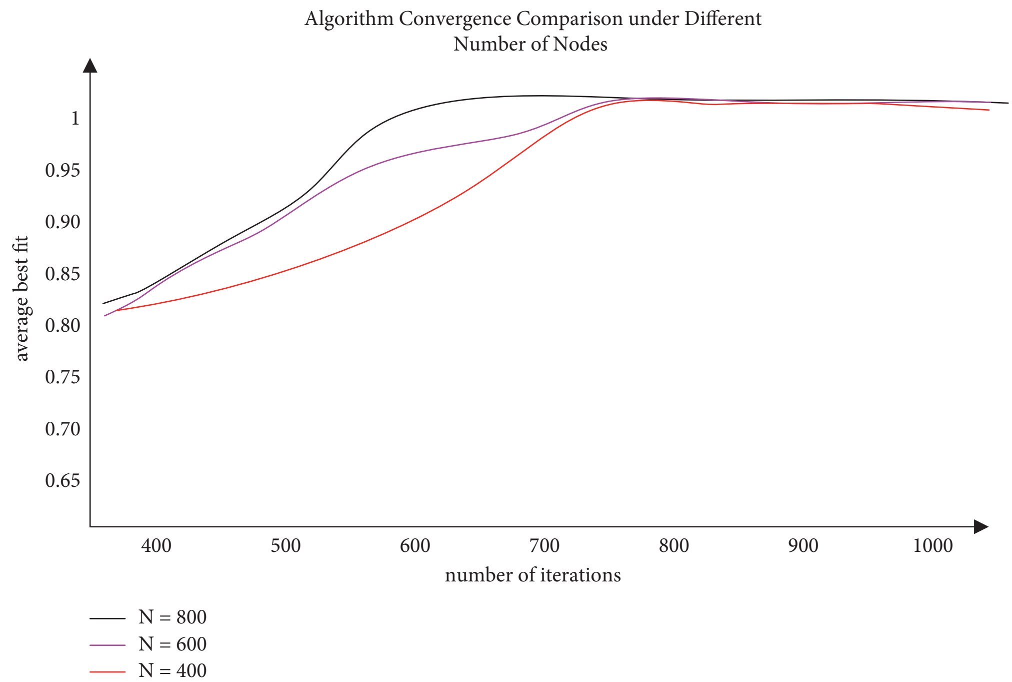

Figure 5: Convergence speed of different algorithms at the same number of nodes and different number of nodes.

speed of convergence of the SMPSO-BP algorithm is indeed faster than that of the improved LEACH algorithm.

The SMPSO-BP algorithm obtained from the experimental analysis is due to the other two algorithms, but at the expense of simulation time. Through 60 independent simulation experiments, the average operation time of SMPSO-BP algorithm, LEACH algorithm, and improved LEACH algorithm is obtained. The results are shown in Table 3.

Compared with the GABP algorithm, the BP network optimization algorithm requires longer operation time, and the BP algorithm without any optimization measures requires the shortest operation time. Although the SMPOS-BP algorithm achieves the optimization of the BP network at the expense of extending the operation time, from the results in the above table, the extended time is relatively within an acceptable range. Therefore, in general, for the application of data fusion in wireless sensor networks, the SMPSO-BP algorithm has shown good performance in terms of efficiency and accuracy.

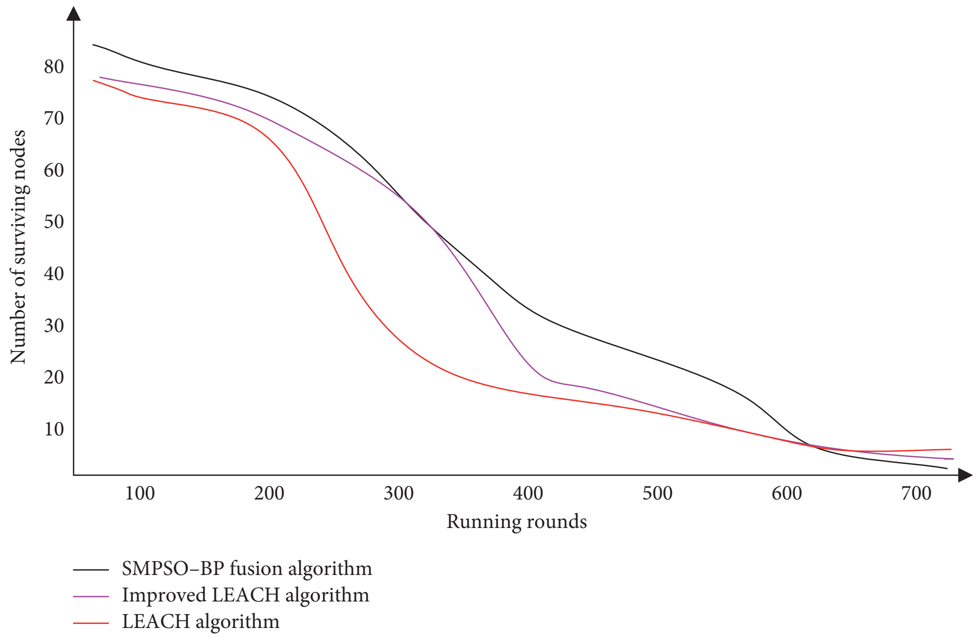
The survival rate of sensor nodes is crucial to the normal operation of wireless sensor networks. Once a node enters a state of death due to energy exhaustion or other failures, the node cannot perform the task of sensing and collecting data.

Table 3: Comparison of operation time of different algorithms.

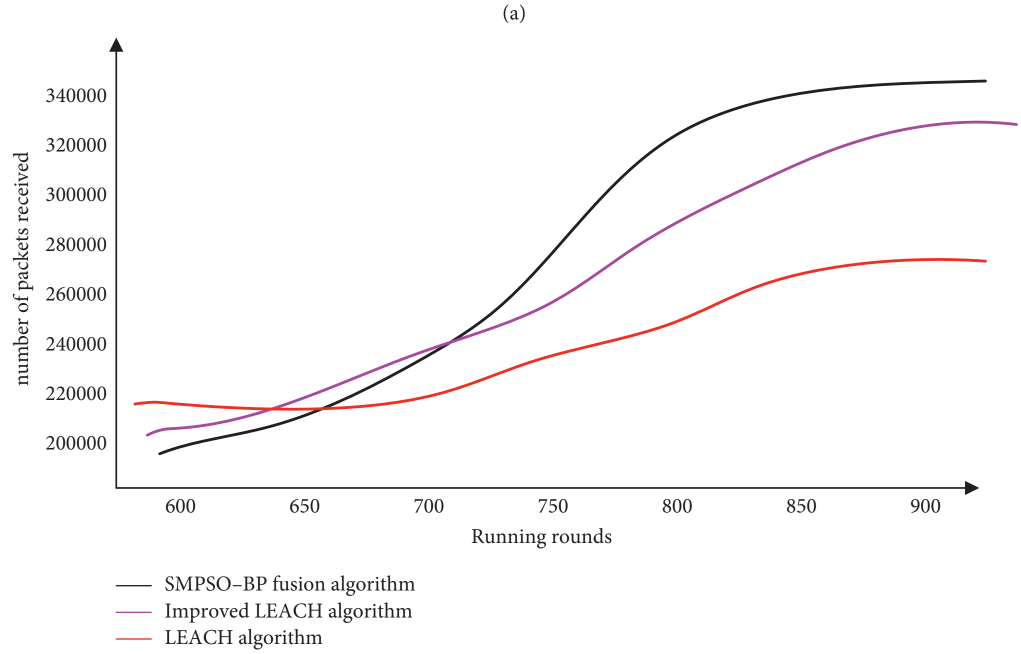
Algorithm	Operation time/s
LEACH algorithm	4.13
Improved LEACH algorithm	3.89
SMPSO-BP	3.55

Therefore, after the network has been running for a period of time, the comparison and analysis of the number of surviving nodes are an important part of examining the performance of the improved data fusion algorithm. The SMPSO-BP algorithm, the LEACH algorithm, and the improved LEACH algorithm are simulated and compared, and the results are shown in Figure 6.

The curve of the LEACH protocol is greater than the previous version in the early stages of network operation than in the other two cases, as shown in Figure 6. This is due to the fact that the data fusion mechanism is not constrained, so it is sent directly to the socket head point node. The node survival rate drops dramatically as the number of data transmissions grows too large. When the data fusion mechanism is implemented in a network where the SMPSO-BP operator performs the SMPSO-BP approach to



(a)

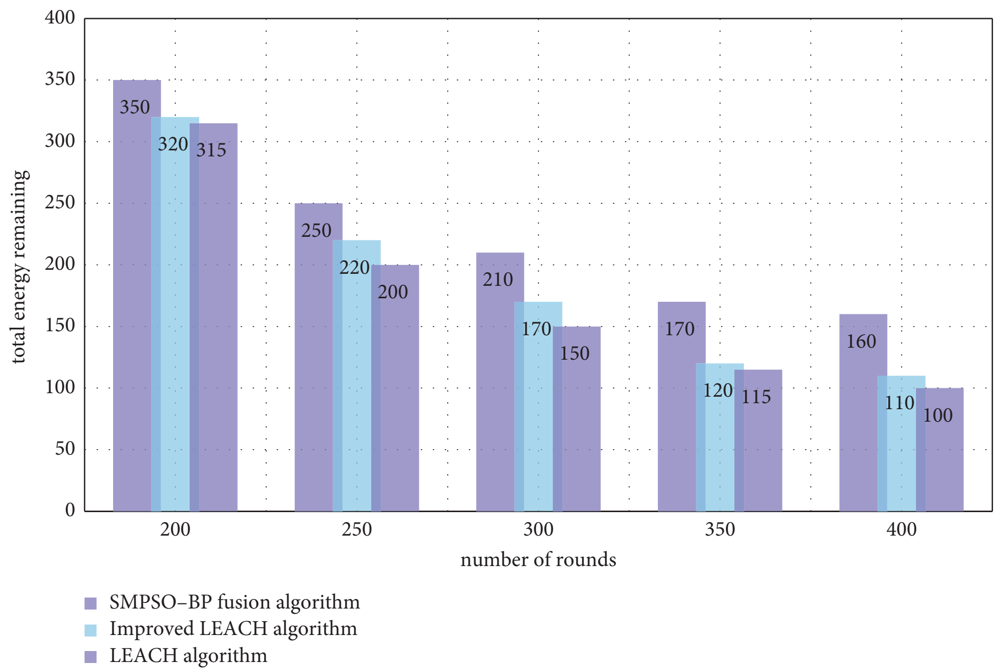


(b)

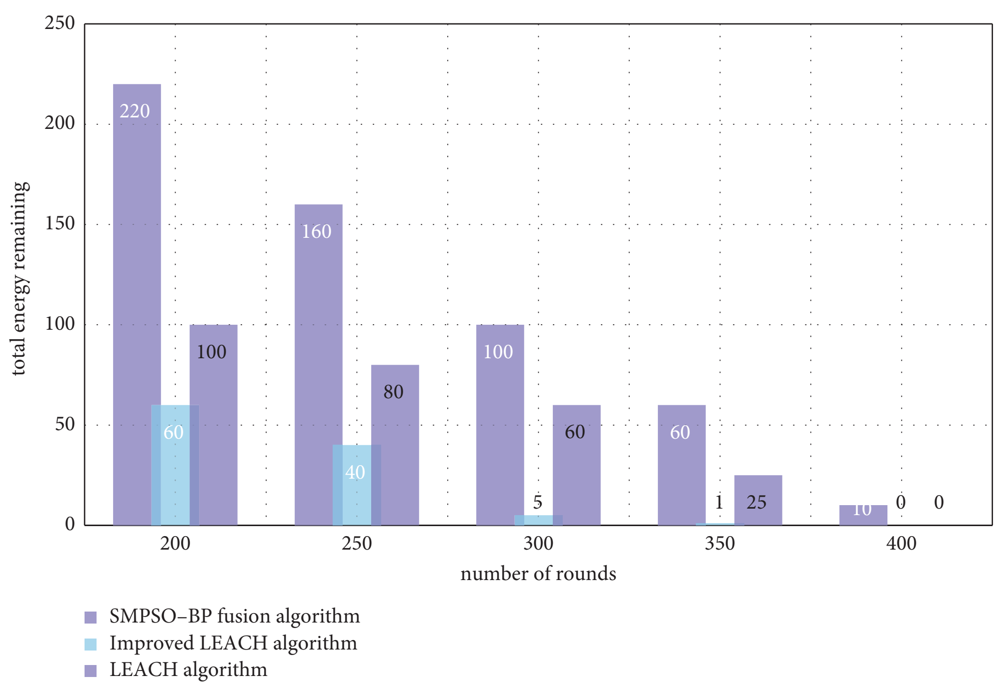
Figure 6: Survival number of network nodes with different algorithms. (a) Comparison of the number of surviving nodes in the network. (b) Comparison of the amount of data received by the node.

processing, the processed data is sent to the repository junction nodes in a stable manner as the amount of transmitted data grows. Because the amount of redundant data is reduced, and the nodes' energy consumption is low, environmental monitoring and data transmission can still be carried out normally, especially at a later stage. The fact that the number of packets received by the water sink nodes increased even after the death of a large number of sensor nodes shows that data fusion can reduce data traffic in the network effectively. During this time, the optimized LEACH protocol also played a supporting role, helping achieve the goal of extending the network's working time.

4.3. Comparison of Energy Consumption in the Network. In order to understand and solve the problem of energy consumption of routing nodes in wireless sensor networks, this paper uses SMPSO-BP algorithm, LEACH algorithm, and improved LEACH algorithm to calculate the change of the remaining energy of the whole network in the base



(a)



(b)

Figure 7: (a) The remaining energy of the whole network of the base station in the node area. (b) The remaining energy of the entire network of the base station outside the node area.

station node area and outside the area with time, to understand the energy consumption of the wireless sensor network routing nodes by the neural network of the data fusion technology.

Figure 7 shows the remaining energy of the whole network when the base station is in the node area, and the remaining energy of the whole network for the three protocols in the initial state is the same. The vertical axis in Figure 7 represents the total energy remaining in the network, and the horizontal axis represents the number of rounds performed. The steep energy curves of the LEACH algorithm and the improved LEACH algorithm indicate that the energy consumption per round is more, while the corresponding SMPSO-BP algorithm protocol energy curve is the flattest, indicating that the energy consumption per round is smaller than the other two. As the round increases, the nodes far from the base station in LEACH begin to die, resulting in a reduction in the number of nodes and a reduction in energy consumption. In this experiment, the SMPSO-BP algorithm, the LEACH algorithm, and the improved LEACH algorithm are simulated and compared, and the overall energy consumption of the network is analyzed. The results are shown in Figure 7.

The node death time in the improved LEACH algorithm is later than that in the LEACH algorithm. The SMPSO-BP algorithm does not need to select a new cluster head every round. The clustering is uniform, the position and residual energy of the candidate nodes are considered when the cluster head is rotated within the cluster, and the cluster head communicates with the base station in multiple hops. These measures make the SMPSO-BP algorithm consume less energy in a single round. The residual energy of the whole network is higher than that of the LEACH algorithm and the improved LEACH algorithm. Regarding the remaining energy of the entire network when the base station is outside the node area, due to the increase in the communication distance, the energy consumed by the three protocols in each round increases. The improved LEACH algorithm has the greatest impact because all nodes need to send messages to the base station. In the SMPSO-BP algorithm, the cluster head uses multihop to transmit data to the base station, reducing the loss caused by the long-distance communication.

5. Conclusion

The emergence of neural network data fusion technology can better and more comprehensively simulate the cognitive ability of the sensor node ad hoc network. Its application will greatly improve the intelligence level of sensor network applications, reduce node energy consumption, and effectively prolong the lifetime of sensor networks. Three kinds of routing nodes are analyzed by the convergence speed of node data and the survival rate of nodes when data transmission is increased, and the SMPSO-BP algorithm supported by neural network is compared with other algorithms. The convergence of the SMPSO-BP algorithm and the number of surviving nodes during the operation of the wireless sensor network are all due to the other two algorithms, and it can avoid falling into the local optimum. And the cluster head election process is more reasonable, which can achieve energy balance to a certain extent. The data fusion mechanism of the SMPSO-BP algorithm does reduce the amount of data transmission during the operation of the wireless sensor network, reduce the energy consumption of nodes, and achieve the purpose of extending the network life cycle. It is believed that the energy consumption of wireless sensor network routing nodes can be better reduced based on the neural network data fusion mechanism algorithm. Wireless communication is realized through the automatic data exchange of sensors, which improves the efficiency of data transmission, provides convenience for people's daily life, and has a positive impact.

Academic Editor: Xin Ning

Training simulators have been gradually evolving in the direction of software, virtualization, networking, and multiplatform in recent years, with the continuous development of hardware and software technologies, particularly the maturity of VR (Virtual Reality) related technologies. The network intrusion program allows remote hackers to take control of the system, posing a serious threat to the network and computer security. As a result, this paper proposes a VR-based ID (intrusion detection) simulation training system. This paper proposes an ID model based on CNN (Convolutional Neural Networks) and LSTM to address these issues (Long Short-term Memory Networks). This model oversamples data from unbalanced data sets, reducing the difference in category data and thus improving the ID model's performance and existing detection methods to compensate for the flaw. 3DSMAX technology is used to simulate the process visualization scene, as well as some key equipment models and signal transmission simulations, during the system design and implementation process. The experimental results show that CNN LSTM outperforms BP, and the overall evaluation index $F1$ has significantly improved, particularly the $F1$ index of D4. CNN LSTM outperforms GA (genetic algorithm) by 12.75 percent and BP by 14.07 percent. The system essentially accomplishes the anticipated simulation training goal, and the simulation training effect is impressive.

1. Introduction

As a means of information transmission and communication, virtual reality technology can intuitively and realistically provide students with visual information such as the structure, size, working principle, and assembly process of equipment, allowing them to observe the team in a virtual environment. The working process and direct operation of each component help students understand and perceive tasks more effectively. Virtual reality is a new technology. Its goal is to make the information system as user-friendly as possible, to improve the direct interaction between users and data, and to make human-computer interaction more convenient and humanized [1]. The simulation training system based on VR technology has low cost, high versatility, easy upgrade, and easy maintenance, among other features, and is particularly well suited to the primary training of students' operation skills.

Network security technology has become a key technology of computer networks. ID (intrusion detection) is considered the second security door behind the firewall. It can monitor the network without affecting the network performance, provide real-time protection against internal attacks, external attacks, and improper operations, and greatly improve network security [2]. An efficient ID system can provide security for the computer system, network system, and even the whole information system and prevent huge economic losses. Wang et al. have studied and implemented a real-time ID system model, which is based on the profile of user behavior characteristics and uses statistical methods to describe the behavior of system subjects relative to system objects [3]. Riyaz and Ganapathy adopted a recursive network and combined it with traditional expert system for ID [4]. Esmeir and Markovitch proposed an anomaly detection algorithm based on a one-dimensional self-organizing feature mapping network [5]. Alkadi et al.

introduced information retrieval technology into ID. However, some algorithms are not practical, such as expert methods [6], and some algorithms are still in the experimental research stage, such as immunological methods and neural networks.

By examining the current state of information security, we can see that traditional security technology is unable to fully guarantee network security, and the existing ID system has numerous flaws. As a result, the development of identification technology must meet higher requirements in order to protect network security. The system may be attacked, according to the current security situation. If the system is attacked, further losses can be avoided if the attack is detected as quickly as possible, even in real time. In this regard, identity verification is critical for establishing a security system capable of compensating for the shortcomings of traditional security measures. This document develops an ID simulation training system using VR technology based on the ID process and the use of 3DSMAX software. Simultaneously, it can effectively solve students' learning and training problems, improve the efficiency of students' knowledge absorption, master skills, and improve the effectiveness of education and training. This paper contains the following innovations:

(1) In this paper, a simulation training system is established, and the virtual training scene is constructed and optimized by 3D modeling and 3DSMAX rendering software. Finally, the interactive settings of die-cutting, paper, and die-cutting actions are made by VR software, and the training interaction of virtual ID is realized.

(2) This paper presents an ID detection model based on a neural network. This model can extract the local features of data in the network by using CNN's deep feature learning [7, 8], which can improve the accuracy of ID and reduce the false alarm rate.

This paper has the following organizational structure: The first chapter discusses the research's background and significance before moving on to the paper's main work. The second chapter focuses on the technologies that are needed to implement the simulation training system. The research's concrete methods and implementation are presented in the third chapter. The superiority and feasibility of this research model are confirmed in the fourth chapter. The summary of the full text appears in the fifth chapter.

2. Related Work

2.1. ID System Research. After analyzing the characteristics of the traffic flowing through the network, ID can analyze the user's behavior to see if it is malicious, which is an active tracking behavior. From here on, ID has entered the development stage of network detection.

Fan et al. adopted a multilevel hierarchical ID method based on GA (genetic algorithm) to solve the problems of a single-level ID system [9]. Ghosh et al. proposed a method of constructing an ID system with a decision tree, which can identify unknown attacks in the network [10]. Alotaibi and Alotaibi proposed an abnormal traffic detection method based on a deep neural network, which can identify the normal or abnormal connections in the network, and the detection effect is good [11]. Kumar et al. proposed a deep neural network ID system based on context LSTM (Long Short-term Memory Networks) [12]. Firstly, the original data is obtained by social media on the internet, from which the push-level bots are detected, and then the context features are extracted and detected by LSTM. However, this method is only suitable for the detection of specific bots.

Kim et al. used a standard BP network to train and recognize the formed user behavior feature vectors [13]. Choobdar et al. used two different statistical analysis detection techniques to detect the abnormal behavior of the system [14]. Tian et al. used comprehensive traffic monitoring to find anomalies, combined with geographic information to show the location of intrusion events and applied the corresponding relationship between intrusion and vulnerability to give the risk analysis results between intrusion threats and asset vulnerability so as to effectively manage security events and timely handle and respond [15]. Rezaei and Liu applied the immune principle to the field of distributed ID [16].

2.2. VR Technology Research. In recent years, with the continuous development of computer hardware and software, new technology has developed rapidly-VR. It is an ideal man-machine interface between VR computers and users. VR system has three important characteristics: immersion, interactivity, and imagination. VR technology has a wide range of potential applications, such as national defense, architectural design, industrial design, training, medical treatment, and other fields.

With the help of specially designed sensors, users can interact with 3D images and manipulate virtual objects so that users can perceive the virtual environment equivalent to the real world [17]. Xue et al. further simplified it into a computer program that can present a simulated world [18]. It can be defined as a highly interactive three-dimensional digital media environment. Users can intuitively experience the simulated environment and get multisensory feedback such as hearing, touch, and vision. Wang and Zhu think that good spatial audio not only makes users deeply immersed in a virtual environment but also is an important channel for users to obtain environmental information [19]. Yong proposed an optical mapping near-eye 3D display method for wearable devices, the core of which is to adjust the eyes to the same distance as a binocular stereo vision to relieve eye fatigue and discomfort [20]. Compared with previous methods, this monitor has outstanding advantages in adaptability, dynamic range of images, and refresh rate.

It is a somatosensory interaction technology to interact with the virtual environment in a noncontact way through physical natural behaviors such as actions, sounds, or expressions. Foreign scholars generally believe that somatosensory interaction technology is a key component of VR and plays an important role in VR training. Yang et al. put forward a soft motion sensing device for measuring lower limb joint motion, which can effectively improve the shortcomings of the prior art in mobility and wear resistance [21]. Xia and Qi proved that distributed VR system can build a 3D collaboration environment for distributed users to interact with each other and complete various collaboration tasks [22]. Distributed VR system conforms to the new demands of the times, promotes communication and collaboration among users, and their application potential needs to be explored more. Bai et al. are committed to improving the user experience of VR devices, suggesting that a multiuser VR environment and wireless connection should be considered in future VR devices [23].

3. Methodology

3.1. ID Model Design. The algorithm used by the ID system has a direct impact on detection efficiency and accuracy. Pattern matching is now one of the most widely used detection methods and mechanisms in the field of identification. The next step in this concept is to define the pattern of existing problems. Then look for event data that corresponds to the pattern. Anomaly detection and production ID systems frequently employ statistics. Statistics is a relatively mature ID method that allows the ID system to learn the subjects' daily behavior and identify those activities that statistically differ from normal activities as abnormal. Because of the immune system's unique capabilities, an ID system based on immunological methods offers numerous benefits, including diversity, fault tolerance, distribution, dynamics, self-management, and adaptability.

The neural network has the ability of self-adaptation, self-organization, and self-learning. It can deal with some problems with complex environmental information and unknown background knowledge, which makes the samples have big defects and deficiencies [2]. From the perspective of pattern recognition, an ID system can use a neural network to extract pattern features from user behavior and then create profiles of user behavior features. In a word, the introduction of the neural network into the ID system can solve the dynamic characteristics of user behavior and the difficulty of accurate detection caused by incomplete and uncertain search data. The attack behavior in the network is not completed at a single point in time but will be sent continuously over a period of time. By analyzing the correlation performance of the time series before and after the network data, the intrusion behavior can be best detected. In this paper, an ID model combining CNN (Progressive Neural Network) and LSTM (Long Short-term Memory Networks) is proposed, and the loss function is optimized to improve the ID accuracy and reduce the false alarm rate. The ID is shown in Figure 1.

In this model, CNN is first used to extract depth local features in order to effectively extract sample data, and then LSTM is used to learn and extract correlation features between continuous data in both positive and negative directions. Finally, the softmax layer is used for classification, and the Focal Loss function is used to optimize the model. The model takes into account the temporal and spatial correlation of intrusion data and can extract unknown features and internal dependencies between data, lowering false alarm rates and improving detection effectiveness.

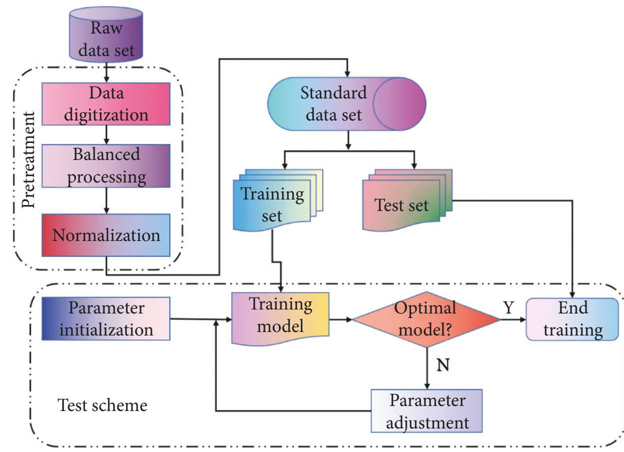

Figure 1: ID structure.

The role of the ID model based on deep learning is to divide the emerging abnormal data traffic into a group of known attack types according to their function or behavior. In the actual detection process, it is often necessary to preprocess the samples, including digitization, normalization, data equalization, and other operations, so as to make the data conform to the input format of the detection algorithm.

Select to keep the useful information in the memory cell, discard the unnecessary information, and normalize the value by activating the function. The specific calculation formula is shown as follows:

$$f_t = \sigma\left(W_f \cdot [h_{t-1}, x_t] + b_f\right). \tag{1}$$

σ is the sigmoid function. At $t-1$ time, the output vector of the hidden layer is expressed as $h(t-1)$, at t time, the input vector is expressed as x_t, and in f state, the weight matrix of x_t is expressed as W_f, and b_f is offset.

In the ID model designed in this paper, there is only one full connection layer, and the upper layer information is integrated and transmitted to LSTM. The output calculation formula of neurons in the whole layer is shown in the following:

$$y_j^l = \sum_i w_{ij}^l * x_i^{l-1} + b_j^l, \tag{2}$$

where w_{ij}^l represents the connection weight; x_i^{l-1} is the i th eigenvalue of the eigenvector in layer $l-1$; b_j^l represents the offset value; y_j^l is the calculated output of the j-th neuron in layer l.

Input the sample vector into the X competition layer, calculate the Euclidean distance between the sample point and the subcategory, and find the most suitable subcategory to belong to the following:

$$d(X, W_c) = \min\{d(X, W_i)\} \quad i = 1, 2, \ldots, R, \tag{3}$$

where W_c represents the initial weight of the network, $d(X, W_c)$ represents the distance between the i th input sample and the subcategory, and W_i represents the subcategory after winning the competition.

x_{ij} is set as training data, which contains data elements with large variation. The goal is to make the variation between elements less than 1. First calculate the average of all elements in X:

$$p_0 = \frac{1}{m*n}\sum_{i=1}^{n}\sum_{j=1}^{n} x_{ij}. \tag{4}$$

Among them, $i = 1, 2, \ldots, m$; $j = 1, 2, \ldots, n$.

Then, through a mapping function, the numerical values are mapped to each subinterval to be quantified so as to achieve the goal of normalization. The normalization method used here is linear normalization, and the expression is as shown in the following formula:

$$y = \frac{x - \text{Min Value}}{\text{Max Value} - \text{Min Value}}, \tag{5}$$

where x, y is the value before and after conversion, and Max Value, Min Value is the maximum and minimum value of the sample.

If the output is close to [0, 1], it is assumed that an intrusion has occurred, and the control center should be notified and appropriate measures taken. If the intrusion is new, the neural network should be investigated, retrained, the weights corrected, and the network's performance improved. Distributed object technology, software agent technology, and mobile code technology are all combined in mobile agent technology. It is a brand new computing technique for dealing with complex, dynamic, and distributed intelligent applications. The concept of distributed computing has been greatly expanded by the addition of intelligent functions and mobile creativity. Artificial intelligence combined with distributed computing is likely to become a key component of intelligent distributed computing. Figure 2 is the flow chart of mobile agent task analysis.

The scheduling manager is the core component of the mobile agent service environment. Assign all kinds of services required for normal mobile agent operation to the corresponding submodules, including setting the mobile agent execution environment, starting services, etc. In addition, it is also responsible for coordinating the cooperation among submodules to ensure their normal operation. Static agent mainly completes the interaction between agent scheduling manager and front-end agent.

3.2. Scene Modeling. One of the keys to building a high-fidelity virtual scene is to use 3D modeling technology and modeling software to present a scene almost identical to the real environment on the computer. Realistic virtual ID model is the basis of designing a virtual die-cutting training system as a visual, interactive, and realistic simulation training scene of die-cutting equipment. Virtual identity recognition is an important core part of the virtual simulation training system. Because these devices require high precision, this paper uses Solidworks to build parametric

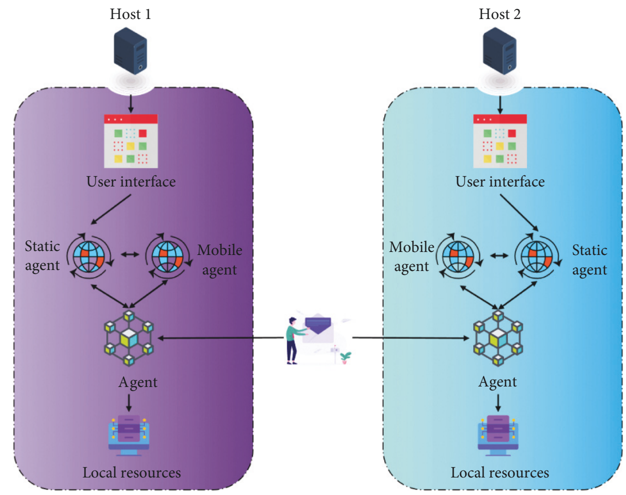

FIGURE 2: Flow chart of mobile agent task solving.

models of these devices and then imports them into 3DsMax for rendering, which can not only ensure the model precision but also ensure the fidelity.

Unique training is done by plane animation. An image is an original hand-drawn painting, and Photoshop is used to perform the effects of the image, such as color correction, motion processing, and stereo effects. The transition and continuity of actions are completed through key frames to ensure the accuracy and consistency of actions. It should be noted that when modeling in 3D Studio Max, the material must use standard material or multisubobject material and use the default scanline renderer. All the sizes of the maps are set according to the pixel of 2 to the n power, so as to reduce the memory overhead and improve the fluency of the software.

For a surface S, suppose we need to paste texture lines on the surface. First, we need to find out the relationship between space A and B. Let the radius of the surface S be R, and the chord height PF $= h$ be OP $= R - h$; Make AB $= x$, so we can get the following relationship:

$$\frac{R}{R+x} = \frac{R-h}{R}. \tag{6}$$

After simplification, you get the following:

$$x = \frac{hR}{h-R}. \tag{7}$$

There are

$$(s - x^*)^2 + (t - y^*)^2 + z^* = \left(\frac{hR}{h-R}\right)^2. \tag{8}$$

Then the $B(x^*, y^*, z^*)$ on the curved surface corresponds to the $A(s, t)$ on the texture pattern one by one, and similarly, other surfaces on the curved surface also have this corresponding relationship.

So you can get the following:

$$\sin\theta = \frac{|AB|}{|A^* B^*|} = \frac{am + bn + cp}{\sqrt{(x_1^* - x_2^*)^2 (y_1^* - y_2^*)^2 (z_1^* - z_2^*)^2}}. \tag{9}$$

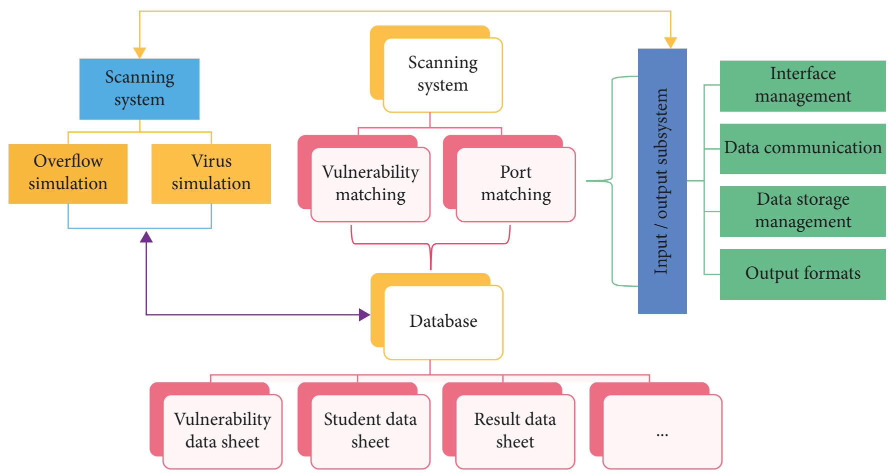

Figure 3: System structure.

After the above transformation, the texture space coordinate (x, y) and the concave-convex model mapping area coordinate (x^*, y^*, z^*) can form a one-to-one correspondence relationship so as to better realize concave-convex model mapping.

The color and properties of materials should be as close to real objects as possible to improve the fidelity of virtual scenes. Material Editor and Material/Map Browser tools are included in 3ds Max. You can choose different types of shading for objects, use different material components, and enhance materials with maps to make them look more realistic in light and environment in the Material Editor. To achieve the desired effect, we simply need to set and adjust the parameters of the particle system according to the characteristics of special effects during the development process. The time it takes to write and develop code can be cut in half while achieving special effects, and good results have been obtained [12].

3.3. Realization of Interactive Effect of Virtual Scene. As an important part of the network attack and defense training system, ID simulation training system mainly includes four main subsystems, as shown in Figure 3. The subsystem uses the database SQLServer database (the database name is net_fight) to store data. As the data storage center of the whole education and training system, the input subsystem is the general part of the whole education and training system and undertakes various input and output functions.

In this virtual simulation training system, there are many virtual scenes that need to interact with each other in order to realize the real representation of identity. Paper feeding includes two parts: paper feeding and paper discharging after die-cutting. Paper movement is set interactively with the path node, and the path node can move or rotate its parent node. In its property box, you can enter the moving position and direction of the paper at each time point to make the paper move along a certain path. Use the place node to complete the previous movement. When the start button is pressed, the template immediately rises. A user-defined function node can be described using a Script node. You must define a field list, event input and output, and what to do with these operations in this function node. The student users enter the Train system and begin attack training after the teacher has been set up. The student's attack is successful if the attack condition matches successfully; if the condition fails, the student immediately enters the temporary result and starts over. The attack subsystem's network intrusion function simulation module also sends interface information to the input-output subsystem, which saves the final information in the result data table.

Attack sequence table attack_state table stores information about students' attacks and Source_IP field indicates the IP address of the attacker. Server setup simulation includes verification code setting, password setting, server name setting, online prompt setting of the destination host and sending to mailbox, etc. When "student_state" = "1," the target IP is online; when "student_server" = "1," the target host has an intrusion server installed on the network.

4. Experiment and Results

In the experiment, 100,216 randomly selected and preprocessed data blocks are used as training sets for model training, and 4,227 randomly selected data blocks are used as test sets for performance testing. After numerical processing in data preprocessing, the single record in the set is finally changed from the original 40-dimensional feature vector to the 120-dimensional binary feature vector. Therefore, the model input in this document is a numerical array with a fixed size of $1 * 120$. In this paper, the loss function parameter $\alpha = 0.2, \gamma = 3$, which has been verified by the existing experiments, has been used for many experiments. Recall rate and false alarm rate are used as performance evaluation criteria. Experimental results are shown in Table 1.

The experimental results in the above table are displayed visually by charts, as shown in Figures 4 and 5.

According to the analysis of Figure 4, the recall rate first rises and then falls with the increase of the convolution kernel, and the difference is obvious. When the convolution kernel size is 5 and the number of hidden layer ganglia is 30,

Table 1: Influence of the number of hidden layer nodes on performance.

Convolution kernel size	Number of hidden layer nodes	Precision (%)	False alarm rate (%)
1	10	93.31	2.17
1	30	94.15	2.26
1	60	93.36	2.54
5	10	93.01	2.24
5	30	94.41	2.01
5	60	93.96	2.21
8	10	93.02	2.23
8	30	92.28	2.63
8	60	94.65	2.51
13	10	94.55	2.66
13	30	93.38	2.71
13	60	92.16	2.89

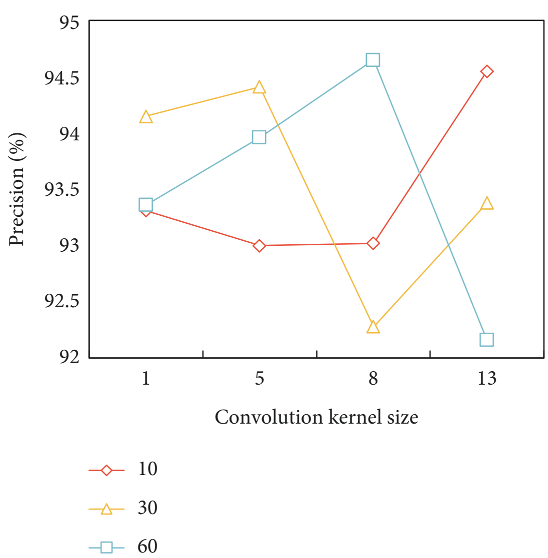

Figure 4: Influence of convolution kernel size and number of hidden layer nodes on recall.

the recall rate reaches the maximum value. According to the false alarm rate in Figure 5, when the convolution kernel size is 5 and the number of hidden layer nodes is 30, the false alarm rate is the lowest, and the larger the convolution kernel, the greater the error. Considering these two results, the optimal combination scheme is selected. In this paper, the size of the convolution kernel is set to 5, and the number of ganglion points in the hidden layer is set to 30.

In this paper, the experimental results of *F*1 overall evaluation indexes of three models on five data types are also given to verify the classification effect of the models on a few classes. The results are shown in Figure 6.

It can be seen that CNN_LSTM has more advantages than BP, and the overall evaluation index *F*1 has improved a lot. The *F*1 index of D_4 CNN_LSTM is 12.75% higher than GA and 14.07% higher than BP. The results verify the effectiveness of the data processed by oversampling method and the model trained by the Focal Loss function on unbalanced data sets.

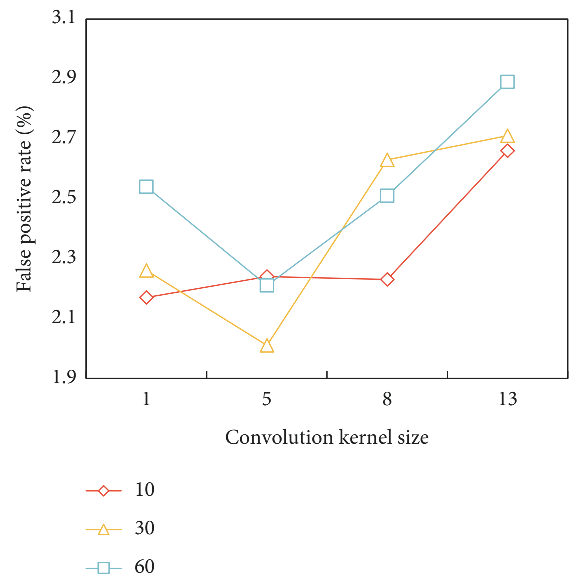

Figure 5: Influence of convolution kernel size and numb of hidden layer node on false alarm rate.

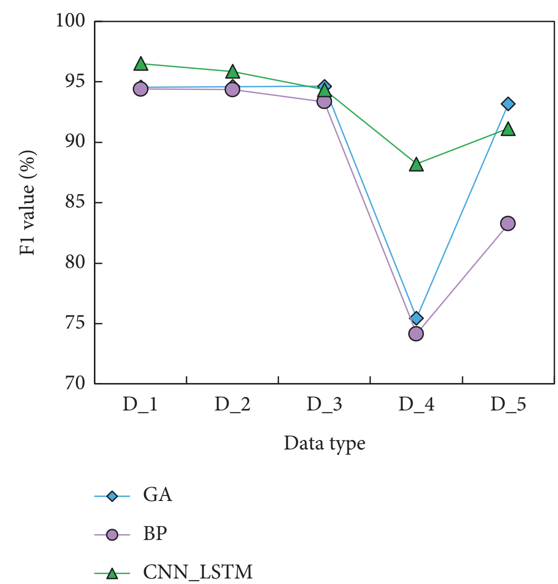

Figure 6: The *F*1 values of three types of detection for different categories.

The false positive and false negative rates have a direct impact on whether the system can be used in real-world situations. Although the neural model ID system can detect new types of intrusions that were previously unknown, it cannot completely eliminate the problem of false positives and false negatives. Establish the object's abnormal activity pattern, and by observing the proximity between current activity and the abnormal activity pattern, detect the same type of intrusion behaviour. The neural network is used for reverse learning when the rule system detects the intrusion, and the neural network ID is used at other times. When an intrusion occurs, the double detection system can reduce false alarms.

Table 2: Experimental results with different thresholds.

Threshold value	False alarm rate	False alarm rate
0.2	0.0061	0.22
0.4	0.0073	0.26
0.6	0.0082	0.12
0.8	0.021	0.086

The training data is input into CNN_LSTM for training, and the actual output simout is compared with the expected output simt, and the detection result of the whole neural network is obtained. Make $\theta_1 = \theta_2$, then take different values, and test with CNN_LSTM, which has been trained before. The experimental results are shown in Table 2:

It can be seen from the above table that the higher the threshold, the higher the false alarm rate and the lower the false alarm rate, while the lower the threshold, the lower the false alarm rate and the higher the false alarm rate, which is a contradictory relationship. If the false alarm rate is low, the false alarm rate will increase. If the false alarm rate is low, the false alarm rate will increase. Therefore, users can set appropriate thresholds according to their own needs so that the ID system can achieve the best detection performance.

Learning network intrusion takes place in virtual machines, and it consists of two parts: learning the statistical characteristics of normal users during operation and learning intrusion. When the system is in place, ordinary users' operation learning is completed, and many existing research results can be used as a reference. The virtual machine adapts the running parameters, extracts statistical data from the data packet conversion expert database, adjusts the input, and performs network learning based on the situation, determining if the learning is complete in light of the convergence situation and updating the neural network detection model. Following the completion of the neural network's learning and training, the pattern discrimination work is converted into a numerical operation that can be executed at high speed on a computer, resulting in an efficient parallel nonlinear dynamic processing system that can meet real-time processing requirements. The false alarm should theoretically be a subset of two independent systems for dual-system operation, which can greatly reduce the false alarm rate. New intrusion rules can be obtained through log analysis, and rule detection rules can be added to the rule detection system to make it more perfect.

The efficiency of the pattern matching algorithm is determined by three factors: text length, pattern length, and alphabet size. Because no pattern matching algorithm is optimal under all conditions, the purpose of the experiment is to test the performance of each algorithm when the above factors are modified. Figure 7 shows the execution time comparison of the three algorithms.

It can be seen from Figure 7 that the execution speed of CNN_LSTM is slightly faster than that of reference [18] algorithm and reference [20] algorithm. When the protected system is very important and the system manager needs to constantly correct the rules, it is necessary to collect the information of intruders, constantly improve and optimize the system, and transfer intruders to dedicated servers. The

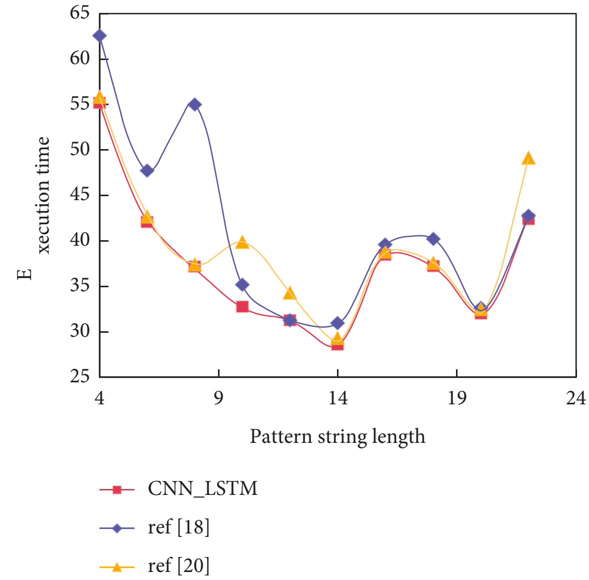

Figure 7: Comparison of the execution time of three algorithms.

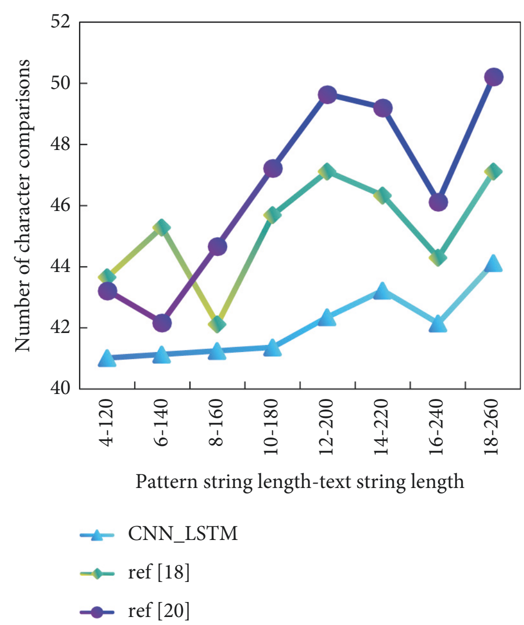

Figure 8: Total character comparison times of various algorithms.

most common alarm and notification method provided by the ID system is the screen alarm. When the ID system is installed, this alarm information will appear on the ID system console or other user-configured systems. They only process local data and only return the results to the control center, so there is no delay caused by network transmission, and the bandwidth occupied by original data transmission can be saved. Another advantage of processing data on each node is that it can be processed in parallel, which will improve the detection speed.

It can be found from Figure 8 that the total number of character comparisons of CNN_LSTM is always less than that of reference [18] algorithm and reference [20] algorithm, no matter how the pattern string length and text string length change.

This advantage becomes more apparent as the pattern string length increases. Because the length of a pattern string in an ID system is usually between 20 and 30, the CNN LSTM algorithm has some utility in an ID system. Finally, when compared to the first two algorithms, the CNN LSTM algorithm has a shorter execution time. As a result, each algorithm corresponds to a specific number of simple operations, and the more times an algorithm is executed, the longer the execution time. As a result, the number of simple operations included in an algorithm is commonly referred to as the algorithm's time complexity, which is used to assess the algorithm's runtime or computational performance. We must set up a neural network module for unknown intrusion behavior to judge whether it is an attack behavior through repeated training of unknown behavior. The data from the data processing module cannot be sent directly to the neural network for identification; instead, it must be preprocessed to obtain data that meets the requirements. Then, the next time the system is used, the uncertain "behaviour" judged in the first job is updated to the known attack information, and the alarm module is directly used to give an alarm, eliminating the need to enter the neural network and greatly improving the ID system's efficiency and practicability.

5. Conclusions

In this paper, VR technology is applied to ID simulation training, and an ID simulation training system is designed and implemented using the 3DSMAX software development platform. Through the combination of virtual and real simulation, the problem is that network intrusion software has special functions and powerful remote control functions, and it is difficult to achieve good simulation results while ensuring network security is overcome. File management, registration, etc., and safely complete functions such as table management, video monitoring, screen control, etc. In this paper, a detection method combining CNN and LSTM is proposed. Softmax is used for classification, and the Focal Loss function is used on the Softmax layer to optimize the model. This method comprehensively considers the temporal and spatial correlation of intrusion data and can extract unknown features and internal dependencies between data, improve the ID accuracy, and reduce the false alarm rate. The experimental results show that CNN_LSTM has more advantages than BP, and the overall evaluation rate $F1$ has been greatly improved. The $F1$ rate of D_4 CNN_LSTM is 12.75% higher than GA and 14.07% higher than BP. The results verify the effectiveness of the data processed by oversampling method and the model trained by the Focal Loss function on unbalanced data sets.

In the era of knowledge economy, the competition between countries and enterprises is increasingly manifested in the competition of talents and education system. In this article, aiming at the drawbacks of the traditional HRM model of university teachers, we design and construct a management innovation model and decision-making model based on intelligent big data analysis. This article introduces DM technology. It also introduces the related knowledge of DM and the analysis and design process of HRM decision system. In this system, DM technology is used to analyze and process the existing data, predict the future situation, and provide auxiliary support for decision-making. Through simulation, the decision-making accuracy of this model can reach 95.68%, which is about 10.02% higher than other systems. It has certain practicability and reliability. This article makes a useful attempt for the application of DM technology in HRM. The research in this article is expected to play an important decision-making reference and service support for HRM of university teachers and further promote the development of HRM innovation of university teachers.

1. Introduction

In the modern environment, the demand for knowledge and intellectual capital in society is stronger than in any previous era, which leads to the aggravation of talent shortage. In some ways, economic growth mainly depends on the quality of labor force. Therefore, human resources are increasingly becoming strategic resources for economic and social development [1]. The competition between countries and enterprises is increasingly manifested as the competition of talents and the competition of educational system. As the quality of teaching in institution of higher learning directly determines the level of knowledge and personal quality of talents, the society has paid more attention to the management of college teachers who train senior talents [2]. However, the traditional management mode is increasingly showing many drawbacks. For example, the ideas of managers and managed people lag behind; the management mode is relatively closed and rigid; operating mechanisms such as competition mechanism, incentive mechanism, interest mechanism, responsibility mechanism, and flow mechanism are not well introduced into the management of teachers; the overall quality of teachers needs to be further improved; and teachers' resources have not been effectively allocated and developed. College teachers are the direct undertaker of college production activities and the main body and core of college human resources. The quantity, quality, and structure of teachers' resources directly determine the educational quality and school-running efficiency of institution of higher learning and then affect the national human resources and the level of economic and social development [3]. The purpose of human resource management of teachers in institution of higher learning is to mobilize the enthusiasm and creativity of every faculty member to the maximum extent and make more contributions to the school. Under the background of economic globalization, in order to realize the scientific task of human resource management in institution of higher learning, we must actively and effectively reform and innovate the human resource management of college teachers.

Relevant personnel should elevate HRM (human resource management) to the forefront of school development strategy; create a harmonious system for seeking, selecting, cultivating, knowing, loving, and employing talents; and establish a new HRM mode for modern university teachers [4]. This is critical in order to fully mobilize teachers' enthusiasm for teaching, scientific research, and work; effectively improve the quality and efficiency of school education; and promote the healthy development of higher education institutions. Various industries have accumulated a large amount of data in recent years as a result of the advancement of information technology. People's requirements for data processing technology are constantly improving due to the increasing importance of data in daily decision-making. In terms of university teacher human resource management, using intelligent big data to analyze all types of university human resource data has some practical implications for its management. We should clearly define the problems in HRM that need to be solved and recognize that DM (data mining) [5, 6] is an important step. Although the final outcome of excavation is unpredictable, the problems to be investigated should be. The requirements of DM in institutions of higher learning will continue to rise as the human management system develops [7]. As a result, improving university teachers' application research of DM technology in HRM is conducive to improving the further understanding of the theory of the HRM system in universities and promoting the improvement in the HRM system's application level. This article develops an innovative mode and decision-making model for university teachers' human resource management using intelligent big data. The following are some of its innovations: (1) This article systematically consults the theoretical and practical materials about human resource management at home and abroad, analyzes the characteristics and significance of human resource management of university teachers, and establishes the theoretical basis for research. Guided by the modern HRM theory, this article systematically analyzes the HRM situation in institution of higher learning by using DM technology "intelligently" and "automatically," so that a large amount of data information can be effectively utilized. (2) Based on the comparative analysis of the HRM modes of Chinese and foreign university teachers, this article constructs the innovative mode and decision-making model of university teachers' HRM. The research shows that the decision-making accuracy of this model can reach 95.68%, which is about 10.02% higher than other systems. And on the basis of studying relevant models, this article finds valuable knowledge.

2. Related Works

The development of society requires a sufficient number of high-level human resources, and a strong country also urgently needs the growth of outstanding talents from all walks of life. Under this premise, the construction of teaching staff in institution of higher learning has been promoted to a high position, and the requirements for teachers are quite different from those before. At present, many scholars have explored the HRM of university teachers.

Ke analyzed and discussed the existing practical problems in the development and management of human resources for college teachers and put forward corresponding strategies for the development and management of human resources for college teachers [8]. Zhao et al. pointed out that HRM of college teachers is a systematic project. It not only needs to optimize the internal elements of the system as a whole, but also needs to strengthen the construction of external related systems to jointly improve the level and efficiency of management [9]. Zhou et al. outlined the application conditions of DM technology in HRM in institution of higher learning, the application of DM technology in HRM in institution of higher learning, and the scope of application of DM technology in HRM in institution of higher learning [1]. Shu outlined the meaning of human resources and HRM and analyzed the current situation of human resources and management of teachers in institution of higher learning [11]. Kessler et al. conducted a comparative analysis of the HRM models of Chinese and foreign college teachers and obtained reference and inspiration from them [12]. Haneda and I put forward a series of forward-looking and pragmatic countermeasures and solutions for strengthening the incentive mechanism of human resource development and management of college teachers [13]. Its purpose is to strengthen the management of human resources of college teachers, so as to improve the overall level of the development and management of human resources of college teachers. Sadiq et al. pointed out that due to the improvement in teachers' subject status, the special group of teachers is more suitable for people-oriented management because of their knowledge-based human resources [14]. Cerne et al., based on the relevant theories of harmonious management, put forward the idea of constructing the harmonious management model of human resources for college teachers and pointed out its operation mechanism [15]. Dhar studied the rationality and fairness of salary distribution and its impact on employees; he believes that employees not only care about the absolute amount of their own compensation, but also care about the relationship between their own pay and other' pay [16]. Sandra and Rothenberg established a dynamic programming model based on the big data background to realize the dynamic planning of enterprise human resources and proposed the initial priority table of the intelligent scheduling algorithm [17].

The related literatures are thoroughly examined in this article. Then, DM technology is used to solve the problems of talent type division and performance appraisal system in human resource management in institutions of higher learning, starting with the theory of big data analysis and combining it with the theory of human resource management in institutions of higher learning. This article proposes an innovative mode and decision-making model for managing university teachers' human resources using intelligent big data. This model employs DM technology to analyze and process existing data and forecast future outcomes and provide decision-making support. This study has a lot of practical implications for the practice of intelligent decision-making in university teacher human resource management.

3. Methodology

3.1. HRM System for College Teachers. Human resources refer to the sum total of people with intellectual and physical labor ability who can promote the development of the whole society and economy within a certain range, and it is a group that can exert creative labor on the basis of labor resources [18]. It can also be said that within a certain range, it is the ability of working-age people who have been directly invested in construction and who have not yet invested in construction. Modern management science generally believes that running institution of higher learning well requires four resources: human resources, economic resources, material resources, and information resources. Among these four resources, human resources are the most important. It is the most active factor in production activities and the most important resource among all resources, which is called the first resource by economists. The macro concept of human resources is divided and measured by countries or regions. In the micro sense, the concept is divided and measured by departments, enterprises, and institutions. The most basic aspects of manpower include physical strength and intelligence. Human resource is a special and important resource for social production. Compared with other resources, this kind of resource has its own unique and distinct personality characteristics, including the times, initiative, sociality, creativity with great potential, etc. Compared with other resources, the particularity of human resources lies in the fact that it can only be developed and utilized through an effective incentive mechanism and brings visible economic value to the organization. The increasing income of human resources and its increasing economic role are not only the result of improving the quality of human resources, but also the self-enrichment characteristics of human resources. HRM refers to the use of modern scientific methods to train and allocate human resources reasonably, and at the same time to guide people's thoughts, psychology, and behaviors properly. The HRM system of college teachers constructed in this article is shown in Figure 1.

Human resources in higher education institutions cover a wide range of skills, including the total labor ability of teaching staff engaged in teaching, scientific research, management, and logistics services. The main body is that teachers demonstrate the significant social value that their teaching and educational activities, as well as scientific research and innovation activities, generate [19]. Teachers' human resource management system in higher education institutions considers all human resource management subsystems as a management engineering system. The HRM system for university teachers is built through group management. First and foremost, we must define the overall organizational goals, use these goals as the foundation for college teacher human resource management, and then create a human resource plan. Teachers' human resources refer to the sum of their knowledge, skills, attitudes, experiences, and creative ideas from the perspective of human resources. When compared to the human resources of other organizations, university teachers' human resources are unique. For example: (1) high educational level, (2) pursuing autonomy, (3) unique values, (4) strong desire to learn, and (5) strong willingness to flow. Teachers are the most precious human resources in institution of higher learning, but they are also the difficulties and emphases of human resources development in institution of higher learning. College teachers, in comparison to other human resources, have high subjective initiative, sense of accomplishment, and self-realization needs. The work is distinguished by its creativity and mobility, as well as the difficulty in monitoring and measuring the labor process. As a result, adopting a humanized and democratic management mode for teacher management is even more critical. At this stage, it is necessary to analyze the characteristics of university teachers' special human resource groups, as well as the existing problems with university teachers' human resource management, and to invent a new mode of university teachers' human resource management. The overall evaluation of university teachers' human resource management system is not only the foundation for implementing the talent rejuvenation strategy, but it is also a necessary precondition for improving the quality of university teachers' human resources and HRM efficiency. As a result, in today's environment, research on university teachers' innovative human resource management has both theoretical and practical implications. DM can identify talent patterns and rules within an organization, and thus the talent model. Simultaneously, studying DM methods, extracting valuable information, determining a reasonable human resource structure in accordance with the development goals of institutions of higher learning, and determining talent introduction and training goals are all critical.

3.2. Application of DM Technology. Various industries have accumulated a large amount of data in recent years as a result of the development of information technology, while the database system only provides data management and simple processing functions [20]. People require a method for assisting with these complex data, locating valuable information or knowledge to aid decision-making, and reducing workload. In this case, the DM technology was proposed. DM is the process of extracting hidden information and knowledge from a large number of incomplete, noisy, fuzzy, and random practical application data that people do not know about ahead of time but could be useful. We can automatically acquire useful knowledge from fault data accumulated by human users and expand the knowledge base using DM technology. This knowledge is objective and avoids the generation of accurate knowledge because it is based on the fault data that have occurred. The problem of automatic knowledge acquisition can be solved by combining DM technology and an expert system. One of the main tasks of DM is clustering [21]. Clustering is the process of dividing data objects into subsets so that each subset is a cluster, and the objects in the cluster are similar to each other but the cluster is not similar to the objects in the cluster, that is, the cluster has the maximum similarity within the cluster but the cluster has the least similarity between clusters. The clustering model divides data into different groups which is based on the

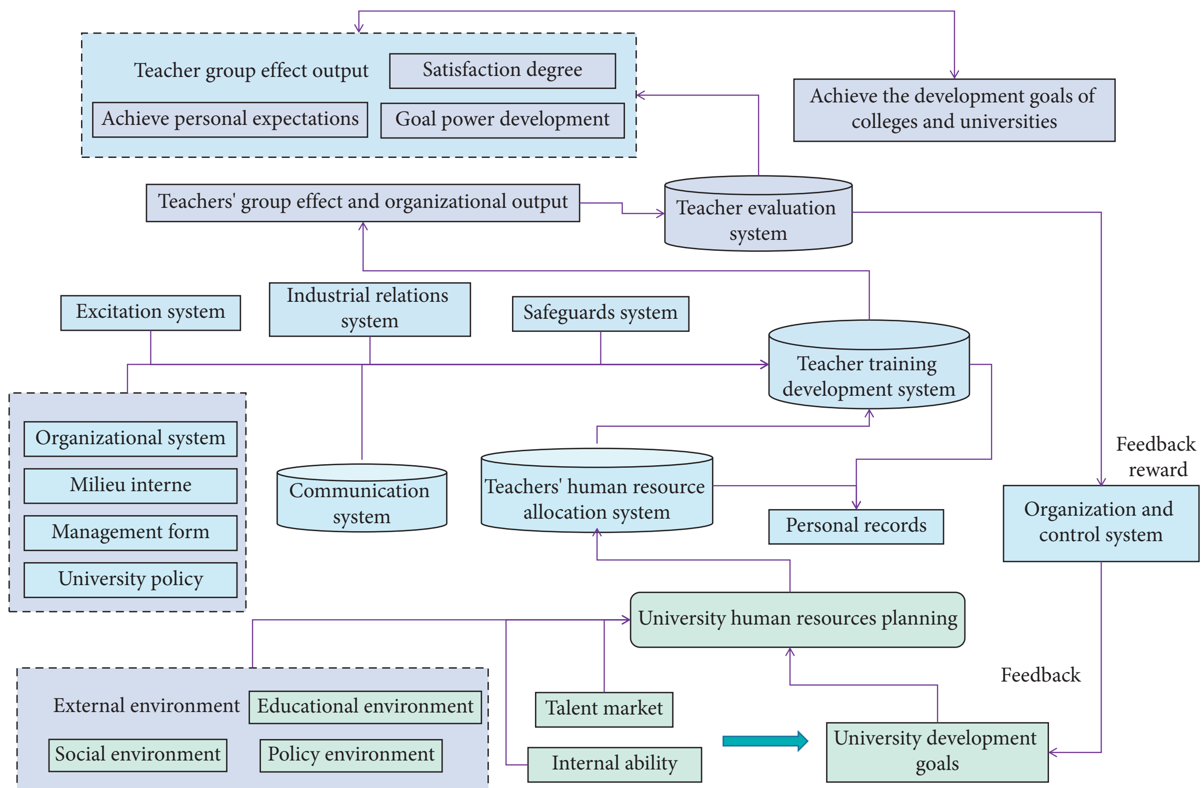

Figure 1: University teachers' human resource management system.

relationship between data content and data. Clustering patterns are highly random and arbitrarily distributed [22]. Association analysis uncovers two types of relationships: frequent itemsets and association rules. The frequent itemsets refer to a group of attributes that frequently appear together at the same time, whereas the association rules imply that the two attributes may have a strong relationship. Students' data are analyzed using DM technology, and a mathematical model is created using a clustering algorithm. The students are then analyzed using the correlation analysis algorithm, and an overall correlation analysis model of students is created. The DM architecture is shown in Figure 2.

To apply DM to this model, the following steps should be followed: (1) Determining the objects and targets of mining and finding out the problems clearly, (2) collecting the data, (3) carrying out the data conversion process, (4) classification and mining of data, (5) analyzing the results of classification rules, and (6) applying knowledge. The mining process is divided into two basic stages: initialization and iteration. The initial data structure is set in the initialization stage, and the decision tree is generated in the iterative process. Data cleaning of data warehouse is similar to data cleaning of DM. If the data have been cleaned when it is imported into data warehouse, it is probably unnecessary to clean it again when doing DM, and all data inconsistencies have been solved. Data extraction is the process of extracting data from the data source database of application system to the target database. Data extraction methods mainly include total extraction and incremental extraction. There are two factors to consider when choosing a mining algorithm. First, data with different properties should use algorithms related to their characteristics, and second, the user's requirements for the discovery results. If the discovered knowledge cannot meet the user's requirements, the whole discovery process needs to be returned to the discovery stage, and data should be re-selected, new data transformation methods should be adopted, new DM parameter values should be set, or even another mining algorithm should be changed. In addition, selecting and analyzing data may be the most important part of DM, even more important than algorithm selection. The reason is that DM is usually not driven by assumptions, but by data. DM can receive data and discover new associations, instead of selecting and testing variables in advance, so DM should obtain as clean data as possible and perform data profiling before trying any models. According to the requirements of DM, we should check the spelling and errors of the extracted data, check and fill the gaps in the data records, and convert the data types, which is called preprocessing.

3.3. Innovative Model of Teacher HRM Based on Big Data Analysis. With the enhancement of informatization in institution of higher learning, institution of higher learning now have a relatively complete information management system, and the basic data of human resource management are sufficient, which can select, preprocess, and convert human resources data and make data preparation for DM. Considering the structure of specific human resources, this article chooses the decision tree of classified knowledge discovery as the DM method. A decision tree is a tree

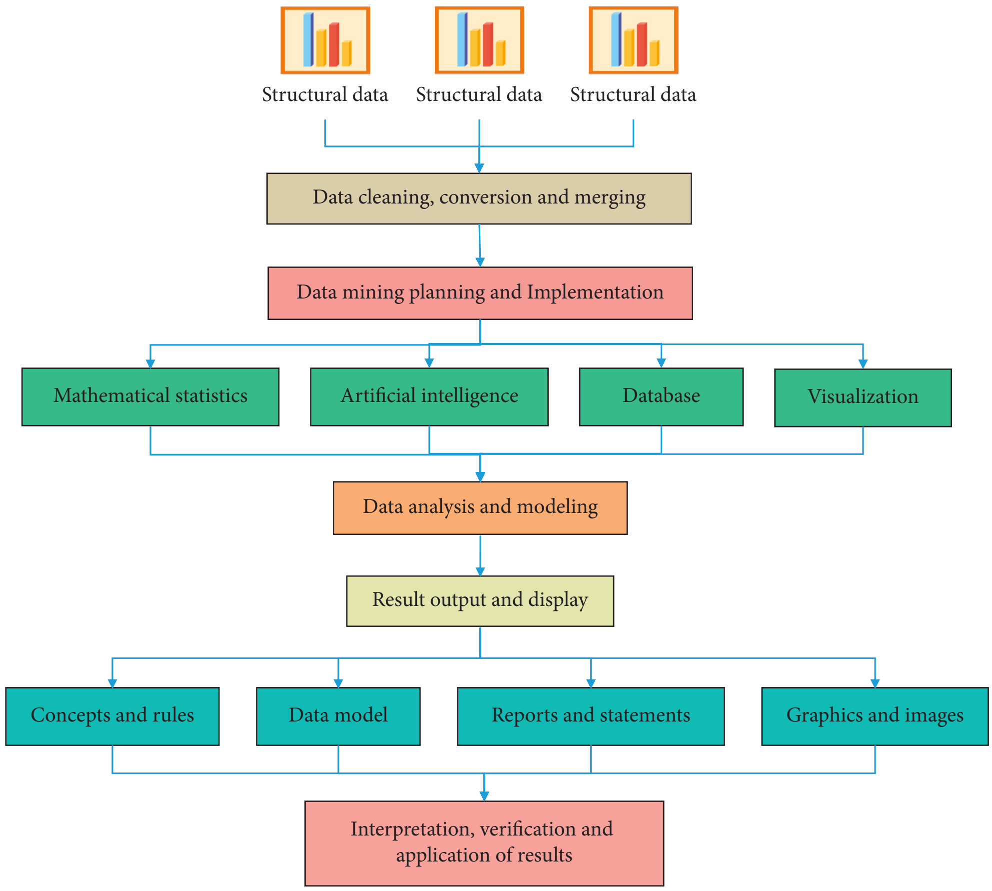

Figure 2: DM architecture.

structure similar to a flowchart, in which each internal node of the tree represents a test of an attribute, its branches represent each result of the test, and each leaf node of the tree represents a category. The top node of the tree is the root node. First, the data source is selected and the database is established. In order to prevent the repetition of data and the inconsistency of calling data, the data source is discretized before calling data, and the specific data are converted into unique letters or numbers. The quality of research data, in preparation for further analysis. And determine the type of mining operation to be performed. Data cleaning refers to the process of finding and correcting identifiable errors in data files, including checking data consistency, dealing with invalid values and missing values, etc. Generally, the principle of data cleaning is the process of reducing the database to eliminate duplicate attributes and converting the format into an acceptable standard format. Establishing a correspondence table between source data and processed data is equivalent to establishing a mapping relationship between them, which ensures that the change of one data will not affect the other, thus realizing the independence of source data and programs.

Assuming that the dataset S contains a set of s data samples, the category attribute can take m different values, corresponding to m different categories, namely:

$$C_i, i \in \{1, 2, 3, \ldots, m\}. \tag{1}$$

Assuming s_i is the number of samples in class C_i, the amount of information required to classify a given data object is

$$I(s_1, s_2, \ldots, s_m) = -\sum_{i=1}^{m} p_i \log(p_i), \tag{2}$$

where p_i is the probability that any data object belongs to category C_i, which can be calculated by s_i/s. The function of log is based on 2, because in information theory, information is encoded in bits.

Let an attribute A take v different $\{a_1, a_2, \ldots, a_v\}$. The set can be divided into v subsets using the attribute A, namely

$$\{S_1, S_2, \ldots, S_v\}, \tag{3}$$

where S_j contains the data samples whose public attribute value of S set is a_j. If the attribute is selected as the test attribute A, let s_{ij} be the number of samples of the attribute C_i category in the subset S_j. Then the information entropy required to divide the current sample set using attribute A can be calculated as follows:

$$E(A) = \sum_{j=1}^{v} \frac{s_{1j} + s_{2j} + \ldots + s_{mj}}{s} I\left(s_{ij}, \ldots, s_{mj}\right), \tag{4}$$

where $s_{1j} + s_{2j} + \ldots + s_{mj}/s$ is taken as the weight of the ith subset. It is divided by the sum of the sample data of attribute A taking a_j in all subsets by the total number of samples in the S set. The smaller the $E(A)$ calculation result, the better the result of its subset division. Assuming that there are n samples in the sample set, n data can be obtained for a certain indicator k of the samples, namely

$$h'_{1k}, h'_{2k}, \ldots, h'_{nk}, \tag{5}$$

where h'_{nk} represents the data obtained by the ith sample for the kth index. Their average is calculated as

$$h^{'}_{\overline{k}} = \frac{\left(h'_{1k}, h'_{2k}, \ldots, h'_{nk}\right)}{n} = \frac{\Sigma h'_{ik}}{n}, \quad k = 1, 2, \ldots, m. \tag{6}$$

The standard deviation of these raw data is as follows:

$$S_k = \sqrt{\frac{\sum_{i=1}^{n}\left(h'_{ik} - h'_{\overline{k}}\right)}{n}}. \tag{7}$$

The normalized value of each data is obtained by the following formula:

$$h''_{ik} = \left|\frac{h'_{ik} - h'_{k}}{S_k}\right|. \tag{8}$$

If the extreme value standardization formula of the obtained standardized data h''_{ik} is not within the closed interval of $[0, 1]$, the following extreme value standardization formula is used:

$$h_{ik} = \frac{h''_{ik} - h''_{\min k}}{h''_{\max k} - h''_{\min k}}, \tag{9}$$

where $h''_{\max k}$ and $h''_{\min k}$ represent the maximum and minimum values in $h''_{1k}, h''_{2k}, \ldots, h''_{nk}$, respectively.

DM technology can extract human resources data from a variety of databases containing information about the working conditions of the organization's employees as well as find connections and patterns among them, objectively reflecting the organization's talent pool. The most frequent set among the generated frequent sets is found and an algorithm is used to determine whether the data have any implicit relationships. Users or machines must evaluate the patterns discovered during the DM stage. Any redundant or irrelevant patterns are removed and returned to the previous stage if the mode cannot meet the user's needs. Re-selecting data, implementing new data transformation methods, adjusting parameter values, and so on are examples of such tasks. In DM, data preparation is a critical step in the knowledge discovery process, accounting for more than half of the workload. It is necessary to preprocess data, especially when DM is performed on data that contain noise, incompleteness, or even inconsistency, in order to improve the quality of DM and, ultimately, the quality of pattern knowledge acquired by DM. This article examines the human resources system's staff information database as well as the staff assessment results database. It has a relational database format, which sorts information attributes that are thought to be closely related to assessment results into data tables and deletes information attributes that are not. In order to figure out a few key variables for the DM process, the qualitative index attributes are calculated. The primary task of the implementation of the HRM plan of university teachers is to equip the organization with personnel and change the internal environment according to the requirements of the organization and then to establish the post responsibilities of all staff in each internal department. Therefore, this article establishes the following subsystems: (1) organization system, (2) incentive system, (3) communication system, (4) management relationship system and guarantee system, and (5) evaluation system. According to this HRM system, all subsystem plans and actions complement each other.

When the state is determined in the human resource scheduling of university teachers, the state transition equation can be used to show the law of this state deduction:

$$x_{p+1} = B_p\left(x_p, w_p\left(x_p\right)\right), p = 1, 2, \ldots n. \tag{10}$$

From the above equation, it is possible to further deduce the indexes that help define the whole stage process and all the back subprocesses. The formula of the index is:

$$Q_{kn}\left(x_p, w_p, \ldots, x_{n+1}\right), p = 1, 2 \ldots n. \tag{11}$$

According to the state transition equation and the formula of the indicator function, in the actual scheduling of human resources, the decision set x_p can be determined by the characteristics of the state variable x_p and the decision variable $W_n(x_n)$ itself, and then substituted into the state transition of equation (10). Suppose a real-time computing task requests R, then the sequence is

$$R = \left(e_i^{\text{born}}, e_i^{\text{wait}}, e_i^{\text{dead}}, y_i\right), \tag{12}$$

where i represents the real-time task number waiting to be executed, e_i^{born} represents the generation time of the real-time task, and e_i^{wait} represents the maximum waiting time when the task is queued for execution. This value is determined by the number of institution of higher learning, business volume, etc. Whereas e_i^{dead} stands for task deadline and y_i stands for the initial priority of the task. The smaller the value, the higher the initial priority of the task. When the current time is assumed to be s, then the relative deadline a_i of the real-time task satisfies:

$$a_i = e_i^{\text{dead}} - s. \tag{13}$$

From this, it can be calculated that the relative deadline a_i of a real-time task will gradually decrease over time, which means that its task priority will increase with time.

The association rule generation module's main task is to extract strong association rules from frequently occurring sets with the least amount of support and confidence. Because the association rules to be mined are strong association rules, and because the rules are generated by frequent itemsets, each rule meets the minimum support degree automatically, so generating association rules for frequent itemsets only requires meeting the confidence level. The decision tree induction algorithm calculates each attribute's information gain and chooses the attribute with the highest information gain as the test attribute of a given set, resulting in the branch nodes. The corresponding attributes are marked on the generated nodes, and corresponding branches of the decision tree are generated based on different values of this attribute, with each branch representing a partitioned sample subset. The generated selection tree can be used to define a rule set. A rule set is made up of a number of rules, each of which corresponds to a different path in the selection tree, which represents a link chevalier. The abstract preprocessing, frequent set mining, algorithm execution, and association rule generation processes are all intuitively displayed on the page in this article via FLASH animation. When that user enters the degree of trust and the degree of support, the text expression that corresponds to the generated strong regular formula is displayed, making it easy for the user to understand and analyze the relationship between the attribute fields.

4. Result Analysis and Discussion

This article studies the application of intelligent big data analysis in college teachers' human resource management, mainly using DM to solve problems in human resource management and innovating college teachers' human resource model and decision-making model. In this article, HRM is quoted from the market concept, and the management function of the HRM department in institution of higher learning is given by the internal faculty of institution of higher learning. In order to verify the feasibility of the innovative model and decision-making model of human resource management of university teachers designed and constructed in this article, this chapter conducts simulation experiments to test the performance of the model in all aspects. First, the feature selection of the five-fold cross data of the model in this article is carried out, and the experimental results are shown in Table 1.

Table 1: Feature subset selected by quintuple cross data.

Dataset	Feature subset
Train1	4, 6, 8, 9, 11, 13, 15, 21, 26, 28
Train2	5, 6, 8, 9, 11, 13, 15, 18, 26, 28
Train3	4, 5, 6, 8, 9, 11, 13, 15, 26, 28
Train4	4, 6, 8, 9, 11, 13, 15, 16, 19, 26, 28
Train5	4, 5, 6, 8, 9, 11, 13, 15, 26, 28

First of all, the data should be selected, all the internal and external data information related to the HRM issues is searched, the data suitable for DM applications are selected, then the data are preprocessed, and, finally, the data are converted into an analysis model. This analysis model is built for mining algorithm. The purpose of using decision tree to classify teachers' resources is to dig out potential turnover among teachers in the management office. Then, some measures should be taken to retain some potential important teachers, so as to reduce the losses of institution of higher learning and form a stable group of teachers. To verify the performance of this algorithm, three indexes, namely recall rate, average absolute error, and F1 value, are selected for testing, and the obtained result is compared with different algorithms. The result of the recall rate is shown in Figure 3. The mean square error comparison results are shown in Figure 4. The comparison results of F1 values are shown in Figure 5.

As can be seen from the data in Figure 3, the recall rate of this algorithm has certain advantages in comparison of the recall rates of different algorithms. Its recall rate is better. As can be seen from the data in Figure 4, with the increase of iteration index, the error of each algorithm becomes smaller and smaller. However, the error of this algorithm decreases faster and its error value is lower. From the data in Figure 5, it can be seen that the F1 value of this method is always at a high level in the comparison of F1 values of different algorithms. Generally speaking, the performance of this algorithm is better. It has certain accuracy and reliability.

In order to make the algorithm in this article more in line with the needs of human resource management of university teachers in the current era, we should give full consideration to innovating the scheduling decision algorithm of the platform and summarize the advantages and disadvantages of the algorithms that have been put into application before. Comparing the running time of different algorithms, the results are shown in Figure 6.

It can be seen that compared with the traditional algorithm, the decision algorithm proposed in this article can effectively shorten the time required to fuse and calculate the stage task data. Its operation performance and fusion effect are superior. Performance appraisal is an important task of HRM in institution of higher learning. Other work of HRM needs to be completed based on the results of performance appraisal. Therefore, the use of quantitative analysis methods to evaluate the performance appraisal system is of great significance for the effective implementation of performance appraisal. This article analyzes from two aspects: the correlation analysis between the assessment index variables, and the correlation analysis between the original index variables and the assessment index variables. Table 2 shows the teacher metrics chosen in this article.

In order to verify the feasibility of the innovative model and decision-making model of teacher human resource management constructed in this article, we make an experimental analysis of the decision-making accuracy of this model. The results obtained are compared with other models. The decision accuracy of different models is shown in Figure 7.

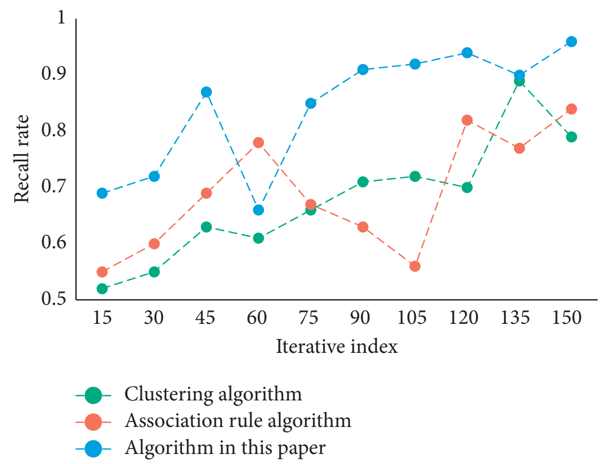

Figure 3: Recall results of different algorithms.

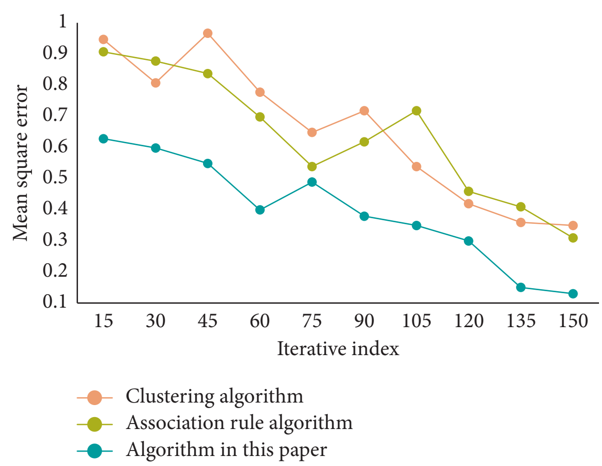

Figure 4: Comparison of mean square error of different algorithms.

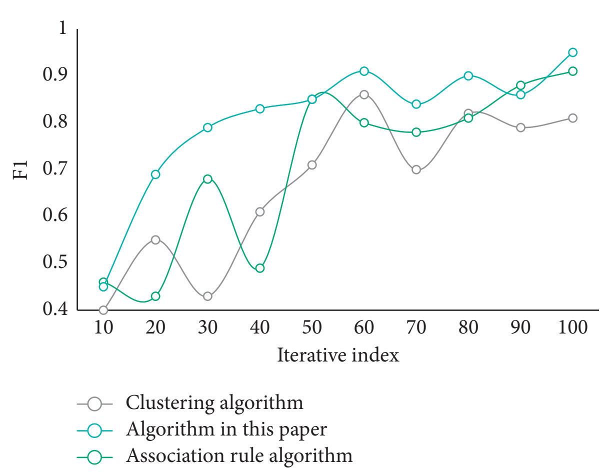

Figure 5: Comparison of F1 results of different algorithms.

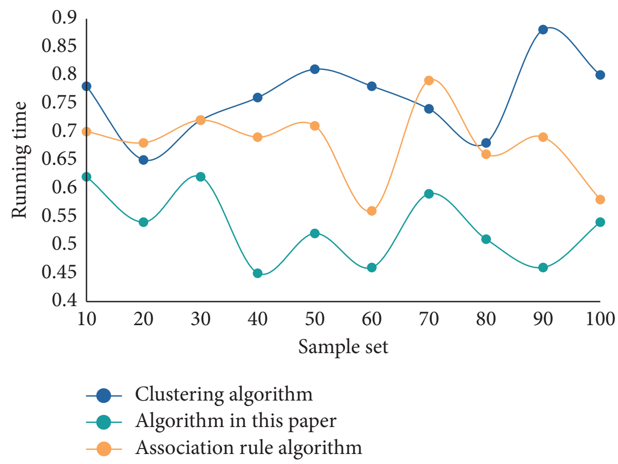

Figure 6: Time-consuming running of different algorithms.

Table 2: Selected teacher indicators.

Program	Knowledge level	Teaching skills	Teaching quality	Teaching effect
Teacher 1	4	3	3	3
Teacher 2	2	3.5	5	2
Teacher 3	3	3	5	4
Teacher 4	5	4	4	4
Teacher 5	4	4	3	3
Teacher 6	6	3	3	3
Teacher 7	5	3.5	2	2
Teacher 8	4	2	3	2
Teacher 9	5	2.5	4	3
Teacher 10	3	4	5	4

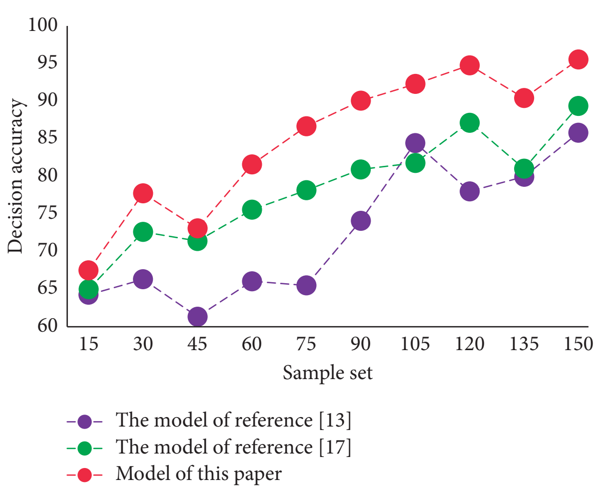

Figure 7: Decision accuracy results of different models.

According to the data analysis in the figure, compared with the other two decision-making models, the decision-making accuracy of the teacher HRM decision-making model in this article is the highest. It has certain decision-making effectiveness and accuracy. In this chapter, several simulation experiments were conducted to verify the performance of the innovative model and decision-making model of university teachers' human resource management based on intelligent big data. Experimental results show that the accuracy of the system can reach 95.68%, which is about 10.02% higher than other systems. From the test results, this system performs well, is feasible, and has excellent systematic performance.

5. Conclusions

Human resources, in comparison to other economic resources, have a distinct purpose, subjective initiative, and unique creativity. Traditional human resource management modes and information acquisition methods limit the development of human resource management in higher education institutions. In light of the growing drawbacks of traditional HRM, this article investigates various issues in HRM in higher education institutions using intelligent big data analysis technology and related HRM and DM theories. This article develops and implements an innovative mode and decision-making model for university teachers' human resource management. This system employs DM technology to analyze and process existing data and forecast future events and provide decision-making support. The outcome of the experiment is in line with the hypothesis. This model has a decision-making accuracy of 95.68%, which is 10.02% higher than other systems. This system can significantly reduce the workload of intelligent scheduling of university teachers' human resources based on big data analysis as well as the time it takes to fuse and calculate stage task data. It is feasible and practicable in some ways. This research has yielded some results, but due to my limited knowledge and research time, there are still some areas that could be improved. The model structure will be improved in future work, as will the model performance, and a quantitative analysis scheme will be proposed to solve the HRM problems of university teachers.

The factors that influence how people play mobile games have been studied from a variety of perspectives in the wireless broadband environment. The original data in the background of the game, such as user operation records, consumption records, and social behavior records, are converted into user attributes, user tags are generated, and data sets are constructed in this study, which primarily uses data mining technology to study user behavior and form user portraits. By incorporating the similarity of players' subspace interests into the CFR (collaborative filtering recommendation) algorithm, a personalized game recommendation model, as well as the relationship management level of mobile game players, is created. The final fusion model's ROC-AUC value is 0.921, which has a percentile enhancement effect, according to the results. The findings show that using a personalized game recommendation model can help to improve the scalability of the CFR algorithm and the impact of data scarcity on the quality of mobile games recommended by players.

1. Introduction

People are increasingly using mobile devices as smartphones become more affordable and mobile data networks improve. Mobile games are a popular leisure activity due to their convenience, portability, and low cost. In the domestic game market, the rate of growth of game users has slowed, and users are showing signs of saturation. The cost of acquiring traffic for game companies is continuing to rise against the backdrop of wireless broadband, but the resulting increase in revenue is unlikely to be proportional. The popularity of smartphones, combined with the ongoing enrichment of mobile game content, has greatly increased users' interest in and experience with mobile games. Mobile games will become a high-growth business sector of the mobile Internet in the future. Measuring and evaluating the quality of the user experience are critical. Displaying abstract user experience in a user-friendly manner can directly reflect the benefits and drawbacks of products, which is useful for product improvement.

With the development of wireless broadband, the scale of mobile Internet is constantly expanding, and the users of mobile game industry are growing rapidly. Ma et al. proposed that the experience economy is being separated from the service economy to provide users with unique experiences. Experience transcends service because it realizes users' self-realization and is free [1]. Brand et al. put forward three quantification methods, namely behavior-centered quantification method, experience-centered quantification method, and task-centered quantification method [2]. Narudin et al. put forward that user experience is the user's experience of brand information, functionality, information availability, and content [3]. Yamamoto proposed that the user experience should include the environment used, the user's perception, and expectation [4]. Jeon et al. expounded the development status of mobile games [5], analyzed the characteristics of mobile games, such as portability, diversified game modes, and rich social interaction, and looked forward to the future development of mobile games. The loss of users can be divided into two situations: one is the lost users, who completely stop trading with the enterprise; the other is potential churn users, who tend to churn but are not completely cut off from the enterprise, but their purchase frequency has decreased, and they will go to their competitors to buy similar products or services.

Mobile games combine the benefits of mobile Internet with game entertainment. This study examines users' willingness to play mobile games and the factors that influence their willingness to play mobile games from the user's perspective using empirical research. A general model of mobile game users' willingness to use is constructed through literature reading and summarization, in combination with the technology acceptance model, opinion leader theory, and related theories, and combined with innovation and communication. Not only will this allow mobile game manufacturers and other content providers to improve their products on a continuous basis, but it will also encourage game operators, game platforms, and other service providers in the game industry chain to do so. More importantly, they have improved the game industry's service level and promoted the industry's development and progress. Innovations in research are as follows: (1) the factors influencing the variables are further explored, and a general model of mobile game users' willingness to use is established, by combining innovative variables such as endogenous value, perceived compatibility, and perceived ease of use. (2) This study divides the item set into several subspaces based on fuzzy clustering based on player behavior situation, considers the proportion of players' common game scores in each scoring scale, and introduces the similarity of players' interest differences in subspaces to improve the calculation of player similarity.

The organizational structure of this study is as follows: the first section introduces the research background and significance and then introduces the main work of this study. The second section mainly introduces the related technologies of user behavior analysis. The third section puts forward the specific methods and implementation of this research. The fourth section verifies the superiority and feasibility of this research model. The fifth section is the summary of the full text.

2. Related Work

2.1. Research on Mobile Games. The mobile game industry began to develop rapidly, and the number of users increased exponentially. Many mobile game manufacturers have emerged, and mobile games are gradually showing their charm. The entertainment, convenience, and universality of mobile games are more in line with the tastes of fashion people. There are three main reasons behind the rapid development of mobile games [6]: first, the rapid development of wireless broadband and hardware technology [7] has provided a good technical guarantee for the upgrading of mobile games, which has strongly stimulated the market demand; secondly, with the development of economy, the pressure of life is increasing, and the lifetime is becoming more and more fragmented. Mobile games can better fill the fragmented time and bring people psychological relaxation. Third, compared with traditional PC games, mobile games have the advantages of high investment, high return rate, short capital return cycle, and more attractive investment.

Fu et al.'s research shows that the cultural industry, as an important part of China's national economy, has made great progress in the past 40 years of reform and opening-up, with its overall scale greatly expanded, high growth rate, strong stages, and large increase of market players [8]. Duarte et al.'s research also shows that with the help of wireless broadband, a large number of new cultural industries, represented by the electronic economy, have begun to grow and develop, putting forward new requirements for national supervision and policy-making [9]. Liu et al. focused on the deep-seated reasons behind the intellectual property fever of mobile games and discussed the formation law and derivative ability of high-quality intellectual property [10]. Bell pointed out that emotional experience captures the psychology of consumers and makes them deeply impressed by the new products they come into contact with and dominate their own behavior [11]. Li and Bhanu put forward the first game evaluation method, referring to the usability evaluation method and the practical experience of game development companies, and divided the game design into three dimensions: game interface, game mechanism, and gameplay [12]. Takano et al. proposed that the game design is based on the user's interactive experience and the game should include immersion, pleasure, operability, and repeated playability [13]. Yang et al. applied immersion theory to the study of intention to use, and it proved to be effective. With the deepening of research, new theories will be introduced continuously, but the research has never been separated from users [14].

2.2. Research on User Behavior Analysis. User preference can be simply understood as the degree, to which a user prefers one thing to another. It is a subjective psychological tendency of users and belongs to the category of psychology. This research has penetrated into the fields of economics and computer science. Li et al. pointed out that user preferences can be simply summarized into two categories: individual preferences and situational preferences. The user's preference model is quantitatively constructed by assigning a certain value to each candidate by using the function [15]. Ye et al. use ontology knowledge to build a complex user preference model based on user text description information [16]. Nowadays, the widely used personalized service system uses the statistical learning method to model user preferences.

For games with a large number of users and complex data attributes, especially online games, data extraction, and utilization are very important. It is a set of behaviors derived from users' psychology. Only through the user's psychology, we can better predict the content of the game mechanism to meet the internal needs and desires, so as to create a successful game. Zhang et al. used a clustering algorithm to segment customers and a genetic algorithm to optimize variables, so as to build a customer lifetime value segmentation model [17]. Sarker et al. respectively selected customer segmentation variables and adjusted variable weights through group decision-making and analytic hierarchy process and then used clustering technology to segment customers of a rubber product manufacturer [18]. Teng and Khong first reduced the dimension of variables, then subdivided four kinds of customers by clustering method, and analyzed the customer characteristics of different subdivided types by the DT (decision tree) method [19]. Zhang et al. used the Bayesian method to calculate the category preference of situational users, and based on context awareness, adopted CFR (collaborative filtering recommendation) algorithm to recommend personalized information to users [20].

3. Methodology

3.1. Research on Mobile Game Users' Preference. Mobile games are mainly provided by mobile devices such as smartphones and tablets. In mobile games, there is no cost to produce virtual goods, so the more virtual goods players buy, the more profits operators will make [3]. In this study, the perceived usefulness of mobile games is defined as the degree, to which users can enhance the game experience by purchasing virtual goods and other consumer behaviors. The quality of service experience is influenced by many factors, such as personal background, environment, and product itself. Different people will have different judgments on the same product. The quantitative evaluation of user experience can better evaluate the service quality of products, and the evaluation results can also be used to improve products.

Game factors include system quality, service quality, game design, and brand image. The quality of the game system represents the stability, usability, and other factors of the game system, which is the key factor to ensure the normal experience of users when using the game. Service quality can guarantee users' use and ensure users feel comfortable and happy in the process of game experience; the performance of skill and effort games depends on the player's physical and mental state and subjective will at that time, while luck itself is the biggest uncertainty in theory, which may or may not have a certain probability. However, in game design, events are often regarded as a set with a specific probability, and the most interesting thing is the difficulty of the task. Mobile games are entertainment value-added services with the purpose of entertainment. People's increasing work, life pressure, and "fragmentation" time increase the demand for entertainment and leisure, so this study puts forward the variable of perceived entertainment.

User preferences do not remain constant over time; they evolve and change. The preferences of users will emerge, develop, and fade over time. It has qualities of immediacy, randomness, and spontaneity, is easily influenced by the user's situation, is elicited by the attraction of the characteristics of things themselves, and is a type of instantaneous feeling. People are gradually realizing that the quality of personalized service is dependent not only on algorithmic development and improvement but also on the quality of user preference models, which has become a research hotspot and direction. The reasonable acquisition and analysis of user data are the main focus of the user demand analysis of mobile games based on problem situations. The personas are modeled using the interview content, and typical users with common characteristics are created, such as goals and behavioral characteristics. The scenario scripts are created according to modeling roles, so as to easily extract and analyze user requirements. The specific process is shown in Figure 1.

If the m-dimensional data set is X, the cluster is divided into k clusters $w_1, \ldots, w_k$, and their centroids are $c_1, \ldots, c_k$; then,

$$c_i = \frac{1}{n} \sum_{x \in w_i} x. \tag{1}$$

Among them, the number of data points in cluster w_i is denoted as i and the number of objects in data set X is denoted as n.

In the above iteration process, the square error criterion is adopted to judge whether the iteration is finished or not, as shown in the following formula:

$$E = \sum_{i}^{k} \sum_{p \in c_i} \left| p - c_i \right|^2, \tag{2}$$

where p is a point in space, representing a given object.

This study simply divides user preferences into positive preferences and negative preferences. At this point, the problem of user preference extraction can be simply understood as a common binary classification problem in machine learning. The SVM (support vector machine) algorithm has a good classification effect when the number of samples is small. Based on the kernel function technique, it can handle nonlinear separable problems well, has strong generalization ability, and can handle high-dimensional data well. XGBoost, like DT, draws on the idea of boosting algorithm. The former has made some improvements on the latter algorithm, and its performance is better. The overall principle of the algorithm is shown in Figure 2.

SVM, RF (random forest), DT, and XGBoost are selected as the basic user preference extraction models. Based on the parameter optimization of single-model user preference extraction methods, the stacking integrated learning framework is used to model the extraction of individual user preferences fusion. The weights of single-model user preference extraction models are obtained through the training of logistic regression method, and the final user preference extraction method is obtained according to the combination of weights.

Logistic regression is a classification model [18], which is expressed by conditional probability $P(Y|X)$ and formalized as a parameterized logistic distribution. The value of random variable X is a real number; that is, the user preference characteristics extracted from each single model, and the value of random variable Y is 1 or 0, that is, the positive and negative preferences of users.

Binomial logistic regression is the following conditional probability distribution:

$$P(Y = 1|X) = \frac{\exp(w \cdot x + b)}{1 + \exp(w \cdot x + b)}, \tag{3}$$

$$P(Y = 0|X) = \frac{1}{1 + \exp(w \cdot x + b)}. \tag{4}$$

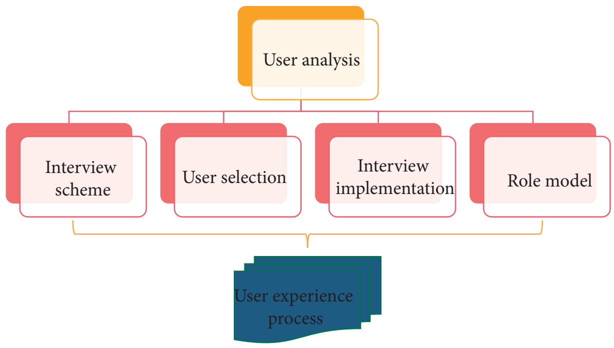

Figure 1: User experience process of mobile game.

By comparing the two conditional probabilities of users' positive and negative preferences, it classifies users' preferences into the one with higher probability. It can be obtained from the above two formulas:

$$\log \frac{P(Y=1\mid X)}{1-P(Y=1|X)} = w\cdot x + b. \tag{5}$$

That is to say, in the logistic regression model, the logarithmic probability of positive preference of output $Y=1$ users is a linear function of input x. The closer the obtained linear function value is to positive infinity, the closer its probability value is to linear function value, the closer it is to negative infinity, and the closer it is to zero.

We set the probability of user loss leave = T as p and the probability of nonloss as q, and then the probability of user loss is α times higher than that of nonloss under different behaviors, which is OR in logistic regression:

$$\log\text{it}(p) = \log(o\,dd\,s) = \log\left(\frac{p}{q}\right). \tag{6}$$

The log here is equivalent to ln at the base of e. Logistic regression is actually an ordinary regression process using logical functions, so

$$\log\text{it}(p) = \log(o\,dd\,s) = \log\left(\frac{p}{q}\right) = a + bX, \tag{7}$$

X is a variable, b is a coefficient, and p is the probability of Class = true, which means the coefficient of logistic regression is defined in terms of log ($odds$)interm of $\log(o\ dd\ s)$ [14].

3.2. Construction of Personalized Recommendation Model for Mobile Games. The utility derived from the perceived quality and expected performance of mobile game services is known as quality. The ability to play games on the go is a key feature of mobile game services. It means that users can play mobile games at any time and have complete control over the amount of time they spend playing [4]. Many gamers use video games as a time-consuming stress reliever. This means that the convenience of mobile games as a form of entertainment that is not constrained by time or space has a significant impact on player usage. The difficulty and complexity of users will increase as each link in the process becomes more complex. As a result, in order to measure the perception of global users, this study combines many practical features of the mobile game business in its analysis of perception and usability.

Quality of the system, information, service, game content design, brand image, and other factors all have an impact on game users' participation behavior. Satisfaction is a user's assessment of a product or service's ability to meet their own needs, and it has a positive impact on consumers' purchase intent. Opinion leaders are now inextricably linked to mobile game online marketing. The choices of friends around them will be influenced by the opinions of a group of leaders who are willing to try and spread new games. We can find the influence of opinion leaders in the field of games and the radiation of people through the investigation. In the investigation of this study, enabling factors are expanded into social driving factors according to individual wishes and purposes, such as the promotion of games and a series of marketing strategies adopted by operators. For mobile value-added services, enabling factors are an important means to transform potential users into actual users. Rich data insights can bring higher dimensional data features. When the amount of data is large enough, even if a relatively simple algorithm is selected, better performance can be obtained. In addition, entertainment is the main purpose for users to use mobile games. The greater the entertainment of mobile games, the easier it is to achieve its purpose. Therefore, this study believes that perceived entertainment affects perceived usefulness. The research model of this work is put forward, as shown in Figure 3.

Because these behavioral context attributes of mobile gamers have a certain correlation, this study uses the transitive closure grouping method based on fuzzy equivalence relation to group players. In this study, the ratio of the difference between the number of clusters before and after and the difference between the two clustering thresholds is used as an index to evaluate the clustering quality. The index for evaluating the clustering quality is shown in the following formula:

$$\Delta\delta_i = \frac{K_i - K_{i+1}}{\lambda_i - \lambda_{i+1}}, \tag{8}$$

K_i represents the number of clusters for the ith time and λ_i is the clustering threshold for the ith time. When the threshold value of the jth clustering is the maximum value of all clusters and the ratio is the minimum value of all clusters, as shown in the following formula, λ_j is the best threshold value:

$$\begin{cases} \lambda_j &= \max(\lambda_i) \\ \Delta\delta_j &= \min(\delta_i). \end{cases} \tag{9}$$

This work thinks that the evaluation of the surprise degree of recommendation system should be based on the similarity with users' long-term preferences and the quality of the game itself. As time goes by, preferences are gradually forgotten, and users tend to get a higher degree of surprise. Surprise evaluation of the recommendation results of the whole recommendation system can be expressed as follows:

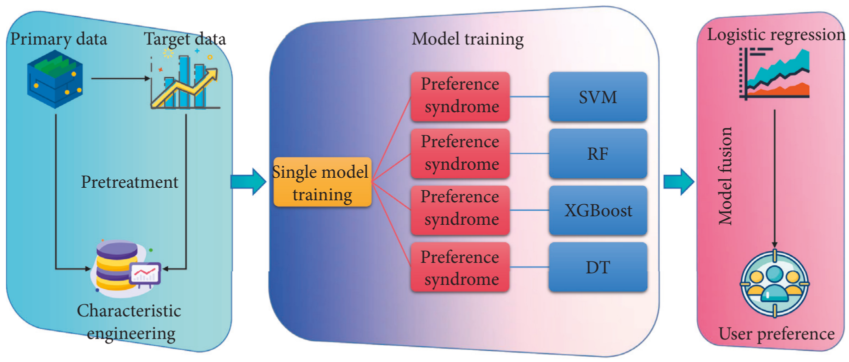

Figure 2: Principle block diagram of the user preference extraction algorithm based on multimodel fusion.

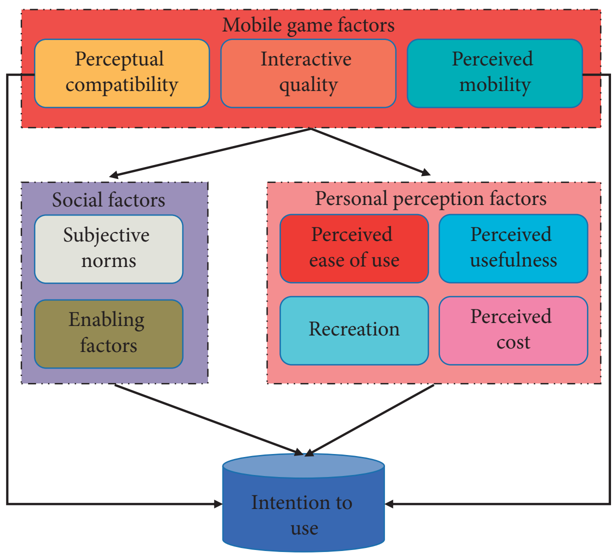

Figure 3: Model of influencing factors of mobile game use intention.

$$S_{\text{top}-K} = \frac{1}{K}\sum_{k=1}^{K} S_{i,K}, \tag{10}$$

where K represents the length of the whole recommendation list.

The main process of personalized game recommendation for mobile gamers is as follows:

(1) Audit the sample, select the sample player that meets the requirements, eliminate the users with missing or abnormal attribute values, and finally determine the sample users.

(2) Calculate the player's interest and fill it into the scoring matrix.

(3) The behavior and situational factors of mobile gamers are eliminated, and the original data format is clustered by transitive closure based on fuzzy equivalence relation.

(4) In these subspaces, the player game score matrix of the category of the target player is generated. Then, through the improved subspace player similarity calculation formula, the similarity between the target player and all players in the same class is obtained.

(5) Get the final player's predicted score value for the unrated game, and recommend the top N games with the highest score to the target player.

The personalized game recommendation process is shown in Figure 4.

4. Experiment and Results

The mobile game user acceptance model studied in this study has six variables, namely, convenience, ease of use, perceived pleasure, social needs, attitude, and willingness to use. Through the relevant statistical analysis of each model variable, the test results of mobile gamers' acceptance model of combined samples are obtained, as listed in Table 1.

H1–H5, respectively, indicate that convenience has a positive impact on the attitude of using mobile games; ease-of-use has a positive impact on the attitude of using mobile games; perceived fun has a positive impact on the attitude of using mobile games; social needs have a positive impact on the willingness to use mobile games.

As can be seen from Table 1, the P value of convenience reaches a significant level of 0.001, and the path coefficient is 0.263, indicating that convenience has a significant positive impact on the attitude of mobile gamers. When players choose mobile games, the convenience of mobile games improves their attitude towards mobile games. The P value of social demand reached a significant level of 0.05, and the path coefficient was 0.136, indicating that social demand can have a significant positive impact on mobile gamers' willingness to use. When players choose mobile games, mobile games that meet their social needs will increase their willingness to use mobile games. In the test results, ease of use has a significant negative impact on players' attitudes, but the coefficient is relatively small and the degree of impact is not high.

In this study, SPSS statistical software is used to analyze 180 sample data and 25 categories of mobile game user experience. For KMO and Bartlett tests, the value of KMO test is 0.933, indicating that it is very suitable for factor analysis, while the significance of Bartlett test is 0.000,

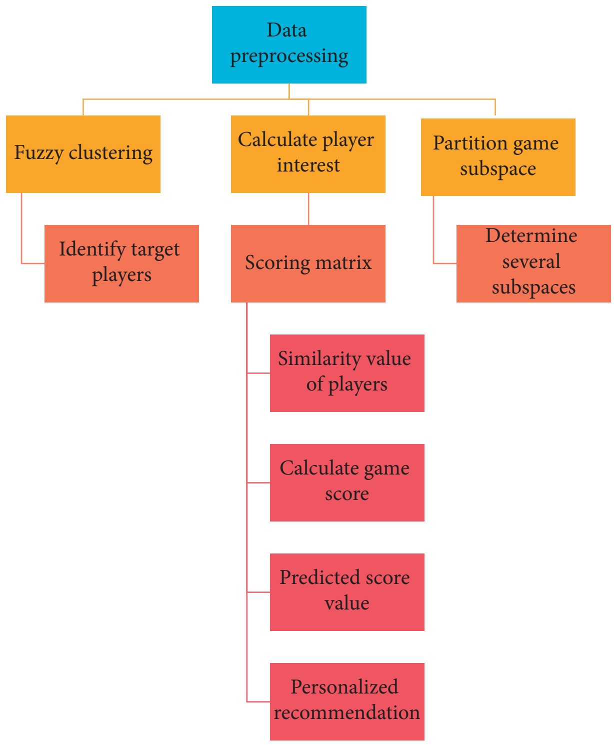

Figure 4: Personalized recommendation process of mobile games.

Table 1: Hypothesis test result.

Hypothesis	Standardized path coefficient	Test result
H1	0.263	Support
H2	−0.096	Refuse
H3	0.913	Support
H4	0.245	Support
H5	0.136	Support

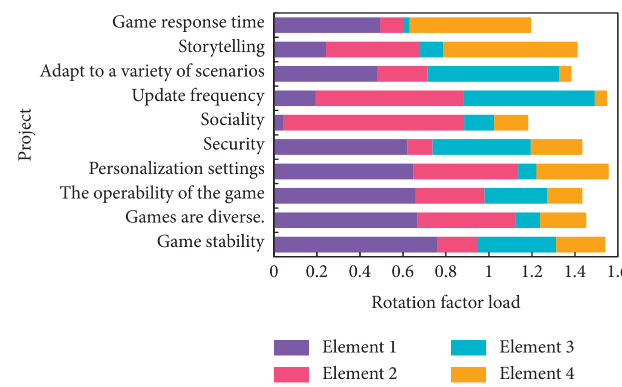

Figure 5: Rotating component matrix.

which has reached a significant level, indicating that the data come from a normal distribution and can be further analyzed. The result of rotating the component array is shown in Figure 5.

It can be seen that the effect of extracting the main factors is that the characteristic value of the first factor is particularly high, which contributes more to the interpretation of the original variables, and the factors that tend to be flat can be eliminated. Among the above assumptions, this study assumes that perceived compatibility, perceived mobility, subjective norms, enabling factors, perceived usefulness, perceived ease of use, and perceived entertainment have a positive impact on intention to use, while perceived cost has a negative impact on intention to use. The relevant analysis results are listed in Table 2.

Perceived compatibility, perceived mobility, subjective norms, causes, perceived usefulness, perceived ease of use, perceived entertainment, and perceived cost are all significantly positively correlated with the intention to use. The original hypothesis is accepted because it is negatively related to the clear intention of use. When making predictions, most students will generate a continuous truth value or probability value for the test sample and compare it to a given threshold. It is considered a positive example if the value exceeds the threshold; it is considered a negative example if the value falls below the threshold. Generally, the generalization performance of the classifier is measured by the area under the ROC (receiver operating characteristic) curve, namely, AUC (area under the curve). In this study, ROC-AUC is used as a standard to evaluate the experimental performance, as shown in Figure 6.

Among them, the user preference extraction results of SVM, RF, XGBoost, and DT in the ROC-AUC evaluation index are 0.501, 0.663, 0.724, and 0.799, respectively. After the stacked models are fused, the ROC-AUC value of the final fused model is 0.921, which has a percentile enhancement effect. In order to further explain the calculation formula of surprise score and its specific meaning and explore the influence of game quality and game similarity and user preference on the surprise score of recommendation system, the following two cases will be discussed. There are 4 games and 5 users in the item rating array, and the default values are filled with hyphens. In order to express the data more intuitively, we plot the data on a line chart, as shown in Figure 7.

It can be seen from Figure 7 that game 1 and game 2 have been scored by user 5, and these scores represent the user's long-term preference information, while game 3 and game 4 have not been scored by user 5. We can not only get the user's preference information but also get the preference similarity information by looking at the trend of the graph. If the line charts of two games have roughly the same trend, then they are similar. That is, the average score of game 4 is higher than that of game 3, which means that the quality of game 4 is higher than that of game 3. This is because when the 3rd and 4th games are the same as the long-term distance of the user 5, game 4 has a higher quality. This case illustrates the importance of game quality in surprise calculation.

To solve the problem that players are "different" due to data sparseness and alleviate the influence of data sparseness on recommendation quality, an improved subspace player similarity calculation method is proposed, which introduces the interest of players in subspace. The improved player similarity calculation method is compared with the traditional method in two different data sparseness. In terms of setting experimental parameters, the balance weight in the

Table 2: Correlation statistics.

Variable	Intention to use	Sig.
Perceptual compatibility	0.566	0.000
Perceptual mobility	0.347	0.000
Subjective norm	0.511	0.000
Contributing factors	0.286	0.000
Perceived ease of use	0.589	0.000
Perceptual entertainment	0.663	0.000
Perceived cost	−0.184	0.001

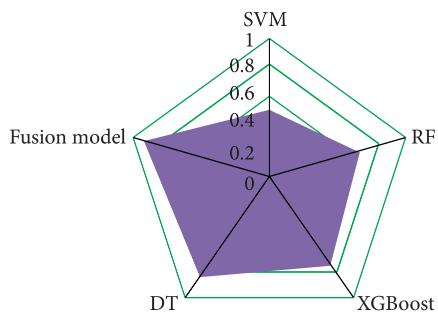

Figure 6: Model performance comparison.

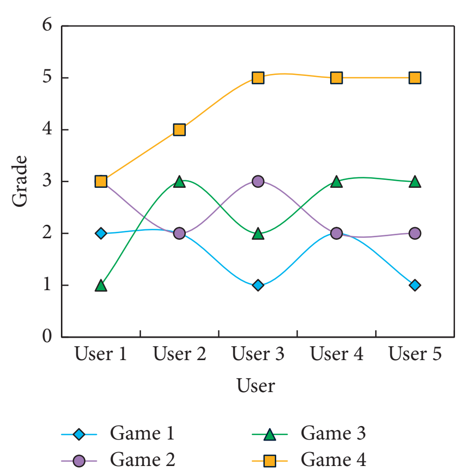

Figure 7: An analysis case of the influence of shadow quality on surprise.

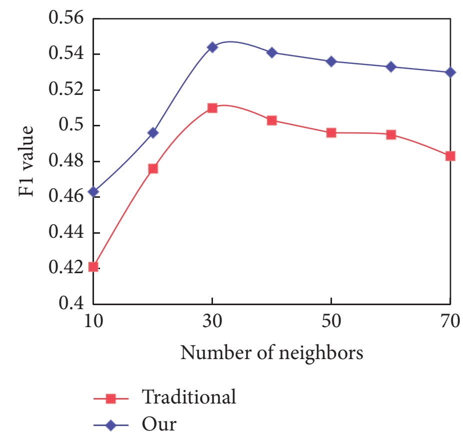

Figure 8: Performance comparison of two methods for calculating player similarity in an 80% training set.

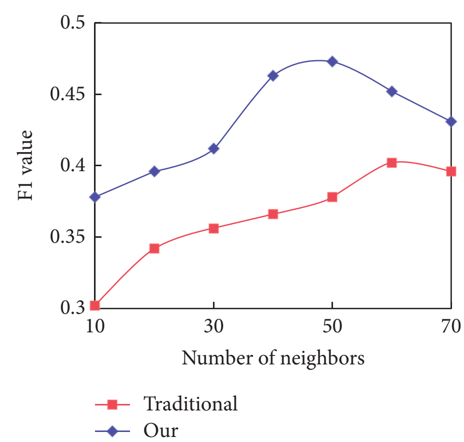

Figure 9: Performance comparison of two methods for calculating player similarity in a 20% training set.

new method of calculating player similarity is 0.8, and the weight of each subspace is equal. The number of adjacent players is selected from 10 to 70, and the recommended number of games is 15. The experimental results are shown in Figures 8 and 9, respectively.

The new method combining the interest differences in player subspace is slightly better than the traditional method in the 80% training set. With the scarcity of data, the difference of F1 index level between the two methods is increasing. Under the training set of 20%, the level difference of F1 indicators produced by the two methods is more obvious. Therefore, a new method of calculating players' similarity by introducing interest differences into subspace can improve the influence of sparse data on CFR quality to some extent by overcoming the problem of "similarity mismatch."

Through empirical research, it is found that the variable that has the greatest influence on the willingness to use mobile games is the perceived entertainment of games, and entertainment is the highest value attraction point for users to choose to use mobile games. Perceived compatibility, interactivity, and perceived mobility significantly affect the intention of perceived entertainment use. Mobile games should fully consider the different needs of segmented users and design game content according to the entertainment habits and value demands of segmented customer groups. With the accelerated pace of life, people's entertainment time is becoming more and more fragmented, and the demand for light mobile games is increasing. Therefore, game development can balance the two values of entertainment and lightweight and carry out the effective content design.

In the innovation and dissemination of mobile games, light gamers (casual gamers) have less recommendation, less communication, low self-confidence, and their game choices are easily influenced by others, and social channels are easy to reach. Excellent players have rich game experiences, and their game preferences are more consistent in different types of games. Perceived usability and perceived compatibility have limited influence on the reasons why mobile gamers use games, and they are variables that have no significant influence. It shows that the measurement of the above influencing factors is not applicable to mobile games, and mobile game manufacturers need to make other attempts and think about mode planning and promotion.

From the conclusion of the study, it can be found that for mobile game consumers in most areas, whether the game can bring fun or not is the main factor that everyone pays attention to, so it still needs a lot of investment in the future game design. Specifically, mobile games can establish a game community belonging to players in various ways and guide and encourage players to strengthen communication in the community by means of information dissemination, personal status display, and game sharing, so as to gather players with the same preferences. The player's recognition and dependence on the game are enhanced, and the player's sense of identity and participation are enhanced through self-display. At the same time, taking some skillful and complicated operations as the internal design of game level upgrading can not only meet the general users' game experience needs but also produce natural player level differentiation in the game and meet the users' achievement needs.

5. Conclusions

In the wireless broadband environment, this research divides the game factors into three main factors: game design, path dependence, and comparative advantage. Using scenario-based theoretical sampling method to conduct interviews, create task models, and scenario scripts, users' needs are analyzed, and preliminary analysis materials are collected. In the process of applying CFR, it is necessary to flexibly adjust the appropriate similarity weight according to the scarcity of data, so as to achieve the best recommendation quality of the algorithm. Experiments show that the new method of calculating the similarity of subspace players can improve the robustness of the algorithm in the case of sparse data, thus improving the impact of sparse data on the performance of the algorithm. In the future, there will be a large number of small models in the game operation, which are more likely to directly become a part of the game, bringing a better game experience to the end users and a long-term beneficial impact on the future development of the game field.

Retracted: Personalized Teaching Strategy of University Ideology Course Based on Lagrange Neural Network and Big Data Technology

Computational Intelligence and Neuroscience

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Individualized instruction is a type of educational principle. On the one hand, it necessitates the creation of individualized teaching resources, courses, and methods. Students, on the other hand, require a high level of autonomy and the ability to make personalized plans based on their own cognitive characteristics and needs. The big data (BD) era opens up new possibilities for IE (ideological education) work in universities, but it also poses some challenges. IE development will be greatly aided by recognizing opportunities to meet challenges and optimizing and integrating PL (political lesson) resources. The LNN (Lagrange neural network) model has been established. The simulation results show that the LNN network can converge to the optimal solution quickly and effectively and then reconstruct sparse signals. Individualized college PL instruction using LNN and BD technology helps students communicate more effectively and improves the pertinence, immediacy, and positivity of IE.

1. Introduction

Massive data provide great value for people. Contemporary young students can be said to grow up together with the Internet [1, 2], so contemporary youth can be described as real participants and pioneers. The corresponding BD (big data) [3–5] era also has a profound impact on the education of universities. BD has brought profound changes to all fields. Faced with the great transformation power of BD, ideological teachers' way of thinking is bound to change, actively adapt to the requirements of the BD era, keep up with the times to the greatest extent, and make rational use of its advantages and characteristics to improve teaching effect.

Many large-capacity data sets are obtained from many large-scale data sets through intelligent statistical measures [6], and BD capacity exceeds traditional data storage capacity. Large capacity, fast processing speed, high total value, and diverse data types are all characteristics of BD [7]. The research on PL (political lesson) teaching mode innovation is also slightly involved, but the research results on BD's influence on college PL practice teaching are almost blank [8, 9]. As a result, when developing university PL personalization with a BD background, we must fully grasp BD's development opportunity, fully comprehend and grasp the theoretical hotspots and academic frontiers of college students' IE (ideological education) personalization by BD, and perfectly connect academic research results with actual teaching [10]. Universities' ideological staffs should focus on overcoming the dilemma of BD personalized teaching in the BD era, actively creating a variety of personalized teaching conditions.

The construction of teaching systems in research universities has given the teaching quality standard a new meaning and orientation. We should not only reflect the teaching quality standards of research universities in the index system of teaching evaluation but also reflect the teaching ideas of research education through the corresponding evaluation models, methods, and operating mechanisms when assessing classroom teaching quality. Finding new ways to do things has become a top priority. This paper examines the challenges faced by ideological network teaching resources and proposes optimization and integration methods to improve the teaching effect of ideological network teaching, based on the connotation and characteristics of BD.

2. Related Work

Literature [11] pointed out that the development of freshmen's online teaching should give priority to solving the problems of standardization and process, improving the platform of online education and teaching, and realizing the guarantee of infrastructure. Literature [12, 13] points out that with the popularization of online education and teaching in all parts of the country, many problems faced by online education and teaching are gradually exposed. Literature [14, 15] optimizes the current teaching mode by the BD method, provides teachers with information about students' learning behaviors and learning ways, and helps teachers understand the areas that students are good at and interested in. Literature [16] makes a preliminary study on personalized teaching and makes a superficial analysis of the influence of teachers' personalities and other factors on cultivating students from the perspective of establishing personalized consciousness and concept. Literature [17] studies the development process of personalized teaching from the perspective of teachers and puts forward that personalized teaching means that teachers fully integrate their own knowledge, experience, personality, and other factors with teaching activities to form a kind of teaching with unique style, stability, and personal characteristics of teachers. Literature [18] analyzes the personalized teaching mode by using the role theory and points out the premise guarantee and countermeasures of personalized teaching in combination with the opportunities and challenges faced by personalized teaching, so as to promote the teaching reform. Literature [19] holds that a personalized teaching classroom should be characterized by selectivity, daily life, and democracy, in which selectivity is the basic feature of personalized teaching, returning to students' life world is the essence of personalized teaching, and democracy is the premise and guarantee of personalized teaching.

In literature [20], a single-layer feedback neural network based on projection operation is proposed to solve the nonsmooth optimization problem with different objective functions. Literature [21, 22] puts forward a new type of neural network to solve general nonlinear programming problems. Literature [23] proposed a new type of neural network, LNN (Lagrange neural network), to solve nonlinear programming problems. Literature [24] studies the stability and convergence time of LNN in solving optimization problems. However, the objective functions of the optimization problems they solve are only smooth functions, so it is necessary to extend the application and research of this kind of neural network to nonsmooth optimization problems.

To summarize, online learning is attracting an increasing number of students due to its time and space flexibility as well as significant cost savings. With the rise of fragmented learning, customized and personalized online teaching based on BD has become the online teaching platform's development trend, providing a large number of potential users for BD in the development of online teaching, and the combination of BD and online teaching also has promising practices and research prospects.

3. Research Method

3.1. Personalized Instructional Design Based on BD. Personalized teaching is becoming a hot topic in China's educational circles as they try to reform the curriculum and change teaching methods. Because students differ in cognitive ability, cognitive level, and personality, educators should integrate students' personalities and teaching activities, put people first, begin teaching with students' needs, respect students' personalities, and use personalized teaching. Personalized teaching is a type of teaching idea that has three meanings: first, personalized teaching emphasizes the diversification of teaching, and teaching materials, teaching resources, teaching forms, and teaching methods should be rich and colorful; second, personalized teaching is learner-centered, values learners' subjectivity, respects students' individual differences, and meets students' diverse needs; and third, personalized teaching is learner-centered, attaches importance to learners' subjectivity, respects students' individual differences, and meets students' diverse needs.

The data of a learner's entire learning process can be recorded using BD technology. Knowledge points are assigned to every topic and data collected in tests, assignments, and exams. Encourage students to study more effectively and improve the quality of their learning. Various text and video resources can also be pushed to learners to help them internalize and absorb knowledge points. Students' learning motivation and interest are stimulated, and students' innovative, problem-solving, and practical abilities are developed. The implementation process is shown in Figure 1.

Through digital analysis to build a data model and use this resource to get students' psychological feelings during this period. For students who behave abnormally, find the source of the problem through data analysis and guide the wrong ideas in time.

At the same time, abundant IE resources and various forms of IE models provide students with a comprehensive platform for learning, which can satisfy students' personality styles and learning initiatives. Therefore, study in an online classroom or use WeChat to brainstorm and learn. In short, college PL teachers should comply with the development requirements of the BD era, further use BD to find favorable resources and information to master the IE initiative, and enrich and adjust teaching content with dynamic data. Before entering the course, connect and arrange the learning contents according to the key points and subkey points; at the same time, arrange your own learning time, which time period to learn what content, and when to conduct self-evaluation; and constantly revise your personal plan in combination with teachers' teaching.

On the one hand, independent assessment has no bearing on the teaching process. Only in an environment where teaching quality is highly valued and pursued can the evaluation result information be considered an integral part of school decision-making, and it is this information that the school administrators use. On the other hand, schools' value choice in using teaching evaluation results should be based

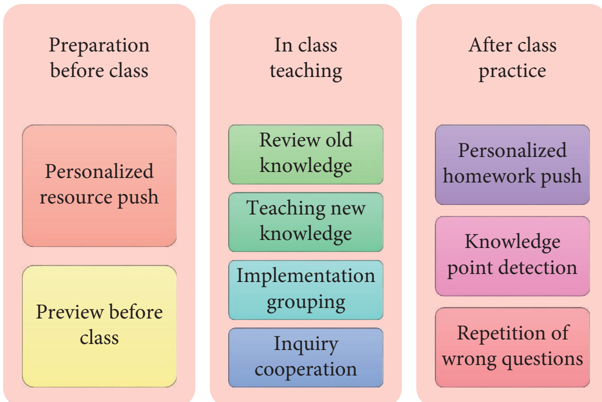

FIGURE 1: Implementation flow chart.

on improving teachers' teaching ability, promoting teachers' development, then promoting students' development, fully mobilizing teachers' enthusiasm, and stimulating teachers' potential so that both teachers and students can benefit from teaching evaluation and so that teaching evaluation can be widely recognized and continuously promote the improvement of both teachers and students.

The penalty coefficient of LNN is variable, and the neural network can still converge to the optimal solution of the optimization problem without calculating the initial value of the penalty term in advance. A neural network model of differential inclusion is established to solve the optimization problem. The similarity calculation formula of the two nodes is

$$\mathrm{sim}(U,U') = \sum_{i=1}^{n} w_j \cdot \mathrm{sim}P(U,U')_i, \tag{1}$$

where $\mathrm{sim}P_i(U,U')$ represents the similarity between node U and CN U' and w_j represents the weight value of this attribute in the i-th attribute.

$MAXL$ represents the length of the longest path in the tree and $P(a_1,a_2)$ represents the distance between nodes. Therefore, the similarity calculation formula is:

$$\mathrm{sim}_{cp} = (cp_1,cp_2) = \frac{MAXL - |p(cp_1,cp_2)|}{MAXL}. \tag{2}$$

Teachers can assign different difficulty problems to students at different levels in class, which meets the individualized needs of students at each level, increases teaching efficiency, and truly realizes individualized teaching. Teachers can also gather students with problems in the same knowledge point based on the correct or incorrect situation of knowledge points and provide targeted explanations and training to help students improve and progress quickly. To help students master the content related to knowledge points, focus on synchronous or asynchronous explanations of common problems. Students can have individualized communication for personality issues. The explanation methods for students vary according to different knowledge points, which can promote the development of students' personalities and allow questions to be solved and answered at any time.

Personalized teaching based on BD can collect all of the students' data automatically; manage all types of learning materials digitally, such as students' homework, pictures, grades, and teachers' comments; track and record students' learning behaviors with BD technology; provide adaptive learning feedback; and provide students with personalized learning guidance. It is more convenient for students to think and reflect, objectively promote students' progress, and make students more active in self-evaluation by collecting and managing their entire process data.

3.2. Probe into the Personalized Teaching Path of University PL Based on LNN. Introducing the thinking mode of planning into college IE teaching based on BD is to break through the fixed thinking mode, with new eyes, new viewpoints, and new methods, from the establishment of the thinking mode of college IE planning to the implementation of the plan and the realization of the target requirements. Under the influence of BD, the way of IE in traditional mode has undergone great changes.

One is to accurately judge the resources of ideological network teaching, that is, the selected teaching resources can be authentic, effective, and reliable enough. The second is to find the best resources from massive IE resources, so as to ensure the best teaching effect. Of course, on the basis of the principle of scientific construction, should reach a certain degree of adaptability, specifically, the selected materials can adapt to students' physical and mental characteristics and knowledge structure characteristics. This work should also pay attention to two points: one is to choose the teaching resources that fit the students' actual network, and the other is to seriously explore the students' concerns and interests and find out the places where students have insufficient knowledge to enhance the pertinence of the teaching process.

The goal of this paper is to design a neural network so that its equilibrium point can meet the optimal conditions. In order to explain the neural network model, firstly, a Lagrangian-like function is defined as follows:

$$L(x,\lambda) = f(x) + \lambda H(x). \tag{3}$$

in which Lagrange multiplier $\lambda > 0$.

$$H(x) = \begin{cases} 0, & x \in S, \\ \sum\limits_{j\in I^{+}(x)} h_j(x), & x \notin S. \end{cases} \tag{4}$$

Find the $L_1(x,\lambda)$-square x-guide number of the Lagrange function:

$$\nabla_x L(x,\lambda) = \partial f(x) + \lambda^T \nabla h(x). \tag{5}$$

According to the gradient descent, the following neural network can be constructed:

$$\left.\begin{aligned}\frac{\mathrm{d}x}{\mathrm{d}t} &= -\nabla_x E = -\nabla_x f(x) - \lambda A - \mu A^T (Ax - b)\\ \frac{\mathrm{d}\lambda}{\mathrm{d}t} &= \nabla_\lambda E = Ax - b\end{aligned}\right\}. \tag{6}$$

Because the operator $\|\cdot\|_0$ is not differentiable, the function $f(x_i) \approx x_i^2/x_i^2 + \sigma$ is considered to approximate $\|x\|_0$. The smaller σ is, the more accurate the approximation effect is, that is:

$$\|x\|_0 \approx f(x) = \sum_{i=1}^{n} f(x_i) = \sum_{i=1}^{n} \frac{x_i^2}{x_i^2 + \sigma}. \tag{7}$$

Differentiated assessment is possible thanks to the teaching cloud platform's ability to personalize curriculum assessment strategies for different classes. Most students who major in art or sports, for example, are outgoing and good communicators, but they dislike reading. College PL teachers can focus on content material learning and knowledge consolidation exercises and strive to help students lay a strong theoretical foundation and develop a practical learning attitude, depending on their characteristics. Create more personalized practice plans and improve the methods and forms of practice. Personalized practice schemes can effectively stimulate students' interest in learning, arouse participation in practical activities, and improve their overall creative ability in the relatively relaxed, happy, and free practice process.

Evaluate and judge the similarity between the given user portrait model and the user portrait model in the user portrait database. The user's current learning user portrait is called the main learning user portrait. The user portrait similarity calculation obtains the user portrait similarity by constructing a decision tree and performing node operation. Taking the user attribute elements as an example, the user portrait model tree is constructed, as shown in Figure 2.

Teachers' personalized teaching system is used to watch the completion and accuracy of students' preview self-test questions. Because each test question has different knowledge points, the students' mastery degree is analyzed to understand the overall preview of students. According to the real-time updated ranking of students' preview scores, this paper analyzes the changes in students' grades and the wrong questions of each student, so as to teach students in accordance with their aptitude in the process of teaching.

Cloud engine in BD infrastructure module realizes the management of distributed Hadoop nodes through task scheduling function. Considering that other modules in the system, such as database management module of user portrait, also need to manage the database by task scheduling, asynchronous task transfer is adopted, which also ensures the rapid development and debugging of submodules as shown in Figure 3.

The script is developed in python, which mainly includes two parts, task and task fragment. The task is initialized in the management server by reading the policy file, and the task script and shell script are packaged according to the corresponding configuration in the policy file. After the packaging is completed, it is sent to the proxy service module of the Hadoop node through socket. The proxy service module decompresses the task and shell script, executes the task fragment script, calls the corresponding shell script, completes the task scheduling, and returns the execution result to the cloud engine.

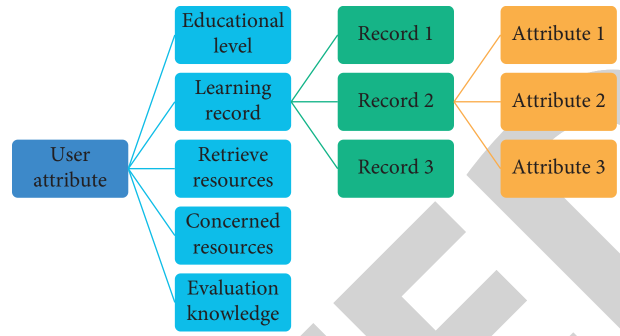

Figure 2: Schematic diagram of user attribute tree.

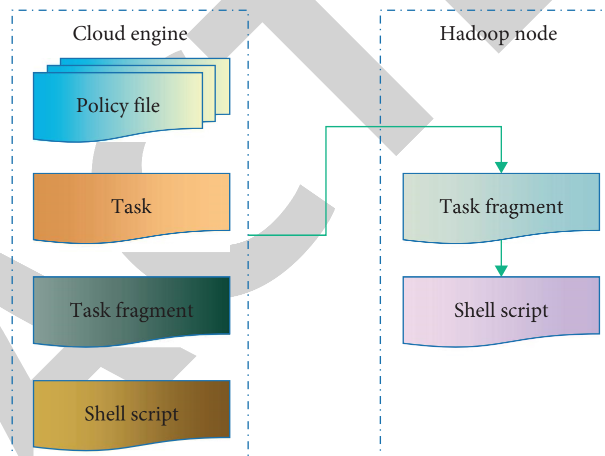

Figure 3: Working mechanism of task submodule.

Individualized teaching creates a democratic and harmonious atmosphere for teachers and students and allows students to have their own thoughts and answers, thus fully expressing their individuality. Personalized teaching is personalized in curriculum, teacher's teaching, and students' learning. Mind mapping also reflects personalization. Deal with the problem according to the way you handle the information, which obviously has a strong personal color. When thinking or solving problems and combine multidimensional information into a dynamic structure diagram, what is completed is a personalized mind map.

4. Results Analysis and Discussion

Under BD background, IE personalized teaching needs the comprehensive strength of teachers and technical teams. Specifically, the construction of a personalized teaching team can improve BD development literacy through the optimization and potential stimulation of the internal staff of the teaching team and strengthen the screening and optimization of massive teaching data. It can focus on future development education and fully absorb data professionals from all aspects to strengthen personalized teaching. This innovative personalized teaching method can gradually transform the traditional IE work from the extensive passive response mode to the active intervention and active guidance mode and create a new personalized teaching mode of college IE.

Using MATLAB to generate sparse signal x of order k, without losing generality, the positions of these k nonzero elements are randomly generated and meet the uniform distribution of $[1, n]$, and the sizes of the corresponding nonzero elements are randomly generated and meet the uniform distribution among [1, 100]. The generation of random signals is shown in Figure 4.

Students' intuitive and comprehensive qualitative evaluation of teachers and courses is referred to as aspect evaluation. The individual evaluation reflects the quantitative requirements for teaching based on subject characteristics or course nature. Teachers' personal styles and preferences, as well as the school's current reform focus, are reflected in the selective evaluation. Subjective evaluation captures characteristics of teaching quality that aren't captured by standardized indicators. Teachers can also use a specific knowledge point or piece of content as a theme for each group to investigate and promote. Teachers can allow students to create their own personalized mind map during the evaluation stage, which includes not only the relationships between knowledge points but also their own learning methods and cognitive strategies. Students can use this map to learn about their learning situation and provide timely feedback, making it easier for them to identify and correct their own flaws, humanize the evaluation, and make the cognitive and thinking processes operable.

Virtual practice teaching alleviates the difficulties of traditional practice teaching, such as students' lack of subjectivity, limited teaching time and space, shortage of teaching resources, and so on; highlights students' dominant position; expands the field of teaching virtual space; and enriches teaching resources. In the course system construction of personalized teaching, the setting of emotion and belief courses cannot be ignored. A complete personalized teaching course system should be the integration of three courses. Therefore, on the basis of the main courses, emotion and belief courses should be properly arranged, and at the same time, emotion courses should be refined into the specific teaching of the first two courses. Teachers can link the first two courses with the third related part in teaching; for example, they are often combined with corresponding emotions in the teaching of psychology, and the beliefs and thoughts of historical figures are linked with them in the teaching of anthropology so that the three courses are harmonious and unified.

In order to test the relationship between the observation times m and the correct reconstruction probability under different sparsity, take different sparsity $k = [10, 15, 20, 25]$ and perform 1,000 random experiments on each group of (k, m, n).

It can be seen from Figure 5 that for different sparsity k, when the number of observation points m is greater than or equal to 110, the probability that LNN method can correctly recover sparse signals is extremely high.

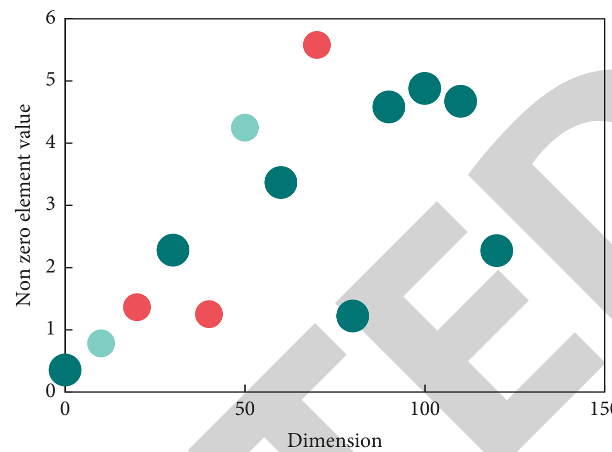

Figure 4: Discrete sparse signal.

The integration of BD and teaching is conducive to strengthening the supervision and management of college students' ideological fields. Through the digital analysis of students' ideological status, to control the operating mechanism of ideological education in colleges and universities, introduce new thinking ways and teaching methods, integrate the working resources of college IE, give full play to the advantages of digital technology, and cultivate the ability of college ideological educators to use data. Enhance the scientificity and modernity of college IE.

BD should be introduced into practice teaching, and more space for students to choose independently should be reserved in the PL teaching practice theme design. This can effectively stimulate students' initiative of independent innovation in the process of stimulating students' personal development potential. In the BD development environment, it can provide differentiated teaching ideas for college PL teaching and realize individualized education development. In personalized education, pay attention to actively listening to students' opinions and suggestions, praising students' personal strengths, which can safeguard students' personal dignity and interest.

As can be seen from Figure 6, for $m = [10, 15, 20, 25]$ with different observation points, when the sparsity k is less than or equal to 20, the LNN method has a very high probability of correctly recovering sparse signals.

Provide training, expert guidance, and technical support for teachers to help them improve their teaching level. Establish a website for the purpose of "serving teachers' teaching" to provide teachers with places for learning and communication. Organize a series of discussion lectures and classroom observations to help young teachers learn from other teachers' advanced teaching experiences and form their own teaching style and characteristics. Hire experienced old teachers as teaching consultants, listen to young teachers' classes regularly, and give guidance. Carry out a series of educational technology training to improve teachers' ability to master modern technologies such as multimedia.

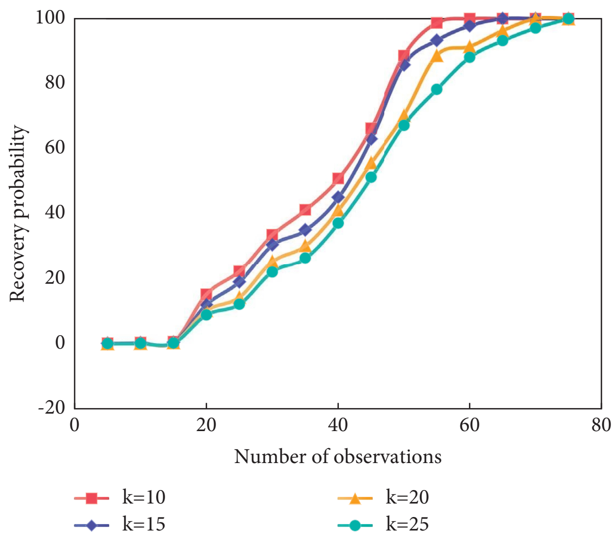

FIGURE 5: The relationship between the measured number m and the probability of successful recovery.

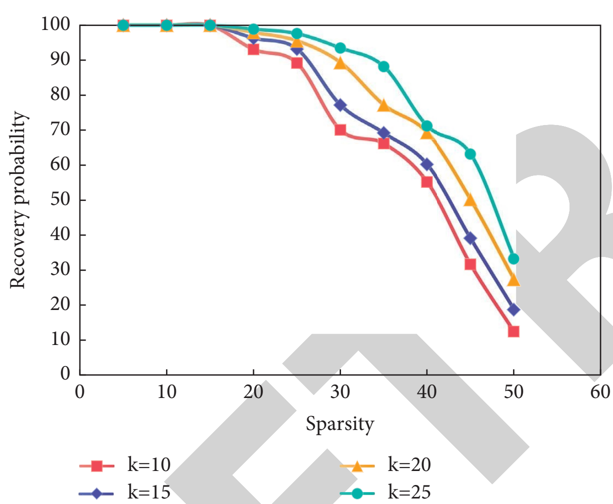

FIGURE 6: Relationship between sparsity k and probability of successful recovery.

The visualization of a mind map can help students understand the solutions and methods adopted by teachers and classmates when solving the same problem. At the same time, continuous reflection and regulation can promote the formation and transfer of their own cognitive strategies and cultivate their metacognitive ability. The explicit way of mind map opens tacit knowledge, realizes information exchange, connects more information to expand the breadth and depth of thinking, inadvertently exercises thinking, and lays the foundation for the emergence of new inspiration and the stimulation of creativity, thus promoting the innovation and perfection of knowledge.

Use MATLAB software programming to simulate the behavior of the neural network. Figure 7 shows the trajectory diagram of x_1, x_2. Figure 8 shows the trajectories in these four points x_1. Therefore, this is consistent with the minimum point set in problem analysis.

Learning objectives have a specific order, and they do not exist in parallel. Similarly, knowledge points follow a logical order: before learning a specific knowledge point, you must first learn its lower knowledge points, which serves as a necessary prelude to learning the upper knowledge points and improving the upper knowledge points. Students will be pushed to master the basic knowledge points, then the writing knowledge points of chemical equations, and finally the knowledge points related to the simple calculation of chemical equations. Students will master knowledge content ranging from easy to difficult, and personalized learning will be realized. There are two types of personalized teaching resources: static and dynamic. Words, pictures, animations, courseware, and material conditions are examples of static resources, whereas dynamic resources refer to dynamic information and active human resources. The construction of static resources is currently mostly in the stage of low-level repeated construction in the resource creation process, and the lack of individuality cannot meet the needs of students. Furthermore, it frequently overlooks the discovery of dynamic resources hidden in teaching activities, such as creativity and intellectual resources. However, mind maps can assist in the resolution of these issues.

It can be seen from Figure 9 that the initial point $(x_1 = 1, x_2 = 0.5)$ inside the feasible region finally converges to the minimum point. It can be seen from Figure 10 that the initial point $(x_1 = 0, x_2 = 5)$ outside the feasible region enters the feasible region after a period of operation and finally converges to the minimum point $(x_1 = 0, x_2 = 2)$.

In order to facilitate code maintenance and subsequent expansion of functions, Python and Shell scripts that can explain execution are selected. When running on the system line, the code can be modified. The task dispatching room executes in sequence through queues, and the cloud engine executes corresponding tasks according to the priority of the queues. So the elements that make up the user portrait must be able to be automatically identified by the computer, or the user can provide explicit information about the elements of the user portrait. When building a user portrait model, the finer the entity elements that make up the model, the more accurate the description of the model is. However, in the actual application process, many and fine user portrait elements will be dull. Therefore, the scope and accuracy of the user portrait model must meet the actual needs.

The platform will continuously collect user information and apply it to the current user portrait and constantly improve the user's portrait features through the current user portrait's use of data, so as to realize the continuous enrichment and perfection of data and portrait and ensure that the model has good adaptability. According to the difference of data dimensions, starting from multidimensions, the data is finally aggregated into a cluster set with the least differentiation in a certain dimension. There are often great differences between different clusters, so cluster analysis has become a commonly used data processing method in the field of machine learning.

5. Conclusion

Students have more autonomy with personalized instruction. They will not get the corresponding effect if they are too free, so educators, particularly front-line teachers, must grasp and control it properly. Furthermore, no idea or tool can be flawless. We can make them work by constantly exploring and tapping their useful value. When incorporating the LNN development concept into university PL personalized teaching, it is important to keep in mind that students' personalized development differs. Encourage students to actively change their learning styles, pique their curiosity about learning, and develop their practical skills and creative spirit. Establish and improve the incentive and restraint mechanisms in the classroom, as well as stimulate teachers' awareness of the need to continually improve teaching and their level of expertise. The outcome of classroom evaluation is useful for postappointment teaching, professional and technical postappointment, and various awards.

Folk dance is a very unique local culture in China, and dances in different regions have different characteristics. With the development of 3D digital technology and human gesture recognition technology, how to apply it in folk dance is a question worth thinking about. So, this paper recognizes and collects dance movements through human body detection and tracking technology in human gesture recognition technology. Then, this paper writes the data into the AAM model for 3D digital modeling and retains the information by integrating the manifold ordering. Finally, this paper designs a folk dance learning method combined with the Few-Shot learning method. This paper also designs a data set test experiment, an algorithm data set comparison experiment, and a target matching algorithm comparison experiment to optimize the learning method designed in this paper. The final results show that the Few-Shot learning method based on gesture recognition 3D digital modeling of folk dances designed in this paper reduces the learning time by 17% compared with the traditional folk dance learning methods. And the Few-Shot learning method designed in this paper improves the dance action score by 14% compared with the traditional learning method.

1. Introduction

Dance is an art with soul. It not only brings beautiful enjoyment to people, but also inherits rich and profound cultural connotations and is a cultural carrier. China is a multiethnic country, ethnic dance is prosperous, and the art of each ethnic group has a long history of development, and all have distinctive dance art culture. Ethnic folk dance is an important artistic carrier in the long history of China since ancient times, and it inherits and develops the cultural origin and artistic orientation of various ethnic groups.

The research on human action cognition, from simple to complex, can be summarized into three levels: mobile vision, action vision, and action vision according to the content of the action. At present, there are two main problems in studying the action vision of video people. One is that, during the recognition process, most of the action frame information in the video will be repeated, or the correlation with action recognition will be very low, the calculation will become complicated, and it will also affect the action. Second, in the process of feature selection and understanding, the main methods include fusing representational and pose-based features. However, the costumes of the stage background and dance moves can be changed, so in many cases, the motion information of the human body cannot be accurately and completely represented in the fusion of the expression information, and the static state of the human body is ignored according to the characteristics of the posture. The Few-Shot learning method based on gesture recognition 3D digital modeling of ethnic dance designed in this paper has great significance for students majoring in ethnic dance, which can allow students to learn ethnic dance very effectively.

The innovation of this paper is as follows: through the method of human body detection and tracking technology in the human body gesture recognition technology, this paper recognizes and collects the movements and human body postures of folk dances. Then, the AAM model is used for 3D digital modeling. In this paper, the information of manifold ordering is integrated and retained. Then, through the analysis, this paper designs a folk dance Few-Shot learning method. In order to optimize the Few-Shot learning method of 3D digital modeling of folk dance based on gesture recognition, this paper also designs a data set test experiment, an algorithm data set comparison experiment, and a target matching algorithm comparison experiment.

2. Related Work

Cell line screening has created extensive datasets for learning predictive markers of drug response, but these models are not easily translated to the clinic due to their diverse backgrounds and limited data. Ma J applies a recently developed technique, few-shot machine learning, to train a general neural network model in cell lines that can be adapted to new environments using few additional samples. His main research is based on medical aspects although it combines small sample methods, but it has little relevance in gesture recognition technology. Spectral prediction using deep learning [1, 2] has attracted a lot of attention in recent years. While existing deep learning methods have shown significant improvements in prediction accuracy, there is still considerable room for improvement, currently limited by differences in debris types or instrument settings. Lu Z presented an algorithmic framework to process acceleration and surface electromyography (SEMG) signals for gesture recognition. It includes a novel segmentation scheme, a score-based sensor fusion scheme, and two new features. The framework uses a Bayesian linear classifier and an improved dynamic time warping algorithm [3]. Human gesture recognition plays an important role in many human interaction applications, such as cell phones, health monitoring systems, and human-assisted robots. Electromyography (EMG) is one of the most common and intuitive methods for detecting gestures based on muscle activity. However, EMGs are often overly sensitive to environmental disturbances such as electrical noise, electromagnetic signals, and humidity. Jung P G proposed a new method for muscle activity recognition based on air pressure sensor and air bag. It detects muscle activity by measuring changes in air pressure in air sacs that contact the muscle of interest [4]. Numerous folk dance videos are uploaded online or added to Bollywood movies as situational songs. Classification of folk dance videos is critical for dance education, preservation of cultural heritage, and better customer-oriented service by music companies. Bhatt M proposed a folk dance classification framework. The framework extracts the audio signal from the video, extracts a 125-second segment from the beginning, and further divides it into a set of small segments. It computes Mel-Frequency Cepstral Coefficients (MFCC) and Linear Predictive Coding (LPC) coefficients to generate high-dimensional feature vectors. He uses Principal Component Analysis (PCA) to reduce dimensionality and uses a scale conjugate gradient neural network to classify segments [5]. Maintaining the quality of 3D data in the potentially long chain from digital scan to 3D model deployment is critical for the increasing number of advanced geometric design processes in the mesh domain, including digital fabrication. Centin M proposes an extremely general solution. It handles all previously described problems in a user-friendly way. And it is based on the original multiforward propulsion triangulation technique guided by implicit surfaces and based on the priority mechanism, which greatly reduces the frontal interference [6]. The three-dimensional (3D) revolution promises to transform archaeological practice. Among the techniques that aid in the proliferation of 3D data, photogrammetry facilitates fast and inexpensive digitization of complex subjects in field and laboratory settings. Magnani M discusses how the technique adapts and extends existing document and data visualization routines, while evaluating the opportunities it offers to solve archaeological problems and problems in innovative ways [7]. To sum up, most of the literature is about Few-Shot learning and pose recognition. Although it involves folk dance, the focus is not on the creation of its 3D digital model. So, the next focus of this paper is to combine Few-Shot learning and gesture recognition to perform 3D digital modeling of traditional folk dance.

3. Few-Shot Learning Method for 3D Digital Modeling of Folk Dance Based on Gesture Recognition Technology

3.1. Human Pose Recognition

3.1.1. Principle of Depth Map Acquisition. Since the release of Kinect [8, 9], depth cameras have received more and more attention. Depth cameras currently in the market can be divided into the following three categories according to technology: structured light-based cameras (SL), time-of-flight cameras (ToF), and stereo vision-based cameras (Stereovision).

3.1.2. Structured Light. The depth acquisition method based on structured light [10] is an active stereo vision technique. A series of known patterns are projected onto the object in turn and deformed according to the object's geometry, viewing the object from different directions. Depth information is extracted by analyzing the distortion of the observed patterns (e.g., differences from original mode), as detailed in Figure 1.

3.1.3. Flight Time. The acquisition method based on the time of flight [11] is to continuously send light pulses of different phases to the object and then use the sensor to receive the light reflected by the object to calculate the round-trip time (i.e., phase difference). A pulse of light is used to obtain the distance between the device and the object. As shown in Figure 2, the red line represents the infrared light wave transmitted to the object, and the infrared component reflected by the sensor is detected.

3.2. Human Detection and Tracking Technology. From photo and video streams, human detection techniques [12] extract people. Traditional detection technology [13, 14] and statistical principle detection technology are commonly used in human body detection technology. Human detection techniques based on statistics can be divided into two stages:

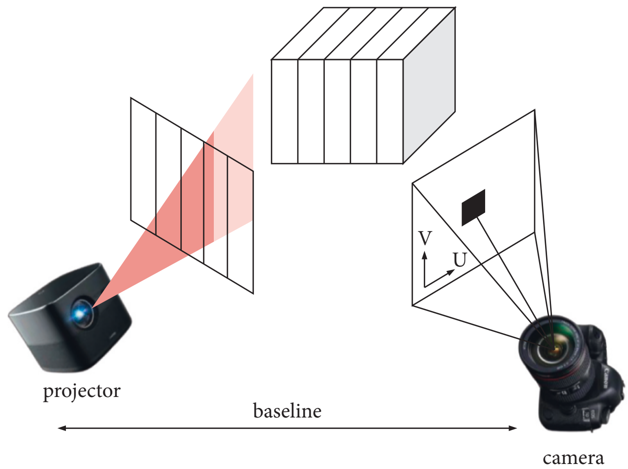

Figure 1: Principle of structured light collection.

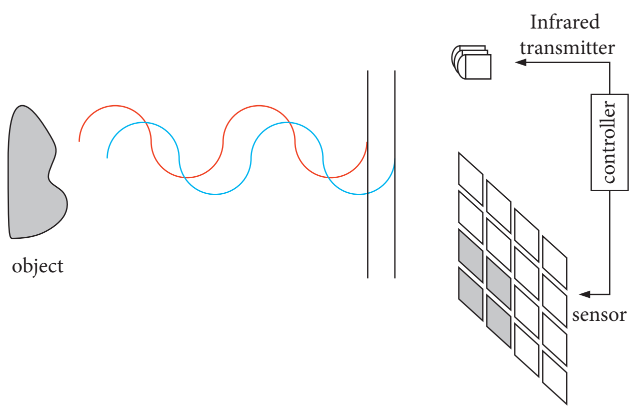

Figure 2: The principle of time-of-flight acquisition.

training and detection. Multiple detected and noise samples are collected during the training phase, positive and negative feature vectors are created, and features are created based on training and classification. The video frames to be detected are scanned one by one in the detection phase. At the corresponding position, a feature is formed, and then the person's target is determined.

So far, the human body detection technology needs to realize the detection of moving objects first, and the optical flow method and the adjacent frame difference method are general. Humans and non-humans are then classified based on the foreground, that is, the ratios and shapes of parts of the human body, or by analyzing the color of human skin against the characteristics of the image. This traditional detection method is not effective for the interference of complex external environment and external objects and is also easily affected by the noise of the underlying image features.

3.3. Moving Human Target Detection. Detecting moving objects is viewed as a spatial domain partition of video objects. Specifically, this refers to the detection and separation of regions of people moving independently in the video sequence for each frame. The most common ways of distinguishing are as follows.

Frame Difference Method [15]: the frame difference method is one of the commonly used moving object detection and segmentation methods. The basic idea is to use strong correlations between adjacent frames of an animation sequence in order to detect changes. The algorithm is characterized by high speed and high real-time performance, and changes in light have little effect on the algorithm. However, the segmentation accuracy of moving objects is not guaranteed, and large holes can be simply generated.

Background difference method [16]: the background difference method uses the difference between the current image and the background image to detect moving regions. This method is typically used for background static or slowly changing and provides the most complete characteristic data. However, due to the sensitivity to the interference of irrelevant objects in the scene, many scholars have focused on the research of background update algorithms.

Optical flow method [17]: the optical flow method is an approximate estimation of the plane projection of the two-dimensional image of the three-dimensional motion of the actual sports field scene, lens, target, etc. Its characteristic is that it can deal with the motion of the background more appropriately, but it is sensitive to noise and the calculation is very complicated.

3.4. Action Sequence Segmentation. The initial action recognition was only to recognize human movement through the computer, and later, it developed into simple actions including some simple actions, such as walking, running, and jumping. Each video frame sequence contains multiple types of actions, and each type of action contains multiple simple actions. Each simple movement consists of multiple human poses. The consistency and smoothness of various actions are due to the convergence of transition actions. In the case of dance moves, a complete dance performance includes multiple movement groups. Each action group consists of multiple simple actions, such as clips and steps, and simple actions consist of multiple basic poses such as raising hands and kicking feet. Therefore, the purpose of video frame sequence segmentation is to segment human action sequences into small actions. This will keep action sequences as short as possible but contain enough action information to identify the type of action. It is difficult to precisely find the dividing point if the human action is continuous and smooth. This is the main reason why the segmentation of video action sequences is not ideal, and only by extracting key frames for action sequence segmentation cannot achieve the shortest possible data to contain the most human action information. In fact, in most cases of video action recognition research work, we choose to manually process video, such as using manual segmentation to obtain the action sequence of the main data, or planning the action to be collected when collecting data. A whole video is divided into multiple small videos according to simple actions and recorded separately, and then the action sequences formed by all video frames are used for video action recognition].

3.5. 3D Digital Modeling

3.5.1. Motion Capture. People look forward to capturing human movements in the most intuitive and natural way. That is, the human body can move freely, and the camera can capture and record motion information just like the human eye. This is what the motion capture system based on computer vision system pursues, and its typical processing process is shown in Figure 3.

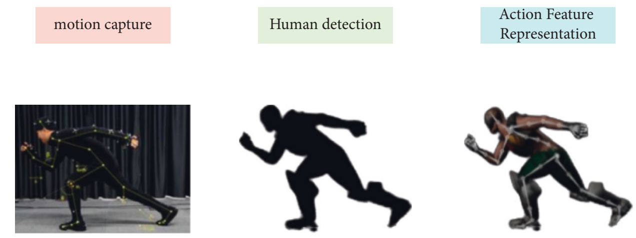

Figure 3: Motion capture system.

3.5.2. Overview of the AAM Model. Active appearance model is a feature point localization method widely used in pattern recognition and computer vision. In the process of establishing the AAM model, the global shape and texture information are fully considered, and the final AAM model can be obtained by modeling the shape and texture respectively, and by instantiating the model. In the process of image matching, the reverse composite method is adopted, which has achieved very good results in real-time and accuracy.

The establishment of AAM model is mainly divided into shape modeling, texture modeling, and the appearance model generated by combining these two models. The instantiation of the model is to map the appearance model to the corresponding shape instance through affine transformation.

The shape model of AAM refers to the ASM model. ASM is a model based on point distribution. It only trains the shape model and lacks the texture model, so the location of the feature points of the face is not accurate. The AAM model can solve this problem very well.

The general modeling object of the AAM model is a nonrigid object, such as a human face, and the main purpose is to describe the object through model parameters (feature points). Then, it can use this description to complete other tasks, such as image alignment, target location, tracking [18, 19], and recognition [20].

Because the active shape model ASM model only counts the shape model, we need to build a texture model that uses the grayscale information of the face to model, which is actually the grayscale value of the pixel. The number of pixels in the shape needs to be transformed to be consistent, and the method used is piecewise linear affine transformation. As shown in Figure 4, it is a piecewise linear affine transformation.

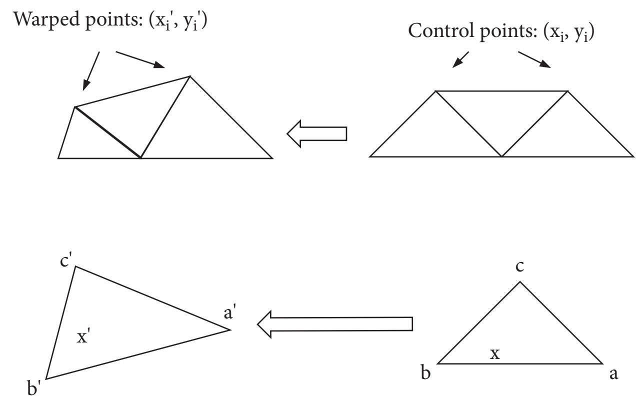

Figure 4: Piecewise affine transformation.

The calculation method of piecewise linear affine transformation [21] is shown in Figure 5:

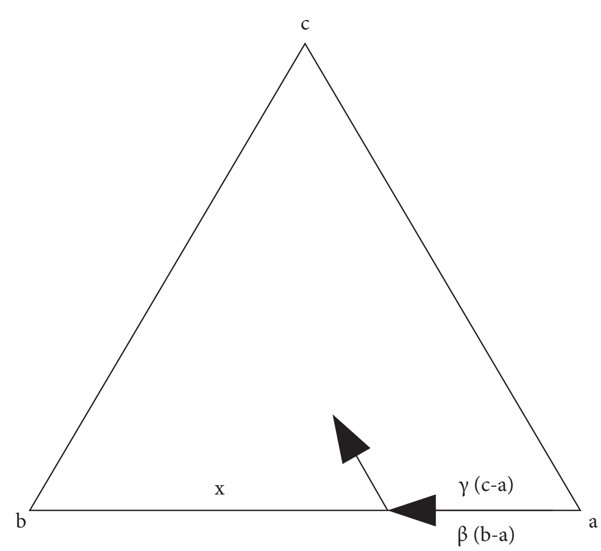

Figure 5: Calculation process of piecewise linear affine transformation.

3.5.3. Real-Time Control Technology of 3D Human Model. Controlling the human body model has always been an important direction of virtual reality research. Considering from different aspects to control the virtual human body model, the main methods are as follows: key frame control method, motion capture method, and dynamic method.

The key technology is to study the earliest method of controlling mannequins. The concept of keyframes started with the process of manga animation. In the process of making animation, the superior animator first made the main animation of the comic, which is the so-called key frame, and then the general staff completed the design and realization of the frame in the middle. After that, with the development of computer technology, the generation of the intermediate frame is gradually completed by computer. In animation, the parameters that affect the image of the screen are the parameters that affect the keyframes later.

Due to the particularity of human motion, the best way to use the human body model to express the human motion is to start directly from the motion of the human body. By using the sensor to directly capture the information of each position of the human body, use the parameters obtained by the sensor to reproduce the movement of the human body. Since the parameters obtained in this way are very real human state numbers, it is easy to restore the movement of the human body. However, motion capture technology also has many problems that restrict it to solve all practical applications.

The methods of kinematics are divided into forward kinematics and inverse kinematics. The joints of the virtual human can achieve effective movement through the forward kinematics method and the inverse kinematics method. In cis-kinematics, end-effectors (hands, feet, etc.) are used as a function of time. The position of the end effector is independent of the force or moment causing the action and is resolved by a fixed reference frame. Converting positions and velocities from joint space to Cartesian coordinates is a well-established method. The first application of cis-kinematics was a parametric keyframe animation, where the motion of the joint body was driven by interpolating the major joint angles into the cis-kinematics of the hands and feet. Advanced animators with years of experience can produce very realistic motions by means of cis-kinematics. But it is difficult for ordinary animators to produce realistic motion by setting individual keyframes in combination.

3.6. Integrated Manifold Ordering Information Retention. A new manifold supervised dimensionality reduction algorithm is proposed, that is, Integrated Manifold Ordering Information Preservation (EMRP). First, in order to solve the phenomenon of measurement concentration, we need to retain the ranking information of the samples within the class, and in order to extract the discriminative information, we need to maximize the edge distance of the samples between classes. To better understand the difference between method and other manifold supervision methods, this section adopts the PAF framework to construct EMRP.

For a certain recognition problem, K samples can be expressed by a matrix composed of fixed-length features:

$$A = [a_1, a_2, \ldots, a_K] \in R^{D\times K}. \tag{1}$$

The class of each D-dimensional feature vector $a_i \in R^D$ is labeled as

$$Z = [z_1, z_2, \ldots z_K] \in C^K. \tag{2}$$

The purpose of manifold supervised dimensionality reduction learning is to find the projection matrix $U \in R^{D\times d}$ to project the original sample A from the high-dimensional space to the low-dimensional subspace R^d, so as to obtain a concise expression:

$$B = U^S A = [b_1,, b_2, \ldots b_K] \in R^{d\times K}. \tag{3}$$

Here, $d < D$.

Under the PAF framework, we define an arbitrary sample a_i, its intraclass neighbor samples $a_{i_1}, \ldots, a_{i_{n_1}}$ and n_2 interclass neighbor samples $a_{i_1}, \ldots, a_{i_{n_2}}$ as a local block:

$$A_i = \left[a_{i_1}, a_{i_2}, \ldots, a_{i_{n_1}}, a_{i_1}, \ldots, a_{i_{n_2}}\right] \in R^{D\times\left(k_1+k_2+1\right)}. \tag{4}$$

EMRP finds the corresponding low-dimensional expression as

$$B_i = \left[b_{i_1}, b_{i_2}, \ldots, b_{i_{n_1}}, b_{i_1}, \ldots, b_{i_{n_2}}\right] \in R^{D\times\left(k_1+k_2+1\right)}. \tag{5}$$

The optimization goals on the block include the following:

(1) Retain the sorting and retention information between samples within a class;

(2) Maximize the discriminative information of between-class samples.

3.6.1. Retention of Sorting Information. The ranking information of the samples within the class is available for classification. Inspired by the LE algorithm, we define the intraclass ordering information on a local block as

$$R(b_i) = \sum_{j=1}^{n_1} b_i - b_{ij}^2 \left(w_i\right)_j. \tag{6}$$

Here, the weight factor (w_i) is defined as

$$(w_i)_j = \begin{cases} xp\left(-\dfrac{a_i - a_{ij}^2}{s}\right), & e \text{ if } a_{ij} \in K_{n_1}(a_i); \\ 0 & \text{otherwise} \end{cases}. \tag{7}$$

According to the PAF framework, we can deduce (6) as follows:

$$R(b_i) = \operatorname{tr}\left(B_{R(i)} L_{R(i)} B_{R(i)}^S\right). \tag{8}$$

Here,

$$L_{R(i)} = \begin{bmatrix} -e_{n_1}^S \\ I_{n_1} \end{bmatrix} \operatorname{diag}(w_i)\left[-e_{n_1} \ \ I_{n_1}\right],$$
$$e_{n_1} = \left[\overbrace{1, \ldots, 1}^{n_1}\right]^S, I_{n_1} = \operatorname{diag}\left[\overbrace{1, \ldots, 1}^{n_1}\right], B_{R(i)} = \left[b_i, b_{i_1}, \ldots, b_{i_{n_1}}\right]. \tag{9}$$

3.6.2. Maximize Identification Information. For popular supervised learning, discriminative information plays a crucial role. As far as the EMRP algorithm is concerned, we consider that the purpose of extracting discriminative information is achieved by maximizing the distance sum of the samples between b_i and n_2 classes, namely,

$$D(b_i) = \sum_{p=1}^{n_2} b_i - b_{i_p}^2 \left(v_i\right)_j. \tag{10}$$

The definition of the weight factor (v_i) here considers the factor of removing the ranking information between classes, namely,

$$(v_i)_j = \begin{cases} 1, & \text{if } a_{ij} \in K_{n_1}(a_i); \\ 0 & \text{otherwise} \end{cases}. \tag{11}$$

Under the framework of PAF, we can further derive (10) as

$$D(b_i) = \operatorname{tr}\left(B_{D(i)} L_{D(i)} B_{D(i)}^S\right). \tag{12}$$

Here,

$$\begin{aligned} L_{D(i)} &= \begin{bmatrix} -e_{n_2}^S \\ I_{n_2} \end{bmatrix} \operatorname{diag}(v_i)\left[-e_{n_2}\ \ I_{n_2}\right], \\ e_{n_2} &= [\overbrace{1, \ldots, 1}^{n_2}]^S, I_{n_2} = \operatorname{diag}[\overbrace{1, \ldots, 1}^{n_2}], B_{D(i)} = \left[b_i, b_{i_1}, \ldots, b_{i_{n_2}}\right]. \end{aligned} \tag{13}$$

Therefore, we can get the optimization objective function on the local block:

$$\arg\min\left(\sum_{j=1}^{n_1} b_i - b_{ij}{}^2 (w_i)_j - \gamma \sum_{p=1}^{n_2} b_i - b_{i_p}{}^2 (v_i)_j\right). \tag{14}$$

However, different hyperparameters (such as n_1 in (6) and n_2 in (10)) correspond to manifold with different geometric information, which can seriously affect the final recognition accuracy. In EMPR algorithm, the hyperparameters s, n_1, and n_2 that affect the objective function are difficult to choose optimal settings. Therefore, an automatic manifold estimation method is valuable for solving this problem.

3.7. Folk Dance. China is a multiethnic country. Every nation has a distinct national culture. Ethnic folk dance originates from life labor and is a dance that people dance to entertain themselves. People express their life through dance and show their unique national charm. The types of Chinese folk dances are shown in Figure 6.

With the changes of the times, ethnic folk dance has gradually evolved into a dance form with its own national characteristics and advancing with the times in the new era on the premise of retaining its original characteristics. It has also gradually expanded from a self-entertainment model to a professional and large-scale system. It is a dance course processed and refined by professional dancers. It is a dance work that expresses ideas in combination with life. The stage sublimation of the national folk dance drama flourished.

Folk dance is the art form of a people who have lived in a specific geographical location for a long time and have developed unique folk customs, religious beliefs, and agricultural civilization. It gradually developed a unique aesthetic taste when combined with the unique natural environment. Ethnic dance can be described as an important cultural carrier that can pass down ancient Chinese folk culture and serves as an external manifestation of national cohesion. Because each ethnic group has its own unique history, rich cultural connotation, and independent national aesthetic habits, each ethnic group has its own dance art language. Folk dance, as a result, has a distinct national character, a limited regional character, and a high level of "self-entertainment."

Ethnic dance has a long history and is created by workers of all ethnic groups in the context of long-term production practices and life changes. They use innovative dance techniques to convey national history, religious beliefs, life lessons, and even myths and stories. With so many cultural contents, the folk dance is destined to have historical and cultural value, as it is the spiritual wealth left by the forefathers. We can better inherit folk dance by learning it, and we can bring out the functions of cultural inheritance, cultural accumulation, cultural exchange, and cultural innovation of folk dance by learning it.

4. Algorithm Data Set Comparison Test Experiment

4.1. Dataset Test Experiment. Some images are randomly taken from a subset of the source data and test set LFW, it may be difficult to distinguish where they come from, and the image distributions of the source and target domains are similar. Table 1 shows experimental results on a subset of the test set LFW dataset.

It can be observed that the model learned in this paper in the source domain is directly tested in the target domain without transfer learning. The results are unsatisfactory, using the cosine and LRA methods to measure the similarity between faces with the lowest results of 82.01% and 85.23%, respectively.

The image distributions of the source and target domains are quite different. Considering the variation of expression, illumination, and occlusion, restricted parameter learning method RPL shows its superiority in the FERET dataset.

Two 2048-dimensional representative feature vectors are concatenated to a 4096-dimensional feature vector without principal component analysis (PCA) dimensionality reduction for face recognition. The similarity between features is then measured with the LRA method. The results of the RPL method in this paper on the two databases and the comparison results of other methods and other recent works are shown in Table 2.

All in all, using the restricted parameter learning (RPL) deep transfer learning method, the learning space of parameters in the target domain is constrained. By adjusting the source domain knowledge of the scarce target domain samples, overfitting and parameter structure damage can be prevented, and ideal results can be obtained in the same and different distributions. Unlike other state-of-the-art techniques, method can adjust knowledge from the source domain to the target domain offline; that is, it does not require training on both source and target data simultaneously. Therefore, the RPL method in this paper can be easily applied to many scenarios. The results validate the effectiveness of RPL, which uses very deep convolutional networks fine-tuned with sample knowledge in the target domain.

4.2. Algorithm Dataset Comparison Experiment. Figure 7 shows the best average recognition rate of the test set for the six algorithms under different training samples on the

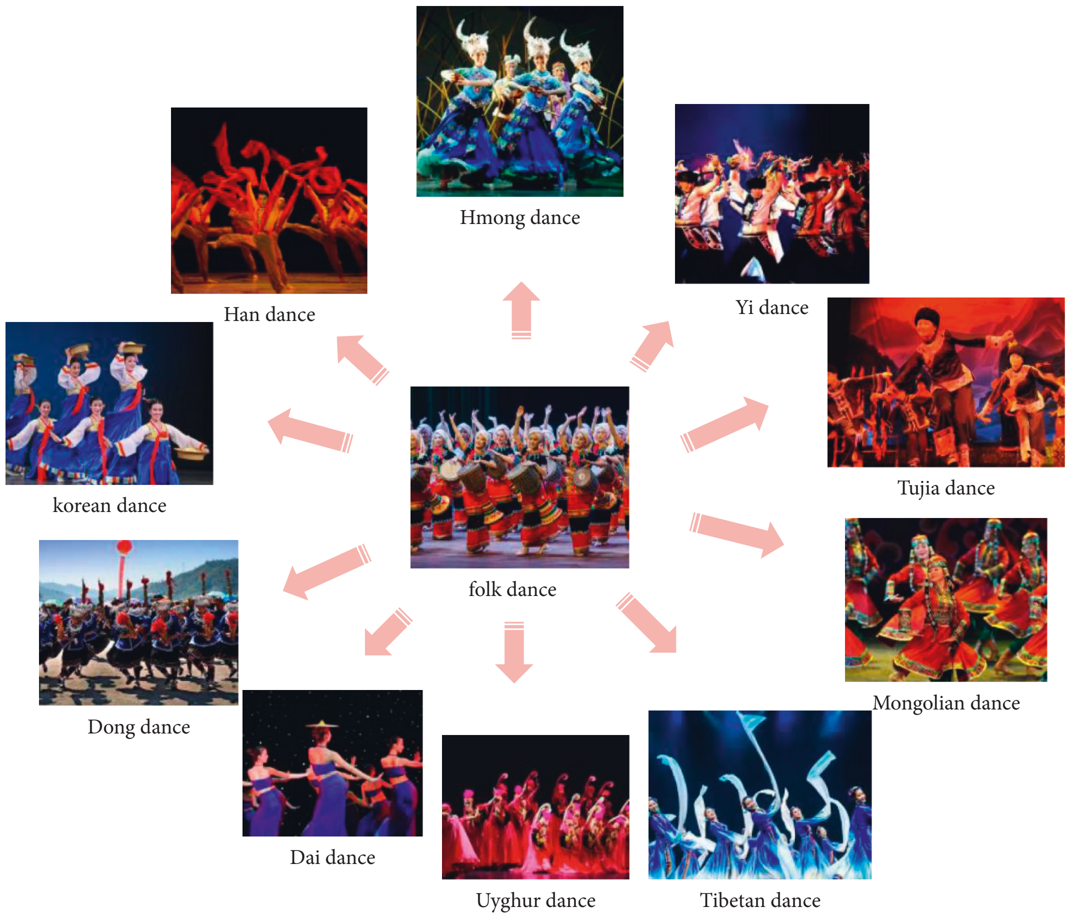

Figure 6: Types of Chinese folk dances.

NMHA-TP dataset (including two cases of $p = 20$ and $p = 30$).

It can be seen that, compared with several other algorithms, the EMPR algorithm can obtain the best classification performance on the NMHA-TP dataset.

Figure 8 shows the best average recognition rate of the six algorithms in the test set under different training samples on the NMHA-WP dataset (including two cases of $p = 20$ and $p = 30$).

It can be seen that, compared with several other algorithms, the EMPR algorithm can obtain the best classification performance on the NMHA-WP dataset.

Table 3 presents the best average recognition rates and corresponding dimensions of the six algorithms on the NMHA-TP-WP dataset.

It can be seen that, compared with several other algorithms, the EMPR algorithm can obtain the best classification performance on the NMHA-TP-WP dataset.

In addition, Table 4 shows the comparison results of the six algorithms and the RPDA algorithm on the SCUTNAA dataset. It can be seen that the EMRP algorithm has a certain advantage in the recognition rate compared with the RPDA algorithm. In addition, the experimental results of EMRP-81 and EMRP-9 show that more candidate matrices are helpful for the learning of the essential manifold.

The main conclusions of the EMRP-related experiments can be summarized as follows:

(1) Algorithms such as EMRP, RPDA, LSDA, and MFA are suitable for human action recognition based on acceleration sensor due to the intuitive consideration of the geometric information on the local block. The EMRP and RPDA algorithms perform better because of considering the balance between the ranking information of the intraclass neighbor samples and the neighbor ranking information of the interclass samples.

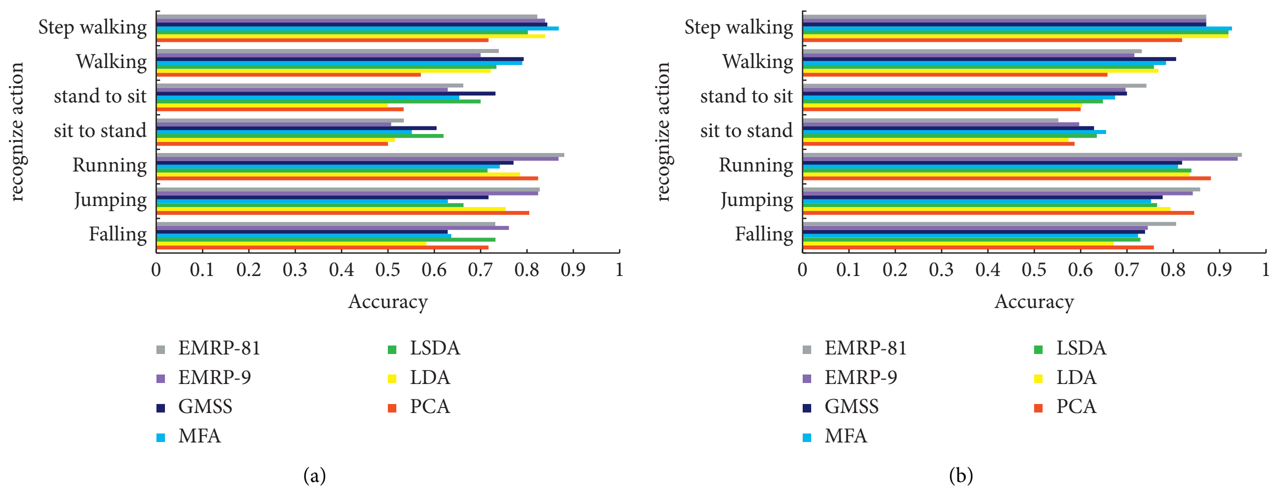

Figure 7: Best Average Recognition Rate of 6 Algorithms on NMHA-TP Dataset (a) $p = 20$ (b) $p = 30$.

(2) In the human action recognition test based on the acceleration sensor of mobile phone, EMRP-81 significantly improves the recognition accuracy and obtains the best average recognition rate. All of these demonstrate the robustness and effectiveness of the EMRP algorithm in the human action classification task. This also proves that the EMRP-based algorithm can learn a linear combination of candidate registration matrices to obtain better system performance.

4.3. Comparison Experiment of Target Matching Algorithms. The VOT dataset and six representative image sequences from the TempleColor128 dataset are used to evaluate the algorithm in this paper. The Juice image sequence is specifically included. The target has a slight spatial transformation, while the background has a small spatial transformation. The background in this data changes dramatically, the target is scaled and rotated, and there is also similar target interference. There are severe illumination changes in this data, as well as deformation in the target itself, in the motorcycle image sequence. The target in this data has scale, illumination, and certain morphological transformations, as seen in a helicopter image sequence. The shape of the target changes, the background changes slightly,

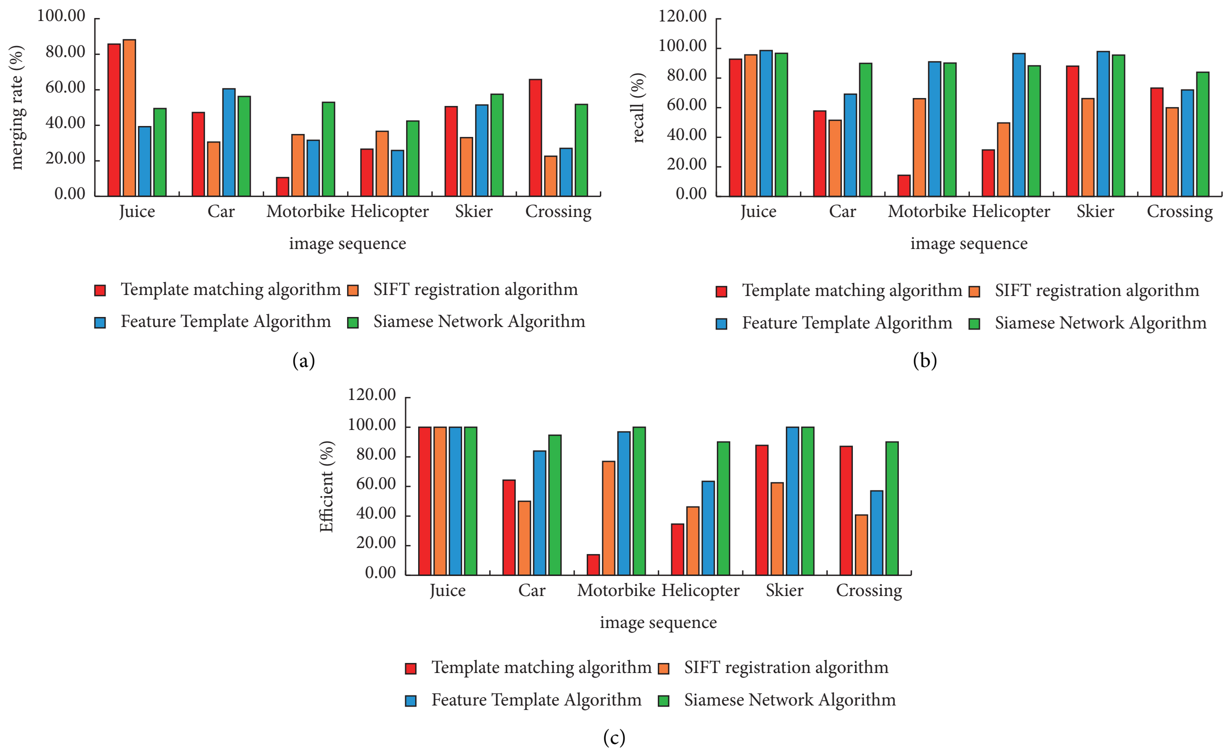

Figure 9: Comparison of experimental results of target matching algorithms. (a) Cross-comparison experimental results. (b) Recall experiment results. (c) Effectiveness experimental results.

and there is partial occlusion in this data from a skier image sequence. In this data, there are similar targets, the target has large deformation and scale transformation, and the background also has transformation. After manually culling the images whose targets were completely occluded and difficult to identify in the image sequence, about 10 images were selected as training data, and other images were used as test data in the experiment. The intersection ratio, recall, and efficiency of the four algorithms on six groups of image sequences are shown in Figure 9.

According to the experimental data, it can be seen that the traditional algorithm only has good results in some scenarios, while the method based on machine learning can take into account most scenarios.

The grayscale template matching based on the correlation coefficient has a good effect on simple scenes such as Juice image sequences and also has a good effect on scenes with simple backgrounds and small target deformation, such as Skier and Crossing image sequences. However, the target matching performance of these scenes depends on the influence of template selection, which is not very stable. Only when the template is selected properly, there is a better matching effect. The overall performance is not very stable.

The algorithm based on SIFT registration has better performance in simple scenes such as Juice image sequences, but when the target is deformed, or the imaging quality is poor, the matching effect is obviously degraded. The overall performance is poor.

The algorithm based on feature template also performs well in simple scenes, but when the scene is complex, the performance deteriorates, and the algorithm's intersection and union are relatively low, and the matching accuracy is poor. And the overall performance is poor.

5. Comparative Analysis of Few-Shot Learning for 3D Digital Modeling of Folk Dance Based on Gesture Recognition

The algorithm data set is analyzed through experiments, and finally the Few-Shot learning method for 3D digital modeling of folk dance based on gesture recognition designed in this paper is optimized. In order to verify how this Few-Shot method is different from traditional learning methods for folk dance learning, this paper designs a set of comparative experiments. In this paper, 20 students majoring in folk dance are divided into two groups. One group uses the Few-Shot learning method designed in this paper based on the three-dimensional digital modeling of folk dance based on gesture recognition. The other group used traditional folk dance learning methods and then judged their learning efficiency based on the learning time and movement scores of the two groups of students. The experimental data is shown in Figure 10.

As can be seen from Figure 10, the time for students majoring in ethnic dance to learn the Few-Shot learning method based on gesture recognition 3D digital modeling of ethnic dance designed in this paper is only 8.93 minutes for the same dance. The time used in the traditional folk dance learning method is 10.77 minutes. Compared with the traditional learning method, the Few-Shot learning method

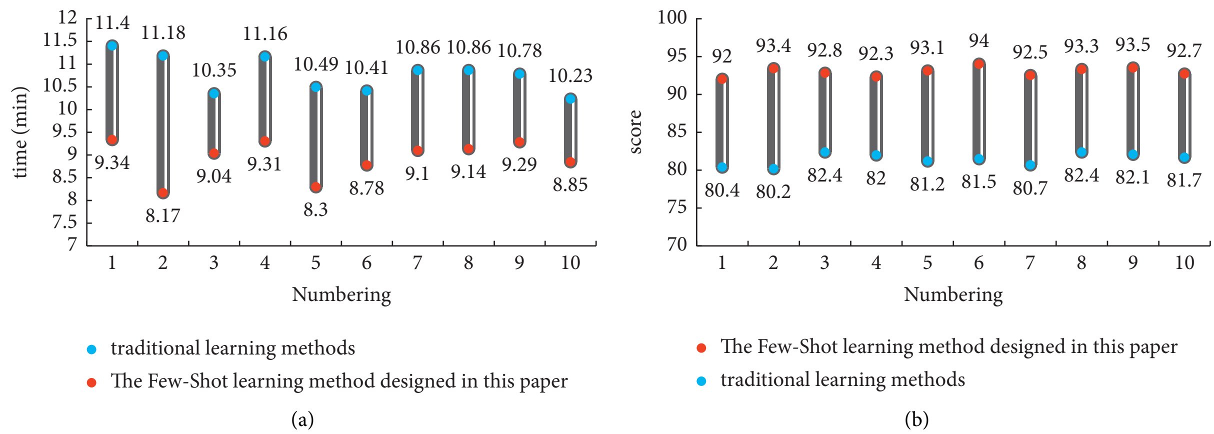

FIGURE 10: Comparison of learning efficiency between the few-shot learning method designed in this paper and the traditional learning method. (a) Study time comparison. (b) Action score comparison.

TABLE 4: Comparison of RPDA algorithm and 6 algorithms on SCUT NAA dataset.

number Of training samples					$P = 20$			
Algorithm	PCA	LDA	LSDA	MFA	GMSS	RPDA	EMRP-9	EMRP-81
Average accuracy	0.732	0.736	0.751	0.755	0.767	0.773	0.778	0.780
Dimensionality reduction	(30)	(8)	(7)	(9)	(5)	(27)	(27)	(28)

based on gesture recognition 3D digital modeling of folk dance designed in this paper reduces the learning time by 17%. And the dance action score of the Few-Shot learning method designed in this paper reaches 92.96 points, while the traditional learning method is only 81.46 points. It can be seen that the Few-Shot learning method designed in this paper is 14% higher than the traditional learning method. To sum up, the Few-Shot learning method based on gesture recognition and three-dimensional digital modeling of ethnic dance designed in this paper can effectively improve the learning efficiency of ethnic dance students majoring in ethnic dance.

6. Conclusion

This paper mainly studies the 3D digital model of folk dance based on Few-Shot learning and gesture recognition. Therefore, this paper combines the human body detection and tracking technology of human body posture recognition technology to collect the movement posture and human body posture data of folk dance. Then, this paper uses the AAM model to perform 3D digital modeling of the collected action poses. Then, this paper retains by integrating the manifold ordering information and finally designs a folk dance learning method combined with the Few-Shot learning method. This paper also designs a data set test experiment and an algorithm data set comparison experiment to optimize the algorithm test and data set design. Then, this paper carries out the final optimization according to the experimental results of the target matching algorithm comparison experiment. This paper designs a Few-Shot learning method for 3D digital modeling of folk dance based on gesture recognition. This method can scientifically and effectively improve the learning efficiency and performance of students majoring in ethnic dance.

Dance is constantly discovering truth, goodness, and beauty in human social life, spreading truth, goodness, and beauty, and fully expressing the artistic pursuit of dance beauty. It shapes different dance images, expresses the aesthetic consciousness and feelings of dance, and resonates with the audience to meet their aesthetic needs through various forms of movement. Because the RBF neural network model is good at approximating functions, many researchers have begun to use the RBNN approximation model for engineering design. Due to the limited dance data available for research, this paper uses radial basis function neural network model to study the aesthetic characteristics of dance in the context of few-shot learning. When the time index reaches 50, the average ratio of the L-MBP algorithm is 33.4 percent, 32.5 percent for the RBNN algorithm, and 46.3 percent for this method. As can be seen, this method has the highest ratio of the three algorithms, giving it a distinct advantage in terms of dance aesthetics. As a result, this paper establishes a neural network model, trains and simulates the network model, studies and analyzes the influence of changes in influencing factors on the aesthetic characteristics of dance, and provides a new idea for the prediction of the aesthetic characteristics of dance and a reference for optimizing the design of the aesthetic system of dance using the prediction ability of radial basis function neural networks.

1. Introduction

Dance existed as a form of culture long before it was considered aesthetically pleasing. The evolution of cultural dance to aesthetic dance has become a historical necessity as time passes, productivity improves, and class emerges. The emergence of dance with aesthetic significance not only makes dance an art in the strict sense but also gradually forms a dance art discipline, and then produces a new discipline—dance aesthetics. Dance art incisively and vividly seeks out truth, goodness, and beauty in human social life; spreads truth, goodness, and beauty; and embodies the artistic pursuit of dance beauty. It shapes various dance images, expresses the aesthetic consciousness and aesthetic emotion of dance through various action forms, resonates with the audience, and meets their aesthetic needs through various action forms [1]. Don't you know that when you dance with beautiful eyes, a slim waist, and graceful hands and feet, your beautiful posture of expressing feelings and ideas is like flowing sculptures, shocking, and fascinating enough to arouse the viewer's resonance and reverie? Is n't this a one-of-a-kind dance language? The artistic effect of "silence is better than sound at this time" can often be obtained by the visual beauty of the image without saying anything. Dance, in contrast to Chinese national folk dance, transcends cultural boundaries. The inheritance and promotion of Chinese traditional culture, Chinese national temperament, and Chinese classical spirit are primarily reflected in its aesthetic characteristics. Dance beauty is a pleasurable psychological state in which people use their vision, hearing, and other senses to perceive, comprehend, and taste the dance image and spiritual needs. Only those with the ability to appreciate things can generate "aesthetic feelings" in the realm of sound. Aesthetics must also have a certain amount of imagination. Dance, in addition to vertical absorption, horizontally absorbs some characteristics of other art forms, and dance itself is constantly changing and developing, resulting in new developments in the dance inheritance, but it never changes, and the inheritance of Chinese national temperament and dance spirit is always the main vein of dance [2]. The more the life experience is, particularly life experience related to specific works, the more conducive to art appreciation one has. As far as dance appreciation is concerned, the appreciator should also know something about the characteristics, types, styles, and different styles of dance art, which is conducive to the in-depth feeling and comprehension of dance works. Being able to correctly discover, recognize, and evaluate beauty is the basic aesthetic ability to learn dance art. Therefore, in dance teaching, the study of dance aesthetic characteristics is closely related to improving students' aesthetic ability.

Because the RBF neural network model [3] is good at approximating functions, many researchers have begun to use the RBNN approximation model for engineering design. The radial basis function neural network is a feedforward neural network with only one hidden layer that can realize the hidden layer's nonlinear mapping and the output layer's linear mapping. The action function of the radial basis function neural network's hidden layer node generates a local response to the input signal. The hidden layer node produces a large output when the input signal is close to the basis function's central range. According to the RBF neural network model, the RBF neural network's training algorithm is investigated, and the K-means clustering algorithm is used to determine the hidden layer node center, hidden layer node width, and output weight of the network, as well as the network model framework [4]. The impact of the number of hidden layer nodes and distribution coefficient on the accuracy of the RBF neural network model is investigated using an empirical formula and a comparative test method, and the two parameters are finally determined to complete the RBF neural network model's establishment.

The dance focuses on "quietness," "harmony" is the most important, the coordination between breathing and body is emphasized, the harmony and unity between every detail is emphasized, and a kind of harmony and coordination is emphasized in the dance movements. This kind of adduction and harmony of dance comes from the Chinese character, characteristics of "harmony is the most important thing" and "the beauty of neutralization," and it is a highlight of the Chinese nation's aesthetic psychology. Its round, curved, twisted, and inclined posture and circular track of movements can well reflect the Chinese philosophical spirit of repeated cycles and constant renewal [5]. Therefore, with the help of the prediction ability of radial basis function neural network, this paper establishes a neural network model, trains and simulates the network model, studies and analyzes the influence of the changes of influencing factors on the aesthetic characteristics of dance, and provides a new idea for the prediction of the aesthetic characteristics of dance and a reference for optimizing the design of the aesthetic system of dance. Under the radial basis function neural network model, the aesthetic characteristics of dance are mainly embodied in original ecology, where original ecology is relative to performance and folk, and folk is relative to the former court [6]. Folk of dance refers to the folk customs and nationality reflected from dance movements and dance images, and the nationality of dance refers to the common national style, temperament, and spirit reflected from dance movements and dance images. Folk is the foundation of nationality, and nationality is folk. The innovations in this paper are as follows:

(1) This paper constructs the model diagram of radial basis function neural network. RBF neural network model reflects the nonlinear evolution relationship of the overall structure through repeated learning of sample data, so as to predict the unknown data. Therefore, the training sample data are very important for the fitting accuracy and generalization ability of neural network.

(2) The aesthetic characteristics of dance are tested and analyzed. When the time index reaches 50, the average proportion of L-MBP algorithm is 33.4%, the average proportion of RBNN algorithm is 32.5%, and the average proportion of this method is 46.3%. It can be seen that the proportion of this method in the three algorithms is the highest, so it plays a greater advantage in the aesthetic characteristics of dance.

The overall structure of this paper consists of five parts. The first section introduces the background and significance of dance aesthetic characteristics, and then introduces the main work of this paper. The second section mainly introduces the research status of dance aesthetic characteristics at home and abroad. The third section introduces the radial basis function neural network model. The fourth section introduces the aesthetic characteristics of dance and the analysis of the experimental part. The fifth chapter is the summary of the full text.

2. Research Status of Aesthetic Characteristics of Dance at Home and Abroad

So put forward that when people's inner feelings reach the point where language and words cannot express them, they cannot help dancing and expressing their inner feelings. This kind of progressive emotional expression from low to high just reflects that dance, as a "silent art," has surpassed such vocal languages as poetry and music, and has become the highest level of emotional expression, reflecting the strong lyrical aesthetic characteristics of dance art [7]. Habron and Merwe put forward that dance images are mainly figures, animal and plant images, or morphological objects created by dancers through their movements. Image is an important aesthetic feature of dance [8]. Christmas in dance teaching, capturing vivid dance images, is the premise and foundation of dance learning [9]. K. Skjoldager-Nielsen and D. Skjoldager-Nielsen put forward that this dance feature is also the inheritance of ancient Chinese dance. In ancient Chinese dance, people like to get close to the Earth or the site, and the dancers are mainly focused on gaining momentum. Generally, they rarely raise their feet, but move their feet slowly along the intended geometric figure, which is in favor of the ever-changing movements of arms and hands [10]. Lustig and Tan put forward that in dance teaching, it is important for students to understand and master the aesthetic characteristics and types of dance lyricism to improve their aesthetic ability [11]. Anderson put forward that accumulating rich life experience and artistic practice experience, going deep into the folk to carry out art gathering activities, being good at discovering and digging beauty from life, and absorbing rich nutrition from the "root" of dance art are important methods to capture dance images and enhance aesthetic ability, so as to better serve the shaping of dance images [12]. A. Wang and C. Wang proposed that many original ecological folk dances are formed within the same nation due to different branches, geographical distribution, economic status, and cultural development. These seemingly different original ecological folk dances have the nationality of the same nation and reflect the same aesthetic psychology and aesthetic habits [13]. Schuh proposed that the shape of dance occupies space and the melody of music occupies time. The audience's appreciation of dance must first be accepted through vision. Visibility has become a feature of dance aesthetics [14]. Jürgens puts forward that the aesthetic characteristics of ethnic minority dance are mainly embodied in performance, nationality, and folk. Both academic folk dance and ethnic minority dance have the characteristics of performance, nationality, and folk. Their dance movements are derived from the dance movements of original folk dance, which have been processed, refined, integrated, and transcended [15]. Adewale proposed that the aesthetic feature of dance is lyricism. Dance is good at lyricism and bad at narration. Only when poetry, song, and music are not enough to express feelings can we "dance with hands and dance with feet" [16].

Based on the above analysis, this paper puts forward a radial basis function neural network model to study the aesthetic characteristics of dance and then uses the improved optimal stop training method to control the training of these two parameters so that the established prediction model can obtain better generalization ability. Under the radial basis function neural network model, human body movements can only be developed into dance language with dance artistic attributes after people's artistic processing and creation in accordance with the regularity and purpose of dance aesthetic features, and can only become a tool for shaping dance images and a means of expressing dance so that the beauty of dance works can be planed and embodied on this basis. The dance features in the aesthetic features of dance reflect the psychological characteristics of outward development, the belief in God, and the commonness of Western traditional culture. Of course, this psychological feature of outward development is inseparable from the geographical environment in the west. Under the aesthetic characteristics of dance of radial basis function neural network model, the enthusiastic and unrestrained mental state of the actors and the rhythm of their feet with a sense of the times make the audience feel the pulse and rhythm of modern life psychologically, and bring people's thoughts to a brand-new realm, so as to arouse people's inner pursuit of beauty and inspire people's strong love for life, work, and study. The expression in the radial neural network model is the soul of form through facial expressions and body expressions. As the saying goes, "superb" means this. Therefore, in the performance, students should follow the principle of "taking the shape with the spirit," "expressing the spirit with the shape," and "having both the form and the spirit," as well as the artistic law of "taking the lead with the spirit before the body moves, and arriving with the spirit when the shape fails."

3. Radial Basis Function Neural Network Model

3.1. Principle and Algorithm of Radial Basis Function Neural Network. Radial basis function neural network is a feedforward neural network based on interpolation algorithm, which can approximate any nonlinear function with any accuracy [17]. Compared with BP network, the excitation function of RBF neural network is radial symmetric function, which only responds to the input signal locally, so it avoids the problem of long training time and easy to fall into local minimum of BP network. RBF neural network model reflects the nonlinear evolution relationship of the overall structure through repeated learning of sample data, so as to predict the unknown data. Therefore, the training sample data are very important for the fitting accuracy and generalization ability of neural network. When selecting sample data, we pay attention to the following three points:

① The sample data should be widely distributed, covering the whole structure of the problem and fully reflecting the potential law.

② The sample data should be distributed evenly to avoid the phenomenon of too dense local data.

③ Remove the impossible data, so as to prevent it from generating data noise and affecting the convergence of the network.

In the work of multilayer perceptron neural network, the function coincidence is imminent, which is defined by the nested function set of the weighted sum of input and threshold value, and the weight matrix is calculated through recursive iteration, and the output is calculated. Different from other feedforward neural networks such as MLP, the working principle of RBF neural network function fitting is to map the input directly to the high-dimensional space, and then carry out a single linear weighting and output in the output layer, so that the supervision and training time of weights are greatly reduced [18, 19]. In radial basis function neural network, the number of nodes in the input layer is consistent with the input dimension of the learning sample, while the number of nodes in the output layer is consistent with the output dimension of the actual problem. Therefore, once the learning sample is determined, the number of nodes in the input layer and the number of nodes in the output layer are determined at the same time [20]. The input layer node only transmits the input signal to the hidden layer. After the nonlinear transformation of the hidden layer node, the output is generated by the linear function of the output layer node. The neural network model consists of three layers, and its structure is shown in Figure 1.

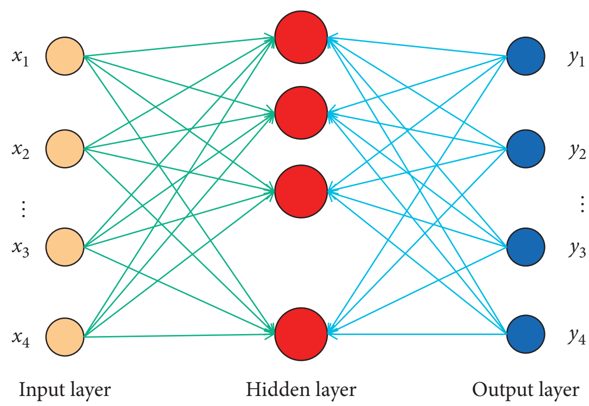

FIGURE 1: Radial basis function neural network model.

The first layer is the input layer, which consists of signal source nodes. The number of input nodes is the dimension of the input sample. Assuming that there are N input samples, each input sample is a I dimension column vector, that is, $X = (x_1, x_2, \ldots, x_1)^T$, and each element of the sample column vector is the node of the input layer. The second layer is the hidden layer, and the number of neurons in the hidden layer varies with the application to be solved. The activation function of each hidden node adopts radial basis function. Radial basis function is a kind of non-negative nonlinear function, which is symmetrical about the center point and attenuates radially, and it has local response function. The third layer is the output layer, which responds to the output of the hidden layer. Assuming that the number of nodes in the output layer is K, this layer maps the hidden layer space to the output layer. Because of the special properties of radial basis function, it has the selective response ability to input variables, which makes RBF network to have the local tuning ability. We take the hidden layer action function as Gaussian function, and the hidden layer output is

$$R_i(x) = \exp\left(-\frac{\|X - C_i\|^2}{2\sigma_i^2}\right), i = 1, 2, \ldots, h, \tag{1}$$

where h is the number of neurons in the hidden layer; $X = (X_1, X_2, \ldots, X_k)$ is the k dimensional input vector; C_i and σ_i are the center vector and width of the ith radial basis function in the hidden layer; $\|\circ\|$ is the 2 norm, representing the Euler distance between X and C_i; and $R_i(X)$ is the output of the i radial basis function. The output of the whole RBF neural network is

$$y_j = \sum_{i=1}^{h} w_{ji} R_j(X), j = 1, 2, \ldots, c_i = 1, 2, \ldots h, \tag{2}$$

where y_j is the output of j neuron in the output layer, and w_{ji} is the connection weight between i neuron in the hidden layer and j neuron in the output layer.

Let MN be the number of hidden nodes, CN be the number of original clusters of samples, and β be the redundancy coefficient of hidden nodes. Its value can be determined according to the network learning situation, and it is generally acceptable as $0 < \beta < 0.5$. The number of hidden nodes of radial neural network can be determined by formula.

$$MN = CN + \beta \circ CN. \tag{3}$$

In order to speed up the training of RBF neural network, it is necessary to initialize the center and width of hidden layer RBF appropriately. The center of hidden layer neurons is intuitively taken as the class mean value. The selection of width takes into account the dispersion of samples within the class and the distance between classes. If the dispersion of samples within the class is large or the distance between classes is large, the width of radial basis function shall be larger; otherwise, it shall be smaller, and its value shall be determined according to the formula.

$$\sigma_i = d_{dj} - d_j^{\text{inner}} = m_i n\left\|C_i - C_j\right\| - \sqrt{\frac{1}{\left|Y_i\right| \sum_{x\in Y}\left\|X - C_i\right\|_i^2}}, \tag{4}$$

where d_{ij} is the distance between class center C_i and C_j, m is the number of classes, d_j^{inner} is the dispersion degree within classes, X is the sample point within class Y_i, and $|Y_i|$ is the total number of samples in class Y_i.

The basic idea of this algorithm is that the response of hidden layer nodes in radial basis function neural network to input depends on the distance between the input vector and the center of hidden layer nodes. The smaller the distance between the input vector and the center, the greater the response of hidden layer nodes. Therefore, the process of determining the hidden layer nodes is the process of clustering the input samples according to the distance between samples. The input vectors with small distance from each other belong to the same category, and the clustering center is the center of the hidden layer nodes. Different network structures and weight training algorithms lead to different characteristics and application functions of the network. At the early stage of neural network development, the network structure was simple, with only input layer and output layer, and its application was single. The emergence of multilayer neural networks [21–23] is the inevitable result of the development of neural networks [24]. Besides the input layer and the output layer, the middle layer of the multilayer neural network is called the hidden layer, which can be one or more layers. The radial basis neural network is composed of radial base layer and linear output layer, and the first layer is radial base layer, which is composed of radial basis neurons. The second layer is a linear output layer composed of linear neurons. The structure diagram of radial neural network model is shown in Figure 2.

In Figure 2, R is the dimension of the input vector, S^1 is the number of neurons in the radial base layer, S^2 is the number of neurons in the linear output layer, and $\mathrm{IW}_{1,1}$ represents the $\mathrm{IW}_{1,1}$ row element of the weight matrix i. $\|\mathrm{dist}\|$ is the Euclidean distance between the input vector P and the weight matrix $\mathrm{IW}_{1,1}$, so the output vector consists of S_1 elements, which are the distance between the input vector P and the vector $\mathrm{IW}_{1,1}$ composed of the row vectors of the input weight matrix.

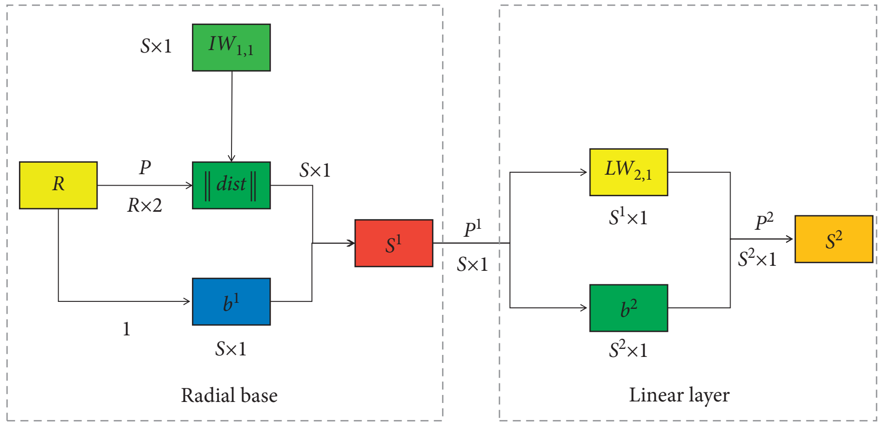

Figure 2: Structure diagram of radial basis function neural network.

The expression of radial neuron transfer function is shown in formula.

$$a = \text{radbas}\,(n) = \exp\left(-n^2\right). \tag{5}$$

The input n of the transfer function is the product of the weighted input $\|w - P\|$ and the offset b, w is the weight vector of the radial basis function neuron, and p is the input vector. The distribution coefficient SPREAD of radial basis function is defined as $0.8326/b$, so the output a of radial basis function neurons can be expressed as follows:

$$a = \text{radbas}\left\{0.8326 \times \frac{w - p}{\text{SPREAD}}\right\}. \tag{6}$$

When $\|w - p\|$ is equal to SPREAD, n is 0.8326, and the output a of neurons is exactly 0.5. When $\|w - p\|$ is greater than SPREAD, neurons will produce less than 0.5 output; when $\|w - p\|$ is less than SPREAD, neurons will produce an output higher than 0.5. The above is the mathematical significance of radial basis function distribution coefficient.

In order to facilitate processing, we use root mean square error (RMSE) to describe the average level of Q cross-validation errors

$$\text{RMSE} = \sqrt{\frac{1}{Q}\sum_{\text{i}=1}^{Q} cve_i^2}. \tag{7}$$

To sum up, when the training sample is given, the root mean square error (RMSE) is actually a function with the distribution coefficient SPREAD as the independent variable.

v_i represents the i element of vector v, and M_i represents the i row of matrix M; then, there is the following relationship:

$$n_i^1 = \left\|\left(\text{IW}_i^{1,1}\right)^T - p\right\| b_i^1;\, i = 1, \ldots, S^1, \tag{8}$$

$$a_i^1 = \text{rabdas}\left(n_i^1\right);\, i = 1, \ldots, S^1, \tag{9}$$

$$y_i = a_i^2 = \text{IW}_i^{2,1};\, a^1 + b_i^2;\, i = 1, \ldots, S^2. \tag{10}$$

It can be seen from the above formula that for a given input vector p, the output vector FF of RBF neural network can be completely determined according to $\text{IW}^{1,1}$, b^1, $\text{LW}^{2,1}$, b^2, and y.

The RBF neural network maps the input to the high-dimensional space by calculating the functional of the distance function between the input and the point in the hidden layer; that is, it completes the mapping by activating the function. The activation function is the basis function, which is radially symmetrical about a central point of the dimensional space. The activation degree of the input at the hidden layer neuron has a strong correlation with its distance from the middle, so this hidden layer node has "local characteristics."

3.2. Characteristics of Dance Beauty. Dance art is a comprehensive art that includes lyricism, movement, and image. To better understand dance, we must not only improve our aesthetic ability in dance but also our aesthetic ability in related arts. This will allow us to better appreciate the formal beauty of dance. Dance's history reveals that it coexists with human history and keeps pace with human social development, which is why it is so popular. As a result, its purpose is socially significant. Many countries now include dance in their school curricula. Dance classes have been offered in some university elective courses, which are very popular with young students, despite China's late start. It demonstrates that people's perceptions of dance's social function have been greatly enhanced. Nowadays, high speed and efficiency are valued in modern civilized life. The information society and the electronic world are icons of the industrial era, and they have had a significant influence on the original dance form. People prefer strong, powerful, heroic, and confident dancing when this psychological factor is in control. They perform a series of complex dance steps in a short amount of time, including rapid and colorful rotation, and rapid twisting. At the same time, people's aesthetic feelings about dance works are inextricably linked to the beauty of dance; however, people's subjective feelings must be grounded in the objectively existing beauty of dance, which must possess the basic characteristics of originality, craftsmanship, and comprehensiveness. This kind of originality is the result of a lot of sweat and hard work, and it is attained through a lot of hard study and exploration, even after a lot of failures. All of this reflects a spiritual beauty, and it is admirable. The created dance image can give people an aesthetic feeling, and this unique skill is beyond the reach of ordinary people.

In a dance work, first of all, it should have aesthetic characteristics such as originality, skill, and comprehensiveness, so as to give people a feeling of dance beauty, be loved by people, and be called excellent dance works. "Form and spirit, spirit and rhyme" is to analyze the aesthetic characteristics of dance movements through the research category of dance aesthetics, and it shows that the improvement of dance aesthetic ability plays an important role in teaching. Dance expresses thoughts through the moving human body, and the human body movements are linked by emotional logic. Like poetry and music, it has the structural method of literary thoughts. The structure of the article is words, words, sentences, paragraphs, and chapters, and the structure of dance is dancing, dancing, dancing, dancing, and dancing. Although in the long history, poetry, music, and dance have gradually taken an independent development path, and their respective artistic characteristics have been relatively highlighted, their internal relationship, that is, comprehensiveness, has never been interrupted or independent, and they have always maintained a state of "you and me" or "you and me." For dance, this phenomenon is more obvious and prominent.

As the external form of dance beauty, after having the artistic attribute of dance, the dance image must also go through the comprehensive development of dance aesthetic creation, that is, the integration of dance, music, poetry, and other different arts, so as to better understand the aesthetic attribute of dance, and finally complete the aesthetic of dance. Dance is embodied by a unique rhythm of "force." The movement of dance is the movement of "Qi." It is the rhythm of "force" of human body's "Qi" sensing the "Qi" of the universe. All dances should use the internal "Qi" to show the external "force." With the help of the research on the aesthetic characteristics of dance, this paper demonstrates the important role of dance aesthetic ability in dance teaching, which can provide some enlightenment to the theory and practice of dance teaching. There is a lack of exploration and innovation in artistic conception and artistic expression; that is, there is no originality; instead, the old routine is adopted in a light and familiar manner or in a conventional manner, and the performance is the theme and content that we have seen and understood for a long time. There will be no new ideas for people, and bringing beauty to people is impossible. As a result, dance must possess unique aesthetic characteristics. Dance serves as a vehicle for moral and emotional education. Real, kind, and beautiful feelings, wishes, and ideals of choreographers and dancers are reflected in the pleasing dance image. It has a subtle positive effect, cultivating people's temperament, evoking noble sentiment, inspiring emotion, inspiring fighting spirit, and so on. Because dance is a form of art in which human body movements are the primary means of expression, it is unavoidable that the means of expression of dance become more artistry as the scope of dance performance subjects and the depth of the theme content expands. The colorful life content and rich characters' inner world can only be fully displayed through a high level of artistry. These characteristics are often integrated and penetrated into each other in an excellent dance work, but they are sometimes hidden and sometimes prominent. However, a close examination reveals that these qualities are present in excellent works as well and that they are interdependent or inseparable.

4. Simulation and Results

4.1. Determination of the Number of Hidden Layer Nodes. In order to establish an ideal dance aesthetic feature model, the commonly used method of gradually increasing the number of hidden layer nodes is adopted to adjust the neural network, and 30, 70, and 120 hidden layer nodes are selected for experiments, respectively, and then, the mean square error between each output variable and the real value is calculated. Tables 1–3 show the mean variance of the output values of the three networks.

From Tables 1 to 3, it can be seen that the fitting accuracy of training data is higher and higher with the increase in hidden layer nodes. When the number of hidden layer nodes is the same as the number of training samples, the fitting error of the network to the training set reaches 0. But at this time, the prediction accuracy of the three dance aesthetic feature test sets is not high. However, because the proportion of dance aesthetic feature training samples in the total data is not large, and its absolute accuracy is not low, the interval of the number of hidden layer nodes can be preliminarily determined.

Table 1: Mean square error of 30 hidden layer nodes.

30	Test 1	Test 2	Test 3	Train
L	4.0276	4.3147	6.582	2.9947
A	5.051	4.4913	5.4983	3.2176
B	5.6398	5.7176	7.8707	3.3521

Table 2: Mean square error of 70 hidden layer nodes.

70	Test 1	Test 2	Test 3	Train
L	2.6595	1.9798	2.5888	0.5702
A	3.0583	2.7625	3.1556	0.97
B	3.5221	2.9441	4.1052	1.0325

Table 3: Mean square error of 120 hidden layer nodes.

120	Test 1	Test 2	Test 3	Train
L	0.9653	1.0663	1.225	0.1925
A	1.2467	1.1262	1.3702	0.2345
B	1.3062	1.3823	1.5531	0.2244

4.2. Analysis of Aesthetic Characteristics of Dance. In this experiment, L-MBP algorithm, RBNN algorithm, and this method are used to compare the aesthetic characteristics of dance, and the calculation results of RBNN approximate model are attached in Figure 3. The initial weights of FNN are randomly generated, and the set initial weights directly affect the final training results. The experimental results are shown in Figure 3.

As can be seen from Figure 3, when the conditions other than the initial weight under the aesthetic characteristics of dance are the same, the values of FNN approximate model based on L-MBP algorithm vary greatly; by contrast, when the training sample of dance aesthetic characteristics is given, the quality of RBNN approximate model is only related to the value of distribution coefficient. Once the value of spread is determined, the RBNN approximate model and its values will be completely determined. The RBF neural network model predicts the aesthetic characteristics of dance; that is, the principal component score coefficient is used to calculate the principal component value, and the data of dance aesthetic characteristics are normalized; finally, L-MBP algorithm, RBNN algorithm, and this method are used to establish the RBF neural network of dance aesthetic features in the mapping relationship, which constitutes the proportion of PCA-RBF network. The experimental results are shown in Figure 4.

As can be seen from Figure 4, when the time index reaches 50, the average proportion of L-MBP algorithm is 33.4%, RBNN algorithm is 32.5%, and the average proportion of this method is 46.3%. It can be seen that this method accounts for the highest proportion of the three algorithms, so it plays a greater advantage in the aesthetic characteristics of dance. In order to verify the advantages of radial basis function neural network over other networks, this paper constructs PCA-BP network and uses machine learning, decision tree algorithm, and this method to repredict the aesthetic characteristics of dance. Similarly, 2~20 groups of data are used as training samples, and 22~26 groups of data are used to evaluate and test the model. The test simulation results of soft sensor model are shown in Figure 5.

As can be seen from Figure 5, when the time index reaches 60, the average ratio of machine learning algorithm is 44.3%, that of decision tree algorithm is 49.5%, and that of this method is 57.8%. Similarly, the change of this method in the training of dance aesthetic feature errors among the three algorithms is the highest, which proves the feasibility and accuracy of this method. In the experiment, we use the proposed EDIW-PSO algorithm, LDIW-PSO algorithm, NDIW-PSO algorithm, and GLBESTIW-PSO algorithm to optimize the RBF neural network, train the training samples, and obtain the fitness function curves of the four optimization algorithms. When the fitness function reaches the

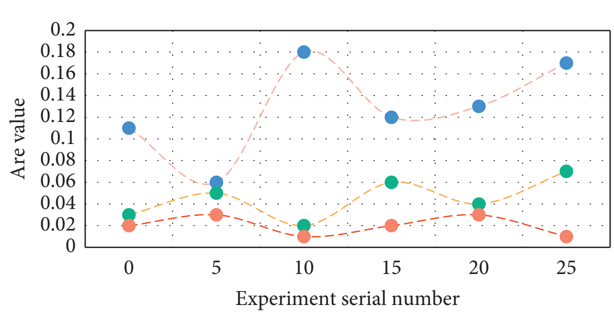

Figure 3: Comparison results of approximate models of dance aesthetic characteristics.

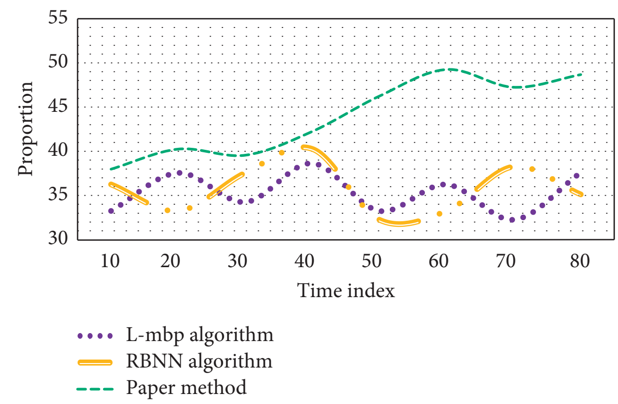

Figure 4: Error curves of dance aesthetic characteristics under different algorithms.

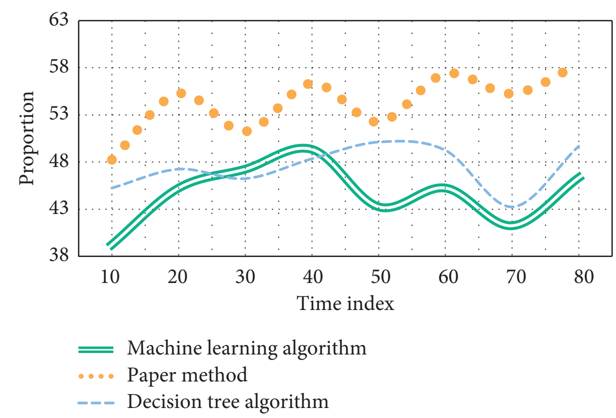

Figure 5: Training curve of dance aesthetic characteristic error under different algorithms.

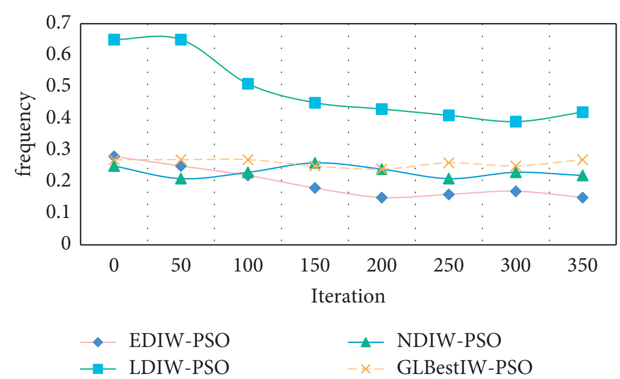

Figure 6: Fitness function curve.

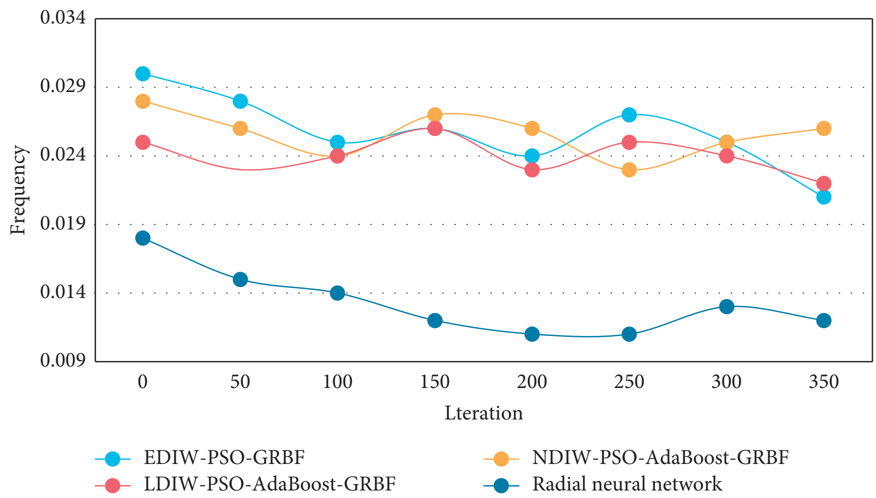

Figure 7: Fitness change of dance aesthetic characteristics of four models fitting two-dimensional nonlinear function.

minimum value, the optimal parameter value of neural network obtained by algorithm optimization is shown in the table. The fitness function curves of the four optimization algorithms are shown in Figure 6.

As can be seen from Figure 6, among the four methods, the PSO algorithm, which is an exponential declining inertia weight strategy, has a faster convergence rate, the smallest fitness function value, and the smallest training error of the neural network. The formal beauty of dance art is relatively independent, and formal beauty is one of the common forms of common beauty, which is most likely to cause a common sense of beauty, and the popularity of dance works is also likely to cause people's common sense of beauty. Because of the existence of common aesthetic feeling, good works can transcend national and national boundaries and reflect people's common interests, life ideals, and psychological needs. In this experiment, the changes of dance aesthetic feature fitness function fitting two-dimensional nonlinear function of four models are compared experimentally. EDIW-PSO-GRBF model, NDIW-PSO-ADABOOST GRBF model, LDIW-PSO-ADABOOST GRBF model, and radial basis function neural network model in this paper are used for experiments, respectively. The experimental results are shown in Figure 7.

As can be seen from Figure 7, the radial basis function neural network model in this paper has the fastest convergence speed, and the global optimal solution searched is better than the other four models, with smaller training error. The subjectivity embodied in aesthetic judgment created aesthetic comprehension's subjectivity. Aesthetic comprehension's subjectivity, as a form of rationality, is based on objectivity, but at the same time, it is latent and fuzzy.

5. Conclusions

The purpose of the rhythm of movements in dance works is to investigate the rhythm of dance by drawing inspiration from natural phenomena such as river, lake, and sea fluctuations, as well as the flashing of stars in the universe and the swaying of weeping willows by the lake. As a result, we must be adept at recognizing and learning the beauty and inner spirit of rhythm. Based on the RBF neural network model, this paper investigates the aesthetic characteristics of dance. When the time index reaches 50, the average proportion of L-MBP algorithm is 33.4 percent, 32.5 percent for RBNN algorithm, and 46.3 percent for this method. As can be seen, this method has the highest proportion in the three algorithms, so it has a greater advantage in the aesthetic characteristics of dance. The more difficult it will be, the higher the RBF neural network model's skill in dance performance. This is not something that ordinary people can do, which just goes to show how unique dance is in terms of innovation and creativity. With the ever-changing nature of life, dance art will change, develop, and improve, and will play a role in the construction of both material and spiritual civilizations. The simulation of surgery in the radial basis function neural network model can make people happy. On the contrary, the form of simulation content is changing and even deepening with the advancement of society and human civilization. The mode of production, lifestyle, and ideology is changing, much like China's transition from an agricultural to an industrial society, and the dance form and content of the aesthetic characteristics of dance are bound to change as well.

British and American literature is a compulsory course for English majors in Chinese colleges and universities. It plays an important role in cultivating students' aesthetic consciousness and moral cultivation, improving students' humanistic quality and cultural taste, and shaping students' complete personalities. With the rapid development of cloud technology and mobile Internet technology, mobile learning based on mobile devices will become an important direction of mobile Internet technology applications. Based on cloud computing, this paper studies the construction of digital teaching resources of the British and American literature. Through the experiment on the learning simplicity of literature courses for English majors, it is found that during the learning period of 40 people, the average proportion of the most difficult is 16.3%, the average proportion of the second difficult is 35.2%, and the average proportion of the easier is 18.5%. Compared with the next difficulty, the proportion of difficulty is the highest, followed by the easy and finally the most difficult. As one of the core technologies of cloud computing, data split storage technology adopts measures such as isomorphism and interchangeability of computing nodes, redundant storage, and multicopy fault tolerance to ensure the high security and reliability of user data and users do not have to worry about data loss and virus invasion. As a new generation of technical means, cloud computing can realize the unified management and scheduling of distributed and heterogeneous resources and provide a new development direction for promoting the coconstruction and sharing of the British and American literature digital teaching platforms in higher vocational colleges and truly realizing national learning and lifelong learning.

1. Introduction

British and American literature, as a required course for Chinese English majors in their third year, serves a critical function in broadening students' cultural horizons and cultivating high quality. It is critical in developing students' aesthetic consciousness and moral development, as well as strengthening their humanistic quality and cultural taste and forming their entire personality [1, 2]. The authorized curriculum of the postgraduate entrance test for English majors includes British and American literature. In recent years, this course's information has been included in the CET8 test content [3]. There are a variety of causes for the marginalization of British and American literature at colleges and universities, but there are two major reasons. It is a result of the contemporary mercantilist social climate. Some colleges and universities continue to add practical and effective Applied English courses such as business English, economic and trade English, financial English, legal English, and computer English when teachers are strictly prohibited in order to reduce the number of class hours of English and American literature courses as much as possible [4, 5]. Students dig deeper into and investigate the contents of literary works, fully integrating the collected information into their English knowledge system. They enhance their English level in addition to enhancing their literary literacy [6].

Mobile learning based on mobile devices will become an important path for mobile Internet technology applications with the rapid growth of cloud technology and mobile Internet technology. Based on the cloud platform, the mobile digital resource platform mines related learning needs and habits using cloud computing technology's storage space and data analysis capabilities [7, 8], allowing students and teachers to access the network resource cloud service platform and obtain resources at any time and from any location. The process of data processing is relocated from personal computers or servers to computer clusters on the Internet, which is dubbed "cloud" [9], using the high-speed transmission capabilities of cloud computing on the Internet. Cloud computing has accelerated the evolution of information technology and IT application mode, fundamentally altered working and business modes in the traditional mode, and increased resource utilization and computing speed, simplifying software, business processes, and access services. Cloud computing provides computation, services, software, and other services to a large number of users at the same time, and maintaining data security is the foundation for gaining consumers' trust. Data sharing storage technology, as one of the core technologies of cloud computing, employs features [10, 11] such as isomorphic and interchangeable computing nodes, redundant storage, multicopy fault tolerance, and other features to ensure that user data are secure and reliable, and users do not have to worry about data loss or virus intrusion [12, 13]. The core objective of cloud computing is to share the processing and storage resources of each node in the cloud, to deliver to end-users, and to take the required computer resources as its main role. Cloud computing will inevitably find its way into more and more digital teaching tools for British and American literature [14, 15]. In the cloud computing mode, by building a common cloud platform for digital teaching resources of British and American literature, the links within schools, between schools, and between schools and enterprises can be closer, and educational information resources can be effectively integrated and shared. With this platform, schools and enterprises can also effectively save human and material resources, realize resource complementarity, and promote two-way cooperation. As a new generation of technical means, cloud computing can realize the unified management and scheduling of distributed and heterogeneous resources so as to provide a new development direction for promoting the coconstruction and sharing of British and American literature digital teaching platforms in higher vocational colleges and truly realizing national learning and lifelong learning.

This article studies and innovates the above problems from the following aspects:

(1) A cloud server model of English and American literature digital teaching resources based on cloud computing is proposed. The digital teaching resource base based on cloud computing also reduces the difficulty of operation, and users can easily use the resource base without mastering complicated software operations. Digital resources store information in data centers to meet the needs of students and teachers; memory management is used to organize and manage data from cloud service end to mobile client application end; the management layer realizes the interaction between security control and memory management through the cloud management platform.

(2) A digital teaching resource construction system of British and American literature based on cloud computing is constructed. Through the digital teaching resources construction system of British and American literature, a resource information database and a resource catalogue database are established to manage resources and provide support for the rapid retrieval of resources. Because resources need to be shared with different databases, it is necessary to establish common technical standards and build database platforms according to the same specifications to prevent data incompatibility.

The article is divided into five parts, and the organizational structure is as follows: Section 1 introduces the research background and present situation of digital teaching resources of British and American literature and puts forward and summarizes the main tasks of this paper. Section 2 introduces the related work of digital teaching resources of British and American literature at home and abroad. Section 3 introduces the algorithms and models of cloud computing. Section 4 introduces the realization of the digital teaching resources of British and American literature and compares the performance of the system through experiments. Section 5 is the full-text summary.

2. Related Work

2.1. Research Status at Home and Abroad. Zhang L et al. put forward that there are many problems in the teaching materials of British and American literature. First, most of the teaching materials are of single style and not readable, which is difficult to attract students' interest; second, the replacement speed of teaching materials is too slow. Many teaching materials are old in content and viewpoint, which can not meet the students' desire to know the latest things; third, the textbook pays too much attention to the indoctrination of knowledge and lacks enlightenment, ignoring the cultivation of students' intelligence and ability [16]. Li proposed that the purpose of literature course is to cultivate students' ability to read, appreciate, and understand the original works of English literature, master the basic knowledge and methods of literary criticism, improve students' basic language skills and humanistic quality through reading and analyzing British and American literary works, and enhance students' understanding of western literature and culture [17]. Yi proposed that the construction of a digital teaching platform of British and American literature can integrate the existing human resources and academic resources, use the huge text, video, and audio information to increase students' knowledge, cultivate students' correct learning methods, and improve learning efficiency. In turn, it can enable students to join the classroom teaching links and the construction of a digital teaching platform, highlight their subjectivity and exercise their reading ability, scientific research ability, and expression ability [18]. Shan proposed that in view of the problems existing in the current British and American literature course, I think it is necessary to make use of the current rich network resources and use modern teaching methods to improve the teaching effect of the British and American literature course, so as to play its due role in higher education and get rid of its marginalization [19]. Ma and Bo proposed to improve students' basic language skills and humanistic quality and enhance students' understanding of western literature and culture by reading and analyzing British and American literary works [20]. Campbell put forward that it is necessary for teachers to optimize and reform the existing teaching mode of British and American literature, make full use of modern educational technology and network multimedia, update teaching contents, improve teaching efficiency, and cultivate students to master effective learning methods [21]. Al-Zoube et al. pointed out that some teachers of English and American literature courses started to use multimedia in the teaching process, but many of them just showed the contents of textbooks in the form of courseware. This kind of "textbook moving" courseware did not give full play to the advantages of multimedia, so it was not attractive [22]. Hwang and Li put forward the compiling characteristics of foreign English and American literature textbooks, analyzed the shortcomings in domestic textbooks, and put forward corresponding reform suggestions [23]. Yang pointed out that the contents of most English and American literature textbooks are relatively outdated, but the use of network resources can make up for this deficiency. Teachers can collect, download, and sort out some resources to meet students' needs from the Internet and selectively integrate the latest contents and research results of British and American literature into the lecture notes in time [24]. Li pointed out that literary appreciation ability, cross-cultural ability, and critical thinking ability are essential basic abilities for foreign language majors. Whether students have these abilities depends largely on the quality of teaching materials used in literature courses and the teaching effect on teachers and students [25].

2.2. Research Status of Digital Teaching Resources of the British and American Literature Based on Cloud Computing. This article analyzes the construction of digital teaching resources of British and American literature under cloud computing, the opportunities, and challenges faced by British and American literature teaching in Chinese universities and discusses how to reform the teaching mode and improve the teaching efficiency under cloud computing. Building and sharing a British and American literature teaching resource library using cloud computing technology is critical for China's talent development so that high-quality educational resources may be popularized and more students can benefit from them. It is difficult for pupils to understand abstract concepts solely through linguistic interpretation during the educational process. Cloud computing technology can help concretize abstract ideas and simplify complex situations, allowing you to achieve twice the outcome with half the effort. The use of cloud computing technology, on the other hand, offers teachers with a new digital teaching resource teaching system of British and American literature, which encourages teachers to challenge traditional teaching notions and promote constant innovation in all parts of education. Improving their English language skills is also conducive to creating a literary learning atmosphere integrating knowledge and interest, stimulating their interest in learning, and cultivating their autonomous learning habits. Therefore, the teaching of British and American literature can fully reflect its humanistic knowledge and improve its teaching quality.

3. Algorithm and Model of Cloud Computing

Cloud computing is a network made up of a large number of computers that can offer consumers the necessary computer services. This supercomputing mode reflects the future development trend of computer applications and is the newest development achievement of distributed computing, parallel computing, and grid computing in the field of computer science. "Computing" refers to a "computing resource pool" in cloud computing, while "cloud" refers to multiple networks that provide resource services. Cloud computing service providers are in charge of virtualized device management and operation, as well as dynamic resource deployment, real-time scheduling, and autonomous recycling, among other things. Virtualization technology is used to make cloud computing a reality. In general, the computer element runs on a real basis, but in virtualization technology, the computing element runs on a virtual basis. Cloud computing resources are always developing dynamically, and different computer terminals can add different types of information to the cloud for other users to download and share. End consumers do not need to understand how the cloud works, let alone have expert knowledge, and everything is as simple as connecting to the Internet.

Cloud services can govern and administer a vast number of educational information resources with the use of cloud computing. Any learner requires only a cloud-connected computer or a mobile terminal device that operates on a 3G or WiFi network. In any place and at any time, they can get the learning resources and services he needs from the cloud resource library in real time. They can also use cloud resources to debate a specific problem with teachers and specialists, making virtual network learning a reality. The operating difficulties are also reduced by the digital instructional resource library based on cloud computing. The resource library is simple to use and does not need users to grasp sophisticated software processes. The user interface is welcoming, and the experience is very humanized, which can help to boost the learning effect significantly. The following are the basic components of the mobile digital cloud server: The data center's information is stored in digital resources, which are used to suit the demands of students and teachers. From the cloud service to the mobile consumer application, memory management is used to organize and manage data. Through the cloud management platform, the management processing layer accomplishes the connection between security control and memory management. The cloud server model of digital teaching resources of British and American literature is shown in Figure 1.

Allocate virtual machines to each application according to the resource vector $R = (R_1, \ldots, R_j, \ldots, R_c)$ allocated to each application output by the application monitoring program module so as to minimize the total allocation cost. In other words, the purpose of this module is to assign the virtual machine of each application that minimizes the objective function as follows:

$$C = \min\left(\sum_{i=1}^{m} \cos t \cdot N_i\right), \tag{1}$$

where m is the number of applications, $\cos t$ is the operation cost vector of virtual machines, each item corresponds to the allocation cost of each type of virtual machine, N_i is the virtual machine vector allocated to application i and $N_i = (n_{i1}, \ldots, n_{ij}, \ldots, n_{ic})$, n_{ij} is the number of j-type virtual machines allocated to application i, and $\cos t \cdot N_i$ represents the cost of allocating virtual machine vector N_i to application i.

According to the assumption in this article, the number of each type of virtual machines in the data center is limited; that is, there is an upper threshold. The threshold vector of each type of virtual machine is defined as $N^{\max} = (n_1^{\max}, \ldots, n_j^{\max}, \ldots, n_c^{\max})$ and has the following relationship:

$$\sum_{i=1}^{m} n_{ij} \le N_j^{\max}, \quad 1 \le j \le c. \tag{2}$$

The number of resources allocated to each application should meet the resource requirements determined by the application monitoring module, namely,

$$\begin{aligned} &\sum_{j=1}^{c} n_{ij} \cdot V_j^{CPU} \ge R_i^{CPU}, \quad 1 \le i \le m, \\ &\sum_{j=1}^{c} n_{ij} \cdot V_j^{\text{memory}} \ge R_i^{\text{menory}}, \quad 1 \le i \le m, \\ &\sum_{j=1}^{c} n_{ij} \cdot V_j^{\text{network}} \ge R_i^{\text{network}}, \quad 1 \le i \le m. \end{aligned} \tag{3}$$

At the same time, the total resources of all virtual machines deployed on physical machines cannot exceed the total resources of all physical machines, so there is the following relationship:

$$\begin{aligned} &\sum_{i=1}^{m}\sum_{j=1}^{c} n_{ij} \cdot V_j^{CPU} \le \sum_{j=1}^{n} p_j^{CPU}, \\ &\sum_{i=1}^{m}\sum_{j=1}^{c} n_{ij} \cdot V_j^{\text{memory}} \le \sum_{j=1}^{n} p_j^{\text{memory}}, \\ &\sum_{i=1}^{m}\sum_{j=1}^{c} n_{ij} \cdot V_j^{\text{network}} \le \sum_{j=1}^{n} p_j^{\text{network}}. \end{aligned} \tag{4}$$

By solving the above model with the constraint method, we can get the virtual machine allocation vector with the lowest total cost, and each virtual machine allocation vector corresponds to the virtual machine allocation situation of each application, that is, what kind of virtual machines are allocated and the number of virtual machines allocated.

Therefore, a teaching resource model with the best energy consumption of heterogeneous servers can be established:

$$\text{minimize} \sum_{i \in P}\left(H_i \cdot E_i^{\text{dynamic}} + E_i^{\text{static}}\right), \tag{5}$$

where E_i is the energy consumption of physical server p_i. It can be concluded that the constraints on energy consumption are

$$E_i^{\text{static}} + H_i \cdot E_i^{\text{dynamic}} \le E_i^{\text{Max}} \, (1 \le i \le n). \tag{6}$$

Among them, E_i^{Max} is the maximum energy consumption that physical server p_i can bear; that is, the actual energy consumption of the physical server p_i must be less than or equal to E_i^{Max}.

Cloud computing provides resources, services, and platforms for users. It can provide users with safe, convenient, and efficient services as needed at any time, anywhere, and anyway. It has the characteristics of superscale, safety and reliability, on-demand service, and strong versatility. Cloud computing is a service-centered networked computing resource sharing pool. The main body of its architecture includes the application layer, platform layer, infrastructure layer, and virtualization layer, which provide software as a service, platform as a service, and infrastructure as a service, respectively. On-demand access through service support. In addition, the client and management together constitute the architecture of cloud computing. The architecture of cloud computing is shown in Figure 2.

The architecture of cloud computing is mainly divided into six layers:

① Application layer

In the application layer, services are provided through software applications, which interact with the client through web service and other technologies to realize the corresponding functions.

② Platform layer

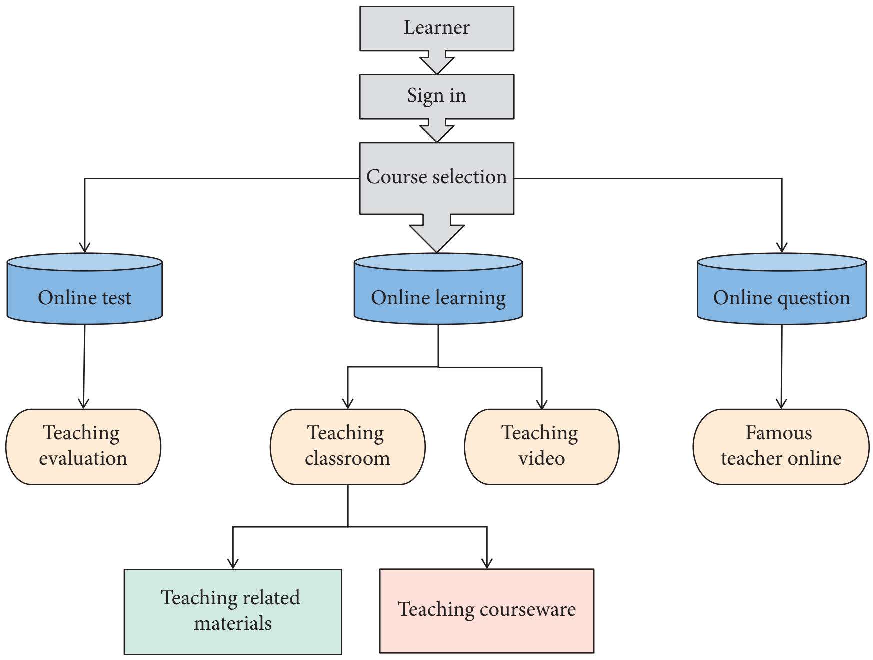

FIGURE 1: Cloud service model of British and American literature digital teaching resources.

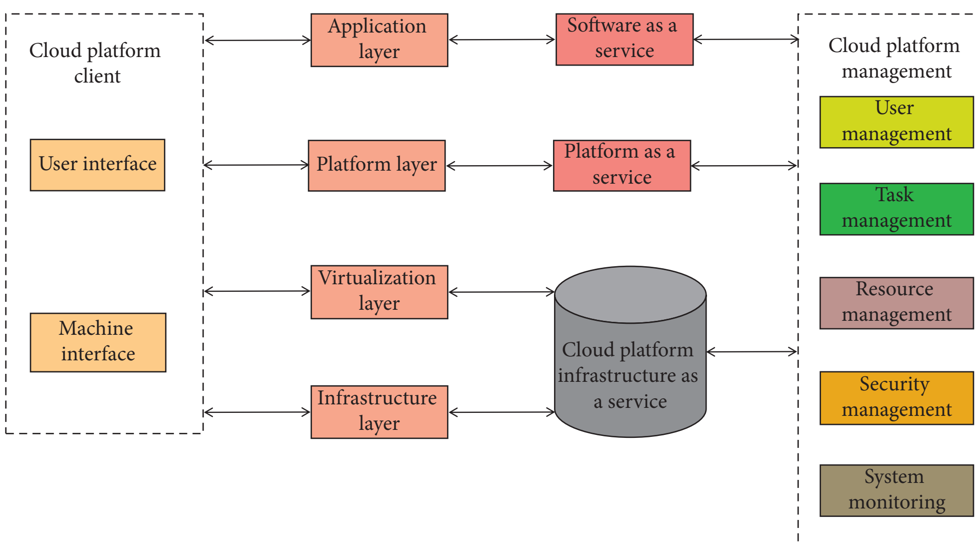

FIGURE 2: Architecture of cloud computing.

Based on the virtualization layer, the platform layer plays an important role in connecting the preceding and the following. It is responsible for responding to the requests sent by the application layer, using distributed technology to process massive data in parallel, dynamically allocating various resources of the virtualization layer according to the requests, and providing platform services is a key step to improving efficiency.

③ Virtualization layer

The virtualization layer is based on the infrastructure layer, which virtualizes the resources provided by the infrastructure layer. It can also be understood as the "multitenant" of the infrastructure layer, which makes efficient and rational use of the resources provided by the infrastructure according to the processing needs sent by the platform layer.

④ Infrastructure layer

The infrastructure layer provides the necessary resources for the virtualization layer, including software resources, network resources, and hardware resources. This layer can expand and optimize management based on the database.

⑤ Client

The client is used for human-computer interaction, including user interface and machine interface.

⑥ Management

The management manages the as a service at all levels. Through good user management technology, users can quickly log in under safe conditions and facilitate the unified management of accounts by administrators. Resource management is the overall allocation of all resources.

Cloud computing is to centralize computers in different parts of the country and realize collaborative work through the network. Users can get the services they need only through the network. In this way, there is no need to add a lot of computer hardware equipment and install various software programs for certain needs, which directly saves a lot of costs. Cloud computing users will have their own resource requirements. In order to make the resources requested by users run, it is necessary to allocate the specific resources requested by users to them. Typical cloud computing resource provision strategies include the strategy based on lease theory and dynamic multilevel resource pool, the strategy based on economics college, the strategy based on general optimization algorithm, and the optimal strategy based on random integer programming.

4. The Construction and Realization of Digital Teaching Resources of the British and American Literature

4.1. Teaching Resource Construction System under Cloud Computing. After the learner is authenticated and authorized, the cloud platform analyzes the learning contents of the digital teaching resources of British and American literature according to the learner's historical track and displays them in a list, thanks to the cloud platform's data analysis and processing capability. It may learn at any time and from any location, which is incredibly handy for students and teachers and boosts their efficiency. Many large network companies have now developed a number of relevant processes and standards to ensure customer data security, provided various solutions for schools based on their needs, built a cloud platform that meets the needs of schools, and created a private "public resource cloud" for schools to better serve their teachers and students. You may also specify multiple levels of permissions to link with external units to create a "hybrid cloud" that allows you to share resources. The operating system and computer hardware are targeted for virtualization in the instructional resource creation system platform. Application virtualization includes simulation, simulation, and interpretation technology. Resource virtualization focuses on specific system resources such as network resources, storage, and memory; resource virtualization focuses on specific system resources such as network resources, storage, and memory. Virtualization technology optimizes resource use and eliminates resource waste. Both software and hardware are capable of performing well. Computers solve real problems at a far faster rate. Light resources, accessible resource deployment, diversified resource channels, ubiquitous resource acquisition, and speedy resource browsing should be characteristics of the cloud-based digital teaching resources development system for British and American literature. On the basis of knowledge deconstruction, lightweight development of teaching resources is carried out to fulfill the needs of fragmented learning, MOOC teaching, and flipped classroom. The particle size of resources not only follows the instructional principles but also helps with network transmission. We should take full advantage of the resource pool's openness and boost its interactivity when building a cloud-based system of digital teaching tools for British and American literature. Despite the fact that the cloud stores a wide range of educational and teaching resources, users may quickly access them and set up storage, editing, calling, querying, and downloading. It is the primary driving factor behind the English and American literature digital teaching resource creation system. The construction will lack scale if the application scope is too narrow; the promotion will be worthless if the application is ineffective.

The building and application of digital teaching resources must be led by the construction and improvement of British and American literary resources, which should begin with the construction and improvement of British and American literature resources and formulate a professional curriculum system based on the professional talent training plan, which includes professional core courses, professional support courses, and expansion courses. Professional core courses are those that reflect professional core competencies, while professional support courses are those that provide support and basic support to the core courses. The efficient management of digital teaching resources in the resource cloud for British and American literature plays a critical role in increasing user experience and promotion effect. Rapid resource retrieval, fair resource scheduling, resource approved access, and so on are all aspects of management. The resource information database and resource directory database are established through the digital teaching resource construction system of British and American literature to manage resources and give support for speedy resource retrieval. Because separate databases must share resources, consistent technological standards must be established and a database platform built to the same specifications to avoid data incompatibility. Because the digital teaching resource construction system based on cloud computing for British and American literature is still in its early stages of development and research, the technology is not fully mature, and various standards are not fully unified. It is critical to establish corresponding technical specifications.

4.2. Experimental Results and Analysis. In this experiment, the students' interest and liking for digital teaching resource databases were investigated, and the interest and liking of secondary vocational school students for digital teaching resource database were basically the same. The degree of students' interest in the resource pool is shown in Table 1. The degree of students' liking for the resource pool is shown in Table 2.

Table 1: Questionnaire on students' interest in the resource database.

Degree	Very interested	Be interested	Commonly	Uninterested
Number of people	425	204	56	34
Proportion	58.8%	28.3%	7.8%	4.7%

Table 2: Questionnaire on students' preference for resource database.

Degree	Like it very much	Like	Commonly	Dislike
Number of people	397	222	67	33
Proportion	55.2%	30.7%	9.3%	4.6%

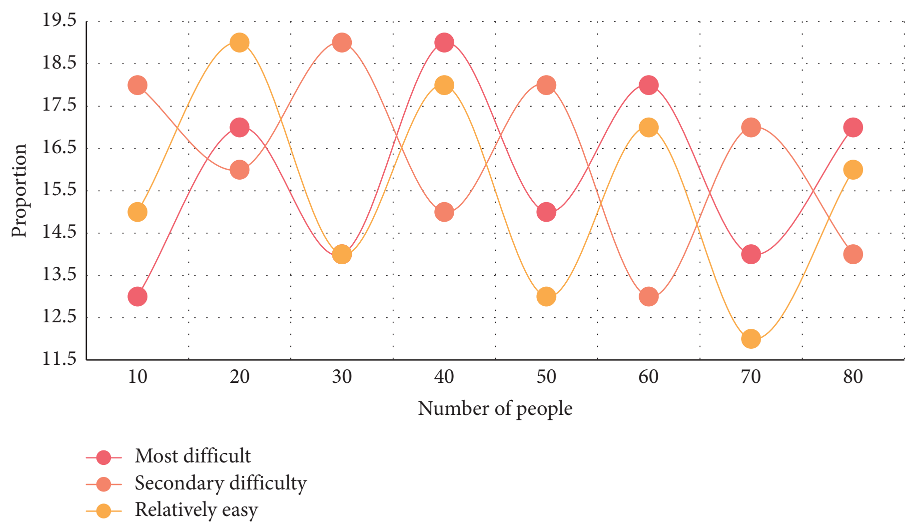

Figure 3: Learning effects of public English courses at different levels of difficulty.

From Tables 1 to 2, it can be seen that 58.8% and 55.2% of students are very interested in and like the resource bank, 28.3% and 30.7% are interested and like, 7.8% and 9.3% are generally interested and like, and 4.7% and 4.6% are not interested and dislike, respectively. In terms of content construction, we should comply with the characteristics and teaching methods of secondary vocational schools, update the content in time, and keep pace with teaching, and students can find the content they want in time to truly serve teachers' teaching and students' learning. The resource bank is mainly for teaching. In the design and construction, we should widely solicit the opinions of students and teachers, especially the direct and in-depth participation of front-line teachers. In addition to the systematic design of the content in line with the characteristics of secondary vocational teaching, it also needs to be designed in terms of management to facilitate teachers' teaching management and teacher-student interaction on the resource database platform.

In this experiment, the first three aspects of students' simplicity in learning English and American literature courses are analyzed. Two experiments were conducted to compare the most difficult and the second most difficult, respectively, and the total time spent by students studying the course after class was compared. The experimental results are shown in Figures 3 and 4.

From Figures 3 to 4, it can be seen that the three learning points of traditional language, cultural background, and text content have different difficult relationships in students' activities of learning English and American literature. According to the experiment of English major students' ease of learning literature courses, it is found that during the period of 40 students, the average proportion of the most difficult is 16.3%, the average proportion of the next difficult is 35.2%, and the average proportion of the easier is 18.5%. Compared with the next difficult one, the proportion of the difficulty in learning is the highest, followed by the easier one, and finally the most difficult one. Most students have greater difficulties than language barriers in understanding the content of literary works and related knowledge reflected by them. Only a small number of students' language barriers exceed the cognitive barriers of text content and related knowledge.

In this experiment, during the classroom teaching, after the teacher has finished explaining the works preliminarily, the students are divided into several groups, each with 4–6 people, to discuss a certain problem in the preview tips, respectively. According to the order in which these teaching

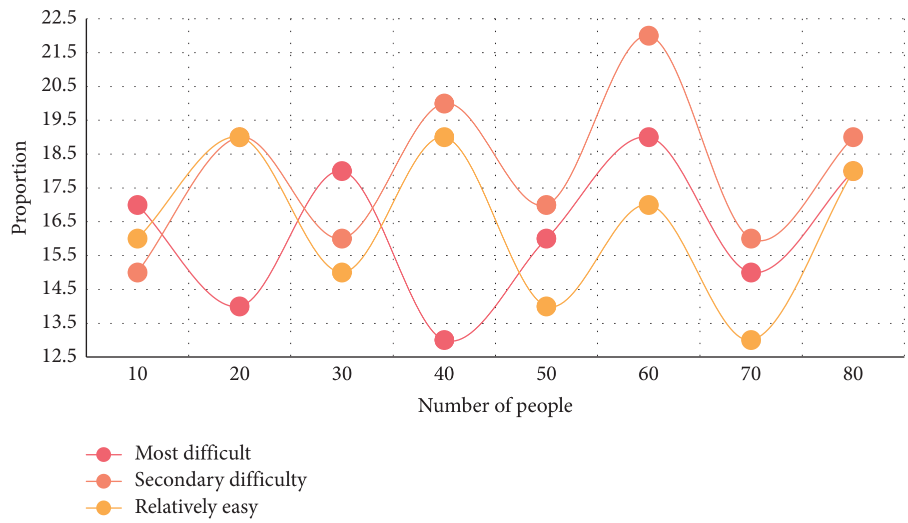

Figure 4: Learning effects of professional English courses at different levels of difficulty.

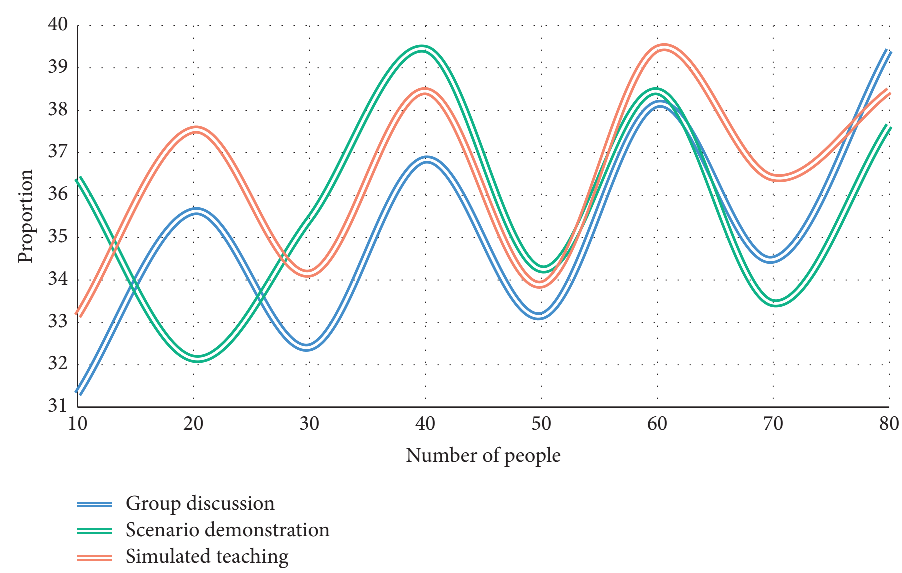

Figure 5: English majors' satisfaction with the reception response teaching model on 10% training samples.

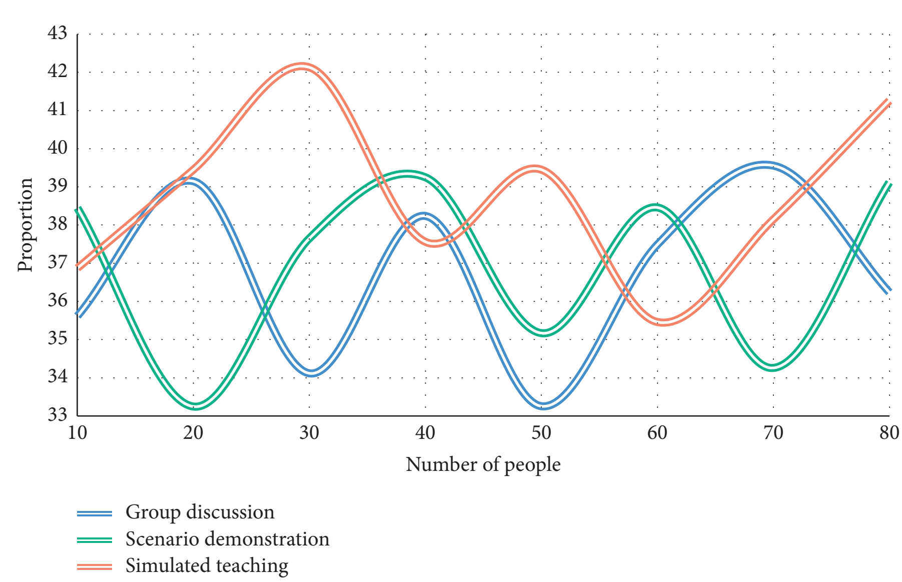

Figure 6: English majors' satisfaction with the reception response teaching model on 20% training samples.

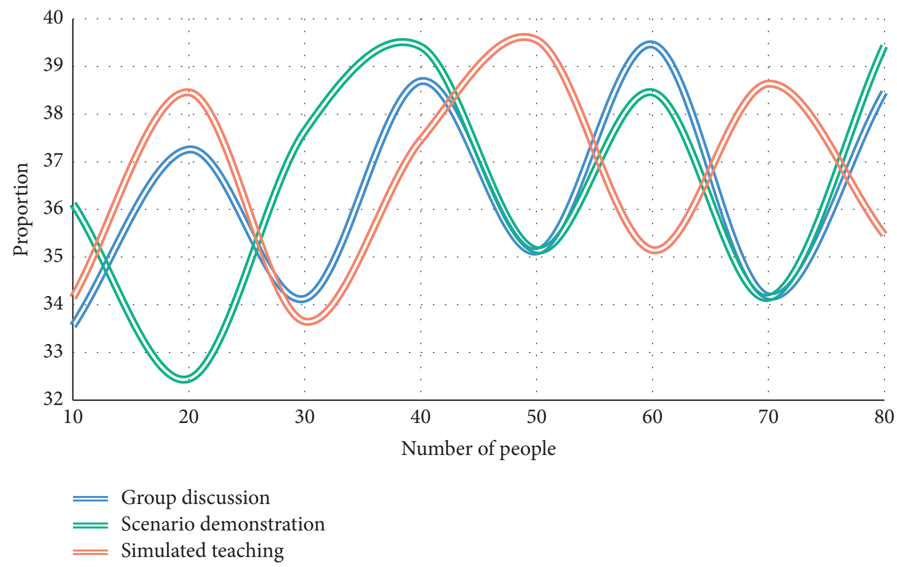

Figure 7: English majors' satisfaction with the reception response teaching model on 30% training samples.

AIDS appear in the teaching process, the order is as follows: (1) discuss in groups; (2) scenario demonstration; (3) simulation teaching. Group discussion aims to improve the efficiency of preview before class by training students' ability to collect effective information and communicate. Once again, we conducted three experiments to compare English majors' preferences for the response teaching mode. The experimental results are shown in Figures 5, 6, and 7.

As can be seen from Figures 5 to 7, for each single teaching auxiliary means of group discussion, scenario demonstration, and simulated teaching, when the number of students is 50, the average satisfaction rates of group discussion, scenario demonstration, and simulated teaching are 34.6%, 34.9%, and 37.6%, respectively. The results of this experiment reflect that the students affirmed the three teaching aids adopted under the guidance of reception response theory. The improvement of students' learning quality and learning interest shows the effectiveness of the above auxiliary teaching means: that is, to strengthen students' understanding of literary texts and promote the exchange and communication between learning subjects so as to obtain a better literary teaching effect.

5. Conclusions

It is of great significance for China's talent training to build and share the British and American literature teaching resource library through cloud computing technology so that high-quality educational resources can be popularized and more students can enjoy high-quality educational resources. The development and utilization of digital teaching resources of British and American literature based on cloud computing is not only conducive to creating a multimode humanistic teaching environment in which multiple meaningful symbols work together, enhancing the intuition and vividness of teaching, mobilizing students' multiple senses to participate in language information perception, and effectively improving English language skills but also conducive to creating a literary learning atmosphere in which knowledge and interest are combined and stimulating students' interest in learning, Cultivate students' autonomous learning habits, improve literary literacy, fully realize the teaching objectives of British and American literature, and reflect the teaching knowledge of British and American literature. Through the experiment on the difficulty and ease of learning literature courses for English majors, it is found that among the 40 students, the average proportion of the most difficult is 16.3%, the average proportion of the second difficult is 35.2%, and the average proportion of the easier is 18.5%. Compared with the next difficulty, the proportion of learning difficulty is the highest, followed by the easier, and finally the most difficult. Various materials provided by the cloud computing British and American literature teaching platform improve students' literary appreciation ability and critical judgment ability, enhance students' scientific research ability, expression ability, and innovation ability and improve students' comprehensive quality.

Academic Editor: Xin Ning

In order to achieve efficient and accurate breast tumor recognition and diagnosis, this paper proposes a breast tumor ultrasound image segmentation method based on U-Net framework, combined with residual block and attention mechanism. In this method, the residual block is introduced into U-Net network for improvement to avoid the degradation of model performance caused by the gradient disappearance and reduce the training difficulty of deep network. At the same time, considering the features of spatial and channel attention, a fusion attention mechanism is proposed to be introduced into the image analysis model to improve the ability to obtain the feature information of ultrasound images and realize the accurate recognition and extraction of breast tumors. The experimental results show that the Dice index value of the proposed method can reach 0.921, which shows excellent image segmentation performance.

1. Introduction

As a malignant disease with high mortality, breast cancer has seriously threatened the physical and mental health and life safety of women worldwide [1, 2]. According to the American Cancer Society, in 2017, 255180 new cases of breast cancer and 41070 deaths of breast cancer were reported in the United States. In China, there are about 66 thousand female breast cancer deaths each year, accounting for 7.82% of the total number of deaths from female malignant tumors. After breast cancer cells proliferate, free diffusion can occur. Breast cancer forms a tumor metastasis site through local invasion, intravascular infiltration, circulatory system, and/or lymphatic system transmission [3–5]. Clinically, the process of multiple organ disease caused by metastasis is one of the important factors leading to high mortality of breast cancer. The prognosis of patients with metastatic breast cancer usually is not good, and the average 5-year survival rate is only 27%. In the formation of clinically detectable cancer cell metastasis, often the patient's condition has developed into advanced tumor [6]. Thus, early detection, early diagnosis, and early treatment of breast cancer are of great significance.

With the development and application of computer technology, researchers choose to continuously train the tumor ultrasound image dataset to learn with the help of deep learning network and independently extract the information features in the dataset, so as to realize noninvasive tumor medical auxiliary judgment [7]. However, it should also be noted that, due to the deep structure of the depth network model, the gradient is easy to disappear when training the dataset to learn, which makes it difficult for the image segmentation network model to realize accurate and effective tumor region recognition.

In this study, U-Net network and attention mechanism module are combined to construct breast tumor ultrasound image segmentation model, improve image recognition accuracy, and provide auxiliary reference for medical staff. The contributions of the proposed method lie in the following:

(1) The residual block is used to optimize and improve the U-Net network, and the residual mapping is

obtained by convoluting the input features through the convolution layer, which can effectively solve the gradient disappearance problem of the deep network.

(2) The hybrid attention mechanism module is added to the image segmentation model to optimize the training and learning process of the image segmentation model, enhance the information feature acquisition ability of the model, and support the accurate and efficient recognition of the image segmentation model.

The remaining chapters are arranged as follows. The second chapter introduces the relevant work in this field. The third chapter introduces the breast tumor ultrasound image segmentation method based on improved residual U-Net network. In Chapter 4, experiments are designed to verify the performance of the proposed model. The fifth chapter is the conclusion.

2. Related Researches

Image segmentation is a technology to extract the region of interest in the image according to the pixel features (gray, texture, etc.). For breast ultrasound images, the region of interest is the breast nodule. It is necessary to extract the diseased nodule from the normal tissue region to provide input data for the next classification operation. At present, the main algorithms proposed by domestic and foreign scholars in the research of ultrasound image segmentation are threshold and edge method, region method, graph theory and clustering method, energy functional method, and neural network method [8].

Traditional image segmentation algorithms, such as threshold method, edge method, and region method, do not easily obtain ideal segmentation results directly. General researchers will make a lot of improvements and integration on the above algorithms. Liu et al. [9] proposed a framework for fully automatic segmentation of breast ultrasound image lesion area, which used Otsu-based adaptive thresholding (OBAT) method and morphological filtering method to locate the region of interest (ROI) and initialize the nodule contour [9]. Jiang et al. [10] used AdaBoost + Haar framework to locate a set of potential lesion locations in breast ultrasound images [10]. However, if only these methods are used in the above references, when the gray difference of the image to be segmented is small, there is large overlap within the gray value range, or the noise is serious, the accuracy of lesion area segmentation will be greatly reduced, especially when there is fat area near the breast nodule or the contrast is low, which will seriously affect the segmentation effect. Therefore, after initializing the nodule contour, Liu et al. [9] achieved accurate segmentation of breast nodules by improving the Chan-Vese model. Jiang et al. [10] further screened the detected lesion area set by using Support Vector Machine (SVM) on the basis of the original framework and refined and segmented the lesion area by Random Walk algorithm.

In recent years, ultrasound image segmentation algorithm based on neural network has been proposed continuously. For example, Li et al. [11] used encoder-decoder structure to segment amniotic fluid and fetal tissue in fetal ultrasound image effectively [11]. Zhang et al. [12] segmented the lesion area of lymph node ultrasound image from coarse to fine by improving Fully Convolutional Networks (FCN) [12]. Wu et al. [13] used Convolutional Neural Networks (CNN) to find the ROI in the fetal abdomen in the ultrasound image and evaluated the image quality by judging the clarity of description of the key structures of gastric vesicle and umbilical vein through another CNN, so as to screen high-quality ultrasound images for the measurement of fetal Abdominal Circumference (AC) [13]. Ma et al. [14] and Ma et al. [15] randomly cut the thyroid ultrasound image into multiple overlapping subgraphs, took the pixel ratio of normal tissue to lesion area as the classification label of each subgraph, trained the Deep Convolutional Neural Networks (DCNN), and finally used the trained DCNN for subgraph-level classification to realize the lesion area segmentation of thyroid ultrasound image. Among them, some scholars have achieved good research results in the field of breast ultrasound image nodule segmentation. Wang and Jiao [16] proposed an improved Simplified Pulse Coupled Neural Network (SPCNN) combined with fuzzy mutual information, which took the maximum fuzzy mutual information as the optimal decision criterion to obtain the result of whether each pixel belongs to the nodule area, and carried out morphological processing on the binary image after pixel classification to extract the breast lesion area [16]. Cao et al. [17] conducted multiscale transformation of breast ultrasound dataset and input it into the current mainstream target detection framework (including Fast R–CNN, Faster R–CNN, YOLO, and SSD) and backbone network (ZF-Net, VGG-16) [17]. The results show that SSD300 is more suitable for breast ultrasound lesion extraction. Although the deep learning method has made good achievements in the field of natural image processing, due to the characteristics of ultrasound imaging, breast ultrasound images have defects such as low resolution, low contrast, and a large amount of speckle noise and artifacts, and due to data sensitivity, there is a lack of large public breast ultrasound dataset. For the above reasons, the dataset-driven deep learning technology is disturbed in breast ultrasound image processing [18].

Vakanski et al. [19] integrated visual saliency into the U-Net segmentation model, drove the model to give priority to the highly significant spatial region features in the image, and obtained good experimental results on a small sample dataset composed of 510 breast ultrasound images [19]. Zhang et al. [20] proposed to optimize the convolution network AlexNet network with full connection structure to obtain the information features of the image, so as to complete the ultrasound image analysis of breast mass [20]. Ilesanmi et al. [21] optimized the processing of breast ultrasound images based on cascaded convolution network to realize image information recognition and segmentation [21]. Tang et al. [22] introduced the Transform Modal Ensemble Learning module into the nonlocal network of feature pyramid to construct the breast ultrasound image-aided diagnosis model and realize autonomous image analysis [22]. Fang et al. [23] constructed a full convolution network model M-Net to realize breast abnormal image analysis. The above methods still have limitations [23]. Due to deep network structure, the gradient of image segmentation model may disappear when recognizing images, resulting in the decline of image segmentation accuracy. At the same time, due to the large noise interference in the ultrasound image, there is independent phase interference when the depth model obtains the image features, resulting in the further decline of segmentation accuracy. This paper proposes a recognition method for breast tumor ultrasound images, improves the U-Net network, and integrates it with the hybrid attention mechanism network, which overcomes the problems of the current depth network model.

3. The Proposed Image Segmentation Method

The overall framework of the proposed model is shown in Figure 1. The model takes U-Net as the backbone network structure and includes three parts: encoder module, hybrid attention module, and decoder module. In each level of the codec in Figure 1, the characteristic tensor passes through a residual block and a multiscale convolution block in turn. First, the image is subjected to residual multiscale convolution and downsampling encoding. At the same time, the feature map output at each level is copied to the decoder at the corresponding level through the attention module, and then the feature map obtained by downsampling is concatenate and upsampled. Finally, the breast tumor ultrasound image segmentation is realized through the loss function [24, 25]. In this method, the features extracted by the shallow encoder are connected to the corresponding level of the decoder through the attention module, which can give higher weight to the edge details in those shallow features and suppress the useless information or noise in the shallow features to a certain extent while retaining the edge information.

3.1. Residual Block. In order to extract more detailed information from the image and alleviate the problem of undersegmentation in low contrast areas and weak edges, residual blocks are introduced into U-Net to replace the traditional convolution layer. The use of residual blocks can solve the problem of gradient disappearance with the deepening of network layers. The calculation formula of residual block foundation is

$$u = c\left(v, w_h\right) + v, \tag{1}$$

where v and u are, respectively, the input and output of the network, w_h is the parameter of h-th layer, and $c\left(v, w_h\right)$ is the residual mapping. Using residual block learning to fit a residual map $u - v$ is easier than directly learning to fit an approximate identity map u. The residual block solves the problem of gradient disappearance in deep network. The partial derivative of formula (1) is

$$\frac{\partial u}{\partial v} = 1 + \frac{\partial c\left(v, w_h\right)}{\partial v}. \tag{2}$$

Since the gradient of formula (2) is always greater than 1, the gradient will not disappear with the deepening of the number of network layers. In general, the feature dimension of $c\left(v, w_h\right)$ is different from that of v, so linear transformation parameter w is introduced to complete dimension matching. The calculation formula is

$$u = c\left(v, w_h\right) + w_v. \tag{3}$$

The network structure of the residual block is shown in Figure 2. The input features are convoluted through two-standard 6×6 convolution layers to obtain the residual mapping, then the feature dimension matching is completed through the 1×1 convolution layer, and finally the feature fusion is completed through the Add operation. This module avoids the degradation of model performance caused by the disappearance of gradient, reduces the training difficulty of deep network, and only increases the 1×1 convolution layer, which will not increase the computational complexity of the model. At the same time, the module shortens the distance between the front and back layers, effectively improves the learning ability of features, and helps to extract more detailed information, which reduces the interference of low contrast between cells and background to the model to a certain extent.

3.2. Attention Module. Although the spatial attention can find the relationship between features and task objectives from a global perspective and strengthen the attention to the target task, the spatial attention ignores the information in the channel and treats the feature map in each channel equally. Based on the attention of the channel, the global context information is extracted through the global maximum pooling and average pooling. As a guide, the correlation of the global information is judged from the perspective of channel correlation, and then the global features with high correlation are selected [26]. However, the attention of the channel is to pool the information in the channel globally, which ignores the local information in each channel. Combining the above two kinds of attention, a Spatial Channel Attention Block (SCAB) is proposed to allocate the weights of channel and spatial attention. The specific implementation process is shown in Figure 3.

As can be seen from the figure, the output d can be obtained by the following formula:

$$d = \mathrm{Cat}\left[e_s, e_c\right], \tag{4}$$

where e_s is the feature with spatial attention and e_c is the feature with channel attention.

SCAB combines channel attention and spatial attention to obtain a comprehensive attention information. It not only analyzes the relationship between each pixel and the task target but also distinguishes the correlation between each channel and the task. Specifically, by inputting the input features $b \in R(G \times P \times Q)$ into the spatial attention block and the channel attention block, respectively, the output of the spatial attention block e_s and the output of the channel attention block e_c can be obtained. e_s and e_c are combined to get the final output $d \in R(G \times P \times Q)$.

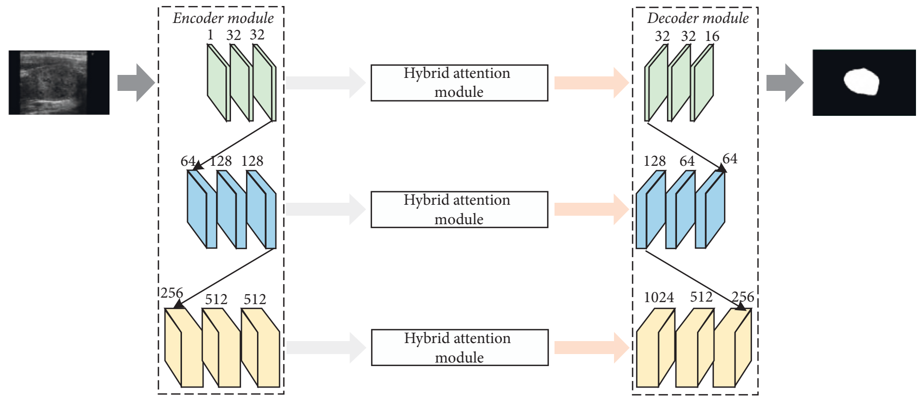

FIGURE 1: Image segmentation model based on improved residual U-Net network.

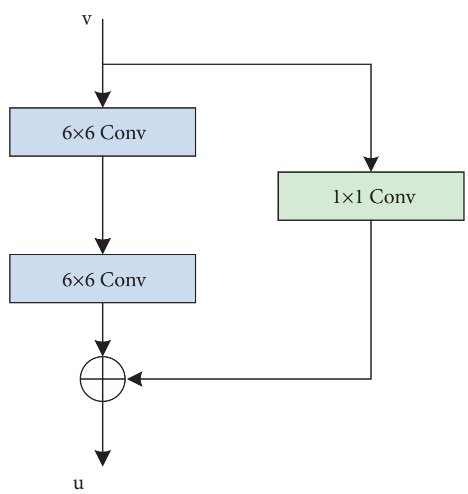

FIGURE 2: U-Net residual block structure.

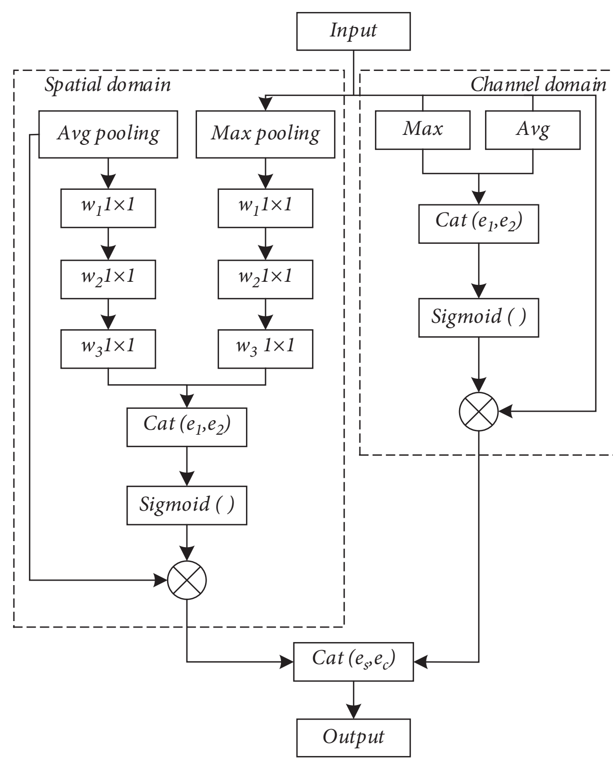

FIGURE 3: Space and channel attention module.

The structure of feature extraction block in U-Net is two 2×2 convolutions to extract the input features. The feature learning is carried out by fusing the input with the output in the way of skip connection. This method has the following advantages: (1) it simplifies the learning process and enhances the propagation of gradient. Due to the inclusion of residual structural identity, the backpropagation can be carried out effectively. (2) This design can break the asymmetry of the network. If only a small number of hidden units in each layer of the network change their activation value for different inputs, and most hidden units respond the same way to different inputs, the problem of network degradation will occur. (3) The generalization ability of the network is enhanced. Residual SCAB (RSCAB) is a new feature extraction module combined with attention mechanism and residual structure.

The specific implementation of RSCAB is as follows:

$$d_{\text{att}} = \text{SCAB}(\alpha\, d + \beta), \tag{5}$$

$$b = \alpha \text{Cat}\left[d_{\text{att}}, d\right] + \beta, \tag{6}$$

where the function of 1×1 convolution is to raise the input dimension. d_{att} is the feature map obtained by raising dimension and SCAB, and b is obtained by feature extraction again after feature fusion of d_{att} and d.

By embedding the attention transmitted by the residual connection, the module enables the network to obtain the location of the task target in the feature extraction stage. It has the following advantages:

(1) The shallow attention features are transferred to the deep by residual connection, which can pay more attention to the feature learning of the task target area.

(2) In this way, the interaction between layers can be closer, so as to facilitate the calculation of feature information.

(3) It enhances the information and gradient transmission between networks and facilitates the training of deeper networks.

3.3. Loss Function. In the classical U-Net model training, the output result of Softmax is used to calculate the cross entropy, which is regarded as the optimization function of the whole network. In medical image segmentation, there are usually only two classifications: lesions and background. At this time, the loss function is Binary Cross Entropy (BCE), and its formula is

$$\text{loss}_{\text{BCE}} = -\frac{1}{N}\left[t_j \sum_{j=1} p_j + \left(1 - t_j\right) \sum_{j=1} \left(1 - p_j\right)\right], \tag{7}$$

where N is the total number of pixels of the input image, t_j is the truth label of the j-th pixel, $t_j \in [0, 1]$ is the probability that the corresponding pixel is predicted as the foreground, 0 represents the background, and 1 represents the mass. When the number of foreground pixels is far less than the number of background pixels, that is, the number of $t_j = 0$ is far greater than the number of $t_j = 1$, the component $t_j = 0$ in the optimization process will dominate, making the model seriously biased towards the background.

There is a serious imbalance between foreground and background pixels in the dataset. Using the binary classification cross entropy loss function alone may mislead the optimization direction of the model and finally can only predict the meaningless background area with a larger area.

Dice similarity coefficient is a set similarity measurement function, which is usually used to calculate the similarity of two types of pixel samples, with a value range of [0, 1]. When the number difference between the two types of samples is huge, $\text{loss}_{\text{DICE}}$ can alleviate the problem of sample imbalance to a certain extent. $\text{loss}_{\text{DICE}}$ is defined as

$$\text{loss}_{\text{DICE}} = 1 - \frac{2\sum_j p_j t_j + \gamma}{\sum_j p_j^2 + \sum_j t_j^2 + \gamma}, \tag{8}$$

where γ is a constant added to maintain numerical stability and prevent denominator from changing to 0. In breast image segmentation, due to the extreme imbalance between tumor pixels and background pixels, using Dice loss function alone will make the whole optimization process unstable and reduce the reliability of the index. Therefore, in the training process, two loss functions are used to constrain the network training, and a weighted composite loss function loss_{NEW} is proposed, which is defined as follows:

$$\text{loss}_{\text{NEW}} = \tau \text{loss}_{\text{BCE}} + \text{loss}_{\text{DICE}}, \tag{9}$$

where τ is a constant weight to control the balance of optimization strength between cross entropy loss and Dice loss. After testing different τ values, it is found that better segmentation effect can be achieved at $\tau = 1.5 \times 10^{-3}$.

3.4. Network Training. Deep learning network training aims at minimizing the loss function and iteratively updating the weight parameters of the model. It consists of two parts: weight initialization and updating algorithm.

3.4.1. Weight Initialization. The weight initialization method in deep learning network model is very important, which affects the convergence performance and convergence speed of network model training. With the deepening of layers of neural network, the optimization method based on gradient descent is prone to gradient explosion and gradient disappearance, and a good weight initialization method can alleviate this problem.

The ReLU function is used as the activation function. The specific operation is to initialize the weight parameters of the convolution kernel using a Gaussian distribution with a mean value of 0 and a standard deviation of $\sqrt{2/\delta}$, where $\delta = k_r^2 z_{r-1}$, in which k_r refers to the size of the convolution kernel of r convolution layer and z_{r-1} represents the number of convolution kernels in the $r - 1$ layer.

3.4.2. Weight Update Method. The training of neural network is a process of finding the optimal value, and this process is actually a process of iteratively updating the weights. The optimization algorithm contains different weight updating methods. The optimization algorithm used in this paper is Adam algorithm. Adam algorithm is a stochastic optimization method of adaptive momentum, which iteratively updates the training parameters by combining the first-order moment and second-order moment information of the gradient. The specific update calculation is as follows:

$$y_t \leftarrow \nabla_\theta x_t\left(\theta_{t-1}\right), \tag{10}$$

$$o_t \leftarrow \varphi_1 \cdot o_{t-1} + \left(1 - \varphi_1\right) \cdot y_t, \tag{11}$$

$$z_t \leftarrow \varphi_2 \cdot z_{t-1} + \left(1 - \varphi_2\right) \cdot y_t^2. \tag{12}$$

$$\widehat{o}_t \leftarrow \frac{o_t}{\varphi_1}, \tag{13}$$

$$\widehat{z}_t \leftarrow \frac{z_t}{\varphi_2}, \tag{14}$$

$$\theta_t \leftarrow \theta_{t-1} - \frac{\varepsilon \cdot \widehat{o}_t}{\left(\sqrt{\widehat{z}_t + \sigma}\right)}, \tag{15}$$

where t is the number of iterations, $x(\theta)$ refers to the loss function, θ is the training parameter, that is, the weight or bias, y_t is the gradient calculated by the derivation of the loss function from the training parameter, φ_1 is the first-order moment attenuation coefficient, φ_2 is the second-order moment attenuation coefficient, ε is the learning rate, o_t is the first-order moment of the gradient y_t, z_t is the second-order moment of the gradient y_t, $\widehat{o}_t$ and $\widehat{z}_t$ are the deviation correction of o_t and z_t, and σ is a positive number to prevent the denominator from being zero.

The value of each parameter is as follows: $\varphi_1 = 0.95$, $\varphi_2 = 1.00$, $\varepsilon = 0.00015$, and $\sigma = 1.5 \times 10^{-8}$. Adam algorithm combines the characteristics of momentum method and RMSprop method to jump out of the local optimal solution as much as possible and accelerate the convergence speed of the network.

4. Experiment and Analysis

The computer hardware configuration of the experimental simulation is Intel Core i5-10400 and Nvidia GeForce RTX 3080Ti. The network model is trained and tested using the Keras open-source library with TensorFlow as the backend.

4.1. Experimental Dataset and Preprocessing. The experimental dataset is the Wisconsin Diagnostic Breast Cancer (WDBC) dataset. Breast ultrasound image has three inherent characteristics, including high noise, low contrast, and nonuniformity. Therefore, the segmentation of breast ultrasound image is still a challenging task. At the same time, a series of preprocessing operations are needed to process this kind of image.

4.1.1. Cutting of Region of Interest. For breast ultrasound image segmentation task, the region of interest is breast tumor. In the original breast ultrasound image, the proportion of tumor area is often small. In order to improve the efficiency of subsequent superpixel generation, the region of interest of the original image is cut. In the original breast ultrasound image, the operator determines two diagonal points and then draws a rectangular box. The box needs to meet two requirements: (1) the rectangular box contains breast tumors and (2) the area of the tumor accounts for about 30% of the area of the rectangular box. The region of interest is cut from the original Image, which greatly reduces the interference of irrelevant regions and improves the efficiency of the algorithm.

4.1.2. Image Denoising. Breast ultrasound image is full of noise, and the main noise is speckle noise, which needs denoising. In this paper, bilateral filter is used. The ultrasound image is denoised by bilateral filter. The filtering process integrates the gray similarity and spatial information between pixels, which can not only preserve the tumor edge but also reduce the noise.

4.1.3. Contrast Enhancement. In addition to high noise, breast ultrasound images also have the characteristics of low contrast. Specifically, the gray values of breast tumor area and some adjacent normal tissue areas are close, and the difference is small. It is easy to mistake this part of normal tissue area for tumor area. Therefore, it is necessary to enhance the contrast and the method of gray histogram equalization is adopted. The mathematical description of the specific transformation of histogram equalization is as follows:

$$e_j = U\left(v_j\right) = \sum_{i=1}^{j} G\left(v_i\right) = \sum_{i=1}^{j} \frac{c_i}{c}, \quad j = 1, 2, \ldots, J, \tag{16}$$

where the number of pixels of the input image is c, J represents the gray level, $G(v_i), i = 1, 2, \ldots, J$ represents the gray histogram of the region of interest, c_i is the number of pixels with gray level i, v_i is the gray value of the image before processing, and e_j is the gray value after equalization. The flow of image preprocessing is shown in Figure 4.

4.2. Evaluation Index. In addition to the loss function mentioned above, the ultrasound image segmentation reference indices with universality, objectivity, and quantifiability are still selected to evaluate the above algorithm, specifically including Dice, Intersection over Union (IoU), Hausdorff Distance (HD), and Mean Absolute Deviation (MAD). Dice is a regional error evaluation method. The pixels of the segmented region and the actual lesion area are calculated in a certain way. The higher the value, the better the segmentation effect. The principle of IoU is similar to the previous index, which refers to the overlap rate between the segmented area and ROI. In the ideal state, the ratio is 1; that is, the two completely overlap. Hausdorff Distance (HD) measures the maximum distance between the boundary generated by segmentation and the true subset of the actual lesion area. The lower the value, the smaller the boundary error. Mean Absolute Deviation (MAD) reflects the average dispersion between the real lesion area and the segmented area pixels. The lower the value, the more accurate the segmentation. The calculation formulas are shown in (17)–(20).

$$\text{Dice} = \frac{2|R \cap G|}{(|R| + |G|)}, \tag{17}$$

where R is the segmentation result area and G is the real lesion area.

$$\text{IoU} = \frac{|R \cap G|}{|R \cup G|}, \tag{18}$$

$$\text{HD} = \max\left\{\max_{x \in R}\{d(x, G)\}, \max_{y \in G}\{d(y, R)\}\right\}, \tag{19}$$

where $d(x, C) = \max_{y \in G}\{\|x - y\|\}$, $C = R \text{ or } G$.

$$\text{MAD} = \frac{1}{2}\left(\sum_{x \in R} \frac{d(x, G)}{N_R} + \sum_{y \in G} \frac{d(y, R)}{N_G}\right), \tag{20}$$

where N_R is the total number of pixels in the segmentation result area and N_G is the total number of pixels in the real lesion area.

4.3. Ultrasound Image Segmentation Model Analysis. In order to prove the feasibility of the proposed model, first, the performance of the segmentation model is evaluated. Figure 5 shows the change of Dice value curve on the validation set when the proposed network uses different loss functions in the training process, including loss function $\text{loss}_{\text{DICE}}$, loss function loss_{BCE}, and composite weighted loss function loss_{NEW} proposed in this experiment.

It can be seen from Figure 5 that when using the composite weighted loss function loss_{NEW} for training, the Dice value curve rises steadily, and the segmentation accuracy can reach more than 0.95 on the validation set in the

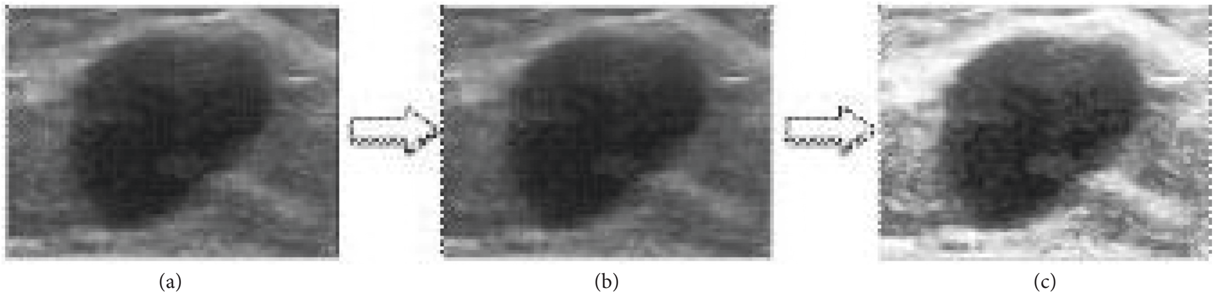

Figure 4: Process of image preprocessing. (a) Captured image. (b) Denoised image. (c) Enhanced image.

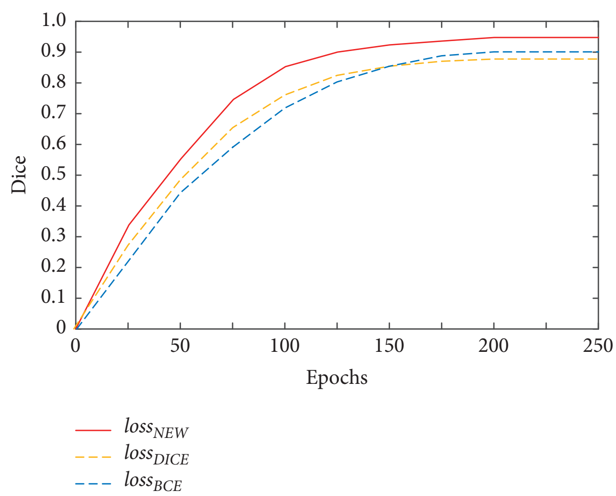

Figure 5: Changes of Dice value under different loss functions.

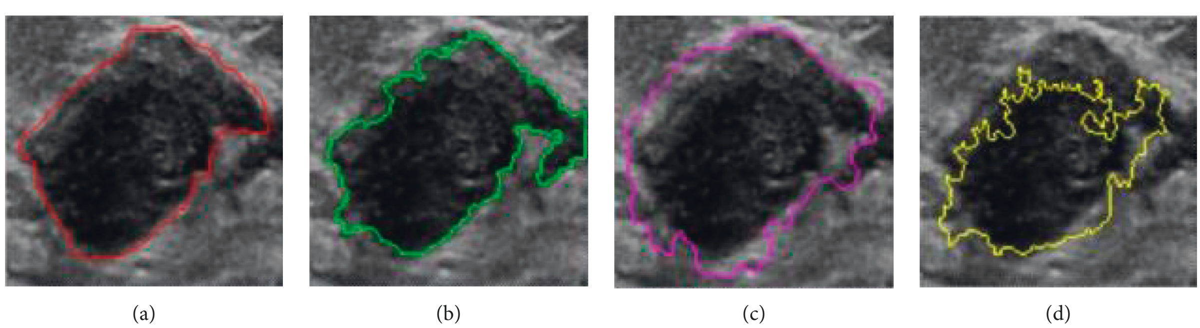

Figure 6: Image segmentation results under different methods. (a) Manual label. (b) Proposed model. (c) Reference [20]. (d) Reference [23].

later stage of training, while the other two loss functions enter the training bottleneck after reaching more than 0.85, and the Dice values do not break through 0.9 in the end.

Using [20, 23] as comparison methods, the experimental datasets are analyzed in the same environment. As shown in Figure 6, different colors represent the segmentation contour obtained by different methods. Among them, (a) is the image with the contour manually labeled by the doctor, (b) is the result of the segmentation model proposed in this paper, (c) is the segmentation result of the method in [20], and (d) is the segmentation result of the method in [23].

According to the qualitative experimental results shown in Figure 6, the segmentation performance of the segmentation model proposed in this paper is better than the comparison algorithms. Although there are still some defects in the extracted edge, compared with the other two methods, it is the closest to the manually labeled edge and has better visual effect. Methods of [20, 23] produce a certain degree of undersegmentation, the edge obtained by [23] is also rough, and [20] produces obvious oversegmentation. The reason is that the comparison method cannot obtain the data features in the sample set well and ignores some local features in the image. The segmentation model proposed in this paper adds the fusion attention mechanism module to the model, which can realize the global data feature extraction and analysis and help to realize the accurate image segmentation combined

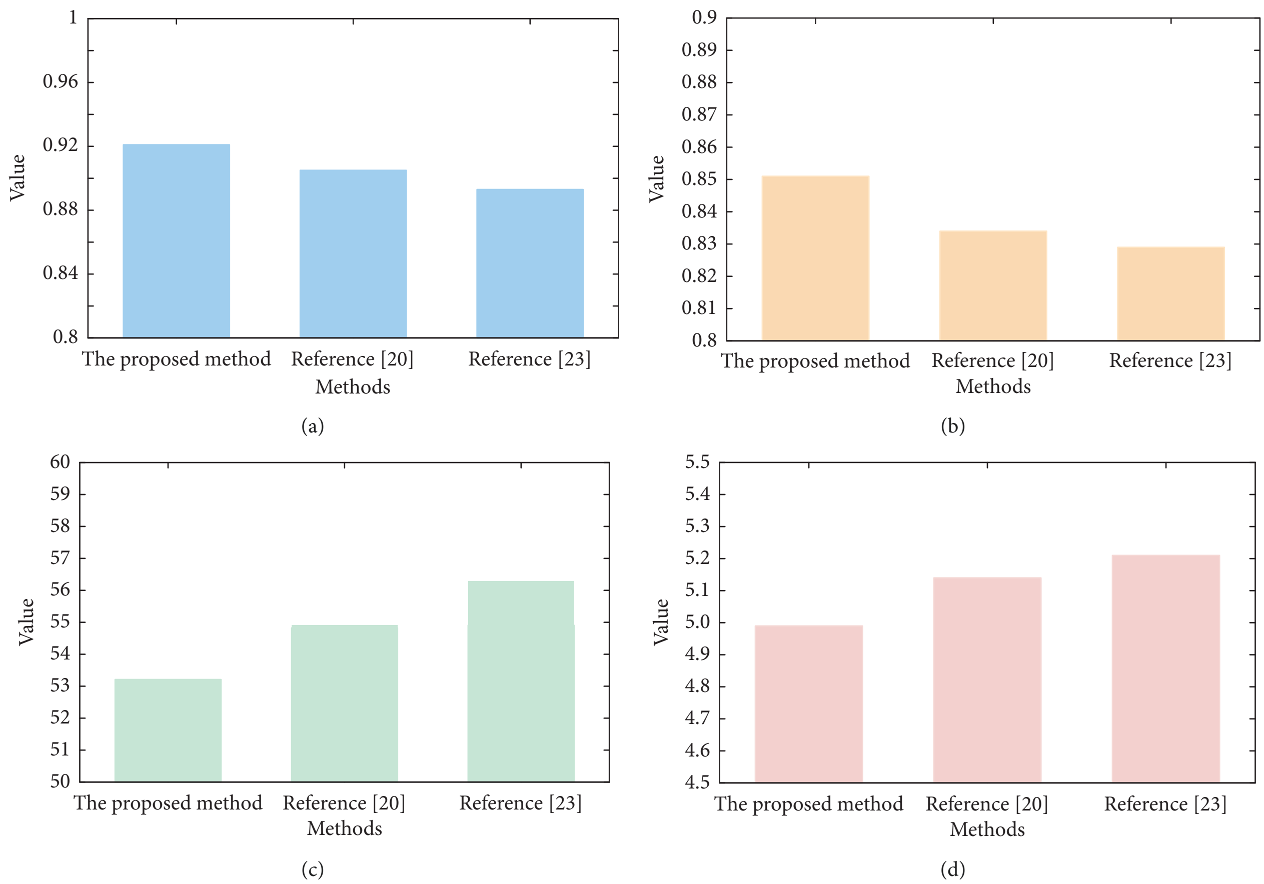

Figure 7: Comparison of segmentation results of different methods. (a) Dice index. (b) IoU index. (c) HD index. (d) MAD index.

with context-related information. In addition, due to the improvement and optimization of the loss function, it can also make the model perform calculation and analysis in the direction of global optimization, so as to avoid the interference of noise on the recognition results.

Further quantitative analysis is carried out. Figure 7 shows the comparison of quantitative segmentation results of different methods.

It can also be seen from Figure 7 that, for the analysis of ultrasound images of complex breast tumors, the segmentation errors of the comparison methods are large, and the accuracy of the proposed model is higher than those of other comparison methods. The Dice value of the proposed method is 0.921, which is 0.016 and 0.028 higher than those in [20, 23]. In terms of nodule edge segmentation accuracy, the HD index of the proposed model is 3.08 lower than that in [23]. IoU is 0.851 and MAD is 4.99, which are better than the evaluation indices in [20, 23]. This shows that the proposed model can effectively improve the accuracy of ultrasound image region segmentation.

5. Conclusion

A breast tumor ultrasound image segmentation method based on improved residual U-Net network is proposed. The U-Net network model is improved by introducing residual block optimization to avoid the disappearance of gradient caused by too deep network structure. Furthermore, the hybrid attention mechanism network is introduced into the ultrasound image segmentation model to obtain the global information features of the sample dataset and effectively improve the image analysis performance of the analysis model. The experimental results show that the proposed method can realize the analysis and processing of actual complex breast tumor ultrasound images and provide reliable medical diagnosis assistance for medical staff.

This paper mainly studies the shape feature constraints of breast nodules, but the situation of breast ultrasound images is complex and changeable. In real life, there are other types of difficult samples based on texture characteristics such as artifact and calcification. How to automatically mine these different types of difficult samples becomes the next research work.

Academic Editor: Xin Ning

Despite a number of adverse factors, China's steel industry has maintained a rapid growth trend. China continues to consume two-thirds of the world's iron ore, the majority of which is imported. In this context, Chinese steel companies have begun to consider integrating their supply chains to increase efficiency and lower costs. However, the increasingly volatile international environment makes this an extremely risky proposition. As a result, the issue of how Chinese steel producers should participate in global supply chain integration has emerged as a critical research question that requires investigation. In this paper, we examine the supply chain integration problem using a typical China–Australia steel trade as an example. Specifically, we discuss in detail whether relevant firms should continue to promote supply chain integration in the Chinese–Australian steel industry, as well as the decision boundary of influence, using evolutionary game theory and policy risk cost factors. The empirical analysis demonstrates that policy risk has a range of effects on different types of steel firms. Even when international tensions are considered, smaller steel companies may retain a greater willingness to integrate their supply chains. Overall, the above findings can provide necessary decision support for enterprises to formulate supply chain management strategies.

1. Introduction

Iron ore is one of the main raw materials of the steel industry. The bulk of Chinese iron ore reserves is of a poor grade, technically difficult to exploit, and located far from the major steel-producing centers on the eastern seaboard [1] (pp. 1084–1094). With the rapid development of the domestic steel industry, Chinese iron ore reserves and their exploitation cannot meet the large demand. Australia has long been China's primary iron ore supplier [2] (pp. 95–106). Despite the impact of the COVID-19 pandemic in 2019 and the deterioration of China–Australia relations, the two countries' iron ore trade has remained relatively stable. In 2020, China imported 712.986 million tons of iron ore from Australia (see Figure 1), accounting for 60.93 percent of total Chinese iron ore imports. It demonstrates that Australia remains a vital and irreplaceable source of high-quality iron ore for China.

Of course, the impact of political factors on the China–Australia iron ore trade cannot be underestimated. With the development of an intense rivalry between the two countries, both governments have imposed a number of explicit and implicit restrictions on iron ore trade and business cooperation in related areas. The Chinese government, for example, has restricted the offloading of iron ore ships from Australia and is actively developing or seeking alternative sources of Australian iron ore in Southeast Asia. The Australian government also announced plans to cancel mining rights already acquired by some Chinese companies in April 2021. Once implemented, the aforementioned measures will undoubtedly result in massive financial losses for the affected companies.

Although political factors have had a significant negative impact on the two countries' iron ore trade, both governments are well aware of the economic fundamentals: the iron

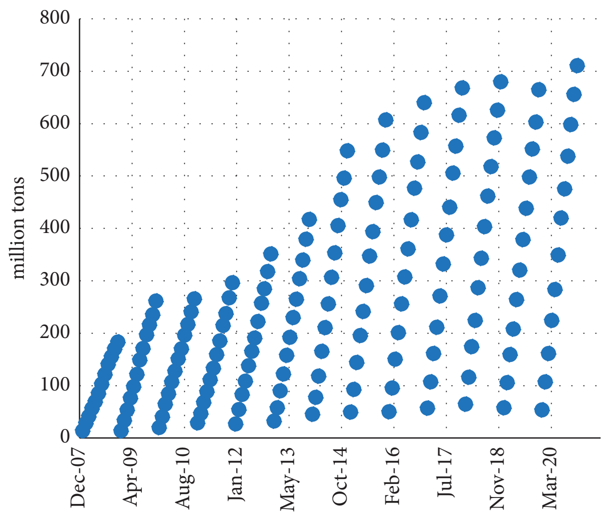

Figure 1: Comparison of cumulative annual data of Australian iron ore imports, 2006–2020.

ore trade between Australia and China cannot be artificially halted [3] (pp. 331–339). On the one hand, the China–Australia iron ore trade is critical to Australia's economic development, and a complete shutdown of the China–Australia iron ore trade would severely impair Australia's economic growth. On the other hand, China would have difficulty obtaining such a large supply of high-quality iron ore from other global suppliers. Additionally, Chinese companies have already invested significant capital in Australia. Numerous projects have been secured or put into operation, and the industrial integration of related resources is progressing steadily. As a result, we believe that with the adjustment of the new U.S. administration's anti-China sanctions policy, the intensity of trade frictions between China and Australia is likely to decrease, resulting in the recovery of the China–Australia iron ore trade.

In the aforementioned complex international political and economic environment, how Chinese steel producers should participate in the Chinese–Australian steel industry's supply chain integration (SCI) has become an important issue worth investigating. SCI takes many forms in practice, including the purchase of mining rights, direct investment in ore exploration or smelting, and so forth. Although SCI can help steel producers lower their operating costs and improve their competitiveness, it can also make them more vulnerable to changes in the trade environment and policies, exposing them to more operational risks. As a result, the decision makers in Chinese steel producers and the Chinese government must respond two questions in the face of an increasingly complex economic and trade environment, which are as follows: is it necessary for steel producers to continue to promote SCI? What effect will trade restrictions on iron ore have on Chinese steel producers' SCI? Based on evolutionary game theory, we will discuss these research questions in depth in this paper.

Overall, the contributions of this paper are broadly twofold. Firstly, for the first time, we consider the impact of political factors on related trade activities in the discussion of iron ore trade. Secondly, we use an evolutionary game model to provide decision recommendations of practical value for Chinese steel firms' decisions.

The remainder of this paper is divided into the following sections: Section 2 examines the relevant literature and identifies the research gap this paper attempts to fill. The model is introduced in Section 4, where we also analyze the evolutionary game and the case study we later conduct in Section 5. Section 3 introduces the evolutionary game framework of this paper, introducing the relevant hypotheses and the game mechanism. Section 4 introduces the model, where we also analyze the evolutionary game, and Section 5 introduces the case study we conduct. Finally, Section 6 contains the paper's conclusion and policy recommendations.

2. Literature Review

Over the years, scholars' focus on SCI practices has shifted significantly [4] (pp. 353–361) [5] (pp. 42–55). The majority of these studies agree on the fundamental premise that implementing SCI effectively throughout the supply chain is vital to modern businesses' capacity to maintain a competitive edge [6] (pp. 24–41).

Robinson believes that a paradigm shift is taking place in which value is sought and delivered through integrative efficiency rather than operational efficiency [7] (pp. 89–106). Effective SCI is crucial for some firms to minimize supply chain expenses and achieve a competitive edge [8] (pp. 119–134). Establishing strategic partnerships or alliances with suppliers increases the interaction between businesses and suppliers, enhancing the supply chain's performance [9] (pp. 58–71). SCI appears to be a primary method for Chinese steel makers to address their iron ore supply chain difficulties. For example, Baosteel Group, the second largest steel-producing company in China and the fourth largest steel-producing company in the world, established Baosteel Resources as a wholly owned subsidiary that is mainly engaged in mineral resource investment, trade, and logistics services and claimed that its 2009 investment in Aquila Resources would strengthen Baosteel's control over resources and lower purchasing costs.

Although most researchers accept that SCI can contribute to increasing supply network performance, it is notable that only a few studies have focused on the conditions of implementing SCI because SCI is not applicable in all cases. Mouritsen et al. demonstrate that similar levels of implementation of SCI practices do not always result in comparable improvements [10] (pp. 686–695). O'Leary-Kelly and Flores, as well as Wong et al., emphasize the urgent need to understand the conditions that maximize performance improvements [11] (pp. 221–240) [12] (pp. 604–615). Smith et al. note that trade costs along domestic and international supply chains in Asian economies can be significantly reduced by improving the logistics performance in each mode of transport involved in various logistics and supply chain transactions [13].

If steel-producing firms choose SCI, they must bear a considerable investment cost and substantial financial pressure. Although Chinese steel-producing firms can obtain assistance from the Chinese state-owned banking system, which can provide steel-producing firms loan finance on concessionary terms for investment in iron ore projects overseas, applying this strategy entails high risk and capital costs. Therefore, it is essential to investigate the conditions under which SCI can be more beneficial for Chinese steel-producing firms. As a result, it is critical to investigate the circumstances under which SCI can be more beneficial to Chinese steel producers.

Numerous scholars have already conducted research on the implementation conditions of SCI. According to Beresford et al., the optimal mode of transport for iron ore is a combination of sea and rail [14] (pp. 32–42). The global supply chain for iron ore is complex and involves multiple, diverse stakeholders, including foreign iron ore suppliers, foreign port authorities, shipping companies, domestic port authorities, and domestic logistics service providers. This makes it extremely difficult to directly assess SCI implementation conditions. However, the steel production market is typically monopolistic, which allows for the possibility of analyzing the implementation of SCI in this market. For instance, a monopolistic steel manufacturer can have a significant impact on another firm's decision to adopt SCI by adjusting the price of its products.

This study builds on this foundation by employing an evolutionary game approach to analyze the decision-making behavior of participants in the steel-producing market. From a managerial perspective, this paper emphasizes the critical nature of comprehending the conditions that enable SCI to be highly effective, as well as the impact of government relationships on the revenue of the companies involved and their willingness to integrate the supply chain.

3. Game Model

3.1. Problem Description and Setting. As the systematic establishment of SCI is not easily accomplished in a short period of time [5] (pp. 42–55), we can regard SCI as a long-term process. Additionally, while implementing SCI may result in increased productivity, it may also amplify the impact of political risk factors on a company's manufacturing activities. Because SCI connects steel producers to iron ore suppliers, the more integrated a supply chain, the greater the political risk the businesses face. We established the steel and iron ore supply markets as follows based on the foregoing facts.

Assume there are two distinct types of firms in the market (designated firm A and firm B), and they differ substantially in terms of not only profitability but also in SCI costs [15] (pp. 235–253). For each type of firm, two pure strategies are assumed: SCI or no SCI, and to simplify the problem, SCI is defined as the acquisition of mineral resource exploration rights, resource extraction facilities, and transportation investments. Additionally, we assume that the two types of firms are in an incomplete information game relationship, which means that they both have limited cognition and lack access to all necessary information when making SCI decisions. As a result, they cannot make perfectly rational decisions and must instead revise their decision strategies based on incomplete information, gradually improving their position in the game through adaptive learning in the process of continuous improvement. Furthermore, we postulate that the outcomes of the SCI decisions made by two distinct types of firms can affect one another.

The cost of SCI is assumed to consist of two components [16] (pp. 281–294). One is the fixed cost incurred as a result of chain integration, which includes investment in resource exploration, excavation, and transportation. The other is the loss incurred as a result of investment not being recovered (or the project being unable to proceed) because of political factors when Chinese firms invest their fixed assets overseas. In the following, we will utilize the fixed asset investment loss ratio to quantify the cost increase caused by political considerations. For instance, if we assume that the relationship between the Chinese and Australian governments deteriorates significantly and Chinese firms' licenses to develop mineral resources in Australia are completely terminated, then the associated loss ratio of investment is 100 percent, and this coefficient is treated as an exogenous variable in subsequent discussions.

In summary, we assume that the firms A and B face limited cognitive and information access difficulties, are not completely rational, and have asymmetric strategy choices and benefits. As a result, the problem is an asymmetric evolutionary game with imperfect information. As firms A and B must determine whether to integrate their supply chains in this game, there are four possible outcomes, as illustrated in Figure 2. We use the vectors (π_A^1, π_B^1), (π_A^2, π_B^2), (π_A^3, π_B^3), and (π_A^4, π_B^4) to denote the payoff of each game participant in different situations. For instance, in the first case, π_A^1 symbolizes the payment to firm A (where firms A and B implement integration strategies). The payouts of firms A and B are calculated in Table 1 for a variety of game outcomes.

3.2. Evolutionary Game Model. We investigate the behavior of firms A and B described above in this paper using an evolutionary game framework. The fundamental premise of this framework is to represent the two distinct types of firms as two distinct biological groups, dubbed group A and group B [17] (pp. 32–38). Individuals in the two groups mimic and refine their own strategies based on the available local information, and therefore, they learn to optimize their returns adaptively in a multistage (denoted as t) dynamic game process. Finally, the two groups' game results are evaluated in terms of the proportion of people who choose distinct decision options in the game equilibrium.

According to this framework, we use the terms x and x' for group A to denote individuals who use integrated versus nonintegrated strategies and $s_t(x)$ and $s_t(x')$ to denote the proportion of individuals who use strategies x and x′ in group A at stage t, respectively. For group B, we define similar variables, y and y' to denote individuals who use integrated versus nonintegrated strategies, and $s_t(y)$ and $s_t(y')$ to denote the proportion of individuals who use

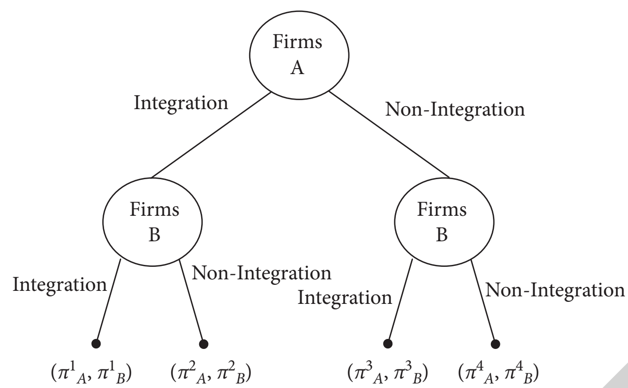

Figure 2: The four situations of the game.

Table 1: The payoff under different situations.

Firms A	Firms B	
	Integration	Nonintegration
Integration	$(P_A + S_A - C_A - R_A,\ P_B + S_B - C_B - R_B)$	$(P_A + S_A - C_A - R_A + E_A,\ P_B - L_B)$
Nonintegration	$(P_A - L_A,\ P_B + S_B - C_B - R_B + E_B)$	$(P_A,\ P_B)$

where P_A, P_B are the original profits of group A and group B under the nonintegration strategy. S_A, S_B are the supply chain cost savings of group A and group B under the integration strategy. C_A, C_B are the costs of supply chain integration of group A and group B. R_A, R_B are the SCI costs of risk $R_A = \alpha C_A$, $R_B = \alpha C_B$, where α is the investment loss ratio. E_A, E_B are the extra earnings of group A and group B. L_A, L_B are the extra losses of group A and group B.

strategies y and y' in group B at stage t, respectively. Based on the above settings, we can then define the expected payoff functions for strategies x and x', denoted as $u_t(x)$ and $u_t(x')$, respectively, as shown in (1) and (2). The average expected payoff $\overline{u_t^b}$ for group A is shown in (3).

$$u_t(x) = s_t(y)\pi_A^1 + s_t(y')\pi_A^2, \tag{1}$$

$$u_t(x') = s_t(y)\pi_A^3 + s_t(y')\pi_A^4, \tag{2}$$

$$\overline{u_t^b} = s_t(x)u_t(x) + s_t(x')u_t(x'). \tag{3}$$

Based on the fundamental concept of Taylor and Jonker's replication dynamic (RD) model [18, 19], we can then derive the RD equations for firm A and firm B to choose an integration strategy, as illustrated in (4) and (5) They will be used in the next sections to conduct an analysis of the evolutionary game's stable strategy.

$$\dot{s}_x = s(x)[1 - s(x)][S_A - C_A + E_A + s(y)(L_A - E_A), \tag{4}$$

$$\dot{s}_y = s(y)[1 - s(y)][S_B - C_B + E_B + s(y)(L_B - E_B). \tag{5}$$

4. ESS Analysis

4.1. Parameter Discussion. An evolutionary stable strategy (ESS) is one that is formed when all individuals in a finite-information repeated game adjust their strategies continuously until they reach equilibrium. An ESS can be either static or changing in a cyclical fashion. We can discuss ESS with the help of RD equations [20, 21].

4.1.1. Analysis for Firm A. Based on the RD equation of firm A, let $f(y) = a_1 s(y) + b_1$, $a_1 = L_A - E_A$, and $b_1 = S_A - C_A + E_A$. Then, (4) can be replaced by $\dot{s}_x = s(x)[1 - s(x)]f(y)$, $s(x) \in (0, 1)$.

If $a_1 = 0$, then the value of $f(y)$ depends on the value of b_1. If $b_1 > 0$, then $\dot{s}_x > 0$, and if $b_1 < 0$ then $\dot{s}_x < 0$.

If $a_1 \neq 0$, as $s(x) \in [0, 1]$, the value of $f(y)$ depends on the value of $-b_1/a_1$. Hence, the value of $-b_1/a_1$ needs to be discussed under different conditions.

(1) When $-b_1/a_1 \leq 0$, if $a_1 > 0$, then $\dot{s}_x > 0$; if $a_1 < 0$, then $\dot{s}_x < 0$.

(2) When $0 < -b_1/a_1 < 1$, if $a_1 > 0$ and $-b_1/a_1 < s(y) \leq 1$, then $\dot{s}_x > 0$, if $a_1 > 0$ and $0 \leq s(y) < -b_1/a_1$, then $\dot{s}_x < 0$, if $a_1 < 0$ and $0 \leq s(y) < -b_1/a_1$, then $\dot{s}_x > 0$, if $a_1 < 0$, and $-b_1/a_1 < s(y) \leq 1$, then $\dot{s}_x < 0$, and if $s(y) = -b_1/a_1$, then $\dot{s}_x = 0$.

(3) When $-b_1/a_1 \geq 1$, if $a_1 > 0$, then $\dot{s}_x < 0$; if $a_1 < 0$, then $\dot{s}_x > 0$.

Through the above discussion, we can conclude that if $-b_1/a_1 \leq 0$ or $-b_1/a_1 \geq 1$, the value of $\dot{s}_x$ is not affected by the value of $s(y)$, which means that, under this condition, firm A's decision is not affected by the choice of firm B. Otherwise, if $0 < -b_1/a_1 < 1$, firm A's decision is affected by the choice of firm B.

4.1.2. Analysis for Firm B. Based on the RD equation of firm B, let $g(x) = a_2 s(x) + b_2$, $a_2 = L_B - E_B$, and $b_2 = S_B - C_B + E_B$; then, $\dot{s}_y = s(y)[1 - s(y)]g(x)$. Similarly, we can conclude that if $-b_2/a_2 \leq 0$ or $-b_2/a_2 \geq 1$, the value of $\dot{s}_y$ is not affected by the value of $s(x)$, which means that firm B's decision is not affected by the choice of firm A under this condition.

Table 2: Game situations under different parameter values.

Classification	Situation	Parameter values of firm A	Parameter values of firm B
Unrelated	Firms A and B are independent of each other	$a_1 = 0$ or $-b_1/a_1 \le 0$ or $-b_1/a_1 \ge 1$	$a_2 = 0$ or $-b_2/a_2 \le 0$ or $-b_2/a_2 \ge 1$
One-way influence	Firm B is affected by firm A	$a_1 = 0$ or $-b_1/a_1 \le 0$ or $-b_1/a_1 \ge 1$	$0 < -b_2/a_2 < 1$
	Firm A is affected by firm B	$0 < -b_1/a_1 < 1$	$a_2 = 0$ or $-b_2/a_2 \le 0$ or $-b_2/a_2 \ge 1$
Mutual influence	Firms A and B interact with each other	$0 < -b_1/a_1 < 1$	$0 < -b_2/a_2 < 1$

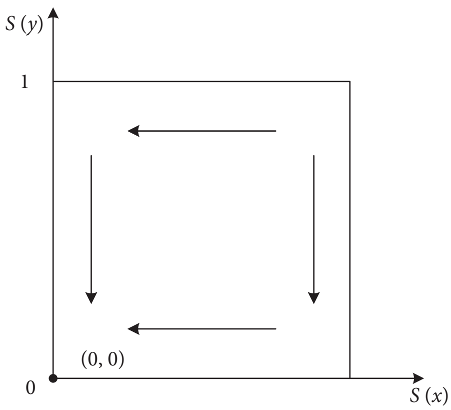

Figure 3: The evolutionary process in the unrelated situation.

Table 3: ESS in the unrelated situation.

Classification	Parameter value of firm A	ESS	Parameter value of firm B	ESS
Unrelated	$-b_1/a_1 \le 0$ and $a_1 < 0$	0	$-b_2/a_2 \le 0$ and $a_2 < 0$	0
	$-b_1/a_1 \le 0$ and $a_1 > 0$	1	$-b_2/a_2 \le 0$ and $a_2 > 0$	1
	$-b_1/a_1 \ge 1$ and $a_1 < 0$	1	$-b_2/a_2 \ge 1$ and $a_2 < 0$	1
	$-b_1/a_1 \ge 1$ and $a_1 > 0$	0	$-b_2/a_2 \ge 1$ and $a_2 > 0$	0

However, if $0 < -b_2/a_2 < 1$, firm B's decision will depend on the action of firm A. Different situations under different parameter values are shown in Table 2.

According to the results of the preceding analysis (as shown in Table 2), there are three basic game relationships: unrelated, one-way influence, and mutual influence. Each of these three scenarios will be discussed further below.

4.2. RD Process Analysis for the Unrelated Situation. In such states, the decisions of firms A and B do not affect each other. For example, if $-b_1/a_1 \le 0$, $a_1 < 0$, $-b_2/a_2 \ge 1$, and $a_2 > 0$, then $\dot{s_x} < 0$ and $\dot{s_y} < 0$. At this stage, as illustrated in Figure 3, the average probability that firms A and B will choose an integration approach diminishes, resulting in an ESS of (nonintegration, nonintegration). Similarly, we can derive more ESSs for this condition, as detailed in Table 3.

4.3. RD Process Analysis under One-Way Influence. This situation can be further classified into two categories based on the variations in the game's dominant player: (1) the one-way influence game in which firm A exerts influence over firm B and (2) the one-way influence game in which firm B exerts influence over firm A. For example, if $s(y) \in [0, -b_1/a_1)$, $-b_1/a_1 \in (0,1)$, $a_1 > 0$, $-b_2/a_2 \le 0$, and $a_2 > 0$, then $\dot{s_y} > 0$; if $s(y) \in [-b_1/a_1, 1)$, $-b_1/a_1 \in (0,1)$, $a_1 > 0$, $-b_2/a_2 \le 0$ and $a_2 > 0$, then $\dot{s_x} > 0$. The RD process is shown in Figure 4.

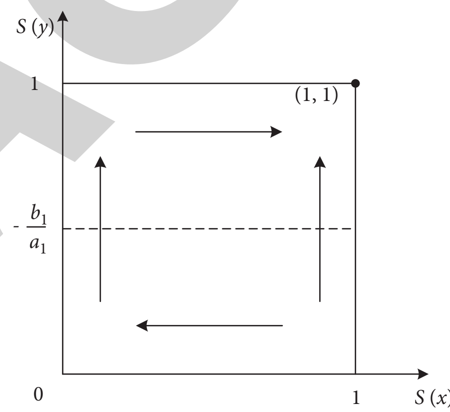

Figure 4: The evolutionary process of one-way influence.

The preceding results imply that if firm B's initial likelihood of integrating is within $[0, -b_1/a_1)$, firm B is more likely to select the integration strategy. When this likelihood reaches the interval $[-b_1/a_1, 1)$, firm B's decision begins to impact firm A, favoring the integration option. This step is repeated until the strategy's final ESS for both is established (integration, integration). Additional ESS results in this state are listed in Table 4.

4.4. RD Process Analysis in the Mutual Affect Situation. When $-b_1/a_1 \in (0,1)$ and $-b_2/a_2 \in (0,1)$, the decisions of firms A and B mutually affect each other.

When $a_1 a_2 > 0$, if $s(y) \in [0, -b_1/a_1)$, $-b_1/a_1 \in (0,1)$, $a_1 < 0$, $-b_2/a_2 \in (0,1)$ and $a_2 < 0$, then $\dot{s_x} > 0$; if $s(y) \in [-b_1/a_1, 1)$, $-b_1/a_1 \in (0,1)$, $a_1 < 0$, $-b_2/a_2 \in (0,1)$ and $a_2 < 0$, then $\dot{s_x} < 0$; if $s(x) \in [0, -b_2/a_2)$, $-b_1/a_1 \in (0,1)$, $a_1 < 0$, $-b_2/a_2 \in (0,1)$ and $a_2 < 0$, then $\dot{s_y} > 0$; and if $s(x) \in [-b_2/a_2, 1)$, $-b_1/a_1 \in (0,1)$, $a_1 < 0$, $-b_2/a_2 \in (0,1)$ and $a_2 < 0$, then $\dot{s_y} < 0$. The RD process for the preceding situation is depicted in Figure 5, and the figure contains four sections, A–D. If $(s(x), s(y))$ is located in region A, then ESS is (nonintegration, integration), which means that firm A pursues a nonintegration strategy, whereas firm B pursues an integration strategy. If $(s(x), s(y))$ is located in region C, then ESS is (nonintegration, integration). If $(s(x), s(y))$ is

Table 4: ESS in the situation that only one party is affected.

Classification	Parameter value of firm A	Parameter value of firm B	ESS
Firm B influences firm A	$0 < -b_1/a_1 < 1$ and $a_1 > 0$	$-b_2/a_2 \le 0$ and $a_2 < 0$	(0, 0)
		$-b_2/a_2 \le 0$ and $a_2 > 0$	(1, 1)
		$-b_2/a_2 \ge 1$ and $a_2 < 0$	(1, 1)
		$-b_2/a_2 \ge 1$ and $a_2 > 0$	(0, 0)
	$0 < -b_1/a_1 < 1$ and $a_1 < 0$	$-b_2/a_2 \le 0$ and $a_2 < 0$	(1, 0)
		$-b_2/a_2 \le 0$ and $a_2 > 0$	(0, 1)
		$-b_2/a_2 \ge 1$ and $a_2 < 0$	(0, 1)
		$-b_2/a_2 \ge 1$ and $a_2 > 0$	(1, 0)
Firm A influences firm B	$-b_1/a_1 \le 0$ and $a_1 < 0$	$0< -b_2/a_2 < 1$ and $a_2 > 0$	(0, 0)
	$-b_1/a_1 \le 0$ and $a_1 > 0$		(1, 1)
	$-b_1/a_1 \ge 1$ and $a_1 < 0$		(1, 1)
	$-b_1/a_1 \ge 1$ and $a_1 > 0$		(0, 0)
	$-b_1/a_1 \le 0$ and $a_1 < 0$	$0< -b_2/a_2 < 1$ and $a_2 < 0$	(1, 0)
	$-b_1/a_1 \le 0$ and $a_1 > 0$		(0, 1)
	$-b_1/a_1 \ge 1$ and $a_1 < 0$		(0, 1)
	$-b_1/a_1 \ge 1$ and $a_1 > 0$		(1, 0)

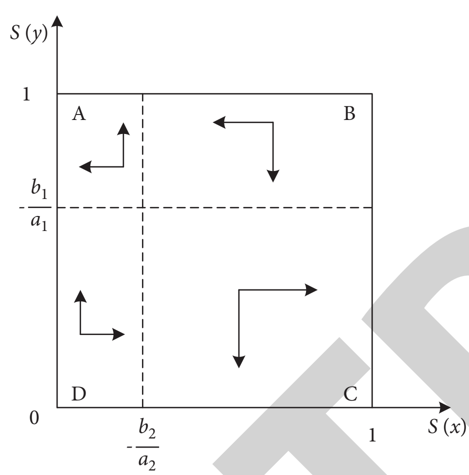

Figure 5: The evolutionary process of mutual effect under $a_1 a_2 > 0$.

located in region B or D, then ESS is (integration, nonintegration) or (nonintegration, integration). When $0 < -b_1/a_1 < 1$, $a_1 > 0$ and $0 < -b_2/a_2 < 1$, $a_2 > 0$, see Table 5 for the relevant results.

When $a_1 a_2 < 0$, if $s(y) \in [-b_1/a_1, 1)$, $-b_1/a_1 \in (0,1)$, $a_1 > 0$, $-b_2/a_2 \in (0,1)$ and $a_2 < 0$, then $\dot{s_x} > 0$; if $s(y) \in [0, -b_1/a_1)$, $-b_1/a_1 \in (0,1)$, $a_1 > 0$, $-b_2/a_2 \in (0,1)$ and $a_2 < 0$, then $\dot{s_x} < 0$; if $s(x) \in [0, -b_2/a_2)$, $-b_1/a_1 \in (0,1)$, $a_1 > 0$, $-b_2/a_2 \in (0,1)$ and $a_2 < 0$, then $\dot{s_y} > 0$; and if $s(x) \in [-b_2/a_2, 1)$, $-b_1/a_1 \in (0,1)$, $a_1 > 0$, $-b_2/a_2 \in (0,1)$, and $a_2 < 0$, then $\dot{s_y} < 0$. The RD process is shown in Figure 6. Finally, there is only one stable state in which each side will adapt to the mixed strategy and the ESS is $(-b_2/a_2, -b_1/a_1)$. Similarly, when $-b_1/a_1 \in (0,1)$, $a_1 < 0$ and $-b_2/a_2 \in (0,1)$, $a_2 > 0$, we obtain the results shown in Table 5.

5. Case Study

5.1. Background. The iron ore trade value between Australia and China is growing rapidly. According to the latest data from the China Iron and Steel Association (CISA), the volume of Chinese iron ore imports from Australia in 2020 was 713 million tons (accounting for 60.9% of the year's total). Western Australia is the main producer of iron ore in Australia, accounting for 99% of Australia's iron ore production. Western Australia had 836 Mt of iron ore sales in 2019–2020, which were mostly exported to China (83 percent). The main origin in Western Australia is the Pilbara Region (accounting for 97%), as shown in Figure 7.

According to the data from the Government of Western Australia Department of Mines and Petroleum, there are approximately 17 principal iron ore producers in Western Australia. Among them, three companies, Rio Tinto, BHP Billiton, and Fortescue Metals Group, account for more than 90% of production. These companies have built their own export supply chains, including rail lines and port facilities, as shown in Table 6.

Thus far, through joint-venture packages, which include Chinese firms taking minority equity stakes and offering long-term contracts for new iron ore exports, many Chinese steel-producing firms have taken measures to integrate their supply chains, as shown in Table 7.

5.2. Numerical Examples. We designed different scenarios based on data collected from Chinese steel-producing companies and iron-ore suppliers in Australia to analyze the best options for Chinese steel-producing firms. We observe two primary patterns used in SCI: the joint-venture pattern (which includes long-term contracts) and the self-support pattern. Figures 8 and 9 depict two integrated supply chain patterns. As a result, we created two cases, one to represent each integration pattern.

As firms with different market scales have different cost structures, we need to consider the influence that market scale has on decision-making. We choose Baosteel Group and Benxi Steel as targets, which are Chinese steel-producing firms but do not have same level of production. According to the data from the World Steel Association, their crude steel production for the period 2017–2020 is listed in Table 8. We chose their net profits in 2011 as original profits, which were

Table 5: ESS under mutual influence.

Situations	Parameter of firm A	Parameter of firm B	ESS
Mutual influence	$0 < -b_1/a_1 < 1$ and $a_1 < 0$	$0 < -b_2/a_2 < 1$ and $a_2 < 0$	(0, 1) or (1, 0)
	$0 < -b_1/a_1 < 1$ and $a_1 > 0$	$0 < -b_2/a_2 < 1$ and $a_2 > 0$	(0, 0) or (1, 1)
	$0 < -b_1/a_1 < 1$ and $a_1 > 0$	$0 < -b_2/a_2 < 1$ and $a_2 < 0$	$(-b_2/a_2, -b_1/a_1)$
	$0 < -b_1/a_1 < 1$ and $a_1 < 0$	$0 < -b_2/a_2 < 1$ and $a_2 > 0$	$(-b_2/a_2, -b_1/a_1)$

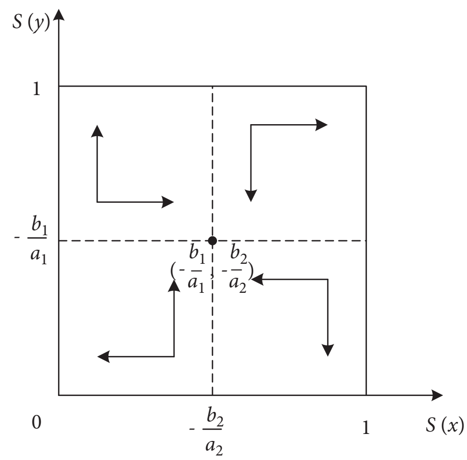

Figure 6: The evolutionary process of mutual effect under $a_1a_2 < 0$.

US\$ 2.895 billion and US\$542 million. Therefore, their unit profits in 2011 were US\$ 66.8/ton and US\$ 32.8/ton. Hence, $P_A = 66.8$ and $P_B = 32.8$. Following that, we will consider two scenarios. In scenario 1, we assume that both players can only use the "joint-venture pattern" to integrate their supply chains. We suppose in scenario 2 that they can only follow the "self-support pattern."

5.2.1. Scenario 1. In scenario 1, we consider the joint-venture pattern. Under this condition, Chinese steel-producing firms obtain cheaper iron ore by taking minority equity stakes and offering long-term contracts for new iron ore exports. As most Chinese steel-producing companies are in the process of integration projects, it is difficult to calculate supply chain cost savings from the whole raw material cost. Therefore, we obtain data on supply chain cost savings from iron ore producers in Australia, which provided the cost savings from integrating their export supply chains in their annual reports. Take, for example, the case of FMG, which committed to expansion in November 2010. We chose its cost data after expansion. As in the previous discussion, we believe that the supply chain cost saving consists of the saving of rail costs, port costs, and shipping costs. By decreasing the average cost, we can obtain $S_A = 3.6$, $S_B = 3.6$. Table 9.

To determine the cost of SCI in this model, we choose two real cases. One is Baosteel Group's investment in Aquila in 2009. In this case, Baosteel Group invested as much as US\$285.6 million in Aquila to obtain a 50% share of one 30 Mtpa project. The other case is Shougang investment in Balmoral in 2008. The specific data are shown in the table below. Assuming that the costs are shared equally from 2011 to 2014, we can obtain $C_A = 1.65$ and $C_B = 1.04$.

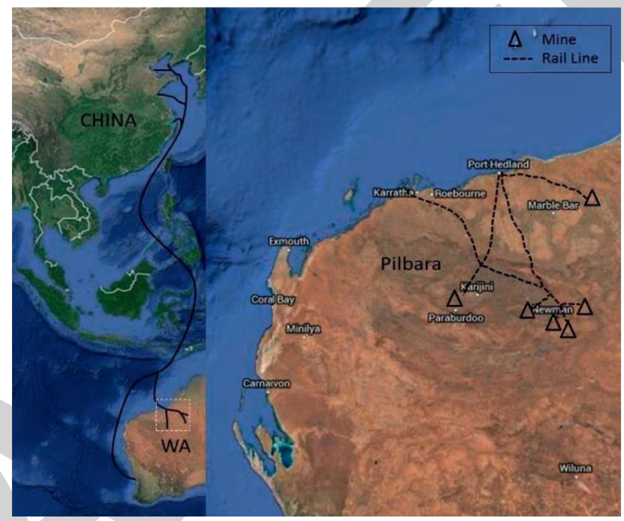

Figure 7: Iron ore transport routes between Australia and China.

Table 6: Iron ore export supply chain of the main producers.

Iron ore producer	Rail (km)	Port facility
Rio Tinto	1600	4 ports with 11 berths (Dampier port)
BHP	1000	8 berths (port Hedland)
FMG	620	4 berths and 1 under construction (port Hedland)

Table 7: Investment of Chinese steel-producing firms.

Firm	Project	Value (A\$ millions)	Size (Mtpa) and associated LTCs (% of output)
Ansteel	Karara JV	530	Plan 10 (100%)
Shougang	Balmoral south	58	Plan 12 (100%)
Shagang	Grange	NA	2.5 (100%)
Baosteel	Aquila	286	Plan 30 (50%)

As the steel-producing market is oligopolistic, we assume that company A with a larger market share will gain 10% excess profits if only it implements the SCI strategy. Otherwise, it will face a 20% excess loss. The same situation for company B (smaller market share) is 20% excess profits and 10% excess loss. Therefore, we can obtain $E_A = 6.68$, $L_A = 13.36$, $E_B = 6.56$, and $L_B = 3.28$. By applying MATLAB, we obtain the ESS (integration, integration) after deriving hundreds of initial solutions, as shown in Figure 10.

It means that in the short term, firms A and B will choose the joint-venture pattern for SCI. We perform a sensitivity analysis on the proportional coefficient of fixed asset

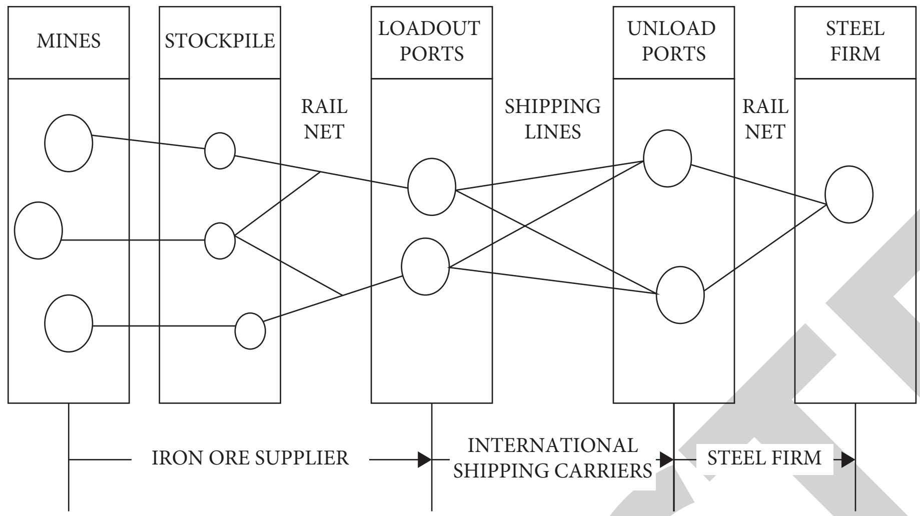

Figure 8: Joint-venture mode.

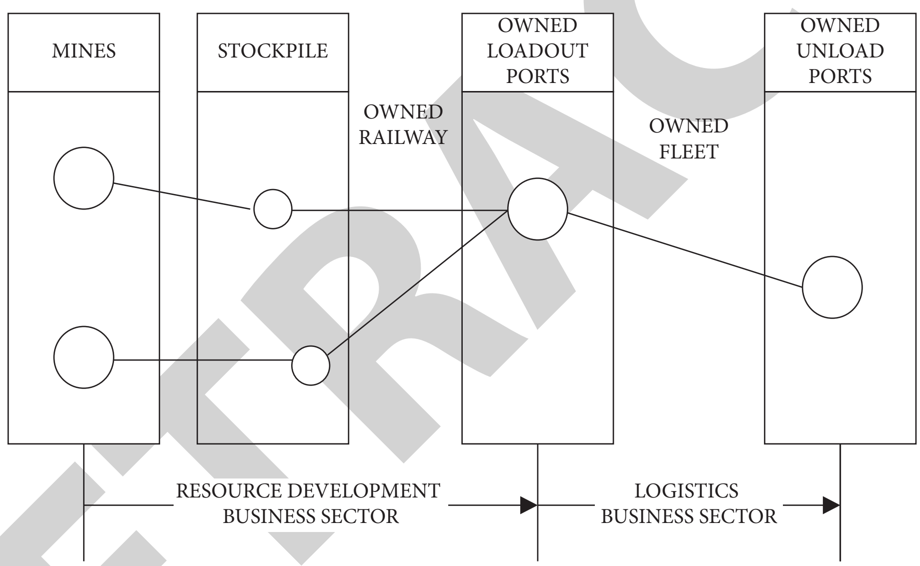

Figure 9: Self-support model.

Table 8: Crude steel production, 2017–2020.

Tonnage (million tonnes)	2017	2018	2019	2020
Baosteel group	46.17	47.10	46.88	45.62
Benxi steel	15.49	15.47	15.83	16.63

Table 9: FMG supply chain cost after expansion.

Supply chain costs U.S.$ m	After 1 year	After 2 years	After 3 years	After 4 years
Rail costs	128	139	182	238
Port costs	97	125	181	252
Shipping cost	509	672	769	1210
Ore shipped	40.9	57.5	75.9	118.4
Average cost U.S.$/wmt	17.95	16.28	14.91	14.35

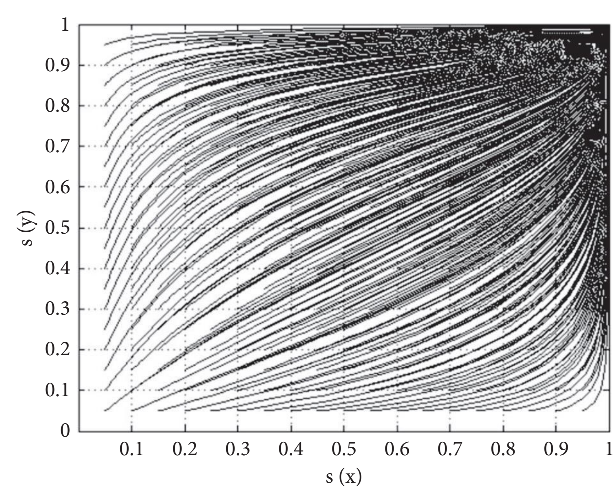

Figure 10: The simulation result of Scenario 1.

Supply chain costs	2011	2012	2013	2014
Total delivered cost US$/wmt	67	69	62	52

investment loss P. The calculation shows that the ESS is (integration, integration) for any P. It indicates that the decisions of firms A and B are not affected by the coefficient P in the short term if they are integrated using the joint-venture pattern.

5.2.2. Scenario 2. In Scenario 2, we consider the self-support model. The data on original profits are the same. Hence, $P_A = 66.8$ and $P_B = 32.8$. We also obtain data on supply chain cost savings from the case of FMG. The total delivered cost of FMG was significantly lower in 2014 than in 2011, as shown in Table 10, because of its expansion in the supply chain. However, as a result of their small size and comparatively high costs, it is unlikely that most of these projects will be cost-competitive with the Big-3 incumbents. Therefore, we assume that $S_A = 13.5$ ($15 * 90\%$) and $S_B = 12$ ($15 * 80\%$).

We choose BHP exploration projects as the data source. These projects included the Jimblebar Mine Expansion project and Orebody 24 mine project. The Jimblebar Mine expansion project costed U.S.$3.6 billion and achieved a capacity of 35 Mtpa. The Orebody 24 mine project costed U.S.$0.7 billion and achieved a capacity of 17 Mtpa after one year of construction. Both projects were approved in 2011 and lasted 4 years. Then, we can obtain $C_A = 24.28$ and $C_B = 16.12$. Similar to Scenario 1, $E_A = 6.68$, $L_A = 13.36$, $E_B = 6.56$, and $L_B = 3.28$. By applying MATLAB, we obtain the ESS (0.74, 0.61) after conducting hundreds of initial solutions, as shown in Figure 11.

Additionally, we conduct a sensitivity analysis for P in the following section. We make P take values between 0 and 1 and perform the calculations, obtaining the following results.

When $0 \leq p \leq 0.106$, the dynamic evolutionary process will reach an equilibrium state characterized by mixed strategies. As illustrated in Figure 12, the ESS equilibrium state moves to the upper left as the value of p increases, indicating that the probability of firm A (with a large market share) choosing an integration strategy continues to decrease, while the probability of firm B choosing an integration strategy increases. Note that because the investment loss ratio coefficient P can be interpreted as the probability of experiencing policy risk, the results of this calculation indicate that the probability of choosing an integration strategy for firm a with its dominant market share decreases significantly as the probability of experiencing policy risk increases.

When $0.106 < p \leq 0.151$, $-b1/a1 \geq 1$, and $0 < -b2/a2 < 1$. It means that in this case, the strategy evolution process of firm A is not influenced by the decision of firm B, while the strategy evolution process of firm B is influenced by firm A. In this case, the ESS is (nonintegration, integration), i.e., firm A chooses not to integrate, and firm B chooses to

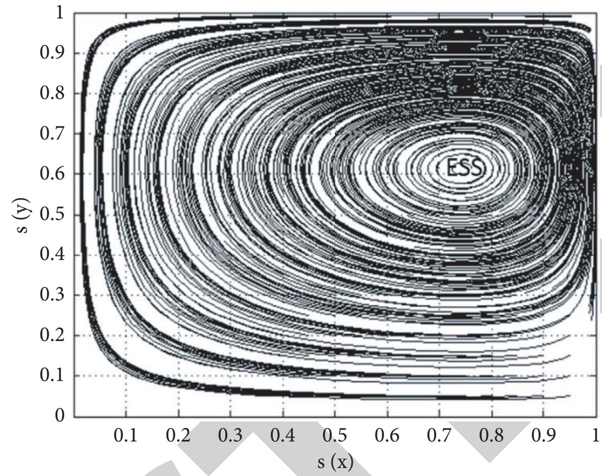

Figure 11: The simulation result of Scenario 2.

integrate. It indicates that as the probability of policy risk expands further, firm A's decision will change from preferring integration to nonintegration, while firm B still prefers to choose integration.

When $p > 0.151$, $-b_1/a_1 \geq 1$, and $-b_2/a_2 \leq 0$. Here, the strategy evolution processes of firms A and B are independent. At this stage, the ESS is (nonintegration, nonintegration). This finding implies that when risk reaches a particular level, both types of firms choose to pursue a nonintegration strategy. This outcome is entirely consistent with our expectations.

5.3. Discussion. The findings of the preceding study are congruent with the reality of the situation. Actual economic and trade data indicate that the relationship between China and Australia has a substantial impact on investment activity between the two countries. Because of ongoing tensions between the two nations, Chinese investment in Australia fell to its lowest level in nearly six years in 2020, as shown in Figure 13, by 61% year-on-year to $783 million from $2.08 billion the previous year. There were only 20 Chinese investment projects in Australia throughout 2019, far fewer than the 111 in 2016. From the standpoint of steel SCI, the model described in this article provides a quantitative explanation for this phenomenon.

In Scenario 1, the value of each parameter accords with the situation "unrelated," which means that firms A and B will make decisions based on their own situations, without considering the competitor's strategy. In this case, both of them will gain profits if they apply an SCI strategy. Additionally, we can see that, regardless of the value of p, neither side of the game can affect the other's decisions in Scenario 1, and the ESS is (integration, integration). It is primarily because both parties to the game employ the short-term joint venture pattern for SCI, which is an "asset-light pattern" with low investment and risk, and thus the integration decision effectively mitigates political concerns.

Unlike in Scenario 1, we assume that both players adopt the self-support pattern for SCI in Scenario 2. Because this

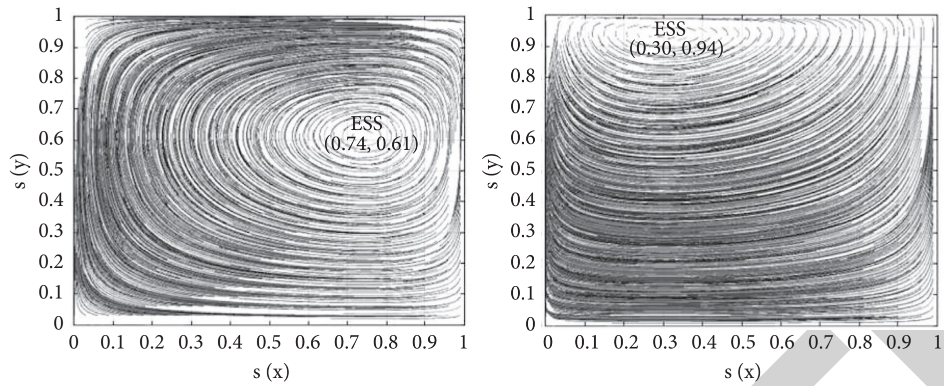

Figure 12: The comparison of simulation results under $p = 0$ & $p = 0.09$.

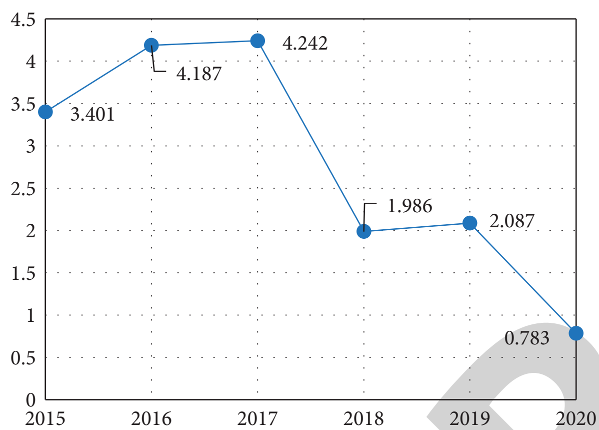

Figure 13: China's investment in Australia 2015–2020 ($ billion).

model requires significant investment and is essentially a fixed asset investment, it can be considered an "asset-heavy pattern." While SCI based on the self-support pattern can significantly reduce operating costs and increase efficiency, there is a significant investment risk associated with it. If the countries' relationship deteriorates, it will result in a series of irreversible and significant losses for the firms.

Note that the political risk factor has varying effects on firms in various market positions under the self-support pattern. Specifically, as risk (p) increases, the probability that firm A will choose the integration strategy decreases continuously until $p = 0.106$, at which point firm A becomes unwilling to choose the integration strategy, however, firm B always prefers the integration strategy when p is less than 0.106. At $p = 0.151$, the response of firm B changes. It demonstrates that even when p is less than 0.151, firm B is willing to accept the risk posed by policy factors. When p exceeds 0.151, firm B is also forced to abandon its integration strategy because of the high policy risk.

6. Summary and Conclusions

In this paper, we developed an evolutionary game model to analyze the decision-making of an SCI strategy for steel-producing firms. Considering the characteristics of an oligopolistic market, we formulated the supply chain decision-making problem as an asymmetric RD model and then proposed an RD process analysis to obtain every ESS result under different parameter situations. In addition, two scenarios were designed to demonstrate that such problems can be formulated and solved well by an evolutionary game model. Importantly, this paper adds to the literature by empirically testing the SCI strategy indirectly. Furthermore, it also allows for the generalization of special cases of oligopolistic market equilibrium problems and provides a detailed case study of Chinese steel-producing firms' iron ore supply chain.

In conclusion, there are some limitations of the research in this paper that suggest that future studies can be extended in several directions. Firstly, the complexity of participators' behavior in this oligopolistic market has been simplified in this evolutionary game model. Future studies can consider the cost structure of steel-producing firms and introduce a pricing model to analyze the extra profits and losses that each firm may face. Secondly, collecting data from steel-producing firms' supply chains could be more appropriate for evaluating the cost savings of the total supply network. Therefore, future research should replicate and integrate our study using numerical data from iron ore-producing firms. Obviously, it would also be worthwhile for further theoretical developments and empirical applications.
